What is Amazon Elastic File System?

Amazon Elastic File System (Amazon EFS) provides a simple, serverless, set-and-forget elastic file system for use with AWS Cloud services and on-premises resources. It is built to scale on demand to petabytes without disrupting applications, growing and shrinking automatically as you add and remove files, eliminating the need to provision and manage capacity to accommodate growth. Amazon EFS has a simple web services interface that allows you to create and configure file systems quickly and easily. The service manages all the file storage infrastructure for you, meaning that you can avoid the complexity of deploying, patching, and maintaining complex file system configurations.

Amazon EFS supports the Network File System version 4 (NFSv4.1 and NFSv4.0) protocol, so the applications and tools that you use today work seamlessly with Amazon EFS. Multiple compute instances, including Amazon EC2, Amazon ECS, and AWS Lambda, can access an Amazon EFS file system at the same time, providing a common data source for workloads and applications running on more than one compute instance or server.

With Amazon EFS, you pay only for the storage used by your file system and there is no minimum fee or setup cost. Amazon EFS offers a range of storage classes designed for different use cases. These include:

- **Standard storage classes** – EFS Standard and EFS Standard–Infrequent Access (Standard–IA), which offer multi-AZ resilience and the highest levels of durability and availability.
- **One Zone storage classes** – EFS One Zone and EFS One Zone–Infrequent Access (EFS One Zone–IA), which offer customers the choice of additional savings by choosing to save their data in a single AZ.

For more information, see Managing EFS storage classes (p. 87). Costs related to Provisioned Throughput are determined by the throughput values you specify. For more information, see Amazon EFS Pricing.

The service is designed to be highly scalable, highly available, and highly durable. Amazon EFS file systems using Standard storage classes store data and metadata across multiple Availability Zones in an AWS Region. EFS file systems can grow to petabyte scale, drive high levels of throughput, and allow massively parallel access from compute instances to your data.

Amazon EFS provides file system access semantics, such as strong data consistency and file locking. For more information, see Data consistency in Amazon EFS (p. 9). Amazon EFS also enables you to control access to your file systems through Portable Operating System Interface (POSIX) permissions. For more information, see Security in Amazon EFS (p. 169).

Amazon EFS supports authentication, authorization, and encryption capabilities to help you meet your security and compliance requirements. Amazon EFS supports two forms of encryption for file systems, encryption in transit and encryption at rest. You can enable encryption at rest when creating an Amazon EFS file system. If you do, all your data and metadata is encrypted. You can enable encryption in transit when you mount the file system. NFS client access to EFS is controlled by both AWS Identity and Access Management (IAM) policies and network security policies like security groups. For more information, see Data encryption in Amazon EFS (p. 169), Identity and access management for Amazon EFS (p. 175), and Controlling network access to Amazon EFS file systems for NFS clients (p. 195).

Amazon EFS is designed to provide the throughput, IOPS, and low latency needed for a broad range of workloads. With Amazon EFS, you can choose from two performance modes and two throughput modes:

- The default General Purpose performance mode is ideal for latency-sensitive use cases, like web serving environments, content management systems, home directories, and general file serving. File systems in the Max I/O mode can scale to higher levels of aggregate throughput and operations per
second with a tradeoff of slightly higher latencies for file metadata operations. For more information, see **Performance modes** (p. 122).

- Using the default Bursting Throughput mode, throughput scales as your file system grows. Using Provisioned Throughput mode, you can specify the throughput of your file system independent of the amount of data stored. For more information, see **Amazon EFS performance** (p. 120).

**Note**

Using Amazon EFS with Microsoft Windows–based Amazon EC2 instances is not supported.

**Are you a first-time user of Amazon EFS?**

If you are a first-time user of Amazon EFS, we recommend that you read the following sections in order:

1. For an Amazon EFS product and pricing overview, see **Amazon EFS**.
2. For an Amazon EFS technical overview, see **Amazon EFS: How it works** (p. 3).
3. Try the introductory exercises:
   - **Getting started** (p. 13)
   - **Walkthroughs** (p. 135)

If you want to learn more about Amazon EFS, the following topics discuss the service in greater detail:

- **Working with Amazon EFS resources** (p. 19)
- **Managing Amazon EFS file systems** (p. 83)
- **Amazon EFS API** (p. 230)
Amazon Elastic File System User Guide

Overview

Amazon EFS: How it works

Following, you can find a description about how Amazon EFS works, its implementation details, and security considerations.

Topics
- Overview (p. 3)
- How Amazon EFS works with Amazon EC2 and other supported compute instances (p. 4)
- How Amazon EFS works with AWS Direct Connect and AWS Managed VPN (p. 6)
- How Amazon EFS works with AWS Backup (p. 7)
- Implementation summary (p. 8)
- Authentication and access control (p. 9)
- Data consistency in Amazon EFS (p. 9)
- Storage classes (p. 9)

Overview

Amazon EFS provides a simple, serverless, set-and-forget elastic file system. With Amazon EFS, you can create a file system, mount the file system on an Amazon EC2 instance, and then read and write data to and from your file system. You can mount an Amazon EFS file system in your virtual private cloud (VPC), through the Network File System versions 4.0 and 4.1 (NFSv4) protocol. We recommend using a current generation Linux NFSv4.1 client, such as those found in the latest Amazon Linux, Amazon Linux 2, Red Hat, Ubuntu, and macOS Big Sur AMIs, in conjunction with the Amazon EFS mount helper. For instructions, see Using the amazon-efs-utils Tools (p. 47).

For a list of Amazon EC2 Linux and macOS Amazon Machine Images (AMIs) that support this protocol, see NFS support (p. 356). For some AMIs, you must install an NFS client to mount your file system on your Amazon EC2 instance. For instructions, see Installing the NFS client (p. 357).

You can access your Amazon EFS file system concurrently from multiple NFS clients, so applications that scale beyond a single connection can access a file system. Amazon EC2 and other AWS compute instances running in multiple Availability Zones within the same AWS Region can access the file system, so that many users can access and share a common data source.

For a list of AWS Regions where you can create an Amazon EFS file system, see the Amazon Web Services General Reference.

To access your Amazon EFS file system in a VPC, you create one or more mount targets in the VPC.

- For file systems using Standard storage classes, you can create a mount target in each availability Zone in the AWS Region.
- For file systems using One Zone storage classes, you create only a single mount target that is in the same Availability Zone as the file system.

For more information, see Managing EFS storage classes (p. 87).

A mount target provides an IP address for an NFSv4 endpoint at which you can mount an Amazon EFS file system. You mount your file system using its Domain Name Service (DNS) name, which resolves to the IP address of the EFS mount target in the same Availability Zone as your EC2 instance. You can create one mount target in each Availability Zone in an AWS Region. If there are multiple subnets in an Availability Zone in your VPC, you create a mount target in one of the subnets. Then all EC2 instances in that Availability Zone share that mount target.
Note
An Amazon EFS file system can only have mount targets in one VPC at a time.

Mount targets themselves are designed to be highly available. As you design for high availability and failover to other Availability Zones, keep in mind that while the IP addresses and DNS for your mount targets in each Availability Zone are static, they are redundant components backed by multiple resources.

After mounting the file system by using its DNS name, you use it like any other POSIX-compliant file system. For information about NFS-level permissions and related considerations, see Working with users, groups, and permissions at the Network File System (NFS) Level (p. 198).

You can mount your Amazon EFS file systems on your on-premises data center servers when connected to your Amazon VPC with AWS Direct Connect or AWS VPN. You can mount your EFS file systems on on-premises servers to migrate datasets to EFS, enable cloud bursting scenarios, or backup your on-premises data to Amazon EFS.

How Amazon EFS works with Amazon EC2 and other supported compute instances

This section explains how Amazon EFS file systems that use Standard and One Zone storage classes are mounted to EC2 instances in an Amazon VPC.

Amazon EFS with Standard storage classes

The following illustration shows multiple EC2 instances accessing an Amazon EFS file system that is configured with Standard storage classes from multiple Availability Zones in an AWS Region.
In this illustration, the Amazon Virtual Private Cloud (VPC) has three Availability Zones. Because the file system uses Standard storage classes, a mount target was created in each Availability Zone. We recommend that you access the file system from a mount target within the same Availability Zone for performance and cost reasons. One of the Availability Zones has two subnets. However, a mount target is created in only one of the subnets. Creating this setup works as follows:

1. Create your Amazon EC2 resources and launch your Amazon EC2 instance. For more information on Amazon EC2, see Amazon EC2 - Virtual Server Hosting.
2. Choose Regional durability and availability when creating your Amazon EFS file system.
3. Connect to each of your Amazon EC2 instances, and mount the Amazon EFS file system.

For detailed steps, see Getting started with Amazon Elastic File System (p. 13).

### Amazon EFS with One Zone storage classes

The following illustration shows multiple EC2 instances that are accessing an Amazon EFS file system. This file system is configured with One Zone storage from multiple Availability Zones in an AWS Region.

In this illustration, the VPC has two Availability Zones, each with one subnet. The file system uses One Zone storage classes, so it can only have a single mount target. For better performance and cost, we recommend that you access the file system from a mount target in the same Availability Zone as the EC2 instance that you’re mounting it on.

In this example, the EC2 instance in the us-west-2c Availability Zone will pay EC2 data access charges for accessing a mount target in a different Availability Zone. Creating this setup works as follows:

1. Create your Amazon EC2 resources and launch your Amazon EC2 instance. For more information about Amazon EC2, see Amazon EC2.
2. Create your Amazon EFS file system with One Zone storage.
3. Connect to each of your Amazon EC2 instances, and mount the Amazon EFS file system using the same mount target for each instance.

How Amazon EFS works with AWS Direct Connect and AWS Managed VPN

By using an Amazon EFS file system mounted on an on-premises server, you can migrate on-premises data into the AWS Cloud hosted in an Amazon EFS file system. You can also take advantage of bursting. In other words, you can move data from your on-premises servers into Amazon EFS and analyze it on a fleet of Amazon EC2 instances in your Amazon VPC. You can then store the results permanently in your file system or move the results back to your on-premises server.

Keep the following considerations in mind when using Amazon EFS with an on-premises server:

- Your on-premises server must have a Linux-based operating system. We recommend Linux kernel version 4.0 or later.
- For the sake of simplicity, we recommend mounting an Amazon EFS file system on an on-premises server using a mount target IP address instead of a DNS name.

There is no additional cost for on-premises access to your Amazon EFS file systems. You are charged for the AWS Direct Connect connection to your Amazon VPC. For more information, see [AWS Direct Connect pricing](https://aws.amazon.com/directconnect/pricing/).

The following illustration shows an example of how to access an Amazon EFS file system from on-premises (the on-premises servers have the file systems mounted).
You can use any mount target in your VPC if you can reach that mount target's subnet by using an AWS Direct Connect connection between your on-premises server and VPC. To access Amazon EFS from an on-premises server, add a rule to your mount target security group to allow inbound traffic to the NFS port (2049) from your on-premises server.

To create a setup like this, you do the following:

1. Establish an AWS Direct Connect connection between your on-premises data center and your Amazon VPC. For more information on AWS Direct Connect, see AWS Direct Connect.
2. Create your Amazon EFS file system.
3. Mount the Amazon EFS file system on your on-premises server.

For detailed steps, see Walkthrough: Create and mount a file system on-premises with AWS Direct Connect and VPN (p. 153).

How Amazon EFS works with AWS Backup

For a comprehensive backup implementation for your file systems, you can use Amazon EFS with AWS Backup. AWS Backup is a fully managed backup service that makes it easy to centralize and automate data backup across AWS services in the cloud and on-premises. Using AWS Backup, you can centrally configure backup policies and monitor backup activity for your AWS resources. Amazon
EFS always prioritizes file system operations over backup operations. To learn more about backing up EFS file systems using AWS Backup, see Using AWS Backup to back up and restore Amazon EFS file systems (p. 130).

Implementation summary

In Amazon EFS, a file system is the primary resource. Each file system has properties such as ID, creation token, creation time, file system size in bytes, number of mount targets created for the file system, and the file system lifecycle state. For more information, see CreateFileSystem (p. 238).

Amazon EFS also supports other resources to configure the primary resource. These include mount targets and access points:

- **Mount target** – To access your file system, you must create mount targets in your VPC. Each mount target has the following properties: the mount target ID, the subnet ID in which it is created, the file system ID for which it is created, an IP address at which the file system may be mounted, VPC security groups, and the mount target state. You can use the IP address or the DNS name in your `mount` command.

  Each file system has a DNS name of the following form.

  \[ \text{file-system-id.efs.aws-region.amazonaws.com} \]

  You can specify this DNS name in your `mount` command to mount the Amazon EFS file system. Suppose you create an `efs-mount-point` subdirectory off of your home directory on your EC2 instance or on-premises server. Then, you can use the mount command to mount the file system. For example, on an Amazon Linux AMI, you can use the following `mount` command.

  ```
  $ sudo mount -t nfs -o nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport `file-system-DNS-name`:/~/efs-mount-point
  ```

  For more information, see Creating and managing mount targets (p. 31). First, you need to install the NFS client on your EC2 instance. The Getting started (p. 13) exercise provides step-by-step instructions.

- **Access Points** – An access point applies an operating system user, group, and file system path to any file system request made using the access point. The access point's operating system user and group override any identity information provided by the NFS client. The file system path is exposed to the client as the access point's root directory. This ensures that each application always uses the correct operating system identity and the correct directory when accessing shared file-based datasets. Applications using the access point can only access data in its own directory and below. For more information, see Working with Amazon EFS Access Points (p. 202).

  Mount targets and tags are *subresources* that are associated with a file system. You can only create them within the context of an existing file system.

  Amazon EFS provides API operations for you to create and manage these resources. In addition to the create and delete operations for each resource, Amazon EFS also supports a describe operation that enables you to retrieve resource information. You have the following options for creating and managing these resources:

  - Use the Amazon EFS console – For an example, see Getting started (p. 13).
  - Use the Amazon EFS command line interface (CLI) – For an example, see Walkthrough: Create an Amazon EFS file system and mount it on an Amazon EC2 instance using the AWS CLI (p. 135).
You can also manage these resources programmatically as follows:

- Use the AWS SDKs – The AWS SDKs simplify your programming tasks by wrapping the underlying Amazon EFS API. The SDK clients also authenticate your requests by using access keys that you provide. For more information, see Sample Code and Libraries.
- Call the Amazon EFS API directly from your application – If you cannot use the SDKs for some reason, you can make the Amazon EFS API calls directly from your application. However, you need to write the necessary code to authenticate your requests if you use this option. For more information about the Amazon EFS API, see Amazon EFS API (p. 230).

Authentication and access control

You must have valid credentials to make Amazon EFS API requests, such as create a file system. In addition, you must also have permissions to create or access resources. By default, when you use the root account credentials of your AWS account you can create and access resources owned by that account. However, we don't recommend using root account credentials. In addition, any AWS Identity and Access Management (IAM) users and roles that you create in your account must be granted permissions to create or access resources. For more information about permissions, see Identity and access management for Amazon EFS (p. 175).

IAM authorization for NFS clients is an additional security option for Amazon EFS that uses IAM to simplify access management for Network File System (NFS) clients at scale. With IAM authorization for NFS clients, you can use IAM to manage access to an EFS file system in an inherently scalable way. IAM authorization for NFS clients is also optimized for cloud environments. For more information on using IAM authorization for NFS clients, see Using IAM to control file system data access (p. 185).

Data consistency in Amazon EFS

Amazon EFS provides the close-to-open consistency semantics that applications expect from NFS.

In Amazon EFS, write operations are durably stored across Availability Zones on file systems using Standard storage classes in these situations:

- An application performs a synchronous write operation (for example, using the open Linux command with the O_DIRECT flag, or the fsync Linux command).
- An application closes a file.

Depending on the access pattern, Amazon EFS can provide stronger consistency guarantees than close-to-open semantics. Applications that perform synchronous data access and perform non-appending writes have read-after-write consistency for data access.

Storage classes

With Amazon EFS, you can choose from a range of storage classes that are designed for different use cases:

- **EFS Standard** – A regional storage class for frequently accessed data. It offers the highest levels of availability and durability by storing file system data redundantly across multiple Availability Zones in an AWS Region.
- **EFS Standard-Infrequent Access (Standard-IA)** – A regional storage class for infrequently accessed data. It offers the highest levels of availability and durability by storing file system data redundantly across multiple Availability Zones in an AWS Region.
- **EFS One Zone** – For frequently accessed files stored redundantly within a single Availability Zone in an AWS Region.
- **EFS One Zone-IA (One Zone-IA)** – A lower-cost storage class for infrequently accessed files stored redundantly within a single Availability Zone in an AWS Region.

The EFS Standard storage classes are regional storage classes that store file system data and metadata redundantly across multiple geographically separated Availability Zones within an AWS Region. They offer the highest levels of availability and durability, providing continuous availability to data even when one or more Availability Zones in a Region are unavailable.

The EFS One Zone storage classes are lower cost, single Availability Zone storage classes. They store file system data and metadata redundantly in a single Availability Zone within an AWS Region.

Both of the IA storage classes reduce storage costs for files that aren't accessed every day. We recommend using IA storage if you need your full dataset to be readily accessible, and you want to automatically save on storage costs for files that are less frequently accessed. Examples include keeping files accessible to satisfy audit requirements, perform historical analysis, or perform backup and recovery. For more information about Amazon EFS storage classes, see Managing EFS storage classes (p. 87).

**EFS lifecycle management**

Amazon EFS lifecycle management automatically manages cost-effective file storage for your file systems. When enabled, lifecycle management migrates files that haven't been accessed for a set period of time to an infrequent access storage class, Standard-IA or One Zone-IA. You define that period of time by using a lifecycle policy. For more information, see Amazon EFS lifecycle management (p. 90).

**EFS Intelligent-Tiering**

Amazon EFS Intelligent-Tiering uses lifecycle management to monitor the access patterns of your workload and is designed to automatically transition files to and from your corresponding Infrequent Access (IA) storage class. With intelligent tiering, files in the standard storage class (EFS Standard or EFS One Zone) that are not accessed for a period of time, for example 30 days, are transitioned to the corresponding Infrequent Access (IA) storage class. Additionally, if access patterns change, EFS Intelligent-Tiering automatically moves files back to the EFS Standard or EFS One Zone storage classes. This helps to eliminate the risk of unbounded access charges, while providing consistent low latencies. For more information, see Amazon EFS Intelligent-Tiering (p. 90).
Setting Up

Before you use Amazon EFS for the first time, complete the following tasks:

1. Sign up for AWS (p. 11)
2. Create an IAM User (p. 11)

Sign up for AWS

When you sign up for Amazon Web Services (AWS), your AWS account is automatically signed up for all services in AWS, including Amazon EFS. You are charged only for the services that you use.

With Amazon EFS, you pay only for the storage you use. For more information about Amazon EFS usage rates, see the Amazon Elastic File System Pricing. If you are a new AWS customer, you can get started with Amazon EFS for free. For more information, see AWS Free Usage Tier.

If you have an AWS account already, skip to the next task. If you don’t have an AWS account, use the following procedure to create one.

**To create an AWS account**

2. Follow the online instructions.

   Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

   Note your AWS account number, because you’ll need it for the next task.

Create an IAM User

Services in AWS, such as Amazon EFS, require that you provide credentials when you access them, so that the service can determine whether you have permissions to access its resources. AWS recommends that you do not use the root credentials of your AWS account to make requests. Instead, create an IAM user, and grant that user full access. We refer to these users as administrator users. You can use the administrator user credentials, instead of root credentials of your account, to interact with AWS and perform tasks, such as create a bucket, create users, and grant them permissions. For more information, see Root Account Credentials vs. IAM User Credentials in the AWS General Reference and IAM Best Practices in the IAM User Guide.

If you signed up for AWS but have not created an IAM user for yourself, you can create one using the IAM console.

**To create an administrator user for yourself and add the user to an administrators group (console)**

1. Sign in to the IAM console as the account owner by choosing Root user and entering your AWS account email address. On the next page, enter your password.
Create an IAM User

2. In the navigation pane, choose Users and then choose Add user.
3. For User name, enter Administrator.
4. Select the check box next to AWS Management Console access. Then select Custom password, and then enter your new password in the text box.
5. (Optional) By default, AWS requires the new user to create a new password when first signing in. You can clear the check box next to User must create a new password at next sign-in to allow the new user to reset their password after they sign in.
6. Choose Next: Permissions.
7. Under Set permissions, choose Add user to group.
8. Choose Create group.
9. In the Create group dialog box, for Group name enter Administrators.
10. Choose Filter policies, and then select AWS managed - job function to filter the table contents.
11. In the policy list, select the check box for AdministratorAccess. Then choose Create group.
   **Note**
   You must activate IAM user and role access to Billing before you can use the AdministratorAccess permissions to access the AWS Billing and Cost Management console. To do this, follow the instructions in step 1 of the tutorial about delegating access to the billing console.
12. Back in the list of groups, select the check box for your new group. Choose Refresh if necessary to see the group in the list.
13. Choose Next: Tags.
14. (Optional) Add metadata to the user by attaching tags as key-value pairs. For more information about using tags in IAM, see Tagging IAM entities in the IAM User Guide.
15. Choose Next: Review to see the list of group memberships to be added to the new user. When you are ready to proceed, choose Create user.

You can use this same process to create more groups and users and to give your users access to your AWS account resources. To learn about using policies that restrict user permissions to specific AWS resources, see Access management and Example policies.

To sign in as this new IAM user, sign out of the AWS Management Console, and then use the following URL, where your_aws_account_id is your AWS account number without the hyphens (for example, if your AWS account number is 1234-5678-9012, your AWS account ID is 123456789012):

https://your_aws_account_id.signin.aws.amazon.com/console/

Enter the IAM user name and password that you just created. When you're signed in, the navigation bar displays your_user_name@your_aws_account_id.

If you don't want the URL for your sign-in page to contain your AWS account ID, you can create an account alias. From the IAM dashboard, locate IAM users sign-in link: and choose Customize. Enter an alias, such as your company name. To sign in after you create an account alias, use the following URL:

https://your_account_alias.signin.aws.amazon.com/console/

To verify the sign-in link for IAM users for your account, open the IAM console and check under AWS account Alias on the dashboard.
Getting started with Amazon Elastic File System

In this Getting Started exercise, you can learn how to quickly create an Amazon Elastic File System (Amazon EFS) file system. As part of this process, you mount your file system on an Amazon Elastic Compute Cloud (Amazon EC2) instance in your virtual private cloud (VPC). You also test the end-to-end setup.

There are four steps that you need to perform to create and use your first Amazon EFS file system:

- Create your Amazon EFS file system.
- Create your Amazon EC2 resources, launch your instance, and mount the file system.
- Transfer files to your EFS file system using AWS DataSync.
- Clean up your resources and protect your AWS account.

Topics

- Assumptions (p. 13)
- Related topics (p. 13)
- Step 1: Create your Amazon EFS file system (p. 14)
- Step 2: Create your EC2 resources and launch your EC2 instance (p. 16)
- Step 3: Transfer files to Amazon EFS using AWS DataSync (p. 17)
- Step 4: Clean up resources and protect your AWS account (p. 18)

Assumptions

For this exercise, we assume the following:

- You're already familiar with using the Amazon EC2 console to launch instances.
- Your Amazon VPC, Amazon EC2, and Amazon EFS resources are all in the same AWS Region. This guide uses the US West (Oregon) Region (us-west-2).
- You have a default VPC in the AWS Region that you're using for this Getting Started exercise. If you don't have a default VPC, or if you want to mount your file system from a new VPC with new or existing security groups, you can still use this Getting Started exercise. To do so, configure Using VPC security groups for Amazon EC2 instances and mount targets (p. 195).
- You haven't changed the default inbound access rule for the default security group.

You can use your AWS account root user credentials to sign in to the console and try the Getting Started exercise. However, AWS Identity and Access Management (IAM) recommends that you do not use the account root user credentials. Instead, create an administrator user in your account and use those credentials to manage resources in your account. For more information, see Setting Up (p. 11).

Related topics

This guide also provides a walkthrough to perform a similar Getting Started exercise using AWS Command Line Interface (AWS CLI) commands to make the Amazon EFS API calls. For more information,
Step 1: Create your Amazon EFS file system

In this step, you create your Amazon EFS file system that has the service recommended settings using the Amazon EFS console.

To create your Amazon EFS file system

1. Open the Amazon EFS Management Console at https://console.aws.amazon.com/efs/.
2. Choose Create file system to open the Create file system dialog box.
3. (Optional) Enter a Name for your file system.
4. For Virtual Private Cloud (VPC), choose your VPC, or keep it set to your default VPC.
5. For Availability and Durability, choose one of the following:
   - Regional to create a file system that uses Standard storage classes (p. 87). Standard storage classes store file system data and metadata redundantly across all Availability Zones within an AWS Region. Regional offers the highest levels of availability and durability.
   - One Zone to create a file system that uses One Zone storage classes (p. 87). One Zone storage classes store file system data and metadata redundantly within a single Availability Zone which makes it less expensive than Standard storage classes.

Because EFS One Zone storage classes store data in a single AWS Availability Zone, data stored in these storage classes may be lost in the event of a disaster or other fault that affects all copies of the data within the Availability Zone, or in the event of Availability Zone destruction resulting from disasters, such as earthquakes and floods.
If you choose One Zone, choose the Availability Zone that you want the file system created in, or leave the default setting.

**Note**
One Zone storage classes are not available in all Availability Zones in AWS Regions where Amazon EFS is available.

For more information, see Managing EFS storage classes (p. 87).

6. Choose **Create** to create a file system that uses the following service recommended settings:

- Automatic backups turned on, for more information, see Using AWS Backup to back up and restore Amazon EFS file systems (p. 130).
- Mount targets – Amazon EFS creates mount targets with the following settings:
  - For file systems that use Standard storage classes, a mount target is created in each Availability Zone in the AWS Region in which the file system is created. For file systems that use One Zone storage classes, a single mount target is created in the Availability Zone you specified.
  - Located in the default subnets of the VPC you selected.
  - Using the VPC's default security group – You can manage security groups after the file system is the created.

    For more information, see Managing file system network accessibility (p. 83).

- General Purpose performance mode – For more information, see Performance modes (p. 122).
- Bursting throughput mode – For more information, see Throughput modes (p. 123).
- Encryption of data at rest enabled using your default key for Amazon EFS (aws/elasticfilesystem) – For more information, see Encrypting data at rest (p. 170).
- Lifecycle Management – Amazon EFS creates the file system with the following lifecycle policies:
  - Transition into IA set to 30 days since last access
  - Transition out of IA set to On first access

    For more information, see Amazon EFS lifecycle management (p. 90).

After you create the file system, you can customize the file system's settings with the exception of availability and durability, encryption, and performance mode.

If you want to create a file system with a customized configuration, choose **Customize**. For more information about creating a file system with customized settings, see Creating a file system with custom settings using the Amazon EFS console (p. 22).

7. The **File systems** page appears with a banner across the top showing the status of the file system you created. A link to access the file system details page appears in the banner when the file system becomes available.
Step 2: Create your EC2 resources and launch your EC2 instance

**Note**
You can’t use Amazon EFS with Microsoft Windows–based Amazon EC2 instances with Amazon EFS.

Before you can launch and connect to an Amazon EC2 instance, you need to create a key pair, unless you already have one. You can create a key pair using the Amazon EC2 console, and then you can launch your EC2 instance.

**To create a key pair**
- Follow the steps in Setting up with Amazon EC2 in the *Amazon EC2 User Guide for Linux Instances* to create a key pair. If you already have a key pair, you don't need to create a new one. You can use your existing key pair for this exercise.

**To launch the EC2 instance and mount an EFS file system**
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Launch Instance**.
3. In **Step 1: Choose an Amazon Machine Image (AMI)**, find an Amazon Linux 2 AMI at the top of the list and choose **Select**.
4. In **Step 2: Choose an Instance Type**, choose **Next: Configure Instance Details**.
5. In **Step 3: Configure Instance Details**, provide the following information:
Step 3: Transfer files using DataSync

Now that you have created a functioning Amazon EFS file system, you can use AWS DataSync to transfer files from an existing file system to Amazon EFS. AWS DataSync is a data transfer service that simplifies, automates, and accelerates moving and replicating data between on-premises storage systems and AWS storage services over the internet or AWS Direct Connect. AWS DataSync can transfer your file data, and also file system metadata such as ownership, timestamps, and access permissions.

Before you begin

In this step, we assume that you have the following:

- A source NFS file system that you can transfer files from. This source system needs to be accessible over NFS version 3, version 4, or 4.1. Example file systems include those located in an on-premises data center, self-managed in-cloud file systems, and Amazon EFS file systems.
- A destination Amazon EFS file system to transfer files to. If you don't have an Amazon EFS file system, create one. For more information, see Getting started with Amazon Elastic File System (p. 13).
- Your server and network meet the AWS DataSync requirements. To learn more, see the AWS DataSync requirements.
To transfer files from a source location to a destination location using AWS DataSync, you do the following:

- Download and deploy an agent in your environment and activate it.
- Create and configure a source and destination location.
- Create and configure a task.
- Run the task to transfer files from the source to the destination.

To learn how to transfer files from an existing on-premises file system to your EFS file system, see Getting Started with AWS DataSync in the AWS DataSync User Guide. To learn how to transfer files from an existing in-cloud file system to your EFS file system, see Deploying the AWS DataSync Agent as an Amazon EC2 Instance in the AWS DataSync User Guide, and the Amazon EFS AWS DataSync In-Cloud Transfer Quick Start and Scheduler.

Step 4: Clean up resources and protect your AWS account

This guide includes walkthroughs that you can use to further explore Amazon EFS. Before you perform this clean-up step, you can use the resources you've created and connected to in this Getting Started exercise in those walkthroughs. For more information, see Walkthroughs (p. 135). After you finish the walkthroughs, or if you don't want to explore the walkthroughs, take the following steps to clean up your resources and protect your AWS account.

To clean up resources and protect your account

1. Connect to your Amazon EC2 instance.
2. Unmount the Amazon EFS file system with the following command.

   ```bash
   # sudo umount efs
   ```
3. Open the Amazon EFS console at https://console.aws.amazon.com/efs/.
4. Choose the Amazon EFS file system that you want to delete from the list of file systems.
5. For Actions, choose Delete file system.
6. In the Permanently delete file system dialog box, type the file system ID for the Amazon EFS file system that you want to delete, and then choose Delete File System.
7. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
8. Choose the Amazon EC2 instance that you want to terminate from the list of instances.
9. For Actions, choose Instance State and then choose Terminate.
10. In Terminate Instances, choose Yes, Terminate to terminate the instance that you created for this Getting Started exercise.
11. In the navigation pane, choose Security Groups.
12. Select the name of the security group that you created for this Getting Started exercise in Step 2: Create your EC2 resources and launch your EC2 instance (p. 16) as a part of the Amazon EC2 instance Launch Wizard.
   
   **Warning**
   
   Don't delete the default security group for your VPC.
14. In Delete Security Group, choose Yes, Delete to delete the security group you created for this Getting Started exercise.
Working with Amazon EFS resources

Amazon EFS provides elastic, shared file storage that is POSIX-compliant. The file system you create supports concurrent read and write access from multiple Amazon EC2 instances and is accessible from all of the Availability Zones in the AWS Region where it is created.

You can mount an Amazon EFS file system on EC2 instances in your virtual private cloud (VPC) based on Amazon VPC using the Network File System versions 4.0 and 4.1 protocol (NFSv4). For more information, see Amazon EFS: How it works (p. 3).

As an example, suppose that you have one or more EC2 instances launched in your VPC. Now you want to create and use a file system on these instances. Following are the typical steps you need to perform to use Amazon EFS file systems in the VPC:

- **Create an Amazon EFS file system** – When creating a file system, we recommend that you consider using the Name tag because the Name tag value appears in the console and makes it easier to identify the file system. You can also add other optional tags to the file system.
- **Create mount targets for the file system** – To access the file system in your VPC and mount the file system to your Amazon EC2 instance, you must create mount targets in the VPC subnets.
- **Create security groups** – Both an Amazon EC2 instance and a mount target need to have associated security groups. These security groups act as a virtual firewall that controls the traffic between them. You can use the security group you associated with the mount target to control inbound traffic to your file system by adding an inbound rule to the mount target security group that allows access from a specific EC2 instance. Then, you can mount the file system only on that EC2 instance.

If you are new to Amazon EFS, we recommend that you try the following exercises that provide a first-hand, end-to-end experience of using an Amazon EFS file system:

- **Getting started (p. 13)** – The Getting Started exercise walks you through creating a file system with the service recommended settings using the Amazon EFS QuickCreate wizard, mounting it on an EC2 instance, and testing the setup. The console takes care of many things for you and helps you set up the end-to-end experience quickly.
- **Walkthrough: Create an Amazon EFS file system and mount it on an Amazon EC2 instance using the AWS CLI (p. 135)** – The walkthrough is similar to the Getting Started exercise, but it uses the AWS Command Line Interface (AWS CLI) to perform most of the tasks. Because the AWS CLI commands closely map to the Amazon EFS API, the walkthrough can help you familiarize yourself with the Amazon EFS API operations.

For more information about creating EFS resources and accessing a file system, see the following topics.

**Topics**

- Resource IDs (p. 20)
- Creating Amazon EFS file systems (p. 20)
- Deleting an Amazon EFS file system (p. 30)
- Creating and managing mount targets (p. 31)
- Creating security groups (p. 38)
- Creating file system policies (p. 39)
- Creating and deleting access points (p. 41)
Resource IDs

Amazon EFS assigns unique resource identifiers (IDs) to all EFS resources when they are created. All EFS resource IDs consist of a resource identifier and a combination of digits 0-9 and lowercase letters a-f.

Prior to October 2021, the IDs assigned to newly created file system and mount target resources used 8 characters after the hyphen (for example, fs-12345678). From May 2021 to October 2021, we changed the IDs of these resource types to use 17 characters after the hyphen (for example, fs-1234567890abcdef0). Depending on when your account was created, you might have file system and mount target resources with short IDs, though any new resources of these types receive the longer IDs. The IDs of existing EFS resources never change.

Creating Amazon EFS file systems

Following, you can find an explanation about how to create an Amazon EFS file system using the AWS Management Console and the AWS CLI.

If you are new to Amazon EFS, we recommend you go through the Getting Started exercise, which provides console-based end-to-end instructions to create and access a file system in your VPC. For more information, see Getting started (p. 13).

Topics
• Requirements (p. 20)
• Configuration options when creating a file system (p. 21)
• Creating a file system with custom settings using the Amazon EFS console (p. 22)
• Creating a file system using the AWS CLI (p. 28)

Requirements

This section describes requirements and prerequisites for creating Amazon EFS file systems.

Creation token and idempotency

To create a file system, the only requirement is that you create a token to ensure idempotent operation. If you use the console, it generates the token for you. If you use the Custom Create flow in the console, the creation token that is generated for you has the following format:

"CreationToken": "console-d215fa78-1f83-4651-b026-facafd8a7da7"

If you use QuickCreate to create a file system with the service recommended settings, the creation token has the following format:

"CreationToken": "quickCreated-d7f56c5f-e433-41ca-8307-9d9c0f8a77a2"

Permissions required

To create EFS resources such as a file system and access points, a user must have AWS Identity and Access Management (IAM) permissions for the corresponding API action and resource.
You can perform any Amazon EFS operations using your AWS account root user credentials, but using root user credentials is not recommended. We recommend that you create IAM users in your account, and grant them permissions for Amazon EFS actions with user policies. You can also use roles to grant cross-account permissions. Amazon Elastic File System also uses an AWS IAM service-linked role that includes permissions required to call other AWS services on your behalf. For more information about managing permissions for the API actions, see Identity and access management for Amazon EFS (p. 175).

Configuration options when creating a file system

You can create a file system using the Amazon EFS console or using the AWS Command Line Interface (AWS CLI). You can also create file systems programmatically using AWS SDKs or the Amazon EFS API directly.

When creating an Amazon EFS file system using the custom create flow or the AWS CLI, you can choose settings for the following file system features and configuration options.

Availability and durability

Availability and durability refer to the redundancy with which an Amazon EFS file system stores data within an AWS Region. You have the following choices for your file system's availability and durability:

- Choosing **Regional** creates a file system that uses Standard storage classes (p. 87) that store file system data and metadata redundantly across all Availability Zones within an AWS Region. You can also create mount targets in each Availability Zone in the AWS Region. **Regional** offers the highest levels of availability and durability.

- Choosing **One Zone** creates a file system that uses One Zone storage classes (p. 87) that store file system data and metadata redundantly within a single Availability Zone. File systems using One Zone storage classes can have only a single mount target which is located in the Availability Zone in which the file system is created.

Amazon EFS One Zone storage classes store data in a single AWS Availability Zone. Therefore, data stored in these storage classes may be lost in the event of a disaster or other fault that affects all copies of the data within the Availability Zone, or in the event of Availability Zone destruction.

If you choose One Zone, you can choose the Availability Zone in which the file system is created.

Automatic backups

Automatic backups are always enabled by default when you create a file system using the console. When you use the CLI or API to create a file system, automatic backups are enabled by default only when you are creating file systems using One Zone storage classes. For more information, see Automatic backups (p. 132).

EFS Lifecycle Management and EFS Intelligent-Tiering

EFS Intelligent-Tiering uses lifecycle management to automatically move files into and out of the lower-cost Infrequent Access (IA) storage class based on access patterns. When you create a file system using the AWS Management Console, the file system's lifecycle policy is configured with the following default settings:

- **Transition into IA** set to 30 days since last access
- **Transition out of IA** set to After first access

When you create a file system using the AWS CLI, API or SDKs, you cannot set a lifecycle policy. You have to wait until the file system is created, and then use the `PutLifecycleConfiguration` (p. 310).
Creating a file system using the console

API action to update the lifecycle configuration. For more information, see Amazon EFS lifecycle management (p. 90).

Performance modes

When creating a file system, you also choose a performance mode. There are two performance modes to choose from—General Purpose and Max I/O. For the majority of use cases, we recommend that you use the General Purpose performance mode for your file system. For more information, see Performance modes (p. 122).

Note
For file systems that use One Zone storage classes, only the General Purpose performance mode is available.

Throughput modes

There are two throughput modes to choose from—Bursting Throughput and Provisioned Throughput. The default Bursting Throughput mode is simple to work with and is suitable for a majority of applications and a wide range of performance requirements. Provisioned Throughput mode is for applications that require a greater ratio of throughput to storage capacity than allowed by Bursting Throughput mode. For more information, see Throughput modes (p. 123).

Note
Additional charges are associated with using Provisioned Throughput mode. For more information, see Amazon EFS pricing.

Encryption

You can enable encryption at rest when creating a file system. If you enable encryption at rest for your file system, all data and metadata stored on it are encrypted. You can enable encryption in transit later, when you mount the file system. For more information about Amazon EFS encryption, see Data encryption in Amazon EFS (p. 169).

To create the file system mount targets in your VPC, you must specify VPC subnets. The console pre-populates the list of VPCs in your account that are in the selected AWS Region. First, you select your VPC, and then the console lists the Availability Zones in the VPC. For each Availability Zone, you can select a subnet from the list, or use the default subnet if it exists. After you select a subnet, you can either specify an available IP address in the subnet or let Amazon EFS choose an address automatically.

Creating a file system with custom settings using the Amazon EFS console

This section describes the process of using the Amazon EFS console to create an EFS file system with customized settings instead of using the service recommended settings. For more information about creating a file system using the service recommended settings, see Step 1: Create your Amazon EFS file system (p. 14).

Creating an Amazon EFS file system using the console is a four-step process:

- Step 1 - Configure general file system settings, including availability and durability, lifecycle management, performance and throughput modes, and encryption of data at rest.
- Step 2 - Configure file system network settings, including the virtual private cloud (VPC) and mount targets. For each mount target, set the Availability Zone, subnet, IP address, and security groups.
- Step 3 - (Optional) Create a file system policy to control NFS client access to the file system.
- Step 4 - Review the file system settings, make any changes, and then create the file system.
Step 1: Configure file system settings

1. Sign in to the AWS Management Console and open the Amazon EFS console at https://console.aws.amazon.com/efs/.

2. Choose Create file system to open the Create file system dialog box.

3. Choose Customize to create a customized file system instead of creating a file system using the service recommended settings.

   The File system settings page appears.
4. For **General** settings, enter the following.
   a. (Optional) Enter a **Name** for the file system.
   b. For **Availability and Durability**, choose one of the following:
• Choose **Regional** to create a file system that uses Standard storage classes. Standard storage classes store file system data and metadata redundantly across all Availability Zones within an AWS Region. **Regional** offers the highest levels of availability and durability.

• Choose **One Zone** to create a file system that uses One Zone storage classes. One Zone storage classes store file system data and metadata redundantly within a single Availability Zone.

Amazon EFS One Zone storage classes store data in a single AWS Availability Zone. Therefore, data stored in these storage classes might be lost in the event of a disaster or other fault that affects all copies of the data within the Availability Zone, or in the event of Availability Zone destruction.

If you choose One Zone, choose the **Availability Zone** that you want the file system created in, or keep the default setting.

For more information, see Managing EFS storage classes (p. 87).

c. **Automatic backups** are turned on by default. You can turn off automatic backups by clearing the check box. For more information, see Using AWS Backup to back up and restore Amazon EFS file systems (p. 130).

d. For **Lifecycle management**, the default policy sets **Transition into IA** to **30 days after last access** and **Transition out of IA** to **After first access**. If you don't want to use intelligent tiering, choose None for each of these policy settings. For more information, see Amazon EFS lifecycle management (p. 90).

e. Choose a **Performance mode**, either the default **General Purpose** mode or **Max I/O**. You can change the performance mode after the file system becomes available. For more information, see Performance modes (p. 122).

   **Note**
   Only the General Purpose mode is available for file systems that are configured for One Zone availability and durability.

   f. Choose a **Throughput mode**, either the default **Bursting** mode or **Provisioned** mode.

   If you choose **Provisioned**, the **Provisioned Throughput (MiB/s)** section appears. Enter the amount of **Throughput** to provision for file system requests.

   The amount of **Maximum Read Throughput** is displayed at three times the amount of the throughput you enter. EFS file systems meter read requests at one-third the rate of other requests. After you enter the throughput, an estimate of the monthly cost for the file system is displayed.

   You can change the amount of write throughput anytime after the file system becomes available. For more information, see Throughput modes (p. 123).

   g. For **Encryption**, encryption of data at rest is enabled by default. It uses your AWS Key Management Service (AWS KMS) EFS service key (aws/elasticfilesystem) by default. To choose a different KMS key to use for encryption, expand **Customize encryption settings** and choose a key from the list. Or, enter a KMS key ID or Amazon Resource Name (ARN) for the KMS key you want to use.

   If you need to create a new key, choose **Create an AWS KMS key** to launch the AWS KMS console and create a new key.

   You can turn off encryption of data at rest by clearing the check box.

5. (Optional) Add tag key-value pairs to your file system.

6. Choose **Next** to continue to the **Network Access** step in the configuration process.
Step 2: Configure network access

In Step 2, you configure the file system's network settings, including the VPC and mount targets.

![Network access](image)

1. Choose the **Virtual Private Cloud (VPC)** where you want EC2 instances to connect to your file system. For more information, see Managing file system network accessibility (p. 83).

2. For **Mount targets**, you create one or more mount targets for your file system. For each mount target, set the following properties:

   - **Availability zone** – By default, a mount target is configured in each Availability Zone in an AWS Region. If you don't want a mount target in a particular Availability Zone, choose **Remove** to delete the mount target for that zone. Create a mount target in every Availability Zone that you plan to access your file system from – there is no cost to do so.

   - **Subnet ID** – Choose from the available subnets in an Availability Zone. The default subnet is preselected.

   - **IP Address** – By default, Amazon EFS chooses the IP address automatically from the available addresses in the subnet. Or, you can enter a specific IP address that's in the subnet. Although mount targets have a single IP address, they are redundant, highly available network resources.
• **Security groups** – You can specify one or more security groups for the mount target. For more information, see Using VPC security groups for Amazon EC2 instances and mount targets (p. 195).

To add another security group, or to change the security group, choose Choose security groups and add another security group from the list. If you don't want to use the default security group, you can delete it. For more information, see Creating security groups (p. 38).

3. Choose **Add mount target** to create a mount target for an Availability Zone that doesn't have one. If a mount target is configured for each Availability Zone, this choice is not available.

4. Choose **Next** to continue. The File system policy page is displayed.

### Step 3: Create a file system policy (optional)

Optionally, you can create a file system policy for your file system. An EFS file system policy is an IAM resource policy that you use to control NFS client access to the file system. For more information, see Using IAM to control file system data access (p. 185).

1. In **Policy options**, you can choose any combination of the available preconfigured policies:
   - Prevent root access by default
   - Enforce read-only access by default
   - Enforce in-transit encryption for all clients

2. Use the **Policy editor** to customize a preconfigured policy or to create your own policy. When you choose one of the preconfigured policies, the JSON policy definition appears in the policy editor. You can edit the JSON to create a policy of your choice. To undo your changes, choose **Clear**.

   The preconfigured policies become available once again in **Policy options**.
3. Choose Next to continue. The Review and create page appears.

Step 4: Review and create

1. Review each of the file system configuration groups. You can make changes to each group at this time by choosing Edit.
2. Choose Create to create your file system and return to the File systems page.

   A banner across the top shows that the new file system is being created. A link to access the new file system details page appears in the banner when the file system becomes available.
3. The File systems page displays the file system and its configuration details, as shown following.

Creating a file system using the AWS CLI

When using the AWS CLI, you create these resources in order. First, you create a file system. Then, you can create mount targets and any additional optional tags for the file system using corresponding AWS CLI commands.

The following examples use the adminuser as the profile parameter values. You need to use an appropriate user profile to provide your credentials. For information about the AWS CLI, see Installing the AWS CLI in the AWS Command Line Interface User Guide.

- To create an encrypted file system that uses Standard storage classes, with automatic backups enabled, use the Amazon EFS create-file-system CLI command (the corresponding operation is CreateFileSystem (p. 238)), as shown following.

```bash
$ aws efs create-file-system \
  --creation-token creation-token \
  --encrypted true \
  --backup true \
  --performance-mode generalPurpose \
  --throughput-mode bursting \
```

---

---

28
For example, the following `create-file-system` command creates a file system in the `us-west-2` AWS Region. The command specifies `MyFirstFS` as the creation token. For a list of AWS Regions where you can create an Amazon EFS file system, see the Amazon Web Services General Reference.

```
$ aws efs create-file-system \
  --creation-token MyFirstFS \
  --encrypted true \
  --performance-mode generalPurpose \
  --throughput-mode bursting \
  --region us-west-2 \
  --tags Key=Name,Value="Test File System" Key=developer,Value=rhoward \
  --profile adminuser
```

After successfully creating the file system, Amazon EFS returns the file system description as JSON, as shown in the following example.

```
{
  "OwnerId": "123456789abcd",
  "CreationToken": "MyFirstFS",
  "Encrypted": true,
  "FileSystemId": "fs-c7a0456e",
  "CreationTime": 1422823614.0,
  "LifeCycleState": "creating",
  "Name": "Test File System",
  "NumberOfMountTargets": 0,
  "SizeInBytes": {
    "Value": 6144,
    "ValueInIA": 0,
    "ValueInStandard": 6144
  },
  "PerformanceMode": "generalPurpose",
  "ThroughputMode": "bursting",
  "Tags": [
    {
      "Key": "Name",
      "Value": "Test File System"
    }
  ]
}
```

- The following example creates a file system that uses One Zone storage classes in the `us-west-2a` Availability Zone using the `availability-zone-name` property.

```
$ aws efs create-file-system \
  --creation-token MyFirstFS \
  --availability-zone-name us-west-2a \
  --encrypted true \
  --performance-mode generalPurpose \
  --throughput-mode bursting \
  --region us-west-2 \
  --tags Key=Name,Value="Test File System" Key=developer,Value=rhoward \
  --profile adminuser
```
After successfully creating the file system, Amazon EFS returns the file system description as JSON, as shown in the following example.

```json
{
    "AvailabilityZoneId": "usw-az1",
    "AvailabilityZoneName": "us-west-2a",
    "OwnerId": "123456789abcd",
    "CreationToken": "MyFirstFS",
    "Encrypted": true,
    "FileSystemId": "fs-c7a0456e",
    "CreationTime": 1422823614.0,
    "LifeCycleState": "creating",
    "Name": "Test File System",
    "NumberOfMountTargets": 0,
    "SizeInBytes": {
        "Value": 6144,
        "ValueInIA": 0,
        "ValueInStandard": 6144
    },
    "PerformanceMode": "generalPurpose",
    "ThroughputMode": "bursting",
    "Tags": [
        {
            "Key": "Name",
            "Value": "Test File System"
        }
    ]
}
```

Amazon EFS also provides the describe-file-systems CLI command (the corresponding API operation is DescribeFileSystems (p. 279)), which you can use to retrieve a list of file systems in your account, as shown following.

```
$ aws efs describe-file-systems
  --region aws-region
  --profile adminuser
```

Amazon EFS returns a list of the file systems in your AWS account created in the specified Region.

Deleting an Amazon EFS file system

File system deletion is a destructive action that you can't undo. You lose the file system and any data you have in it. Any data that you delete from a file system is gone, and you can't restore the data. When users delete data from a file system, that data is immediately rendered unusable. EFS force-overwrites the data in an eventual manner.

**Important**

You should always unmount a file system before you delete it.

Using the console

To delete a file system

2. Select the file system that you want to delete in the **File systems** page.
3. Choose **Delete**.
4. In the **Delete file system** dialog box, enter the file system id shown, and choose **Confirm** to confirm the delete.

![Delete file system](image)

The console simplifies the file system deletion for you. First it deletes the associated mount targets, and then it deletes the file system.

**Using the CLI**

Before you can use the AWS CLI command to delete a file system, you must delete all of the mount targets and access points created for the file system.

For example AWS CLI commands, see Step 4: Clean up (p. 146).

**Related topics**

Managing Amazon EFS file systems (p. 83)

**Creating and managing mount targets**

After you create an Amazon EFS file system, you can create mount targets. For Amazon EFS file systems that use Standard storage classes, you can create a mount target in each Availability Zone in an AWS Region. For EFS file systems that use One Zone storage classes, you can only create a single mount target in the same Availability Zone as the file system. Then you can mount the file system on compute instances, including Amazon EC2, Amazon ECS, and AWS Lambda in your virtual private cloud (VPC).

The following diagram shows an Amazon EFS file system that uses Standard storage classes, with mount targets created in all Availability Zones in the VPC.
The following diagram shows an Amazon EFS file system using One Zone storage classes, with a single mount target created in the same Availability Zone as the file system. Accessing the file system using the EC2 instance in the us-west2c Availability Zone incurs data access charges because it is located in a different Availability Zone than the mount target.
Creating and managing mount targets

The mount target security group acts as a virtual firewall that controls the traffic. For example, it determines which clients can access the file system. This section explains the following:

- Managing mount target security groups and enabling traffic.
- Mounting the file system on your clients.
- NFS-level permissions considerations.

Initially, only the root user on the Amazon EC2 instance has read-write-execute permissions on the file system. This topic discusses NFS-level permissions and provides examples that show you how to grant permissions in common scenarios. For more information, see Working with users, groups, and permissions at the Network File System (NFS) Level (p. 198).

You can create mount targets for a file system using the AWS Management Console, AWS CLI, or programmatically using the AWS SDKs. When using the console, you can create mount targets when you first create a file system or after the file system is created.

For instructions to create mount targets using the Amazon EFS console when creating a new file system, see Step 2: Configure network access (p. 26).

Managing mount targets using the Amazon EFS console

Use the following procedure to add or modify mount targets for an existing Amazon EFS file system.

To manage mount targets on an Amazon EFS file system (console)

1. Sign in to the AWS Management Console and open the Amazon EFS console at https://console.aws.amazon.com/efs/.
2. In the left navigation pane, choose File systems. The File systems page displays the EFS file systems in your account.
3. Choose the file system that you want to manage mount targets for by choosing its Name or the File system ID to display the file system details page.

4. Choose Network to display the list of existing mount targets.

5. Choose Manage to display the Availability zone page and make modifications.

On this page, for existing mount targets, you can add and remove security groups, or delete the mount target. You can also create new mount targets.

**Note**
For file systems that use One Zone storage classes, you can only create a single mount target that is in the same Availability Zone as the file system.

- To remove a security group from a mount target, choose X next to the security group ID.
- To add a security group to a mount target, choose Select security groups to display a list of available security groups. Or, enter a security group ID in the search field at the top of the list.
• To queue a mount target for deletion, choose **Remove**.

  **Note**
  Before deleting a mount target, first unmount the file system.

• To add a mount target, choose **Add mount target**. This is available only for file systems that use Standard storage classes, and if mount targets do not already exist in each Availability Zone for the AWS Region.

6. Choose **Save** to save any changes.

**To change the VPC for an Amazon EFS file system (console)**

To change the VPC for a file system's network configuration, you must delete all of the file system's existing mount targets.

2. In the left navigation pane, choose **File systems**. The **File systems** page shows the EFS file systems in your account.
3. For the file system that you want to change the VPC for, choose the **Name** or the **File system ID**. The file system details page is displayed.
4. Choose **Network** to display the list of existing mount targets.
5. Choose **Manage**. The **Availability zone** page appears.
6. Remove all mount targets displayed on the page.
7. Choose **Save** to save changes and delete the mount targets. The **Network** tab shows the mount targets status as **deleting**.
8. When all the mount targets statuses show as **deleted**, choose **Manage**. The **Availability zone** page appears.
9. Choose the new VPC from the **Virtual Private Cloud (VPC)** list.
10. Choose **Add mount target** to add a new mount target. For each mount target you add, enter the following:

  • An **Availability zone**
  • A **Subnet ID**
  • An **IP address**, or keep it set to **Automatic**
  • One or more **Security groups**

11. Choose **Save** to implement the VPC and mount target changes.

**Managing mount targets using the AWS CLI**

**Note**
For file systems that use One Zone storage classes, you can only create a single mount target that is in the same Availability Zone as the file system.

**To create a mount target (CLI)**

• To create a mount target, use the **create-mount-target** CLI command (corresponding operation is **CreateMountTarget** (p. 248)), as shown following.

```
$ aws efs create-mount-target \
  --file-system-id file-system-id \
  --subnet-id subnet-id \
  --security-group ID-of-the-security-group-created-for-mount-target \
  --region aws-region \
  --profile adminuser
```
The following example shows the command with sample data.

```
$ aws efs create-mount-target
  --file-system-id fs-0123467
  --subnet-id subnet-b3983dc4
  --security-group sg-01234567
  --region us-east-2
  --profile adminuser
```

After successfully creating the mount target, Amazon EFS returns the mount target description as JSON as shown in the following example.

```
{
  "MountTargetId": "fsmt-f9a14450",
  "NetworkInterfaceId": "eni-3851ec4e",
  "FileSystemId": "fs-b6a0451f",
  "LifeCycleState": "available",
  "SubnetId": "subnet-b3983dc4",
  "OwnerId": "23124example",
  "IpAddress": "10.0.1.24"
}
```

To retrieve a list of mount targets for a file system (CLI)

- You can also retrieve a list of mount targets created for a file system using the `describe-mount-targets` CLI command (the corresponding operation is `DescribeMountTargets` (p. 286)), as shown following.

```
$ aws efs describe-mount-targets --file-system-id fs-a576a6dc
```

```
{
  "MountTargets": [
    {
      "OwnerId": "111122223333",
      "MountTargetId": "fsmt-48518531",
      "FileSystemId": "fs-a576a6dc",
      "SubnetId": "subnet-88556633",
      "LifeCycleState": "available",
      "IpAddress": "172.31.25.203",
      "NetworkInterfaceId": "eni-0123456789abcdef1",
      "AvailabilityZoneId": "use2-az2",
      "AvailabilityZoneName": "us-east-2b"
    },
    {
      "OwnerId": "111122223333",
      "MountTargetId": "fsmt-5651852f",
      "FileSystemId": "fs-a576a6dc",
      "SubnetId": "subnet-44223377",
      "LifeCycleState": "available",
      "IpAddress": "172.31.25.203",
      "NetworkInterfaceId": "eni-0123456789abcdef1",
      "AvailabilityZoneId": "use2-az3",
      "AvailabilityZoneName": "us-east-2c"
    },
    {
      "OwnerId": "111122223333",
      "MountTargetId": "fsmt-5751852e",
      "FileSystemId": "fs-a576a6dc",
      "SubnetId": "subnet-b3983dc4",
      "LifeCycleState": "available",
      "IpAddress": "172.31.25.203",
      "NetworkInterfaceId": "eni-0123456789abcdef1",
      "AvailabilityZoneId": "use2-az4",
      "AvailabilityZoneName": "us-east-2d"
    }
  ]
}
```
To delete an existing mount target (CLI)

- To delete an existing mount target, use the `delete-mount-target` AWS CLI command (corresponding operation is `DeleteMountTarget (p. 264)`), as shown following.

  Note
  Before deleting a mount target, first unmount the file system.

```
$ aws efs delete-mount-target \
  --mount-target-id mount-target-ID-to-delete \
  --region aws-region-where-mount-target-exists
```

The following is an example with sample data.

```
$ aws efs delete-mount-target \
  --mount-target-id fsmt-5751852e \
  --region us-east-2 \
```

To modify the security group of an existing mount target

- To modify security groups that are in effect for a mount target, use the `modify-mount-target-security-group` AWS CLI command (the corresponding operation is `ModifyMountTargetSecurityGroups (p. 299)`) to replace any existing security groups, as shown following.

```
$ aws efs modify-mount-target-security-groups \
  --mount-target-id mount-target-ID-whose-configuration-to-update \
  --security-groups security-group-ids-separated-by-space \
  --region aws-region-where-mount-target-exists \
  --profile adminuser
```

The following is an example with sample data.

```
$ aws efs modify-mount-target-security-groups \
  --mount-target-id fsmt-5751852e \
  --security-groups sg-1004395a sg-1114433a \
  --region us-east-2
```

For more information, see Walkthrough: Create an Amazon EFS file system and mount it on an Amazon EC2 instance using the AWS CLI (p. 135).
Creating security groups

Note
The following section is specific to Amazon EC2 and discusses how to create security groups so you can use Secure Shell (SSH) to connect to any instances that have mounted Amazon EFS file systems. If you're not using SSH to connect to your Amazon EC2 instances, you can skip this section.

Both an Amazon EC2 instance and a mount target have associated security groups. These security groups act as a virtual firewall that controls the traffic between them. If you don't provide a security group when creating a mount target, Amazon EFS associates the default security group of the VPC with it.

Regardless, to enable traffic between an EC2 instance and a mount target (and thus the file system), you must configure the following rules in these security groups:

- The security groups you associate with a mount target must allow inbound access for the TCP protocol on the NFS port from all EC2 instances on which you want to mount the file system.
- Each EC2 instance that mounts the file system must have a security group that allows outbound access to the mount target on the NFS port.

For more information about security groups, see Amazon EC2 Security Groups in the Amazon EC2 User Guide for Linux Instances.

Creating security groups using the AWS Management Console

You can use the AWS Management Console to create security groups in your VPC. To connect your Amazon EFS file system to your Amazon EC2 instance, you must create two security groups: one for your Amazon EC2 instance and another for your Amazon EFS mount target.

1. Create two security groups in your VPC. For instructions, see Creating a Security Group in the Amazon VPC User Guide.
2. In the VPC console, verify the default rules for these security groups. Both security groups should have only an outbound rule that allows traffic to leave.
3. You need to authorize additional access to the security groups as follows:
   a. Add a rule to the EC2 security group to allow SSH access to the instance on port 22 as shown following. This is useful if you're planning on using an SSH client like PuTTY to connect to and administer your EC2 instance through a terminal interface. Optionally, you can restrict the Source address.

   For instructions, see Adding, removing, and updating rules in the Amazon VPC User Guide.
   b. Add a rule to the mount target security group to allow inbound access from the EC2 security group, as shown following (where the EC2 security group is identified as the source).
Creating security groups using the AWS CLI

For an example that shows how to create security groups using the AWS CLI, see Step 1: Create Amazon EC2 resources (p. 137).

Creating file system policies

You can create a file system policy using the Amazon EFS console or using the AWS CLI. You can also create a file system policy programmatically using AWS SDKs or the Amazon EFS API directly. EFS file system policies have a 20,000 character limit. For more information about using an EFS file system policy and examples, see Using IAM to control file system data access (p. 185).

Note
Amazon EFS file system policy changes can take several minutes to take effect.

Creating a file system policy (console)

3. On the File systems page, choose the file system that you want to edit or create a file system policy for. The details page for that file system is displayed.
4. Choose File system policy, then choose Edit. The File system policy page appears.
5. In **Policy options**, you can choose any combination of the preconfigured file system policies:

- Prevent root access by default - This option removes `ClientRootAccess` from the set of allowed EFS actions.
- Enforce read-only access by default - This option removes `ClientWriteAccess` from the set of allowed EFS actions.
- Prevent anonymous access - This option removes `ClientMount` from the set of allowed EFS actions.
- Enforce in-transit encryption for all clients - This option denies access to unencrypted clients.

When you choose a preconfigured policy, the policy JSON object is displayed in the **Policy editor** pane.

6. Use **Grant additional permissions** to grant file system permissions to additional IAM principals, including another AWS account. Choose **Add**, and enter the principal ARN of the entity that you are granting permissions to. Then choose the **Permissions** that you want to grant. The additional permissions are shown in the **Policy editor**.

7. You can use the **Policy editor** to customize a preconfigured policy or to create your own file system policy. When you use the editor, the preconfigured policy options become unavailable. To clear the current file system policy and start creating a new policy, choose **Clear**.

When you clear the editor, the preconfigured policies become available once again.

8. After you complete editing the policy, choose **Save**.

### Creating a file system policy (CLI)

In the following example, the `put-file-system-policy` CLI command creates a file system policy that allows the specified AWS account read-only access to the EFS file system. The equivalent API command is **PutFileSystemPolicy** (p. 306).

```bash
aws efs put-file-system-policy --file-system-id fs-01234567 --policy '{
  "Id": "1",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "elasticfilesystem:ClientMount"
      ],
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:root"
      }
    }
  ]
}
```

```json
{"FileSystemId": "fs-01234567",
 "Policy": "{"Version": "2012-10-17",
  "Id": "1",
  "Statement" : [
    {
      "Sid": "efs-statement-7c8d8687-1c94-4fde-98b7-555555555555",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:root"
      }
    }
  ]
}"
```
Creating and deleting access points

You can create Amazon EFS access points using the AWS Management Console or the AWS CLI. You can also create access points programmatically using the AWS SDKs or the Amazon EFS API directly. For more information about EFS access points, see Working with Amazon EFS Access Points (p. 202).

The following procedures describe how to create an access point using the console and the AWS CLI.

Creating an access point (console)

2. Choose Access points to open the Access points window.
3. Choose Create access point to display the Create access point page.

You can also open the Create access point page by choosing File Systems. Choose a file system Name or File system ID and then choose Access points and Create access point to create an access point for that file system.
a. Enter the following information in the Details panel:

- **File system** – Enter a file system name or ID and choose the matching file system, or just choose from the list that appears when you choose the input field.
- **(Optional) Name** – Enter a name for the access point.
Deleting an access point

- (Optional) **Root directory path** – You can specify a root directory for the access point; the default access point root is /. To enter a root directory path, use the format `/foo/bar`. For more information, see Enforcing a Root Directory with an Access Point (p. 203).

  b. (Optional) In the POSIX user panel, you can specify the full POSIX identity to use to enforce user and group information for all file operations by NFS clients using the access point. For more information, see Enforcing a User Identity Using an Access Point (p. 203).

  - **User ID** – Enter a numeric POSIX user ID for the user.
  - **Group ID** – Enter a numeric POSIX group ID for the user.
  - **Secondary group IDs** – Enter an optional comma-separated list of secondary group IDs.

c. (Optional) For **Root directory creation permissions** you can specify the permissions to use when Amazon EFS creates the root directory path, if specified and it doesn't already exist. For more information, see Enforcing a Root Directory with an Access Point (p. 203).

  - **Owner user ID** – enter the numeric POSIX user ID to use as the root directory owner.
  - **Owner group ID** – enter the numeric POSIX group ID to use as the root directory owner group.
  - **Permissions** – enter the Unix mode of the directory. A common configuration is 755. Ensure that the execute bit is set for the access point user so they are able to mount.

4. Choose **Create access point** to create the access point using this configuration.

### Creating an access point (CLI)

In the following example, the `create-access-point` CLI command creates an access point for the file system. The equivalent API command is CreateAccessPoint (p. 233).

```bash
aws efs create-access-point --file-system-id fs-01234567 --client-token 010102020-3 
{
  "ClientToken": "010102020-3",
  "Tags": [],
  "AccessPointId": "fsap-092e9f80b3fb5e6f3",
  "AccessPointArn": "arn:aws:elasticfilesystem:us-east-2:111122223333:access-point/fsap-092e9f80b3fb5e6f3",
  "FileSystemId": "fs-01234567",
  "RootDirectory": { "Path": "/" },
  "OwnerId": "111122223333",
  "LifeCycleState": "creating"
}
```

### Deleting an access point

When you delete an access point, any clients using the access point lose access to the Amazon EFS file system that it's configured for.

#### Deleting an access point (console)

2. In the left navigation pane, choose **Access points** to open the **Access points** page.
3. Select the access point to delete.
4. Choose **Delete**.
5. Choose **Confirm** to confirm the action and delete the access point.
Tagging resources

To help you manage your Amazon EFS resources, you can assign your own metadata to each resource in the form of tags. Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. This is useful when you have many resources of the same type—you can quickly identify a specific resource based on the tags that you’ve assigned to it. This topic describes tags and shows you how to create them.

Tag basics

A tag is a label that you assign to an AWS resource. Each tag consists of a key and an optional value, both of which you define.

Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. For example, you could define a set of tags for your account's Amazon EFS file systems that helps you track each file system's owner.

We recommend that you devise a set of tag keys that meets your needs for each resource type. Using a consistent set of tag keys makes it easier for you to manage your resources. You can search and filter the resources based on the tags you add. For more information about how to implement an effective resource tagging strategy, see the AWS whitepaper Tagging Best Practices.

Tags don't have any semantic meaning to Amazon EFS and are interpreted strictly as a string of characters. Also, tags are not automatically assigned to your resources. You can edit tag keys and values, and you can remove tags from a resource at any time. You can set the value of a tag to an empty string, but you can't set the value of a tag to null. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value. If you delete a resource, any tags for the resource are also deleted.

Tag your resources

You can tag Amazon EFS file system and access point resources that already exist in your account.

You can use the Amazon EFS console to apply tags to existing resources by using the Tags tab on the resource details screen. The Amazon EFS console enables you to specify tags for a resource when you create the resource; for example, a tag with a key of Name and a value that you specify. In most cases, the console applies the tags immediately after the resource is created (rather than during resource creation). The console may organize resources according to the Name tag, but this tag doesn't have any semantic meaning to the Amazon EFS service.

If you're using the Amazon EFS API, the AWS CLI, or an AWS SDK, you can use the TagResource EFS API action to apply tags to existing resources. Additionally, some resource-creating actions enable you to specify tags for a resource when the resource is created.

The AWS CLI commands for managing tags, and the equivalent Amazon EFS API actions, are listed in the following table.

Deleting an access point (CLI)

In the following example, the delete-access-point CLI command deletes the specified access point. The equivalent API command is DeleteAccessPoint (p. 258). If the command is successful, the service returns an HTTP 204 response with an empty HTTP body.

```
aws efs delete-access-point --access-point-id fsap-092e9f80b3fb5e6f3 --client-token 010102020-3
```
Tag restrictions

The following basic restrictions apply to tags:

- Maximum number of tags per resource – 50
- For each resource, each tag key must be unique, and each tag key can have only one value.
- Maximum key length – 128 Unicode characters in UTF-8
- Maximum value length – 256 Unicode characters in UTF-8
- Although Amazon EFS allows for any character in its tags, other services are more restrictive. The allowed characters across services are: letters, numbers, and spaces representable in UTF-8, and the following characters: + - = . _ : / @.
- Tag keys and values are case-sensitive.
- The aws: prefix is reserved for AWS use. If a tag has a tag key with this prefix, then you can't edit or delete the tag's key or value. Tags with the aws: prefix do not count against your tags per resource limit.

You can't update or delete a resource based solely on its tags; you must specify the resource identifier. For example, to delete file systems that you tagged with a tag key called DeleteMe, you must use the DeleteFileSystem action with the resource identifiers of the file system, such as fs-1234567890abcdef0.

When you tag public or shared resources, the tags you assign are available only to your AWS account; no other AWS account will have access to those tags. For tag-based access control to shared resources, each AWS account must assign its own set of tags to control access to the resource.

You can tag Amazon EFS file system and access point resources.
Using file systems in Amazon EFS

Amazon Elastic File System presents a standard file-system interface that supports full file-system access semantics. Using Network File System (NFS) version 4.1 (NFSv4.1), you can mount your Amazon EFS file system on any Amazon Elastic Compute Cloud (Amazon EC2) Linux-based instance. After your system is mounted, you can work with the files and directories just as you do with a local file system. For more information on mounting, see Mounting EFS file systems (p. 59).

After you create a file system and mount it on your EC2 instance, to use your file system effectively you need to know about managing NFS-level permissions for users, groups, and related resources. When you first create your file system, there is only one root directory at / . By default, only the root user (UID 0) has read-write-execute permissions. For other users to modify the file system, the root user must explicitly grant them access. You use EFS access points to provision directories that are writable from a specific application. For more information, see Working with users, groups, and permissions at the Network File System (NFS) Level (p. 198) and Working with Amazon EFS Access Points (p. 202).

Amazon EFS: How it works (p. 3)
Getting started (p. 13)
Walkthroughs (p. 135)
Overview

The Amazon EFS client (amazon-efs-utils) is an open-source collection of Amazon EFS tools. There's no additional cost to use the Amazon EFS client, which you can download from GitHub here: https://github.com/aws/efs-utils. The amazon-efs-utils package is available in the Amazon Linux package repositories, and you can build and install the package on other Linux distributions. You can also use AWS Systems Manager to automatically install or update the package. For more information, see Using AWS Systems Manager to automatically install or update Amazon EFS clients (p. 48).

Note

The amzn-efs-utils package comes preinstalled on Amazon Linux and Amazon Linux 2 Amazon Machine Images (AMIs).

The Amazon EFS client includes a mount helper and tooling that makes it easier to perform encryption of data in transit for Amazon EFS file systems. A mount helper is a program that you use when you mount a specific type of file system. We recommend that you use the mount helper included with the Amazon EFS client to mount your Amazon EFS file systems. Using the Amazon EFS client simplifies mounting EFS file systems, and can provide improved file system performance. For more information about using the EFS client and mount helper, see Mounting EFS file systems (p. 59).

The following dependencies exist for amazon-efs-utils and are installed when you install the amazon-efs-utils package:

- NFS client
- nfs-utils for RHEL, CentOS, Amazon Linux, and Fedora distributions
- nfs-common for Debian and Ubuntu distributions
- Network relay (stunnel package, version 4.56 or later)
- Python (version 3.4 or later)
- OpenSSL 1.0.2 or newer

Note

By default, when using the Amazon EFS mount helper with Transport Layer Security (TLS), the mount helper enforces certificate hostname checking. The Amazon EFS mount helper uses the
stunnel program for its TLS functionality. Some versions of Linux don't include a version of stunnel that supports these TLS features by default. When using one of those Linux versions, mounting an Amazon EFS file system using TLS fails. When you've installed the amazon-efs-utils package, to upgrade your system's version of stunnel, see Upgrading stunnel (p. 56).

You can use AWS Systems Manager to manage Amazon EFS clients and automate the tasks required to install or update the amazon-efs-utils package on your EC2 instances. For more information, see Using AWS Systems Manager to automatically install or update Amazon EFS clients (p. 48).

For issues with encryption, see Troubleshooting Encryption (p. 228).

**Supported distributions**

The Amazon EFS client has been verified against the following Linux and Mac distributions:

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Package type</th>
<th>init system</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Linux 2017.09</td>
<td>rpm</td>
<td>upstart</td>
</tr>
<tr>
<td>Amazon Linux 2</td>
<td>rpm</td>
<td>systemd</td>
</tr>
<tr>
<td>CentOS 7, 8</td>
<td>rpm</td>
<td>systemd</td>
</tr>
<tr>
<td>Debian 9, 10</td>
<td>deb</td>
<td>systemd</td>
</tr>
<tr>
<td>Fedora 28 - 32</td>
<td>rpm</td>
<td>systemd</td>
</tr>
<tr>
<td>macOS Big Sur</td>
<td></td>
<td>launchd</td>
</tr>
<tr>
<td>OpenSUSE Leap, Tumbleweed</td>
<td>rpm</td>
<td>systemd</td>
</tr>
<tr>
<td>Red Hat Enterprise Linux (RHEL) 7, 8</td>
<td>rpm</td>
<td>systemd</td>
</tr>
<tr>
<td>SUSE Linux Enterprise Server (SLES) 12, 15</td>
<td>rpm</td>
<td>systemd</td>
</tr>
<tr>
<td>Ubuntu 16.04 LTS, 18.04 LTS, 20.04 LTS</td>
<td>rpm</td>
<td>systemd</td>
</tr>
</tbody>
</table>

For a complete list of supported distributions that the package has been verified against, see the efs-utils README on Github.

In the following sections, you can learn how to install the Amazon EFS client on your EC2 Linux or Mac instances.

**Using AWS Systems Manager to automatically install or update Amazon EFS clients**

You can use AWS Systems Manager to simplify the management of Amazon EFS clients (amazon-efs-utils). AWS Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS. With AWS Systems Manager you can automate the tasks required to install or update the amazon-efs-utils package on your EC2 instances. The Systems Manager capabilities like Distributor and State Manager enable you to automate the following processes:

- Maintaining control over Amazon EFS client versioning.
- Centrally storing and systematically distributing the Amazon EFS client to your Amazon EC2 instances.
• Automate the process of keeping your Amazon EC2 instances in a defined state.

For more information, see *AWS Systems Manager User Guide*.

**Systems Manager Distributor supported operating systems**

Your EC2 instances must be running one of the following operating systems in order to be used with AWS Systems Manager to automatically update or install the Amazon EFS client.

<table>
<thead>
<tr>
<th>Platform</th>
<th>Platform version</th>
<th>Architecture</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Linux</td>
<td>2017.09, 2018.03</td>
<td>x86_64</td>
</tr>
<tr>
<td>Amazon Linux 2</td>
<td>2.0</td>
<td>x86_64, arm64 (Amazon Linux 2, A1 instance types)</td>
</tr>
<tr>
<td>CentOS</td>
<td>7, 8</td>
<td>x86_64</td>
</tr>
<tr>
<td>Red Hat Enterprise Linux (RHEL)</td>
<td>7, 8</td>
<td>x86_64, arm64 (RHEL 7.6 and later, A1 instance types)</td>
</tr>
<tr>
<td>SUSE Linux Enterprise Server (SLES)</td>
<td>12, 15</td>
<td>x86_64</td>
</tr>
<tr>
<td>Ubuntu Server</td>
<td>16.04, 18.04, 20.04</td>
<td>x86_64, arm64 (Ubuntu Server 16 and later, A1 instance types)</td>
</tr>
</tbody>
</table>

**How to use AWS Systems Manager to automatically install or update amazon-efs-utils**

There are two one-time configurations required to setup Systems Manager to automatically install or update the amazon-efs-utils package.

1. Configure an AWS Identity and Access Management (IAM) instance profile with the required permissions.
2. Configure an Association (including the schedule) used for installation or updates by the State Manager

**Step 1: Configure an IAM instance profile with the required permissions**

By default, AWS Systems Manager doesn't have permission to manage your Amazon EFS clients and install or update the amazon-efs-utils package. You must grant access to Systems Manager by using an AWS Identity and Access Management (IAM) instance profile. An instance profile is a container that passes IAM role information to an Amazon EC2 instance at launch.

Use the `AmazonElasticFileSystemsUtils` AWS managed permission policy to assign the appropriate permissions to roles. You can create a new role for your instance profile or add the `AmazonElasticFileSystemsUtils` permission policy to an existing role. You must then use this instance profile to launch your Amazon EC2 instances. For more information, see Step 4: Create an IAM instance profile for Systems Manager.
**Step 2: Configure an Association used by State Manager for installing or updating the Amazon EFS client**

The `amazon-efs-utils` package is included with Distributor and is ready for you to deploy to managed EC2 instances. To view the latest version of `amazon-efs-utils` that is available for installation, you can use the AWS Systems Manager console or your preferred AWS command line tool. To access Distributor, open the [https://console.aws.amazon.com/systems-manager/](https://console.aws.amazon.com/systems-manager/) and choose Distributor in the left navigation pane. Locate `AmazonEFSUtils` in the Owned by Amazon section. Choose `AmazonEFSUtils` to see the package details. For more information, see View packages.

Using State Manager, you can install or update the `amazon-efs-utils` package on your managed EC2 instances immediately or on a schedule. Additionally, you can ensure that `amazon-efs-utils` is automatically installed on new EC2 instances. For more information about installation or updating packages using Distributor and State Manager, see Working with Distributor.

To automatically install or update the `amazon-efs-utils` package on instances using the Systems Manager console, see Scheduling a package installation or update (console). This will prompt you to create an association for State Manager, which defines the state you want to apply to a set of instances. Use the following inputs when you create your association:

- **Parameters**: choose Action > Install and Installation Type > In-place update.
- **Targets**: the recommended setting is Choose all instances to register all new and existing EC2 instances as targets to automatically install or update `AmazonEFSUtils`. Alternatively, you can specify instance tags, select instances manually, or choose a resource group to apply the association to a subset of instances. If you specify instance tags, you must launch your EC2 instances with the tags to allow AWS Systems Manager to automatically install or update the Amazon EFS client.
- **Specify schedule**: the recommended setting for `AmazonEFSUtils` is every 30 days. You can use controls to create a cron or rate schedule for the association.

To use AWS Systems Manager to mount multiple an Amazon EFS file system to multiple EC2 instances, see Mounting EFS to multiple EC2 instances using AWS Systems Manager (p. 72).

**Manually installing the Amazon EFS client**

You can manually install the Amazon EFS client on your Amazon EC2 Linux instances running Amazon Linux and Amazon Linux 2, and EC2 Mac instances running macOS Big Sur, and other supported Linux distributions. The installation procedures are described in the following sections.

**Topics**

- Installing the Amazon EFS client on Amazon Linux and Amazon Linux 2 (p. 50)
- Installing the Amazon EFS client on other Linux distributions (p. 51)
- Installing the Amazon EFS client on EC2 Mac instances running macOS Big Sur (p. 53)

**Installing the Amazon EFS client on Amazon Linux and Amazon Linux 2**

The `amazon-efs-utils` package comes with Amazon Linux and Amazon Linux AMIs, and is available for installation on EC2 instances running these AMIs. To install the Amazon EFS client on other Linux distributions, see Installing the Amazon EFS client on other Linux distributions (p. 51).
Note
If you're using AWS Direct Connect, you can find installation instructions in Walkthrough: Create and mount a file system on-premises with AWS Direct Connect and VPN (p. 153).

To install the amazon-efs-utils package

1. Make sure that you've created an Amazon Linux or Amazon Linux 2 EC2 instance. For information on how to do this, see Step 1: Launch an Instance in the Amazon EC2 User Guide for Linux Instances.
2. Access the terminal for your instance through Secure Shell (SSH), and log in with the appropriate user name. For more information on how to do this, see Connecting to your Linux instance using SSH in the Amazon EC2 User Guide for Linux Instances.
3. Run the following command to install the amazon-efs-utils package.

   ```
   sudo yum install -y amazon-efs-utils
   ```

Installing the Amazon EFS client on other Linux distributions

If you don't want to get the amazon-efs-utils package from Amazon Linux or Amazon Linux 2 AMIs, the amazon-efs-utils package is also available on GitHub.

After you clone the package, you can build and install amazon-efs-utils using one of the following methods, depending on the package type supported by your Linux distribution:

- **RPM** – This package type is supported by Amazon Linux, Red Hat Linux, CentOS, and similar.
- **DEB** – This package type is supported by Ubuntu, Debian, and similar.

To build and install amazon-efs-utils as an RPM package (for distributions other than OpenSUSE or SLES)

1. Connect to the EC2 instance using Secure Shell (SSH), and log in with the appropriate user name. For more information, see Connecting to Your Linux Instance Using SSH in the Amazon EC2 User Guide for Linux Instances.
2. Install git using the following command:

   ```
   sudo yum -y install git
   ```
3. Install the rpm-build package if it's not already installed using the following command:

   ```
   sudo yum -y install rpm-build
   ```
4. Clone amazon-efs-utils from GitHub using the following command.

   ```
   git clone https://github.com/aws/efs-utils
   ```
5. Open a terminal on your client and navigate to the directory that contains the amazon-efs-utils package.

   ```
   cd /path/efs-utils
   ```
6. Install the bash make command if your operating system doesn't already have it as follows.
sudo yum -y install make

7. Install the rpm-build package if it's not already installed using the following command:

    sudo yum -y install rpm-build

8. Build the `amazon-efs-utils` package using the following command:

    sudo make rpm

9. Install the `amazon-efs-utils` package with the following command.

    sudo yum -y install ./build/amazon-efs-utils*.rpm

To build and install `amazon-efs-utils` as an RPM package for OpenSUSE and SLES

1. Connect to the EC2 instance using Secure Shell (SSH), and log in with the appropriate user name. For more information, see Connecting to Your Linux Instance Using SSH in the Amazon EC2 User Guide for Linux Instances.

2. Install `zypper` using the following command:

    sudo zypper refresh

3. Install the `rpm-build` package and the bash `make` command if either are not already installed using the following command:

    sudo zypper install -y git rpm-build make

   a. For OpenSUSE, if you get an error similar to the following:

    File './suse/noarch/bash-completion-2.11-2.1.noarch.rpm' not found on medium 'http://download.opensuse.org/tumbleweed/repo/oss/'

    Run the following command to re-add the repo OSS and NON-OSS.

    sudo zypper ar -f -n OSS http://download.opensuse.org/tumbleweed/repo/oss/ OSS
    sudo zypper ar -f -n NON-OSS http://download.opensuse.org/tumbleweed/repo/non-oss/ NON-OSS
    sudo zypper refresh

   b. Re-run the git install script again:

    sudo zypper install -y git rpm-build make

4. Clone `amazon-efs-utils` from GitHub using the following command.

    git clone https://github.com/aws/efs-utils

5. Open a terminal on your client and navigate to the directory that contains the `amazon-efs-utils` package.
Installing the EFS client on EC2 Mac instances running macOS Big Sur

The `amazon-efs-utils` package is available for installation on EC2 Mac instances running macOS Big Sur.

To build and install `amazon-efs-utils` as a Debian package

1. Connect to the EC2 instance using Secure Shell (SSH), and log in with the appropriate user name. For more information, see Connecting to Your Linux Instance Using SSH in the Amazon EC2 User Guide for Linux Instances.
2. (Optional) Apply updates before installing the package with the following command:

```
sudo apt-get update
```

Install updates as needed.
3. Install `git` and `binutils`, using the following command. `binutils` is required for building DEB packages,

```
sudo apt-get -y install git binutils
```
4. Clone `amazon-efs-utils` from GitHub using the following command.

```
git clone https://github.com/aws/efs-utils
```
5. Navigate to the directory that contains the `amazon-efs-utils` package.

```
cd /path/efs-utils
```
6. Build `amazon-efs-utils` using the following command:

```
./build-deb.sh
```
7. Install the package with the following command.

```
sudo apt-get -y install ./build/amazon-efs-utils*.deb
```

Installing the Amazon EFS client on EC2 Mac instances running macOS Big Sur

The `amazon-efs-utils` package is available for installation on EC2 Mac instances running macOS Big Sur.
To install the `amazon-efs-utils` package

1. Make sure that you’ve created an EC2 Mac instance running macOS Big Sur. For information on how to do this, see Step 1: Launch an Instance in the Amazon EC2 User Guide for Mac Instances.

2. Access the terminal for your instance through Secure Shell (SSH), and log in with the appropriate user name. For more information on how to do this, see Connecting to your instance using SSH in the Amazon EC2 User Guide for Mac Instances.

3. Run the following command to install `amazon-efs-utils`.

   ```bash
brew install amazon-efs-utils
   ```

   The system responds with instructions to follow to complete the installation.

   Perform below actions to start using efs:
   ```bash
   sudo mkdir -p /Library/Filesystems/efs.fs/Contents/Resources
   sudo ln -s /usr/local/bin/mount.efs /Library/Filesystems/efs.fs/Contents/Resources/mount_efs
   ```

   To enable watchdog for using TLS mounts:
   ```bash
   sudo cp /usr/local/Cellar/amazon-efs-utils/<version>/libexec/amazon-efs-mount-watchdog.plist /Library/LaunchAgents
   sudo launchctl load /Library/LaunchAgents/amazon-efs-mount-watchdog.plist
   ```

4. In order mount an EFS file system, you need to ensure that the EFS mount helper in `amazon-efs-utils` is accessible by the mount command. To do so, run following commands:

   ```bash
   sudo mkdir -p /Library/Filesystems/efs.fs/Contents/Resources
   sudo ln -s /usr/local/bin/mount.efs /Library/Filesystems/efs.fs/Contents/Resources/mount_efs
   ```

5. Run the following commands to enable the watchdog process (`amazon-efs-mount-watchdog`) that monitors the health of TLS mounts on your EFS file system.

   ```bash
   sudo cp /usr/local/Cellar/amazon-efs-utils/<version>/libexec/amazon-efs-mount-watchdog.plist /Library/LaunchAgents
   sudo launchctl load /Library/LaunchAgents/amazon-efs-mount-watchdog.plist
   ```

### Installing botocore

The Amazon EFS client uses botocore to send a file system’s mount status to Amazon CloudWatch Logs. For more information, see Monitoring EFS file system mount status (p. 109). This section describes how install and upgrade botocore on an Amazon EC2 instance.

#### To install botocore as an RPM package

1. Run the following command to install `wget`.

   ```bash
   sudo yum -y install wget
   ```

2. Use the following script to install the appropriate version of the `pip` package manager.

   ```bash
   if [[ "$(python3 -V 2>&1)" =~ ^(Python 3.5.*) ]]; then
     sudo wget https://bootstrap.pypa.io/3.5/get-pip.py -O /tmp/get-pip.py
   elif [[ "$(python3 -V 2>&1)" =~ ^(Python 3.4.*) ]]; then
     sudo wget https://bootstrap.pypa.io/3.4/get-pip.py -O /tmp/get-pip.py
   ```
3. Run the following commands to install botocore.

```bash
sudo python3 /tmp/get-pip.py
sudo pip3 install botocore
```

Or

```bash
sudo /usr/local/bin/pip3 install botocore
```

**To install botocore as an DEB package**

1. Run the following commands to install `wget`.

```bash
sudo apt-get update
sudo apt-get -y install wget
```

2. Use the following script to install the appropriate version of the pip package manager.

```bash
if echo $(python3 -V 2>&1) | grep -e "Python 3.5"; then
    sudo wget https://bootstrap.pypa.io/3.5/get-pip.py -O /tmp/get-pip.py
elif echo $(python3 -V 2>&1) | grep -e "Python 3.4"; then
    sudo wget https://bootstrap.pypa.io/3.4/get-pip.py -O /tmp/get-pip.py
else
    sudo apt-get -y install python3-distutils
    sudo wget https://bootstrap.pypa.io/get-pip.py -O /tmp/get-pip.py
fi
```

3. Run the following commands to install botocore.

```bash
sudo python3 /tmp/get-pip.py
sudo pip3 install botocore
```

Or

```bash
sudo /usr/local/bin/pip3 install botocore
```

If you are installing on Debian10 or Ubuntu20, use the following commands to install botocore in the specified target folder. For Debian10:

```bash
sudo python3 /tmp/get-pip.py
sudo pip3 install --target /usr/lib/python3/dist-packages botocore
```

For Ubuntu20:

```bash
sudo /usr/local/bin/pip3 install --target /usr/lib/python3/dist-packages botocore
```

**To install botocore on a Mac instance**

- Run the following command to install botocore on your Mac instance.
Upgrading botocore

To upgrade to the latest compatible version of botocore, use the --upgrade option. For example:

```bash
sudo pip3 install botocore --upgrade
```

Upgrading stunnel

Encryption of data in transit with the Amazon EFS mount helper requires OpenSSL version 1.0.2 or newer, and a version of stunnel that supports both Online Certificate Status Protocol (OCSP) and certificate hostname checking. The Amazon EFS mount helper uses the stunnel program for its TLS functionality. Note that some versions of Linux don't include a version of stunnel that supports these TLS features by default. When using one of those Linux distributions, mounting an Amazon EFS file system using TLS fails.

After installing the Amazon EFS mount helper, you can upgrade your system's version of stunnel with the following instructions.

**To upgrade stunnel on Amazon Linux, Amazon Linux 2, and other supported Linux distributions (except for SLES 12 (p. 57))**

1. In a web browser, go to the stunnel downloads page [https://stunnel.org/downloads.html](https://stunnel.org/downloads.html).
2. Locate the latest stunnel version that is available in tar.gz format. Note the name of the file as you will need it in the following steps.
3. Open a terminal on your Linux client, and run the following commands in the order presented.
   a. For RPM:
      ```bash
      sudo yum install -y gcc openssl-devel tcp_wrappers-devel
      ```
   b. For DEB:
      ```bash
      sudo apt-get install build-essential libwrap0-dev libssl-dev
      ```
   c. Replace `latest-stunnel-version` with the name of the file you noted previously in Step 2.
      ```bash
      ```
   d. `cd latest-stunnel-version/`
   e. ```
      sudo ./configure
      ```
   f. ```
      sudo make
      ```
g. The current stunnel package is installed in `bin/stunnel`. So that the new version can be installed, remove that directory with the following command.

```
sudo rm /bin/stunnel
```

h. Install the latest version:

```
sudo make install
```

i. **Note**
The default CentOS shell is csh, which has different syntax than the bash shell. The following code first invokes bash, then moves `/bin/stunnel` to `/root`.

```
bash
if [[ -f /bin/stunnel ]]; then
    sudo mv /bin/stunnel /root
fi
```

j. Create a symlink:

```
sudo ln -s /usr/local/bin/stunnel /bin/stunnel
```

To upgrade stunnel on macOS Big Sur

- Open a terminal on your EC2 Mac instance, and run the following command to upgrade to the latest version of stunnel.

```
brew upgrade stunnel
```

Upgrading stunnel for SLES 12

- Run the following commands and follow the zypper package manager instructions to upgrade stunnel on your compute instance running SLES12.

```
sudo zypper refresh
sudo zypper install -y stunnel
```

After you've installed a version of stunnel with the required features, you can mount your file system using TLS with the Amazon EFS recommended settings.

### Disabling Certificate Hostname Checking

If you are unable to install the required dependencies, you can optionally disable certificate hostname checking inside the Amazon EFS mount helper configuration. We do not recommend that you disable this feature in production environments. To disable certificate host name checking, do the following:

1. Using your text editor of choice, open the `/etc/amazon/efs/efs-utils.conf` file.
2. Set the `stunnel_check_certHostname` value to false.
3. Save the changes to the file and close it.
For more information on using encryption of data in transit, see Mounting EFS file systems (p. 59).

**Enabling Online Certificate Status Protocol**

In order to maximize file system availability in the event that the CA is not reachable from your VPC, the Online Certificate Status Protocol (OCSP) is not enabled by default when you choose to encrypt data in transit. Amazon EFS uses an Amazon certificate authority (CA) to issue and sign its TLS certificates, and the CA instructs the client to use OCSP to check for revoked certificates. The OCSP endpoint must be accessible over the Internet from your Virtual Private Cloud in order to check a certificate's status. Within the service, EFS continuously monitors certificate status, and issues new certificates to replace any revoked certificates it detects.

In order to provide the strongest security possible, you can enable OCSP so that your Linux clients can check for revoked certificates. OCSP protects against malicious use of revoked certificates, which is unlikely to occur within your VPC. In the event that an EFS TLS certificate is revoked, Amazon will publish a security bulletin and release a new version of EFS mount helper that rejects the revoked certificate.

**To enable OCSP on your Linux client for all future TLS connections to EFS**

1. Open a terminal on your Linux client.
2. Using your text editor of choice, open the `/etc/amazon/efs/efs-utils.conf` file.
3. Set the `stunnel_check_cert_validity` value to true.
4. Save the changes to the file and close it.

**To enable OCSP as part of the `mount` command**

- Use the following mount command to enable OCSP when mounting the file system.

```
$ sudo mount -t efs -o tls,ocsp fs-12345678:/ /mnt/efs
```

**Related Topics**

For more information on the Amazon EFS mount helper, see these related topics:

- Data encryption in Amazon EFS (p. 169)
- Mounting EFS file systems (p. 59)
Mounting EFS file systems

In the following sections you can learn how to mount your Amazon EFS file system using the Amazon EFS mount helper. In addition, learn how to automatically remount your file system after any system restarts using the file `fstab` file. Using the EFS mount helper, you have the following options for mounting your Amazon EFS file system:

- Mounting on supported EC2 instances
- Mounting with IAM authorization
- Mounting with Amazon EFS access points
- Mounting with an on-premise Linux client
- Auto-mounting when an EC2 instance reboots
- Mounting a file system when a new EC2 instance launches

**Note**

Amazon EFS does not support mounting from Amazon EC2 Windows instances.

The EFS mount helper is part of the `amazon-efs-utils` package. The `amazon-efs-utils` package is an open-source collection of Amazon EFS tools. For more information, see Manually installing the Amazon EFS client (p. 50).

Before the Amazon EFS mount helper was available, we recommended mounting your Amazon EFS file systems using the standard Linux NFS client. For more information, see Mounting file systems without the EFS mount helper (p. 355).

**Topics**

- Mounting file systems using the EFS mount helper (p. 59)
- Additional mounting considerations (p. 75)
- Troubleshooting AMI and kernel versions (p. 77)

Mounting file systems using the EFS mount helper

The EFS mount helper helps you mount your EFS file systems on your EC2 Linux and Mac instances running the the supported distributions listed in Overview (p. 47).

The Amazon EFS mount helper simplifies mounting your file systems. It includes the Amazon EFS recommended mount options by default. Additionally, the mount helper has built-in logging for troubleshooting purposes. If you encounter an issue with your Amazon EFS file system, you can share these logs with AWS Support. For more information about mounting your file system, see Mounting EFS file systems (p. 59).

**Note**

Amazon EFS does not support mounting from Amazon EC2 Windows instances.

**Topics**

- How it works (p. 60)
- Getting support logs (p. 61)
- Prerequisites for using the EFS mount helper (p. 61)
- Mounting on Amazon EC2 Linux instances using the EFS mount helper (p. 62)
How it works

The mount helper defines a new network file system type, called efs, which is fully compatible with the standard mount command in Linux. The mount helper also supports mounting an Amazon EFS file system at instance boot time automatically by using entries in the /etc/fstab configuration file.

Warning
Use the _netdev option, used to identify network file systems, when mounting your file system automatically. If _netdev is missing, your EC2 instance might stop responding. This result is because network file systems need to be initialized after the compute instance starts its networking. For more information, see Automatic Mounting Fails and the Instance Is Unresponsive (p. 224).

You can mount a file system by specifying one of the following properties:

- **File system DNS name** – If you use the file system DNS name, and the mount helper cannot resolve it, for example when you are mounting a file system in a different VPC, it will fall back to using the mount target ip address. For more information, see Mounting EFS file systems from another AWS account or VPC (p. 73).
- **File system ID** – If you use the file system ID, the mount helper resolves the it to the local IP address of the mount target elastic network interface (ENI) without calling external resources.
- **Mount target IP address** – You can use the IP address of one of the file systems mount targets.

You can find the value for all of these properties in the Amazon EFS console. The file system DNS name is found in the Attach screen.

When encryption of data in transit is declared as a mount option for your Amazon EFS file system, the mount helper initializes a client stunnel process, and a supervisor process called amazon-efs-mount-watchdog. The amazon-efs-mount-watchdog process monitors the health of TLS mounts, and is started automatically the first time an EFS file system is mounted over TLS. This process is managed by either upstart or systemd depending on your Linux distribution, and by launchd on the macOS Big Sur distribution.

Stunnel is an open-source multipurpose network relay. The client stunnel process listens on a local port for inbound traffic, and the mount helper redirects NFS client traffic to this local port.

The mount helper uses TLS version 1.2 to communicate with your file system. Using TLS requires certificates, and these certificates are signed by a trusted Amazon Certificate Authority. For more information on how encryption works, see Data encryption in Amazon EFS (p. 169).

Mount options used by Amazon EFS client

The Amazon EFS client uses the following mount options that are optimized for Amazon EFS:
Getting support logs

The mount helper has built-in logging for your Amazon EFS file system. You can share these logs with AWS Support for troubleshooting purposes.

You can find the logs stored in `/var/log/amazon/efs` for systems with the mount helper installed. These logs are for the mount helper, the stunnel process itself, and for the `amazon-efs-mount-watchdog` process that monitors the stunnel process.

**Note**

The watchdog process ensures that each mount’s stunnel process is running, and stops the stunnel when the Amazon EFS file system is unmounted. If for some reason a stunnel process is terminated unexpectedly, the watchdog process restarts it.

You can change the configuration of your logs in `/etc/amazon/efs/efs-utils.conf`. However, doing so requires unmounting and then remounting the file system with the mount helper for the changes to take effect. Log capacity for the mount helper and watchdog logs is limited to 20 MiB. Logs for the stunnel process are disabled by default.

**Important**

You can enable logging for the stunnel process logs. However, enabling the stunnel logs can use up a nontrivial amount of space on your file system.

Prerequisites for using the EFS mount helper

You can mount an Amazon EFS file system on an Amazon EC2 instance using the Amazon EFS mount helper. To use the mount helper, you need the following:

- **File system ID of the file system to mount** - The EFS mount helper resolves the file system ID to the local IP address of the mount target elastic network interface (ENI) without calling external resources.

- **An Amazon EFS mount target** – You create mount targets in your virtual private cloud (VPC). If you create your file system in the console using the service recommended settings, a mount target is created in each availability zone in the AWS Region that the file system is in. For instructions to create mount targets, see Creating and managing mount targets (p. 31).

  **Note**

  We recommend that you wait 90 seconds after creating a mount target before you mount your file system. This wait lets the DNS records propagate fully in the AWS Region where the file system is.

If you use a mount target in an Availability Zone different from that of your Amazon EC2 instance, you incur standard EC2 charges for data sent across Availability Zones. You also might see increased latencies for file system operations.
Note
Amazon EFS file systems using One Zone storage classes have a single mount target located in the same availability zone as the file system. To use the EFS mount helper, the AWS compute instance mounting the file system must be located in the same availability zone as the file system.

- For mounting file systems with One Zone storage classes from a different Availability Zone:
  - The name of the file system's Availability Zone – If you are mounting an EFS file system using One Zone storage classes that is located in a different Availability Zone than the EC2 instance.
  - Mount target DNS name – Alternatively, you can specify the mount target's DNS name instead of the Availability Zone.
  - An Amazon EC2 instance running one of the supported Linux or macOS distributions – The supported distributions for mounting your file system with the mount helper are the following:
    - Amazon Linux 2
    - Amazon Linux 2017.09 and newer
    - macOS Big Sur
    - Red Hat Enterprise Linux (and derivatives such as CentOS) version 7 and newer
    - Ubuntu 16.04 LTS and newer

Note
EC2 Mac instances running macOS Big Sur support NFS 4.0 only.

- The Amazon EFS mount helper installed on the EC2 instance – The mount helper is a tool in the amazon-efs-utils. For information about installing amazon-efs-utils, see Manually installing the Amazon EFS client (p. 50).
- The EC2 instance is in a VPC – The connecting EC2 instance must be in a virtual private cloud (VPC) based on the Amazon VPC service. It also must be configured to use the DNS server provided by AWS. For information about the Amazon DNS server, see DHCP Options Sets in the Amazon VPC User Guide.
- VPC has DNS hostnames enabled – The VPC of the connecting EC2 instance must have DNS hostnames enabled. For more information, see Viewing DNS Hostnames for Your EC2 Instance in the Amazon VPC User Guide.

Mounting on Amazon EC2 Linux instances using the EFS mount helper

To mount your Amazon EFS file system using the mount helper on EC2 Linux instances

1. Open a terminal window on your EC2 instance through Secure Shell (SSH), and log in with the appropriate user name. For more information, see Connect to your Linux instance using SSH for Linux instances.
2. Run one of the following commands to mount your file system.

   Note
   If the EC2 instance and the file system you are mounting are located in different AWS Regions, see Mounting Amazon EFS file systems from a different AWS Region (p. 65) to edit the region property in the efs-utils.conf file.

- To mount using the file system id:

```
sudo mount -t efs file-system-id efs-mount-point/
```

```
sudo mount -t efs fs-12345678 efs/
```
Alternatively, if you want to use encryption of data in transit, you can mount your file system with the following command.

```
sudo mount -t efs -o tls fs-12345678 efs/
```

- To mount using the file system DNS name:

```
sudo mount -t efs -o tls file-system-dns-name efs-mount-point/
```

```
sudo mount -t efs -o tls fs-12345678.efs.us-east-2.amazonaws.com efs/
```

- To mount using the mount target IP address:

```
sudo mount -t efs -o tls,mounttargetip=mount-target-ip file-system-id efs-mount-point/
```

```
sudo mount -t efs -o tls,mounttargetip=192.0.2.0 fs-12345678 efs/
```

You can view and copy the exact commands to mount your file system in the Attach dialog box.

a. In the Amazon EFS console, choose the file system that you want to mount to display its details page.

b. To display the mount commands to use for this file system, choose Attach in the upper right.

The Attach screen displays the exact commands to use for mounting the file system in the following ways:

- (Mount via DNS) Using the file system’s DNS name with the EFS mount helper or an NFS client.

- (Mount via IP) Using the mount target IP address in the selected Availability Zone with an NFS client.
Mounting on Amazon EC2 Mac instances using the EFS mount helper

To mount your Amazon EFS file system using the mount helper on EC2 Mac instances running macOS Big Sur

1. Open a terminal window on your EC2 Mac instance through Secure Shell (SSH), and log in with the appropriate user name. For more information, see Connect to your instance using SSH for Mac instances, in the Amazon EC2 User Guide for Linux Instances.

2. Run the following command to mount your file system.

   Note
   By default, the EFS mount helper uses encryption in transit when mounting on EC2 Mac instances, whether or not you use the tls option in the mount command.

   ```bash
   sudo mount -t efs file-system-id efs-mount-point/
   ```

   ```bash
   sudo mount -t efs fs-12345678 efs/
   ```

   You can also use the tls option when mounting.

   ```bash
   sudo mount -t efs -o tls fs-12345678:/ efs
   ```

   To mount a file system on an EC2 Mac instance without using encryption in transit, use the notls option, as shown in the following command.

   ```bash
   sudo mount -t efs -o notls file-system-id efs-mount-point/
   ```

   You can view and copy the exact commands to mount your file system in the management console’s Attach dialog box, described as follows.

   a. In the Amazon EFS console, choose the file system that you want to mount to display its details page.

   b. To display the mount commands to use for this file system, choose Attach in the upper right.

      ![Attach dialog box](image)

      The Attach screen displays the exact commands to use for mounting the file system in the following ways:
Mounting from a different region

- **(Mount via DNS)** Using the file system's DNS name with the EFS mount helper or an NFS client.
- **(Mount via IP)** Using the mount target IP address in the selected Availability Zone with an NFS client.

**Note**
If the EC2 instance and the file system you are mounting are located in different AWS Regions, see Mounting Amazon EFS file systems from a different AWS Region (p. 65) to edit the `region` property in the `efs-utils.conf` file.

### Mounting Amazon EFS file systems from a different AWS Region

If you are mounting your EFS file system from an Amazon EC2 instance that is in a different AWS Region than the file system, you will need to edit the `region` property value in the `efs-utils.conf` file.

**To edit the region property in `efs-utils.conf`**

1. Access the terminal for your EC2 instance through Secure Shell (SSH), and log in with the appropriate user name. For more information on how to do this, see Connecting to your Linux instance using SSH in the Amazon EC2 User Guide for Linux Instances.
2. Locate the `efs-utils.conf` file, and open it using your preferred editor.
3. Locate the following line:

```
#region = us-east-1
```
   a. Uncomment the line.
   b. If the file system is not located in the `us-east-1` region, replace `us-east-1` with the ID of the region in which the file system is located.
   c. Save the changes.
4. Mount the file system using the EFS mount helper for Linux (p. 62) or Mac (p. 64) instances.

### Mounting file systems with One Zone storage classes

Amazon EFS file systems that use One Zone storage classes support only a single mount target which is located in the same Availability Zone as the file system. You cannot add additional mount targets. This section describes things to consider when mounting Amazon EFS file systems that use One Zone storage classes.

You can avoid data transfer charges between Availability Zones and achieve better performance by accessing an EFS file system using an Amazon EC2 compute instance that is located in the same Availability Zone as that of the file system's mount target. This applies to file systems using EFS Standard or One Zone storage classes.

**Mounting file systems that use One Zone storage classes on EC2 in a different Availability Zone**

If you are mounting an EFS file system using One Zone storage classes on an EC2 instance that is located in a different Availability Zone, you have to specify the file system's Availability Zone name or the DNS name of the file system's mount target in the mount helper mount command.
The following command specifies the file system's availability zone name.

```bash
sudo mount -t efs -o az=availability-zone-name,tls file-system-id /mnt
```

This is the command with sample values:

```bash
sudo mount -t efs -o az=us-east-1a,tls file-system-id /mnt
```

The following command specifies the DNS name of the file system's mount target.

```bash
sudo mount -t efs tls mount-target-dns-name /mnt
```

This is the command with an example mount target DNS name.

```bash
sudo mount -t efs tls us-east-1a.fs-12345678.efs.amazonaws.com /mnt
```

### Mounting file systems with One Zone storage with other AWS compute instances

When you use an Amazon EFS file system with One Zone storage classes with Amazon Elastic Container Service, Amazon Elastic Kubernetes Service, or AWS Lambda, you need to configure the service to use the same Availability Zone that the EFS file system is located in, illustrated as follows, and described in the following sections.
Connecting from Amazon Elastic Container Service

You can use Amazon EFS file systems with Amazon ECS to share file system data across your fleet of container instances so your tasks have access to the same persistent storage, no matter the instance on which they land. To use Amazon EFS One Zone storage classes with Amazon ECS, you should choose only subnets that are in the same Availability Zone as your file system when launching your task. For more information, see Amazon EFS volumes in the Amazon Elastic Container Service Developer Guide.

Connecting from Amazon Elastic Kubernetes Service

When mounting an Amazon EFS file system that uses One Zone storage classes from Amazon EKS, you can use the Amazon EFS Container Storage Interface (CSI) driver, which supports Amazon EFS access points, to share a file system between multiple pods in an Amazon EKS or self-managed Kubernetes cluster. The Amazon EFS CSI driver is installed in the Fargate stack. When using the Amazon EFS CSI driver with Amazon EFS One Zone storage classes, you can use the nodeSelector option when launching your pod to ensure it gets scheduled within the same availability zone as your file system.

Connecting from AWS Lambda

You can use Amazon EFS with AWS Lambda to share data across function invocations, read large reference data files, and write function output to a persistent and shared store. AWS Lambda securely connects the function instances to the Amazon EFS mount targets that are in the same Availability Zone and subnet. When you use AWS Lambda with Amazon EFS file systems using EFS One Zone storage classes, configure your function to only launch invocations into subnets that are in the same Availability Zone as your file system.

Mounting with IAM authorization

To mount your Amazon EFS file system on Linux instances using AWS Identity and Access Management (IAM) authorization, you use the EFS mount helper. For more information about IAM authorization for NFS clients, see Using IAM to control file system data access (p. 185).

Mounting with IAM using an EC2 instance profile

If you are mounting with IAM authorization to an Amazon EC2 instance with an instance profile, use the tls and iam mount options, shown following.

```
$ sudo mount -t efs -o tls,iam file-system-id efs-mount-point
```

To automatically mount with IAM authorization to an Amazon EC2 instance that has an instance profile, add the following line to the `/etc/fstab` file on the EC2 instance.

```
file-system-id:/ efs-mount-point efs _netdev,tls,iam 0 0
```

Mounting with IAM using a named profile

You can mount with IAM authorization using the IAM credentials located in the AWS CLI credentials file `~/.aws/credentials`, or the AWS CLI config file `~/.aws/config`. If "awsprofile" is not specified, the "default" profile is used.

To mount with IAM authorization to a Linux instance using a credentials file, use the tls, awsprofile, and iam mount options, shown following.

```
$ sudo mount -t efs -o tls,iam,awsprofile=namedprofile file-system-id efs-mount-point/
```
To automatically mount with IAM authorization to a Linux instance using a credentials file, add the following line to the `/etc/ fstab` file on the EC2 instance.

```
file-system-id: /efs-mount-point efs _netdev,tls,iam,awsprofile=namedprofile 0 0
```

### Mounting with EFS access points

You can mount an EFS file system using an EFS access point. To do this, use the EFS mount helper.

When you mount a file system using an access point, the mount command includes the `access-point-id` and the `tls` mount option in addition to the regular mount options. An example is shown following.

```
$ sudo mount -t efs -o tls,accesspoint=access-point-id file-system-id /efs-mount-point
```

To automatically mount a file system using an access point, add the following line to the `/etc/ fstab` file on the EC2 instance.

```
file-system-id efs-mount-point efs _netdev,tls,accesspoint=access-point-id 0 0
```

For more information about EFS access points, see [Working with Amazon EFS Access Points](p. 202).

### Mounting on your on-premises Linux client with the EFS mount helper over AWS Direct Connect and VPN

You can mount your Amazon EFS file systems on your on-premises data center servers when connected to your Amazon VPC with AWS Direct Connect or VPN. Mounting your Amazon EFS file systems with `amazon-efs-utils` also makes mounting simpler with the mount helper and allows you to enable encryption of data in transit.

To see how to use `amazon-efs-utils` with AWS Direct Connect and VPN to mount Amazon EFS file systems onto on-premises Linux clients, see [Walkthrough: Create and mount a file system on-premises with AWS Direct Connect and VPN](p. 153).

### Mounting your Amazon EFS file system automatically

You can configure an Amazon EC2 instance to automatically mount an EFS file system when it reboots in two ways:

- When you create a new EC2 instance using the Launch Instance Wizard.
- Update the EC2 `/etc/ fstab` file with an entry for the EFS file system.

Both of these methods use the EFS mount helper to mount the file system. The mount helper is part of the `amazon-efs-utils` set of tools.

The `amazon-efs-utils` tools are available for installation on Amazon Linux and Amazon Linux 2 Amazon Machine Images (AMIs). For more information about `amazon-efs-utils`, see [Using the amazon-efs-utils Tools](p. 47). If you are using another Linux distribution, such as Red Hat Enterprise Linux (RHEL), manually build and install `amazon-efs-utils`. For more information, see [Installing the Amazon EFS client on other Linux distributions](p. 51).

**Note**

Amazon EFS file systems do not support automatic mounting on Amazon EC2 Mac instances running macOS Big Sur.
Configuring EC2 instances to mount an EFS file system at instance launch

When you create a new Amazon EC2 Linux instance using the EC2 Launch Instance Wizard, you can configure it to mount your Amazon EFS file system automatically. The EC2 instance mounts the file system automatically the instance first launched and also whenever it restarts.

**Note**
Amazon EFS file systems do not support mounting on Amazon EC2 Mac instances running macOS Big Sur at instance launch.

Before you perform this procedure, make sure that you have created your Amazon EFS file system. For more information, see Step 1: Create your Amazon EFS file system (p. 14) in the Amazon EFS Getting Started exercise.

**Note**
You can't use Amazon EFS with Microsoft Windows–based Amazon EC2 instances.

Before you can launch and connect to an Amazon EC2 instance, you need to create a key pair, unless you already have one. Follow the steps in Setting Up with Amazon EC2 in the Amazon EC2 User Guide for Linux Instances to create a key pair. If you already have a key pair, you can use it for this exercise.

**To configure your EC2 instance to mount an EFS file system automatically at launch**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Launch Instance**.
3. In **Step 1: Choose an Amazon Machine Image (AMI)**, find an Amazon Linux AMI at the top of the list and choose **Select**.
4. In **Step 2: Choose an Instance Type**, choose **Next: Configure Instance Details**.
5. In **Step 3: Configure Instance Details**, provide the following information:
   - For **Network**, choose the entry for the same VPC that the EFS file system you're mounting is in.
   - For **Subnet**, choose a default subnet in any Availability Zone.
   - For **File systems**, choose the EFS file system that you want to mount. The path shown next the file system ID is the mount point that the EC2 instance will use, which you can change.
   - Under **Advanced Details**, the **User data** is automatically generated, and includes the commands needed to mount the EFS file systems you specified under **File systems**.
6. Choose **Next: Add Storage**.
7. Choose **Next: Add Tags**.
8. Name your instance and choose **Next: Configure Security Group**.
9. In **Step 6: Configure Security Group**, set **Assign a security group** to **Select an existing security group**. Choose the default security group to make sure that it can access your EFS file system.

You can't access your EC2 instance by Secure Shell (SSH) using this security group. For access by SSH, later you can edit the default security and add a rule to allow SSH or a new security group that allows SSH. You can use the following settings:

- **Type**: SSH
- **Protocol**: TCP
- **Port Range**: 22
- **Source**: Anywhere 0.0.0.0/0
10. Choose **Review and Launch**.
11. Choose **Launch**.
12. Select the check box for the key pair that you created, and then choose Launch Instances.

Your EC2 instance is now configured to mount the EFS file system at launch and whenever it’s rebooted.

**Using /etc/fstab to mount automatically**

To automatically remount your Amazon EFS file system directory when the Amazon EC2 instance reboots, use the file /etc/fstab. The /etc/fstab file contains information about file systems. The command `mount -a`, which runs during instance start-up, mounts the file systems listed in /etc/fstab. This procedure uses the EFS mount helper to mount the file system which needs to be installed on the EC2 instance.

**Note**
Amazon EFS file systems do not support automatic mounting using /etc/fstab on Amazon EC2 Mac instances running macOS Big Sur.

The mount helper is part of the amazon-efs-utils set of tools, which is available for installation on Amazon Linux and Amazon Linux 2 Amazon Machine Images (AMIs). For more information about installing amazon-efs-utils on an Amazon Linux or Amazon Linux 2 AMI, see Manually installing the Amazon EFS client (p. 50). If you are using another Linux distribution, such as Red Hat Enterprise Linux (RHEL), manually build and install amazon-efs-utils. For more information, see Installing the Amazon EFS client on other Linux distributions (p. 51).

**Note**
Before you can update the /etc/fstab file of your EC2 instance, make sure that you already created your Amazon EFS file system. For more information, see Step 1: Create your Amazon EFS file system (p. 14).

**To update the /etc/fstab file on your EC2 instance**

1. Connect to your EC2 instance:
   - To connect to your instance from a computer running macOS or Linux, specify the .pem file for your SSH command. To do this, use the -i option and the path to your private key.
   - To connect to your instance from a computer running Windows, you can use either MindTerm or PuTTY. To use PuTTY, install it and convert the .pem file to a .ppk file.

   For more information, see the following topics in the Amazon EC2 User Guide for Linux Instances:
   - Connecting to your Linux instance from Windows using PuTTY
   - Connecting to your Linux instance using SSH

2. Open the /etc/fstab file in an editor.

3. Automatically mount your EFS file system using either IAM authorization or an EFS access point:
   - To automatically mount with IAM authorization to an Amazon EC2 instance that has an instance profile, add the following line to the /etc/fstab file.

     ```
     file-system-id:/  efs-mount-point  efs _netdev,norevsport,tls,iam 0 0
     ```
   - To automatically mount with IAM authorization to a Linux instance using a credentials file, add the following line to the /etc/fstab file.

     ```
     file-system-id:/  efs-mount-point  efs _netdev,norevsport,tls,iam,awsprofile=namedprofile 0 0
     ```
   - To automatically mount a file system using an EFS access point, add the following line to the / etc/fstab file.
Warning
Use the _netdev option, used to identify network file systems, when mounting your file system automatically. If _netdev is missing, your EC2 instance might stop responding. This result is because network file systems need to be initialized after the compute instance starts its networking. For more information, see Automatic Mounting Fails and the Instance Is Unresponsive (p. 224).

For more information, see Mounting with IAM authorization (p. 67) and Mounting with EFS access points (p. 68).

4. Save the changes to the file.
5. Test the fstab entry by using the mount command with the 'fake' option along with the 'all' and 'verbose' options.

```
$ sudo mount -fav
home/ec2-user/efs      : successfully mounted
```

Your EC2 instance is now configured to mount the EFS file system whenever it restarts.

Note
In some cases, your Amazon EC2 instance might need to start regardless of the status of your mounted Amazon EFS file system. In such cases, add the nofail option to your file system's entry in your /etc/fstab file.

The line of code you added to the /etc/fstab file does the following.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file-system-id:/</td>
<td>The ID for your Amazon EFS file system. You can get this ID from the console or programmatically from the CLI or an AWS SDK.</td>
</tr>
<tr>
<td>efs-mount-point</td>
<td>The mount point for the EFS file system on your EC2 instance.</td>
</tr>
<tr>
<td>efs</td>
<td>The type of file system. When you're using the mount helper, this type is always efs.</td>
</tr>
<tr>
<td>mount options</td>
<td>Mount options for the file system. This is a comma-separated list of the following options:</td>
</tr>
<tr>
<td></td>
<td>• _netdev – This option tells the operating system that the file system resides on a device that requires network access. This option prevents the instance from mounting the file system until the network has been enabled on the client.</td>
</tr>
<tr>
<td></td>
<td>• noresvport – Tells the NFS client to use a new Transmission Control Protocol (TCP) source port when a network connection is reestablished. Doing this helps make sure that the EFS file system has uninterrupted availability after a network recovery event.</td>
</tr>
<tr>
<td></td>
<td>• tls – Enables encryption of data in transit.</td>
</tr>
<tr>
<td></td>
<td>• iam – Use this option to mount with IAM authorization to an Amazon EC2 that has an instance profile. Using the iam mount option requires also using the tls option. For more information, see Using IAM to control file system data access (p. 185).</td>
</tr>
</tbody>
</table>
Mounting EFS to multiple EC2 instances using AWS Systems Manager

You can mount EFS file systems to multiple Amazon EC2 instances remotely and securely without having to log in to the instances by using AWS Systems Manager Run Command. For more information about AWS Systems Manager Run Command, see AWS Systems Manager run command in the AWS Systems Manager User Guide. The following prerequisites are required before mounting EFS file systems using this method:

1. The EC2 instances are launched with an instance profile that includes the AmazonElasticFileSystemsUtils permissions policy. For more information, see Step 1: Configure an IAM instance profile with the required permissions (p. 49).
2. Version 1.28.1 or later of the Amazon EFS client (amazon-efs-utils package) is installed on the EC2 instances. You can use AWS Systems Manager to automatically install the package on your instances. For more information, see Step 2: Configure an Association used by State Manager for installing or updating the Amazon EFS client (p. 50).

To mount multiple EFS file systems to multiple EC2 instances using the console

2. In the navigation pane, choose Run Command.
3. Choose Run a command.
4. Enter AWS-RunShellScript in the Commands search field.
5. Select AWS-RunShellScript.
6. In Command parameters enter the mount command to use for each EFS file system that you want to mount. For example:
   
   sudo mount -t efs -o tls fs-12345678:/ /mnt/efs
   sudo mount -t efs -o tls,accesspoint=fsap-12345678 fs-01233210 /mnt/efs

   For more information about EFS mount commands using the Amazon EFS client, see Mounting on Amazon EC2 Linux instances using the EFS mount helper (p. 62) or Mounting on Amazon EC2 Mac instances using the EFS mount helper (p. 64).
7. Select the target AWS Systems Manager managed EC2 instances that you want the command to run on.
8. Make any other additional settings you would like. Then choose Run to run the command and mount the EFS file systems specified in the command.

Once you run the command, you can see its status in the command history.

**Mounting EFS file systems from another AWS account or VPC**

You can mount your Amazon EFS file system using IAM authorization for NFS clients and EFS Access Points using the EFS mount helper. By default, the EFS mount helper uses domain name service (DNS) to resolve the IP address of your EFS mount target. If you are mounting the file system from a different account or virtual private cloud (VPC), you need to resolve the EFS mount target manually.

Following, you can find instructions for determining the correct EFS mount target IP address to use for your NFS client. You can also find instructions for configuring the client to mount the EFS file system using that IP address.

**Mounting using IAM or access points from another VPC**

When you use a VPC peering connection or transit gateway to connect VPCs, Amazon EC2 instances that are in one VPC can access EFS file systems in another VPC, even if the VPCs belong to different accounts.

**Prerequisites**

Before using the following the procedure, take these steps:

- Install the Amazon EFS client, part of the Amazon-efs-utils set of utilities on the compute instance you're mounting the EFS file system on. You use the EFS mount helper, which is included in Amazon-efs-utils, to mount the file system. For instructions on installing Amazon-efs-utils, see Using the Amazon-efs-utils Tools (p. 47).
- Allow the ec2:DescribeAvailabilityZones action in the IAM policy for the IAM role you attached to the instance. We recommend that you attach the AWS managed policy AmazonElasticFileSystemsUtils to an IAM entity to provide the necessary permissions for the entity.
- When mounting from another AWS account, update the file system resource policy to allow the elasticfilesystem:DescribeMountTarget action for the principal ARN of other AWS account. For example:

```json
{
    "Id": "access-point-example03",
    "Statement": [
        {
            "Sid": "access-point-statement-example03",
            "Effect": "Allow",
            "Principal": {"AWS": "arn:aws:iam::555555555555"},
            "Action": "elasticfilesystem:DescribeMountTargets",
        }
    ]
}
```

For more information about EFS file system resource policies, see Resource-based policies (p. 178).
- Install botocore. The EFS client uses botocore to retrieve the mount target ip address when the file system DNS name cannot be resolved when mounting a file system in another VPC. For more information, see Install botocore in the efs-utils README file.
• Set up either a VPC peering connection or a VPC transit gateway.

You connect the client's VPC and your EFS file system's VPC using either a VPC peering connection or a VPC transit gateway. When you use a VPC peering connection or transit gateway to connect VPCs, Amazon EC2 instances that are in one VPC can access EFS file systems in another VPC, even if the VPCs belong to different accounts.

A transit gateway is a network transit hub that you can use to interconnect your VPCs and on-premises networks. For more information about using VPC transit gateways, see Getting Started with transit gateways in the Amazon VPC Transit Gateways Guide.

A VPC peering connection is a networking connection between two VPCs. This type of connection enables you to route traffic between them using private Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) addresses. You can use VPC peering to connect VPCs within the same AWS Region or between AWS Regions. For more information on VPC peering, see What is VPC Peering? in the Amazon VPC Peering Guide.

To ensure high availability of your file system, we recommend that you always use an EFS mount target IP address that is in the same availability zone as your NFS client. If you're mounting an EFS file system that is in another account, ensure that the NFS client and EFS mount target are in the same availability zone ID. This requirement applies because AZ names can differ from one account to another.

To mount an EFS file system in another VPC using IAM or an access point

1. Connect to your EC2 instance:
   • To connect to your instance from a computer running macOS or Linux, specify the .pem file for your SSH command. To do this, use the -i option and the path to your private key.
   • To connect to your instance from a computer running Windows, you can use either MindTerm or PuTTY. To use PuTTY, install it and convert the .pem file to a .ppk file.

   For more information, see the following topics in the Amazon EC2 User Guide for Linux Instances:
   • Connecting to Your Linux Instance from Windows Using PuTTY
   • Connecting to Your Linux Instance Using SSH

2. Create a directory for mounting the file system using the following command.

   ```bash
   # sudo mkdir /mnt/efs
   ```

3. To mount the file system using IAM authorization, use the following command:

   ```bash
   # sudo mount -t efs -o tls,iam file-system-dns-name /mnt/efs/
   ```

   For more information about using IAM authorization with EFS, see Using IAM to control file system data access (p. 185).

   To mount the file system using an EFS access point, use the following command:

   ```bash
   # sudo mount -t efs -o tls,accesspoint=access-point-id file-system-dns-name /mnt/efs/
   ```

   For more information about EFS access points, see Working with Amazon EFS Access Points (p. 202).
Mounting Amazon EFS file systems from a different AWS Region

If you are mounting your EFS file system from another VPC that is in a different AWS Region than the file system, you will need to edit the `efs-utils.conf` file. In `efs-utils.conf`, locate the following lines:

```
#region = us-east-1
```

Uncomment the line, and replace the value for the ID of the region in which the file system is located, if it is not in `us-east-1`.

Mounting from another AWS account in the same VPC

Using shared VPCs, you can mount an Amazon EFS file system that is owned by one AWS account from Amazon EC2 instances that are owned by a different AWS account. For more information about setting up a shared VPC, see Working with shared VPCs in the Amazon VPC Peering Guide.

After you set up VPC sharing, the EC2 instances can mount the EFS file system using Domain Name System (DNS) name resolution or the EFS mount helper. We recommend using the EFS mount helper to mount your EFS file systems.

Additional mounting considerations

We recommend the following default values for mount options on Linux:

- `rsize=1048576` – Sets the maximum number of bytes of data that the NFS client can receive for each network READ request. This value applies when reading data from a file on an EFS file system. We recommend that you use the largest size possible (up to 1048576) to avoid diminished performance.
- `wsize=1048576` – Sets the maximum number of bytes of data that the NFS client can send for each network WRITE request. This value applies when writing data to a file on an EFS file system. We recommend that you use the largest size possible (up to 1048576) to avoid diminished performance.
- `hard` – Sets the recovery behavior of the NFS client after an NFS request times out, so that NFS requests are retried indefinitely until the server replies. We recommend that you use the hard mount option (`hard`) to ensure data integrity. If you use a `soft` mount, set the `timeo` parameter to at least 150 deciseconds (15 seconds). Doing so helps minimize the risk of data corruption that is inherent with soft mounts.
- `timeo=600` – Sets the timeout value that the NFS client uses to wait for a response before it retries an NFS request to 600 deciseconds (60 seconds). If you must change the timeout parameter (`timeo`), we recommend that you use a value of at least 150, which is equivalent to 15 seconds. Doing so helps avoid diminished performance.
- `retrans=2` – Sets to 2 the number of times the NFS client retries a request before it attempts further recovery action.
- `noresvport` – Tells the NFS client to use a new Transmission Control Protocol (TCP) source port when a network connection is reestablished. Doing this helps make sure that the EFS file system has uninterrupted availability after a network recovery event.
- `_netdev` – When present in `/etc/fstab`, prevents the client from attempting to mount the EFS file system until the network has been enabled.

In general, avoid setting any other mount options that are different from the defaults, which can cause reduced performance and other issues. If you don't use the preceding defaults, be aware of the following:
• Changing read or write buffer sizes or disabling attribute caching can result in reduced performance.
• Amazon EFS ignores source ports. If you change Amazon EFS source ports, it doesn't have any effect.
• Amazon EFS doesn't support any of the Kerberos security variants. For example, the following mount command fails.

```bash
$ mount -t nfs4 -o krb5p <DNS_NAME>:/ /efs/
```

• We recommend that you mount your file system using its DNS name. Amazon EFS resolves this name to the IP address of the Amazon EFS mount target in the same Availability Zone as your Amazon EC2 instance without calling external resources. If you use a mount target in an Availability Zone different from that of your Amazon EC2 instance, you incur standard EC2 charges for data sent across Availability Zones. You also might see increased latencies for file system operations.

• For more mount options, and detailed explanations of the defaults, see the `man fstab` and `man nfs` pages in the Linux documentation.

**Note**
If your EC2 instance needs to start regardless of the status of your mounted EFS file system, add the `nofail` option to your file system's entry in your `/etc/fstab` file.

**Unmounting file systems**

Before you delete a file system, we recommend that you unmount it from every Amazon EC2 instance that it's connected to. You can unmount a file system on your Amazon EC2 instance by running the `umount` command on the instance itself. You can't unmount an Amazon EFS file system through the AWS CLI, the AWS Management Console, or through any of the AWS SDKs. To unmount an Amazon EFS file system connected to an Amazon EC2 instance running Linux, use the `umount` command as follows:

```bash
umount /mnt/efs
```

We recommend that you do not specify any other `umount` options. Avoid setting any other `umount` options that are different from the defaults.

You can verify that your Amazon EFS file system has been unmounted by running the `df` command. This command displays the disk usage statistics for the file systems currently mounted on your Linux-based Amazon EC2 instance. If the Amazon EFS file system that you want to unmount isn't listed in the `df` command output, this means that the file system is unmounted.

**Example Example: Identify the mount status of an Amazon EFS file system and unmount it**

```bash
$ df -T
Filesystem Type 1K-blocks Used Available Use% Mounted on
/dev/sda1 ext4 8123812 1138920 6884644 15% /
availability-zone.file-system-id.efs.aws-region.amazonaws.com :/ nfs4 9007199254740992 0
9007199254740992 0% /mnt/efs

$ umount /mnt/efs

$ df -T
Filesystem Type 1K-blocks Used Available Use% Mounted on
/dev/sda1 ext4 8123812 1138920 6884644 15% /
```
To troubleshoot issues related to certain Amazon Machine Image (AMI) or kernel versions when using Amazon EFS from an Amazon EC2 instance, see Troubleshooting AMI and Kernel Issues (p. 222).

Note
Amazon EFS does not support mounting from Amazon EC2 Windows instances.
Transferring data into and out of Amazon EFS

You can use AWS Transfer Family and AWS DataSync to transfer data into and out of your Amazon EFS file systems. AWS DataSync is an online data transfer service that can copy data between Network File System (NFS), Server Message Block (SMB) file servers, self-managed object storage, and also between AWS services. For more information about using DataSync with Amazon EFS, see Using AWS DataSync to transfer data in Amazon EFS (p. 78).

AWS Transfer Family is a fully managed AWS service that you can use to transfer files into and out of Amazon EFS file systems over the Secure File Transfer Protocol (SFTP), File Transfer Protocol (FTP), and FTP over Secure Sockets Layer (FTPS) protocol. Using Transfer Family, you can provide your business partners access to files stored in your Amazon EFS file systems for use cases such as data distribution, supply chain, content management, and web serving applications. For more information about using Transfer Family with Amazon EFS, see Using AWS Transfer Family to access files in your Amazon EFS file system (p. 78).

Topics

- Using AWS DataSync to transfer data in Amazon EFS (p. 78)
- Using AWS Transfer Family to access files in your Amazon EFS file system (p. 78)

Using AWS DataSync to transfer data in Amazon EFS

AWS DataSync is an online data transfer service that simplifies, automates, and accelerates moving and replicating data between on-premises storage systems, and also between AWS storage services. DataSync can copy data between Network File System (NFS), Server Message Block (SMB) file servers, self-managed object storage, AWS Snowcone, Amazon S3 buckets, Amazon EFS file systems, and FSx for Windows File Server file systems.

You can also use DataSync to transfer files between two EFS file systems, including file systems in different AWS Regions and file systems owned by different AWS accounts. Using DataSync to copy data between EFS file systems, you can perform one-time data migrations, periodic data ingestion for distributed workloads, and automate replication for data protection and recovery.

To simplify transfer files between two EFS file systems using DataSync, you can use the AWS DataSync In-Cloud QuickStart and Scheduler.

For more information, see Getting started with Amazon Elastic File System (p. 13) and the AWS DataSync User Guide.

Using AWS Transfer Family to access files in your Amazon EFS file system

AWS Transfer Family is a fully managed AWS service that you can use to transfer files into and out of Amazon EFS file systems over the following protocols:
- Secure Shell (SSH) File Transfer Protocol (SFTP) (AWS Transfer for SFTP)
- File Transfer Protocol Secure (FTPS) (AWS Transfer for FTPS)
- File Transfer Protocol (FTP) (AWS Transfer for FTP)

Using Transfer Family, you can securely enable third parties such as your vendors, partners, or customers access to your files over the supported protocols at scale globally, without needing to manage any infrastructure. Additionally, you can now easily access your EFS file systems from Windows, macOS, and Linux environments using SFTP, FTPS, and FTP clients. This helps expand the accessibility of your data beyond NFS clients and access points, to users across multiple environments.

Using Transfer Family to transfer data in Amazon EFS file systems is accounted for in the same manner as other client usage. For more information, see Throughput modes (p. 123) and Amazon EFS quotas and limits (p. 212).

To learn more about AWS Transfer Family, see the AWS Transfer Family User Guide.

**Note**
Using Transfer Family with Amazon EFS is disabled by default for AWS accounts that have Amazon EFS file systems with policies that allow public access that were created before January 6, 2021. To enable using Transfer Family to access your file system, contact AWS Support.

**Topics**
- Prerequisites for using AWS Transfer Family with Amazon EFS (p. 79)
- Configuring your Amazon EFS file system to work with AWS Transfer Family (p. 79)

## Prerequisites for using AWS Transfer Family with Amazon EFS

To use Transfer Family to access files your Amazon EFS file system, your configuration must meet the following conditions:

- The Transfer Family server and your Amazon EFS file system are located in the same AWS Region.
- IAM policies are configured to enable access to the IAM role used by Transfer Family. For more information, see Create an IAM role and policy in the AWS Transfer Family User Guide.
- (Optional) If the Transfer Family server is owned by a different account, enable cross-account access.
  - Ensure that your file system policy does not allow public access. For more information, see Blocking public access (p. 191).
  - Modify the file system policy to enable cross-account access. For more information, see Configuring cross-account access for Transfer Family (p. 81).

## Configuring your Amazon EFS file system to work with AWS Transfer Family

Configuring an Amazon EFS file system to work with Transfer Family requires the following steps:

- **Step 1.** Get the list of POSIX IDs that are allocated to the Transfer Family users.
- **Step 2.** Ensure that your file system’s directories are accessible to the Transfer Family users by using the POSIX IDs allocated to the Transfer Family users.
- **Step 3.** Configure IAM to enable access to the IAM role used by Transfer Family.
Setting file and directory permissions for Transfer Family users

Make sure that the Transfer Family users have access to the necessary file and directories on your EFS file system. Assign access permissions to the directory using the list of POSIX IDs allocated to the Transfer Family users. In this example, a user creates a directory named `transferFam` under the EFS mount point. Creating a directory is optional, depending on your use case. If needed, you can choose its name and location on the EFS file system.

To assign file and directory permissions to POSIX users for Transfer Family

1. Connect to your Amazon EC2 instance. Amazon EFS only supports mounting by Linux-based EC2 instances.
2. Mount your EFS file system if it is not already mounted on the EC2 instance. For more information, see Mounting EFS file systems (p. 59).
3. The following example creates the directory on the EFS file system, and changes its group to the POSIX group ID for the Transfer Family users, which is 1101 in this example.
   a. Create the directory `efs/transferFam` using the following commands. In practice, you can use a name and location on the file system of your choosing.

   ```bash
   [ec2-user@ip-192-0-2-0 ~]$ ls
   efs  efs-mount-point  efs-mount-point2
   [ec2-user@ip-192-0-2-0 ~]$ ls efs
   [ec2-user@ip-192-0-2-0 ~]$ sudo mkdir efs/transferFam
   [ec2-user@ip-192-0-2-0 ~]$ ls -l efs
   total 0
   drwxr-xr-x 2 root root 6 Jan 6 15:58 transferFam
   ```
   b. Use the following command to change the group of `efs/transferFam` to the POSIX GID assigned to the Transfer Family users.

   ```bash
   [ec2-user@ip-192-0-2-0 ~]$ sudo chown :1101 efs/transferFam/
   ```
   c. Confirm the change.

   ```bash
   [ec2-user@ip-192-0-2-0 ~]$ ls -l efs
   total 0
   drwxr-xr-x 2 root 1101 6 Jan 6 15:58 transferFam
   ```

Enable access to the IAM role used by Transfer Family

In Transfer Family, you create a resource-based IAM policy and an IAM role that define user access to the EFS file system. For more information, see Create an IAM role and policy in the AWS Transfer Family User Guide. You must grant that Transfer Family IAM role access to your EFS file system using either an IAM identity policy or a file system policy.

The following is an example file system policy that grants `ClientMount` (read) and `ClientWrite` access to the IAM role `EFS-role-for-transfer`.

```json
{
   "Version": "2012-10-17",
   "Id": "efs-policy-wizard-8698b356-4212-4d30-901e-ad2030b57762",
   "Statement": [
      {
         "Sid": "Grant-transfer-role-access",
         "Effect": "Allow",
         "Principal": {
```

80
Configuring your Amazon EFS file system to work with AWS Transfer Family

For more information about creating a file system policy, see Creating file system policies (p. 39). For more information about using identity-based IAM policies to manage access to EFS resources, see Managing access to resources (p. 177).

Configuring cross-account access for Transfer Family

If the Transfer Family server used to access your file system belongs to a different AWS account, you must grant that account access to your file system. Also, your file system policy has to be non-public. For more information about blocking public access to your file system, see Blocking public access (p. 191).

You can grant a different AWS account access to your file system in the file system policy. In the Amazon EFS console, use the Grant additional permissions section of the File system policy editor to specify the AWS account and the level of file system access you are granting. For more information about creating or editing a file system policy, see Creating file system policies (p. 39).

You can specify the account using the account ID or the account Amazon Resource Name (ARN). For more information about ARNs, see IAM ARNs in the IAM User Guide.

The following example is a non-public file system policy that grants cross-account access to the file system. It has the following two statements:

1. The first statement, NFS-client-read-write-via-fsmt, grants read, write, and root privileges to NFS clients accessing the file system using a file system mount target.
2. The second statement, Grant-cross-account-access, grants only read and write privileges to the AWS account 111122223333, which is the account that owns the Transfer Family server that needs access to this EFS file system in your account.

```json
{
  "Statement": [
    {
      "Sid": "NFS-client-read-write-via-fsmt",
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": [
        "elasticfilesystem:ClientRootAccess",
        "elasticfilesystem:ClientWrite",
        "elasticfilesystem:ClientMount"
      ],
      "Condition": {
        "Bool": {
          "elasticfilesystem:AccessedViaMountTarget": "true"
        }
      }
    },
    {
      "Sid": "Grant-cross-account-access",
      "Effect": "Allow",
      "Principal": {
```
The following file system policy adds a statement granting access to the IAM role used by Transfer Family.

```
{
    "Statement": [
        {
            "Sid": "NFS-client-read-write-via-fsmt",
            "Effect": "Allow",
            "Principal": { "AWS": "*" },
            "Action": [
                "elasticfilesystem:ClientRootAccess",
                "elasticfilesystem:ClientWrite",
                "elasticfilesystem:ClientMount"
            ],
            "Condition": {
                "Bool": {
                    "elasticfilesystem:AccessedViaMountTarget": "true"
                }
            }
        },
        {
            "Sid": "Grant-cross-account-access",
            "Effect": "Allow",
            "Principal": { "AWS": "arn:aws:iam::111122223333:root" },
            "Action": [
                "elasticfilesystem:ClientWrite",
                "elasticfilesystem:ClientMount"
            ]
        },
        {
            "Sid": "Grant-transfer-role-access",
            "Effect": "Allow",
            "Principal": { "AWS": "arn:aws:iam::111122223333:role/EFS-role-for-transfer" },
            "Action": [
                "elasticfilesystem:ClientWrite",
                "elasticfilesystem:ClientMount"
            ]
        }
    ]
}
```
Managing Amazon EFS file systems

File system management tasks refer to creating and deleting file systems and managing tags, file system backups, access, and network accessibility with mount targets of existing file systems.

You can perform these file system management tasks using the AWS Management Console, or programmatically using the AWS Command Line Interface (AWS CLI) or API, as discussed in the following sections.

Topics

- Managing file system network accessibility (p. 83)
- Managing EFS storage classes (p. 87)
- Amazon EFS lifecycle management (p. 90)
- Managing access to encrypted file systems (p. 94)
- Metering: How Amazon EFS reports file system and object sizes (p. 95)
- Managing Amazon EFS file system costs using AWS Budgets (p. 97)
- File system status (p. 98)

If you are new to Amazon EFS, we recommend that you try the following exercises that provide you with first-hand end-to-end experience using an Amazon EFS file system:

- Getting started (p. 13) – This exercise provides a console-based, end-to-end setup in which you create a file system, mount it on an Amazon EC2 instance, and test the setup. The console takes care of many things for you and thus helps you quickly set up the end-to-end experience.

- Walkthrough: Create an Amazon EFS file system and mount it on an Amazon EC2 instance using the AWS CLI (p. 135) – This walkthrough is similar to the Getting Started exercise, but it uses the AWS CLI to perform most of the tasks. Because the CLI commands closely map to the Amazon EFS API, the walkthrough can help you familiarize yourself with the Amazon EFS API.

Managing file system network accessibility

You mount your file system on Amazon EC2 or other AWS compute instance in your virtual private cloud (VPC) using a mount target that you create for the file system. Managing file system network accessibility refers to managing a file system's mount targets.

The following illustration shows how EC2 instances in a VPC access an Amazon EFS file system using a mount target.
The illustration shows three EC2 instances launched in different VPC subnets accessing an Amazon EFS file system. The illustration also shows one mount target in each of the Availability Zones (regardless of the number of subnets in each Availability Zone).

You can create only one mount target per Availability Zone. If an Availability Zone has multiple subnets, as shown in one of the zones in the illustration, you create a mount target in only one of the subnets. As long as you have one mount target in an Availability Zone, the EC2 instances launched in any of its subnets can share the same mount target.

Managing mount targets refers to these activities:

- **Creating and deleting mount targets in a VPC** – At a minimum, you should create a mount target in each Availability Zone from which you want to access the file system.

  **Note**
  We recommend that you create mount targets in all the Availability Zones. If you do, you can easily mount the file system on EC2 instances that you might launch in any of the Availability Zones.

If you delete a mount target, the operation forcibly breaks any mounts of the file system, which might disrupt instances or applications using those mounts. To avoid application disruption, stop applications and unmount the file system before deleting the mount target.

You can use a file system only in one VPC at a time. That is, you can create mount targets for the file system in one VPC at a time. If you want to access the file system from another VPC, first delete the mount targets from the current VPC. Then create new mount targets in another VPC.

- **Updating the mount target configuration** – When you create a mount target, you associate security groups with the mount target. A security group acts as a virtual firewall that controls the traffic to and from the mount target. You can add inbound rules to control access to the mount target, and thus the
After creating a mount target, you might want to modify the security groups assigned to them.

Each mount target also has an IP address. When you create a mount target, you can choose an IP address from the subnet where you are placing the mount target. If you omit a value, Amazon EFS selects an unused IP address from that subnet.

There is no Amazon EFS operation to change the IP address after creating a mount target. Thus, you can't change the IP address programmatically or by using the AWS CLI. But the console enables you to change the IP address. Behind the scenes, the console deletes the mount target and creates the mount target again.

**Warning**
If you change the IP address of a mount target, you break any existing file system mounts and you need to remount the file system.

None of the configuration changes to file system network accessibility affects the file system itself. Your file system and data remain unchanged.

The following sections provide information about managing network accessibility of your file system.

**Topics**
- Creating or deleting mount targets in a VPC (p. 85)
- Changing the VPC for your mount target (p. 86)
- Updating the mount target configuration (p. 86)

## Creating or deleting mount targets in a VPC

To access an Amazon EFS file system in a VPC, you need mount targets. For an Amazon EFS file system, the following is true:

- You can create one mount target in each Availability Zone.
- If the VPC has multiple subnets in an Availability Zone, you can create a mount target in only one of those subnets. All EC2 instances in the Availability Zone can share the single mount target.

**Note**
We recommend that you create a mount target in each of the Availability Zones. There are cost considerations for mounting a file system on an EC2 instance in an Availability Zone through a mount target created in another Availability Zone. For more information, see Amazon EFS. In addition, by always using a mount target local to the instance's Availability Zone, you eliminate a partial failure scenario. If the mount target's zone goes down, you can't access your file system through that mount target.

You can delete mount targets. A mount target deletion forcibly breaks any mounts of the file system using that mount target, which might disrupt instances or applications using those mounts. For more information, see Creating and managing mount targets (p. 31).

**Note**
Before deleting a mount target, first unmount the file system. For more information, see Unmounting file systems (p. 76).

Using the AWS Management Console, the AWS CLI, and the API, you can create and manage mount targets on file systems. For existing mount targets, you can add and remove security groups, or delete the mount target. For more information, see Creating and managing mount targets (p. 31).
Changing the VPC for your mount target

You can use an Amazon EFS file system in one VPC based on the Amazon VPC service at a time. That is, you create mount targets in a VPC for your file system, and use those mount targets to provide access to the file system.

You can mount the Amazon EFS file system from these targets:

- Amazon EC2 instances in the same VPC
- EC2 instances in a VPC connected by VPC peering
- On-premises servers by using AWS Direct Connect
- On-premises servers over an AWS virtual private network (VPN) by using Amazon VPC

A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them. The connection can use private Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) addresses. For more information on how Amazon EFS works with VPC peering, see Mounting EFS file systems from another AWS account or VPC (p. 73).

To access the file system from EC2 instances in another VPC, you have to:

- Delete the current mount targets.
- Change the VPC.
- Create new mount targets.

For more information on performing these steps in the AWS Management Console, see To change the VPC for an Amazon EFS file system (console) (p. 35).

Using the CLI

To use a file system in another VPC, first delete any mount targets that you previously created in a VPC. Then create new mount targets in another VPC. For example AWS CLI commands, see Managing mount targets using the AWS CLI (p. 35).

Updating the mount target configuration

After you create a mount target for your file system, you might want to update the security groups that are in effect. You can't change the IP address of an existing mount target. To change an IP address, delete the mount target and create a new one with the new address. Deleting a mount target breaks any existing file system mounts.

Note
Before deleting a mount target, first unmount the file system.

Modifying a security group

Security groups define inbound and outbound access. When you change security groups associated with a mount target, make sure that you authorize necessary inbound and outbound access. Doing so enables your EC2 instance to communicate with the file system.

For more information about security groups, see Amazon EC2 Security Groups in the Amazon EC2 User Guide for Linux Instances.

To modify a mount target's security group using the AWS Management Console, see Managing mount targets using the Amazon EFS console (p. 33).
Managing EFS storage classes

Amazon EFS offers a range of storage classes that are designed for different use cases. These include EFS Standard, EFS Standard–Infrequent Access (Standard-IA), EFS One Zone, and EFS One Zone–Infrequent Access (EFS One Zone-IA). The following sections provide details of these storage classes.

Amazon EFS Standard and Standard–IA storage classes

EFS Standard and Standard-IA storage classes are regional storage classes that are designed to provide continuous availability to data, even when one or more Availability Zones in an AWS Region are unavailable. They offer the highest levels of availability and durability by storing file system data and metadata redundantly across multiple geographically separated Availability Zones within a Region.

The EFS Standard storage class is used for frequently accessed files. It is the storage class to which customer data is initially written for Standard storage classes.

The Standard–IA storage class reduces storage costs for files that are not accessed every day. It does this without sacrificing the high availability, high durability, elasticity, and POSIX file system access that Amazon EFS provides. We recommend Standard-IA storage if you need your full dataset to be readily accessible and want to automatically save on storage costs for files that are less frequently accessed. Examples include keeping files accessible to satisfy audit requirements, performing historical analysis, or performing backup and recovery. Standard-IA storage is compatible with all Amazon EFS features, and is available in all AWS Regions where Amazon EFS is available.

Amazon EFS One Zone and EFS One Zone–IA storage classes

EFS One Zone and One Zone–IA storage classes are designed to provide continuous availability to data within a single Availability Zone. The EFS One Zone storage classes store file system data and metadata redundantly within a single Availability Zone in an AWS Region. Because they store data in a single AWS Availability Zone, data that is stored in these storage classes might be lost in the event of a disaster or other fault that affects all copies of the data within the Availability Zone, or in the event of Availability Zone destruction.

For added data protection, Amazon EFS automatically backs up file systems using One Zone storage classes with AWS Backup. You can restore file system backups to any operational Availability Zone within an AWS Region, or you can restore them to a different Region. Amazon EFS file system backups that are created and managed using AWS Backup are replicated to three Availability Zones and are designed for 11 9's durability. For more information, see Resilience in AWS Backup.

EFS One Zone–Standard is used for frequently accessed files. It is the storage class to which customer data is initially written for One Zone storage classes.

The EFS One Zone–IA storage class reduces storage costs for files that are not accessed every day. We recommend EFS One Zone–IA storage if you need your full dataset to be readily accessible and want to automatically save on storage costs for files that are less frequently accessed. One Zone-IA storage is compatible with all Amazon EFS features, and is available in all AWS Regions where Amazon EFS is available.
Infrequent access performance

First-byte latency when reading from or writing to either of the IA storage classes is higher than that for the EFS Standard or EFS One Zone storage classes.

You can move files from an IA storage class to a frequently accessed storage class by copying them to another location on your file system. If you want your files to remain in the frequently accessed storage class, stop Lifecycle Management on the file system, and then copy your files.

Comparing Amazon EFS storage classes

The following table compares the storage classes, including their availability, durability, minimum storage duration, and other considerations.

<table>
<thead>
<tr>
<th>Storage class</th>
<th>Designed for</th>
<th>Durability (designed for)</th>
<th>Availability %</th>
<th>Availability zones</th>
<th>Other considerations</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFS Standard</td>
<td>Frequently accessed data requiring the highest durability and availability.</td>
<td>99.999999999% (11 9's)</td>
<td>99.99%</td>
<td>&gt;=3</td>
<td>None</td>
</tr>
<tr>
<td>EFS Standard–Infrequent Access (IA)</td>
<td>Long lived, infrequently accessed data requiring the highest durability and availability.</td>
<td>99.999999999% (11 9's)</td>
<td>99.99%</td>
<td>&gt;=3</td>
<td>Per GB retrieval fees apply.</td>
</tr>
<tr>
<td>EFS One Zone</td>
<td>Frequently accessed data that doesn't require highest levels of durability and availability.</td>
<td>99.999999999% (11 9')*</td>
<td>99.90%</td>
<td>1</td>
<td>Not resilient to the loss of the Availability Zone.</td>
</tr>
<tr>
<td>EFS One Zone-IA</td>
<td>Long lived, infrequently accessed data that doesn't require highest levels of durability and availability.</td>
<td>99.999999999% (11 9')*</td>
<td>99.90%</td>
<td>1</td>
<td>Not resilient to the loss of the Availability Zone. Per GB retrieval fees apply.</td>
</tr>
</tbody>
</table>

*Because EFS One Zone storage classes store data in a single AWS Availability Zone, data stored in these storage classes may be lost in the event of a disaster or other fault that affects all copies of the data within the Availability Zone, or in the event of Availability Zone destruction.

Storage class pricing

You are billed for the amount of data in each storage class. You are also billed for data access when files in IA storage are read and when files are transitioned to IA storage from EFS Standard or One Zone storage. The AWS bill displays the capacity for each storage class and the metered access against the file system’s IA storage class (Standard-IA or One Zone-IA). To learn more, see Amazon EFS Pricing.

For file systems using Bursting Throughput, the allowed throughput is determined based on the amount of the data stored in the EFS Standard and EFS One Zone storage classes only. For file systems using
Provisioned Throughput mode, you're billed for the throughput provisioned above what you are provided based on the amount of data that is in the EFS Standard and EFS One Zone storage classes. For more information on EFS performance, see Throughput modes (p. 123).

Note
You don't incur data access charges when using AWS Backup to back up lifecycle management-enabled EFS file systems. To learn more about AWS Backup and EFS lifecycle management, see EFS storage classes (p. 131).

Viewing storage class size

You can view how much data is stored in each storage class of your file system using the Amazon EFS console, the AWS CLI, or the EFS API.

Viewing storage data size in the Amazon EFS console

The Metered size tab on the File system details page displays the current metered size of the file system in binary multiples of bytes (kibibytes, mebibytes, gibibytes, and tebibytes). The metric is emitted every 15 minutes and lets you view your file system’s metered size over time. Metered size displays the following information for the file system storage size:

- **Total size** is the size (in binary bytes) of data stored in the file system, including all storage classes.
- **Size in Standard / One Zone** is the size (in binary bytes) of data stored in the EFS Standard or EFS One Zone storage class.
- **Size in Standard-IA / One Zone-IA** is the size (in binary bytes) of data stored in the Standard-IA or One Zone-IA storage class, depending on whether your file system uses Standard or One Zone storage classes.

You can also view the Storage bytes metric on the Monitoring tab on the File system details page in the Amazon EFS console. For more information, see Accessing CloudWatch metrics (p. 110).

Viewing storage data size using the AWS CLI

You can view how much data is stored in each storage class of your file system using the AWS CLI or EFS API. View data storage details by calling the describe-file-systems CLI command (the corresponding API operation is DescribeFileSystems (p. 279)).

```
$ aws efs describe-file-systems \\
  --region us-west-2 \\
  --profile adminuser
```

In the response, SizeInBytes.ValueInIA displays the last metered size in bytes in the file system's IA storage class, either Standard-IA or One Zone-IA. ValueInStandard displays the last metered size in bytes in either the EFS Standard or EFS One Zone storage class, depending on the file system configuration. Added together, they equal the size of the entire file system, displayed by Value.

```json
{
  "FileSystems": [
    {
      "OwnerId": "251839141158",
      "CreationToken": "MyFileSystem1",
      "FileSystemId": "fs-47a2c22e",
      "PerformanceMode": "generalPurpose",
      "CreationTime": 1403301078,
      "LifeCycleState": "created",
      "NumberOfMountTargets": 1,
      "SizeInBytes": {
        "Value": 29313417216,
```
Using Amazon EFS storage classes

To use the EFS Standard and Standard–IA storage classes, create a file system that stores data redundantly across multiple Availability Zones in an AWS Region. To do this when creating a file system using the AWS Management Console, choose Availability and Durability, and then choose Regional.

To use the Standard–IA storage class, you must enable the Amazon EFS lifecycle management feature. When enabled, lifecycle management automates moving files from Standard storage to IA storage. When you create a file system using the console, Lifecycle management is enabled by default with a setting of 30 days since last access. For more information, see Amazon EFS lifecycle management (p. 90).

To use the EFS One Zone and One Zone–IA storage classes, you must create a file system that stores data redundantly within a single Availability Zone in an AWS Region. To do this when creating a file system using the console, choose Availability and Durability, and then choose One Zone.

To use the One Zone–IA storage class, you must enable the Amazon EFS lifecycle management feature. When enabled, lifecycle management automates moving files from Standard storage to IA storage. When you create a file system using the console, Lifecycle management is enabled by default with a setting of 30 days since last access. For more information, see Amazon EFS lifecycle management (p. 90).

Amazon EFS lifecycle management

Amazon EFS lifecycle management automatically manages cost-effective file storage for your file systems. When enabled, lifecycle management migrates files that have not been accessed for a set period of time to the EFS Standard–Infrequent Access (Standard-IA) or One Zone–Infrequent Access (One Zone-IA) storage class, depending on your file system. You define that period of time by using the Transition into IA lifecycle policy.

Amazon EFS lifecycle management uses an internal timer to track when a file was last accessed, and not the POSIX file system attributes that are publicly viewable. Whenever a file in Standard or One Zone storage is accessed, the lifecycle management timer is reset. After lifecycle management moves a file into one of the IA storage classes, the file remains there indefinitely if Amazon EFS Intelligent-Tiering is not enabled.

Metadata operations, such as listing the contents of a directory, don't count as file access. During the process of transitioning a file's content to one of the IA storage classes, the file is stored in the Standard or One Zone storage class and billed at that storage rate.

Lifecycle management applies to all files in the file system.

Amazon EFS Intelligent-Tiering

Amazon EFS Intelligent-Tiering uses lifecycle management to monitor the access patterns of your workload and is designed to automatically transition files to and from the file system's Infrequent Access
(IA) storage class. With intelligent tiering, files in the standard storage class (EFS Standard or EFS One Zone) that are not accessed for the duration of the Transition into IA lifecycle policy setting, for example 30 days, are transitioned to the corresponding Infrequent Access (IA) storage class. Additionally, if access patterns change, EFS Intelligent-Tiering automatically moves files back to the EFS Standard or EFS One Zone storage classes when the Transition out of IA lifecycle policy is set to On first access. This helps to eliminate the risk of unbounded access charges, while providing consistent low latencies.

Using lifecycle policies

Amazon EFS supports two lifecycle policies. Transition into IA instructs lifecycle management when to transition files into the file system's Infrequent Access storage class. Transition out of IA instructs intelligent tiering when to transition files out of IA storage. Lifecycle policies apply to the entire Amazon EFS file system.

The Transition into IA lifecycle policy has the following values:

- None
- 7 days since last access
- 14 days since last access
- 30 days since last access
- 60 days since last access
- 90 days since last access

The Transition out of IA lifecycle policy can have the following values

- None
- On first access

You can combine the two EFS lifecycle policies to achieve a variety of storage patterns, shown in the following table.

<table>
<thead>
<tr>
<th>Transition into IA &lt;br&gt;7-90 days</th>
<th>Transition out of IA</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>On</td>
<td>Off</td>
<td>Classic lifecycle management policy&lt;br&gt;Files stay in IA storage</td>
</tr>
<tr>
<td>On</td>
<td>On</td>
<td>EFS Intelligent-Tiering&lt;br&gt;Files move into and out of IA storage</td>
</tr>
<tr>
<td>Off</td>
<td>On</td>
<td>All files in IA are moved into standard, eventually</td>
</tr>
<tr>
<td>Off</td>
<td>Off</td>
<td>Only standard storage class is used</td>
</tr>
</tbody>
</table>

For more information about setting lifecycle policies, see Using EFS Lifecycle Management and EFS Intelligent Tiering (p. 92).
**File system operations for lifecycle management**

File system operations for lifecycle management and intelligent tiering, have a lower priority than operations for EFS file system workloads. The time required to transition files into or out of IA storage varies depending on the file size and file system workload.

File metadata, including file names, ownership information, and file system directory structure, is always stored in standard storage (Standard or One Zone) to ensure consistent metadata performance. All write operations to files in the file system's IA storage class (Standard-IA or One Zone-IA) are first written to standard storage, then transitioned to the applicable infrequent access storage class. Files smaller than 128 KB aren't eligible for lifecycle management and are always stored in the file system's standard storage class.

**Using EFS Lifecycle Management and EFS Intelligent Tiering**

When you create an Amazon EFS file system that uses the service recommended settings using the AWS Management Console, the file system's lifecycle policies use the following default settings:

- **Transition into IA** is set to **30 days since last access**
- **Transition out of IA** is set to **On first access**

For more information about creating a file system with the service recommended settings, see Step 1: Create your Amazon EFS file system (p. 14).

When you create a new file system with customized settings, you can set the lifecycle policies as needed. For more information, see Creating a file system with custom settings using the Amazon EFS console (p. 22).

You can configure lifecycle policies using the AWS Management Console and the AWS CLI, as described in the following procedures.

**Manage lifecycle policies on an existing file system (console)**

You can use the AWS Management Console to set the lifecycle policies for an existing file system.

1. Sign in to the AWS Management Console and open the Amazon EFS console at [https://console.aws.amazon.com/efs/](https://console.aws.amazon.com/efs/).
2. Choose **File systems** to display the list of file systems in your account.

   Choose the file system on which you want to modify lifecycle policies.

3. On the file system details page, in the **General** panel, choose **Edit**. The **Edit >> General** settings page displays.
4. For Lifecycle management, you can change the following lifecycle policies:

- Set **Transition into IA** to one of the available settings. To stop moving files into IA storage, choose **None**.

- Set **Transition out of IA** to **On first access** to move files that are in IA storage to standard storage when they're accessed for non-metadata operations.

To stop moving files from IA to standard storage on first access, set to **None**.

5. Choose **Save changes** to save your changes.

**Manage lifecycle policies on an existing file system (CLI)**

You can use the AWS CLI to set or modify a file system's lifecycle policies:

- Run the `put-lifecycle-configuration` AWS CLI command or the `PutLifecycleConfiguration` (p. 310) API command, specifying the file system ID of the file system for which you are managing lifecycle management.

```bash
$ aws efs put-lifecycle-configuration \
  --file-system-id File-System-ID \
  --lifecycle-policies "[{{"TransitionToIA":\"AFTER_60_DAYS\"}, \\
  {{"TransitionToPrimaryStorageClass":\"AFTER_1_ACCESS\"}}}]" \
  --region us-west-2 \
  --profile adminuser
```

You get the following response.

```json
{
  "LifecyclePolicies": [
    {
      "TransitionToIA": "AFTER_60_DAYS"
    },
    {
      "TransitionToPrimaryStorageClass": "AFTER_1_ACCESS"
    }
  ]
}
```
Managing access to encrypted file systems

Using Amazon EFS, you can create encrypted file systems. Amazon EFS supports two forms of encryption for file systems, encryption in transit and encryption at rest. Any key management you need to perform is only related to encryption at rest. Amazon EFS automatically manages the keys for encryption in transit.

If you create a file system that uses encryption at rest, data and metadata are encrypted at rest. Amazon EFS uses AWS Key Management Service (AWS KMS) for key management. When you create a file system using encryption at rest, you specify a customer master key (CMK). The CMK can be `aws/elasticfilesystem` (the AWS managed CMK for Amazon EFS), or it can be a CMK that you manage.

File data—the contents of your files—is encrypted at rest using the CMK that you specified when you created your file system. Metadata—file names, directory names, and directory contents—is encrypted by a key that Amazon EFS manages.

The AWS managed CMK for your file system is used as the master key for the metadata in your file system, for example file names, directory names, and directory contents. You own the CMK used to encrypt file data (the contents of your files) at rest.

You manage who has access to your CMKs and the contents of your encrypted file systems. This access is controlled by both AWS Identity and Access Management (IAM) policies and AWS KMS. IAM policies control a user's access to Amazon EFS API actions. AWS KMS key policies control a user's access to the CMK you specified when the file system was created. For more information, see the following:

- IAM Users in the IAM User Guide
- Using Key Policies in AWS KMS in the AWS Key Management Service Developer Guide
- Using Grants in the AWS Key Management Service Developer Guide.

As a key administrator, you can import external keys. You can also modify keys by enabling them, disabling them, or deleting them. The state of the CMK that you specified (when you created the file system with encryption at rest) affects access to its contents. The CMK must be in the enabled state for users to have access to the contents of an encrypted-at-rest file system.
Performing administrative actions on Amazon EFS customer master keys

Following, you can find how to enable, disable, or delete the CMKs associated with your Amazon EFS file system. You can also learn about the behavior to expect from your file system when you perform these actions.

Disabling, deleting, or revoking access to the CMK for a file system

You can disable or delete your customer managed CMKs, or you can revoke Amazon EFS access to your CMKs. Disabling and revoking access for Amazon EFS to your keys are reversible actions. Exercise significant caution when deleting CMKs. Deleting a CMK is an irreversible action.

If you disable or delete the CMK used for your mounted file system, the following is true:

- That CMK can't be used as the master key for new encrypted-at-rest file systems.
- Existing encrypted-at-rest file systems that use that CMK stop working after a period of time.

If you revoke Amazon EFS access to a grant for any existing mounted file system, the behavior is the same as if you disabled or deleted the associated CMK. In other words, the encrypted-at-rest file system continues to function, but stops working after a period of time.

You can prevent access to a mounted encrypted-at-rest file system that has a CMK that you disabled, deleted, or revoked Amazon EFS access to. To do this, unmount the file system and delete your Amazon EFS mount targets.

You can't immediately delete an AWS KMS CMK, but you can schedule it for deletion in 7-30 days. While a CMK is scheduled for deletion, you can't use it for cryptographic operations. You can also cancel a CMK's scheduled deletion.

To learn how to disable and re-enable customer managed CMKs, see Enabling and Disabling Keys in the AWS Key Management Service Developer Guide. To learn how to schedule deletion of customer managed CMKs, see Deleting Customer Master Keys in the AWS Key Management Service Developer Guide.

Metering: How Amazon EFS reports file system and object sizes

In the following section, find how Amazon EFS reports file system sizes and sizes of objects within a file system.
Metering Amazon EFS file system objects

Objects that you can view in an Amazon EFS system include regular files, directories, symbolic links, and special files (FIFOs and sockets). Each of these objects is metered for 2 kibibytes (KiB) of metadata (for its inode) and one or more increments of 4 KiB of data. The following list explains the metered data size for different types of file system objects:

- **Regular files** – The metered data size of a regular file is the logical size of the file rounded to the next 4-KiB increment, except that it might be less for sparse files.

  A **sparse file** is a file to which data is not written to all positions of the file before its logical size is reached. For a sparse file, in some cases the actual storage used is less than the logical size rounded to the next 4-KiB increment. In these cases, Amazon EFS reports actual storage used as the metered data size.

- **Directories** – The metered data size of a directory is the actual storage used for the directory entries and the data structure that holds them, rounded to the next 4-KiB increment. The metered data size doesn't include the actual storage used by the file data.

- **Symbolic links and special files** – The metered data size for these objects is always 4 KiB.

When Amazon EFS reports the space used for an object, through the NFSv4.1 `space_used` attribute, it includes the object's current metered data size but not its metadata size. You can use two utilities for measuring the disk usage of a file, the `du` and `stat` utilities. Following is an example of how to use the `du` utility on an empty file, with the `-k` option to return the output in kilobytes.

```
$ du -k file
4      file
```

Following is an example of how to use the `stat` utility on an empty file to return the file's disk usage.

```
$ /usr/bin/stat --format="%b*%B" file | bc
4096
```

To measure the size of a directory, use the `stat` utility. Find the `Blocks` value, and then multiply that value by the block size. Following is an example of how to use the `stat` utility on an empty directory:

```
$ /usr/bin/stat --format="%b*%B" . | bc
4096
```

Metering an Amazon EFS file system

The metered size of an Amazon EFS file system includes the sum of the sizes of all current objects in the Standard and IA storage classes. The size of each object is calculated from a representative sampling that represents the size of the object during the metered hour. An example is the hour from 8 AM to 9 AM.

For example, an empty file contributes 6 KiB (2 KiB metadata + 4 KiB data) to the metered size of its file system. Upon creation, a file system has a single empty root directory and therefore has a metered size of 6 KiB.

The metered sizes of a particular file system define the usage for which the owner account is billed for that file system for that hour.

**Note**

The computed metered size doesn't represent a consistent snapshot of the file system at any particular time during that hour. Instead, it represents the sizes of the objects that existed in the file system at varying times within each hour, or possibly the hour before it. These sizes
are summed to determine the file system's metered size for the hour. The metered size of a file system is thus eventually consistent with the metered sizes of the objects stored when there are no writes to the file system.

You can see this metered size for an Amazon EFS file system in the following ways:

- Call the DescribeFileSystems operation (p. 279) using one the SDKs, HTTP, or the AWS CLI.
- View the File Systems table, for each file system listed in the AWS Management Console.
- Run the `df` command in Linux at the terminal prompt of an EC2 instance.

Use the `df` command and not the `du` command. Don’t use the `du` command on the root of the file system for storage metering purposes. The results don’t provide full data.

**Note**

The metered size of the Standard storage class is also used to determine your I/O throughput baseline and burst rates. For more information, see Throughput scaling with bursting mode (p. 123).

**Metering for infrequent access**

Infrequent Access (IA) storage is metered in 4 KiB increments. IA file metadata (2 KiB per file) is always stored and metered in the Standard storage class. Data access for IA storage is metered in 1 MiB increments.

**Metering provisioned throughput**

Customers only pay for the amount of time that Provisioned Throughput is enabled. Provisioned Throughput is metered once every hour. For metering when Provision Throughput is set for less than one hour, Amazon EFS calculates the time-average using millisecond precision.

Amazon EFS file systems meter the throughput for read requests at one-third the rate of the other file system I/O operations. For example, if you are driving 30 MB/s of both read throughput and write throughput, the read portion counts as 10 MB/s of effective throughput, the write portion counts as 30 MB/s, and the combined metered throughput is 40 MB/s. This combined throughput adjusted for consumption rates is reflected in the MeteredIOBytes CloudWatch metric.

**Managing Amazon EFS file system costs using AWS Budgets**

You can plan and manage your Amazon EFS file system costs by using AWS Budgets.

You can work with AWS Budgets from the AWS Billing and Cost Management console. To use AWS Budgets, you create a monthly cost budget for your EFS file systems. You can set up your budget to notify you if your costs are forecast to exceed your budgeted amount, and then make adjustments to maintain your budget as needed.

There are costs associated with using AWS Budgets. For regular AWS accounts, your first two budgets are free. For more information about AWS Budgets, including costs, see Managing Your Costs with Budgets in the AWS Billing and Cost Management User Guide.

You can set custom budgets for your Amazon EFS costs and usage at the account, AWS Region, service, or tag level by using budget parameters. In the following section, you can find a high-level description of how to set up a cost budget on an EFS file system with AWS Budgets. You do so by using cost allocation tags.
Prerequisites

To perform the procedures referenced in the following sections, make sure that you have the following:

- An EFS file system
- An AWS Identity and Access Management (IAM) policy with the following permissions:
  - Ability to perform the `elasticfilesystem:CreateTags` and `elasticfilesystem:DescribeTags` actions.

Creating a monthly cost budget for an EFS file system

Creating a monthly cost budget for your Amazon EFS file system using tags is a three-step process.

To create a monthly cost budget for your EFS file system using tags

1. Create a tag to use to identify the file system that you want to track costs for. To learn how, see Tagging resources (p. 44).
2. In the Billing and Cost Management console, activate the tag as a cost allocation tag. For a detailed procedure, see Activating user-defined cost allocation tags in the AWS Billing and Cost Management User Guide.

After you create your EFS monthly cost budget, you can view it in the Budgets dashboard, which displays the following budget data:

- Your current costs and usage incurred for a budget during the budget period.
- Your budgeted costs for the budget period.
- Your forecast costs for the budget period.
- A percentage that shows your costs compared to your budgeted amount.
- A percentage that shows your forecast costs compared to your budgeted amount.

For more information about viewing your EFS cost budget, see Viewing your budgets in the AWS Billing and Cost Management User Guide.

File system status

You can view the status of Amazon EFS file systems using the Amazon EFS console or the AWS CLI. An Amazon EFS file system can have one of the status values described in the following table.

<table>
<thead>
<tr>
<th>File system state</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVAILABLE</td>
<td>The file system is in a healthy state, and is reachable and available for use.</td>
</tr>
<tr>
<td>File system state</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>CREATING</td>
<td>Amazon EFS is in the process of creating the new file system.</td>
</tr>
<tr>
<td>DELETING</td>
<td>Amazon EFS is deleting the file system in response to a user-initiated delete request. For more information, see Deleting an Amazon EFS file system (p. 30).</td>
</tr>
<tr>
<td>DELETED</td>
<td>Amazon EFS has deleted the file system in response to a user-initiated delete request. For more information, see Deleting an Amazon EFS file system (p. 30).</td>
</tr>
<tr>
<td>UPDATING</td>
<td>The file system is undergoing an update in response to a user-initiated update request.</td>
</tr>
<tr>
<td>ERROR</td>
<td>Applicable only for file systems using One Zone storage classes – The file system is in a failed state and is unrecoverable. To access the file system data, restore a backup of this file system to a new file system. For more information, see Restore a recovery point (p. 133).</td>
</tr>
</tbody>
</table>
Monitoring Amazon EFS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon EFS and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. Before you start monitoring Amazon EFS, however, you should create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

The next step is to establish a baseline for normal Amazon EFS performance in your environment, by measuring performance at various times and under different load conditions. As you monitor Amazon EFS, you should consider storing historical monitoring data. This stored data will give you a baseline to compare against with current performance data, identify normal performance patterns and performance anomalies, and devise methods to address issues.

For example, with Amazon EFS, you can monitor network throughput, I/O for read, write, and/or metadata operations, client connections, and burst credit balances for your file systems. When performance falls outside your established baseline, you might need to change the size of your file system or the number of connected clients to optimize the file system for your workload.

To establish a baseline you should, at a minimum, monitor the following items:

- Your file system’s network throughput.
- The number of client connections to a file system.
- The number of bytes for each file system operation, including data read, data write, and metadata operations.

Monitoring tools

AWS provides various tools that you can use to monitor Amazon EFS. You can configure some of these tools to do the monitoring for you, while some of the tools require manual intervention. We recommend that you automate monitoring tasks as much as possible.

Automated monitoring tools

You can use the following automated monitoring tools to watch Amazon EFS and report when something is wrong:

- **Amazon CloudWatch Alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because
they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see Monitoring EFS with Amazon CloudWatch (p. 101).

- **Amazon CloudWatch Logs** – Monitor, store, and access your log files from AWS CloudTrail or other sources. For more information, see Monitoring Log Files in the Amazon CloudWatch User Guide.

- **Amazon CloudWatch Events** – Match events and route them to one or more target functions or streams to make changes, capture state information, and take corrective action. For more information, see What is Amazon CloudWatch Events in the Amazon CloudWatch User Guide.

- **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see Working with CloudTrail Log Files in the AWS CloudTrail User Guide.

**Manual monitoring tools**

Another important part of monitoring Amazon EFS involves manually monitoring those items that the Amazon CloudWatch alarms don’t cover. The Amazon EFS, CloudWatch, and other AWS Management Console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on file system.

- From the Amazon EFS console, you can find the following items for your file systems:
  - The current metered size
  - The number of mount targets
  - The lifecycle state

- CloudWatch home page shows:
  - Current alarms and status
  - Graphs of alarms and resources
  - Service health status

In addition, you can use CloudWatch to do the following:

- Create customized dashboards to monitor the services you use
- Graph metric data to troubleshoot issues and discover trends
- Search and browse all your AWS resource metrics
- Create and edit alarms to be notified of problems

**Monitoring EFS with Amazon CloudWatch**

You can monitor file systems using Amazon CloudWatch, which collects and processes raw data from Amazon EFS into readable, near real-time metrics. These statistics are recorded for a period of 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing.

By default, Amazon EFS metric data is automatically sent to CloudWatch at 1-minute periods, unless noted for some individual metrics. The Amazon EFS console displays a series of graphs based on the raw data from Amazon CloudWatch. Depending on your needs, you might prefer to get data for your file systems from CloudWatch instead of the graphs in the console.

For more information about Amazon CloudWatch, see the Amazon CloudWatch User Guide.

**Topics**

- Amazon CloudWatch metrics for Amazon EFS (p. 102)
- How do I use Amazon EFS metrics? (p. 105)
Amazon CloudWatch metrics for Amazon EFS

Amazon EFS metrics use the **EFS** namespace and provide metrics for a single dimension, **FileSystemId**. A file system's ID can be found in the Amazon EFS console, and it takes the form of `fs-XXXXXXXX`. The **AWS/EFS** namespace includes the following metrics.

**PercentIOLimit**

Shows how close a file system is to reaching the I/O limit of the General Purpose performance mode. If this metric is at 100 percent more often than not, consider moving your application to a file system using the Max I/O performance mode.

**Note**

This metric is only submitted for file systems using the General Purpose performance mode.

Units: Percent

**BurstCreditBalance**

The number of burst credits that a file system has. Burst credits allow a file system to burst to throughput levels above a file system's baseline level for periods of time. For more information, see Throughput scaling with bursting mode (p. 123).

The **Minimum** statistic is the smallest burst credit balance for any minute during the period. The **Maximum** statistic is the largest burst credit balance for any minute during the period. The **Average** statistic is the average burst credit balance during the period.

Units: Bytes

Valid statistics: Minimum, Maximum, Average

**PermittedThroughput**

The maximum amount of throughput that a file system can drive. For file systems in the Provisioned Throughput mode, if the amount of data stored in the standard storage class allows your file system to drive a higher throughput than you provisioned, this metric will reflect the higher throughput instead of the provisioned amount. For file systems in Bursting Throughput mode, this value is a function of the file system size and **BurstCreditBalance**. For more information, see Amazon EFS performance (p. 120).

The **Minimum** statistic is the smallest throughput permitted for any minute during the period. The **Maximum** statistic is the highest throughput permitted for any minute during the period. The **Average** statistic is the average throughput permitted during the period.

**Note**

Read operations are metered at one-third the rate of other operations.

Units: Bytes per second

Valid statistics: Minimum, Maximum, Average

**MeteredIOBytes**

The number of metered bytes for each file system operation, including data read, data write, and metadata operations, with read operations metered at one-third the rate of other operations.
You can create a **CloudWatch metric math expression** (p. 107) that compares `MeteredIOBytes` to `PermittedThroughput`. If these values are equal, then you are consuming the entire amount of throughput allocated to your file system. In this situation, you might consider changing the file system's throughput mode to Provisioned Throughput to get higher throughput.

The **Sum** statistic is the total number of metered bytes associated with all file system operations. The **Minimum** statistic is the size of the smallest operation during the period. The **Maximum** statistic is the size of the largest operation during the period. The **Average** statistic is the average size of an operation during the period. The **SampleCount** statistic provides a count of all operations.

**Units:**
- Bytes for **Minimum**, **Maximum**, **Average**, and **Sum** statistics.
- Count for **SampleCount**.

**Valid statistics:** Minimum, Maximum, Average, Sum, SampleCount

**TotalIOBytes**

The actual number of bytes for each file system operation, including data read, data write, and metadata operations. This is the actual amount that your application is driving, and not the throughput the file system is being metered at. It might be higher than the numbers shown in `PermittedThroughput`.

The **Sum** statistic is the total number of bytes associated with all file system operations. The **Minimum** statistic is the size of the smallest operation during the period. The **Maximum** statistic is the size of the largest operation during the period. The **Average** statistic is the average size of an operation during the period. The **SampleCount** statistic provides a count of all operations.

**Note**

To calculate the average operations per second for a period, divide the **SampleCount** statistic by the number of seconds in the period. To calculate the average throughput (bytes per second) for a period, divide the **Sum** statistic by the number of seconds in the period.

**Units:**
- Bytes for **Minimum**, **Maximum**, **Average**, and **Sum** statistics.
- Count for **SampleCount**.

**Valid statistics:** Minimum, Maximum, Average, Sum, SampleCount

**DataReadIOBytes**

The number of bytes for each file system read operation.

The **Sum** statistic is the total number of bytes associated with read operations. The **Minimum** statistic is the size of the smallest read operation during the period. The **Maximum** statistic is the size of the largest read operation during the period. The **Average** statistic is the average size of read operations during the period. The **SampleCount** statistic provides a count of read operations.

**Units:**
- Bytes for **Minimum**, **Maximum**, **Average**, and **Sum**.
- Count for **SampleCount**.

**Valid statistics:** Minimum, Maximum, Average, Sum, SampleCount

**DataWriteIOBytes**

The number of bytes for each file write operation.

The **Sum** statistic is the total number of bytes associated with write operations. The **Minimum** statistic is the size of the smallest write operation during the period. The **Maximum** statistic is the size of the largest write operation during the period. The **Average** statistic is the average size of write operations during the period. The **SampleCount** statistic provides a count of write operations.
size of the largest write operation during the period. The Average statistic is the average size of write operations during the period. The SampleCount statistic provides a count of write operations.

Units:
- Bytes are the units for the Minimum, Maximum, Average, and Sum statistics.
- Count for SampleCount.

Valid statistics: Minimum, Maximum, Average, Sum, SampleCount

**MetadataIOBytes**

The number of bytes for each metadata operation.

The Sum statistic is the total number of bytes associated with metadata operations. The Minimum statistic is the size of the smallest metadata operation during the period. The Maximum statistic is the size of the largest metadata operation during the period. The Average statistic is the size of the average metadata operation during the period. The SampleCount statistic provides a count of metadata operations.

Units:
- Bytes are the units for the Minimum, Maximum, Average, and Sum statistics.
- Count for SampleCount.

Valid statistics: Minimum, Maximum, Average, Sum, SampleCount

**ClientConnections**

The number of client connections to a file system. When using a standard client, there is one connection per mounted Amazon EC2 instance.

*Note*
To calculate the average ClientConnections for periods greater than one minute, divide the Sum statistic by the number of minutes in the period.

Units: Count of client connections

Valid statistics: Sum

**StorageBytes**

The size of the file system in bytes, including the amount of data stored in the Standard and Infrequent Access storage classes. This metric is emitted every 15 minutes to CloudWatch. For more information about storage classes, see Managing EFS storage classes (p. 87).

The StorageBytes metric has three dimensions:
- Total is the latest known metered size (in bytes) of data stored in the file system, including both storage classes.
- Standard is the latest known metered size (in bytes) of data stored in the Standard storage class.
- IA is the latest known metered size (in bytes) of data stored in the Infrequent Access storage class.

Units: Bytes

*Note*
Storage Bytes is displayed on the EFS console File system metrics page using base 1024 units (kibibytes, mebibytes, gibibytes, and tebibytes).

**Bytes reported in CloudWatch**

Amazon EFS CloudWatch metrics are reported as raw bytes. Bytes are not rounded to either a decimal or binary multiple of the unit. Keep this in mind when calculating your burst rate using the data you
How do I use Amazon EFS metrics?

The metrics reported by Amazon EFS provide information that you can analyze in different ways. The following list shows some common uses for the metrics. These are suggestions to get you started, not a comprehensive list.

<table>
<thead>
<tr>
<th>How do I?</th>
<th>Relevant metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>How can I determine my throughput?</td>
<td>You can monitor the daily sum statistic of the TotalIOBytes metric to see your throughput.</td>
</tr>
<tr>
<td>How can I track the number of Amazon EC2 instances that are connected to a file system?</td>
<td>You can monitor the sum statistic of the ClientConnections metric. To calculate the average ClientConnections for periods greater than one minute, divide the sum by the number of minutes in the period.</td>
</tr>
<tr>
<td>How can I see my burst credit balance?</td>
<td>You can see your balance by monitoring the BurstCreditBalance metric for your file system. For more information on bursting and burst credits, see Throughput scaling with bursting mode (p. 123).</td>
</tr>
</tbody>
</table>

Using CloudWatch metrics to monitor throughput performance

The Amazon EFS CloudWatch metrics for throughput monitoring—TotalIOBytes, ReadIOBytes, WriteIOBytes, and MetadataIOBytes—represent the actual throughput that you are driving on your file system. The metric MeteredIOBytes represents the calculation of the overall metered throughput (p. 121) that you are driving. You can use the Throughput utilization (%) graph in the Amazon EFS console Monitoring section to monitor your throughput utilization. If you use custom Amazon CloudWatch dashboards or another monitoring tool, you can create a CloudWatch metric math expression (p. 107) that compares MeteredIOBytes to PermittedThroughput.

PermittedThroughput measures the amount of allowed throughput for the file system (either based on the size the file system in Standard storage class for Bursting throughput, or the amount of Provisioned Throughput for file). When the values for MeteredIOBytes and PermittedThroughput are equal, your file system is consuming all available throughput. For file systems using Provisioned Throughput mode, you can provision additional throughput.

For file systems using Bursting Throughput mode, monitor BurstCreditBalance to ensure that your file system is operating at its burst rate rather than its base rate. If the balance is consistently at or near zero, you will need to switch to Provisioned Throughput mode to get additional throughput.

Using metric math with Amazon EFS

Using metric math, you can query multiple CloudWatch metrics and use math expressions to create new time series based on these metrics. You can visualize the resulting time series in the CloudWatch console and add them to dashboards. For example, you can use Amazon EFS metrics to take the sample count of DataRead operations divided by 60. The result is the average number of reads per second on your file system for a given 1-minute period. For more information on metric math, see Use Metric Math in the Amazon CloudWatch User Guide.

Following, find some useful metric math expressions for Amazon EFS.

Topics
Metric math: Throughput in MiB/second

To calculate the average throughput (in MiB/second) for a time period, first choose a sum statistic (DataReadIOBytes, DataWriteIOBytes, MetadataIOBytes, or TotalIOBytes). Then convert the value to MiB, and divide that by the number of seconds in the period.

Suppose that your example logic is this: \((\text{sum of TotalIOBytes} ÷ 1,048,576 \text{ (to convert to } \text{MiB)}) ÷ \text{seconds in the period})\)

Then your CloudWatch metric information is the following.

<table>
<thead>
<tr>
<th>ID</th>
<th>Usable metrics</th>
<th>Statistic</th>
<th>Period</th>
</tr>
</thead>
<tbody>
<tr>
<td>m1</td>
<td>• DataReadIOBytes</td>
<td>sum</td>
<td>1 minute</td>
</tr>
<tr>
<td></td>
<td>• DataWriteIOBytes</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• MetadataIOBytes</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• TotalIOBytes</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Your metric math ID and expression are the following.

<table>
<thead>
<tr>
<th>ID</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>e1</td>
<td>((m1/1048576)/\text{PERIOD}(m1))</td>
</tr>
</tbody>
</table>

Metric math: Percent throughput

This metric math expression calculates the percent of overall throughput used for the different I/O types—for example, the percentage of total throughput that is driven by read requests. To calculate the percent of overall throughput used by one of the I/O types (DataReadIOBytes, DataWriteIOBytes, or MetadataIOBytes) for a time period, first multiply the respective sum statistic by 100. Then divide the result by the sum statistic of TotalIOBytes for the same period.

Suppose that your example logic is this: \((\text{sum of DataReadIOBytes x } 100 \text{ (to convert to percentage)}) ÷ \text{sum of TotalIOBytes})\)

Then your CloudWatch metric information is the following.

<table>
<thead>
<tr>
<th>ID</th>
<th>Usable metric or metrics</th>
<th>Statistic</th>
<th>Period</th>
</tr>
</thead>
<tbody>
<tr>
<td>m1</td>
<td>• TotalIOBytes</td>
<td>sum</td>
<td>1 minute</td>
</tr>
<tr>
<td>m2</td>
<td>• DataReadIOBytes</td>
<td>sum</td>
<td>1 minute</td>
</tr>
</tbody>
</table>
Your metric math ID and expression are the following.

<table>
<thead>
<tr>
<th>ID</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>e1</td>
<td>( \frac{(m2*100)}{m1} )</td>
</tr>
</tbody>
</table>

**Metric math: Percentage of permitted throughput utilization**

To calculate the percentage of permitted throughput utilization (MeteredIOBytes) for a time period, first multiply the throughput in MiB/second by 100. Then divide the result by the sum statistic of PermittedThroughput converted to MiB for the same period.

Suppose that your example logic is this: \((\text{metric math expression for throughput in MiB/second} \times 100 \text{ (to convert to percentage)}) \div (\text{sum of PermittedThroughput} \div 1,048,576 \text{ (to convert bytes to MiB)})\)

Then your CloudWatch metric information is the following.

<table>
<thead>
<tr>
<th>ID</th>
<th>Usable metric or metrics</th>
<th>Statistic</th>
<th>Period</th>
</tr>
</thead>
<tbody>
<tr>
<td>m1</td>
<td>MeteredIOBytes</td>
<td>sum</td>
<td>1 minute</td>
</tr>
<tr>
<td>m2</td>
<td>PermittedThroughput</td>
<td>sum</td>
<td>1 minute</td>
</tr>
</tbody>
</table>

Your metric math ID and expression are the following.

<table>
<thead>
<tr>
<th>ID</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>e1</td>
<td>( \frac{(m1/1048576)\text{/PERIOD(m1)}}{m2/1048576} )</td>
</tr>
<tr>
<td>e2</td>
<td>( \frac{m2/1048576}{(e1)*100)/(e2)} )</td>
</tr>
</tbody>
</table>

**Metric math: Throughput IOPS**

To calculate the average operations per second (IOPS) for a time period, divide the sample count statistic (DataReadIOBytes, DataWriteIOBytes, MetadataIOBytes, or TotalIOBytes) by the number of seconds in the period.

Suppose that your example logic is this: \(\text{sample count of DataWriteIOBytes} \div \text{seconds in the period}\)

Then your CloudWatch metric information is the following.

<table>
<thead>
<tr>
<th>ID</th>
<th>Usable metrics</th>
<th>Statistic</th>
<th>Period</th>
</tr>
</thead>
<tbody>
<tr>
<td>m1</td>
<td>• DataReadIOBytes • DataWriteIOBytes • MetadataIOBytes • TotalIOBytes</td>
<td>sample count</td>
<td>1 minute</td>
</tr>
</tbody>
</table>
Your metric math ID and expression are the following.

<table>
<thead>
<tr>
<th>ID</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>e1</td>
<td>m1/PERIOD(m1)</td>
</tr>
</tbody>
</table>

### Metric math: Percentage of IOPS

To calculate the percentage of IOPS per second of the different I/O types (DataReadIOBytes, DataWriteIOBytes, or MetadataIOBytes) for a time period, first multiply the respective sample count statistic by 100. Then divide that value by the sample count statistic of TotalIOBytes for the same period.

Suppose that your example logic is this: (sample count of MetadataIOBytes x 100 (to convert to percentage)) ÷ sample count of TotalIOBytes

Then your CloudWatch metric information is the following.

<table>
<thead>
<tr>
<th>ID</th>
<th>Usable metrics</th>
<th>Statistic</th>
<th>Period</th>
</tr>
</thead>
<tbody>
<tr>
<td>m1</td>
<td>TotalIOBytes</td>
<td>sample count</td>
<td>1 minute</td>
</tr>
<tr>
<td>m2</td>
<td>DataReadIOBytes, DataWriteIOBytes, MetadataIOBytes</td>
<td>sample count</td>
<td>1 minute</td>
</tr>
</tbody>
</table>

Your metric math ID and expression are the following.

<table>
<thead>
<tr>
<th>ID</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>e1</td>
<td>(m2*100)/m1</td>
</tr>
</tbody>
</table>

### Metric math: Average I/O size in KiB

To calculate the average I/O size (in KiB) for a period, divide the respective sum statistic for the DataReadIOBytes, DataWriteIOBytes, or MetadataIOBytes metric by the same sample count statistic of that metric.

Suppose that your example logic is this: (sum of DataReadIOBytes ÷ 1,024 (to convert to KiB)) ÷ sample count of DataReadIOBytes

Then your CloudWatch metric information is the following.

<table>
<thead>
<tr>
<th>ID</th>
<th>Usable metrics</th>
<th>Statistic</th>
<th>Period</th>
</tr>
</thead>
<tbody>
<tr>
<td>m1</td>
<td>DataReadIOBytes, DataWriteIOBytes, MetadataIOBytes</td>
<td>sum</td>
<td>1 minute</td>
</tr>
<tr>
<td>m2</td>
<td>DataReadIOBytes, DataWriteIOBytes</td>
<td>sample count</td>
<td>1 minute</td>
</tr>
</tbody>
</table>
Monitoring EFS file system mount status

You can use Amazon CloudWatch Logs to monitor the status of EFS file system mounts remotely without having to log into the EC2 instances. The following pre-requisites are required in order to use CloudWatch Logs to monitor for file system mount status:

1. The EC2 instances are launched with an instance profile that includes the `AmazonElasticFileSystemsUtils` permission policy. For more information, see Step 1: Configure an IAM instance profile with the required permissions (p. 49).
2. Version 1.28.1 or later of the Amazon EFS client (`amazon-efs-utils` package) is installed on the EC2 instances. You can use AWS Systems Manager to automatically install the package on your instances. For more information, see Step 2: Configure an Association used by State Manager for installing or updating the Amazon EFS client (p. 50).
3. The `botocore` package is installed on the EC2 instance. For more information, see Installing `botocore` (p. 54).
4. The `efs-utils.conf` configuration file is updated to enable CloudWatch Logs. When you use AWS Systems Manager to install and configure the `amazon-efs-utils` package, this update to enable CloudWatch logging is automatically done for you. When you install the `amazon-efs-utils` package from the yum repository, you have to manually update the `/etc/amazon/efs/efs-utils.conf` configuration file by uncommenting the `# enabled = true` line in the `cloudwatch-log` section.

Here are examples of mount status log entries:

<table>
<thead>
<tr>
<th>ID</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>e1</td>
<td>((m1/1024)/m2)</td>
</tr>
</tbody>
</table>

Using metric math through an AWS CloudFormation template for Amazon EFS

You can also create metric math expressions through AWS CloudFormation templates. One such template is available for you to download and customize for use from the Amazon EFS tutorials on GitHub. For more information about using AWS CloudFormation templates, see Working with AWS CloudFormation Templates in the AWS CloudFormation User Guide.

To view mount status in CloudWatch Logs

2. Choose Log groups in the left-hand navigation bar.
3. Choose the `/aws/efs/utils` log group. You will see a log stream for each EC2 instance and EFS file system combination.
4. Choose a log stream to view specific log events including the file system mount status.
Accessing CloudWatch metrics

You can view Amazon EFS metrics for CloudWatch in several ways:

- In the Amazon EFS console
- In the CloudWatch console
- Using the CloudWatch CLI
- Using the CloudWatch API

The following procedures show you how to access the metrics using these various tools.

**To view CloudWatch metrics and alarms in the Amazon EFS console**

1. Sign in to the AWS Management Console and open the Amazon EFS console at [https://console.aws.amazon.com/efs/](https://console.aws.amazon.com/efs/).
2. Choose **File systems**.
3. Choose the file system that you want to view CloudWatch metrics for.
4. Choose **Monitoring** to display the **File system metrics** page.

   The **File system metrics** page displays a default set of CloudWatch metrics for the file system. Any CloudWatch alarms that you have configured also display with these metrics. For file systems that use Max I/O performance mode, the default set of metrics includes Burst Credit balance in place of Percent IO limit. You can override the default settings using the **Metrics settings** dialog box, accessed by choosing the settings icon (⚙).

   **Note**
   The Throughput utilization (%) metric is not a CloudWatch metric, it is derived using CloudWatch metric math.

5. You can adjust the way metrics and alarms are displayed using the controls on the **File system metric** page, as follows.

![Metrics controls](image)

   - Toggle the **Display mode** between **Time series** or **Single value**.
   - Show or hide any CloudWatch alarms configured for the file system.
   - Choose **See more in CloudWatch** to view the metrics in CloudWatch.
   - Choose **Add to dashboard** to open your CloudWatch dashboard and add the displayed metrics.
   - Adjust the metric time window displayed from 1 hour to 1 week.

**To view metrics using the CloudWatch console**

2. In the navigation pane, choose **Metrics**.
3. Select the **EFS** namespace.
4. (Optional) To view a metric, enter its name in the search field.
5. (Optional) To filter by dimension, select **FileSystemId**.

### To access metrics from the AWS CLI

- Use the `list-metrics` command with the `--namespace "AWS/EFS"` namespace. For more information, see the [AWS CLI Command Reference](https://aws.amazon.com/documentation/cli/command-reference/).

### To access metrics from the CloudWatch API

- Call `GetMetricStatistics`. For more information, see the [Amazon CloudWatch API Reference](https://aws.amazon.com/documentation/cloudwatch/api-reference/).

## Creating CloudWatch alarms to monitor Amazon EFS

You can create a CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period you specify, and performs one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Auto Scaling policy.

Alarms invoke actions for sustained state changes only. CloudWatch alarms don't invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods.

One important use of CloudWatch alarms for Amazon EFS is to enforce encryption at rest for your file system. You can enable encryption at rest for an Amazon EFS file system when it's created. To enforce data encryption-at-rest policies for Amazon EFS file systems, you can use Amazon CloudWatch and AWS CloudTrail to detect the creation of a file system and verify that encryption at rest is enabled. For more information, see the [Walkthrough: Enforcing Encryption on an Amazon EFS File System at Rest](https://docs.aws.amazon.com/efs/latest/file Sistema/Security.html).

**Note**

Currently, you can't enforce encryption in transit.

The following procedures outline how to create alarms for Amazon EFS.

### To set alarms using the CloudWatch console

2. Choose **Create Alarm**. This launches the **Create Alarm Wizard**.
3. Choose **EFS Metrics** and scroll through the Amazon EFS metrics to locate the metric you want to place an alarm on. To display just the Amazon EFS metrics in this dialog box, search on the file system id of your file system. Select the metric to create an alarm on and choose **Next**.
4. Fill in the **Name**, **Description**, **Whenever** values for the metric.
5. If you want CloudWatch to send you an email when the alarm state is reached, in the **Whenever this alarm** field, choose **State is ALARM**. In the **Send notification to** field, choose an existing SNS topic. If you select **Create topic**, you can set the name and email addresses for a new email subscription list. This list is saved and appears in the field for future alarms.

**Note**

If you use **Create topic** to create a new Amazon SNS topic, the email addresses must be verified before they receive notifications. Emails are only sent when the alarm enters an alarm state. If this alarm state change happens before the email addresses are verified, they do not receive a notification.

6. At this point, the **Alarm Preview** area gives you a chance to preview the alarm you're about to create. Choose **Create Alarm**.
To set an alarm using the AWS CLI

• Call `put-metric-alarm`. For more information, see the AWS CLI Command Reference.

To set an alarm using the CloudWatch API

• Call `PutMetricAlarm`. For more information, see the Amazon CloudWatch API Reference.

Logging Amazon EFS API Calls with AWS CloudTrail

Amazon EFS is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Amazon EFS. CloudTrail captures all API calls for Amazon EFS as events, including calls from the Amazon EFS console and from code calls to Amazon EFS API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Amazon EFS. If you don’t configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request that was made to Amazon EFS, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Amazon EFS Information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Amazon EFS, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for Amazon EFS, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in the AWS CloudTrail User Guide:

• Overview for Creating a Trail
• CloudTrail Supported Services and Integrations
• Configuring Amazon SNS Notifications for CloudTrail
• Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All Amazon EFS API calls (p. 230) are logged by CloudTrail. For example, calls to the `CreateFileSystem`, `CreateMountTarget` and `CreateTags` operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

• Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
• Whether the request was made with temporary security credentials for a role or federated user.
• Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element in the AWS CloudTrail User Guide.

Understanding Amazon EFS Log File Entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the CreateTags operation when a tag for a file system is created from the console.

```json
{
  "eventVersion": "1.06",
  "userIdentity": {
    "type": "Root",
    "principalId": "111122223333",
    "arn": "arn:aws:iam::111122223333:root",
    "accountId": "111122223333",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "attributes": {
        "mfaAuthenticated": "false",
        "creationDate": "2017-03-01T18:02:37Z"
      }
    }
  },
  "eventTime": "2017-03-01T19:25:47Z",
  "eventSource": "elasticfilesystem.amazonaws.com",
  "eventName": "CreateTags",
  "awsRegion": "us-west-2",
  "sourceIPAddress": "192.0.2.0",
  "userAgent": "console.amazonaws.com",
  "requestParameters": {
    "fileSystemId": "fs-00112233",
    "tags": [{
      "key": "TagName",
      "value": "AnotherNewTag"
    }]
  },
  "responseElements": null,
  "requestID": "dEXAMPLE-feb4-11e6-85f0-736EXAMPLE75",
  "eventID": "eEXAMPLE-2d32-4619-bd00-657EXAMPLEe4",
  "eventType": "AwsApiCall",
  "apiVersion": "2015-02-01",
  "recipientAccountId": "111122223333"
}
```

The following example shows a CloudTrail log entry that demonstrates the DeleteTags action when a tag for a file system is deleted from the console.

```json
{
  "eventVersion": "1.06",
  "userIdentity": {
    "type": "Root",
    "principalId": "111122223333",
    "arn": "arn:aws:iam::111122223333:root",
    "accountId": "111122223333",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "attributes": {
        "mfaAuthenticated": "false",
        "creationDate": "2017-03-01T18:02:37Z"
      }
    }
  },
  "eventTime": "2017-03-01T19:25:47Z",
  "eventSource": "elasticfilesystem.amazonaws.com",
  "eventName": "DeleteTags",
  "awsRegion": "us-west-2",
  "sourceIPAddress": "192.0.2.0",
  "userAgent": "console.amazonaws.com",
  "requestParameters": {
    "fileSystemId": "fs-00112233",
    "tags": [{
      "key": "TagName",
      "value": "AnotherNewTag"
    }]
  },
  "responseElements": null,
  "requestID": "dEXAMPLE-feb4-11e6-85f0-736EXAMPLE75",
  "eventID": "eEXAMPLE-2d32-4619-bd00-657EXAMPLEe4",
  "eventType": "AwsApiCall",
  "apiVersion": "2015-02-01",
  "recipientAccountId": "111122223333"
}
```
Log Entries for EFS Service Linked Roles

The Amazon EFS service linked role makes API calls to AWS resources. You will see CloudTrail log entries with username: AWSServiceRoleForAmazonElasticFileSystem for calls made by the EFS service linked role. For more information about EFS and service linked roles, see Using the Amazon EFS Service-Linked Role (p. 192).

The following example shows a CloudTrail log entry that demonstrates a CreateServiceLinkedRole action when Amazon EFS creates the AWSServiceRoleForAmazonElasticFileSystem service linked role.

```json
{
"eventVersion": "1.05",
"userIdentity": {
  "type": "IAMUser",
  "principalId": "111122223333",
  "arn": "arn:aws:iam::111122223333:user/user1",
  "accountId": "111122223333",
  "accessKeyId": "A111122223333",
  "userId": "user1",
  "sessionContext": {
    "attributes": {
      "mfaAuthenticated": "false",
      "creationDate": "2019-10-23T22:45:41Z"
    }
  },
  "invokedBy": "elasticfilesystem.amazonaws.com"
},
"eventTime": "2019-10-23T22:45:41Z",
"eventSource": "iam.amazonaws.com",
"eventName": "CreateServiceLinkedRole",
"awsRegion": "us-east-1",
"sourceIPAddress": "192.0.2.0",
"userAgent": "user_agent",
"requestParameters": {
  "accountId": "111122223333",
  "serviceLinkedRoleName": "AWSServiceRoleForAmazonElasticFileSystem",
  "serviceLinkedRoleArn": "arn:aws:iam::111122223333:role/AWSServiceRoleForAmazonElasticFileSystem"
}
}
```
The following example shows a CloudTrail log entry that demonstrates a `CreateNetworkInterface` action made by the `AWSServiceRoleForAmazonElasticFileSystem` service linked role, noted in the `sessionContext`.

```json
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "AIDACKC6V56Q2XEC6EXAMPLE",
        "arn": "arn:aws:sts::0123456789ab:assumed-role/AWSServiceRoleForAmazonElasticFileSystem/0123456789ab",
        "accountId": "0123456789ab",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "AIDACKC6V56Q2XEC6EXAMPLE",
                "arn": "arn:aws:iam::0123456789ab:role/aws-service-role/elasticfilesystem.amazonaws.com/AWSServiceRoleForAmazonElasticFileSystem",
                "accountId": "0123456789ab",
                "userName": "AWSServiceRoleForAmazonElasticFileSystem"
            },
            "webIdFederationData": {},
            "attributes": {
                "mfaAuthenticated": "false",
                "creationDate": "2019-10-23T22:50:05Z"
            }
        }
    },
    "invokedBy": "AWS Internal",
    "eventTime": "20You 19-10-23T22:50:05Z",
    "eventSource": "ec2.amazonaws.com",
    "eventName": "CreateNetworkInterface",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "elasticfilesystem.amazonaws.com",
    "userAgent": "elasticfilesystem.amazonaws.com",
    "requestParameters": {
        "subnetId": "subnet-71e2f83a",
        "description": "EFS mount target for fs-1234567 (fsmt-1234567)",
        "groupSet": {},
        "privateIpAddressesSet": {}
    },
    "responseElements": {
```

```
Log Entries for EFS IAM Authentication

Amazon EFS IAM authorization for NFS clients emits NewClientConnection and UpdateClientConnection CloudTrail events. A NewClientConnection event is emitted when a connection is authorized immediately after an initial connection, and immediately after a re-connection. An UpdateClientConnection is emitted when a connection is reauthorized and the list of permitted actions has changed, it's also emitted when the new list of permitted actions doesn't include ClientMount. For more information about EFS IAM authorization, see Using IAM to control file system data access (p. 185).

The following example shows a CloudTrail log entry that demonstrates a NewClientConnection event.

```json
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "AIDACKCEVSQ6C2EXAMPLE",
    "arn": "arn:aws:sts::0123456789ab:assumed-role/abcdef0123456789",
    "accountId": "0123456789ab",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "sessionIssuer": {
        "type": "Role",
        "principalId": "AIDACKCEVSQ6C2EXAMPLE",
        "arn": "arn:aws:sts::0123456789ab:assumed-role/abcdef0123456789",
        "accountId": "0123456789ab",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
          "sessionIssuer": {
            "type": "Role",
            "principalId": "AIDACKCEVSQ6C2EXAMPLE",
            "arn": "arn:aws:sts::0123456789ab:assumed-role/abcdef0123456789",
            "accountId": "0123456789ab",
            "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
            "sessionContext": {
              "sessionIssuer": {
                "type": "Role",
                "principalId": "AIDACKCEVSQ6C2EXAMPLE",
                "arn": "arn:aws:sts::0123456789ab:assumed-role/abcdef0123456789",
                "accountId": "0123456789ab",
                "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
                "sessionContext": {
                  "sessionIssuer": {
                    "type": "Role",
                    "principalId": "AIDACKCEVSQ6C2EXAMPLE",
                    "arn": "arn:aws:sts::0123456789ab:assumed-role/abcdef0123456789",
                    "accountId": "0123456789ab",
                    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
                    "sessionContext": {
                      "sessionIssuer": {
                        "type": "Role",
                        "principalId": "AIDACKCEVSQ6C2EXAMPLE",
                        "arn": "arn:aws:sts::0123456789ab:assumed-role/abcdef0123456789",
                        "accountId": "0123456789ab",
                        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
                        "sessionContext": {
                          "sessionIssuer": {
                            "type": "Role",

                                                    "accountId": "0123456789ab",
                                                    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
                                                    "sessionContext": {
                                                      "sessionIssuer": {
                                                        "type": "Role",
                                                        "principalId": "AIDACKCEVSQ6C2EXAMPLE",
                                                        "arn": "arn:aws:sts::0123456789ab:assumed-role/abcdef0123456789",
                                                        "accountId": "0123456789ab",
                                                        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
                                                        "sessionContext": {
                                                          "sessionIssuer": {
                                                            "type": "Role",
                                                            "principalId": "AIDACKCEVSQ6C2EXAMPLE",
                                                            "arn": "arn:aws:sts::0123456789ab:assumed-role/abcdef0123456789",
                                                            "accountId": "0123456789ab",
                                                            "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
                                                            "sessionContext": {
                                                              "sessionIssuer": {
                                                                "type": "Role",
                                                                "principalId": "AIDACKCEVSQ6C2EXAMPLE",
                                                                "arn": "arn:aws:sts::0123456789ab:assumed-role/abcdef0123456789",
                                                                "accountId": "0123456789ab",
                                                                "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
                                                                "sessionContext": {
                                                                  "sessionIssuer": {
                                                                    "type": "Role",
                                                                    "principalId": "AIDACKCEVSQ6C2EXAMPLE",
                                                                    "arn": "arn:aws:sts::0123456789ab:assumed-role/abcdef0123456789",
                                                                    "accountId": "0123456789ab",
                                                                    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
                                                                    "sessionContext": {
                                                                      "sessionIssuer": {
                                                                        "type": "Role",
                                                                        "principalId": "AIDACKCEVSQ6C2EXAMPLE",
                                                                        "arn": "arn:aws:sts::0123456789ab:assumed-role/abcdef0123456789",

Amazon EFS Log File Entries for Encrypted-at-Rest File Systems

Amazon EFS Log File Entries for Encrypted-at-Rest File Systems

Amazon EFS gives you the option of using encryption at rest, encryption in transit, or both, for your file systems. For more information, see Data encryption in Amazon EFS (p. 169).

If you're using an encrypted-at-rest file system, the calls that Amazon EFS makes on your behalf appear in your AWS CloudTrail logs as coming from an AWS-owned account. If you see one of the following account IDs in your CloudTrail logs, depending on the AWS Region that your file system is created in, this ID is one owned by the Amazon EFS service.
Amazon EFS Encryption Context for Encryption at Rest

Amazon EFS sends encryption context when making AWS KMS API requests to generate data keys and decrypt Amazon EFS data. The file system ID is the encryption context for all file systems that are encrypted at rest. In the requestParameters field of a CloudTrail log entry, the encryption context looks similar to the following.

"EncryptionContextEquals": { }
"aws:elasticfilesystem:filesystem:id" : "fs-4EXAMPLE"
Amazon EFS performance

Following, you can find an overview of Amazon EFS performance, with a discussion of the available performance and throughput modes and some useful performance tips.

Note
For Linux kernel versions 5.4.*, the Linux NFS client uses a default `read_ahead_kb` value of 128 KB. We recommend increasing this value to 15 MB. For more information, see Optimizing the NFS `read_ahead_kb` size (p. 128).

Performance overview

Amazon EFS file systems are distributed across an unconstrained number of storage servers. This distributed data storage design enables file systems to grow elastically to petabyte scale. It also enables massively parallel access from compute instances, including Amazon EC2, Amazon ECS, and AWS Lambda, to your data. The Amazon EFS distributed design avoids the bottlenecks and constraints inherent to traditional file servers.

This distributed data storage design means that multithreaded applications and applications that concurrently access data from multiple compute instances can drive substantial levels of aggregate throughput and IOPS. Big data and analytics workloads, media processing workflows, content management, and web serving are examples of these applications.

In addition, for Amazon EFS file systems using Regional storage classes, data is distributed across multiple Availability Zones in an AWS Region, providing the highest level of durability and availability. The following tables compare high-level performance and storage characteristics for Amazon EFS and Amazon Elastic Block Store (Amazon EBS) cloud storage services.

Performance comparison: Amazon EFS and Amazon EBS

</tr>
</tbody>
</table>
The distributed nature of Amazon EFS file systems enables high levels of availability, durability, and scalability. EFS file systems using Regional storage classes store data redundantly across multiple Availability Zones and offer the highest levels of availability and durability. This distributed architecture results in a small latency overhead for each file operation. Due to this per-operation latency, overall throughput generally increases as the average I/O size increases, because the overhead is amortized over a larger amount of data. Amazon EFS supports highly parallelized workloads (for example, using concurrent operations from multiple threads and multiple Amazon EC2 instances), which enables high levels of aggregate throughput and operations per second.

**Understanding metered throughput**

All Amazon EFS file systems have an associated metered throughput that is determined by either the amount of provisioned throughput for file systems using Provisioned Throughput, or by the amount of data stored in the EFS Standard or One Zone storage class for file systems using Bursting Throughput. Read requests and write requests are metered at different rates. Amazon EFS meters read requests at one-third the rate of other requests.

For example, if you are driving 30 MiB/s of both read throughput and write throughput, the read portion counts as 10 MiB/s of metered throughput, the write portion counts as 30 MiB/s, and the combined metered throughput is 40 MiB/s. This combined throughput adjusted for metering rates is reflected in the `MeteredIOBytes` CloudWatch metric. For more information, see Amazon CloudWatch metrics for Amazon EFS (p. 102).

**Amazon EFS use cases**

Amazon EFS is designed to meet the performance needs of the following use cases.

**Big data and analytics**

Amazon EFS provides the scale and performance required for big data applications that require high throughput to compute nodes coupled with read-after-write consistency and low-latency file operations.

**Media processing workflows**

Media workflows like video editing, studio production, broadcast processing, sound design, and rendering often depend on shared storage to manipulate large files. A strong data consistency model
with high throughput and shared file access can cut the time it takes to perform these jobs and consolidate multiple local file repositories into a single location for all users.

**Content management and web serving**

Amazon EFS provides a durable, high throughput file system for content management systems that store and serve information for a range of applications like websites, online publications, and archives.

**Home directories**

Amazon EFS can provide storage for organizations that have many users that need to access and share common datasets. An administrator can use Amazon EFS to create a file system accessible to people across an organization and establish permissions for users and groups at the file or directory level.

**Performance modes**

To support a wide variety of cloud storage workloads, Amazon EFS offers two performance modes, *General Purpose* mode and *Max I/O* mode. You choose a file system's performance mode when you create it, and it cannot be changed.

**Note**

Max I/O performance mode is not available for file systems using One Zone storage classes.

The two performance modes have no additional costs, so your Amazon EFS file system is billed and metered the same, regardless of your performance mode. For information about file system quotas, see [Quotas for Amazon EFS file systems](p. 214).

**Note**

An Amazon EFS file system's performance mode can't be changed after the file system is created.

**General Purpose performance mode**

We recommend the General Purpose performance mode for the majority of your Amazon EFS file systems. General Purpose is ideal for latency-sensitive use cases, like web serving environments, content management systems, home directories, and general file serving. If you don't choose a performance mode when you create your file system, Amazon EFS selects the General Purpose mode for you by default.

**Max I/O performance mode**

File systems in the Max I/O mode can scale to higher levels of aggregate throughput and operations per second. This scaling is done with a tradeoff of slightly higher latencies for file metadata operations. Highly parallelized applications and workloads, such as big data analysis, media processing, and genomic analysis, can benefit from this mode.

**Note**

Max I/O performance mode is not available for file systems using One Zone storage classes.

**Using the right performance mode**

Our recommendation for determining which performance mode to use is as follows:

1. Create a new file system (p. 14) using the default General Purpose performance mode.
2. Run your application (or a use case similar to your application) for a period of time to test its performance.

3. Monitor the PercentIOLimit (p. 102) Amazon CloudWatch metric for Amazon EFS during the performance test. For more information about accessing this and other metrics, see Amazon CloudWatch Metrics (p. 100).

If the PercentIOLimit percentage returned was at or near 100 percent for a significant amount of time during the test, your application should use the Max I/O performance mode. Otherwise, it should use the default General Purpose mode.

To move to a different performance mode, migrate the data to a different file system that was created in the other performance mode. You can use DataSync to transfer files between two EFS file systems. To learn more, see Transferring data into and out of Amazon EFS (p. 78).

Some latency-sensitive workloads require the higher I/O levels provided by Max I/O performance mode and the lower latency provided by General Purpose performance mode. For this type of workload, we recommend creating multiple General Purpose performance mode file systems. In this case, we recommend then spreading the application workload across all these file systems, as long as the workload and applications can support it.

By taking this approach, you can create a logical file system and shard data across multiple EFS file systems. Each file system is mounted as a subdirectory, and your application can access these subdirectories in parallel. This approach allows latency-sensitive workloads to scale to higher levels of file system operations per second, aggregated across multiple file systems. At the same time, these workloads can take advantage of the lower latencies offered by General Purpose performance mode file systems.

Throughput modes

There are two throughput modes to choose from for your file system, Bursting Throughput and Provisioned Throughput. With Bursting Throughput mode, throughput on Amazon EFS scales as the size of your file system in the EFS Standard or One Zone storage class grows. For more information about EFS storage classes, see Managing EFS storage classes (p. 87). With Provisioned Throughput mode, you can instantly provision the throughput of your file system (in MiB/s) independent of the amount of data stored.

Note
You can decrease your file system throughput in Provisioned Throughput mode or change between Provisioned Throughput mode and the default Bursting Throughput mode as long as it’s been more than 24 hours since the last throughput mode change or Provisioned Throughput decrease.

Throughput scaling with bursting mode

With Bursting Throughput mode, a file system's throughput scales as the amount of data stored in the EFS Standard or One Zone storage class grows. File-based workloads are typically spiky, driving high levels of throughput for short periods of time, and low levels of throughput the rest of the time. To accommodate this, Amazon EFS is designed to burst to high throughput levels for periods of time.

All EFS file systems, regardless of size, can burst to 100 MiB/s of metered throughput. When calculating a file system's metered throughput (p. 121), Amazon EFS meters read requests at one-third the rate of write requests. File systems that have more than 1 TiB in the EFS Standard or One Zone storage class can burst to 100 MiB/s per TiB of data stored in the file system. For example, a 10 TiB file system can burst to 1,000 MiB/s of metered throughput (10 TiB x 100 MiB/s/TiB).
The portion of time that a file system can burst is determined by its size. The bursting model is designed so that typical file system workloads can burst virtually anytime they need to. For file systems using Bursting Throughput mode, the allowed throughput is determined based on the amount of the data stored in the EFS Standard or One Zone storage class. For more information, see Managing EFS storage classes (p. 87).

Amazon EFS burst credits

Amazon EFS uses a credit system to determine when file systems can burst. Each file system earns credits over time at a baseline rate that is determined by the size of the file system that is stored in the EFS Standard or One Zone storage class. A file system uses credits whenever it reads or writes data. The baseline rate is 50 MiB/s per TiB of storage (equivalently, 50 KiB/s per GiB of storage). Because Amazon EFS meters read operations at a one-third the rate of other operations toward the baseline rate, an EFS file system can drive up to 150 KiB/s per GiB of read throughput, or 50 KiB/s per GiB of write throughput at this baseline rate.

A file system can drive throughput at its baseline metered rate continuously. A file system accumulates burst credits whenever it is inactive or driving throughput below its baseline metered rate. Accumulated burst credits give the file system the ability to drive throughput above its baseline rate.

For example, a 100 GiB file system can burst (at 100 MiB/s) for 5 percent of the time if it's inactive for the remaining 95 percent. Over a 24-hour period, the file system earns 432,000 MiB worth of credit, which can be used to burst at 100 MiB/s for 72 minutes.

File systems larger than 1 TiB can always burst for up to 50 percent of the time if they are inactive for the remaining 50 percent.

The following table provides examples of bursting behavior.

<table>
<thead>
<tr>
<th>File system size</th>
<th>Burst throughput</th>
<th>Baseline throughput</th>
</tr>
</thead>
</table>
| A 100-GiB file system can... | • Burst to 300 MiB/s read-only for up to 72 minutes per day  
• Burst to 100 MiB/s write-only for up to 72 minutes per day, or | • Drive up to 15 MiB/s read-only continuously  
• Drive up to 5 MiB/s write-only continuously |
| A 1-TiB file system can... | • Burst to 300 MiB/s read-only for 12 hour per day  
• Burst to 100 MiB/s write-only for 12 hours per day, or | • Drive 150 MiB/s read-only continuously  
• Drive 50 MiB/s write-only continuously |
| A 10-TiB file system can... | • Burst to 3 GiB/s read-only for 12 hours per day  
• Burst to 1 GiB/s write-only for 12 hours per day, or | • Drive 1.5 GiB/s read-only continuously  
• Drive 500 MiB/s write-only continuously |
| Generally, a larger file system can... | • Burst to 300 MiB/s read-only per TiB of storage for 12 hours per day  
• Burst to 100 MiB/s write-only per TiB of storage for 12 hours per day, or | • Drive 150 MiB/s read-only per TiB of storage continuously  
• Drive 50 MiB/s write-only per TiB of storage continuously |

Note

Amazon EFS gives a metered throughput (p. 121) of 1 MiB/s to all file systems, even if the baseline rate is lower. The file system size used to determine the baseline and burst rates is the metered size available through the DescribeFileSystems operation.
File systems can earn credits up to a maximum credit balance of 2.1 TiB for file systems smaller than 1 TiB, or 2.1 TiB per TiB stored for file systems larger than 1 TiB. This approach implies that file systems can accumulate enough credits to burst for up to 12 hours continuously.

The following table provides more detailed examples of bursting behavior for file systems of different sizes.

<table>
<thead>
<tr>
<th>File system size (GiB)</th>

</tbody>
</table>

Note

* For file systems smaller than 20 GiB, minimum metered throughput (p. 121) is 1 MiB/s.

As previously mentioned, new file systems have an initial burst credit balance of 2.1 TiB. With this starting balance, you can burst at 100 MB/s metered throughput for 6.12 hours without spending any credits that you're earning from your storage. This starting formula is calculated as $2.1 \times 1024 \times (1024/100/3600)$ to get 6.116 hours, rounded up to 6.12.

Managing burst credits

When a file system has a positive burst credit balance, it can drive its burst rate. You can see the burst credit balance for a file system by viewing the BurstCreditBalance Amazon CloudWatch metric for Amazon EFS. For more information about accessing this and other metrics, see Monitoring Amazon EFS (p. 100).

The bursting capability (both in terms of length of time and burst rate) of a file system is directly related to its size. Larger file systems can burst at larger rates for longer periods of time. In some cases, your application might need to burst more (that is, you might find that your file system is running out of burst credits. In these cases, you should increase the size of your file system, or switch to Provisioned Throughput mode.

Use your historical throughput patterns to calculate the file system size you need to sustain the level of activity that you want. The following steps outline how to do this.

To calculate the file system size that you need to sustain the level activity that you want

1. Identify your throughput needs by looking at your historical usage. From the Amazon CloudWatch console, check the sum statistic of the TotalIOPhysical metric with daily aggregation, for the past 14 days. Identify the day with the largest value for TotalIOPhysical.
2. Divide this number by 24 hours, 60 minutes, 60 seconds, and 1024 bytes to get the average KiB/second your application required for that day.
3. Calculate the file system size (in GiB) required to sustain this average throughput by dividing the average throughput number (in KiB/s) by the baseline throughput number (50 KiB/s/GiB) that EFS provides.

**Specifying throughput with Provisioned mode**

Provisioned Throughput mode is available for applications with high throughput to storage (MiB/s per TiB) ratios, or with requirements greater than those allowed by the Bursting Throughput mode. For example, say you're using Amazon EFS for development tools, web serving, or content management applications where the amount of data in your file system is low relative to throughput demands. Your file system can now get the high levels of throughput your applications require without having to pad your file system.

Additional charges are associated with using Provisioned Throughput mode. Using Provisioned Throughput mode, you're billed for the storage that you use and for the throughput that you provision above what you're provided. The amount of throughput that you are provided is based on the amount of data stored in the EFS Standard or One Zone storage class. For more information, see [Managing EFS storage classes](p. 87). For more information on pricing, see [Amazon EFS Pricing](p. 102).

Throughput limits remain the same, regardless of the throughput mode you choose. For more information on these limits, see [Amazon EFS quotas that you can increase](p. 212).

If your file system is in the Provisioned Throughput mode, you can increase the Provisioned Throughput of your file system as often as you want. You can decrease your file system throughput in Provisioned Throughput mode as long as it's been more than 24 hours since the last decrease. Additionally, you can change between Provisioned Throughput mode and the default Bursting Throughput mode as long as it's been more than 24 hours since the last throughput mode change.

If your file system's metered size provides a higher baseline rate than the amount of throughput you provisioned, your file system follows the default Amazon EFS Bursting Throughput model. You don't incur charges for Provisioned Throughput below your file system's entitlement in Bursting Throughput mode. For more information, see [Throughput scaling with bursting mode](p. 123).

**Using the right throughput mode**

By default, we recommend that you run your application in the Bursting Throughput mode. If you experience performance issues, check the BurstCreditBalance CloudWatch metric. If the value of the BurstCreditBalance metric is either zero or steadily decreasing, Provisioned Throughput is right for your application.

If you're planning to migrate large amounts of data into your file system, consider switching to Provisioned Throughput mode. In this case, you can provision a higher throughput beyond your allotted burst capability to accelerate loading data. Following the migration, consider lowering the amount of provisioned throughput or switch to Bursting Throughput mode for normal operations.

Compare the metered throughput (p. 121) that you are driving your file system at, measured by the MeteredIOBytes CloudWatch metric, to the PermittedThroughput metric. If the calculated average throughput that you're driving the file system to (MeteredIOBytes) is less than the PermittedThroughput, consider lowering the amount of provisioned throughput to lower costs. For more information about monitoring your file system using EFS CloudWatch metrics, see [Amazon CloudWatch metrics for Amazon EFS](p. 102).

In some cases, your calculated average throughput during normal operations might be at or below the ratio of metered throughput to storage capacity ratio for Bursting Throughput mode. That ratio is 50 MiB/s per TiB of data stored. In such cases, consider switching to Bursting Throughput mode. In other cases, the calculated average throughput during normal operations might be above this ratio. In
On-premises performance considerations

In these cases, consider lowering the provisioned throughput to a point between your current provisioned throughput and the calculated average throughput during normal operations.

You can change the throughput mode of your file system using the AWS Management Console, the AWS CLI, or the EFS API. With the CLI, use the `update-file-system` action. With the EFS API, use the `UpdateFileSystem` (p. 320) operation.

**Note**

As previously mentioned, new file systems have an initial burst credit balance of 2.1 TB. With this starting balance, you can burst at 100 MB/s for 6.12 hours without spending any credits that you’re earning from your storage. This starting formula is calculated as $2.1 \times 1024 \times \left(\frac{1024}{100}/3600\right)$ to get 6.116 hours, rounded up to 6.12.

---

### On-premises performance considerations

The Bursting Throughput model for Amazon EFS file systems remains the same whether accessed from your on-premises servers or your Amazon EC2 instances. However, when accessing Amazon EFS file data from your on-premises servers, the maximum throughput is also constrained by the bandwidth of the AWS Direct Connect connection.

Because of the propagation delay tied to data traveling over long distances, the network latency of an AWS Direct Connect connection between your on-premises data center and your Amazon VPC can be tens of milliseconds. If your file operations are serialized, the latency of the AWS Direct Connect connection directly impacts your read and write throughput. In essence, the volume of data you can read or write during a period of time is bounded by the amount of time it takes for each read and write operation to complete. To maximize your throughput, parallelize your file operations so that multiple reads and writes are processed by Amazon EFS concurrently. Standard tools like GNU parallel enable you to parallelize the copying of file data.

### Architecting for high availability

To ensure continuous availability between your on-premises data center and your Amazon VPC, we recommend configuring two AWS Direct Connect connections. For more information, see Step 4: Configure Redundant Connections with AWS Direct Connect in the AWS Direct Connect User Guide.

To ensure continuous availability between your application and Amazon EFS, we recommend that your application be designed to recover from potential connection interruptions. In general, there are two scenarios for on-premises applications connected to an Amazon EFS file system; highly available and not highly available.

In the first, your application is highly available (HA) and uses multiple on-premises servers in its HA cluster. In this case, ensure that each on-premises server in the HA cluster connects to a mount target in a different Availability Zone (AZ) in your Amazon VPC. If your on-premises server can’t access the mount target because the AZ in which the mount target exists becomes unavailable, your application should fail over to a server with an available mount target.

In the second, your application is not highly available, and your on-premises server can’t access the mount target because the AZ in which the mount target exists becomes unavailable. In this case, your application should implement restart logic and connect to a mount target in a different AZ.

### Amazon EFS performance tips

When using Amazon EFS, keep the following performance tips in mind:
Average I/O size

The distributed nature of Amazon EFS enables high levels of availability, durability, and scalability. This distributed architecture results in a small latency overhead for each file operation. Due to this per-operation latency, overall throughput generally increases as the average I/O size increases, because the overhead is amortized over a larger amount of data.

Simultaneous connections

You can mount Amazon EFS file systems on up to thousands of Amazon EC2 and other AWS compute instances concurrently. You can drive higher throughput levels on your file system in aggregate across compute instances if you can parallelize your application across more instances.

Request model

By enabling asynchronous writes to your file system, pending write operations are buffered on the Amazon EC2 instance before they are written to Amazon EFS asynchronously. Asynchronous writes typically have lower latencies. When performing asynchronous writes, the kernel uses additional memory for caching. A file system that has enabled synchronous writes, or one that opens files using an option that bypasses the cache (for example, O_DIRECT), issues synchronous requests to Amazon EFS. Every operation goes through a round trip between the client and Amazon EFS.

Note

Your chosen request model has tradeoffs in consistency (if you're using multiple Amazon EC2 instances) and speed.

NFS client mount settings

Verify that you're using the recommended mount options as outlined in Mounting EFS file systems (p. 59) and in Additional mounting considerations (p. 75). Amazon EFS supports the Network File System versions 4.0 and 4.1 (NFSv4) protocols when mounting your file systems on Amazon EC2 instances. NFSv4.1 provides better performance. Only NFSv4.0 is supported for Amazon EC2 Mac instances running macOS Big Sur.

Note

You might want to increase the size of the read and write buffers for your NFS client to 1 MB when you mount your file system.

Optimizing the NFS read_ahead_kb size

Note

For Linux kernel versions 5.4.*, the Linux NFS client uses a default read_ahead_kb value of 128 KB. We recommend increasing this value to 15 MB.

The NFS read_ahead_kb attribute defines the number of kilobytes for the Linux kernel to read ahead or prefetch during a sequential read operation. For Linux kernel versions prior to 5.4.*, the read_ahead_kb value is set by multiplying NFS_MAX_READAHEAD by the value for rsize (the client configured read buffer size set in the mount options). When using the recommended mount options (p. 75), this formula sets read_ahead_kb to 15 MB. However, starting with Linux kernel version 5.4.*, the Linux NFS client uses a default read_ahead_kb value of 128 KB.

We recommend setting the read_ahead_kb size to 15 MB.

The Amazon EFS mount helper that is available in amazon-efs-utils version 1.30.2 and higher, automatically modifies read_ahead_kb to equal 15 * rsize, or 15 MB, after mounting the file system.
For Linux kernels 5.4 or newer, if you do not use the mount helper to mount your file systems, you might consider manually setting `read_ahead_kb` to 15 MB for improved performance. Do so after mounting the file system by using the following command. Replace:

- `read-ahead-value-kb` with the desired size in kilobytes
- `efs-mount-point` with the file system's mount point.

```bash
sudo bash -c "echo read-ahead-value-in-kb > /sys/class/bdi/0:$(stat -c '%d' efs-mount-point)/read_ahead_kb"
```

The following example sets the `read_ahead_kb` size to 15 MB.

```bash
sudo bash -c "echo 15000 > /sys/class/bdi/0:$(stat -c '%d' efs)/read_ahead_kb"
```

### Optimizing Amazon EC2 instances

Applications that perform a large number of read and write operations likely need more memory or computing capacity than applications that don't. When launching your Amazon EC2 instances, choose instance types that have the amount of these resources that your application needs. The performance characteristics of Amazon EFS file systems don't depend on the use of EBS-optimized instances.

### Encryption and performance

Amazon EFS supports two forms of encryption, encryption in transit and encryption at rest. Choosing to enable either or both types of encryption for your file system has a minimal effect on I/O latency and throughput.

For information about the Amazon EFS quotas for total file system throughput, per-instance throughput, and operations per second in General Purpose performance mode, see Amazon EFS quotas and limits (p. 212).

Backing up your Amazon EFS file systems

There are two options available for protecting your data by backing up your EFS file systems:

- AWS Backup service
- The EFS-to-EFS backup solution

AWS Backup is a simple and cost-effective way to back up your Amazon EFS file systems that are in AWS Regions where the AWS Backup service is available. AWS Backup is a unified backup service designed to simplify the creation, migration, restoration, and deletion of backups, while providing improved reporting and auditing. For more information, see Using AWS Backup to back up and restore Amazon EFS file systems (p. 130).

The EFS-to-EFS backup solution is suitable for all Amazon EFS file systems in all AWS Regions. It includes an AWS CloudFormation template that launches, configures, and runs the AWS services required to deploy this solution. This solution follows AWS best practices for security and availability. For more information, see EFS-to-EFS Backup Solution in the AWS Solutions Library.

Using AWS Backup to back up and restore Amazon EFS file systems

AWS Backup is a simple and cost-effective way to protect your data by backing up your Amazon EFS file systems. AWS Backup is a unified backup service designed to simplify the creation, migration, restoration, and deletion of backups, while providing improved reporting and auditing. AWS Backup makes it easier to develop a centralized backup strategy for legal, regulatory, and professional compliance. AWS Backup also makes protecting your AWS storage volumes, databases, and file systems simpler by providing a central place where you can do the following:

- Configure and audit the AWS resources that you want to back up
- Automate backup scheduling
- Set retention policies
- Monitor all recent backup and restore activity

Amazon EFS is natively integrated with AWS Backup. You can use the EFS console, API, and AWS Command Line Interface (AWS CLI) to enable automatic backups for your file system. Automatic backups use a default backup plan with the AWS Backup recommended settings for automatic backups. For more information, see Automatic backups (p. 132). You can also use AWS Backup to manually set (p. 133) your own backup plans where you specify the backup frequency, when to back up, how long to retain backups, and a lifecycle policy for backups. You can then assign Amazon EFS file systems, or other AWS resources, to that backup plan.

Incremental backups

AWS Backup performs incremental backups of EFS file systems. During the initial backup, a copy of the entire file system is made. During subsequent backups of that file system, only files and directories...
that have been changed, added, or removed are copied. With each incremental backup, AWS Backup retains the necessary reference data to allow a full restore. This approach minimizes the time required to complete the backup and saves on storage costs by not duplicating data.

**Backup consistency**

Amazon EFS is designed to be highly available. You can access and modify your Amazon EFS file systems while your backup is occurring in AWS Backup. However, inconsistencies, such as duplicated, skewed, or excluded data, can occur if you make modifications to your file system while the backup is occurring. These modifications include write, rename, move, or delete operations. To ensure consistent backups, we recommend that you pause applications or processes that are modifying the file system for the duration of the backup process. Or, schedule your backups to occur during periods when the file system is not being modified.

**Performance**

In general, you can expect the following backup rates with AWS Backup:

- 100 MB/s for file systems composed of mostly large files
- 500 files/s for file systems composed of mostly small files
- The maximum duration for a backup operation in AWS Backup is seven days.

Complete restore operations generally take longer than the corresponding backup.

Using AWS Backup doesn't consume accumulated burst credits, and it doesn't count against the General Purpose mode file operation limits. For more information, see Quotas for Amazon EFS file systems (p. 214).

**Backup completion window**

You can optionally specify a completion window for a backup. This window defines the period of time in which a backup needs to be completed. If you specify a completion window, make sure that you consider the expected performance and the size and makeup of your file system. Doing this helps make sure that your backup can be completed during the window.

Backups that aren't completed during the specified window are flagged with an incomplete status. During the next scheduled backup, AWS Backup resumes at the point that it left off. You can see the status of all of your backups on the AWS Backup Management Console.

**EFS storage classes**

You can use AWS Backup to back up all data in an EFS file system, whatever storage class the data is in. You don't incur data access charges when backing up an EFS file system that has lifecycle management enabled and has data in the Infrequent Access (IA) storage class.

When you restore a recovery point, all files are restored to the Standard storage class. For more information on storage classes, see Managing EFS storage classes (p. 87) and Amazon EFS lifecycle management (p. 90).

**IAM permissions for creating and restoring backups**

You can use the `elasticfilesystem:backup` and `elasticfilesystem:restore` actions to allow or deny an IAM entity (such as a user, group, or role) the ability to create or restore backups of an EFS file system. You can use these actions in a file system policy or in an identity-based IAM policy. For more
On-demand backups

Using either the AWS Backup Management Console or the CLI, you can save a single resource to a backup vault on-demand. Unlike with scheduled backups, you don't need to create a backup plan to initiate an on-demand backup. You can still assign a lifecycle to your backup, which automatically moves the recovery point to the cold storage tier and notes when to delete it.

Concurrent backups

AWS Backup limits backups to one concurrent backup per resource. Therefore, scheduled or on-demand backups might fail if a backup job is already in progress. For more information about AWS Backup limits, see AWS Backup Limits in the AWS Backup Developer Guide.

Automatic backups

When you create a file system using the Amazon EFS console, automatic backups are turned on by default. You can turn on automatic backups after creating your file system using the CLI or API. The default EFS backup plan uses the AWS Backup recommended settings for automatic backups—daily backups with a 35-day retention period. The backups created using the default EFS backup plan are stored in a default EFS backup vault, which is also created by EFS on your behalf. The default backup plan and backup vault cannot be deleted. You can edit the default backup plan settings using the AWS Backup console. For more information, see Option 3: Create Automatic Backups in the AWS Backup Developer Guide. You can see all of your automatic backups, and edit the default EFS backup plan settings using the AWS Backup console. You can turn off automatic backups at any time using the Amazon EFS console or CLI, described in the following section.

Amazon EFS applies the aws:elasticfilesystem:default-backup system tag key with a value of enabled to EFS file systems when automatic backups are enabled.

Note

Automatic backups are exempt from the AWS Backup service opt-out configuration. For more information, see Getting Started with AWS Backup in the AWS Backup Developer Guide.

Turning automatic backups on or off for existing file systems

After you create a file system you can turn automatic backups on or off using the console, the CLI, or the EFS API.

Turn automatic backups on or off for an existing file system (console)

2. In the File systems page, choose the file system that you want to turn automatic backups on or off for and display the File system details page.
3. Choose Edit in the General settings panel.
4. • To turn on automatic backups, select Enable automatic backups.
   • To turn off automatic backups, clear Enable automatic backups.
5. Choose Save changes.

Turn automatic backups on or off for an existing file system (CLI)

• Use the put-backup-policy CLI command (the corresponding API operation is PutBackupPolicy (p. 304)) turn automatic backups on or off for an existing file system.
• Use the following command to turn on automatic backups.

```
$ aws efs put-backup-policy --file-system-id fs-01234567 --backup-policy Status="ENABLED"
```

EFS responds with the new backup policy.

```
{
    "BackupPolicy": {
        "Status": "ENABLING"
    }
}
```

• Use the following command to turn off automatic backups.

```
$ aws efs put-backup-policy --file-system-id fs-01234567 --backup-policy Status="DISABLED"
```

EFS responds with the new backup policy.

```
{
    "BackupPolicy": {
        "Status": "DISABLING"
    }
}
```

## Using AWS Backup to manually configure backups

When you use AWS Backup to manually set up your file system backups, you first create a backup plan. The backup plan defines backup schedule, backup window, retention policy, lifecycle policy, and tags. You can create a backup plan using the [AWS Backup Management Console](https://aws.amazon.com), the AWS CLI, or the AWS Backup API. As part of a backup plan, you can define the following:

- **Schedule** – When the backup occurs
- **Backup window** – The window of time during which the backup must start
- **Lifecycle** – When to move a recovery point to cold storage and when to delete it
- **Backup vault** – Which vault is used to organize recovery points created by the Backup rule

After your backup plan is created, you assign the specific Amazon EFS file systems to the backup plan by using either tags or the Amazon EFS file system ID. After a plan is assigned, AWS Backup begins automatically backing up the Amazon EFS file system on your behalf according to the backup plan that you defined. You can use the AWS Backup console to manage backup configurations or monitor backup activity. For more information, see the [AWS Backup Developer Guide](https://aws.amazon.com).

**Note**

Sockets and named pipes are not supported, and are omitted from backups.

## Restore a recovery point

Using either the [AWS Backup console](https://aws.amazon.com) or the CLI, you can restore a recovery point to a new EFS file system or to the source file system. You can perform a Complete restore, which restores the entire file system. Or, you can restore specific files and directories using a Partial restore. To restore a specific file or directory, you must specify the relative path related to the mount point. For example, if the file system
is mounted to /user/home/myname/efs and the file path is /user/home/myname/efs/file1, enter /file1. Paths are case sensitive and cannot contain special characters, wildcard characters, or regular expression (regex) strings.

**Note**
To restore a recovery point, users must have the backup:StartRestoreJob permission.

When you perform either a Complete or a Partial restore, your recovery point is restored to the restore directory, `aws-backup-restore_timestamp-of-restore`. When the restore is finished, you can see the restore directory at the root of the file system. If you attempt multiple restores for the same path, several directories containing the restored items might exist. If the restore fails to finish, you can see the directory `aws-backup-failed-restore_timestamp-of-restore`. You must manually delete the restore and failed-restore directories when you are through using them.

**Note**
For Partial restores to an existing EFS file system, AWS Backup restores the files and directories to a new directory under the file system root directory. The full hierarchy of the specified items is preserved in the recovery directory. For example, if directory A contains subdirectories B, C, and D, AWS Backup retains the hierarchical structure when A, B, C, and D are recovered.

After restoring a recovery point, data fragments that can't be restored to the appropriate directory are placed in the `aws-backup-lost+found` directory. Fragments might be moved to this directory if modifications are made to the file system while the backup is occurring.

### Deleting backups

The default EFS backup vault Access policy is set to deny deleting recovery points. To delete existing backups of your EFS file systems, you must change the vault access policy. If you attempt to delete an EFS recovery point without modifying the vault access policy, you receive the following error message:

```
"Access Denied: Insufficient privileges to perform this action. Please consult with the account administrator for necessary permissions."
```

To edit the default backup vault access policy, you must have AWS Identity and Access Management (IAM) permissions to edit your EFS policies. To revise IAM policy settings, you must have Admin rights. For example, you can perform these actions using your AWS account root user, or by using an admin role. For more information, see Allow all IAM actions (admin access).

**To delete an EFS recovery point in AWS Backup**

2. In the left navigation pane, choose Backup vaults.
3. In the list Backup vaults, choose aws/efs/automatic-backup-vault.
4. On the vault details page, choose Manage access in the upper-right corner of the page. The Edit access policy page appears.
5. To allow all actions on the EFS backup vault, find the line "Effect": "Deny", in the JSON editor, and edit the line to read "Effect": "Allow".
6. Choose Save policy to save your changes.
7. On the vault details page, scroll down to the Backups section, and select the recovery points that you want to delete from the list of Backups. Then choose Actions, and then choose Delete.
8. Follow the instructions to confirm the deletion. Then choose Delete recovery points.
Amazon Elastic File System

Walkthroughs

This section provides walkthroughs that you can use to explore Amazon EFS and test the end-to-end setup.

Topics

- Walkthrough: Create an Amazon EFS file system and mount it on an Amazon EC2 instance using the AWS CLI (p. 135)
- Walkthrough: Set up an Apache web server and serve Amazon EFS files (p. 147)
- Walkthrough: Create Writable Per-User Subdirectories and Configure Automatic Remounting on Reboot (p. 152)
- Walkthrough: Create and mount a file system on-premises with AWS Direct Connect and VPN (p. 153)
- Walkthrough: Mount a File System from a Different VPC (p. 160)
- Walkthrough: Enforcing Encryption on an Amazon EFS File System at Rest (p. 164)
- Walkthrough: Enable root squashing using IAM authorization for NFS clients (p. 166)

Walkthrough: Create an Amazon EFS file system and mount it on an Amazon EC2 instance using the AWS CLI

This walkthrough uses the AWS CLI to explore the Amazon EFS API. In this walkthrough, you create an encrypted Amazon EFS file system, mount it on an Amazon EC2 instance in your VPC, and test the setup.

Note

This walkthrough is similar to the Getting Started exercise. In the Getting started (p. 13) exercise, you use the console to create EC2 and Amazon EFS resources. In this walkthrough, you use the AWS CLI to do the same—primarily to familiarize yourself with the Amazon EFS API.

In this walkthrough, you create the following AWS resources in your account:

- Amazon EC2 resources:
  - Two security groups (for your EC2 instance and Amazon EFS file system).
  
  You add rules to these security groups to authorize appropriate inbound/outbound access. Doing this allows your EC2 instance to connect to the file system through the mount target by using a standard NFSv4.1 TCP port.

- An Amazon EC2 instance in your VPC.

- Amazon EFS resources:
  - A file system.
  - A mount target for your file system.

To mount your file system on an EC2 instance you need to create a mount target in your VPC. You can create one mount target in each of the Availability Zones in your VPC. For more information, see Amazon EFS: How it works (p. 3).
Then, you test the file system on your EC2 instance. The cleanup step at the end of the walkthrough provides information for you to remove these resources.

The walkthrough creates all these resources in the US West (Oregon) Region (us-west-2). Whichever AWS Region you use, be sure to use it consistently. All of your resources—your VPC, EC2 resources, and Amazon EFS resources—must be in the same AWS Region.

**Before you begin**

- You can use the root credentials of your AWS account to sign in to the console and try the Getting Started exercise. However, AWS Identity and Access Management (IAM) recommends that you do not use the root credentials of your AWS account. Instead, create an administrator user in your account and use those credentials to manage resources in your account. For more information, see Setting Up (p. 11).
- You can use a default VPC or a custom VPC that you have created in your account. For this walkthrough, the default VPC configuration works. However, if you use a custom VPC, verify the following:
  - DNS hostnames are enabled. For more information, see Updating DNS support for your VPC in the Amazon VPC User Guide.
  - The Internet gateway is attached to your VPC. For more information, see Internet Gateways in the Amazon VPC User Guide.
  - The VPC subnets are configured to request public IP addresses for instances launched in the VPC subnets. For more information, see IP Addressing in Your VPC in the Amazon VPC User Guide.
  - The VPC route table includes a rule to send all Internet-bound traffic to the Internet gateway.
- You need to set up the AWS CLI and add the adminuser profile.

**Setting up the AWS CLI**

Use the following instructions to set up the AWS CLI and user profile.

**To set up the AWS CLI**

1. Download and configure the AWS CLI. For instructions, see the following topics in the AWS Command Line Interface User Guide.
   - Getting Set Up with the AWS Command Line Interface
   - Installing the AWS Command Line Interface
   - Configuring the AWS Command Line Interface
2. Set profiles.

You store user credentials in the AWS CLI config file. The example CLI commands in this walkthrough specify the adminuser profile. Create the adminuser profile in the config file. You can also set the administrator user profile as the default in the config file as shown.

```
[profile adminuser]
aws_access_key_id = admin user access key ID
aws_secret_access_key = admin user secret access key
region = us-west-2

[default]
aws_access_key_id = admin user access key ID
aws_secret_access_key = admin user secret access key
region = us-west-2
```
The preceding profile also sets the default AWS Region. If you don’t specify a region in the CLI command, the us-west-2 region is assumed.

3. Verify the setup by entering the following command at the command prompt. Both of these commands don’t provide credentials explicitly, so the credentials of the default profile are used.

- **Try the help command**

  You can also specify the user profile explicitly by adding the `--profile` parameter.

  ```bash
  aws help
  
  aws help --profile adminuser
  ```

**Next step**

**Step 1: Create Amazon EC2 resources (p. 137)**

**Step 1: Create Amazon EC2 resources**

In this step, you do the following:

- Create two security groups.
- Add rules to the security groups to authorize additional access.
- Launch an EC2 instance. You create and mount an Amazon EFS file system on this instance in the next step.

**Topics**

- **Step 1.1: Create two security groups (p. 137)**
- **Step 1.2: Add rules to the security groups to authorize inbound/outbound access (p. 138)**
- **Step 1.3: Launch an EC2 instance (p. 139)**

**Step 1.1: Create two security groups**

In this section, you create security groups in your VPC for your EC2 instance and Amazon EFS mount target. Later in the walkthrough, you assign these security groups to an EC2 instance and an Amazon EFS mount target. For information about security groups, see Security Groups for EC2-VPC in the Amazon EC2 User Guide for Linux Instances.

**To create security groups**

1. Create two security groups using the `create-security-group` CLI command:

   ```bash
   # aws ec2 create-security-group
   --region us-west-2
   --group-name efs-walkthrough1-ec2-sg
   --description "Amazon EFS walkthrough 1, SG for EC2 instance"
   --vpc-id vpc-id-in-us-west-2
   --profile adminuser
   ```
Step 1: Create Amazon EC2 resources

Write down the security group ID. The following is an example response.

```json
{
   "GroupId": "sg-aexample"
}
```

You can find the VPC ID using the following command.

```
# aws ec2 describe-vpcs
```

b. Create a security group (`efs-walkthrough1-mt-sg`) for your Amazon EFS mount target. You need to provide your VPC ID.

```
# aws ec2 create-security-group \\
   --region us-west-2 \\
   --group-name efs-walkthrough1-mt-sg \\
   --description "Amazon EFS walkthrough 1, SG for mount target" \\
   --vpc-id vpc-id-in-us-west-2 \\
   --profile adminuser
```

Write down the security group ID. The following is an example response.

```json
{
   "GroupId": "sg-aexample"
}
```

2. Verify the security groups.

```
aws ec2 describe-security-groups \\
   --group-ids list of security group IDs separated by space \\
   --profile adminuser \\
   --region us-west-2
```

Both should have only one outbound rule that allows all traffic to leave.

In the next section, you authorize additional access that enables the following:

- Enable you to connect to your EC2 instance.
- Enable traffic between an EC2 instance and an Amazon EFS mount target (with which you associate these security groups later in this walkthrough).

Step 1.2: Add rules to the security groups to authorize inbound/outbound access

In this step, you add rules to the security groups to authorize inbound/outbound access.

To add rules

1. Authorize incoming Secure Shell (SSH) connections to the security group for your EC2 instance (`efs-walkthrough1-ec2-sg`) so you can connect to your EC2 instance using SSH from any host.

```
# aws ec2 authorize-security-group-ingress \\
   --group-id id of the security group created for EC2 instance \\
   --protocol tcp \\
```
Step 1: Create Amazon EC2 resources

Verify that the security group has the inbound and outbound rule you added.

```
aws ec2 describe-security-groups \
--region us-west-2 \
--profile adminuser \
--group-id security-group-id
```

2. Authorize inbound access to the security group for the Amazon EFS mount target (efs-walkthrough1-mt-sg).

At the command prompt, run the following AWS CLI `authorize-security-group-ingress` command using the adminuser profile to add the inbound rule.

```
$ aws ec2 authorize-security-group-ingress \
   --group-id ID of the security group created for Amazon EFS mount target \
   --protocol tcp \
   --port 2049 \
   --source-group ID of the security group created for EC2 instance \
   --profile adminuser \
   --region us-west-2
```

3. Verify that both security groups now authorize inbound access.

```
aws ec2 describe-security-groups \
   --group-names efs-walkthrough1-ec2-sg efs-walkthrough1-mt-sg \
   --profile adminuser \
   --region us-west-2
```

Step 1.3: Launch an EC2 instance

In this step, you launch an EC2 instance.

To launch an EC2 instance

1. Gather the following information that you need to provide when launching an EC2 instance:

   - Key pair name:
     - For introductory information, see Setting Up with Amazon EC2 in the Amazon EC2 User Guide for Linux Instances.
     - For instructions to create a .pem file, see Create a Key Pair in the Amazon EC2 User Guide for Linux Instances.
     - The ID of the Amazon Machine Image (AMI) you want to launch.

   The AWS CLI command that you use to launch an EC2 instance requires the ID of the AMI that you want to deploy as a parameter. The exercise uses the Amazon Linux HVM AMI.

   **Note**
   You can use most general purpose Linux-based AMIs. If you use another Linux AMI, make sure that you use your distribution's package manager to install the NFS client on the instance. Also, you might need to add software packages as you need them.

   For the Amazon Linux HVM AMI, you can find the latest IDs at Amazon Linux AMI. You choose the ID value from the Amazon Linux AMI IDs table as follows:
Step 1: Create Amazon EC2 resources

- Choose the **US West Oregon** region. This walkthrough assumes you are creating all resources in the US West (Oregon) Region (us-west-2).
- Choose the **EBS-backed HVM 64-bit** type (because in the CLI command you specify the t2.micro instance type, which does not support instance store).
- ID of the security group you created for an EC2 instance.
- AWS Region. This walkthrough uses the us-west-2 region.
- Your VPC subnet ID where you want to launch the instance. You can get list of subnets using the describe-subnets command.

```
$ aws ec2 describe-subnets \
--region us-west-2 \
--filters "Name=vpc-id,Values=vpc-id" \
--profile adminuser
```

After you choose the subnet ID, write down the following values from the describe-subnets result:
- **Subnet ID** – You need this value when you create a mount target. In this exercise, you create a mount target in the same subnet where you launch an EC2 instance.
- **Availability Zone of the subnet** – You need this value to construct your mount target DNS name, which you use to mount a file system on the EC2 instance.

2. Run the following AWS CLI **run-instances** command to launch an EC2 instance.

```
$ aws ec2 run-instances \
--image-id AMI ID \
--count 1 \
--instance-type t2.micro \
--associate-public-ip-address \
--key-name key-pair-name \
--security-group-ids ID of the security group created for EC2 instance \
--subnet-id VPC subnet ID \
--region us-west-2 \
--profile adminuser
```

3. Write down the instance ID returned by the run-instances command.

4. The EC2 instance you created must have a public DNS name that you use to connect to the EC2 instance and mount the file system on it. The public DNS name is of the form:

```
ec2-xx-xx-xx-xxx.compute-1.amazonaws.com
```

Run the following CLI command and write down the public DNS name.

```
aws ec2 describe-instances \
--instance-ids EC2 instance ID \
--region us-west-2 \
--profile adminuser
```

If you don't find the public DNS name, check the configuration of the VPC in which you launched the EC2 instance. For more information, see **Before you begin (p. 136)**.

5. (Optional) Assign a name to the EC2 instance that you created. To do so, add a tag with the key name and value set to the name that you want to assign to the instance. You do this by running the following AWS CLI **create-tags** command.

```
$ aws ec2 create-tags \
--resources EC2-instance-ID \
```
Step 2: Create Amazon EFS resources

In this step, you do the following:

• Create an encrypted Amazon EFS file system.
• Enable lifecycle management.
• Create a mount target in the Availability Zone where you have your EC2 instance launched.

Step 2.1: Create an Amazon EFS file system

In this step, you create an Amazon EFS file system. Write down the FileSystemId to use later when you create mount targets for the file system in the next step.

To create a file system

• Create a file system with the optional Name tag.
  a. At the command prompt, run the following AWS CLI `create-file-system` command.

```
$ aws efs create-file-system 
 --encrypted true 
 --creation-token FileSystemForWalkthrough1 
 --tags Key=Name,Value=SomeExampleNameValue 
 --region us-west-2 
 --profile adminuser
```

You get the following response.

```
{
 "OwnerId": "111122223333",
 "CreationToken": "FileSystemForWalkthrough1",
 "FileSystemId": "fs-c657c8bf",
 "CreationTime": 1548950706.0,
 "LifeCycleState": "creating",
 "NumberOfMountTargets": 0,
 "SizeInBytes": {
 "Value": 0,
 "ValueInIA": 0,
 "ValueInStandard": 0
 },
 "PerformanceMode": "generalPurpose",
} 
```
"Encrypted": true,
"KmsKeyId": "arn:aws:kms:us-west-2:111122223333:a5c11222-7a99-43c8-9dcd-
abcdef123456",
"ThroughputMode": "bursting",
"Tags": [
  {
    "Key": "Name",
    "Value": "SomeExampleNameValue"
  }
]
}

b. Note the FileSystemId value. You need this value when you create a mount target for this file
system in Step 2.3: Create a mount target (p. 142).

Step 2.2: Enable lifecycle management

In this step, you enable lifecycle management on your file system in order to use the Infrequent Access
storage class. To learn more, see Amazon EFS lifecycle management (p. 90) and Managing EFS storage
classes (p. 87).

To enable lifecycle management

- At the command prompt, run the following AWS CLI put-lifecycle-configuration command.

```bash
$ aws efs put-lifecycle-configuration \
--file-system-id fs-c657c8bf \
--lifecycle-policies TransitionToIA=AFTER_30_DAYS \
--region us-west-2 \
--profile adminuser
```

You get the following response.

```
{
  "LifecyclePolicies": [
    {
      "TransitionToIA": "AFTER_30_DAYS"
    }
  ]
}
```

Step 2.3: Create a mount target

In this step, you create a mount target for your file system in the Availability Zone where you have your
EC2 instance launched.

1. Make sure you have the following information:
   - ID of the file system (for example, `fs-example`) for which you are creating the mount target.
   - VPC subnet ID where you launched the EC2 instance in Step 1.

   For this walkthrough, you create the mount target in the same subnet in which you launched the
   EC2 instance, so you need the subnet ID (for example, `subnet-example`).
   - ID of the security group you created for the mount target in the preceding step.

2. At the command prompt, run the following AWS CLI create-mount-target command.
Step 3: Mount and test the file system

3. You can also use the `describe-mount-targets` command to get descriptions of mount targets you created on a file system.

```bash
$ aws efs describe-mount-targets \
--file-system-id file-system-id \
--region us-west-2 \
--profile adminuser
```

Next step

**Step 3: Mount the file system on the EC2 instance and test (p. 143)**

**Step 3: Mount the file system on the EC2 instance and test**

In this step, you do the following:

**Topics**
- Step 3.1: Gather Information (p. 143)
- Step 3.2: Install the NFS Client on Your EC2 Instance (p. 144)
- Step 3.3: Mount the file system on your EC2 instance and test (p. 144)

**Step 3.1: Gather Information**

Make sure you have the following information as you follow the steps in this section:

- Public DNS name of your EC2 instance in the following format:

  `ec2-xx-xxx-xxx-xx.aws-region.compute.amazonaws.com`

- DNS name of your file system. You can construct this DNS name using the following generic form:

  `file-system-id.efs.aws-region.amazonaws.com`
Step 3: Mount and test the file system

The EC2 instance on which you mount the file system by using the mount target can resolve the file system's DNS name to the mount target's IP address.

Note
Amazon EFS doesn't require that your Amazon EC2 instance have either a public IP address or public DNS name. The requirements listed preceding are just for this walkthrough example to ensure that you can connect by using SSH into the instance from outside the VPC.

Step 3.2: Install the NFS Client on Your EC2 Instance

You can connect to your EC2 instance from Windows or from a computer running Linux, or macOS X, or any other Unix variant.

To install an NFS client

1. Connect to your EC2 instance:
   - To connect to your instance from a computer running macOS or Linux, specify the .pem file for your SSH command with the 
     \texttt{-i} \ option and the path to your private key.
   - To connect to your instance from a computer running Windows, you can use either MindTerm or PuTTY. If you plan to use PuTTY, you need to install it and use the following procedure to convert the .pem file to a .ppk file.

   For more information, see the following topics in the \textit{Amazon EC2 User Guide for Linux Instances}:
   - Connecting to Your Linux Instance from Windows Using PuTTY
   - Connecting to Your Linux Instance Using SSH

2. Execute the following commands on the EC2 instance by using the SSH session:
   a. (Optional) Get updates and reboot.

      \begin{verbatim}
      $ sudo yum -y update
      $ sudo reboot
      \end{verbatim}

      After the reboot, reconnect to your EC2 instance.

   b. Install the NFS client.

      \begin{verbatim}
      $ sudo yum -y install nfs-utils
      \end{verbatim}

      Note
      If you choose the \texttt{Amazon Linux AMI 2016.03.0} Amazon Linux AMI when launching your Amazon EC2 instance, you don't need to install \texttt{nfs-utils} because it is already included in the AMI by default.

Step 3.3: Mount the file system on your EC2 instance and test

Now you mount the file system on your EC2 instance.

1. Make a directory ("efs-mount-point").

      \begin{verbatim}
      $ mkdir ~/efs-mount-point
      \end{verbatim}
2. Mount the Amazon EFS file system.

```
$ sudo mount -t nfs -o
   nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport
mount-target-DNS:/    ~/efs-mount-point
```

The EC2 instance can resolve the mount target DNS name to the IP address. You can optionally specify the IP address of the mount target directly.

```
$ sudo mount -t nfs -o
   nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport
mount-target-ip:/    ~/efs-mount-point
```

3. Now that you have the Amazon EFS file system mounted on your EC2 instance, you can create files.

   a. Change the directory.

```
$ cd ~/efs-mount-point
```

   b. List the directory contents.

```
$ ls -al
```

It should be empty.

```
drwx------ 4 ec2-user ec2-user 4096 Dec 29 22:54 ..
```

   c. The root directory of a file system, upon creation, is owned by and is writable by the root user, so you need to change permissions to add files.

```
$ sudo chmod go+rw .
```

Now, if you try the `ls -al` command you see that the permissions have changed.

```
drwx------ 4 ec2-user ec2-user 4096 Dec 29 22:54 ..
```

d. Create a text file.

```
$ touch test-file.txt
```

e. List directory content.

```
$ ls -l
```

You now have successfully created and mounted an Amazon EFS file system on your EC2 instance in your VPC.

The file system you mounted doesn't persist across reboots. To automatically remount the directory, you can use the `fstab` file. For more information, see Automatic remounting on reboot (p. 153). If you are using an Auto Scaling group to launch EC2 instances, you can also set scripts in a launch configuration. For an example, see Walkthrough: Set up an Apache web server and serve Amazon EFS files (p. 147).
Step 4: Clean up

If you no longer need the resources you created, you should remove them. You can do this with the CLI.

- Remove EC2 resources (the EC2 instance and the two security groups). Amazon EFS deletes the network interface when you delete the mount target.
- Remove Amazon EFS resources (file system, mount target).

To delete AWS resources created in this walkthrough

1. Terminate the EC2 instance you created for this walkthrough.

   ```
   $ aws ec2 terminate-instances \
   --instance-ids instance-id \
   --profile adminuser
   ```

   You can also delete EC2 resources using the console. For instructions, see Terminating an Instance in the Amazon EC2 User Guide for Linux Instances.

2. Delete the mount target.

   You must delete the mount targets created for the file system before deleting the file system. You can get a list of mount targets by using the describe-mount-targets CLI command.

   ```
   $ aws efs describe-mount-targets \
   --file-system-id file-system-ID \
   --profile adminuser \
   --region aws-region
   ```

   Then delete the mount target by using the delete-mount-target CLI command.

   ```
   $ aws efs delete-mount-target \
   --mount-target-id ID-of-mount-target-to-delete \
   --profile adminuser \
   --region aws-region
   ```

3. (Optional) Delete the two security groups you created. You don't pay for creating security groups.

   You must delete the mount target's security group first, before deleting the EC2 instance's security group. The mount target's security group has a rule that references the EC2 security group. Therefore, you cannot first delete the EC2 instance's security group.

   For instructions, see Deleting a Security Group in the Amazon EC2 User Guide for Linux Instances.

4. Delete the file system by using the delete-file-system CLI command. You can get a list of your file systems by using the describe-file-systems CLI command. You can get the file system ID from the response.

   ```
   aws efs describe-file-systems \
   --profile adminuser \
   --region aws-region
   ```

   Delete the file system by providing the file system ID.
Walkthrough: Set up an Apache web server and serve Amazon EFS files

You can have EC2 instances running the Apache web server serving files stored on your Amazon EFS file system. It can be one EC2 instance, or if your application needs, you can have multiple EC2 instances serving files from your Amazon EFS file system. The following procedures are described.

- Set up an Apache web server on an EC2 instance (p. 147).
- Set up an Apache web server on multiple EC2 instances by creating an Auto Scaling group (p. 149).

You can create multiple EC2 instances using Amazon EC2 Auto Scaling, an AWS service that allows you to increase or decrease the number of EC2 instances in a group according to your application needs. When you have multiple web servers, you also need a load balancer to distribute request traffic among them.

Note
For both procedures, you create all resources in the US West (Oregon) Region (us-west-2).

Single EC2 instance serving files

Follow the steps to set up an Apache web server on one EC2 instance to serve files you create in your Amazon EFS file system.

1. Follow the steps in the Getting Started exercise so that you have a working configuration consisting of the following:
   - Amazon EFS file system
   - EC2 instance
   - File system mounted on the EC2 instance

   For instructions, see Getting started with Amazon Elastic File System (p. 13). As you follow the steps, write down the following:
   - Public DNS name of the EC2 instance.
   - Public DNS name of the mount target created in the same Availability Zone where you launched the EC2 instance.

2. (Optional) You may choose to unmount the file system from the mount point you created in the Getting Started exercise.

   $ sudo umount ~/efs-mount-point

   In this walkthrough, you create another mount point for the file system.

3. On your EC2 instance, install the Apache web server and configure it as follows:
   a. Connect to your EC2 instance and install the Apache web server.
# sudo yum -y install httpd

b. Start the service.

# sudo service httpd start

c. Create a mount point.

First note that the DocumentRoot in the /etc/httpd/conf/httpd.conf file points to /var/www/html (DocumentRoot "/var/www/html").

You will mount your Amazon EFS file system on a subdirectory under the document root.

i. Create a subdirectory efs-mount-point under /var/www/html.

# sudo mkdir /var/www/html/efs-mount-point

ii. Mount your Amazon EFS file system. You need to update the following mount command using the EFS mount helper utility by providing your file system ID.

# sudo mount -t efs fs-12345678:/ /var/www/html/efs-mount-point

4. Test the setup.

   a. Add a rule in the EC2 instance security group, which you created in the Getting Started exercise, to allow HTTP traffic on TCP port 80 from anywhere.

After you add the rule, the EC2 instance security group will have the following inbound rules.

For instructions, see Creating security groups using the AWS Management Console (p. 38).

b. Create a sample html file.

i. Change directory.

   # cd /var/www/html/efs-mount-point

ii. Make a subdirectory for sampledir and change the ownership. And change directory so you can create files in the sampledir subdirectory.

   # sudo mkdir sampledir
   # sudo chown ec2-user sampledir
   # sudo chmod -R o+r sampledir
   # cd sampledir

iii. Create a sample hello.html file.
Multiple EC2 instances serving files

Follow the steps to serve the same content in your Amazon EFS file system from multiple EC2 instances for improved scalability or availability.

1. Follow the steps in the Getting started (p. 13) exercise so that you have an Amazon EFS file system created and tested.

   **Important**
   For this walkthrough, you don’t use the EC2 instance that you created in the Getting Started exercise. Instead, you launch new EC2 instances.

2. Create a load balancer in your VPC using the following steps.

   1. Define a load balancer
      
      In the **Basic Configuration** section, select your VPC where you also create the EC2 instances on which you mount the file system.
      
      In the **Select Subnets** section, select all of the available subnets. For details, see the cloud-config script in the next section.

   2. Assign security groups
      
      Create a new security group for the load balancer to allow HTTP access from port 80 from anywhere, as shown following:
      
      - Type: HTTP
      - Protocol: TCP
      - Port Range: 80
      - Source: Anywhere (0.0.0.0/0)

      **Note**
      When everything works, you can also update the EC2 instance security group inbound rule access to allow HTTP traffic only from the load balancer.

3. Configure a health check

   Set the Ping Path value to /efs-mount-point/test.html. The efs-mount-point is the subdirectory where you have the file system mounted. You add test.html page in it later in this procedure.
Note
Don't add any EC2 instances. Later, you create an Auto Scaling Group in which you launch EC2 instance and specify this load balancer.

For instructions to create a load balancer, see Getting Started with Elastic Load Balancing in the Elastic Load Balancing User Guide.

3. Create an Auto Scaling group with two EC2 instances. First, you create a launch configuration describing the instances. Then, you create an Auto Scaling group by specifying the launch configuration. The following steps provide configuration information that you specify to create an Auto Scaling group from the Amazon EC2 console.

a. Choose Launch Configurations under AUTO SCALING from the left hand navigation.

b. Choose Create Auto Scaling group to launch the wizard.

c. Choose Create launch configuration.

d. From Quick Start, select the latest version of the Amazon Linux (HVM) AMI. This is same AMI you used in Step 2: Create your EC2 resources and launch your EC2 instance (p. 16) of the Getting Started exercise.

e. In the Advanced section, do the following:

   • For IP Address Type, choose Assign a public IP address to every instance.
   • Copy/paste the following script in the User data box.

     You must update the script by providing values for the **file-system-id** and **aws-region** (if you followed the Getting Started exercise, you created the file system in the us-west-2 region).

     In the script, note the following:

     • The script installs the NFS client and the Apache web server.
     • The echo command writes the following entry in the /etc/fstab file identifying the file system's DNS name and subdirectory on which to mount it. This entry ensures that the file gets mounted after each system reboot. Note that the file system's DNS name is dynamically constructed. For more information, see Mounting on Amazon EC2 with a DNS name (p. 359).

     ```
     file-system-ID.efs.aws-region.amazonaws.com:/var/www/html/efs-mount-point
     nfs4  defaults
     ```

     • Creates efs-mount-point subdirectory and mounts the file system on it.
     • Creates a test.html page so ELB health check can find the file (when creating a load balancer you specified this file as the ping point).

     For more information about user data scripts, see Adding User Data in the Amazon EC2 User Guide for Linux Instances.

     ```
     #cloud-config
     package_upgrade: true
     packages:
     - nfs-utils
     - httpd
     runcmd:
     - mkdir /var/www/html/efs-mount-point
     - mount -a
     ```
- touch /var/www/html/efs-mount-point/test.html
- service httpd start
- chkconfig httpd on

f. For **Assign a security group**, choose **Select an existing security group**, and then choose the security group you created for the EC2 instance.

When configuring the Auto Scaling group details, use the following information:

1. For **Group size**, choose **Start with 2 instances**. You will create two EC2 instances.
2. Select your VPC from the **Network** list.
3. Select a subnet in the same Availability Zone that you used when specifying the mount target ID in the User Data script when creating the launch configuration in the preceding step.
4. In the Advanced Details section
   a. For **Load Balancing**, choose **Receive traffic from Elastic Load Balancer(s)**, and then select the load balancer you created for this exercise.
   b. For **Health Check Type**, choose **ELB**.

Follow the instructions to create an Auto Scaling group at **Set Up a Scaled and Load-Balanced Application** in the *Amazon EC2 Auto Scaling User Guide*. Use the information in the preceding tables where applicable.

4. Upon successful creation of the Auto Scaling group, you have two EC2 instances with `nfs-utils` and the Apache web server installed. On each instance, verify that you have the `/var/www/html/efs-mount-point` subdirectory with your Amazon EFS file system mounted on it. For instructions to connect to an EC2 instance, see **Connect to Your Linux Instance** in the *Amazon EC2 User Guide for Linux Instances*.

**Note**
If you choose the **Amazon Linux AMI 2016.03.0** Amazon Linux AMI when launching your Amazon EC2 instance, you won't need to install `nfs-utils` because it is already included in the AMI by default.

5. Create a sample page (index.html).
   a. Change directory.

   ```
   $ cd /var/www/html/efs-mount-point
   ```

   b. Make a subdirectory for `sampledir` and change the ownership. And change directory so you can create files in the `sampledir` subdirectory. If you followed the preceding Single EC2 instance serving files (p. 147), you already created the `sampledir` subdirectory, so you can skip this step.

   ```
   $ sudo mkdir sampledir
   $ sudo chown ec2-user sampledir
   $ sudo chmod -R o+r sampledir
   $ cd sampledir
   ```

c. Create a sample `index.html` file.

   ```
   $ echo "<html><h1>Hello from Amazon EFS</h1></html>" > index.html
   ```

6. Now you can test the setup. Using the load balancer's public DNS name, access the index.html page.
Walkthrough: Create Writable Per-User Subdirectories and Configure Automatic Remounting on Reboot

After you create an Amazon EFS file system and mount it locally on your EC2 instance, it exposes an empty directory called the **file system root**. One common use case is to create a "writable" subdirectory under this file system root for each user you create on the EC2 instance, and mount it on the user's home directory. All files and subdirectories the user creates in their home directory are then created on the Amazon EFS file system.

In this walkthrough, you first create a user "mike" on your EC2 instance. You then mount an Amazon EFS subdirectory onto user mike's home directory. The walkthrough also explains how to configure automatic remounting of subdirectories if the system reboots.

Suppose you have an Amazon EFS file system created and mounted on a local directory on your EC2 instance. Let's call it **EFSroot**.

**Note**
You can follow the Getting started (p. 13) exercise to create and mount an Amazon EFS file system on your EC2 instance.

In the following steps, you create a user (mike), create a subdirectory for the user (**EFSroot/mike**), make user mike the owner of the subdirectory, granting him full permissions, and finally mount the Amazon EFS subdirectory on the user's home directory (**/home/mike**).

1. Create user mike:

   - Log in to your EC2 instance. Using root privileges (in this case, using the `sudo` command), create user mike and assign a password.
   
   ```
   $ sudo useradd -c "Mike Smith" mike
   $ sudo passwd mike
   ```
   
   This also creates a home directory, **/home/mike**, for the user.

2. Create a subdirectory under **EFSroot** for user mike:

   a. Create subdirectory **mike** under **EFSroot**.
   
   ```
   $ sudo mkdir /EFSroot/mike
   ```
   
   You will need to replace **EFSroot** with your local directory name.

   b. The root user and root group are the owners of the **/mike** subdirectory (you can verify this by using the `ls -l` command). To enable full permissions for user mike on this subdirectory, grant mike ownership of the directory.

   ```
   $ sudo chown mike:mike /EFSroot/mike
   ```
3. Use the `mount` command to mount the EFSroot/mike subdirectory onto mike's home directory.

```bash
$ sudo mount -t nfs -o nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport mount-target-DNS:/mike /home/mike
```

The `mount-target-DNS` address identifies the remote Amazon EFS file system root.

Now user mike's home directory is a subdirectory, writable by mike, in the Amazon EFS file system. If you unmount this mount target, the user can't access their EFS directory without remounting, which requires root permissions.

**Automatic remounting on reboot**

You can use the file `fstab` to automatically remount your file system after any system reboots. For more information, see Mounting your Amazon EFS file system automatically (p. 68).

---

**Walkthrough: Create and mount a file system on-premises with AWS Direct Connect and VPN**

This walkthrough uses the AWS Management Console to create and mount a file system on an on-premises client. You do so using either an AWS Direct Connect connection or a connection on an AWS Virtual Private Network (AWS VPN).

**Note**

Using Amazon EFS with Microsoft Windows–based clients isn't supported.

**Topics**

- Before you begin (p. 154)
- Step 1: Create your Amazon Elastic File System resources (p. 154)
- Step 2: Install the NFS client (p. 155)
- Step 3: Mount the Amazon EFS file system on your on-premises Client (p. 156)
- Step 4: Clean up resources and protect your AWS account (p. 157)
- Optional: Encrypting data in transit (p. 157)

In this walkthrough, we assume that you already have an AWS Direct Connect or VPN connection. If you don't have one, you can begin the connection process now and come back to this walkthrough when your connection is established. For more information on AWS Direct Connect, see the AWS Direct Connect User Guide. For more information on setting up a VPN connection, see VPN Connections in the Amazon VPC User Guide.

When you have an AWS Direct Connect or VPN connection, you create an Amazon EFS file system and a mount target in your Amazon VPC. After that, you download and install the amazon-efs-utils tools. Then, you test the file system from your on-premises client. Finally, the clean-up step at the end of the walkthrough provides information for you to remove these resources.
The walkthrough creates all these resources in the US West (Oregon) Region (us-west-2). Whichever AWS Region you use, be sure to use it consistently. All of your resources—your VPC, your mount target, and your Amazon EFS file system—must be in the same AWS Region.

**Note**
In some cases, your local application might need to know if the EFS file system is available. In these cases, your application should be able to point to a different mount point IP address if the first mount point becomes temporarily unavailable. In this scenario, we recommend that you have two on-premises clients connected to your file system through different Availability Zones (AZs) for higher availability.

**Before you begin**

You can use the root credentials of your AWS account to sign in to the console and try this exercise. However, AWS Identity and Access Management (IAM) best practices recommend that you don't use the root credentials of your AWS account. Instead, create an administrator user in your account and use those credentials to manage resources in your account. For more information, see Setting Up (p. 11).

You can use a default VPC or a custom VPC that you have created in your account. For this walkthrough, the default VPC configuration works. However, if you use a custom VPC, verify the following:

- The internet gateway is attached to your VPC. For more information, see Internet Gateways in the Amazon VPC User Guide.
- The VPC route table includes a rule to send all internet-bound traffic to the Internet gateway.

**Step 1: Create your Amazon Elastic File System resources**

In this step, you create your Amazon EFS file system and mount targets.

**To create your Amazon EFS file system**

1. Open the Amazon EFS console at https://console.aws.amazon.com/efs/.
2. Choose Create File System.
3. Choose your default VPC from the VPC list.
4. Select the check boxes for all of the Availability Zones. Make sure that they all have the default subnets, automatic IP addresses, and the default security groups chosen. These are your mount targets. For more information, see Creating and managing mount targets (p. 31).
5. Choose Next Step.
6. Name your file system, keep general purpose selected as your default performance mode, and choose Next Step.
7. Choose Create File System.
8. Choose your file system from the list and make a note of the Security group value. You need this value for the next step.

The file system you just created has mount targets. Each mount target has an associated security group. The security group acts as a virtual firewall that controls network traffic. If you didn't provide a security group when creating a mount target, Amazon EFS associates the default security group of the VPC with it. If you followed the preceding steps exactly, then your mount targets are using the default security group.

Next, you add a rule to the mount target's security group to allow inbound traffic to the Network File System (NFS) port (2049). You can use the AWS Management Console to add the rule to your mount target's security groups in your VPC.
To allow inbound traffic to the NFS port

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
3. Choose the security group associated with your file system. You made a note of this at the end of Step 1: Create your Amazon Elastic File System resources (p. 154).
4. In the tabbed pane that appears below the list of security groups, choose the Inbound tab.
5. Choose Edit.
6. Choose Add Rule, and choose a rule of the following type:
   - Type – NFS
   - Source – Anywhere

We recommend that you only use the Anywhere source for testing. You can create a custom source set to the IP address of the on-premises client, or use the console from the client itself, and choose My IP.

Note
You don’t need to add an outbound rule, because the default outbound rule allows all traffic to leave. If you don’t have this default outbound rule, add an outbound rule to open a TCP connection on the NFS port, identifying the mount target security group as the destination.

Step 2: Install the NFS client

In this step, you install the NFS client.

To install the NFS client on your on-premises server

Note
If you require data to be encrypted in transit, use the Amazon EFS mount helper, amazon-efs-utils, instead of the NFS client. For information on installing amazon-efs-utils, see the section Optional: Encrypting Data in Transit.

1. Access the terminal for your on-premises client.
2. Install NFS.

   If you're using Red Hat Linux, install NFS with the following command.

   ```
   $ sudo yum -y install nfs-utils
   ```

   If you're using Ubuntu, install NFS with the following command.

   ```
   $ sudo apt-get -y install nfs-common
   ```
Step 3: Mount the Amazon EFS file system on your on-premises Client

To create a mount directory

1. Make a directory for the mount point with the following command.

   Example

   ```
   mkdir ~/efs
   ```

2. Choose your preferred IP address of the mount target in the Availability Zone. You can measure the latency from your on-premises Linux clients. To do so, use a terminal-based tool like `ping` against the IP address of your EC2 instances in different Availability Zones to find the one with the lowest latency.

   • Run the mount command to mount the file system using the IP address of the mount target.

   ```
   $ sudo mount -t nfs -o 
   nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport 
   mount-target-IP:/   ~/efs
   ```

   Now that you’ve mounted your Amazon EFS file system, you can test it out with the following procedure.

To test the Amazon EFS file system connection

1. Change directories to the new directory that you created with the following command.

   ```
   $ cd ~/efs
   ```

2. Make a subdirectory and change the ownership of that subdirectory to your EC2 instance user. Then, navigate to that new directory with the following commands.

   ```
   $ sudo mkdir getting-started
   $ sudo chown ec2-user getting-started
   $ cd getting-started
   ```

3. Create a text file with the following command.

   ```
   $ touch test-file.txt
   ```

4. List the directory contents with the following command.

   ```
   $ ls -al
   ```

   As a result, the following file is created.

   ```
   -rw-rw-r-- 1 username username 0 Nov 15 15:32 test-file.txt
   ```

   You can also mount your file system automatically by adding an entry to the `/etc/fstab` file. For more information, see Mounting your Amazon EFS file system automatically (p. 68).
Warning
Use the _netdev option, used to identify network file systems, when mounting your file system automatically. If _netdev is missing, your EC2 instance might stop responding. This result is because network file systems need to be initialized after the compute instance starts its networking. For more information, see Automatic Mounting Fails and the Instance Is Unresponsive (p. 224).

Step 4: Clean up resources and protect your AWS account

After you have finished this walkthrough, or if you don't want to explore the walkthroughs, you should follow these steps to clean up your resources and protect your AWS account.

To clean up resources and protect your AWS account

1. Unmount the Amazon EFS file system with the following command.

   $ sudo umount ~/efs

2. Open the Amazon EFS console at https://console.aws.amazon.com/efs/.
3. Choose the Amazon EFS file system that you want to delete from the list of file systems.
4. For Actions, choose Delete file system.
5. In the Permanently delete file system dialog box, type the file system ID for the Amazon EFS file system that you want to delete, and then choose Delete File System.
6. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
7. In the navigation pane, choose Security Groups.
8. Select the name of the security group that you added the rule to for this walkthrough.

   Warning
   Don't delete the default security group for your VPC.
9. For Actions, choose Edit inbound rules.
10. Choose the X at the end of the inbound rule you added, and choose Save.

Optional: Encrypting data in transit

To encrypt data in transit, use the Amazon EFS mount helper, amazon-efs-utils, instead of the NFS client.

The amazon-efs-utils package is an open-source collection of Amazon EFS tools. The amazon-efs-utils collection comes with a mount helper and tooling that makes it easier to encrypt data in transit for Amazon EFS. For more information on this package, see Using the amazon-efs-utils Tools (p. 47). This package is available as a free download from GitHub, which you can get by cloning the package's repository.

To clone amazon-efs-utils from GitHub

1. Access the terminal for your on-premises client.
2. From the terminal, clone the amazon-efs-utils tool from GitHub to a directory of your choice, with the following command.

   git clone https://github.com/aws/efs-utils
Now that you have the package, you can install it. This installation is handled differently depending on the Linux distribution of your on-premises client. The following distributions are supported:

- Amazon Linux 2
- Amazon Linux
- Red Hat Enterprise Linux (and derivatives such as CentOS) version 7 and newer
- Ubuntu 16.04 LTS and newer

**To build and install amazon-efs-utils as an RPM package**

1. Open a terminal on your client and navigate to the directory that has the cloned amazon-efs-utils package from GitHub.
2. Build the package with the following command.
   ```
   make rpm
   ```

   **Note**
   If you haven't already, install the rpm-builder package with the following command.
   ```
   sudo yum -y install rpm-build
   ```
3. Install the package with the following command.
   ```
   sudo yum -y install build/amazon-efs-utils*rpm
   ```

**To build and install amazon-efs-utils as an deb package**

1. Open a terminal on your client and navigate to the directory that has the cloned amazon-efs-utils package from GitHub.
2. Build the package with the following command.
   ```
   ./build-deb.sh
   ```
3. Install the package with the following command.
   ```
   sudo apt-get install build/amazon-efs-utils*deb
   ```

After the package is installed, configure amazon-efs-utils for use in your AWS Region with AWS Direct Connect or VPN.

**To configure amazon-efs-utils for use in your AWS Region**

1. Using your text editor of choice, open `/etc/amazon/efs/efs-utils.conf` for editing.
2. Find the line “dns_name_format = `{fs_id}.efs.{region}.amazonaws.com`”.
3. Change `{region}` with the ID for your AWS Region, for example `us-west-2`.

To mount the EFS file system on your on-premises client, first open a terminal on your on-premises Linux client. To mount the system, you need the file system ID, the mount target IP address for one of your mount targets, and the file system's AWS Region. If you created multiple mount targets for your file system, then you can choose any one of these.
When you have that information, you can mount your file system in three steps:

**To create a mount directory**

1. Make a directory for the mount point with the following command.
   
   **Example**
   ```
   mkdir ~/efs
   ```

2. Choose your preferred IP address of the mount target in the Availability Zone. You can measure the latency from your on-premises Linux clients. To do so, use a terminal-based tool like `ping` against the IP address of your EC2 instances in different Availability Zones to find the one with the lowest latency.

**To update `/etc/hosts`**

- Add an entry to your local `/etc/hosts` file with the file system ID and the mount target IP address, in the following format.

  ```
  mount-target-IP-Address file-system-ID.efs.region.amazonaws.com
  ```

  **Example**
  ```
  192.0.2.0 fs-12345678.efs.us-west-2.amazonaws.com
  ```

**To make a mount directory**

1. Make a directory for the mount point with the following command.

   **Example**
   ```
   mkdir ~/efs
   ```

2. Run the mount command to mount the file system.

   **Example**
   ```
   sudo mount -t efs fs-12345678 ~/efs
   ```

If you want to use encryption of data in transit, your mount command looks something like the following.

**Example**

```
sudo mount -t efs -o tls fs-12345678 ~/efs
```
Walkthrough: Mount a File System from a Different VPC

In this walkthrough, you set up an Amazon EC2 instance to mount an Amazon EFS file system that is in a different virtual private cloud (VPC). You do this using the EFS mount helper. The mount helper is part of the `amazon-efs-utils` set of tools. For more information about `amazon-efs-utils`, see Using the `amazon-efs-utils` Tools (p. 47).

The client's VPC and your EFS file system's VPC must be connected using either a VPC peering connection or a VPC transit gateway. When you use a VPC peering connection or transit gateway to connect VPCs, Amazon EC2 instances that are in one VPC can access EFS file systems in another VPC, even if the VPCs belong to different accounts.

**Note**
Using Amazon EFS with Microsoft Windows–based clients isn't supported.

**Topics**
- Before You Begin (p. 160)
- Step 1: Determine the Availability Zone ID of the EFS Mount Target (p. 160)
- Step 2: Determine the Mount Target IP Address (p. 161)
- Step 3: Add a Host Entry for the Mount Target (p. 162)
- Step 4: Mount Your File System Using the EFS Mount Helper (p. 162)
- Step 5: Clean Up Resources and Protect Your AWS Account (p. 163)

**Before You Begin**

In this walkthrough, we assume that you already have the following:

- The `amazon-efs-utils` set of tools is installed on the EC2 instance before using this procedure. For instructions on installing `amazon-efs-utils`, see Using the `amazon-efs-utils` Tools (p. 47).
- One of the following:
  - A VPC peering connection between the VPC where the EFS file system resides and the VPC where the EC2 instance resides. A **VPC peering connection** is a networking connection between two VPCs. This type of connection enables you to route traffic between them using private Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) addresses. You can use VPC peering to connect VPCs within the same AWS Region or between AWS Regions. For more information, see Creating and Accepting a VPC Peering Connection in the Amazon VPC Peering Guide.
  - A transit gateway connecting the VPC where the EFS file system resides and the VPC where the EC2 instance resides. A **transit gateway** is a network transit hub that you can use to interconnect your VPCs and on-premises networks. For more information, see Getting Started with Transit Gateways in the Amazon VPC Transit Gateways Guide.

**Step 1: Determine the Availability Zone ID of the EFS Mount Target**

To ensure high availability of your file system, we recommend that you always use an EFS mount target IP address that is in the same Availability Zone as your NFS client. If you are mounting an EFS file system that is in another account, ensure that the NFS client and EFS mount target are in the same Availability Zone ID. This requirement applies because Availability Zone names can differ between accounts.
To determine the Availability Zone ID of the EC2 instance

1. Connect to your EC2 instance:
   - To connect to your instance from a computer running macOS or Linux, specify the .pem file for your SSH command. To do this, use the -i option and the path to your private key.
   - To connect to your instance from a computer running Windows, you can use either MindTerm or PuTTY. To use PuTTY, install it and convert the .pem file to a .ppk file.

For more information, see the following topics in the Amazon EC2 User Guide for Linux Instances:
   - Connecting to Your Linux Instance Using SSH
   - Connecting to Your Linux Instance from Windows Using PuTTY

2. Determine the Availability Zone ID that the EC2 instance is in using the describe-availability-zones CLI command as follows.

   ```bash
   [ec2-user@ip-10.0.0.1]
   {
       "AvailabilityZones": [
           {
               "State": "available",
               "ZoneName": "us-east-2b",
               "Messages": [],
               "ZoneId": "use2-az2",
               "RegionName": "us-east-2"
           }
       ]
   }
   ``

   The Availability Zone ID is returned in the ZoneId property, use2-az2.

Step 2: Determine the Mount Target IP Address

Now that you know the Availability Zone ID of the EC2 instance, you can now retrieve the IP address of the mount target that is in the same Availability Zone ID.

To determine the mount target IP address in the same Availability Zone ID

- Retrieve the mount target IP address for your file system in the use2-az2 AZ ID using the describe-mount-targets CLI command, as follows.

   ```bash
   $ aws efs describe-mount-targets --file-system-id file_system_id
   {
       "MountTargets": [
           {
               "OwnerId": "111122223333",
               "MountTargetId": "fsmt-11223344",
               "AvailabilityZoneId": "use2-az2",
               "NetworkInterfaceId": "eni-048c09a306023eeec",
               "AvailabilityZoneName": "us-east-2b",
               "FileSystemId": "fs-01234567",
               "LifeCycleState": "available",
               "SubnetId": "subnet-06eb0da37ee82a64f",
               "OwnerId": "958322738406",
               "IpAddress": "10.0.2.153"
           },
           ...
   }
   ```
Step 3: Add a Host Entry for the Mount Target

You can now make an entry in the `/etc/hosts` file on the EC2 instance that maps the mount target IP address to your EFS file system's hostname.

**To add a host entry for the mount target**

- Add a line for the mount target IP address to the EC2 instance's `/etc/hosts` file. The entry uses the format `mount-target-IP-Address file-system-ID.efs.region.amazonaws.com`. Use the following command to add the line to the file.

  ```
  echo "10.0.2.153 fs-01234567.efs.us-east-2.amazonaws.com" | sudo tee -a /etc/hosts
  ```

Step 4: Mount Your File System Using the EFS Mount Helper

To mount your EFS file system, you first create a mount directory on the EC2 instance. Then, using the EFS mount helper, you can mount the file system with either IAM authorization or an EFS access point. For more information, see Using IAM to control file system data access (p. 185) and Working with Amazon EFS Access Points (p. 202).

**To create a mount directory**

- Create a directory for mounting the file system using the following command.

  ```
  $ sudo mkdir /mnt/efs/
  ```

**To mount the file system using IAM authorization**

- Use the following command to mount the file system using IAM authorization.

  ```
  $ sudo mount -t efs -o tls,iam file-system-id /mnt/efs/
  ```
To mount the file system using an EFS access point

- Use the following command to mount the file system using an EFS access point.

```
$ sudo mount -t efs -o tls,accesspoint=access-point-id file-system-id /mnt/efs/
```

Now that you've mounted your Amazon EFS file system, you can test it with the following procedure.

To test the Amazon EFS file system connection

1. Change directories to the new directory that you created with the following command.

```
$ cd ~/mnt/efs
```

2. Make a subdirectory and change the ownership of that subdirectory to your EC2 instance user. Then navigate to that new directory with the following commands.

```
$ sudo mkdir getting-started
$ sudo chown ec2-user getting-started
$ cd getting-started
```

3. Create a text file with the following command.

```
$ touch test-file.txt
```

4. List the directory contents with the following command.

```
$ ls -al
```

As a result, the following file is created.

```
-rw-rw-r-- 1 username username 0 Nov 15 15:32 test-file.txt
```

You can also mount your file system automatically by adding an entry to the `/etc/fstab` file. For more information, see Using `/etc/fstab` to mount automatically (p. 70).

Warning

Use the `_netdev` option, used to identify network file systems, when mounting your file system automatically. If `_netdev` is missing, your EC2 instance might stop responding. This result is because network file systems need to be initialized after the compute instance starts its networking. For more information, see Automatic Mounting Fails and the Instance Is Unresponsive (p. 224).

Step 5: Clean Up Resources and Protect Your AWS Account

After you have finished this walkthrough, or if you don't want to explore the walkthroughs, make sure to take the following steps. These clean up your resources and protect your AWS account.

To clean up resources and protect your AWS account

1. Unmount the Amazon EFS file system with the following command.
Walkthrough: Enforcing Encryption on an Amazon EFS File System at Rest

Following, you can find details about how to enforce encryption at rest using Amazon CloudWatch and AWS CloudTrail. This walkthrough is based upon the AWS white paper Encrypt Data at Rest with Amazon EFS Encrypted File Systems.

Note
The method for enforcing the creation of Amazon EFS file systems that are encrypted at rest described in this walkthrough is deprecated. The preferred method to enforce the creation of file systems that are encrypted at rest is to use the elasticfilesystem:Encrypted condition key in AWS Identity and Access Management identity-based policies. For more information, see Using IAM to enforce creating encrypted file systems (p. 188). You can use this walkthrough to create CloudWatch alarms to validate that your IAM policies are preventing the creation of unencrypted file systems.

Enforcing Encryption at Rest

Your organization might require the encryption at rest of all data that meets a specific classification or that is associated with a particular application, workload, or environment. You can enforce policies for data encryption at rest for Amazon EFS file systems by using detective controls. These controls detect the creation of a file system and verify that encryption at rest is enabled.

If a file system that doesn't have encryption at rest is detected, you can respond in a number of ways. These range from deleting the file system and mount targets to notifying an administrator.

If you want to delete an unencrypted-at-rest file system but want to retain the data, first create a new encrypted-at-rest file system. Next, copy the data over to the new encrypted-at-rest file system. After the data is copied over, you can delete the unencrypted-at-rest file system.

Detecting File Systems That are Unencrypted at Rest

You can create a CloudWatch alarm to monitor CloudTrail logs for the CreateFileSystem event. You can then trigger the alarm to notify an administrator if the file system that was created was unencrypted at rest.
Create a Metric Filter

To create a CloudWatch alarm that is triggered when an unencrypted Amazon EFS file system is created, use the following procedure.

Before you begin, you must have an existing trail created that is sending CloudTrail logs to a CloudWatch Logs log group. For more information, see Sending Events to CloudWatch Logs in the AWS CloudTrail User Guide.

To create a metric filter
2. In the navigation pane, choose Logs.
3. In the list of log groups, choose the log group that you created for CloudTrail log events.
4. Choose Create Metric Filter.
5. On the Define Logs Metric Filter page, choose Filter Pattern and then type the following:

   ```
   { ($.eventName = CreateFileSystem) && ($.responseElements.encrypted IS FALSE) }
   ```

6. Choose Assign Metric.
7. For Filter Name, type UnencryptedFileSystemCreated.
8. For Metric Namespace, type CloudTrailMetrics.
9. For Metric Name, type UnencryptedFileSystemCreatedEventCount.
10. Choose Show advanced metric settings.
11. For Metric Value, type 1.
12. Choose Create Filter.

Create an Alarm

After you create the metric filter, use the following procedure to create an alarm.

To create an alarm
1. On the Filters for the Log_Group_Name page, next to the UnencryptedFileSystemCreated filter name, choose Create Alarm.
2. On the Create Alarm page, set the following parameters:
   - For Name, type Unencrypted File System Created
   - For Whenever, do the following:
     - Set to > = 1
     - Set for: to 1 consecutive period(s).
   - For Treat missing data as, choose good (not breaching threshold).
   - For Actions, do the following:
     - For Whenever this alarm, choose State is ALARM.
     - For Send notification to, choose NotifyMe, choose New list, and then type a unique topic name for this list.
     - For Email list, type in the email address where you want notifications sent. You should receive an email at this address to confirm that you created this alarm.
   - For Alarm Preview, do the following:
     - For Period, choose 1 Minute.
     - For Statistic, choose Standard and Sum.
3. Choose **Create Alarm**.

**Test the Alarm for the Creation of Unencrypted File Systems**

You can test the alarm by creating an unencrypted-at-rest file system, as follows.

**To test the alarm by creating an unencrypted-at-rest file system**

1. Sign in to the AWS Management Console and open the Amazon EFS console at https://console.aws.amazon.com/efs/.
2. Choose **Create file system** to display the **Create file system** dialog box.
3. To create a file system that is unencrypted at rest, choose **Customize** to display the **File system settings** page.
4. For **General** settings, enter the following.
   a. (Optional) Enter a **Name** for the file system.
   b. Keep **Lifecycle management**, **Performance mode**, and **Throughput mode** set to the default values.
   c. Turn off **Encryption** by clearing **Enable encryption of data at rest**.
5. Choose **Next** to continue to the **Network Access** step in the configuration process.
6. Choose the default **Virtual Private Cloud (VPC)**.
7. For **Mount targets**, choose the default **Security groups** for each mount target.
8. Choose **Next** to display the **File system policy** page.
9. Choose **Next** to continue to the **Review and create** page.
10. Review the file system, and choose **Create** to create your file system and return to the **File systems** page.

Your trail logs the **CreateFileSystem** operation and delivers the event to your CloudWatch Logs log group. The event triggers your metric alarm and CloudWatch Logs sends you a notification about the change.

**Walkthrough: Enable root squashing using IAM authorization for NFS clients**

In this walkthrough, you configure Amazon EFS to prevent root access to your Amazon EFS file system for all AWS principals except for a single management workstation. You do this by configuring AWS Identity and Access Management (IAM) authorization for Network File System (NFS) clients. For more information about IAM authorization for NFS clients in EFS, see **Using IAM to control file system data access** (p. 185).

To do this requires configuring two IAM permissions policies, as follows:

- Create an EFS file system policy that explicitly allows read and write access to the file system, and implicitly denies root access.
- Assign an IAM identity to the Amazon EC2 management workstation that requires root access to the file system by using an Amazon EC2 instance profile. For more information about Amazon EC2 instance profiles, see **Using Instance Profiles** in the **AWS Identity and Access Management User Guide**.
- Assign the **AmazonElasticFileSystemClientFullAccess** AWS managed policy to the IAM role of the management workstation. For more information about AWS managed policies for EFS, see **AWS managed (predefined) policies for Amazon EFS** (p. 182).
To enable root squashing using IAM authorization for NFS clients, use the following procedures.

**To prevent root access to the file system**

2. Choose **Filesystems**.
3. On the **File systems** page, choose the file system that you want to enable root squashing on.
4. On the file system details page, choose **File system policy**, and then choose **Edit**. The **File system policy** page appears.

   ![File system policy](image)

5. Choose **Prevent root access by default** under **Policy options**. The policy JSON object appears in the **Policy editor**.
6. Choose **Save** to save the file system policy.

Clients that aren't anonymous can get root access to the file system through an identity-based policy. When you attach the `AmazonElasticFileSystemClientFullAccess` managed policy to the workstation's role, IAM grants root access to the workstation based on its identity policy.

**To enable root access from the management workstation**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Create a role for Amazon EC2 called `EFS-client-root-access`. IAM creates an instance profile with the same name as the EC2 role you created.
3. Assign the AWS managed policy `AmazonElasticFileSystemClientFullAccess` to the EC2 role you created. The contents of this policy is shown following.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Resource": "*",
         "Effect": "Allow",
         "Action": "elasticfilesystem:Client*"
       }
     ]
   }
   ```
4. Attach the instance profile to the EC2 instance that you are using as the management workstation, as described following. For more information, see Attaching an IAM Role to an Instance in the Amazon EC2 User Guide for Linux Instances.
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. In the navigation pane, choose Instances.
   c. Choose the instance. For Actions, choose Instance Settings, and then choose Attach/Replace IAM role.
   d. Choose the IAM role that you created in the first step, EFS-client-root-access, and choose Apply.
5. Install the EFS mount helper on the management workstation. For more information about the EFS mount helper and the amazon-efs-utils package, see Using the amazon-efs-utils Tools (p. 47).
6. Mount the EFS file system on the management workstation by using the following command with the iam mount option.

```
$ sudo mount -t efs -o tls,iam file-system-id:/ efs-mount-point
```

You can configure the Amazon EC2 instance to automatically mount the file system with IAM authorization. For more information about mounting an EFS file system with IAM authorization, see Mounting with IAM authorization (p. 67).
Security in Amazon EFS

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon Elastic File System, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company’s requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon EFS. The following topics show you how to configure Amazon EFS to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Amazon EFS resources.

Following, you can find a description of security considerations for working with Amazon EFS. There are four levels of access control to consider for Amazon EFS file systems, with different mechanisms used for each.

**Topics**

- Data encryption in Amazon EFS (p. 169)
- Identity and access management for Amazon EFS (p. 175)
- Controlling network access to Amazon EFS file systems for NFS clients (p. 195)
- Working with users, groups, and permissions at the Network File System (NFS) Level (p. 198)
- Working with Amazon EFS Access Points (p. 202)
- Logging and Monitoring in Amazon EFS (p. 205)
- AWS managed policies for Amazon EFS (p. 206)
- Compliance Validation for Amazon Elastic File System (p. 209)
- Resilience in Amazon Elastic File System (p. 210)
- Amazon Elastic File System Network Isolation (p. 211)

**Data encryption in Amazon EFS**

Amazon EFS supports two forms of encryption for file systems, encryption of data in transit and encryption at rest. You can enable encryption of data at rest when creating an Amazon EFS file system. You can enable encryption of data in transit when you mount the file system.

If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.
When to use encryption

If your organization is subject to corporate or regulatory policies that require encryption of data and metadata at rest, we recommend creating a file system that is encrypted at rest, and mounting your file system using encryption of data in transit.

Related Topics

For more information on encryption with Amazon EFS, see these related topics:

- Working with Amazon EFS resources (p. 19)
- Managing access to encrypted file systems (p. 94)
- Amazon EFS performance tips (p. 127)
- Amazon EFS API permissions: actions, resources, and conditions reference (p. 183)
- Amazon EFS Log File Entries for Encrypted-at-Rest File Systems (p. 117)
- Troubleshooting Encryption (p. 228)

Encrypting data at rest

As with unencrypted file systems, you can create encrypted file systems using the AWS Management Console, the AWS CLI, or programmatically through the Amazon EFS API or one of the AWS SDKs. Your organization might require the encryption of all data that meets a specific classification or is associated with a particular application, workload, or environment.

Note

The AWS key management infrastructure uses Federal Information Processing Standards (FIPS) 140-2 approved cryptographic algorithms. The infrastructure is consistent with National Institute of Standards and Technology (NIST) 800-57 recommendations.

Enforcing the creation of Amazon EFS file systems encrypted at rest

You can use the elasticfilesystem:Encrypted IAM condition key in AWS Identity and Access Management (IAM) identity-based policies to control whether users can create Amazon EFS file systems that are encrypted at rest. For more information about using the condition key, see Using IAM to enforce creating encrypted file systems (p. 188).

You can also define service control policies (SCPs) inside AWS Organizations to enforce EFS encryption for all AWS accounts in your organization. For more information about service control policies in AWS Organizations, see Service control policies in the AWS Organizations User Guide.

Encrypting a file system at rest using the console

When you create a new file system using the Amazon EFS console, encryption at rest is enabled by default. The following procedure describes how to enable encryption for a new file system when you create it from the console.

Note

Encryption at rest is not enabled by default when creating a new file system using the AWS CLI, API, and SDKs. For more information, see Creating a file system using the AWS CLI (p. 28).

To encrypt a new file system using the EFS console

2. Choose **Create file system** to open the **Create file system** dialog box.

![Create file system dialog box]

3. (Optional) Enter a **Name** for your file system.

4. For **Virtual Private Cloud (VPC)**, choose your VPC, or keep it set to your default VPC.

5. Choose **Create** to create a file system that uses the following service recommended settings:

   - Encryption of data at rest enabled using your default key for Amazon EFS (`aws/elasticfilesystem`).
   - Automatic backups turned on – For more information, see Using AWS Backup to back up and restore Amazon EFS file systems (p. 130).
   - Mount targets – Amazon EFS creates mount targets with the following settings:
     - Located in each Availability Zone in the Region where the file system is created.
     - Located in the default subnets of the VPC that you selected.
     - Use the VPC’s default security group. You can manage security groups after the file system is created.

   For more information, see Managing file system network accessibility (p. 83).

   - General Purpose performance mode – For more information, see Performance modes (p. 122).
   - Bursting throughput mode – For more information, see Throughput modes (p. 123).
   - Lifecycle management enabled with a 30-day policy – For more information, see Amazon EFS lifecycle management (p. 90).

6. The **File systems** page appears with a banner across the top showing the status of the file system you created. A link to access the file system details page appears in the banner when the file system becomes available.
You now have a new encrypted-at-rest file system.

**How encryption at rest works**

In an encrypted file system, data and metadata are automatically encrypted before being written to the file system. Similarly, as data and metadata are read, they are automatically decrypted before being presented to the application. These processes are handled transparently by Amazon EFS, so you don't have to modify your applications.

Amazon EFS uses industry-standard AES-256 encryption algorithm to encrypt EFS data and metadata at rest. For more information, see Cryptography Basics in the AWS Key Management Service Developer Guide.

**How Amazon EFS uses AWS KMS**

Amazon EFS integrates with AWS Key Management Service (AWS KMS) for key management. Amazon EFS uses customer master keys (CMKs) to encrypt your file system in the following way:

- **Encrypting metadata at rest** – Amazon EFS uses the AWS managed CMK for Amazon EFS, aws/elasticfilesystem, to encrypt and decrypt file system metadata (that is, file names, directory names, and directory contents).
- **Encrypting file data at rest** – You choose the CMK used to encrypt and decrypt file data (that is, the contents of your files). You can enable, disable, or revoke grants on this CMK. This CMK can be one of the two following types:
  - **AWS managed CMK for Amazon EFS** – This is the default CMK, aws/elasticfilesystem. You're not charged to create and store a CMK, but there are usage charges. To learn more, see AWS Key Management Service pricing.
  - **Customer-managed CMK** – This is the most flexible master key to use, because you can configure its key policies and grants for multiple users or services. For more information on creating CMKs, see Creating Keys in the AWS Key Management Service Developer Guide.

If you use a customer-managed CMK as your master key for file data encryption and decryption, you can enable key rotation. When you enable key rotation, AWS KMS automatically rotates your
key once per year. Additionally, with a customer-managed CMK, you can choose when to disable, re-enable, delete, or revoke access to your CMK at any time. For more information, see Disabling, deleting, or revoking access to the CMK for a file system (p. 95).

Important
Amazon EFS accepts only symmetric CMKs. You cannot use asymmetric CMKs with Amazon EFS.

Data encryption and decryption at rest are handled transparently. However, AWS account IDs specific to Amazon EFS appear in your AWS CloudTrail logs related to AWS KMS actions. For more information, see Amazon EFS Log File Entries for Encrypted-at-Rest File Systems (p. 117).

Amazon EFS key policies for AWS KMS
Key policies are the primary way to control access to CMKs. For more information on key policies, see Using Key Policies in AWS KMS in the AWS Key Management Service Developer Guide. The following list describes all the AWS KMS–related permissions supported by Amazon EFS for encrypted at rest file systems:

- **kms:Encrypt** – (Optional) Encrypts plaintext into ciphertext. This permission is included in the default key policy.
- **kms:Decrypt** – (Required) Decrypts ciphertext. Ciphertext is plaintext that has been previously encrypted. This permission is included in the default key policy.
- **kms:ReEncrypt** – (Optional) Encrypts data on the server side with a new customer master key (CMK), without exposing the plaintext of the data on the client side. The data is first decrypted and then re-encrypted. This permission is included in the default key policy.
- **kms:GenerateDataKeyWithoutPlaintext** – (Required) Returns a data encryption key encrypted under a CMK. This permission is included in the default key policy under **kms:GenerateDataKey**.
- **kms:CreateGrant** – (Required) Adds a grant to a key to specify who can use the key and under what conditions. Grants are alternate permission mechanisms to key policies. For more information on grants, see Using Grants in the AWS Key Management Service Developer Guide. This permission is included in the default key policy.
- **kms:DescribeKey** – (Required) Provides detailed information about the specified customer master key. This permission is included in the default key policy.
- **kms:ListAliases** – (Optional) Lists all of the key aliases in the account. When you use the console to create an encrypted file system, this permission populates the Select KMS master key list. We recommend using this permission to provide the best user experience. This permission is included in the default key policy.

Encrypting data in transit
You can encrypt data in transit using an Amazon EFS file system, without needing to modify your applications.

Encrypting data in transit with TLS
Enabling encryption of data in transit for your Amazon EFS file system is done by enabling Transport Layer Security (TLS) when you mount your file system using the Amazon EFS mount helper. For more information, see Mounting file systems using the EFS mount helper (p. 59).

When encryption of data in transit is declared as a mount option for your Amazon EFS file system, the mount helper initializes a client stunnel process. Stunnel is an open source multipurpose network relay. The client stunnel process listens on a local port for inbound traffic, and the mount helper redirects Network File System (NFS) client traffic to this local port. The mount helper uses TLS version 1.2 to communicate with your file system.
**To mount your Amazon EFS file system with the mount helper with encryption of data in transit enabled**

1. Access the terminal for your instance through Secure Shell (SSH), and log in with the appropriate user name. For more information on how to do this, see Connecting to Your Linux Instance Using SSH in the Amazon EC2 User Guide for Linux Instances.
2. Run the following command to mount your file system.

```bash
sudo mount -t efs -o tls fs-12345678:/ /mnt/efs
```

**How encrypting in transit works**

To enable encryption of data in transit, you connect to Amazon EFS using TLS. We recommend using the mount helper because it's the simplest option.

If you're not using the mount helper, you can still enable encryption of data in transit. At a high level, the following are the steps to do so.

**To enable encryption of data in transit without the mount helper**

1. Download and install stunnel, and note the port that the application is listening on.
2. Run stunnel to connect to your Amazon EFS file system on port 2049 using TLS.
3. Using the NFS client, mount `localhost:port`, where `port` is the port that you noted in the first step.

Because encryption of data in transit is configured on a per-connection basis, each configured mount has a dedicated stunnel process running on the instance. By default, the stunnel process used by the mount helper listens on local ports 20049 and 20449, and it connects to Amazon EFS on port 2049.

**Note**

By default, when using the Amazon EFS mount helper with TLS, the mount helper enforces certificate hostname checking. The Amazon EFS mount helper uses the stunnel program for its TLS functionality. Some versions of Linux don't include a version of stunnel that supports these TLS features by default. When using one of those Linux versions, mounting an Amazon EFS file system using TLS fails.

After you've installed the amazon-efs-utils package, to upgrade your system's version of stunnel see Upgrading stunnel (p. 56).

For issues with encryption, see Troubleshooting Encryption (p. 228).

When using encryption of data in transit, your NFS client setup is changed. When you inspect your actively mounted file systems, you see one mounted to 127.0.0.1, or localhost, as in the following example.

```
# mount | column -t
127.0.0.1:/ on /home/ec2-user/efs type nfs4
(rw,relatime,vers=4.1,rsize=1048576,wsize=1048576,namlen=255,hard,proto=tcp,port=20127,timeo=600,retrans=2,sec=sys,clientaddr=127.0.0.1,local_lock=none,addr=127.0.0.1)
```

When mounting with TLS and the Amazon EFS mount helper, you are reconfiguring your NFS client to mount to a local port. The mount helper starts a client stunnel process that is listening on this local port, and stunnel is opening an encrypted connection to EFS using TLS. The EFS mount helper is responsible for setting up and maintaining this encrypted connection and associated configuration.

To determine which Amazon EFS file system ID corresponds to which local mount point, you can use the following command. Replace `efs-mount-point` with the local path where you mounted your file system.
When you use the mount helper for encryption of data in transit, it also creates a process called `amazon-efs-mount-watchdog`. This process ensures that each mount's stunnel process is running, and stops the stunnel when the Amazon EFS file system is unmounted. If for some reason a stunnel process is terminated unexpectedly, the watchdog process restarts it.

## Identity and access management for Amazon EFS

Access to Amazon EFS requires credentials that AWS can use to authenticate your requests. Those credentials must have permissions to access AWS resources, such as an Amazon EFS file system or an Amazon EC2 instance. The following sections provide details on how you can use What is IAM and Amazon EFS to help secure your resources by controlling who can access them.

- Authentication (p. 175)
- Access control (p. 176)

### Authentication

You can access AWS as any of the following types of identities:

- **AWS account root user** – When you sign up for AWS, you provide an email address and password that is associated with your AWS account. This is your AWS account root user. Its credentials provide complete access to all of your AWS resources.
  
  **Important**
  
  For security reasons, we recommend that you use the root user only to create an administrator, which is an IAM user with full permissions to your AWS account. You can then use this administrator user to create other IAM users and roles with limited permissions. For more information, see IAM Best Practices and Creating an Admin User and Group in the IAM User Guide.

- **IAM user** – An IAM user is simply an identity within your AWS account that has specific custom permissions (for example, permissions to create a file system in Amazon EFS). You can use an IAM user name and password to sign in to secure AWS web pages like the AWS Management Console, AWS Discussion Forums, or the AWS Support Center.

  In addition to a user name and password, you can also generate access keys for each user. You can use these keys when you access AWS services programmatically, either through one of the several SDKs or by using the AWS Command Line Interface (CLI). The SDK and CLI tools use the access keys to cryptographically sign your request. If you don't use the AWS tools, you must sign the request yourself. Amazon EFS supports Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 Signing Process in the AWS General Reference.

- **IAM role** – An IAM role is another IAM identity that you can create in your account that has specific permissions. It is similar to an IAM user, but it is not associated with a specific person. An IAM role enables you to obtain temporary access keys that can be used to access AWS services and resources. IAM roles with temporary credentials are useful in the following situations:
• **Federated user access** – Instead of creating an IAM user, you can use preexisting user identities from AWS Directory Service, your enterprise user directory, or a web identity provider. These are known as federated users. AWS assigns a role to a federated user when access is requested through an identity provider. For more information about federated users, see Federated Users and Roles in the IAM User Guide.

• **Cross-account administration** – You can use an IAM role in your account to grant another AWS account permissions to administer your account’s Amazon EFS resources. For an example, see Tutorial: Delegate Access Across AWS accounts Using IAM Roles in the IAM User Guide. You can't mount Amazon EFS file systems from across VPCs or accounts. For more information, see Managing file system network accessibility (p. 83).

• **AWS service access** – You can use an IAM role in your account to grant an AWS service permissions to access your account's resources. For example, you can create a role that allows Amazon Redshift to access an Amazon S3 bucket on your behalf and then load data from that bucket into an Amazon Redshift cluster. For more information, see Creating a Role to Delegate Permissions to an AWS Service in the IAM User Guide.

• **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications running on an EC2 instance and making AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs running on the EC2 instance to get temporary credentials. For more information, see Using Roles for Applications on Amazon EC2 in the IAM User Guide.

### Access control

You can have valid credentials to authenticate your requests, but unless you have permissions you can't create or access Amazon Elastic File System resources. For example, you must have permissions to create an Amazon EFS file system.

The following sections describe how to manage permissions for Amazon EFS. We recommend that you read the overview first.

- Overview of managing access permissions to your Amazon EFS resources (p. 176)
- Controlling access to the EFS API (p. 180)

### Overview of managing access permissions to your Amazon EFS resources

Every AWS resource is owned by an AWS account, and permissions to create or access a resource are governed by permissions policies. An account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles). Some services, including Amazon EFS, also support attaching permissions policies to resources.

**Note**

An account administrator (or administrator user) is a user with administrator privileges. For more information, see IAM Best Practices in the IAM User Guide.
When granting permissions, you decide who is getting the permissions, the resources they get permissions for, and the specific actions that you want to allow on those resources.

Topics
- Amazon EFS resources and operations (p. 177)
- Understanding resource ownership (p. 177)
- Managing access to resources (p. 177)
- Specifying policy elements: actions, effects, and principals (p. 179)
- Specifying conditions in a policy (p. 179)

Amazon EFS resources and operations

In Amazon EFS, the primary resource is a file system. Amazon EFS also supports additional resource types, the mount target and access point. However, for Amazon EFS, you can create mount targets and access points only in the context of an existing file system. Mount targets and access points are referred to as subresources.

These resources and subresources have unique Amazon Resource Names (ARNs) associated with them as shown in the following table.

Amazon EFS provides a set of operations to work with Amazon EFS resources. For a list of available operations, see Amazon EFS Actions (p. 231) and EFS actions for clients (p. 186).

Understanding resource ownership

The AWS account owns the resources that are created in the account, regardless of who created the resources. Specifically, the resource owner is the AWS account of the principal entity (that is, the root account, an IAM user, or an IAM role) that authenticates the resource creation request. The following examples illustrate how this works:

- If you use the root account credentials of your AWS account to create a file system, your AWS account is the owner of the resource (in Amazon EFS, the resource is the file system).
- If you create an IAM user in your AWS account and grant permissions to create a file system to that user, the user can create a file system. However, your AWS account, to which the user belongs, owns the file system resource.
- If you create an IAM role in your AWS account with permissions to create a file system, anyone who can assume the role can create a file system. Your AWS account, to which the role belongs, owns the file system resource.

Managing access to resources

A permissions policy describes who has access to what. The following section explains the available options for creating permissions policies.

Note
This section discusses using IAM in the context of Amazon EFS. It doesn’t provide detailed information about the IAM service. For complete IAM documentation, see What Is IAM? in the IAM User Guide. For information about IAM policy syntax and descriptions, see IAM Policy Reference in the IAM User Guide.

Policies attached to an IAM identity are referred to as identity-based policies (IAM policies) and policies attached to a resource are referred to as resource-based policies. Amazon EFS supports both identity-based policies and resource-based policies.
Topics

- Identity-based policies (IAM policies) (p. 178)
- Resource-based policies (p. 178)

Identity-based policies (IAM policies)

You can attach policies to IAM identities to control access to the EFS API or to control NFS client access. For example, to grant a user permissions to create an Amazon EFS resource, such as a file system, you can attach a permissions policy to a user or group that the user belongs to.

For more information about using IAM to delegate permissions, see Access Management in the IAM User Guide.

The following is an example policy that provides the EFS and EC2 permissions required for a user to perform the CreateFileSystem action for your AWS account.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Stmt1EFSpermissions",
            "Effect": "Allow",
            "Action": [
                "elasticfilesystem:CreateFileSystem",
                "elasticfilesystem:CreateMountTarget"
            ],
        },
        {
            "Sid": "Stmt2EC2permissions",
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeSubnets",
                "ec2:CreateNetworkInterface",
                "ec2:DescribeNetworkInterfaces"
            ],
            "Resource": "*"
        }
    ]
}
```

For more information about using identity-based policies with Amazon EFS, see Controlling access to the EFS API (p. 180). For more information about users, groups, roles, and permissions, see Identities (Users, Groups, and Roles) in the IAM User Guide.

Resource-based policies

You can use file system policies to control API access and NFS client access to the file system. Amazon EFS supports a resource-based policy for file systems, called a FileSystemPolicy. Using an EFS FileSystemPolicy you can specify who has access to the file system and what actions they can perform on it. Using file system policies provides you an easy way to control access to your file systems, and lets you grant usage permission to other accounts on a per-file system basis. The following file system policy grants ClientMount, or read-only, permissions to the EfsReadOnly IAM role.

```json
{
    "Version": "2012-10-17",
    "Id": "read-only-example-policy02",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "elasticfilesystem:ClientMount",
                "elasticfilesystem:CreateFileSystem",
                "elasticfilesystem:CreateMountTarget"
            ],
        }
    ]
}
```
Note

Amazon EFS file system policies have a 20,000 character limit.

For more information about using EFS file system policies to control access to file system data, see Using IAM to control file system data access (p. 185).

### Specifying policy elements: actions, effects, and principals

For each Amazon EFS resource (see Amazon EFS resources and operations (p. 177)), the service defines a set of actions API operations (see Actions (p. 231) and EFS actions for clients (p. 186)) that you can grant permissions for. For the Amazon EFS file system resource, example actions are: CreateFileSystem, DeleteFileSystem, and DescribeFileSystems. Performing an API operation can require permissions for more than one action.

The following are the most basic policy elements:

- **Resource** – In resource-based policies (file system policies), the resource that the policy is attached to is the implicit resource. For identity-based policies, you use an Amazon Resource Name (ARN) to identify the resource to which the policy applies. For more information, see Amazon EFS resources and operations (p. 177).

- **Action** – You use action keywords to identify resource operations that you want to allow or deny. For example, depending on the specified Effect, elasticfilesystem:CreateFileSystem either allows or denies the user permissions to perform the Amazon EFS CreateFileSystem operation.

- **Effect** – You specify the effect when the user requests the specific action—this can be either allow or deny. If you don't explicitly grant access to (allow) a resource, access is implicitly denied. You can also explicitly deny access to a resource, which you might do to make sure that a user cannot access it, even if a different policy grants access.

- **Principal** – In identity-based policies (IAM policies), the user that the policy is attached to is the implicit principal. For resource-based policies, you specify the user, account, service, or other entity that you want to receive permissions (applies to resource-based policies only).

To learn more about IAM policy syntax and descriptions, see IAM Policy Reference in the IAM User Guide.

For a table showing all of the Amazon EFS API actions, see Amazon EFS API permissions: actions, resources, and conditions reference (p. 183).

For a table showing all of the Amazon EFS NFS client actions, see Using IAM to control file system data access (p. 185).

### Specifying conditions in a policy

When you grant permissions, you can use the IAM policy language to specify the conditions when a policy should take effect. For more information about specifying conditions in a policy, see IAM JSON Policy Elements: Condition in the IAM User Guide.
There are both EFS-specific and AWS-wide condition keys that you can use as appropriate. For a complete list of AWS-wide keys, see Available Keys for Conditions in the IAM User Guide. For a complete list of EFS-specific condition keys, see EFS condition keys for clients (p. 186).

**Note**

The `aws:SourceIp` AWS-wide condition can be used to control what hosts are able to use EFS actions like CreateFileSystem, CreateMountTarget, DeleteMountTarget, DescribeMountTargetSecurityGroups, or ModifyMountTargetSecurityGroup actions. The `aws:SourceIp` condition can be used to control NFS access to EFS mount targets, but it is not the recommended approach due to security considerations. To control access to EFS mount targets, see Controlling network access to Amazon EFS file systems for NFS clients (p. 195).

### Controlling access to the EFS API

You can use both IAM identity policies and resource policies to grant permissions to perform API operations on Amazon EFS resources. This topic provides examples of identity-based policies that demonstrate how an account administrator can attach permissions policies to IAM identities (that is, users, groups, and roles) because this is the most common way of controlling access to the Amazon EFS API.

**Important**

We recommend that you first review the introductory topics that explain the basic concepts and options available for you to manage access to your Amazon EFS resources. For more information, see Overview of managing access permissions to your Amazon EFS resources (p. 176).

The sections in this topic cover the following:

- Permissions Required to Use the Amazon EFS Console (p. 181)
- AWS managed (predefined) policies for Amazon EFS (p. 182)
- Customer managed policy examples (p. 182)

The following shows an example of a permissions policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowFileSystemPermissions",
      "Effect": "Allow",
      "Action": [
        "elasticfilesystem:CreateFileSystem",
        "elasticfilesystem:CreateMountTarget"
      ],
    },
    {
      "Sid": "AllowEC2Permissions",
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeSubnets",
        "ec2:CreateNetworkInterface",
        "ec2:DescribeNetworkInterfaces"
      ],
      "Resource": "*"
    }
  ]
}
```
The policy has two statements:

- The first statement grants permissions for two Amazon EFS actions (elasticfilesystem:CreateFileSystem and elasticfilesystem:CreateMountTarget) on a resource using the Amazon Resource Name (ARN) for the file system. The ARN specifies a wild card character (*) because you don't know the file system ID until after you create a file system.
- The second statement grants permissions for some of the Amazon EC2 actions because the elasticfilesystem:CreateMountTarget action in the first statement requires permissions for specific Amazon EC2 actions. Because these Amazon EC2 actions don't support resource-level permissions, the policy specifies the wild card character (*) as the Resource value instead of specifying a file system ARN.

The policy doesn't specify the Principal element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permissions policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

For a table showing all of the Amazon EFS API actions and the resources that they apply to, see Amazon EFS API permissions: actions, resources, and conditions reference (p. 183).

**Permissions Required to Use the Amazon EFS Console**

The permissions reference table lists the Amazon EFS API operations and shows the required permissions for each operation. For more information about Amazon EFS API operations, see Amazon EFS API permissions: actions, resources, and conditions reference (p. 183).

To use the Amazon EFS console, you need to grant permissions for additional actions as shown in the following permissions policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Stmt1AdditionalEC2PermissionsForConsole",
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeAvailabilityZones",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeVpcs",
        "ec2:DescribeVpcAttribute"
      ],
      "Resource": "*"
    },
    {
      "Sid": "Stmt2AdditionalKMSPermissionsForConsole",
      "Effect": "Allow",
      "Action": [
        "kms:ListAliases",
        "kms:DescribeKey"
      ],
      "Resource": "*"
    }
  ]
}
```

The Amazon EFS console needs these additional permissions for the following reasons:

- Permissions for the Amazon EFS actions enable the console to display Amazon EFS resources in the account.
• The console needs permissions for the ec2 actions to query Amazon EC2 so it can display Availability Zones, VPCs, security groups, and account attributes.
• The console needs permissions for the kms actions to create an encrypted file system. For more information on encrypted file systems, see Data encryption in Amazon EFS (p. 169).

**AWS managed (predefined) policies for Amazon EFS**

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. Managed policies grant necessary permissions for common use cases so you can avoid having to investigate what permissions are needed. For more information, see AWS Managed Policies in the IAM User Guide.

The following AWS managed policies, which you can attach to users in your account, are specific to Amazon EFS:

- **AmazonElasticFileSystemReadOnlyAccess** – Grants read-only access to Amazon EFS resources.
- **AmazonElasticFileSystemFullAccess** – Grants full access to Amazon EFS resources.

**Note**

You can review these permissions policies by signing in to the IAM management console and searching for specific policies there.

You can also create your own custom IAM policies to allow permissions for Amazon EFS API actions. You can attach these custom policies to the IAM users or groups that require those permissions.

**Customer managed policy examples**

In this section, you can find example user policies that grant permissions for various Amazon EFS actions. These policies work when you are using AWS SDKs or the AWS CLI. When you are using the console, you need to grant additional permissions specific to the console, which is discussed in Permissions Required to Use the Amazon EFS Console (p. 181).

**Note**

All examples use the us-west-2 AWS Region and contain fictitious account IDs.

**Examples**

- **Example 1: Allow a user to create a mount target and tags on an existing file system** (p. 182)
- **Example 2: Allow a user to perform all Amazon EFS actions** (p. 183)

**Example 1: Allow a user to create a mount target and tags on an existing file system**

The following permissions policy grants the user permissions to create mount targets and tags on a particular file system in the us-west-2 Region. To create mount targets, permissions for specific Amazon EC2 actions are also required and are included in the permissions policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
        {
            "Sid": "Stmt1CreateMountTargetAndTag",
            "Effect": "Allow",
            "Action": [
                "elasticfilesystem:CreateMountTarget",
                "elasticfilesystem:DescribeMountTargets",
                "elasticfilesystem:CreateTags",
                "ec2:CreateVolume",
                "ec2:AttachVolume"
            ],
```
Example 2: Allow a user to perform all Amazon EFS actions

The following permissions policy uses a wild card character ("elasticfilesystem:*") to allow all Amazon EFS actions in the us-west-2 Region. Because some of the Amazon EFS actions also require permissions for Amazon EC2 actions, the policy also grants permissions for all those actions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Stmt1PermissionForAllEFSActions",
      "Effect": "Allow",
      "Action": ["elasticfilesystem:*"],
    },
    {
      "Sid": "Stmt2RequiredEC2PermissionsForAllEFSActions",
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

Amazon EFS API permissions: actions, resources, and conditions reference

When you are setting up Access control (p. 176) and writing a permissions policy that you can attach to an IAM identity (identity-based policies), you can use the following list as a reference. The list includes each Amazon EFS API operation, the corresponding actions for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions. You specify the actions in the policy's Action field, and you specify the resource value in the policy's Resource field.

You can use AWS-wide condition keys in your Amazon EFS policies to express conditions. For a complete list of AWS-wide keys, see Available Keys in the IAM User Guide.
Note
To specify an action, use the `elasticfilesystem:` prefix followed by the API operation name (for example, `elasticfilesystem:CreateFileSystem`).

Amazon EFS API and Required Permissions for Actions

CreateFileSystem (p. 238)

**Action or Actions:** `elasticfilesystem:CreateFileSystem`

**Resource:** `arn:aws:elasticfilesystem:region:account-id:file-system/*`

CreateMountTarget (p. 248)

**Action or Actions:** `elasticfilesystem:CreateMountTarget`, `ec2:DescribeSubnets`, `ec2:DescribeNetworkInterfaces`, `ec2:CreateNetworkInterface`

**Resource:** `arn:aws:elasticfilesystem:region:account-id:file-system/file-system-id`

CreateTags (p. 256)

**Action or Actions:** `elasticfilesystem:CreateTags`

**Resource:** `arn:aws:elasticfilesystem:region:account-id:file-system/file-system-id`

DeleteFileSystem (p. 260)

**Action or Actions:** `elasticfilesystem:DeleteFileSystem`

**Resource:** `arn:aws:elasticfilesystem:region:account-id:file-system/file-system-id`

DeleteMountTarget (p. 264)

**Action or Actions:** `elasticfilesystem:DeleteMountTarget`, `ec2:DeleteNetworkInterface`

**Resource:** `arn:aws:elasticfilesystem:region:account-id:file-system/file-system-id`

DeleteTags (p. 267)

**Action or Actions:** `elasticfilesystem:DeleteTags`

**Resource:** `arn:aws:elasticfilesystem:region:account-id:file-system/file-system-id`

DescribeFileSystems (p. 279)

**Action or Actions:** `elasticfilesystem:DescribeFileSystems`

DescribeLifecycleConfiguration (p. 283)

**Action or Actions:** `elasticfilesystem:DescribeLifecycleConfiguration`

**Resource:** `arn:aws:elasticfilesystem:region:account-id:file-system/file-system-id`

DescribeMountTargetSecurityGroups (p. 290)

**Action or Actions:** `elasticfilesystem:DescribeMountTargetSecurityGroups`, `ec2:DescribeNetworkInterfaceAttribute`
Using IAM to control file system data access

You can use both IAM identity policies and resource policies to control client access to Amazon EFS resources in a way that is scalable and optimized for cloud environments. Using IAM, you can permit clients to perform specific actions on a file system, including read-only, write, and root access.
NFS clients can identify themselves using an IAM role when connecting to an EFS file system. When a client connects to a file system, Amazon EFS evaluates the file system's IAM resource policy, which is called a file system policy, along with any identity-based IAM policies to determine the appropriate file system access permissions to grant.

When you use IAM authorization for NFS clients, client connections and IAM authorization decisions are logged to AWS CloudTrail. For more information about how to log Amazon EFS API calls with CloudTrail, see Logging Amazon EFS API Calls with AWS CloudTrail (p. 112).

**Important**
You must use the EFS mount helper to mount your Amazon EFS file systems in order to use IAM authorization to control client access. For more information, see Mounting with IAM authorization (p. 67).

**Default EFS file system policy**

The default EFS file system policy grants full access to any client that can connect to the file system using a file system mount target. The default policy is in effect whenever a user-configured file system policy is not in effect, including at file system creation. Whenever the default file system policy is in effect, a `DescribeFileSystemPolicy` (p. 276) API operation returns a `PolicyNotFound` response.

**EFS actions for clients**

You can specify the following actions for clients accessing a file system using a file system policy.

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>elasticfilesystem:ClientMount</td>
<td>Provides read-only access to a file system.</td>
</tr>
<tr>
<td>elasticfilesystem:ClientWrite</td>
<td>Provides write permissions on a file system.</td>
</tr>
<tr>
<td>elasticfilesystem:ClientRootAccess</td>
<td>Provides use of the root user when accessing a file system.</td>
</tr>
</tbody>
</table>

**EFS condition keys for clients**

To express conditions, you use predefined condition keys. Amazon EFS has the following predefined condition keys for NFS clients.

<table>
<thead>
<tr>
<th>EFS Condition Key</th>
<th>Description</th>
<th>Operator</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws:SecureTransport</td>
<td>Use this key to require clients to use TLS when connecting to an EFS file system.</td>
<td>Boolean</td>
</tr>
<tr>
<td>elasticfilesystem:AccessPointArn</td>
<td>ARN of the EFS access point to which the client is connecting.</td>
<td></td>
</tr>
<tr>
<td>elasticfilesystem:AccessedViaMountTarget</td>
<td>Prevent access to an EFS file system by clients that are not using file system mount targets.</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

**File system policy examples**

In this section, you can find example file system policies that grant or deny permissions for various Amazon EFS actions. Amazon EFS file system policies have a 20,000 character limit. For information
about the elements of a resource-based policy, see Specifying policy elements: actions, effects, and principals (p. 179).

Important

If you grant permission to an individual IAM user or role in a file system policy, don’t delete or recreate that user or role while the policy is in effect on the file system. If this happens, that user or role is effectively locked out from file system and will not be able to access it. For more information, see Specifying a Principal in the IAM User Guide.

For information about how to create a file system policy, see Creating file system policies (p. 39).

Example 1: Grant read and write access to a specific AWS user

This example EFS file system policy has the following characteristics:

- The effect is Allow.
- The principal is set to user CarlosSalazar.
- The action is set to ClientMount (read), and ClientWrite.
- The condition for granting permissions is set to SecureTransport—only clients using the TLS encryption protocol are granted access.

```
{
   "Version": "2012-10-17",
   "Id": "ExamplePolicy01",
   "Statement": [
       {
           "Sid": "ExampleStatement01",
           "Effect": "Allow",
           "Principal": {
               "AWS": "arn:aws:iam::111122223333:user/CarlosSalazar"
           },
           "Action": [
               "elasticfilesystem:ClientMount",
               "elasticfilesystem:ClientWrite"
           ],
           "Condition": {
               "Bool": {
                   "aws:SecureTransport": "true"
               }
           }
       }
   ]
}
```

Example 2: Grant read-only access

The following file system policy only grants ClientMount, or read-only, permissions to the EfsReadOnly IAM role.

```
{
   "Id": "read-only-example-policy02",
   "Statement": [
       {
           "Sid": "efs-statement-example02",
           "Effect": "Allow",
           "Principal": {
               "AWS": "arn:aws:iam::111122223333:role/EfsReadOnly"
           }
       }
   ]
}
```
Using IAM to enforce creating encrypted file systems

You can create an AWS Identity and Access Management (IAM) identity-based policy to control whether users can create Amazon EFS file systems that are encrypted at rest. The Boolean condition key `elasticfilesystem:Encrypted` specifies the type of file system, encrypted or unencrypted, that the policy applies to. You use the condition key with the `elasticfilesystem:CreateFileSystem` action and the policy effect, allow or deny, to create a policy for creating encrypted or unencrypted file systems.

For example, an IAM policy that explicitly allows users to create only encrypted EFS file systems uses the following combination of effect, action, and condition:

- The Effect is Allow.
- The Action is `elasticfilesystem:CreateFileSystem`.
- The Condition `elasticfilesystem:Encrypted` is True.

The following example illustrates an IAM identity-based policy that authorizes principals to create only encrypted file systems.

```
"Action": [
  "elasticfilesystem:ClientMount"
],
}
}
```

To learn how to set additional file system policies, including denying root access to all IAM principals, except for a specific management workstation, see Walkthrough: Enable root squashing using IAM authorization for NFS clients (p. 166).

Example 3: Grant access to an EFS Access Point

You use an EFS access policy to provide an NFS client with an application-specific view into shared file-based datasets on an EFS file system. You grant the access point permissions on the file system using a file system policy. This file policy example uses a condition element to grant a specific access point that is identified by its ARN full access to the file system. For more information about using EFS access points, see Working with Amazon EFS Access Points (p. 202).

```
{
  "Id": "access-point-example03",
  "Statement": [
    {
      "Sid": "access-point-statement-example03",
      "Effect": "Allow",
      "Principal": {"AWS": "arn:aws:iam::555555555555:role/EfsAccessPointFullAccess"},
      "Action": "elasticfilesystem:Client*",
      "Condition": {
        "StringEquals": {
      }
    }
  ]
}
```

Using IAM to enforce creating encrypted file systems

You can create an AWS Identity and Access Management (IAM) identity-based policy to control whether users can create Amazon EFS file systems that are encrypted at rest. The Boolean condition key `elasticfilesystem:Encrypted` specifies the type of file system, encrypted or unencrypted, that the policy applies to. You use the condition key with the `elasticfilesystem:CreateFileSystem` action and the policy effect, allow or deny, to create a policy for creating encrypted or unencrypted file systems.

For example, an IAM policy that explicitly allows users to create only encrypted EFS file systems uses the following combination of effect, action, and condition:

- The Effect is Allow.
- The Action is `elasticfilesystem:CreateFileSystem`.
- The Condition `elasticfilesystem:Encrypted` is True.

The following example illustrates an IAM identity-based policy that authorizes principals to create only encrypted file systems.
If this policy is attached to a user who tries to create an unencrypted file system, the request fails. The user sees a message similar to the following, whether they are using the AWS Management Console, the AWS CLI, or the AWS API or SDK:

An IAM policy that explicitly allows creating only unencrypted EFS file systems can use the following combination of effect, action, and condition:

- The Effect is Allow.
- The Action is elasticfilesystem:CreateFileSystem.
- The Condition elasticfilesystem:Encrypted is False.

The following example illustrates an IAM identity-based policy that authorizes principals to create only unencrypted file systems.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "VisualEditor1",
         "Effect": "Allow",
         "Action": "elasticfilesystem:CreateFileSystem",
         "Condition": {
            "Bool": {
               "elasticfilesystem:Encrypted": "false"
            }
         },
         "Resource": "*"
      }
   ]
}
```

If this policy is attached to a user who tries to create an encrypted file system, the request fails. The user sees a message similar to the following, whether they are using the AWS Management Console, the AWS CLI, or the AWS API or SDK:

You can also use policies like the previous examples in an AWS Organizations service control policy (SCP) to enforce the creation of encrypted Amazon EFS file systems for all AWS accounts in your organization. For more information about service control policies in AWS Organizations, see Service control policies in the AWS Organizations User Guide.

Create an IAM policy that authorizes users to create only encrypted efs file systems

You can create an IAM identity-based policy that authorizes users to create only encrypted Amazon EFS file systems using the console, the AWS CLI, and the API. The following procedure describes how to create such a policy using the IAM console, and then apply the policy to a user in your account.

To create an IAM policy to enforce creating encrypted EFS file systems

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, under Access management, choose Policies.
3. Choose Create policy to display the Create policy page.
4. Enter the following information using the Visual editor:
   - For Service, choose EFS.
   - For Actions, enter create in the search field, and then choose CreateFileSystem.
   - For Request conditions, choose Encrypted.
5. Choose Review policy to display the Review policy page.
6. Provide a Name and a Description for the policy. Verify the policy summary, including the Encrypted request condition. Choose Create policy to create the policy.

To apply the policy to a user in your account

1. In the IAM console, under Access management, choose Users.
2. Select the user that you want to apply the policy to.
3. Choose Add permissions to display the Add permissions page.
4. Choose Attach existing policies directly.
5. Enter the name of the EFS policy that you created in the previous procedure.
6. Select and expand the policy. Then choose JSON to verify the policy content. It should look like the following JSON policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": "elasticfilesystem:CreateFileSystem",
         "Condition": {
            "Bool": {
               "elasticfilesystem:Encrypted": "true"
            }
         },
         "Resource": "*"
      }
   ]
}
```
7. Choose **Next: Review**.
8. Choose **Add permissions** to apply the policy to the user. This user can now only create Amazon EFS file systems that are encrypted at rest.

**Blocking public access**

The Amazon EFS block public access feature provides settings to help you manage public access to Amazon EFS file systems. By default, new Amazon EFS file systems don't allow public access. However, you can modify file system policies to allow public access.

**Topics**
- Blocking public access with AWS Transfer Family (p. 191)
- The meaning of "public" (p. 191)

**Blocking public access with AWS Transfer Family**

When you use Amazon EFS with AWS Transfer Family, file system access requests received from a Transfer Family server that is owned by a different account than the file system are blocked if the file system allows public access. Amazon EFS evaluates the file system's IAM policies, and if the policy is public, it blocks the request. To permit AWS Transfer Family access to your file system, update your file system policy so that it is not considered public.

**Note**

Using Transfer Family with Amazon EFS is disabled by default for AWS accounts that have EFS file systems with policies that allow public access that were created before January 6, 2021. To enable using Transfer Family to access your file system, contact AWS Support.

**The meaning of "public"**

When evaluating whether a file system allows public access, Amazon EFS assumes that the file system policy is public. It then evaluates the file system policy to determine if it qualifies as non-public. To be considered non-public, a file system policy must grant access only to fixed values (values that don't contain a wild card) of one or more of the following:

- A set of Classless Inter-Domain Routings (CIDRs), using `aws:SourceIp`
- An AWS principal, user, role, or service principal (for example, `aws:PrincipalOrgID`)
- `aws:SourceArn`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:SourceOwner`
- `aws:SourceAccount`
- `elasticfilesystem:AccessedViaMountTarget`
- `aws:userid`, outside the pattern "AROLEID:*"

Under these rules, the following example policy is considered public.

```json
{
    "Version": "2012-10-17",
    "Id": "efs-policy-wizard-15ad9567-2546-4bbb-8168-5541b6fc0e55",
    "Statement": [
        {
            "Sid": "efs-statement-14a7191c-9401-40e7-a388-6af6cfb7dd9c",
```
Using the EFS Service-Linked Role

You can make this file system policy non-public by using the EFS condition key elasticfilesystem:AccessedViaMountTarget set to true. You can use elasticfilesystem:AccessedViaMountTarget to allow the specified EFS actions to clients accessing the EFS file system using a file system mount target. The following non-public policy uses the elasticfilesystem:AccessedViaMountTarget condition key set to true.

```json
{
    "Version": "2012-10-17",
    "Id": "efs-policy-wizard-15ad9567-2546-4bbb-8168-5541b6fc0e55",
    "Statement": [
        {
            "Sid": "efs-statement-14a7191c-9401-40e7-a388-6af6cfb7dd9c",
            "Effect": "Allow",
            "Principal": {
                "AWS": "*"
            },
            "Action": [
                "elasticfilesystem:ClientMount",
                "elasticfilesystem:ClientWrite",
                "elasticfilesystem:ClientRootAccess"
            ],
            "Condition": {
                "Bool": {
                    "elasticfilesystem:AccessedViaMountTarget": "true"
                }
            }
        }
    ]
}
```

For more information about Amazon EFS condition keys, see EFS condition keys for clients (p. 186). For more information about creating file system policies, see Creating file system policies (p. 39).

Using the Amazon EFS Service-Linked Role

Amazon Elastic File System uses an AWS Identity and Access Management (IAM) service-linked role. The Amazon EFS service-linked role is a unique type of IAM role that is linked directly to Amazon EFS. The predefined Amazon EFS service-linked role includes permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon EFS easier because you don't have to manually add the necessary permissions. Amazon EFS defines the permissions of its service-linked role, and only Amazon EFS can assume its role. The defined permissions include the trust policy and the permissions policy, and that permissions policy can't be attached to any other IAM entity.

You can delete the Amazon EFS service-linked role only after first deleting your Amazon EFS file systems. This protects your Amazon EFS resources because you can't inadvertently remove permission to access the resources.
The service-linked role enables all API calls to be visible through AWS CloudTrail. This helps with monitoring and auditing requirements because you can track all actions that Amazon EFS performs on your behalf. For more information, see Log Entries for EFS Service Linked Roles (p. 114).

**Service-Linked Role Permissions for Amazon EFS**

Amazon EFS uses the service-linked role named `AWSServiceRoleForAmazonElasticFileSystem` to allow Amazon EFS to call and manage AWS resources on behalf of your EFS file systems.

The `AWSServiceRoleForAmazonElasticFileSystem` service-linked role trusts the following services to assume the role:

* `elasticfilesystem.amazonaws.com`

The role permissions policy allows Amazon EFS to complete the actions included the policy definition JSON:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "backup-storage:MountCapsule",
        "ec2:CreateNetworkInterface",
        "ec2:DeleteNetworkInterface",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeSubnets",
        "ec2:DescribeNetworkInterfaceAttribute",
        "ec2:ModifyNetworkInterfaceAttribute",
        "tag:GetResources"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "kms: DescribeKey"
      ],
      "Resource": "arn:aws:kms:*:*:key/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "backup: CreateBackupVault",
        "backup: PutBackupVaultAccessPolicy"
      ],
      "Resource": ["arn:aws:backup:*:*:backup-vault:aws/efs/automatic-backup-vault"
    },
    {
      "Effect": "Allow",
      "Action": [
        "backup: CreateBackupPlan",
        "backup: CreateBackupSelection"
      ],
      "Resource": ["arn:aws:backup:*:*:backup-plan:*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "backup: CreateBackupPlan",
        "backup: CreateBackupSelection"
      ],
      "Resource": ["arn:aws:backup:*:*:backup-plan:*"
    }
  ]
}
```
You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the IAM User Guide.

**Note**
You must manually configure IAM permissions for AWS KMS when creating a new Amazon EFS file system that is encrypted at rest. To learn more, see Encrypting data at rest (p. 170).

### Creating a Service-Linked Role for Amazon EFS

You don't need to manually create a service-linked role. When you create mount targets for your EFS file system in the AWS Management Console, the AWS CLI, or the AWS API, Amazon EFS creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create mount targets for your EFS file system, Amazon EFS creates the service-linked role for you again.

### Editing a Service-Linked Role for Amazon EFS

Amazon EFS doesn't allow you to edit the AWSServiceRoleForAmazonElasticFileSystem service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the IAM User Guide.

### Deleting a Service-Linked Role for Amazon EFS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.
Note
If the Amazon EFS service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete Amazon EFS resources used by the AWSServiceRoleForAmazonElasticFileSystem

Complete the following steps to delete Amazon EFS resources used by the AWSServiceRoleForAmazonElasticFileSystem. For the detailed procedure, see Step 4: Clean up resources and protect your AWS account (p. 18).

1. On your Amazon EC2 instance, unmount the Amazon EFS file system.
2. Delete the Amazon EFS file system.
3. Delete the custom security group for the file system.

Warning
If you used the default security group for your virtual private cloud (VPC), do not delete that security group.

To manually delete the service-linked role using IAM

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForAmazonElasticFileSystem service-linked role. For more information, see Deleting a Service-Linked Role in the IAM User Guide.

Controlling network access to Amazon EFS file systems for NFS clients

You can control access by NFS clients to Amazon EFS file systems using network layer security and EFS file system policies. You can use the network layer security mechanisms available with Amazon EC2, such as VPC security group rules and network ACLs. You can also use AWS IAM to control NFS access with an EFS file system policy and identity-based policies.

Topics
- Using VPC security groups for Amazon EC2 instances and mount targets (p. 195)
- Source ports for working with EFS (p. 196)
- Security considerations for network access (p. 197)
- Working with Interface VPC Endpoints in Amazon EFS (p. 197)

Using VPC security groups for Amazon EC2 instances and mount targets

When using Amazon EFS, you specify Amazon EC2 security groups for your EC2 instances and security groups for the EFS mount targets associated with the file system. A security group acts as a firewall, and the rules that you add define the traffic flow. In the Getting Started exercise, you created one security group when you launched the EC2 instance. You then associated another with the EFS mount target (that is, the default security group for your default VPC). That approach works for the Getting Started exercise. However, for a production system, you should set up security groups with minimal permissions for use with EFS.

You can authorize inbound and outbound access to your EFS file system. To do so, you add rules that allow your EC2 instance to connect to your Amazon EFS file system through the mount target using the Network File System (NFS) port. Take the following steps to create and update your security groups.
To create security groups for EC2 instances and mount targets

1. Create two security groups in your VPC.

   For instructions, see the procedure "To create a security group" in Creating a Security Group in the Amazon VPC User Guide.

2. Open the Amazon VPC Management Console at https://console.aws.amazon.com/vpc/, and verify the default rules for these security groups. Both security groups should have only an outbound rule that allows traffic to leave.

To update the necessary access for your security groups

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

2. Add a rule for your EC2 security group to allow inbound access using Secure Shell (SSH) from any host. Optionally, restrict the Source address.

   You don't need to add an outbound rule, because the default outbound rule allows all traffic to leave. If this were not the case, you’d need to add an outbound rule to open the TCP connection on the NFS port, identifying the mount target security group as the destination.

3. Add a rule for the mount target security group to allow inbound access from the EC2 security group as shown following. The EC2 security group is identified as the source.

4. Verify that both security groups now authorize inbound and outbound access.

For more information about security groups, see Security Groups for EC2-VPC in the Amazon EC2 User Guide for Linux Instances.

Source ports for working with EFS

To support a broad set of NFS clients, Amazon EFS allows connections from any source port. If you require that only privileged users can access Amazon EFS, we recommend using the following client firewall rule.

```
iptables -I OUTPUT 1 -m owner --uid-owner 1-4294967294 -m tcp -p tcp --dport 2049 -j DROP
```
This command inserts a new rule at the start of the OUTPUT chain (\texttt{\text{-I OUTPUT 1}}). The rule prevents any unprivileged, nonkernel process (\texttt{-m owner --uid-owner 1-4294967294}) from opening a connection to the NFS port (\texttt{-m tcp -p tcp -dport 2049}).

### Security considerations for network access

An NFS version 4.1 (NFSv4.1) client can only mount a file system if it can make a network connection to the NFS port of one of the file system's mount targets. Similarly, an NFSv4.1 client can only assert a user and group ID when accessing a file system if it can make this network connection.

Whether you can make this network connection is governed by a combination of the following:

- **Network isolation provided by the mount targets' VPC** – File system mount targets can't have public IP addresses associated with them. The only targets that can mount file systems are the following:
  - Amazon EC2 instances in the local Amazon VPC
  - EC2 instances in connected VPCs
  - On-premises servers connected to an Amazon VPC by using AWS Direct Connect and an AWS Virtual Private Network (VPN)
- **Network access control lists (ACLs) for the VPC subnets of the client and mount targets, for access from outside the mount target's subnets** – To mount a file system, the client must be able to make a TCP connection to the NFS port of a mount target and receive return traffic.
- **Rules of the client's and mount targets' VPC security groups, for all access** – For an EC2 instance to mount a file system, the following security group rules must be in effect:
  - The file system must have a mount target whose network interface has a security group with a rule that enables inbound connections on the NFS port from the instance. You can enable inbound connections either by IP address (CIDR range) or security group. The source of the security group rules for the inbound NFS port on mount target network interfaces is a key element of file system access control. Inbound rules other than the one for the NFS port, and any outbound rules, aren't used by network interfaces for file system mount targets.
  - The mounting instance must have a network interface with a security group rule that enables outbound connections to the NFS port on one of the file system's mount targets. You can enable outbound connections either by IP address (CIDR range) or security group.

For more information, see Creating and managing mount targets (p. 31).

### Working with Interface VPC Endpoints in Amazon EFS

To establish a private connection between your virtual private cloud (VPC) and the Amazon EFS API, you can create an interface VPC endpoint. You can use this connection to call the Amazon EFS API from your VPC without sending traffic over the internet. The endpoint provides secure connectivity to the Amazon EFS API without requiring an internet gateway, NAT instance, or virtual private network (VPN) connection. For more information, see Interface VPC Endpoints in the Amazon VPC User Guide.

Interface VPC endpoints are powered by AWS PrivateLink, a feature that enables private communication between AWS services using private IP addresses. To use AWS PrivateLink, create an interface VPC endpoint for Amazon EFS in your VPC using the Amazon VPC console, API, or CLI. Doing this creates an elastic network interface in your subnet with a private IP address that serves Amazon EFS API requests. You can also access a VPC endpoint from on-premises environments or from other VPCs using AWS VPN, AWS Direct Connect, or VPC peering. To learn more, see Accessing Services Through AWS PrivateLink in the Amazon VPC User Guide.

### Creating an Interface Endpoint for Amazon EFS

To create an interface VPC endpoint for Amazon EFS, use one of the following:
• `com.amazonaws.region.elasticfilesystem` – Creates an endpoint for Amazon EFS API operations.
• `com.amazonaws.region.elasticfilesystem-fips` – Creates an endpoint for the Amazon EFS API that complies with Federal Information Processing Standard (FIPS) 140-2.

For a complete list of Amazon EFS endpoints, see Amazon Elastic File System in the Amazon Web Services General Reference.

For more information about how to create an interface endpoint, see Creating an Interface Endpoint in the Amazon VPC User Guide.

Creating a VPC Endpoint Policy for Amazon EFS

To control access to the Amazon EFS API, you can attach an AWS Identity and Access Management (IAM) policy to your VPC endpoint. The policy specifies the following:

• The principal that can perform actions.
• The actions that can be performed.
• The resources on which actions can be performed.

For more information, see Controlling Access to Services with VPC Endpoints in the Amazon VPC User Guide.

The following example shows a VPC endpoint policy that denies everyone permission to create an EFS file system through the endpoint. The example policy also grants everyone permission to perform all other actions.

```json
{
  "Statement": [
    {
      "Action": "*",
      "Effect": "Allow",
      "Resource": "*",
      "Principal": "*"
    },
    {
      "Action": "elasticfilesystem:CreateFileSystem",
      "Effect": "Deny",
      "Resource": "*",
      "Principal": "*"
    }
  ]
}
```

For more information, see Using VPC Endpoint Policies in the Amazon VPC User Guide.

Working with users, groups, and permissions at the Network File System (NFS) Level

Topics
• File and directory permissions (p. 199)
• Example Amazon EFS file system use cases and permissions (p. 199)
• User and Group ID Permissions for Files and Directories Within a File System (p. 200)
• No Root Squashing (p. 201)
• Permissions Caching (p. 201)
• Changing File System Object Ownership (p. 201)
• EFS Access Points (p. 202)

After creating a file system, by default only the root user (UID 0) has read, write, and execute permissions. For other users to modify the file system, the root user must explicitly grant them access. You can use access points to automate the creation of directories that a nonroot user can write from. For more information, see Working with Amazon EFS Access Points (p. 202).

Amazon EFS file system objects have a Unix-style mode associated with them. This mode value defines the permissions for performing actions on that object. Users familiar with Unix-style systems can easily understand how Amazon EFS behaves with respect to these permissions.

Additionally, on Unix-style systems, users and groups are mapped to numeric identifiers, which Amazon EFS uses to represent file ownership. For Amazon EFS, file system objects (that is, files, directories, and so on) are owned by a single owner and a single group. Amazon EFS uses the mapped numeric IDs to check permissions when a user attempts to access a file system object.

Following, you can find examples of permissions and a discussion about NFS permissions considerations for Amazon EFS.

File and directory permissions

Files and directories in an EFS file system support standard Unix-style read, write, and execute permissions based on the user and group ID asserted by the mounting NFSv4.1 client, unless overridden by an EFS access point. For more information, see Working with users, groups, and permissions at the Network File System (NFS) Level (p. 198).

Note
By default, this layer of access control depends on trusting the NFSv4.1 client in its assertion of the user and group ID. You can use AWS Identity and Access Management (IAM) resource-based policies and identity policies to authorize NFS clients and provide read-only, write, and root access permissions. You can use EFS access points to override the operating system user and group identity information provided by the NFS client. For more information, see Using IAM to control file system data access (p. 185) and Creating and deleting access points (p. 41).

As an example of read, write, and execute permissions for files and directories, Alice might have permissions to read and write to any files that she wants to in her personal directory on a file system, /alice. However, in this example Alice is not allowed to read or write to any files in Mark's personal directory on the same file system, /mark. Both Alice and Mark are allowed to read but not write files in the shared directory /share.

Example Amazon EFS file system use cases and permissions

After you create an Amazon EFS file system and mount targets for the file system in your VPC, you can mount the remote file system locally on your Amazon EC2 instance. The mount command can mount any directory in the file system. However, when you first create the file system, there is only one root directory at /.

The following mount command mounts the root directory of an Amazon EFS file system, identified by the file system DNS name, on the /efs-mount-point local directory.
The root user and root group own the mounted directory.

The initial permissions mode allows:

- read-write-execute permissions to the owner root
- read-execute permissions to the group root
- read-execute permissions to others

Only the root user can modify this directory. The root user can also grant other users permissions to write to this directory, for example:

- Create writable per-user subdirectories. For step-by-step instructions, see Walkthrough: Create Writable Per-User Subdirectories and Configure Automatic Remounting on Reboot (p. 152).
- Allow users to write to the Amazon EFS file system root. A user with root privileges can grant other users access to the file system.
- To change the Amazon EFS file system ownership to a non-root user and group, use the following:

  ```sh
  $ sudo chown user:group /EFSroot
  ```

- To change permissions of the file system to something more permissive, use the following:

  ```sh
  $ sudo chmod 777 /EFSroot
  ```

  This command grants read-write-execute privileges to all users on all EC2 instances that have the file system mounted.

User and Group ID Permissions for Files and Directories Within a File System

Files and directories in an Amazon EFS file system support standard Unix-style read, write, and execute permissions based on the user ID and group IDs. When an NFS client mounts an EFS file system without using an access point, the user ID and group ID provided by the client is trusted. You can use EFS access points to override user ID and group IDs used by the NFS client. When users attempt to access files and directories, Amazon EFS checks their user IDs and group IDs to verify that each user has permission to access the objects. Amazon EFS also uses these IDs to indicate the owner and group owner for new files and directories that the user creates. Amazon EFS doesn't examine user or group names—it only uses the numeric identifiers.

**Note**

When you create a user on an EC2 instance, you can assign any numeric user ID (UID) and group ID (GID) to the user. The numeric user IDs are set in the `/etc/passwd` file on Linux systems. The numeric group IDs are in the `/etc/group` file. These files define the mappings between names and IDs. Outside of the EC2 instance, Amazon EFS doesn't perform any authentication of these IDs, including the root ID of 0.
If a user accesses an Amazon EFS file system from two different EC2 instances, depending on whether
the UID for the user is the same or different on those instances you see different behavior, as follows:

- If the user IDs are the same on both EC2 instances, Amazon EFS considers them to indicate the same
  user, regardless of the EC2 instance used. The user experience when accessing the file system is the
  same from both EC2 instances.
- If the user IDs aren't the same on both EC2 instances, Amazon EFS considers the users to be different
  users. The user experience isn't the same when accessing the Amazon EFS file system from the two
  different EC2 instances.
- If two different users on different EC2 instances share an ID, Amazon EFS considers them to be the
  same user.

You might consider managing user ID mappings across EC2 instances consistently. Users can check their
numeric ID using the `id` command, as shown following.

```
$ id
uid=502(joe) gid=502(joe) groups=502(joe)
```

**Turn Off the ID Mapper**

The NFS utilities in the operating system include a daemon called an ID Mapper that manages mapping
between user names and IDs. In Amazon Linux, the daemon is called `rpc.idmapd` and on Ubuntu is
called `idmapd`. It translates user and group IDs into names, and vice versa. However, Amazon EFS deals
only with numeric IDs. We recommend that you turn this process off on your EC2 instances. On Amazon
Linux, the ID mapper is usually disabled, and if it is don't enable it. To turn off the ID mapper, use the
commands shown following.

```
$ service rpcidmapd status
$ sudo service rpcidmapd stop
```

**No Root Squashing**

By default, root squashing is disabled on EFS file systems. Amazon EFS behaves like a Linux NFS server
with `no_root_squash`. If a user or group ID is 0, Amazon EFS treats that user as the root user,
and bypasses permissions checks (allowing access and modification to all file system objects). Root
squashing can be enabled on a client connection when the AWS Identity and Access Management (AWS
IAM) identity or resource policy does not allow access to the `ClientRootAccess` action. When root
squashing is enabled, the root user is converted to a user with limited permissions on the NFS server.

**Permissions Caching**

Amazon EFS caches file permissions for a small time period. As a result, there might be a brief window
where a user who had access to a file system object but the access was revoked recently can still access
that object.

**Changing File System Object Ownership**

Amazon EFS enforces the POSIX `chown_restricted` attribute. This means only the root user can
change the owner of a file system object. The root or the owner user can change the owner group of a
file system object. However, unless the user is root, the group can only be changed to one that the owner
user is a member of.
EFS Access Points

An access point applies an operating system user, group, and file system path to any file system request made using the access point. The access point’s operating system user and group override any identity information provided by the NFS client. The file system path is exposed to the client as the access point’s root directory. This approach ensures that each application always uses the correct operating system identity and the correct directory when accessing shared file-based datasets. Applications using the access point can only access data in its own directory and below. For more information about access points, see Working with Amazon EFS Access Points (p. 202).

Working with Amazon EFS Access Points

Amazon EFS access points are application-specific entry points into an EFS file system that make it easier to manage application access to shared datasets. Access points can enforce a user identity, including the user’s POSIX groups, for all file system requests that are made through the access point. Access points can also enforce a different root directory for the file system so that clients can only access data in the specified directory or its subdirectories.

You can use AWS Identity and Access Management (IAM) policies to enforce that specific applications use a specific access point. By combining IAM policies with access points, you can easily provide secure access to specific datasets for your applications.

For more information on creating an access point, see Creating and deleting access points (p. 41).

**Topics**

- Creating an Access Point (p. 202)
- Mounting a File System Using an Access Point (p. 202)
- Enforcing a User Identity Using an Access Point (p. 203)
- Enforcing a Root Directory with an Access Point (p. 203)
- Using Access Points in IAM Policies (p. 204)

Creating an Access Point

You can create access points for an existing Amazon EFS file system using the AWS Management Console, the AWS Command Line Interface (AWS CLI), and the EFS API.

For directions about how to create an access point, see Creating and deleting access points (p. 41).

Mounting a File System Using an Access Point

You use the EFS mount helper when mounting a file system using an access point. In the mount command, include file system ID, the access point ID, and the tls mount option, as shown in the following example.

```
$ mount -t efs -o tls,accesspoint=fsap-12345678 fs-12345678: /localmountpoint
```

For more information on mounting file systems using an access point, see Mounting with EFS access points (p. 68).
Enforcing a User Identity Using an Access Point

You can use an access point to enforce user and group information for all file system requests made through the access point. To enable this feature, you need to specify the operating system identity to enforce when you create the access point.

As part of this, you provide the following:

- **User ID** – The numeric POSIX user ID for the user.
- **Group ID** – The numeric POSIX group ID for the user.
- **Secondary group IDs** – An optional list of secondary group IDs.

When user enforcement is enabled, Amazon EFS replaces the NFS client's user and group IDs with the identity configured on the access point for all file system operations. User enforcement also does the following:

- The owner and group for new files and directories are set to the user ID and group ID of the access point.
- EFS considers the user ID, group ID, and secondary group IDs of the access point when evaluating file system permissions. EFS ignores the NFS client's IDs.

**Important**

Enforcing a user identity is subject to the `ClientRootAccess` IAM permission. For example, in some cases you might configure the access point user ID, group ID, or both to be root (that is, setting the UID, GID, or both to 0). In such cases, you must grant the `ClientRootAccess` IAM permission to the NFS client.

Enforcing a Root Directory with an Access Point

You can use an access point to override the root directory for a file system. When you enforce a root directory, the NFS client using the access point uses the root directory configured on the access point instead of the file system's root directory.

You enable this feature by setting the access point `Path` attribute when creating an access point. The `Path` attribute is the full path of the root directory of the file system for all file system requests made through this access point. The full path can't exceed 100 characters in length. It can include up to four subdirectories.

When you specify a root directory on an access point, it becomes the root directory of the file system for the NFS client mounting the access point. For example, suppose that the root directory of your access point is `/data`. In this case, mounting `efs-12345678:/` using the access point has the same effect as mounting `efs-12345678:/data` without using the access point.

When specifying a root directory in your access point, ensure that the directory permissions are configured to allow the user of the access point to successfully mount the file system. Specifically, make sure that the execute bit is set for the access point user or group, or for everyone. For example, a directory permission value of 755 allows the directory user owner to list files, create files, and mount, and all other users to list files and mount.

Creating the Root Directory for an Access Point

If a root directory path for an access point doesn't exist on the file system, Amazon EFS automatically creates that root directory with configurable ownership and permissions. This approach makes it possible to provision file system access for a specific user or application without mounting your file system from a
Linux host. To create a root directory, you have to configure the root directory ownership and permission by using the following attributes when creating an access point:

- **OwnerUid** – The numeric POSIX user ID to use as the root directory owner.
- **OwnerGID** – The numeric POSIX group ID to use as the root directory owner group.
- **Permissions** – The Unix mode of the directory. A common configuration is 755. Ensure that the execute bit is set for the access point user so they are able to mount. This configuration gives the directory owner permission to enter, list, and write new files in the directory. It gives all other users permission to enter and list files. For more information on working with Unix file and directory modes, see Working with users, groups, and permissions at the Network File System (NFS) Level (p. 198).

Amazon EFS creates a root directories only if you have provided the OwnUid, OwnGID, and permissions for the directory. If you do not provide this information, Amazon EFS does not create the root directory. If the root directory does not exist, attempts to mount using the access point will fail.

When you mount a file system with an access point, the root directory for the access point is created if the directory doesn't already exist. If the root directory configured on the access point already exists before mount time, the existing permissions aren't overwritten by the access point. If you delete the root directory, EFS recreates it the next time that the file system is mounted using the access point.

**Security Model for Access Point Root Directories**

When a root directory override is in effect, Amazon EFS behaves like a Linux NFS server with the no_subtree_check option enabled.

In the NFS protocol, servers generate file handles that are used by clients as unique references when accessing files. EFS securely generates file handles that are unpredictable and specific to an EFS file system. When a root directory override is in place, EFS doesn't disclose file handles for files outside the specified root directory. However, in some cases a user might get a file handle for a file outside of their access point by using an out-of-band mechanism. For example, they might do so if they have access to a second access point. If they do this, they can perform read and write operations on the file.

File ownership and access permissions are always enforced, for access to files within and outside of a user's access point root directory.

**Using Access Points in IAM Policies**

You can use an IAM policy to enforce that a specific NFS client, identified by its IAM role, can only access a specific access point. To do this, you use the elasticfilesystem:AccessPointArn IAM condition key. The AccessPointArn is the Amazon Resource Name (ARN) of the access point that the file system is mounted with.

Following is an example of a file system policy that allows the IAM role app1 to access the file system using access point fsap-01234567. The policy also allows app2 to use the file system using access point fsap-89abcdef.

```json
{
    "Version": "2012-10-17",
    "Id": "MyFileSystemPolicy",
    "Statement": [
        {
            "Sid": "App1Access",
            "Effect": "Allow",
            "Principal": { "AWS": "arn:aws:iam::111122223333:role/app1" },
            "Action": [
                "elasticfilesystem:ClientMount",
                "elasticfilesystem:ClientWrite"
```
Logging and Monitoring in Amazon EFS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon EFS and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon EFS resources and responding to potential incidents:

Amazon CloudWatch Alarms

Using Amazon CloudWatch events, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch events do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see Monitoring EFS with Amazon CloudWatch (p. 101).

Amazon CloudWatch Logs

You can use Amazon CloudWatch Logs to monitor, store, and access your log files from AWS CloudTrail or other sources. For more information, see Monitoring Log Files in the Amazon CloudWatch User Guide.

Amazon CloudWatch Events

Match events and route them to one or more target functions or streams to make changes, capture state information, and take corrective action. For more information, see What is Amazon CloudWatch Events in the Amazon CloudWatch User Guide.

AWS CloudTrail Log Monitoring

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon EFS. Using the information collected by CloudTrail, you can determine the request that was made to Amazon EFS, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Logging Amazon EFS API Calls with AWS CloudTrail (p. 112).
AWS managed policies for Amazon EFS

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ViewOnlyAccess AWS managed policy provides read-only access to many AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

AWS managed policy: AmazonElasticFileSystemFullAccess

You can attach the AmazonElasticFileSystemFullAccess policy to your IAM identities.

This policy grants administrative permissions that allow full access to Amazon EFS and access to related AWS services via the AWS Management Console.

Permissions details

This policy includes the following permissions.

- elasticfilesystem – Allows principals to perform all actions in the Amazon EFS console. It also allows principals to create (elasticfilesystem:Backup) and restore (elasticfilesystem:Restore) backups using AWS Backup.
- cloudwatch – Allows principals to describe Amazon CloudWatch file system metrics and alarms for a metric in the Amazon EFS console.
- ec2 – Allows principals to create, delete, and describe network interfaces, describe and modify network interface attributes, describe Availability Zones, security groups, subnets, virtual private clouds (VPCs) and VPC attributes associated with an Amazon EFS file system in the Amazon EFS console.
- kms – Allows principals to list aliases for AWS Key Management Service (AWS KMS) keys and to describe KMS keys in the Amazon EFS console.
- iam – Grants permission to create a service linked role that allows Amazon EFS to manage AWS resources on the user's behalf.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "cloudwatch:DescribeAlarmsForMetric",
                "..."
            ],
            "Effect": "Allow",
            "Resource": "*"
        }]
}
```

**AWS managed policy:**
**AmazonElasticFileSystemReadOnlyAccess**

You can attach the AmazonElasticFileSystemReadOnlyAccess policy to your IAM identities.

This policy grants read only access to Amazon EFS via the AWS Management Console.

**Permissions details**

This policy includes the following permissions:

- **elasticfilesystem** – Allows principals to describe attributes of Amazon EFS file systems, including account preferences, backup and file system policies, lifecycle configuration, mount targets and their security groups, tags, and access points in the Amazon EFS console.
- **cloudwatch** – Allows principals to retrieve CloudWatch metrics and describe alarms for metrics in the Amazon EFS console.
- **ec2** – Allows principals to view Availability Zones, network interfaces and their attributes, security groups, subnets, VPCs and their attributes in the Amazon EFS console.
- **kms** – Allows principals to list aliases for AWS KMS keys in the Amazon EFS console.

```json

Compliance Validation for Amazon Elastic File System

Third-party auditors assess the security and compliance of Amazon Elastic File System as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, DoD CC SRG, HITRUST CSF, OSPAR, CS, and ENS High.

For a list of AWS services in scope of specific compliance programs, see AWS Services in Scope by Compliance Program. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using EFS is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
Resilience in Amazon Elastic File System

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

Amazon EFS file systems are resilient to one or more Availability Zone failures within an AWS Region. Mount targets themselves are designed to be highly available. As you design for high availability and failover to other Availability Zones (AZs), keep in mind that while the IP addresses and DNS for your mount targets in each AZ are static, they are redundant components backed by multiple resources. For more information, see How Amazon EFS works with Amazon EC2 and other supported compute instances (p. 4).

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.
Amazon Elastic File System Network Isolation

As a managed service, Amazon Elastic File System is protected by the AWS global network security procedures described in the Amazon Web Services: Overview of Security Processes whitepaper.

Access to Amazon EFS by using the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.0. We recommend TLS 1.2. Clients must also support cipher suites with Perfect Forward Secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, requests must be signed by using either an access key ID and a secret access key that is associated with an IAM principal or the AWS Security Token Service (STS) to generate temporary security credentials to sign requests.

These APIs are callable from any network location, but Amazon EFS does support resource-based access policies which can include restrictions based on the source IP address. You can also use Amazon EFS policies to control access from specific Amazon Virtual Private Cloud (Amazon VPC) endpoints, or specific VPCs. Effectively, this isolates network access to a given Amazon EFS resource from only the specific VPC within the AWS network.
Amazon EFS quotas and limits

Following, you can find out about quotas when working with Amazon EFS.

Topics
- Amazon EFS quotas that you can increase (p. 212)
- Resource quotas (p. 213)
- Quotas for NFS clients (p. 214)
- Quotas for Amazon EFS file systems (p. 214)
- Unsupported NFSv4.0 and 4.1 features (p. 215)
- Additional considerations (p. 216)

Amazon EFS quotas that you can increase

Service Quotas is an AWS service that helps you manage your quotas, or limits, from one location. You can view all Amazon EFS limit values in the Service Quotas console. You can also request a quota increase for the number of EFS file systems in an AWS Region using the Service Quotas console.

You can also request an increase to the following Amazon EFS quotas by contacting AWS Support. To learn more, see Requesting a quota increase (p. 213). The Amazon EFS service team reviews each request individually.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Default quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of file systems for each customer account in an AWS Region</td>
<td>1,000</td>
</tr>
</tbody>
</table>

These are the default throughput quotas for Bursting and Provisioned throughput modes. For more information about these different modes, see Amazon EFS performance (p. 120).

<table>
<thead>
<tr>
<th>Resource</th>
<th>AWS Region</th>
<th>Maximum metered (p. 121 throughput)</th>
<th>Maximum bursting read throughput</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total bursting throughput for all connected clients</td>
<td>US East (Ohio) Region</td>
<td>3 GiB/s</td>
<td>5 GiB/s</td>
</tr>
<tr>
<td></td>
<td>US East (N. Virginia) Region</td>
<td>3 GiB/s</td>
<td>5 GiB/s</td>
</tr>
<tr>
<td></td>
<td>US West (N. California) Region</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
</tr>
<tr>
<td></td>
<td>US West (Oregon) Region</td>
<td>3 GiB/s</td>
<td>5 GiB/s</td>
</tr>
<tr>
<td></td>
<td>Africa (Cape Town) Region</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
</tr>
<tr>
<td></td>
<td>Asia Pacific (Hong Kong) Region</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
</tr>
<tr>
<td></td>
<td>Asia Pacific (Mumbai) Region</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
</tr>
<tr>
<td></td>
<td>Asia Pacific (Seoul) Region</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
</tr>
</tbody>
</table>
### Requesting a quota increase

To request an increase for these quotas through AWS Support, take the following steps. The Amazon EFS team reviews each quota increase request.

**To request a quota increase through AWS Support**

1. Open the AWS Support Center page, and sign in if necessary. Then choose Create Case.
2. Under Create case, choose Service Limit Increase.
3. For Limit Type, choose the type of limit to increase. Fill in the necessary fields in the form, and then choose your preferred method of contact.

### Resource quotas

Following are the quotas on Amazon EFS resources for each customer account in an AWS Region.

<table>
<thead>
<tr>
<th>Resource</th>
<th>AWS Region</th>
<th>Maximum metered (p. 121 throughput)</th>
<th>Maximum bursting read throughput</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asia Pacific (Singapore) Region</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
<td></td>
</tr>
<tr>
<td>Asia Pacific (Sydney) Region</td>
<td>3 GiB/s</td>
<td>5 GiB/s</td>
<td></td>
</tr>
<tr>
<td>Asia Pacific (Tokyo) Region</td>
<td>1 GiB/s</td>

<td>3 GiB/s</td>
<td></td>
</tr>
<tr>
<td>Europe (Milan) Region</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
<td></td>
</tr>
<tr>
<td>Europe (Paris) Region</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
<td></td>
</tr>
<tr>
<td>Europe (Stockholm) Region</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
<td></td>
</tr>
<tr>
<td>Middle East (Bahrain) Region</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
<td></td>
</tr>
<tr>
<td>South America (São Paulo) Region</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
<td></td>
</tr>
<tr>
<td>AWS GovCloud (US-East)</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
<td></td>
</tr>
<tr>
<td>AWS GovCloud (US-West)</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
<td></td>
</tr>
<tr>
<td>Total provisioned throughput for all connected clients</td>
<td>All AWS Regions</td>
<td>1 GiB/s</td>
<td>3 GiB/s</td>
</tr>
</tbody>
</table>
Quotas for NFS clients

The following quotas for NFS clients apply, assuming a Linux NFSv4.1 client:

- The maximum throughput you can drive for each NFS client is 500 MB/s. NFS client throughput is calculated as the total number of bytes that are sent and received, with a minimum NFS request size of 4KB (after applying a 1/3 metering rate for read requests).
- Up to 128 active user accounts for each client can have files open at the same time. Each user account represents one local user logged in to the instance. A user account that is logged in multiple times counts as one active user.
- Up to 32,768 files open at the same time on the instance. Listing directory contents doesn't count as opening a file.
- Each unique mount on the client can acquire up to a total of 8,192 locks across a maximum of 256 unique file-process pairs. For example, a single process can acquire one or more locks on 256 separate files. As another example, eight processes can each acquire one or more locks on 32 files.
- When connecting to Amazon EFS, NFS clients located on-premises or in another AWS Region can observe lower throughput than when connecting to EFS from the same AWS Region. This effect is because of increased network latency. Network latency of 1 ms or less is required to achieve maximum per-client throughput. Use the DataSync data migration service when migrating large datasets from on-premises NFS servers to EFS. For more information, see On-premises performance considerations (p. 127).
- Using Amazon EFS with Microsoft Windows isn't supported.

Quotas for Amazon EFS file systems

The following quotas are specific to Amazon EFS file systems:

- Maximum name length: 255 bytes.
- Maximum symbolic link (symlink) length: 4,080 bytes.
- Maximum number of hard links to a file: 177.
Unsupported NFSv4.0 and 4.1 features

Although Amazon Elastic File System doesn't support NFSv2, or NFSv3, Amazon EFS supports both NFSv4.1 and NFSv4.0, except for the following features:

- pNFS
- Client delegation or callbacks of any type
  - Operation OPEN always returns OPEN_DELEGATE_NONE as the delegation type.
  - The operation OPEN returns NFSERR_NOTSUPP for the CLAIM_DELEGATE_CUR and CLAIM_DELEGATE_PREV claim types.
- Mandatory locking
  All locks in Amazon EFS are advisory, which means that READ and WRITE operations don't check for conflicting locks before the operation is executed.
- Deny share
  NFS supports the concept of a share deny. A share deny is primarily used by Windows clients for users to deny others access to a particular file that has been opened. Amazon EFS doesn't support this, and returns the NFS error NFS4ERR_NOTSUPP for any OPEN commands specifying a share deny value other than OPEN4_SHARE_DENY_NONE. Linux NFS clients don't use anything other than OPEN4_SHARE_DENY_NONE.
- Access control lists (ACLs)
  Amazon EFS doesn't update the time_access attribute on file reads. Amazon EFS updates time_access in the following events:
  - When a file is created (an inode is created).
  - When an NFS client makes an explicit setattr call.
  - On a write to the inode caused by, for example, file size changes or file metadata changes.
  - Any inode attribute is updated.
- Namespaces
- Persistent reply cache
- Kerberos based security
- NFSv4.1 data retention
- SetUID on directories
- Unsupported file types when using the CREATE operation: Block devices (NF4BLK), character devices (NF4CHR), attribute directory (NF4ATTRDIR), and named attribute (NF4NAMEDATTR).
- Unsupported attributes: FATTR4_ARCHIVE, FATTR4_FILES_AVAL, FATTR4_FILES_FREE, FATTR4_FILES_TOTAL, FATTR4_CHECKLOCATIONS, FATTR4_MIMETYPE, FATTR4_QUOTA_AVAL_HARD, FATTR4_QUOTA_AVAL_SOFT, FATTR4_QUOTA_USED, FATTR4_TIME_BACKUP, and FATTR4_ACL.
An attempt to set these attributes results in an NFS4ERR_ATTRNOTSUPP error that is sent back to the client.

Additional considerations

In addition, note the following:

- For a list of AWS Regions where you can create Amazon EFS file systems, see the AWS General Reference.
- Amazon EFS does not support the `nconnect` mount option.
- You mount your file system from Amazon EC2 instances in your Amazon VPC by using the mount targets you create in the VPC. You can also mount your file system on your EC2-Classic instances, which are not in the VPC. However, you must first link them to your VPC by using Amazon VPC ClassicLink. For more information about using ClassicLink, see ClassicLink in the Amazon EC2 User Guide for Linux Instances.
- You can mount an Amazon EFS file system from on-premises data center servers using AWS Direct Connect and VPN. For more information, see Mounting with on-premises clients (p. 68).
Troubleshooting Amazon EFS

You can find information about how to troubleshoot the following issues for Amazon Elastic File System (Amazon EFS).

Topics
- Troubleshooting Amazon EFS: General Issues (p. 217)
- Troubleshooting File Operation Errors (p. 220)
- Troubleshooting AMI and Kernel Issues (p. 222)
- Troubleshooting Mount Issues (p. 223)
- Troubleshooting Encryption (p. 228)

Troubleshooting Amazon EFS: General Issues

Use this information to troubleshoot general Amazon EFS issues. For information about performance, see Amazon EFS performance (p. 120).

In general, if you encounter issues with Amazon EFS that you have trouble resolving, confirm that you’re using a recent Linux kernel. If you are using an enterprise Linux distribution, we recommend the following:

- Amazon Linux 2
- Amazon Linux 2015.09 or newer
- RHEL 7.3 or newer
- All versions of Ubuntu 16.04
- Ubuntu 14.04 with kernel 3.13.0-83 or newer
- SLES 12 Sp2 or later

If you are using another distribution or a custom kernel, we recommend kernel version 4.3 or newer.

Note
RHEL 6.9 might be suboptimal for certain workloads due to Poor Performance When Opening Many Files in Parallel (p. 219).

Topics
- Unable to Create an EFS File System (p. 217)
- Errors when accessing the Amazon EFS console (p. 218)
- Amazon EC2 Instance Hangs (p. 218)
- Application Writing Large Amounts of Data Hangs (p. 218)
- Poor Performance When Opening Many Files in Parallel (p. 219)
- Custom NFS Settings Causing Write Delays (p. 219)
- Creating Backups with Oracle Recovery Manager Is Slow (p. 220)

Unable to Create an EFS File System

A request to create an EFS file system fails with the following message:
Errors when accessing the Amazon EFS console

This section describes errors users might experience when accessing the Amazon EFS management console.

Error authenticating credentials for ec2:DescribeVPCs

The following error message displays when accessing the Amazon EFS console:

```
AuthFailure: An error occurred authenticating your credentials for ec2:DescribeVPCs.
```

This error indicates that your login credentials did not successfully authenticate with the Amazon EC2 service. The Amazon EFS console calls the Amazon EC2 service on your behalf when creating EFS file systems in the VPC that you choose.

**Action to take**

Ensure that the time on the client accessing the Amazon EFS console is set correctly.

Amazon EC2 Instance Hangs

An Amazon EC2 instance can hang because you deleted a file system mount target without first unmounting the file system.

**Action to take**

Before you delete a file system mount target, unmount the file system. For more information about unmounting your Amazon EFS file system, see Unmounting file systems (p. 76).

Application Writing Large Amounts of Data Hangs

An application that writes a large amount of data to Amazon EFS hangs and causes the instance to reboot.

**Action to take**

If an application takes too long to write all of its data to Amazon EFS, Linux might reboot because it appears that the process has become unresponsive. Two kernel configuration parameters define this behavior, `kernel.hung_task_panic` and `kernel.hung_task_timeout_secs`.

In the example following, the state of the hung process is reported by the `ps` command with `D` before the instance reboot, indicating that the process is waiting on I/O.

```
$ ps aux | grep large_io.py
root 33253  0.5  0.0 126652 5020 pts/3  D+ 18:22 0:00 python large_io.py
```
Poor Performance When Opening Many Files in Parallel

Applications that open multiple files in parallel do not experience the expected increase in performance of I/O parallelization.

**Action to take**

This issue occurs on Network File System version 4 (NFSv4) clients and on RHEL 6 clients using NFSv4.1 because these NFS clients serialize NFS OPEN and CLOSE operations. Use NFS protocol version 4.1 and one of the suggested Linux distributions (p. 217) that does not have this issue.

If you can't use NFSv4.1, be aware that the Linux NFSv4.0 client serializes open and close requests by user ID and group IDs. This serialization happens even if multiple processes or multiple threads issue requests at the same time. The client only sends one open or close operation to an NFS server at a time, when all of the IDs match. To work around these issues, you can perform any of the following actions:

- You can run each process from a different user ID on the same Amazon EC2 instance.
- You can leave the user IDs the same across all open requests, and modify the set of group IDs instead.
- You can run each process from a separate Amazon EC2 instance.

Custom NFS Settings Causing Write Delays

You have custom NFS client settings, and it takes up to three seconds for an Amazon EC2 instance to see a write operation performed on a file system from another Amazon EC2 instance.

**Action to take**

If you encounter this issue, you can resolve it in one of the following ways:

- If the NFS client on the Amazon EC2 instance that's reading data has attribute caching activated, unmount your file system. Then remount it with the `noac` option to disable attribute caching. Attribute caching in NFSv4.1 is enabled by default.

  **Note**
  Disabling client-side caching can potentially reduce your application's performance.

- You can also clear your attribute cache on demand by using a programming language compatible with the NFS procedures. To do this, you can send an `ACCESS` procedure request immediately before a read request.

  For example, using the Python programming language, you can construct the following call:

  ```python
  # Does an NFS ACCESS procedure request to clear the attribute cache, given a path to the file
  import os
  os.access(path, os.W_OK)
  ```
Creating Backups with Oracle Recovery Manager Is Slow

Creating backups with Oracle Recovery Manager can be slow if Oracle Recovery Manager pauses for 120 seconds before starting a backup job.

Action to take

If you encounter this issue, disable Oracle Direct NFS, as described in Enabling and Disabling Direct NFS Client Control of NFS in the Oracle Help Center.

Note

Amazon EFS doesn't support Oracle Direct NFS.

Troubleshooting File Operation Errors

When you access Amazon EFS file systems, certain limits on the files in the file system apply. Exceeding these limits causes file operation errors. For more information on client and file-based limits in Amazon EFS, see Quotas for NFS clients (p. 214). Following, you can find some common file operation errors and the limits associated with each error.

Topics

- Command Fails with “Disk quota exceeded” Error (p. 220)
- Command Fails with "I/O error" (p. 220)
- Command Fails with "File name is too long" Error (p. 221)
- Command Fails with "File not found" Error (p. 221)
- Command Fails with "Too many links" Error (p. 221)
- Command Fails with "File too large" Error (p. 221)

Command Fails with “Disk quota exceeded” Error

Amazon EFS doesn't currently support user disk quotas. This error can occur if any of the following limits have been exceeded:

- Up to 128 active user accounts can have files open at once for an instance.
- Up to 32,768 files can be open at once for an instance.
- Each unique mount on the instance can acquire up to a total of 8,192 locks across 256 unique file-process pairs. For example, a single process can acquire one or more locks on 256 separate files, or eight processes can each acquire one or more locks on 32 files.

Action to take

If you encounter this issue, you can resolve it by identifying which of the preceding limits you are exceeding, and then making changes to meet that limit.

Command Fails with "I/O error"

This error occurs when you encounter one of the following issues:

- More than 128 active user accounts for each instance have files open at once.
Action to take

If you encounter this issue, you can resolve it by meeting the supported limit of open files on your instances. To do so, reduce the number of active users that have files from your Amazon EFS file system open simultaneously on your instances.

- The AWS KMS key encrypting your file system was deleted.

Action to take

If you encounter this issue, you can no longer decrypt the data that was encrypted under that key, which means that data becomes unrecoverable.

Command Fails with "File name is too long" Error

This error occurs when the size of a file name or its symbolic link (symlink) is too long. File names have the following limits:

- A name can be up to 255 bytes long.
- A symlink can be up to 4080 bytes in size.

Action to take

If you encounter this issue, you can resolve it by reducing the size of your file name or symlink length to meet the supported limits.

Command Fails with "File not found" Error

This error occurs because some older 32-bit versions of Oracle E-Business suite use 32-bit file I/O interfaces, and EFS uses 64-bit inode numbers. System calls that may fail include `stat()` and `readdir()`.

Action to take

If you encounter this error, you can resolve it by using the `nfs.enable_ino64=0 kernel` boot option. This option compresses the 64-bit EFS inode numbers to 32 bits. Kernel boot options are handled differently for different Linux distributions. On Amazon Linux, turn on this option by adding `nfs.enable_ino64=0` kernel to the `GRUB_CMDLINE_LINUX_DEFAULT` variable in `/etc/default/grub`. Please consult your distribution for specific documentation on how to turn on kernel boot options.

Command Fails with "Too many links" Error

This error occurs when there are too many hard links to a file. You can have up to 177 hard links in a file.

Action to take

If you encounter this issue, you can resolve it by reducing the number of hard links to a file to meet the supported limit.

Command Fails with "File too large" Error

This error occurs when a file is too large. A single file can be up to 52,673,613,135,872 bytes (47.9 TiB) in size.

Action to take
Troubleshooting AMI and Kernel Issues

Following, you can find information about troubleshooting issues related to certain Amazon Machine Image (AMI) or kernel versions when using Amazon EFS from an Amazon EC2 instance.

**Topics**
- Unable to chown (p. 222)
- File System Keeps Performing Operations Repeatedly Due to Client Bug (p. 222)
- Deadlocked Client (p. 222)
- Listing Files in a Large Directory Takes a Long Time (p. 223)

**Unable to chown**

You're unable to change the ownership of a file/directory using the Linux `chown` command.

**Kernel Versions with This Bug**

2.6.32

**Action to take**

You can resolve this error by doing the following:

- If you're performing `chown` for the one-time setup step necessary to change ownership of the EFS root directory, you can run the `chown` command from an instance running a newer kernel. For example, use the newest version of Amazon Linux.
- If `chown` is part of your production work flow, you must update the kernel version to use `chown`.

**File System Keeps Performing Operations Repeatedly Due to Client Bug**

A file system gets stuck performing repeated operations due to a client bug.

**Action to take**

Update the client software to the latest version.

**Deadlocked Client**

A client becomes deadlocked.

**Kernel Versions with This Bug**

- CentOS-7 with kernel Linux 3.10.0-229.20.1.el7.x86_64
- Ubuntu 15.10 with kernel Linux 4.2.0-18-generic

**Action to take**

Do one of the following:
- Upgrade to a newer kernel version. For CentOS-7, kernel version Linux 3.10.0-327 or later contains the fix.
- Downgrade to an older kernel version.

**Listing Files in a Large Directory Takes a Long Time**

This can happen if the directory is changing while your NFS client iterates through the directory to finish the list operation. Whenever the NFS client notices that the contents of the directory changed during this iteration, the NFS client restarts iterating from the beginning. As a result, the `ls` command can take a long time to complete for a large directory with frequently changing files.

**Kernel Versions with This Bug**

CentOS and RHEL kernel versions lower than 2.6.32-696.el6

**Action to take**

To resolve this issue, upgrade to a newer kernel version.

**Troubleshooting Mount Issues**

Following, you can find information about troubleshooting file-system mounting issues for Amazon EFS.

- File System Mount on Windows Instance Fails (p. 223)
- Access Denied by Server (p. 223)
- Automatic Mounting Fails and the Instance Is Unresponsive (p. 224)
- Mounting Multiple Amazon EFS File Systems in `/etc/fstab` Fails (p. 224)
- Mount Command Fails with "wrong fs type" Error Message (p. 225)
- Mount Command Fails with "incorrect mount option" Error Message (p. 225)
- File System Mount Fails Immediately After File System Creation (p. 225)
- File System Mount Hangs and Then Fails with Timeout Error (p. 225)
- File System Mount Using DNS Name Fails (p. 226)
- File System Mount Fails with "nfs not responding" (p. 227)
- Mount Target Lifecycle State Is Stuck (p. 227)
- Mount Does Not Respond (p. 227)
- Operations on Newly Mounted File System Return "bad file handle" Error (p. 227)
- Unmounting a File System Fails (p. 228)

**File System Mount on Windows Instance Fails**

A file system mount on an Amazon EC2 instance on Microsoft Windows fails.

**Action to take**

Don't use Amazon EFS with Windows EC2 instances, which isn't supported.

**Access Denied by Server**

A file system mount fails with the following message:
This issue can occur if your NFS client does not have permission to mount the file system.

**Action to take**

If you are attempting to mount the file system using IAM, make sure you are using the `-o iam` option in your mount command. This tells the EFS mount helper to pass your credentials to the EFS mount target. If you still don't have access, check your file system policy and your identity policy to ensure there are no DENY clauses that apply to your connection, and that there is at least one ALLOW clause that applies to the connection.

### Automatic Mounting Fails and the Instance Is Unresponsive

This issue can occur if the file system was mounted automatically on an instance and the `_netdev` option wasn't declared. If `_netdev` is missing, your EC2 instance might stop responding. This result is because network file systems need to be initialized after the compute instance starts its networking.

**Action to take**

If this issue occurs, contact AWS Support.

### Mounting Multiple Amazon EFS File Systems in `/etc/fstab` Fails

For instances that use the systemd init system with two or more Amazon EFS entries at `/etc/fstab`, there might be times where some or all of these entries are not mounted. In this case, the `dmesg` output shows one or more lines similar to the following.

```
NFS: nfs4_discover_server_trunking unhandled error -512. Exiting with error EIO
```

**Action to take**

In this case, we recommend that you create a new systemd service file in `/etc/systemd/system/mount-nfs-sequentially.service` with the following contents.

```
[Unit]
Description=Workaround for mounting NFS file systems sequentially at boot time
After=remote-fs.target

[Service]
Type=oneshot
ExecStart=/bin/mount -avt nfs4
RemainAfterExit=yes

[Install]
WantedBy=multi-user.target
```

After you do so, run the following two commands:

1. `sudo systemctl daemon-reload`
2. `sudo systemctl enable mount-nfs-sequentially.service`
Then restart your Amazon EC2 instance. The file systems are mounted on demand, generally within a second.

**Mount Command Fails with "wrong fs type" Error Message**

The mount command fails with the following error message.

```
mount: wrong fs type, bad option, bad superblock on 10.1.25.30:/,
missing codepage or helper program, or other error (for several filesystems
(e.g. nfs, cifs) you might need a /sbin/mount.<type> helper program)
In some cases useful info is found in syslog - try dmesg | tail or so.
```

**Action to take**

If you receive this message, install the `nfs-utils` (or `nfs-common` on Ubuntu) package. For more information, see Installing the NFS client (p. 357).

**Mount Command Fails with "incorrect mount option" Error Message**

The mount command fails with the following error message.

```
mount.nfs: an incorrect mount option was specified
```

**Action to take**

This error message most likely means that your Linux distribution doesn't support Network File System versions 4.0 and 4.1 (NFSv4). To confirm this is the case, you can run the following command.

```
$ grep CONFIG_NFS_V4_1 /boot/config*
```

If the preceding command returns `# CONFIG_NFS_V4_1 is not set`, NFSv4.1 is not supported on your Linux distribution. For a list of the Amazon Machine Images (AMIs) for Amazon Elastic Compute Cloud (Amazon EC2) that support NFSv4.1, see NFS support (p. 356).

**File System Mount Fails Immediately After File System Creation**

It can take up to 90 seconds after creating a mount target for the Domain Name Service (DNS) records to propagate fully in an AWS Region.

**Action to take**

If you're programmatically creating and mounting file systems, for example with an AWS CloudFormation template, we recommend that you implement a wait condition.

**File System Mount Hangs and Then Fails with Timeout Error**

The file system mount command hangs for a minute or two, and then fails with a timeout error. The following code shows an example.
File System Mount Using DNS Name Fails

A file system mount that is using a DNS name fails. The following code shows an example.

```bash
$ sudo mount -t nfs -o nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport file-system-id.efs.aws-region.amazonaws.com:/ mnt
mount.nfs: Failed to resolve server file-system-id.efs.aws-region.amazonaws.com:
   Name or service not known.
```

Action to take

Check your VPC configuration. If you are using a custom VPC, make sure that DNS settings are enabled. For more information, see Using DNS with Your VPC in the Amazon VPC User Guide. Also, file system and mount target DNS names are not resolvable from outside the VPC where they exist.

To specify a DNS name in the `mount` command, you must do the following:

- Ensure that there's an Amazon EFS mount target in the same Availability Zone as the Amazon EC2 instance.
- Ensure that there's a mount target in the same VPC as the Amazon EC2 instance. Otherwise, you can't use DNS name resolution for EFS mount targets that are in another VPC. For more information, see Mounting EFS file systems from another AWS account or VPC (p. 73).
- Connect your Amazon EC2 instance inside an Amazon VPC configured to use the DNS server provided by Amazon. For more information, see DHCP Options Sets in the Amazon VPC User Guide.
- Ensure that the Amazon VPC of the connecting Amazon EC2 instance has DNS hostnames enabled. For more information, see Updating DNS Support for Your VPC in the Amazon VPC User Guide.
File System Mount Fails with "nfs not responding"

An Amazon EFS file system mount fails on a Transmission Control Protocol (TCP) reconnection event with "nfs: server_name still not responding".

Action to take

Use the noresvport mount option to make sure that the NFS client uses a new TCP source port when a network connection is reestablished. Doing this helps ensure uninterrupted availability after a network recovery event.

Mount Target Lifecycle State Is Stuck

The mount target lifecycle state is stuck in the creating or deleting state.

Action to take

Retry the CreateMountTarget or DeleteMountTarget call.

Mount Does Not Respond

An Amazon EFS mount appears unresponsive. For example, commands like ls hang.

Action to take

This error can occur if another application is writing large amounts of data to the file system. Access to the files that are being written might be blocked until the operation is complete. In general, any commands or applications that attempt to access files that are being written to might appear to hang. For example, the ls command might hang when it gets to the file that is being written. This result is because some Linux distributions alias the ls command so that it retrieves file attributes in addition to listing the directory contents.

To resolve this issue, verify that another application is writing files to the Amazon EFS mount, and that it is in the Uninterruptible sleep (D) state, as in the following example:

```
$ ps aux | grep large_io.py
root 33253 0.5 0.0 126652 5020 pts/3 D+ 18:22 0:00 python large_io.py /efs/large_file
```

After you've verified that this is the case, you can address the issue by waiting for the other write operation to complete, or by implementing a workaround. In the example of ls, you can use the /bin/ls command directly, instead of an alias. Doing this allows the command to proceed without hanging on the file being written. In general, if the application writing the data can force a data flush periodically, perhaps by using fsync(2), doing so can help improve the responsiveness of your file system for other applications. However, this improvement might be at the expense of performance when the application writes data.

Operations on Newly Mounted File System Return "bad file handle" Error

Operations performed on a newly mounted file system return a bad file handle error.

This error can happen if an Amazon EC2 instance was connected to one file system and one mount target with a specified IP address, and then that file system and mount target were deleted. If you create a new file system and mount target to connect to that Amazon EC2 instance with the same mount target IP address, this issue can occur.
Action to take

You can resolve this error by unmounting the file system, and then remounting the file system on the Amazon EC2 instance. For more information about unmounting your Amazon EFS file system, see Unmounting file systems (p. 76).

Unmounting a File System Fails

If your file system is busy, you can't unmount it.

Action to take

You can resolve this issue in the following ways:

- Use lazy unmount, `umount -l` which detaches the filesystem from the filesystem hierarchy when run, then cleans up all references to the filesystem as soon as it is not busy anymore.
- Wait for all read and write operations to finish, and then attempt the `umount` command again.
- Force an unmount using the `umount -f` command.

Warning
Forcing an unmount interrupts any data read or write operations that are currently in process for the file system. See the `umount man page` for more information and guidance when using this option.

Troubleshooting Encryption

Following, you can find information about troubleshooting encryption issues for Amazon EFS.

- Mounting with Encryption of Data in Transit Fails (p. 228)
- Mounting with Encryption of Data in Transit is Interrupted (p. 228)
- Encrypted-at-Rest File System Can't Be Created (p. 229)
- Unusable Encrypted File System (p. 229)

Mounting with Encryption of Data in Transit Fails

By default, when you use the Amazon EFS mount helper with Transport Layer Security (TLS), it enforces hostname checking. Some systems don't support this feature, such as when you use Red Hat Enterprise Linux or CentOS. In these cases, mounting an EFS file system using TLS fails.

Action to take

We recommend that you upgrade the version of stunnel on your client to support hostname checking. For more information, see Upgrading stunnel (p. 56).

Mounting with Encryption of Data in Transit is Interrupted

It's possible, however unlikely, that your encrypted connection to your Amazon EFS file system can hang or be interrupted by client-side events.

Action to take

If your connection to your Amazon EFS file system with encryption of data in transit is interrupted, take the following steps:
Encrypted-at-Rest File System Can't Be Created

You've tried to create a new encrypted-at-rest file system. However, you get an error message saying that AWS KMS is unavailable.

Action to take
This error can occur in the rare case that AWS KMS becomes temporarily unavailable in your AWS Region. If this happens, wait until AWS KMS returns to full availability, and then try again to create the file system.

Unusable Encrypted File System
An encrypted file system consistently returns NFS server errors. These errors can occur when EFS can't retrieve your master key from AWS KMS for one of the following reasons:

- The key was disabled.
- The key was deleted.
- Permission for Amazon EFS to use the key was revoked.
- AWS KMS is temporarily unavailable.

Action to take
First, confirm that the AWS KMS key is enabled. You can do so by viewing the keys in the console. For more information, see Viewing Keys in the AWS Key Management Service Developer Guide.

If the key is not enabled, enable it. For more information, see Enabling and Disabling Keys in the AWS Key Management Service Developer Guide.

If the key is pending deletion, then this status disables the key. You can cancel the deletion, and re-enable the key. For more information, see Scheduling and Canceling Key Deletion in the AWS Key Management Service Developer Guide.

If the key is enabled, and you're still experiencing an issue, or if you encounter an issue re-enabling your key, contact AWS Support.
Amazon EFS API

The Amazon EFS API is a network protocol based on HTTP (RFC 2616). For each API call, you make an HTTP request to the region-specific Amazon EFS API endpoint for the AWS Region where you want to manage file systems. The API uses JSON (RFC 4627) documents for HTTP request/response bodies.

The Amazon EFS API is an RPC model. In this model, there is a fixed set of operations and the syntax for each operation is known to clients without any prior interaction. In the following section, you can find a description of each API operation using an abstract RPC notation. Each has an operation name that doesn't appear on the wire. For each operation, the topic specifies the mapping to HTTP request elements.

The specific Amazon EFS operation to which a given request maps is determined by a combination of the request's method (GET, PUT, POST, or DELETE) and which of the various patterns its Request-URI matches. If the operation is PUT or POST, Amazon EFS extracts call arguments from the Request-URI path segment, query parameters, and the JSON object in the request body.

Note
Although operation names, such as CreateFileSystem, don't appear on the wire, these names are meaningful in AWS Identity and Access Management (IAM) policies. For more information, see Identity and access management for Amazon EFS (p. 175).

The operation name is also used to name commands in command-line tools and elements of the AWS SDK APIs. For example, there is a AWS CLI command named create-file-system that maps to the CreateFileSystem operation.

The operation name also appears in AWS CloudTrail logs for Amazon EFS API calls.

API endpoint

The API endpoint is the DNS name used as a host in the HTTP URI for the API calls. These API endpoints are specific to AWS Regions and take the following form.

elasticfilesystem.aws-region.amazonaws.com

For example, the Amazon EFS API endpoint for the US West (Oregon) Region is the following.

elasticfilesystem.us-west-2.amazonaws.com

For a list of AWS Regions that Amazon EFS supports (where you can create and manage file systems), see Amazon Elastic File System in the AWS General Reference.

The region-specific API endpoint defines the scope of the Amazon EFS resources that are accessible when you make an API call. For example, when you call the DescribeFileSystems operation using the preceding endpoint, you get a list of file systems in the US West (Oregon) Region that have been created in your account.

API version

The version of the API being used for a call is identified by the first path segment of the request URI, and its form is an ISO 8601 date. For example, see CreateFileSystem (p. 238).
The documentation describes API version 2015-02-01.

Related topics

The following sections provide descriptions of the API operations, how to create a signature for request authentication, and how to grant permissions for these API operations using the IAM policies.

- Identity and access management for Amazon EFS (p. 175)
- Actions (p. 231)
- Data Types (p. 325)

Working with the query API request rate for Amazon EFS

Amazon EFS API requests are throttled for each AWS account on a per-region basis to help service performance. All Amazon EFS API calls together, whether they originate from an application, the AWS CLI, or the Amazon EFS console, must not exceed the maximum allowed API request rate. The maximum API request rate can vary across AWS Regions. API requests made by AWS Identity and Access Management (IAM) users are attributed to the underlying AWS account.

If an API request exceeds the API request rate for its category, the request returns the ThrottlingException error code. To prevent this error, ensure that your application doesn't retry API requests at a high rate. You can do this by using care when polling and by using exponential backoff retries.

Polling

Your application might need to call an API operation repeatedly to check for an update in status. Before you start polling, give the request time to potentially complete. When you begin polling, use an appropriate sleep interval between successive requests. For best results, use an increasing sleep interval.

Retries or batch processing

Your application might need to retry an API request after it fails, or to process multiple resources (for example, all of your Amazon EFS file systems). To lower the rate of API requests, use an appropriate sleep interval between successive requests. For best results, use an increasing or variable sleep interval.

Calculating the sleep interval

When you have to poll or retry an API request, we recommend using an exponential backoff algorithm to calculate the sleep interval between API calls. The idea behind exponential backoff is to use progressively longer waits between retries for consecutive error responses. For more information, and implementation examples of this algorithm, see Error Retries and Exponential Backoff in AWS in the Amazon Web Services General Reference.

Actions

The following actions are supported:
• CreateAccessPoint (p. 233)
• CreateFileSystem (p. 238)
• CreateMountTarget (p. 248)
• CreateTags (p. 256)
• DeleteAccessPoint (p. 258)
• DeleteFileSystem (p. 260)
• DeleteFileSystemPolicy (p. 262)
• DeleteMountTarget (p. 264)
• DeleteTags (p. 267)
• DescribeAccessPoints (p. 269)
• DescribeAccountPreferences (p. 272)
• DescribeBackupPolicy (p. 274)
• DescribeFileSystemPolicy (p. 276)
• DescribeFileSystems (p. 279)
• DescribeLifecycleConfiguration (p. 283)
• DescribeMountTargets (p. 286)
• DescribeMountTargetSecurityGroups (p. 290)
• DescribeTags (p. 293)
• ListTagsForResource (p. 296)
• ModifyMountTargetSecurityGroups (p. 299)
• PutAccountPreferences (p. 302)
• PutBackupPolicy (p. 304)
• PutFileSystemPolicy (p. 306)
• PutLifecycleConfiguration (p. 310)
• TagResource (p. 315)
• UntagResource (p. 318)
• UpdateFileSystem (p. 320)
CreateAccessPoint

Creates an EFS access point. An access point is an application-specific view into an EFS file system that applies an operating system user and group, and a file system path, to any file system request made through the access point. The operating system user and group override any identity information provided by the NFS client. The file system path is exposed as the access point’s root directory. Applications using the access point can only access data in its own directory and below. To learn more, see Mounting a file system using EFS access points.

This operation requires permissions for the elasticfilesystem:CreateAccessPoint action.

Request Syntax

```json
POST /2015-02-01/access-points HTTP/1.1
Content-type: application/json

{
  "ClientToken": "string",
  "FileSystemId": "string",
  "PosixUser": {
    "Gid": number,
    "SecondaryGids": [ number ],
    "Uid": number
  },
  "RootDirectory": {
    "CreationInfo": {
      "OwnerGid": number,
      "OwnerUid": number,
      "Permissions": "string"
    },
    "Path": "string"
  },
  "Tags": [
    {
      "Key": "string",
      "Value": "string"
    }
  ]
}
```

URI Request Parameters

The request does not use any URI parameters.

Request Body

The request accepts the following data in JSON format.

**ClientToken (p. 233)**

A string of up to 64 ASCII characters that Amazon EFS uses to ensure idempotent creation.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: .+

Required: Yes
**FileSystemId (p. 233)**

The ID of the EFS file system that the access point provides access to.

Type: String

Length Constraints: Maximum length of 128.

Pattern: `^arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40}$`

Required: Yes

**PosixUser (p. 233)**

The operating system user and group applied to all file system requests made using the access point.

Type: `PosixUser (p. 339)` object

Required: No

**RootDirectory (p. 233)**

Specifies the directory on the Amazon EFS file system that the access point exposes as the root directory of your file system to NFS clients using the access point. The clients using the access point can only access the root directory and below. If the `RootDirectory` > `Path` specified does not exist, EFS creates it and applies the `CreationInfo` settings when a client connects to an access point. When specifying a `RootDirectory`, you need to provide the `Path`, and the `CreationInfo`.

Amazon EFS creates a root directory only if you have provided the `CreationInfo`: `OwnUid`, `OwnGID`, and permissions for the directory. If you do not provide this information, Amazon EFS does not create the root directory. If the root directory does not exist, attempts to mount using the access point will fail.

Type: `RootDirectory (p. 341)` object

Required: No

**Tags (p. 233)**

Creates tags associated with the access point. Each tag is a key-value pair, each key must be unique. For more information, see Tagging AWS resources in the AWS General Reference Guide.

Type: Array of `Tag (p. 342)` objects

Required: No

**Response Syntax**

```json
HTTP/1.1 200
Content-type: application/json

{
  "AccessPointArn": "string",
  "AccessPointId": "string",
  "ClientToken": "string",
  "FileSystemId": "string",
  "LifeCycleState": "string",
  "Name": "string",
  "OwnerId": "string",
  "PosixUser": {
```
"Gid": number,
"SecondaryGids": [ number ],
"Uid": number
}
"RootDirectory": {
"CreationInfo": {
"OwnerGid": number,
"OwnerUid": number,
"Permissions": "string"
},
"Path": "string"
},
"Tags": [
{  
"Key": "string",
"Value": "string"
}
]

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

AccessPointArn (p. 234)

The unique Amazon Resource Name (ARN) associated with the access point.

Type: String

Length Constraints: Maximum length of 128.

Pattern: ^arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:access-point/fsap-[0-9a-f]{8,40}$

AccessPointId (p. 234)

The ID of the access point, assigned by Amazon EFS.

Type: String

Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:access-point/fsap-[0-9a-f]{8,40}|fsap-[0-9a-f]{8,40})$

ClientToken (p. 234)

The opaque string specified in the request to ensure idempotent creation.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: .+

FileSystemId (p. 234)

The ID of the EFS file system that the access point applies to.

Type: String
Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$

**LifeCycleState** (p. 234)

Identifies the lifecycle phase of the access point.

Type: String

Valid Values: creating | available | updating | deleting | deleted | error

**Name** (p. 234)

The name of the access point. This is the value of the Name tag.

Type: String

**OwnerId** (p. 234)

Identified the AWS account that owns the access point resource.

Type: String

Length Constraints: Maximum length of 14.

Pattern: ^(\d{12})|(^\d{4}-\d{4}-\d{4})$

**PosixUser** (p. 234)

The full POSIX identity, including the user ID, group ID, and secondary group IDs on the access point that is used for all file operations by NFS clients using the access point.

Type: PosixUser (p. 339) object

**RootDirectory** (p. 234)

The directory on the Amazon EFS file system that the access point exposes as the root directory to NFS clients using the access point.

Type: RootDirectory (p. 341) object

**Tags** (p. 234)

The tags associated with the access point, presented as an array of Tag objects.

Type: Array of Tag (p. 342) objects

**Errors**

**AccessPointAlreadyExists**

Returned if the access point you are trying to create already exists, with the creation token you provided in the request.

HTTP Status Code: 409

**AccessPointLimitExceeded**

Returned if the AWS account has already created the maximum number of access points allowed per file system.

HTTP Status Code: 403
BadRequest
Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.
HTTP Status Code: 400

FileSystemNotFound
Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.
HTTP Status Code: 404

IncorrectFileSystemLifeCycleState
Returned if the file system's lifecycle state is not "available".
HTTP Status Code: 409

InternalServerError
Returned if an error occurred on the server side.
HTTP Status Code: 500

- AWS SDK for Python
- AWS SDK for Ruby V3
CreateFileSystem

Creates a new, empty file system. The operation requires a creation token in the request that Amazon EFS uses to ensure idempotent creation (calling the operation with same creation token has no effect). If a file system does not currently exist that is owned by the caller’s AWS account with the specified creation token, this operation does the following:

- Creates a new, empty file system. The file system will have an Amazon EFS assigned ID, and an initial lifecycle state creating.
- Returns with the description of the created file system.

Otherwise, this operation returns a FileSystemAlreadyExists error with the ID of the existing file system.

**Note**
For basic use cases, you can use a randomly generated UUID for the creation token.

The idempotent operation allows you to retry a CreateFileSystem call without risk of creating an extra file system. This can happen when an initial call fails in a way that leaves it uncertain whether or not a file system was actually created. An example might be that a transport level timeout occurred or your connection was reset. As long as you use the same creation token, if the initial call had succeeded in creating a file system, the client can learn of its existence from the FileSystemAlreadyExists error.

For more information, see Creating a file system in the Amazon EFS User Guide.

**Note**
The CreateFileSystem call returns while the file system's lifecycle state is still creating. You can check the file system creation status by calling the DescribeFileSystems (p. 279) operation, which among other things returns the file system state.

This operation accepts an optional PerformanceMode parameter that you choose for your file system. We recommend generalPurpose performance mode for most file systems. File systems using the maxIO performance mode can scale to higher levels of aggregate throughput and operations per second with a tradeoff of slightly higher latencies for most file operations. The performance mode can't be changed after the file system has been created. For more information, see Amazon EFS performance modes.

You can set the throughput mode for the file system using the ThroughputMode parameter.

After the file system is fully created, Amazon EFS sets its lifecycle state to available, at which point you can create one or more mount targets for the file system in your VPC. For more information, see CreateMountTarget (p. 248). You mount your Amazon EFS file system on an EC2 instances in your VPC by using the mount target. For more information, see Amazon EFS: How it Works.

This operation requires permissions for the elasticfilesystem:CreateFileSystem action.

**Request Syntax**

```
POST /2015-02-01/file-systems HTTP/1.1
Content-type: application/json

{
    "AvailabilityZoneName": "string",
    "Backup": boolean,
    "CreationToken": "string",
    "Encrypted": boolean,
    "KmsKeyId": "string",
    "PerformanceMode": "string",
    "ProvisionedThroughputInMibps": number,
```

```
"Tags": [ 
  { 
    "Key": "string",
    "Value": "string"
  } 
],
"ThroughputMode": "string"

**URI Request Parameters**

The request does not use any URI parameters.

**Request Body**

The request accepts the following data in JSON format.

**AvailabilityZoneName (p. 238)**

Used to create a file system that uses One Zone storage classes. It specifies the AWS Availability Zone in which to create the file system. Use the format `us-east-1a` to specify the Availability Zone. For more information about One Zone storage classes, see Using EFS storage classes in the Amazon EFS User Guide.

**Note**

One Zone storage classes are not available in all Availability Zones in AWS Regions where Amazon EFS is available.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: .+

Required: No

**Backup (p. 238)**

Specifies whether automatic backups are enabled on the file system that you are creating. Set the value to `true` to enable automatic backups. If you are creating a file system that uses One Zone storage classes, automatic backups are enabled by default. For more information, see Automatic backups in the Amazon EFS User Guide.

Default is `false`. However, if you specify an `AvailabilityZoneName`, the default is `true`.

**Note**

AWS Backup is not available in all AWS Regions where Amazon EFS is available.

Type: Boolean

Required: No

**CreationToken (p. 238)**

A string of up to 64 ASCII characters. Amazon EFS uses this to ensure idempotent creation.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: .+

Required: Yes
Encrypted (p. 238)

A Boolean value that, if true, creates an encrypted file system. When creating an encrypted file system, you have the option of specifying CreateFileSystem::KmsKeyId (p. 240) for an existing AWS Key Management Service (AWS KMS) customer master key (CMK). If you don't specify a CMK, then the default CMK for Amazon EFS, /aws/elasticfilesystem, is used to protect the encrypted file system.

Type: Boolean
Required: No

KmsKeyId (p. 238)

The ID of the AWS KMS CMK that you want to use to protect the encrypted file system. This parameter is only required if you want to use a non-default KMS key. If this parameter is not specified, the default CMK for Amazon EFS is used. This ID can be in one of the following formats:

• Key ID - A unique identifier of the key, for example
  1234abcd-12ab-34cd-56ef-1234567890ab.
• ARN - An Amazon Resource Name (ARN) for the key, for example arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab.
• Key alias - A previously created display name for a key, for example alias/projectKey1.
• Key alias ARN - An ARN for a key alias, for example arn:aws:kms:us-west-2:444455556666:alias/projectKey1.

If KmsKeyId is specified, the CreateFileSystem::Encrypted (p. 240) parameter must be set to true.

Important
EFS accepts only symmetric KMS keys. You cannot use asymmetric KMS keys with EFS file systems.

Type: String

Length Constraints: Maximum length of 2048.

Pattern: ^([0-9a-f]{8}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{12}|mrk-[0-9a-f]{32}|alias/[a-zA-Z0-9/_-]+|(arn:aws[-a-z]*:kms:[a-z0-9-]+:(key/[0-9a-f]{8}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{12})|(key/mrk-[0-9a-f]{32})|(alias/[a-zA-Z0-9-/_-]+))$.

Required: No

PerformanceMode (p. 238)

The performance mode of the file system. We recommend generalPurpose performance mode for most file systems. File systems using the maxIO performance mode can scale to higher levels of aggregate throughput and operations per second with a tradeoff of slightly higher latencies for most file operations. The performance mode can't be changed after the file system has been created.

Note
The maxIO mode is not supported on file systems using One Zone storage classes.

Type: String

Valid Values: generalPurpose | maxIO

Required: No

ProvisionedThroughputInMibps (p. 238)

The throughput, measured in MiB/s, that you want to provision for a file system that you're creating. Valid values are 1-1024. Required if ThroughputMode is set to provisioned. The upper limit for
throughput is 1024 MiB/s. To increase this limit, contact AWS Support. For more information, see Amazon EFS quotas that you can increase in the Amazon EFS User Guide.

Type: Double

Valid Range: Minimum value of 1.0.

Required: No

Tags (p. 238)

Use to create one or more tags associated with the file system. Each tag is a user-defined key-value pair. Name your file system on creation by including a "Key": "Name", "Value": "(value)" key-value pair. Each key must be unique. For more information, see Tagging AWS resources in the AWS General Reference Guide.

Type: Array of Tag (p. 342) objects

Required: No

ThroughputMode (p. 238)

Specifies the throughput mode for the file system, either bursting or provisioned. If you set ThroughputMode to provisioned, you must also set a value for ProvisionedThroughputInMibps. After you create the file system, you can decrease your file system's throughput in Provisioned Throughput mode or change between the throughput modes, as long as it's been more than 24 hours since the last decrease or throughput mode change. For more information, see Specifying throughput with provisioned mode in the Amazon EFS User Guide.

Default is bursting.

Type: String

Valid Values: bursting | provisioned

Required: No

Response Syntax

```
HTTP/1.1 201
Content-type: application/json

{
  "AvailabilityZoneId": "string",
  "AvailabilityZoneName": "string",
  "CreationTime": number,
  "CreationToken": "string",
  "Encrypted": boolean,

  "FileSystemId": "string",
  "KmsKeyId": "string",
  "LifeCycleState": "string",
  "Name": "string",
  "NumberOfMountTargets": number,
  "OwnerId": "string",
  "PerformanceMode": "string",
  "ProvisionedThroughputInMibps": number,
  "SizeInBytes": {
    "Timestamp": number,
    "Value": number,
    "ValueInIA": number,
  }
```
"ValueInStandard": number
},
"Tags": [
{
"Key": "string",
"Value": "string"
}
],
"ThroughputMode": "string"

Response Elements

If the action is successful, the service sends back an HTTP 201 response.

The following data is returned in JSON format by the service.

AvailabilityZoneId (p. 241)

The unique and consistent identifier of the Availability Zone in which the file system's One Zone storage classes exist. For example, use1-az1 is an Availability Zone ID for the us-east-1 AWS Region, and it has the same location in every AWS account.

Type: String

AvailabilityZoneName (p. 241)

Describes the AWS Availability Zone in which the file system is located, and is valid only for file systems using One Zone storage classes. For more information, see Using EFS storage classes in the Amazon EFS User Guide.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: .+

CreationTime (p. 241)

The time that the file system was created, in seconds (since 1970-01-01T00:00:00Z).

Type: Timestamp

CreationToken (p. 241)

The opaque string specified in the request.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: .+

Encrypted (p. 241)

A Boolean value that, if true, indicates that the file system is encrypted.

Type: Boolean

FileSystemArn (p. 241)

The Amazon Resource Name (ARN) for the EFS file system, in the format arn:aws:elasticfilesystem:region:account-id:file-system/file-
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Type</th>
<th>Constraints</th>
</tr>
</thead>
<tbody>
<tr>
<td>FileSystemId</td>
<td>The ID of the file system, assigned by Amazon EFS.</td>
<td>String</td>
<td>Maximum length of 128.</td>
</tr>
<tr>
<td>KmsKeyId</td>
<td>The ID of an AWS Key Management Service customer master key (CMK) that was used to protect the encrypted file system.</td>
<td>String</td>
<td>Maximum length of 2048.</td>
</tr>
<tr>
<td>LifeCycleState</td>
<td>The lifecycle phase of the file system.</td>
<td>String</td>
<td>creating</td>
</tr>
<tr>
<td>Name</td>
<td>You can add tags to a file system, including a Name tag. For more information, see CreateFileSystem (p. 238). If the file system has a Name tag, Amazon EFS returns the value in this field.</td>
<td>String</td>
<td>Maximum length of 256.</td>
</tr>
<tr>
<td>NumberOfMountTargets</td>
<td>The current number of mount targets that the file system has. For more information, see CreateMountTarget (p. 248).</td>
<td>Integer</td>
<td>Minimum value of 0.</td>
</tr>
<tr>
<td>OwnerId</td>
<td>The AWS account that created the file system. If the file system was created by an IAM user, the parent account to which the user belongs is the owner.</td>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>
Length Constraints: Maximum length of 14.

Pattern: ^\d{12}$\d{4}-\d{4}-\d{4}$

**PerformanceMode** (p. 241)

The performance mode of the file system.

Type: String

Valid Values: generalPurpose | maxIO

**ProvisionedThroughputInMibps** (p. 241)

The amount of provisioned throughput, measured in MiB/s, for the file system. Valid for file systems using ThroughputMode set to provisioned.

Type: Double

Valid Range: Minimum value of 1.0.

**SizeInBytes** (p. 241)

The latest known metered size (in bytes) of data stored in the file system, in its Value field, and the time at which that size was determined in its Timestamp field. The Timestamp value is the integer number of seconds since 1970-01-01T00:00:00Z. The SizeInBytes value doesn't represent the size of a consistent snapshot of the file system, but it is eventually consistent when there are no writes to the file system. That is, SizeInBytes represents actual size only if the file system is not modified for a period longer than a couple of hours. Otherwise, the value is not the exact size that the file system was at any point in time.

Type: FileSystemSize (p. 335) object

**Tags** (p. 241)

The tags associated with the file system, presented as an array of Tag objects.

Type: Array of Tag (p. 342) objects

**ThroughputMode** (p. 241)

Displays the file system's throughput mode. For more information, see Throughput modes in the Amazon EFS User Guide.

Type: String

Valid Values: bursting | provisioned

**Errors**

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

**FileSystemAlreadyExists**

Returned if the file system you are trying to create already exists, with the creation token you provided.

HTTP Status Code: 409
FileSystemLimitExceeded

Returned if the AWS account has already created the maximum number of file systems allowed per account.

HTTP Status Code: 403

InsufficientThroughputCapacity

Returned if there's not enough capacity to provision additional throughput. This value might be returned when you try to create a file system in provisioned throughput mode, when you attempt to increase the provisioned throughput of an existing file system, or when you attempt to change an existing file system from bursting to provisioned throughput mode. Try again later.

HTTP Status Code: 503

InternalServerError

Returned if an error occurred on the server side.

HTTP Status Code: 500

ThroughputLimitExceeded

Returned if the throughput mode or amount of provisioned throughput can't be changed because the throughput limit of 1024 MiB/s has been reached.

HTTP Status Code: 400

UnsupportedAvailabilityZone

Returned if the requested Amazon EFS functionality is not available in the specified Availability Zone.

HTTP Status Code: 400

Examples

Create an encrypted EFS file system

The following example sends a POST request to create a file system in the us-west-2 Region with automatic backups enabled. The request specifies myFileSystem1 as the creation token for idempotency.

Sample Request

```
POST /2015-02-01/file-systems HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20140620T215117Z
Authorization: <...>
Content-Type: application/json
Content-Length: 42

{
    "CreationToken" : "myFileSystem1",
    "PerformanceMode" : "generalPurpose",
    "Backup": true,
    "Encrypted": true,
    "Tags": [
        {
            "Key": "Name",
            "Value": "Test Group1"
        }
    ]
```
Create an encrypted EFS file system that uses One Zone storage classes

The following example sends a POST request to create a file system in the us-west-2 Region with automatic backups enabled. The file system will have One Zone storage redundancy in the us-west-2b Availability Zone.

Sample Request

```plaintext
POST /2015-02-01/file-systems HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20140620T215117Z
Authorization: <...>
Content-Type: application/json
Content-Length: 42

{
    "CreationToken": "myFileSystem2",
    "PerformanceMode": "generalPurpose",
    "Backup": true,
    "AvailabilityZoneName": "us-west-2b",
    "Encrypted": true,
    "ThroughputMode": "provisioned",
    "ProvisionedThroughputInMibps": 60,
    "Tags":
    {
        "Key": "Name",
        "Value": "Test Group1"
    }
}
```
Sample Response

HTTP/1.1 201 Created
x-amzn-RequestId: 01234567-89ab-cdef-0123-456789abcdef
Content-Type: application/json
Content-Length: 319

CreateMountTarget

Creates a mount target for a file system. You can then mount the file system on EC2 instances by using the mount target.

You can create one mount target in each Availability Zone in your VPC. All EC2 instances in a VPC within a given Availability Zone share a single mount target for a given file system. If you have multiple subnets in an Availability Zone, you create a mount target in one of the subnets. EC2 instances do not need to be in the same subnet as the mount target in order to access their file system.

You can create only one mount target for an EFS file system using One Zone storage classes. You must create that mount target in the same Availability Zone in which the file system is located. Use the AvailabilityZoneName and AvailabilityZoneId properties in the DescribeFileSystems (p. 279) response object to get this information. Use the subnetId associated with the file system's Availability Zone when creating the mount target.

For more information, see Amazon EFS: How it Works.

To create a mount target for a file system, the file system's lifecycle state must be available. For more information, see DescribeFileSystems (p. 279).

In the request, provide the following:

- The file system ID for which you are creating the mount target.
- A subnet ID, which determines the following:
  - The VPC in which Amazon EFS creates the mount target
  - The Availability Zone in which Amazon EFS creates the mount target
  - The IP address range from which Amazon EFS selects the IP address of the mount target (if you don't specify an IP address in the request)

After creating the mount target, Amazon EFS returns a response that includes, a MountTargetId and an IpAddress. You use this IP address when mounting the file system in an EC2 instance. You can also use the mount target's DNS name when mounting the file system. The EC2 instance on which you mount the file system by using the mount target can resolve the mount target's DNS name to its IP address. For more information, see How it Works: Implementation Overview.

Note that you can create mount targets for a file system in only one VPC, and there can be only one mount target per Availability Zone. That is, if the file system already has one or more mount targets created for it, the subnet specified in the request to add another mount target must meet the following requirements:

- Must belong to the same VPC as the subnets of the existing mount targets
- Must not be in the same Availability Zone as any of the subnets of the existing mount targets

If the request satisfies the requirements, Amazon EFS does the following:

- Creates a new mount target in the specified subnet.
- Also creates a new network interface in the subnet as follows:
  - If the request provides an IpAddress, Amazon EFS assigns that IP address to the network interface. Otherwise, Amazon EFS assigns a free address in the subnet (in the same way that the Amazon EC2 CreateNetworkInterface call does when a request does not specify a primary private IP address).
  - If the request provides SecurityGroups, this network interface is associated with those security groups. Otherwise, it belongs to the default security group for the subnet's VPC.
• Assigns the description `Mount target fsmt-id for file system fs-id` where `fsmt-id` is the mount target ID, and `fs-id` is the `FileSystemId`.

• Sets the `requesterManaged` property of the network interface to `true`, and the `requesterId` value to `EFS`.

Each Amazon EFS mount target has one corresponding requester-managed EC2 network interface. After the network interface is created, Amazon EFS sets the `NetworkInterfaceId` field in the mount target's description to the network interface ID, and the `IpAddress` field to its address. If network interface creation fails, the entire `CreateMountTarget` operation fails.

**Note**
The `CreateMountTarget` call returns only after creating the network interface, but while the mount target state is still `creating`, you can check the mount target creation status by calling the `DescribeMountTargets` (p. 286) operation, which among other things returns the mount target state.

We recommend that you create a mount target in each of the Availability Zones. There are cost considerations for using a file system in an Availability Zone through a mount target created in another Availability Zone. For more information, see Amazon EFS. In addition, by always using a mount target local to the instance's Availability Zone, you eliminate a partial failure scenario. If the Availability Zone in which your mount target is created goes down, then you can't access your file system through that mount target.

This operation requires permissions for the following action on the file system:

• `elasticfilesystem:CreateMountTarget`

This operation also requires permissions for the following Amazon EC2 actions:

• `ec2:DescribeSubnets`
• `ec2:DescribeNetworkInterfaces`
• `ec2:CreateNetworkInterface`

**Request Syntax**

```json
POST /2015-02-01/mount-targets HTTP/1.1
Content-type: application/json

{
  "FileSystemId": "string",
  "IpAddress": "string",
  "SecurityGroups": [ "string" ],
  "SubnetId": "string"
}
```

**URI Request Parameters**

The request does not use any URI parameters.

**Request Body**

The request accepts the following data in JSON format.
**FXMLId** (p. 249)

The ID of the file system for which to create the mount target.

Type: String

Length Constraints: Maximum length of 128.

Pattern: `^arn:aws[-a-z]+:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f](8,40)|fs-[0-9a-f](8,40)$`

Required: Yes

**IpAddress** (p. 249)

Valid IPv4 address within the address range of the specified subnet.

Type: String

Pattern: `^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$`

Required: No

**SecurityGroups** (p. 249)

Up to five VPC security group IDs, of the form sg-xxxxxxxx. These must be for the same VPC as subnet specified.

Type: Array of strings

Array Members: Maximum number of 100 items.

Pattern: `^sg-[0-9a-f](8,40)\$`

Required: No

**SubnetId** (p. 249)

The ID of the subnet to add the mount target in. For file systems that use One Zone storage classes, use the subnet that is associated with the file system's Availability Zone.

Type: String

Pattern: `^subnet-[0-9a-f](8,40)$`

Required: Yes

### Response Syntax

```
HTTP/1.1 200
Content-type: application/json

{
 "AvailabilityZoneId": "string",
 "AvailabilityZoneName": "string",
```
"FileSystemId": "string",
"IpAddress": "string",
"LifeCycleState": "string",
"MountTargetId": "string",
"NetworkInterfaceId": "string",
"OwnerId": "string",
"SubnetId": "string",
"VpcId": "string"
}

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

AvailabilityZoneId (p. 250)

The unique and consistent identifier of the Availability Zone that the mount target resides in. For example, use1-az1 is an AZ ID for the us-east-1 Region and it has the same location in every AWS account.

Type: String

AvailabilityZoneName (p. 250)

The name of the Availability Zone in which the mount target is located. Availability Zones are independently mapped to names for each AWS account. For example, the Availability Zone us-east-1a for your AWS account might not be the same location as us-east-1a for another AWS account.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: .+

FileSystemId (p. 250)

The ID of the file system for which the mount target is intended.

Type: String

Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$

IpAddress (p. 250)

Address at which the file system can be mounted by using the mount target.

Type: String

Pattern: ^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$

LifeCycleState (p. 250)

Lifecycle state of the mount target.

Type: String
Valid Values: creating | available | updating | deleting | deleted | error

**MountTargetId (p. 250)**

System-assigned mount target ID.

Type: String

Pattern: ^fsmt-[0-9a-f]{8,40}$

**NetworkInterfaceId (p. 250)**

The ID of the network interface that Amazon EFS created when it created the mount target.

Type: String

**OwnerId (p. 250)**

AWS account ID that owns the resource.

Type: String

Length Constraints: Maximum length of 14.

Pattern: ^\d{12}|\d{4}-\d{4}-\d{4}$

**SubnetId (p. 250)**

The ID of the mount target's subnet.

Type: String

Pattern: ^subnet-[0-9a-f]{8,40}$

**VpcId (p. 250)**

The virtual private cloud (VPC) ID that the mount target is configured in.

Type: String

**Errors**

**AvailabilityZonesMismatch**

Returned if the Availability Zone that was specified for a mount target is different from the Availability Zone that was specified for One Zone storage classes. For more information, see [Regional and One Zone storage redundancy](#).

HTTP Status Code: 400

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

**FileSystemNotFound**

Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.
HTTP Status Code: 404
**IncorrectFileSystemLifeCycleState**
Returned if the file system's lifecycle state is not "available".

HTTP Status Code: 409
**InternalServerError**
Returned if an error occurred on the server side.

HTTP Status Code: 500
**IpAddressInUse**
Returned if the request specified an IpAddress that is already in use in the subnet.

HTTP Status Code: 409
**MountTargetConflict**
Returned if the mount target would violate one of the specified restrictions based on the file system's existing mount targets.

HTTP Status Code: 409
**NetworkInterfaceLimitExceeded**
The calling account has reached the limit for elastic network interfaces for the specific AWS Region. The client should try to delete some elastic network interfaces or get the account limit raised. For more information, see Amazon VPC Limits in the Amazon VPC User Guide (see the Network interfaces per VPC entry in the table).

HTTP Status Code: 409
**NoFreeAddressesInSubnet**
Returned if IpAddress was not specified in the request and there are no free IP addresses in the subnet.

HTTP Status Code: 409
**SecurityGroupLimitExceeded**
Returned if the size of SecurityGroups specified in the request is greater than five.

HTTP Status Code: 400
**SecurityGroupNotFound**
Returned if one of the specified security groups doesn't exist in the subnet's VPC.

HTTP Status Code: 400
**SubnetNotFound**
Returned if there is no subnet with ID SubnetId provided in the request.

HTTP Status Code: 400
**UnsupportedAvailabilityZone**
Returned if the requested Amazon EFS functionality is not available in the specified Availability Zone.

HTTP Status Code: 400
Examples

Add a mount target to a file system

The following request creates a mount target for a file system. The request specifies values for only the required `FileSystemId` and `SubnetId` parameters. The request does not provide the optional `IpAddress` and `SecurityGroups` parameters. For `IpAddress`, the operation uses one of the available IP addresses in the specified subnet. And, the operation uses the default security group associated with the VPC for the `SecurityGroups`.

Sample Request

```plaintext
POST /2015-02-01/mount-targets HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20140620T221118Z
Authorization: ...
Content-Type: application/json
Content-Length: 160

{"SubnetId": "subnet-748c5d03", "FileSystemId": "fs-01234567"}
```

Sample Response

```plaintext
HTTP/1.1 200 OK
x-amzn-RequestId: 01234567-89ab-cdef-0123-456789abcdef
Content-Type: application/json
Content-Length: 252

{
    "MountTargetId": "fsmt-55a4413c",
    "NetworkInterfaceId": "eni-01234567",
    "FileSystemId": "fs-01234567",
    "LifeCycleState": "available",
    "SubnetId": "subnet-01234567",
    "OwnerId": "231243201240",
    "IpAddress": "172.31.22.183"
}
```

Add a mount target to a file system

The following request specifies all the request parameters to create a mount target.

Sample Request

```plaintext
POST /2015-02-01/mount-targets HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20140620T221118Z
Authorization: ...
Content-Type: application/json
Content-Length: 160

{
    "FileSystemId": "fs-01234567",
    "SubnetId": "subnet-01234567",
    "IpAddress": "10.0.2.42",
    "SecurityGroups": [
        "sg-01234567"
    ]
}
```
Sample Response

HTTP/1.1 200 OK
x-amzn-RequestId: 01234567-89ab-cdef-0123-456789abcdef
Content-Type: application/json
Content-Length: 252

{
  "OwnerId":"251839141158",
  "MountTargetId":"fsmt-9a13661e",
  "FileSystemId":"fs-01234567",
  "SubnetId":"subnet-fd04ff94",
  "LifeCycleState":"available",
  "IpAddress":"10.0.2.42",
  "NetworkInterfaceId":"eni-1bcb7772"
}

CreateTags

Note
DEPRECATED - CreateTags is deprecated and not maintained. Please use the TagResource (p. 315) API action to create tags for EFS resources.

Creates or overwrites tags associated with a file system. Each tag is a key-value pair. If a tag key specified in the request already exists on the file system, this operation overwrites its value with the value provided in the request. If you add the Name tag to your file system, Amazon EFS returns it in the response to the DescribeFileSystems (p. 279) operation.

This operation requires permission for the elasticfilesystem:CreateTags action.

Request Syntax

POST /2015-02-01/create-tags/FileSystemId HTTP/1.1
Content-type: application/json

```
{
   "Tags": [
      {
         "Key": "string",
         "Value": "string"
      }
   ]
}
```

URI Request Parameters

The request uses the following URI parameters.

FileSystemId (p. 256)

The ID of the file system whose tags you want to modify (String). This operation modifies the tags only, not the file system.

Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]:+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$

   Required: Yes

Request Body

The request accepts the following data in JSON format.

Tags (p. 256)

An array of Tag objects to add. Each Tag object is a key-value pair.

Type: Array of Tag (p. 342) objects

Required: Yes
**Response Syntax**

```
HTTP/1.1 204
```

**Response Elements**

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

**Errors**

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

**FileSystemNotFound**

Returned if the specified `FileSystemId` value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**InternalServer**

Returned if an error occurred on the server side.

HTTP Status Code: 500

**See Also**

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java V2
- AWS SDK for JavaScript
- AWS SDK for PHP V3
- AWS SDK for Python
- AWS SDK for Ruby V3
DeleteAccessPoint

Deletes the specified access point. After deletion is complete, new clients can no longer connect to the access points. Clients connected to the access point at the time of deletion will continue to function until they terminate their connection.

This operation requires permissions for the elasticfilesystem:DeleteAccessPoint action.

Request Syntax

```
DELETE /2015-02-01/access-points/AccessPointId HTTP/1.1
```

URI Request Parameters

The request uses the following URI parameters.

**AccessPointId (p. 258)**

The ID of the access point that you want to delete.

Length Constraints: Maximum length of 128.

Pattern: `^arn:aws[-a-zA-Z]+:elasticfilesystem:[0-9a-zA-Z]+:access-point/fsap-[0-9a-f]{8,40}|fsap-[0-9a-f]{8,40}$`

Required: Yes

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 204
```

Response Elements

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

Errors

**AccessPointNotFound**

Returned if the specified AccessPointId value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400
InternalServerError

Returned if an error occurred on the server side.

HTTP Status Code: 500

- AWS SDK for JavaScript
- AWS SDK for PHP V3
- AWS SDK for Python
- AWS SDK for Ruby V3
DeleteFileSystem

Deletes a file system, permanently severing access to its contents. Upon return, the file system no longer exists and you can't access any contents of the deleted file system.

You can't delete a file system that is in use. That is, if the file system has any mount targets, you must first delete them. For more information, see DescribeMountTargets (p. 286) and DeleteMountTarget (p. 264).

Note
The DeleteFileSystem call returns while the file system state is still deleting. You can check the file system deletion status by calling the DescribeFileSystems (p. 279) operation, which returns a list of file systems in your account. If you pass file system ID or creation token for the deleted file system, the DescribeFileSystems (p. 279) returns a 404 FileSystemNotFound error.

This operation requires permissions for the elasticfilesystem:DeleteFileSystem action.

Request Syntax

DELETE /2015-02-01/file-systems/FileSystemId HTTP/1.1

URI Request Parameters

The request uses the following URI parameters.

FileSystemId (p. 260)

The ID of the file system you want to delete.

Length Constraints: Maximum length of 128.

Pattern: ^\{arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40}\}$

Required: Yes

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 204

Response Elements

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

Errors

BadRequest

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.
HTTP Status Code: 400

FileSystemInUse

Returned if a file system has mount targets.

HTTP Status Code: 409

FileSystemNotFoundException

Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

InternalServerError

Returned if an error occurred on the server side.

HTTP Status Code: 500

Examples

Delete a file system

The following example sends a DELETE request to the file-systems endpoint (elasticfilesystem.us-west-2.amazonaws.com/2015-02-01/file-systems/fs-01234567) to delete a file system whose ID is fs-01234567.

Sample Request

DELETE /2015-02-01/file-systems/fs-01234567 HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20140622T233021Z
Authorization: <...>

Sample Response

HTTP/1.1 204 No Content
x-amzn-RequestId: a2d125b3-7ebd-4d6a-ab3d-5548630bff33
Content-Length: 0

See Also

- AWS SDK for Go
- AWS SDK for Java V2
- AWS SDK for JavaScript
- AWS SDK for PHP V3
- AWS SDK for Python
- AWS SDK for Ruby V3
DeleteFileSystemPolicy

Deletes the FileSystemPolicy for the specified file system. The default FileSystemPolicy goes into effect once the existing policy is deleted. For more information about the default file system policy, see Using Resource-based Policies with EFS.

This operation requires permissions for the elasticfilesystem:DeleteFileSystemPolicy action.

Request Syntax

```
DELETE /2015-02-01/file-systems/{FileSystemId}/policy HTTP/1.1
```

URI Request Parameters

The request uses the following URI parameters.

**FileSystemId (p. 262)**

Specifies the EFS file system for which to delete the FileSystemPolicy.

Length Constraints: Maximum length of 128.

Pattern: `^(/arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]:+file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$`

Required: Yes

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 200
```

Response Elements

If the action is successful, the service sends back an HTTP 200 response with an empty HTTP body.

Errors

**FileSystemNotFound**

- Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.
- HTTP Status Code: 404

**IncorrectFileSystemLifecycleState**

- Returned if the file system's lifecycle state is not "available".
- HTTP Status Code: 409

**InternalServer**

- Returned if an error occurred on the server side.
HTTP Status Code: 500

See Also

- AWS Command Line Interface
- AWS SDK for .NET
- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java V2
- AWS SDK for JavaScript
- AWS SDK for PHP V3
- AWS SDK for Python
- AWS SDK for Ruby V3
DeleteMountTarget

Deletes the specified mount target.

This operation forcibly breaks any mounts of the file system by using the mount target that is being deleted, which might disrupt instances or applications using those mounts. To avoid applications getting cut off abruptly, you might consider unmounting any mounts of the mount target, if feasible. The operation also deletes the associated network interface. Uncommitted writes might be lost, but breaking a mount target using this operation does not corrupt the file system itself. The file system you created remains. You can mount an EC2 instance in your VPC by using another mount target.

This operation requires permissions for the following action on the file system:

- `elasticfilesystem:DeleteMountTarget`

**Note**

The `DeleteMountTarget` call returns while the mount target state is still deleting. You can check the mount target deletion by calling the `DescribeMountTargets` operation, which returns a list of mount target descriptions for the given file system.

The operation also requires permissions for the following Amazon EC2 action on the mount target's network interface:

- `ec2:DeleteNetworkInterface`

Request Syntax

```
DELETE /2015-02-01/mount-targets/MountTargetId HTTP/1.1
```

URI Request Parameters

The request uses the following URI parameters.

**MountTargetId** (p. 264)

The ID of the mount target to delete (String).

Pattern: ^fsmt-[0-9a-f]{8,40}$

Required: Yes

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 204
```

Response Elements

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.
Errors

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

**DependencyTimeout**

The service timed out trying to fulfill the request, and the client should try the call again.

HTTP Status Code: 504

**InternalServerError**

Returned if an error occurred on the server side.

HTTP Status Code: 500

**MountTargetNotFound**

Returned if there is no mount target with the specified ID found in the caller's AWS account.

HTTP Status Code: 404

Examples

Remove a file system's mount target

The following example sends a DELETE request to delete a specific mount target.

**Sample Request**

```
DELETE /2015-02-01/mount-targets/fsmt-9a13661e HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20140622T232908Z
Authorization: <...>
```

**Sample Response**

```
HTTP/1.1 204 No Content
x-amzn-RequestId: 01234567-89ab-cdef-0123-456789abcdef
```

DeleteTags

Note
DEPRECATED - DeleteTags is deprecated and not maintained. Please use the UntagResource (p. 318) API action to remove tags from EFS resources.

Deletes the specified tags from a file system. If the DeleteTags request includes a tag key that doesn't exist, Amazon EFS ignores it and doesn't cause an error. For more information about tags and related restrictions, see Tag restrictions in the AWS Billing and Cost Management User Guide.

This operation requires permissions for the elasticfilesystem:DeleteTags action.

Request Syntax

POST /2015-02-01/delete-tags/FileSystemId HTTP/1.1
Content-type: application/json
{
  "TagKeys": [ "string" ]
}

URI Request Parameters

The request uses the following URI parameters.

FileSystemId (p. 267)

The ID of the file system whose tags you want to delete (String).

Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]:+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$

Required: Yes

Request Body

The request accepts the following data in JSON format.

TagKeys (p. 267)

A list of tag keys to delete.

Type: Array of strings

Array Members: Minimum number of 1 item. Maximum number of 50 items.

Pattern: ^([^\[aA\]{1}[wW\]{1}sS\]{1}:)[\\p{L}\\p{Z}\\p{N}_:+=\-=\@]*$?

Required: Yes

Response Syntax

HTTP/1.1 204
Response Elements

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

Errors

BadRequest

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

FileSystemNotFound

Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

InternalServerError

Returned if an error occurred on the server side.

HTTP Status Code: 500

- AWS SDK for Ruby V3
DescribeAccessPoints

Returns the description of a specific Amazon EFS access point if the AccessPointId is provided. If you provide an EFS FileSystemId, it returns descriptions of all access points for that file system. You can provide either an AccessPointId or a FileSystemId in the request, but not both.

This operation requires permissions for the elasticfilesystem:DescribeAccessPoints action.

Request Syntax

GET /2015-02-01/access-points?AccessPointId=AccessPointId&FileSystemId=FileSystemId&MaxResults=MaxResults&NextToken=NextToken
HTTP/1.1

URI Request Parameters

The request uses the following URI parameters.

AccessPointId  (p. 269)

(Optional) Specifies an EFS access point to describe in the response; mutually exclusive with FileSystemId.

Length Constraints: Maximum length of 128.

Pattern: ^arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]:+access-point/fsap-[0-9a-f]{8,40}|fsap-[0-9a-f]{8,40}$

FileSystemId  (p. 269)

(Optional) If you provide a FileSystemId, EFS returns all access points for that file system; mutually exclusive with AccessPointId.

Length Constraints: Maximum length of 128.

Pattern: ^arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]:+file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40}$

MaxResults  (p. 269)

(Optional) When retrieving all access points for a file system, you can optionally specify the MaxItems parameter to limit the number of objects returned in a response. The default value is 100.

Valid Range: Minimum value of 1.

NextToken  (p. 269)

NextToken is present if the response is paginated. You can use NextMarker in the subsequent request to fetch the next page of access point descriptions.

Pattern: .+

Request Body

The request does not have a request body.
Response Syntax

HTTP/1.1 200
Content-type: application/json

{
  "AccessPoints": [
    {
      "AccessPointArn": "string",
      "AccessPointId": "string",
      "ClientToken": "string",
      "FileSystemId": "string",
      "LifeCycleState": "string",
      "Name": "string",
      "OwnerId": "string",
      "PosixUser": {
        "Gid": number,
        "SecondaryGids": [ number ],
        "Uid": number
      },
      "RootDirectory": {
        "CreationInfo": {
          "OwnerGid": number,
          "OwnerUid": number,
          "Permissions": "string"
        },
        "Path": "string"
      },
      "Tags": [
        {
          "Key": "string",
          "Value": "string"
        }
      ]
    },
    "NextToken": "string"
  ]
}

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**AccessPoints (p. 270)**

An array of access point descriptions.

Type: Array of AccessPointDescription (p. 326) objects

**NextToken (p. 270)**

Present if there are more access points than returned in the response. You can use the NextMarker in the subsequent request to fetch the additional descriptions.

Type: String

Pattern: .+
### Errors

**AccessPointNotFound**

Returned if the specified `AccessPointId` value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

**FileSystemNotFound**

Returned if the specified `FileSystemId` value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**InternalServer Error**

Returned if an error occurred on the server side.

HTTP Status Code: 500

### See Also

DescribeAccountPreferences

Returns the account preferences settings for the AWS account associated with the user making the request, in the current AWS Region. For more information, see Managing Amazon EFS resource IDs.

Request Syntax

GET /2015-02-01/account-preferences HTTP/1.1
Content-type: application/json

{   "MaxResults": number,
   "NextToken": "string"
}

URI Request Parameters

The request does not use any URI parameters.

Request Body

The request accepts the following data in JSON format.

MaxResults (p. 272)

(Optional) When retrieving account preferences, you can optionally specify the MaxItems parameter to limit the number of objects returned in a response. The default value is 100.

Type: Integer

Valid Range: Minimum value of 1.

Required: No

NextToken (p. 272)

(Optional) You can use NextToken in a subsequent request to fetch the next page of AWS account preferences if the response payload was paginated.

Type: String

Pattern: .+

Required: No

Response Syntax

HTTP/1.1 200
Content-type: application/json

{   "NextToken": "string",
   "ResourceIdPreference": {   "ResourceIdType": "string",
      "Resources": [ "string" ]
   }
}

272
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

NextToken (p. 272)

Present if there are more records than returned in the response. You can use the NextToken in the subsequent request to fetch the additional descriptions.

Type: String

Pattern: .+

ResourceIdPreference (p. 272)

Describes the resource ID preference setting for the AWS account associated with the user making the request, in the current AWS Region.

Type: ResourceIdPreference (p. 340) object

Errors

InternalServerErro

Returned if an error occurred on the server side.

HTTP Status Code: 500

See Also

DescribeBackupPolicy

Returns the backup policy for the specified EFS file system.

Request Syntax

```plaintext
GET /2015-02-01/file-systems/FileSystemId/backup-policy HTTP/1.1
```

URI Request Parameters

The request uses the following URI parameters.

**FileSystemId (p. 274)**

Specifies which EFS file system to retrieve the BackupPolicy for.

Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$

Required: Yes

Request Body

The request does not have a request body.

Response Syntax

```plaintext
HTTP/1.1 200
Content-type: application/json

{
  "BackupPolicy": {
    "Status": "string"
  }
}
```

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**BackupPolicy (p. 274)**

Describes the file system's backup policy, indicating whether automatic backups are turned on or off.

Type: BackupPolicy (p. 328) object
Errors

BadRequest

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

FileSystemNotFound

Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

InternalServer Error

Returned if an error occurred on the server side.

HTTP Status Code: 500

PolicyNotFound

Returned if the default file system policy is in effect for the EFS file system specified.

HTTP Status Code: 404

ValidationException

Returned if the AWS Backup service is not available in the AWS Region in which the request was made.

HTTP Status Code: 400

DescribeFileSystemPolicy

Returns the FileSystemPolicy for the specified EFS file system.

This operation requires permissions for the elasticfilesystem:DescribeFileSystemPolicy action.

Request Syntax

GET /2015-02-01/file-systems/FileSystemId/policy HTTP/1.1

URI Request Parameters

The request uses the following URI parameters.

FileSystemId (p. 276)

Specifies which EFS file system to retrieve the FileSystemPolicy for.

Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$

Required: Yes

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 200
Content-type: application/json

{
  "FileSystemId": "string",
  "Policy": "string"
}

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

FileSystemId (p. 276)

Specifies the EFS file system to which the FileSystemPolicy applies.

Type: String

Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$
Policy (p. 276)

The JSON formatted FileSystemPolicy for the EFS file system.

Type: String

Pattern: [\s\S]+

Errors

FileSystemNotFound

Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

InternalServer Error

Returned if an error occurred on the server side.

HTTP Status Code: 500

PolicyNotFound

Returned if the default file system policy is in effect for the EFS file system specified.

HTTP Status Code: 404

Examples

Example

This example illustrates one usage of DescribeFileSystemPolicy.

Sample Request

GET /2015-02-01/file-systems/fs-01234567/policy HTTP/1.1

Sample Response

```json
{
  "FileSystemId": "fs-01234567",
  "Policy": {
    "Version": "2012-10-17",
    "Id": "efs-policy-wizard-cdef0123-aaaa-6666-5555-444455556666",
    "Statement": [
      {
        "Sid": "efs-statement-abcdef01-1111-bbbb-2222-111122224444",
        "Effect": "Deny",
        "Principal": {
          "AWS": "*"
        },
        "Action": "*",
        "Condition": {
          "Bool": {
```

```json
{,
  "Sid": "efs-statement-01234567-aaaa-3333-4444-111122223333",
  "Effect": "Allow",
  "Principal": {
    "AWS": "*"
  },
  "Action": [
    "elasticfilesystem:ClientMount",
    "elasticfilesystem:ClientWrite"
  ],
}
}
```

DescribeFileSystems

Returns the description of a specific Amazon EFS file system if either the file system CreationToken or the FileSystemId is provided. Otherwise, it returns descriptions of all file systems owned by the caller's AWS account in the AWS Region of the endpoint that you're calling.

When retrieving all file system descriptions, you can optionally specify the MaxItems parameter to limit the number of descriptions in a response. Currently, this number is automatically set to 10. If more file system descriptions remain, Amazon EFS returns a NextMarker, an opaque token, in the response. In this case, you should send a subsequent request with the Marker request parameter set to the value of NextMarker.

To retrieve a list of your file system descriptions, this operation is used in an iterative process, where DescribeFileSystems is called first without the Marker and then the operation continues to call it with the Marker parameter set to the value of the NextMarker from the previous response until the response has no NextMarker.

The order of file systems returned in the response of one DescribeFileSystems call and the order of file systems returned across the responses of a multi-call iteration is unspecified.

This operation requires permissions for the elasticfilesystem:DescribeFileSystems action.

Request Syntax

GET /2015-02-01/file-systems?
CreationToken=CreationToken&FileSystemId=FileSystemId&Marker=Marker&MaxItems=MaxItems
HTTP/1.1

URI Request Parameters

The request uses the following URI parameters.

CreationToken  (p. 279)

(Optional) Restricts the list to the file system with this creation token (String). You specify a creation token when you create an Amazon EFS file system.

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: .+

FileSystemId  (p. 279)

(Optional) ID of the file system whose description you want to retrieve (String).

Length Constraints: Maximum length of 128.

Pattern: ^arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40}$

Marker  (p. 279)

(Optional) Opaque pagination token returned from a previous DescribeFileSystems operation (String). If present, specifies to continue the list from where the returning call had left off.

Pattern: .+

MaxItems (p. 279)

(Optional) Specifies the maximum number of file systems to return in the response (integer). This number is automatically set to 100. The response is paginated at 100 per page if you have more than 100 file systems.

Valid Range: Minimum value of 1.

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 200
Content-type: application/json

{
  "FileSystems": [
    {
      "AvailabilityZoneId": "string",
      "AvailabilityZoneName": "string",
      "CreationTime": number,
      "CreationToken": "string",
      "Encrypted": boolean,
      "FileSystemArn": "string",
      "FileSystemId": "string",
      "KmsKeyId": "string",
      "LifeCycleState": "string",
      "Name": "string",
      "NumberOfMountTargets": number,
      "OwnerId": "string",
      "PerformanceMode": "string",
      "ProvisionedThroughputInMibps": number,
      "SizeInBytes": {
        "Timestamp": number,
        "Value": number,
        "ValueInIA": number,
        "ValueInStandard": number
      },
      "Tags": [
        {
          "Key": "string",
          "Value": "string"
        }
      ],
      "ThroughputMode": "string"
    }
  ],
  "Marker": "string",
  "NextMarker": "string"
}

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.
**FileSystems** (p. 280)

An array of file system descriptions.

Type: Array of **FileSystemDescription** (p. 331) objects

**Marker** (p. 280)

Present if provided by caller in the request (String).

Type: String

Pattern: .+

**NextMarker** (p. 280)

Present if there are more file systems than returned in the response (String). You can use the NextMarker in the subsequent request to fetch the descriptions.

Type: String

Pattern: .+

**Errors**

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

**FileSystemNotFound**

Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**InternalServer>Error**

Returned if an error occurred on the server side.

HTTP Status Code: 500

**Examples**

**Retrieve a list of 10 file systems**

The following example sends a GET request to the file-systems endpoint (`elasticfilesystem.us-west-2.amazonaws.com/2015-02-01/file-systems`). The request specifies a MaxItems query parameter to limit the number of file system descriptions to 10.

**Sample Request**

```
GET /2015-02-01/file-systems?MaxItems=10 HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20140622T191208Z
```
Authorization: <...>

Sample Response

HTTP/1.1 200 OK
x-amzn-RequestId: 01234567-89ab-cdef-0123-456789abcdef
Content-Type: application/json
Content-Length: 499
{
  "FileSystems": [  
    
    {  
      "OwnerId": "251839141158",
      "CreationToken": "MyFileSystem1",
      "FileSystemId": "fs-01234567",
      "PerformanceMode": "generalPurpose",
      "CreationTime": "1403301078",
      "LifeCycleState": "created",
      "Name": "my first file system",
      "NumberOfMountTargets": 1,
      "SizeInBytes": {  
        "Timestamp": 1403301078,
        "Value": 29313417216,
        "ValueInIA": 675432,
        "ValueInStandard": 29312741784
      }
    }
  ]
}

DescribeLifecycleConfiguration

Returns the current LifecycleConfiguration object for the specified Amazon EFS file system. EFS lifecycle management uses the LifecycleConfiguration object to identify which files to move to the EFS Infrequent Access (IA) storage class. For a file system without a LifecycleConfiguration object, the call returns an empty array in the response.

When EFS Intelligent Tiering is enabled, TransitionToPrimaryStorageClass has a value of AFTER_1_ACCESS.

This operation requires permissions for the elasticfilesystem:DescribeLifecycleConfiguration operation.

Request Syntax

```
GET /2015-02-01/file-systems/FileSystemId/lifecycle-configuration HTTP/1.1
```

URI Request Parameters

The request uses the following URI parameters.

**FileSystemId (p. 283)**

The ID of the file system whose LifecycleConfiguration object you want to retrieve (String).

Length Constraints: Maximum length of 128.

Pattern: `^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$`

Required: Yes

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 200
Content-type: application/json

{
   "LifecyclePolicies": [
   {
      "TransitionToIA": "string",
      "TransitionToPrimaryStorageClass": "string"
   }
   ]
}
```

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.
**LifecyclePolicies (p. 283)**

An array of lifecycle management policies. EFS supports a maximum of one policy per file system.

Type: Array of LifecyclePolicy (p. 336) objects

Array Members: Maximum number of 2 items.

**Errors**

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

**FileSystemNotFound**

Returned if the specified FileSystemId value doesn’t exist in the requester’s AWS account.

HTTP Status Code: 404

**InternalServer**

Returned if an error occurred on the server side.

HTTP Status Code: 500

**Examples**

**Retrieve the lifecycle configuration for a file system**

The following request retrieves the LifecycleConfiguration object for the specified file system.

**Sample Request**

```
GET /2015-02-01/file-systems/fs-01234567/lifecycle-configuration HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20181120T221118Z
Authorization: <...>
```

**Sample Response**

```
HTTP/1.1 200 OK
x-amzn-RequestId: 01234567-89ab-cdef-0123-456789abcdef
Content-Type: application/json
Content-Length: 86
{
    "LifecyclePolicies": [
        {
            "TransitionToIA": "AFTER_14_DAYS"
        },
        {
            "TransitionToPrimaryStorageClass": "AFTER_1_ACCESS"
        }
    ]
}
```

DescribeMountTargets

Returns the descriptions of all the current mount targets, or a specific mount target, for a file system. When requesting all of the current mount targets, the order of mount targets returned in the response is unspecified.

This operation requires permissions for the elasticfilesystem:DescribeMountTargets action, on either the file system ID that you specify in FileSystemId, or on the file system of the mount target that you specify in MountTargetId.

Request Syntax

```
GET /2015-02-01/mount-targets?
AccessPointId=AccessPointId&FileSystemId=FileSystemId&Marker=Marker&MaxItems=MaxItems&MountTargetId=MountTargetId
```

HTTP/1.1

URI Request Parameters

The request uses the following URI parameters.

**AccessPointId (p. 286)**

(Optional) The ID of the access point whose mount targets that you want to list. It must be included in your request if a FileSystemId or MountTargetId is not included in your request. Accepts either an access point ID or ARN as input.

Length Constraints: Maximum length of 128.

Pattern: ^arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:access-point/fsap-[0-9a-f]{8,40}|fsap-[0-9a-f]{8,40}$

**FileSystemId (p. 286)**

(Optional) ID of the file system whose mount targets you want to list (String). It must be included in your request if an AccessPointId or MountTargetId is not included. Accepts either a file system ID or ARN as input.

Length Constraints: Maximum length of 128.

Pattern: ^arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40}$

**Marker (p. 286)**

(Optional) Opaque pagination token returned from a previous DescribeMountTargets operation (String). If present, it specifies to continue the list from where the previous returning call left off.

Pattern: .+

**MaxItems (p. 286)**

(Optional) Maximum number of mount targets to return in the response. Currently, this number is automatically set to 10, and other values are ignored. The response is paginated at 100 per page if you have more than 100 mount targets.

Valid Range: Minimum value of 1.
MountTargetId (p. 286)

(Optional) ID of the mount target that you want to have described (String). It must be included in your request if FileSystemId is not included. Accepts either a mount target ID or ARN as input.

Pattern: \^fsmt-[0-9a-f]{8,40}\$

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 200
Content-type: application/json

{
   "Marker": "string",
   "MountTargets": [
      {
         "AvailabilityZoneId": "string",
         "AvailabilityZoneName": "string",
         "FileSystemId": "string",
         "IpAddress": "string",
         "LifeCycleState": "string",
         "MountTargetId": "string",
         "NetworkInterfaceId": "string",
         "OwnerId": "string",
         "SubnetId": "string",
         "VpcId": "string"
      }
   ],
   "NextMarker": "string"
}
```

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

Marker (p. 287)

If the request included the Marker, the response returns that value in this field.

Type: String

Pattern: .+

MountTargets (p. 287)

Returns the file system's mount targets as an array of MountTargetDescription objects.

Type: Array of MountTargetDescription (p. 337) objects
**NextMarker** (p. 287)

If a value is present, there are more mount targets to return. In a subsequent request, you can provide `Marker` in your request with this value to retrieve the next set of mount targets.

Type: String

Pattern: .+

**Errors**

**AccessPointNotFound**

Returned if the specified `AccessPointId` value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

**FileSystemNotFound**

Returned if the specified `FileSystemId` value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**InternalServerError**

Returned if an error occurred on the server side.

HTTP Status Code: 500

**MountTargetNotFound**

Returned if there is no mount target with the specified ID found in the caller's AWS account.

HTTP Status Code: 404

**Examples**

**Retrieve descriptions of mount targets created for a file system**

The following request retrieves descriptions of mount targets created for the specified file system.

**Sample Request**

```
GET /2015-02-01/mount-targets?FileSystemId=fs-01234567 HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20140622T191252Z
Authorization: <...>
```

**Sample Response**

```
HTTP/1.1 200 OK
```

DescribeMountTargetSecurityGroups

Returns the security groups currently in effect for a mount target. This operation requires that the network interface of the mount target has been created and the lifecycle state of the mount target is not deleted.

This operation requires permissions for the following actions:

- elasticfilesystem:DescribeMountTargetSecurityGroups action on the mount target's file system.
- ec2:DescribeNetworkInterfaceAttribute action on the mount target's network interface.

Request Syntax

GET /2015-02-01/mount-targets/MountTargetId/security-groups HTTP/1.1

URI Request Parameters

The request uses the following URI parameters.

MountTargetId (p. 290)

The ID of the mount target whose security groups you want to retrieve.

Pattern: ^fsmt-[0-9a-f]{8,40}$

Required: Yes

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 200
Content-type: application/json

{
   "SecurityGroups": [ "string" ]
}

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

SecurityGroups (p. 290)

An array of security groups.

Type: Array of strings
Array Members: Maximum number of 100 items.

Pattern: ^sg-[0-9a-f]{8,40}

Errors

BadRequest

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

IncorrectMountTargetState

Returned if the mount target is not in the correct state for the operation.

HTTP Status Code: 409

InternalServerError

Returned if an error occurred on the server side.

HTTP Status Code: 500

MountTargetNotFound

Returned if there is no mount target with the specified ID found in the caller's AWS account.

HTTP Status Code: 404

Examples

Retrieve security groups in effect for a file system

The following example retrieves the security groups that are in effect for the network interface associated with a mount target.

Sample Request

```
GET /2015-02-01/mount-targets/fsmt-9a13661e/security-groups HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20140620T223513Z
Authorization: ...
```

Sample Response

```
HTTP/1.1 200 OK
x-amzn-RequestId: 01234567-89ab-cdef-0123-456789abcdef
Content-Length: 57

{
    "SecurityGroups" : [
        "sg-188d9f74"
    ]
}
```

DescribeTags

Note
DEPRECATED - The DeleteTags action is deprecated and not maintained. Please use the ListTagsForResource (p. 296) API action to remove tags from EFS resources.

Returns the tags associated with a file system. The order of tags returned in the response of one DescribeTags call and the order of tags returned across the responses of a multiple-call iteration (when using pagination) is unspecified.

This operation requires permissions for the elasticfilesystem:DescribeTags action.

Request Syntax

```
GET /2015-02-01/tags/FileSystemId/?Marker=Marker&MaxItems=MaxItems HTTP/1.1
```

URI Request Parameters

The request uses the following URI parameters.

FileSystemId (p. 293)

The ID of the file system whose tag set you want to retrieve.

Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$

Required: Yes

Marker (p. 293)

(Optional) An opaque pagination token returned from a previous DescribeTags operation (String). If present, it specifies to continue the list from where the previous call left off.

Pattern: .+

MaxItems (p. 293)

(Optional) The maximum number of file system tags to return in the response. Currently, this number is automatically set to 100, and other values are ignored. The response is paginated at 100 per page if you have more than 100 tags.

Valid Range: Minimum value of 1.

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 200
Content-type: application/json

{
```

293

"Marker": "string",
"NextMarker": "string",
"Tags": [
  {
    "Key": "string",
    "Value": "string"
  }
]

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

Marker (p. 293)

If the request included a Marker, the response returns that value in this field.

Type: String

Pattern: .+

NextMarker (p. 293)

If a value is present, there are more tags to return. In a subsequent request, you can provide the value of NextMarker as the value of the Marker parameter in your next request to retrieve the next set of tags.

Type: String

Pattern: .+

Tags (p. 293)

Returns tags associated with the file system as an array of Tag objects.

Type: Array of Tag (p. 342) objects

Errors

BadRequest

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

FileSystemNotFound

Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

InternalServer>Error

Returned if an error occurred on the server side.
HTTP Status Code: 500

Examples

Retrieve tags associated with a file system

The following request retrieves tags (key-value pairs) associated with the specified file system.

Sample Request

```plaintext
GET /2015-02-01/tags/fs-01234567/ HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20140620T215404Z
Authorization: <...>
```

Sample Response

```plaintext
HTTP/1.1 200 OK
x-amzn-RequestId: 01234567-89ab-cdef-0123-456789abcdef
Content-Type: application/json
Content-Length: 288
{
    "Tags": [
        {
            "Key": "Name",
            "Value": "my first file system"
        },
        {
            "Key": "Fleet",
            "Value": "Development"
        },
        {
            "Key": "Developer",
            "Value": "Alice"
        }
    ]
}
```

ListTagsForResource

Lists all tags for a top-level EFS resource. You must provide the ID of the resource that you want to retrieve the tags for.

This operation requires permissions for the elasticfilesystem:DescribeAccessPoints action.

Request Syntax

GET /2015-02-01/resource-tags/ResourceId?MaxResults=MaxResults&NextToken=NextToken  HTTP/1.1

URI Request Parameters

The request uses the following URI parameters.

MaxResults (p. 296)

(Optional) Specifies the maximum number of tag objects to return in the response. The default value is 100.

Valid Range: Minimum value of 1.

NextToken (p. 296)

(Optional) You can use NextToken in a subsequent request to fetch the next page of access point descriptions if the response payload was paginated.

Pattern: .+

ResourceId (p. 296)

Specifies the EFS resource you want to retrieve tags for. You can retrieve tags for EFS file systems and access points using this API endpoint.

Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws\[-a-z]*:elasticfilesystem:[0-9a-z-]+:(access-point/fsap|file-system/fs)-[0-9a-f]{8,40}|fs(ap)?-[0-9a-f]{8,40})$

Required: Yes

Request Body

The request does not have a request body.

Response Syntax

HTTP/1.1 200
Content-type: application/json

{
  "NextToken": "string",
  "Tags": [
  {
    "Key": "string",
    "Value": "string"
  }
}
Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**NextToken** *(p. 296)*

NextToken is present if the response payload is paginated. You can use NextToken in a subsequent request to fetch the next page of access point descriptions.

Type: String

Pattern: .+

**Tags** *(p. 296)*

An array of the tags for the specified EFS resource.

Type: Array of **Tag** *(p. 342)* objects

Errors

**AccessPointNotFound**

Returned if the specified AccessPointId value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

**FileSystemNotFound**

Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**InternalServerError**

Returned if an error occurred on the server side.

HTTP Status Code: 500

ModifyMountTargetSecurityGroups

Modifies the set of security groups in effect for a mount target.

When you create a mount target, Amazon EFS also creates a new network interface. For more information, see CreateMountTarget (p. 248). This operation replaces the security groups in effect for the network interface associated with a mount target, with the SecurityGroups provided in the request. This operation requires that the network interface of the mount target has been created and the lifecycle state of the mount target is not deleted.

The operation requires permissions for the following actions:

- elasticfilesystem:ModifyMountTargetSecurityGroups action on the mount target's file system.
- ec2:ModifyNetworkInterfaceAttribute action on the mount target's network interface.

Request Syntax

```
PUT /2015-02-01/mount-targets/MountTargetId/security-groups HTTP/1.1
Content-type: application/json

{
  "SecurityGroups": [ "string" ]
}
```

URI Request Parameters

The request uses the following URI parameters.

MountTargetId (p. 299)

The ID of the mount target whose security groups you want to modify.

Pattern: ^fsmt-[0-9a-f]{8,40}$

Required: Yes

Request Body

The request accepts the following data in JSON format.

SecurityGroups (p. 299)

An array of up to five VPC security group IDs.

Type: Array of strings

Array Members: Maximum number of 100 items.

Pattern: ^sg-[0-9a-f]{8,40}$

Required: No
Response Syntax

HTTP/1.1 204

Response Elements

If the action is successful, the service sends back an HTTP 204 response with an empty HTTP body.

Errors

BadRequest

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

IncorrectMountTargetState

Returned if the mount target is not in the correct state for the operation.

HTTP Status Code: 409

InternalServerError

Returned if an error occurred on the server side.

HTTP Status Code: 500

MountTargetNotFound

Returned if there is no mount target with the specified ID found in the caller's AWS account.

HTTP Status Code: 404

SecurityGroupLimitExceeded

Returned if the size of SecurityGroups specified in the request is greater than five.

HTTP Status Code: 400

SecurityGroupNotFound

Returned if one of the specified security groups doesn't exist in the subnet's VPC.

HTTP Status Code: 400

Examples

Replace a mount target's security groups

The following example replaces security groups in effect for the network interface associated with a mount target.

Sample Request

```
PUT /2015-02-01/mount-targets/fsmt-9a13661e/security-groups HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20140620T223446Z
Authorization: <...>
```
Content-Type: application/json
Content-Length: 57

{
  "SecurityGroups": [
    "sg-188d9f74"
  ]
}

Sample Response

HTTP/1.1 204 No Content
x-amzn-RequestId: 01234567-89ab-cdef-0123-456789abcdef

- AWS SDK for Ruby V3
PutAccountPreferences

Use this operation to set the account preference in the current AWS Region to use either long 17 character (63 bit) or short 8 character (32 bit) IDs for new EFS file systems and mount targets created. All existing resource IDs are not affected by any changes you make. You can set the ID preference during the opt-in period as EFS transitions to long resource IDs. For more information, see Managing Amazon EFS resource IDs.

Request Syntax

```plaintext
PUT /2015-02-01/account-preferences HTTP/1.1
Content-type: application/json

{  
  "ResourceIdType": "string"
}
```

URI Request Parameters

The request does not use any URI parameters.

Request Body

The request accepts the following data in JSON format.

ResourceIdType (p. 302)

Specifies the EFS resource ID preference to set for the user's AWS account, in the current AWS Region, either LONG_ID (17 characters), or SHORT_ID (8 characters).

Type: String

Valid Values: LONG_ID | SHORT_ID

Required: Yes

Response Syntax

```plaintext
HTTP/1.1 200
Content-type: application/json

{  
  "ResourceIdPreference": {  
    "ResourceIdType": "string",
    "Resources": [ "string" ]
  }
}
```

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.
ResourceIdPreference (p. 302)

Describes the resource type and its ID preference for the user's AWS account, in the current AWS Region.

Type: ResourceIdPreference (p. 340) object

Errors

InternalServerError

Returned if an error occurred on the server side.

HTTP Status Code: 500

See Also

- AWS SDK for PHP V3
- AWS SDK for Python
- AWS SDK for Ruby V3
PutBackupPolicy

Updates the file system's backup policy. Use this action to start or stop automatic backups of the file system.

Request Syntax

```
PUT /2015-02-01/file-systems/FileSystemId/backup-policy HTTP/1.1
Content-type: application/json

{
    "BackupPolicy": {
        "Status": "string"
    }
}
```

URI Request Parameters

The request uses the following URI parameters.

**FileSystemId (p. 304)**

Specifies which EFS file system to update the backup policy for.

Length Constraints: Maximum length of 128.

Pattern: `^arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40}$`

Required: Yes

Request Body

The request accepts the following data in JSON format.

**BackupPolicy (p. 304)**

The backup policy included in the PutBackupPolicy request.

Type: **BackupPolicy (p. 328)** object

Required: Yes

Response Syntax

```
HTTP/1.1 200
Content-type: application/json

{
    "BackupPolicy": {
        "Status": "string"
    }
}
```

Response Elements

If the action is successful, the service sends back an HTTP 200 response.
The following data is returned in JSON format by the service.

**BackupPolicy (p. 304)**

Describes the file system's backup policy, indicating whether automatic backups are turned on or off.

Type: BackupPolicy (p. 328) object

**Errors**

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

**FileSystemNotFoundException**

Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**IncorrectFileSystemLifecycleState**

Returned if the file system's lifecycle state is not "available".

HTTP Status Code: 409

**InternalError**

Returned if an error occurred on the server side.

HTTP Status Code: 500

**ValidationException**

Returned if the AWS Backup service is not available in the AWS Region in which the request was made.

HTTP Status Code: 400

PutFileSystemPolicy

Applies an Amazon EFS FileSystemPolicy to an Amazon EFS file system. A file system policy is an IAM resource-based policy and can contain multiple policy statements. A file system always has exactly one file system policy, which can be the default policy or an explicit policy set or updated using this API operation. EFS file system policies have a 20,000 character limit. When an explicit policy is set, it overrides the default policy. For more information about the default file system policy, see Default EFS File System Policy.

**Note**
EFS file system policies have a 20,000 character limit.

This operation requires permissions for the elasticfilesystem:PutFileSystemPolicy action.

**Request Syntax**

```
PUT /2015-02-01/file-systems/{FileSystemId}/policy HTTP/1.1
Content-type: application/json

{
   "BypassPolicyLockoutSafetyCheck": boolean,
   "Policy": "string"
}
```

**URI Request Parameters**

The request uses the following URI parameters.

**FileSystemId (p. 306)**

The ID of the EFS file system that you want to create or update the FileSystemPolicy for.

Length Constraints: Maximum length of 128.

Pattern: `^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$`

Required: Yes

**Request Body**

The request accepts the following data in JSON format.

**BypassPolicyLockoutSafetyCheck (p. 306)**

(Optional) A flag to indicate whether to bypass the FileSystemPolicy lockout safety check. The policy lockout safety check determines whether the policy in the request will prevent the principal making the request will be locked out from making future PutFileSystemPolicy requests on the file system. Set BypassPolicyLockoutSafetyCheck to True only when you intend to prevent the principal that is making the request from making a subsequent PutFileSystemPolicy request on the file system. The default value is False.

Type: Boolean

Required: No
Policy (p. 306)

The FileSystemPolicy that you're creating. Accepts a JSON formatted policy definition. EFS file system policies have a 20,000 character limit. To find out more about the elements that make up a file system policy, see EFS Resource-based Policies.

Type: String

Pattern: [\s\S]+

Required: Yes

Response Syntax

HTTP/1.1 200
Content-type: application/json

{
   "FileSystemId": "string",
   "Policy": "string"
}

Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

FileSystemId (p. 307)

Specifies the EFS file system to which the FileSystemPolicy applies.

Type: String

Length Constraints: Maximum length of 128.

Pattern: ^arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-:]*:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40}$

Policy (p. 307)

The JSON formatted FileSystemPolicy for the EFS file system.

Type: String

Pattern: [\s\S]+

Errors

FileSystemNotFound

Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.

HTTP Status Code: 404
IncorrectFileSystemLifeCycleState

Returned if the file system's lifecycle state is not "available".

HTTP Status Code: 409

InternalServerError

Returned if an error occurred on the server side.

HTTP Status Code: 500

InvalidPolicyException

Returned if the FileSystemPolicy is is malformed or contains an error such as an invalid parameter value or a missing required parameter. Returned in the case of a policy lockout safety check error.

HTTP Status Code: 400

Examples

Create an EFS FileSystemPolicy

The following request creates a FileSystemPolicy that allows all AWS principals to mount the specified EFS file system with read and write permissions.

Sample Request

PUT /2015-02-01/file-systems/fs-01234567/file-system-policy HTTP/1.1
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "elasticfilesystem:ClientMount",
            "elasticfilesystem:ClientWrite"
         ],
         "Principal": {
            "AWS": ["*"
         }
      }]
}

Sample Response

{
   "Version": "2012-10-17",
   "Id": "1",
   "Statement": [
      {
         "Sid": "efs-statement-abcdef01-1111-bbbb-2222-111122224444",
         "Effect": "Allow",
         "Action": [
            "elasticfilesystem:ClientMount",
            "elasticfilesystem:ClientWrite"
         ],
         "Principal": {
            "AWS": ["*"
         }
      }
   ]
}

PutLifecycleConfiguration

Enables lifecycle management by creating a new LifecycleConfiguration object. A LifecycleConfiguration object defines when files in an Amazon EFS file system are automatically transitioned to the lower-cost EFS Infrequent Access (IA) storage class. To enable EFS Intelligent Tiering, set the value of TransitionToPrimaryStorageClass to AFTER_1_ACCESS. For more information, see EFS Lifecycle Management.

Each Amazon EFS file system supports one lifecycle configuration, which applies to all files in the file system. If a LifecycleConfiguration object already exists for the specified file system, a PutLifecycleConfiguration call modifies the existing configuration. A PutLifecycleConfiguration call with an empty LifecyclePolicies array in the request body deletes any existing LifecycleConfiguration and turns off lifecycle management for the file system.

In the request, specify the following:

- The ID for the file system for which you are enabling, disabling, or modifying lifecycle management.
- A LifecyclePolicies array of LifecyclePolicy objects that define when files are moved to the IA storage class. Amazon EFS requires that each LifecyclePolicy object have only have a single transition, so the LifecyclePolicies array needs to be structured with separate LifecyclePolicy objects. See the example requests in the following section for more information.

This operation requires permissions for the elasticfilesystem:PutLifecycleConfiguration operation.

To apply a LifecycleConfiguration object to an encrypted file system, you need the same AWS Key Management Service permissions as when you created the encrypted file system.

Request Syntax

```
PUT /2015-02-01/file-systems/FileSystemId/lifecycle-configuration HTTP/1.1
Content-type: application/json

{
  "LifecyclePolicies": [
    {
      "TransitionToIA": "string",
      "TransitionToPrimaryStorageClass": "string"
    }
  ]
}
```

URI Request Parameters

The request uses the following URI parameters.

**FileSystemId (p. 310)**

The ID of the file system for which you are creating the LifecycleConfiguration object (String).

Length Constraints: Maximum length of 128.

Pattern: `^arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40}$`

Required: Yes
### Request Body

The request accepts the following data in JSON format.

**LifecyclePolicies (p. 310)**

An array of LifecyclePolicy objects that define the file system's LifecycleConfiguration object. A LifecycleConfiguration object informs EFS lifecycle management and intelligent tiering of the following:

- When to move files in the file system from primary storage to the IA storage class.
- When to move files that are in IA storage to primary storage.

**Note**

When using the `put-lifecycle-configuration` CLI command or the `PutLifecycleConfiguration` API action, Amazon EFS requires that each LifecyclePolicy object have only a single transition. This means that in a request body, LifecyclePolicies needs to be structured as an array of LifecyclePolicy objects, one object for each transition, TransitionToIA, TransitionToPrimaryStorageClass. See the example requests in the following section for more information.

Type: Array of LifecyclePolicy (p. 336) objects

Array Members: Maximum number of 2 items.

Required: Yes

### Response Syntax

```
HTTP/1.1 200
Content-type: application/json

{
    "LifecyclePolicies": [
        {
            "TransitionToIA": "string",
            "TransitionToPrimaryStorageClass": "string"
        }
    ]
}
```

### Response Elements

If the action is successful, the service sends back an HTTP 200 response.

The following data is returned in JSON format by the service.

**LifecyclePolicies (p. 311)**

An array of lifecycle management policies. EFS supports a maximum of one policy per file system.

Type: Array of LifecyclePolicy (p. 336) objects

Array Members: Maximum number of 2 items.
Errors

BadRequest

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

FileSystemNotFoundException

Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

IncorrectFileSystemLifeCycleState

Returned if the file system's lifecycle state is not "available".

HTTP Status Code: 409

InternalServerError

Returned if an error occurred on the server side.

HTTP Status Code: 500

Examples

Create a lifecycle configuration

The following example creates a LifecyclePolicy object using the PutLifecycleConfiguration operation. This object tells EFS lifecycle management to do the following:

- Move all files in the file system that haven't been accessed in the last 30 days to the IA storage class.
- Move files that are in IA storage to primary storage after the first access while in IA.

For more information, see EFS storage classes and EFS Intelligent-Tiering and lifecycle management.

Sample Request

```plaintext
PUT /2015-02-01/file-systems/fs-01234567/lifecycle-configuration HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20181122T232908Z
Authorization: <...>
Content-type: application/json
Content-Length: 86

{
  "LifecyclePolicies": [
    {
      "TransitionToIA": "AFTER_60_DAYS"
    },
    {
      "TransitionToPrimaryStorage": "AFTER_1_ACCESS"
    }
  ]
}
```
Sample Response

HTTP/1.1 200 OK
x-amzn-RequestId: 01234567-89ab-cdef-0123-456789abcdef
Content-type: application/json
Content-Length: 86

{
    "LifecyclePolicies": [
        {
            "TransitionToIA": "AFTER_60_DAYS"
        },
        {
            "TransitionToPrimaryStorage": "AFTER_1_ACCESS"
        }
    ]
}

Example put-lifecycle-configuration CLI request

This example illustrates one usage of PutLifecycleConfiguration.

Sample Request

```
aws efs put-lifecycle-configuration \
  --file-system-id fs-1234567890abcdef1 \
  --lifecycle-policies "[{
        "TransitionToIA": "AFTER_60_DAYS",
        "TransitionToPrimaryStorageClass": "AFTER_1_ACCESS"
    }]" \
  --region us-west-2 \
  --profile adminuser
```

Sample Response

```
{
    "LifecyclePolicies": [
        {
            "TransitionToIA": "AFTER_60_DAYS"
        },
        {
            "TransitionToPrimaryStorageClass": "AFTER_1_ACCESS"
        }
    ]
}
```

Disable lifecycle management

The following example disables lifecycle management for the specified file system.

Sample Request

```
PUT /2015-02-01/file-systems/fs-01234567/lifecycle-configuration HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20181122T232908Z
Authorization: <...>
Content-type: application/json
Content-Length: 86

{
}```
Sample Response

HTTP/1.1 200 OK
x-amzn-RequestId: 01234567-89ab-cdef-0123-456789abcdef
Content-type: application/json
Content-Length: 86

{  "LifecyclePolicies": [  ]}

TagResource

Creates a tag for an EFS resource. You can create tags for EFS file systems and access points using this API operation.

This operation requires permissions for the elasticfilesystem:TagResource action.

Request Syntax

POST /2015-02-01/resource-tags/ResourceId HTTP/1.1
Content-type: application/json

{
  "Tags": [
    {
      "Key": "string",
      "Value": "string"
    }
  ]
}

URI Request Parameters

The request uses the following URI parameters.

ResourceId (p. 315)

The ID specifying the EFS resource that you want to create a tag for.

Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:(access-point/fsap|file-system/fs)-[0-9a-f]{8,40}|fs(ap)?-[0-9a-f]{8,40})$

Required: Yes

Request Body

The request accepts the following data in JSON format.

Tags (p. 315)

An array of Tag objects to add. Each Tag object is a key-value pair.

Type: Array of Tag (p. 342) objects

Required: Yes

Response Syntax

HTTP/1.1 200

Response Elements

If the action is successful, the service sends back an HTTP 200 response with an empty HTTP body.
Errors

**AccessPointNotFound**

Returned if the specified `AccessPointId` value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

**FileSystemNotFound**

Returned if the specified `FileSystemId` value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**InternalServerError**

Returned if an error occurred on the server side.

HTTP Status Code: 500

Examples

**Create Tags on a File System**

The following request creates three tags ("key1", "key2", and "key3") on the specified file system.

**Sample Request**

```plaintext
POST /2015-02-01/tag-resource/fs-01234567 HTTP/1.1
Host: elasticfilesystem.us-west-2.amazonaws.com
x-amz-date: 20140620T221118Z
Authorization: <...>
Content-Type: application/json
Content-Length: 160

{
    "Tags": [
        {
            "Key": "key1",
            "Value": "value1"
        },
        {
            "Key": "key2",
            "Value": "value2"
        },
        {
            "Key": "key3",
            "Value": "value3"
        }
    ]
}
```

**Sample Response**

```
HTTP/1.1 204 no content
```

UntagResource

Removes tags from an EFS resource. You can remove tags from EFS file systems and access points using this API operation.

This operation requires permissions for the elasticfilesystem:UntagResource action.

Request Syntax

```
DELETE /2015-02-01/resource-tags/ResourceId?tagKeys=TagKeys HTTP/1.1
```

URI Request Parameters

The request uses the following URI parameters.

ResourceId  (p. 318)

   Specifies the EFS resource that you want to remove tags from.
   
   Length Constraints: Maximum length of 128.
   
   Pattern: `^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:(access-point/fsap|file-system/fs)-[0-9a-f]{8,40}|fs(ap)?-[0-9a-f]{8,40})$`
   
   Required: Yes

TagKeys  (p. 318)

   The keys of the key-value tag pairs that you want to remove from the specified EFS resource.
   
   Array Members: Minimum number of 1 item. Maximum number of 50 items.
   
   
   Pattern: `^(?!\[aA\]{1}\[wW\]{1}\[sS\]{1}:)(\[\p{L}\p{Z}\p{N}_.:/=+-@]+)$`
   
   Required: Yes

Request Body

The request does not have a request body.

Response Syntax

```
HTTP/1.1 200
```

Response Elements

If the action is successful, the service sends back an HTTP 200 response with an empty HTTP body.

Errors

AccessPointNotFound

   Returned if the specified AccessPointId value doesn't exist in the requester's AWS account.
HTTP Status Code: 404

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

**FileSystemNotFound**

Returned if the specified `FileSystemId` value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**InternalServerError**

Returned if an error occurred on the server side.

HTTP Status Code: 500

## See Also

UpdateFileSystem

Updates the throughput mode or the amount of provisioned throughput of an existing file system.

Request Syntax

```
PUT /2015-02-01/file-systems/FileSystemId HTTP/1.1
Content-type: application/json

{
  "ProvisionedThroughputInMibps": number,
  "ThroughputMode": "string"
}
```

URI Request Parameters

The request uses the following URI parameters.

**FileSystemId** (p. 320)

The ID of the file system that you want to update.

Length Constraints: Maximum length of 128.

Pattern: `^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$`

Required: Yes

Request Body

The request accepts the following data in JSON format.

**ProvisionedThroughputInMibps** (p. 320)

(Optional) Sets the amount of provisioned throughput, in MiB/s, for the file system. Valid values are 1-1024. If you are changing the throughput mode to provisioned, you must also provide the amount of provisioned throughput. Required if `ThroughputMode` is changed to `provisioned` on update.

Type: Double

Valid Range: Minimum value of 1.0.

Required: No

**ThroughputMode** (p. 320)

(Optional) Updates the file system's throughput mode. If you're not updating your throughput mode, you don't need to provide this value in your request. If you are changing the `ThroughputMode` to `provisioned`, you must also set a value for `ProvisionedThroughputInMibps`.

Type: String

Valid Values: `bursting` | `provisioned`

Required: No
Response Syntax

HTTP/1.1 202
Content-type: application/json

{
    "AvailabilityZoneId": "string",
    "AvailabilityZoneName": "string",
    "CreationTime": number,
    "CreationToken": "string",
    "Encrypted": boolean,
    "FileSystemArn": "string",
    "FileSystemId": "string",
    "KmsKeyId": "string",
    "LifeCycleState": "string",
    "Name": "string",
    "NumberOfMountTargets": number,
    "OwnerId": "string",
    "PerformanceMode": "string",
    "ProvisionedThroughputInMibps": number,
    "SizeInBytes": {
        "Timestamp": number,
        "Value": number,
        "ValueInIA": number,
        "ValueInStandard": number
    },
    "Tags": [
        {
            "Key": "string",
            "Value": "string"
        }
    ],
    "ThroughputMode": "string"
}

Response Elements

If the action is successful, the service sends back an HTTP 202 response.

The following data is returned in JSON format by the service.

AvailabilityZoneId (p. 321)

The unique and consistent identifier of the Availability Zone in which the file system's One Zone storage classes exist. For example, use1-az1 is an Availability Zone ID for the us-east-1 AWS Region, and it has the same location in every AWS account.

Type: String
AvailabilityZoneName (p. 321)

Describes the AWS Availability Zone in which the file system is located, and is valid only for file systems using One Zone storage classes. For more information, see Using EFS storage classes in the Amazon EFS User Guide.

Type: String
Length Constraints: Minimum length of 1. Maximum length of 64.
Pattern: .+

CreationTime (p. 321)

The time that the file system was created, in seconds (since 1970-01-01T00:00:00Z).
### CreateFileSystem

**CreationToken (p. 321)**

The opaque string specified in the request.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: .+

**Encrypted (p. 321)**

A Boolean value that, if true, indicates that the file system is encrypted.

Type: Boolean

**FileSystemArn (p. 321)**

The Amazon Resource Name (ARN) for the EFS file system, in the format

```
```

Example with sample data: `arn:aws:elasticfilesystem:us-west-2:1111333322238888:file-system/fs-01234567`

Type: String

**FileSystemId (p. 321)**

The ID of the file system, assigned by Amazon EFS.

Type: String

Length Constraints: Maximum length of 128.

Pattern: `^\(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-:]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$`

**KmsKeyId (p. 321)**

The ID of an AWS Key Management Service customer master key (CMK) that was used to protect the encrypted file system.

Type: String

Length Constraints: Maximum length of 2048.

Pattern: `^\([0-9a-f]{8}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{12}|mrk-[0-9a-f]{32}|alias/[a-zA-Z0-9/_-]+|(arn:aws[-a-z]*:kms:[a-z0-9-]+:\d{12}:(key/[0-9a-f]{8}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{12})|(mrk-[0-9a-f]{32})|(alias/[a-zA-Z0-9-/_]+))$`

**LifeCycleState (p. 321)**

The lifecycle phase of the file system.

Type: String

Valid Values: creating | available | updating | deleting | deleted | error

**Name (p. 321)**

You can add tags to a file system, including a Name tag. For more information, see `CreateFileSystem (p. 238)`. If the file system has a Name tag, Amazon EFS returns the value in this field.

Type: String
Length Constraints: Maximum length of 256.

Pattern: ^\([\p{L}\p{Z}\p{N}_.:/=+-@]*\)$

**NumberOfMountTargets** *(p. 321)*

The current number of mount targets that the file system has. For more information, see **CreateMountTarget** *(p. 248).*

Type: Integer

Valid Range: Minimum value of 0.

**OwnerId** *(p. 321)*

The AWS account that created the file system. If the file system was created by an IAM user, the parent account to which the user belongs is the owner.

Type: String

Length Constraints: Maximum length of 14.

Pattern: ^\(\d{12}\)|\(\d{4}-\d{4}-\d{4}\)$

**PerformanceMode** *(p. 321)*

The performance mode of the file system.

Type: String

Valid Values: `generalPurpose` | `maxIO`

**ProvisionedThroughputInMibps** *(p. 321)*

The amount of provisioned throughput, measured in MiB/s, for the file system. Valid for file systems using **ThroughputMode** set to `provisioned`.

Type: Double

Valid Range: Minimum value of 1.0.

**SizeInBytes** *(p. 321)*

The latest known metered size (in bytes) of data stored in the file system, in its `Value` field, and the time at which that size was determined in its `Timestamp` field. The `Timestamp` value is the integer number of seconds since 1970-01-01T00:00:00Z. The `SizeInBytes` value doesn't represent the size of a consistent snapshot of the file system, but it is eventually consistent when there are no writes to the file system. That is, `SizeInBytes` represents actual size only if the file system is not modified for a period longer than a couple of hours. Otherwise, the value is not the exact size that the file system was at any point in time.

Type: **FileSystemSize** *(p. 335) object

**Tags** *(p. 321)*

The tags associated with the file system, presented as an array of `Tag` objects.

Type: Array of **Tag** *(p. 342) objects

**ThroughputMode** *(p. 321)*

Displays the file system's throughput mode. For more information, see **Throughput modes** in the **Amazon EFS User Guide**.

Type: String
Valid Values: bursting | provisioned

**Errors**

**BadRequest**

Returned if the request is malformed or contains an error such as an invalid parameter value or a missing required parameter.

HTTP Status Code: 400

**FileSystemNotFoundException**

Returned if the specified FileSystemId value doesn't exist in the requester's AWS account.

HTTP Status Code: 404

**IncorrectFileSystemLifeCycleState**

Returned if the file system's lifecycle state is not "available".

HTTP Status Code: 409

**InsufficientThroughputCapacity**

Returned if there's not enough capacity to provision additional throughput. This value might be returned when you try to create a file system in provisioned throughput mode, when you attempt to increase the provisioned throughput of an existing file system, or when you attempt to change an existing file system from bursting to provisioned throughput mode. Try again later.

HTTP Status Code: 503

**InternalServerException**

Returned if an error occurred on the server side.

HTTP Status Code: 500

**ThroughputLimitExceeded**

Returned if the throughput mode or amount of provisioned throughput can't be changed because the throughput limit of 1024 MiB/s has been reached.

HTTP Status Code: 400

**TooManyRequests**

Returned if you don't wait at least 24 hours before changing the throughput mode, or decreasing the Provisioned Throughput value.

HTTP Status Code: 429

Data Types

The following data types are supported:

- AccessPointDescription (p. 326)
- BackupPolicy (p. 328)
- CreationInfo (p. 329)
- FileSystemDescription (p. 331)
- FileSystemSize (p. 335)
- LifecyclePolicy (p. 336)
- MountTargetDescription (p. 337)
- PosixUser (p. 339)
- ResourceIdPreference (p. 340)
- RootDirectory (p. 341)
- Tag (p. 342)
AccessPointDescription

Provides a description of an EFS file system access point.

Contents

AccessPointArn

The unique Amazon Resource Name (ARN) associated with the access point.

Type: String

Length Constraints: Maximum length of 128.

Pattern: ^arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:access-point/fsap-[0-9a-f]{8,40}$

Required: No

AccessPointId

The ID of the access point, assigned by Amazon EFS.

Type: String

Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:access-point/fsap-[0-9a-f]{8,40}|fsap-[0-9a-f]{8,40})$

Required: No

ClientToken

The opaque string specified in the request to ensure idempotent creation.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: .+

Required: No

FileSystemId

The ID of the EFS file system that the access point applies to.

Type: String

Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$

Required: No

LifeCycleState

Identifies the lifecycle phase of the access point.

Type: String

Valid Values: creating | available | updating | deleting | deleted | error
Required: No

**Name**

The name of the access point. This is the value of the `Name` tag.

Type: String

Required: No

**OwnerId**

Identified the AWS account that owns the access point resource.

Type: String

Length Constraints: Maximum length of 14.

Pattern: ^(^\d{12})|(\d{4}-\d{4}-\d{4})$  

Required: No

**PosixUser**

The full POSIX identity, including the user ID, group ID, and secondary group IDs on the access point that is used for all file operations by NFS clients using the access point.

Type: `PosixUser (p. 339)` object

Required: No

**RootDirectory**

The directory on the Amazon EFS file system that the access point exposes as the root directory to NFS clients using the access point.

Type: `RootDirectory (p. 341)` object

Required: No

**Tags**

The tags associated with the access point, presented as an array of `Tag` objects.

Type: Array of `Tag (p. 342)` objects

Required: No

**See Also**

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java V2
- AWS SDK for Ruby V3
BackupPolicy

The backup policy for the file system used to create automatic daily backups. If status has a value of ENABLED, the file system is being automatically backed up. For more information, see Automatic backups.

Contents

Status

Describes the status of the file system's backup policy.

- **ENABLED** - EFS is automatically backing up the file system.
- **ENABLING** - EFS is turning on automatic backups for the file system.
- **DISABLED** - automatic backups are turned off for the file system.
- **DISABLING** - EFS is turning off automatic backups for the file system.

Type: String

Valid Values: ENABLED | ENABLING | DISABLED | DISABLING

Required: Yes

See Also

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java V2
- AWS SDK for Ruby V3
CreationInfo

Required if the RootDirectory > Path specified does not exist. Specifies the POSIX IDs and permissions to apply to the access point's RootDirectory > Path. If the access point root directory does not exist, EFS creates it with these settings when a client connects to the access point. When specifying CreationInfo, you must include values for all properties.

Amazon EFS creates a root directory only if you have provided the CreationInfo: OwnUid, OwnGID, and permissions for the directory. If you do not provide this information, Amazon EFS does not create the root directory. If the root directory does not exist, attempts to mount using the access point will fail.

**Important**
If you do not provide CreationInfo and the specified RootDirectory does not exist, attempts to mount the file system using the access point will fail.

Contents

**OwnerGid**

Specifies the POSIX group ID to apply to the RootDirectory. Accepts values from 0 to 2\(^{32}\) (4294967295).

Type: Long

Valid Range: Minimum value of 0. Maximum value of 4294967295.

Required: Yes

**OwnerUid**

Specifies the POSIX user ID to apply to the RootDirectory. Accepts values from 0 to 2\(^{32}\) (4294967295).

Type: Long

Valid Range: Minimum value of 0. Maximum value of 4294967295.

Required: Yes

**Permissions**

Specifies the POSIX permissions to apply to the RootDirectory, in the format of an octal number representing the file's mode bits.

Type: String

Pattern: ^[0-7]{3,4}$

Required: Yes

See Also

• AWS SDK for Ruby V3
**FileSystemDescription**

A description of the file system.

**Contents**

**AvailabilityZoneId**

The unique and consistent identifier of the Availability Zone in which the file system's One Zone storage classes exist. For example, use1-az1 is an Availability Zone ID for the us-east-1 AWS Region, and it has the same location in every AWS account.

Type: String

Required: No

**AvailabilityZoneName**

Describes the AWS Availability Zone in which the file system is located, and is valid only for file systems using One Zone storage classes. For more information, see [Using EFS storage classes](https://docs.aws.amazon.com/efs/latest/ug/) in the *Amazon EFS User Guide*.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: .+

Required: No

**CreationTime**

The time that the file system was created, in seconds (since 1970-01-01T00:00:00Z).

Type: Timestamp

Required: Yes

**CreationToken**

The opaque string specified in the request.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: .+

Required: Yes

**Encrypted**

A Boolean value that, if true, indicates that the file system is encrypted.

Type: Boolean

Required: No

**FileSystemArn**

The Amazon Resource Name (ARN) for the EFS file system, in the format

```
```

Type: String
Required: No

**FileSystemId**

The ID of the file system, assigned by Amazon EFS.

Type: String
Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]+:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$

Required: Yes

**KmsKeyId**

The ID of an AWS Key Management Service customer master key (CMK) that was used to protect the encrypted file system.

Type: String
Length Constraints: Maximum length of 2048.

Pattern: ^([0-9a-f]{8}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{12}|mrk-[0-9a-f]{32}|alias/[a-zA-Z0-9/_-]+|(arn:aws[-a-z]*:kms:[a-zA-Z0-9-]+:(key/09a-f]{8}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{4}-[0-9a-f]{12}|key/mrk-[0-9a-f]{32}|(alias/[a-zA-Z0-9-_]+))))$

Required: No

**LifeCycleState**

The lifecycle phase of the file system.

Type: String
Valid Values: creating | available | updating | deleting | deleted | error

Required: Yes

**Name**

You can add tags to a file system, including a Name tag. For more information, see CreateFileSystem (p. 238). If the file system has a Name tag, Amazon EFS returns the value in this field.

Type: String
Length Constraints: Maximum length of 256.

Pattern: ^([p-zA-Z0-9_.:/=+-@]*$)

Required: No

**NumberOfMountTargets**

The current number of mount targets that the file system has. For more information, see CreateMountTarget (p. 248).

Type: Integer
Valid Range: Minimum value of 0.
Required: Yes

OwnerId

The AWS account that created the file system. If the file system was created by an IAM user, the parent account to which the user belongs is the owner.

Type: String

Length Constraints: Maximum length of 14.

Pattern: ^([0-9]{12})|([0-9]{4}-[0-9]{4}-[0-9]{4})$

Required: Yes

PerformanceMode

The performance mode of the file system.

Type: String

Valid Values: generalPurpose | maxIO

Required: Yes

ProvisionedThroughputInMibps

The amount of provisioned throughput, measured in MiB/s, for the file system. Valid for file systems using ThroughputMode set to provisioned.

Type: Double

Valid Range: Minimum value of 1.0.

Required: No

SizeInBytes

The latest known metered size (in bytes) of data stored in the file system, in its Value field, and the time at which that size was determined in its Timestamp field. The Timestamp value is the integer number of seconds since 1970-01-01T00:00:00Z. The SizeInBytes value doesn't represent the size of a consistent snapshot of the file system, but it is eventually consistent when there are no writes to the file system. That is, SizeInBytes represents actual size only if the file system is not modified for a period longer than a couple of hours. Otherwise, the value is not the exact size that the file system was at any point in time.

Type: FileSystemSize (p. 335) object

Required: Yes

Tags

The tags associated with the file system, presented as an array of Tag objects.

Type: Array of Tag (p. 342) objects

Required: Yes

ThroughputMode

Displays the file system’s throughput mode. For more information, see Throughput modes in the Amazon EFS User Guide.

Type: String

Valid Values: bursting | provisioned
Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java V2
- AWS SDK for Ruby V3
FileSystemSize

The latest known metered size (in bytes) of data stored in the file system, in its Value field, and the time at which that size was determined in its Timestamp field. The value doesn't represent the size of a consistent snapshot of the file system, but it is eventually consistent when there are no writes to the file system. That is, the value represents the actual size only if the file system is not modified for a period longer than a couple of hours. Otherwise, the value is not necessarily the exact size the file system was at any instant in time.

Contents

Timestamp

The time at which the size of data, returned in the Value field, was determined. The value is the integer number of seconds since 1970-01-01T00:00:00Z.

Type: Timestamp

Required: No

Value

The latest known metered size (in bytes) of data stored in the file system.

Type: Long

Valid Range: Minimum value of 0.

Required: Yes

ValueInIA

The latest known metered size (in bytes) of data stored in the Infrequent Access storage class.

Type: Long

Valid Range: Minimum value of 0.

Required: No

ValueInStandard

The latest known metered size (in bytes) of data stored in the Standard storage class.

Type: Long

Valid Range: Minimum value of 0.

Required: No

See Also

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java V2
- AWS SDK for Ruby V3
LifecyclePolicy

Describes a policy used by EFS lifecycle management and EFS intelligent tiering that specifies when to transition files into and out of the file system's Infrequent Access (IA) storage class. For more information, see EFS Intelligent-Tiering and EFS Lifecycle Management.

**Note**
When using the put-lifecycle-configuration CLI command or the PutLifecycleConfiguration API action, Amazon EFS requires that each LifecyclePolicy object have only a single transition. This means that in a request body, LifecyclePolicies needs to be structured as an array of LifecyclePolicy objects, one object for each transition, TransitionToIA, TransitionToPrimaryStorageClass. For more information, see the request examples in PutLifecycleConfiguration (p. 310).

**Contents**

**TransitionToIA**

Describes the period of time that a file is not accessed, after which it transitions to IA storage. Metadata operations such as listing the contents of a directory don't count as file access events.

Type: String

Valid Values: AFTER_7_DAYS | AFTER_14_DAYS | AFTER_30_DAYS | AFTER_60_DAYS | AFTER_90_DAYS

Required: No

**TransitionToPrimaryStorageClass**

Describes when to transition a file from IA storage to primary storage. Metadata operations such as listing the contents of a directory don't count as file access events.

Type: String

Valid Values: AFTER_1_ACCESS

Required: No

**See Also**

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java V2
- AWS SDK for Ruby V3
MountTargetDescription

Provides a description of a mount target.

Contents

AvailabilityZoneId

The unique and consistent identifier of the Availability Zone that the mount target resides in. For example, use1-az1 is an AZ ID for the us-east-1 Region and it has the same location in every AWS account.

Type: String

Required: No

AvailabilityZoneName

The name of the Availability Zone in which the mount target is located. Availability Zones are independently mapped to names for each AWS account. For example, the Availability Zone us-east-1a for your AWS account might not be the same location as us-east-1a for another AWS account.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 64.

Pattern: .+

Required: No

FileSystemId

The ID of the file system for which the mount target is intended.

Type: String

Length Constraints: Maximum length of 128.

Pattern: ^(arn:aws[-a-z]*:elasticfilesystem:[0-9a-z-]:*:file-system/fs-[0-9a-f]{8,40}|fs-[0-9a-f]{8,40})$

Required: Yes

IpAddress

Address at which the file system can be mounted by using the mount target.

Type: String

Pattern: ^[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}\.[0-9]{1,3}$

Required: No

LifeCycleState

Lifecycle state of the mount target.

Type: String

Valid Values: creating | available | updating | deleting | deleted | error
Required: Yes

**MountTargetId**

System-assigned mount target ID.

Type: String

Pattern: ^fsmt-[0-9a-f]{8,40}$

Required: Yes

**NetworkInterfaceId**

The ID of the network interface that Amazon EFS created when it created the mount target.

Type: String

Required: No

**OwnerId**

AWS account ID that owns the resource.

Type: String

Length Constraints: Maximum length of 14.

Pattern: ^\(\d\{12\}\)|\(\d\{4\}-\d\{4\}-\d\{4\}\)$

Required: No

**SubnetId**

The ID of the mount target's subnet.

Type: String

Pattern: ^subnet-[0-9a-f]{8,40}$

Required: Yes

**VpcId**

The virtual private cloud (VPC) ID that the mount target is configured in.

Type: String

Required: No

**See Also**

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java V2
- AWS SDK for Ruby V3
PosixUser

The full POSIX identity, including the user ID, group ID, and any secondary group IDs, on the access point that is used for all file system operations performed by NFS clients using the access point.

Contents

Gid

The POSIX group ID used for all file system operations using this access point.

Type: Long

Valid Range: Minimum value of 0. Maximum value of 4294967295.

Required: Yes

SecondaryGids

Secondary POSIX group IDs used for all file system operations using this access point.

Type: Array of longs

Array Members: Minimum number of 0 items. Maximum number of 16 items.

Valid Range: Minimum value of 0. Maximum value of 4294967295.

Required: No

Uid

The POSIX user ID used for all file system operations using this access point.

Type: Long

Valid Range: Minimum value of 0. Maximum value of 4294967295.

Required: Yes

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java V2
- AWS SDK for Ruby V3
ResourceIdPreference

Describes the resource type and its ID preference for the user's AWS account, in the current AWS Region.

Contents

ResourceIdType

Identifies the EFS resource ID preference, either `LONG_ID` (17 characters) or `SHORT_ID` (8 characters).

Type: String

Valid Values: `LONG_ID` | `SHORT_ID`

Required: No

Resources

Identifies the Amazon EFS resources to which the ID preference setting applies, `FILE_SYSTEM` and `MOUNT_TARGET`.

Type: Array of strings

Valid Values: `FILE_SYSTEM` | `MOUNT_TARGET`

Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java V2
- AWS SDK for Ruby V3
RootDirectory

Specifies the directory on the Amazon EFS file system that the access point provides access to. The access point exposes the specified file system path as the root directory of your file system to applications using the access point. NFS clients using the access point can only access data in the access point's RootDirectory and its subdirectories.

Contents

CreationInfo

(Optional) Specifies the POSIX IDs and permissions to apply to the access point's RootDirectory. If the RootDirectory > Path specified does not exist, EFS creates the root directory using the CreationInfo settings when a client connects to an access point. When specifying the CreationInfo, you must provide values for all properties.

Important

If you do not provide CreationInfo and the specified RootDirectory > Path does not exist, attempts to mount the file system using the access point will fail.

Type: CreationInfo (p. 329) object

Required: No

Path

Specifies the path on the EFS file system to expose as the root directory to NFS clients using the access point to access the EFS file system. A path can have up to four subdirectories. If the specified path does not exist, you are required to provide the CreationInfo.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 100.

Pattern: ^/+|([^/?#]*[^$?#<>;`|&?{}^*/\n]+){1,4}$

Required: No

See Also

For more information about using this API in one of the language-specific AWS SDKs, see the following:

- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java V2
- AWS SDK for Ruby V3
Tag

A tag is a key-value pair. Allowed characters are letters, white space, and numbers that can be represented in UTF-8, and the following characters: + - = . _ : /.

Contents

Key

The tag key (String). The key can't start with aws:

Type: String

Pattern: ^(?![aA]{1}[wW]{1}[sS]{1}:)([\p{L}\p{Z}\p{N}_.:/=+-@]+)$

Required: Yes

Value

The value of the tag key.

Type: String

Length Constraints: Maximum length of 256.

Pattern: ^([\p{L}\p{Z}\p{N}_.:/=+-@]*)_:/+=@)+$  

Required: Yes

Additional information for Amazon EFS

Following, you can find some additional information about Amazon EFS, including features that are still supported but not necessarily recommended.

Topics
- Backing up Amazon EFS file systems using AWS Data Pipeline (p. 343)
- Mounting file systems without the EFS mount helper (p. 355)

Backing up Amazon EFS file systems using AWS Data Pipeline

Note
Using the AWS Data Pipeline to back up your EFS file systems is a legacy solution.

Recommended Amazon EFS backup solutions

There are two recommended solutions available for backing up your Amazon EFS file systems.

- AWS Backup service
- The EFS-to-EFS backup solution

AWS Backup is a simple and cost-effective way to back up your Amazon EFS file systems. AWS Backup is a unified backup service designed to simplify the creation, migration, restoration, and deletion of backups, while providing improved reporting and auditing. For more information, see Using AWS Backup to back up and restore Amazon EFS file systems (p. 130).

The EFS-to-EFS backup solution is suitable for all Amazon EFS file systems in all AWS Regions. It includes an AWS CloudFormation template that launches, configures, and runs the AWS services required to deploy this solution. This solution follows AWS best practices for security and availability. For more information, see EFS-to-EFS Backup Solution in AWS Answers.

Legacy EFS backup solution using AWS Data Pipeline

Using AWS Data Pipeline to back up EFS file systems is a legacy backup solution. In this backup solution, you create a data pipeline by using the AWS Data Pipeline service. This pipeline copies data from your Amazon EFS file system (called the production file system) to another Amazon EFS file system (called the backup file system).

This solution consists of AWS Data Pipeline templates that implement the following:

- Automated EFS backups based on a schedule that you define (for example, hourly, daily, weekly, or monthly).
• Automated rotation of the backups, where the oldest backup is replaced with the newest backup based on the number of backups that you want to retain.
• Quicker backups using rsync, which only back up the changes made between one backup to the next.
• Efficient storage of backups using hard links. A hard link is a directory entry that associates a name with a file in a file system. By setting up a hard link, you can perform a full restoration of data from any backup while only storing what changed from backup to backup.

After you set up the backup solution, this walk-through shows you how to access your backups to restore your data. This backup solution depends on running scripts that are hosted on GitHub, and is therefore subject to GitHub availability. If you'd prefer to eliminate this reliance and host the scripts in an Amazon S3 bucket instead, see Hosting the rsync scripts in an Amazon S3 bucket (p. 354).

Important
This solution requires using AWS Data Pipeline in the same AWS Region as your file system. Because AWS Data Pipeline is not supported in US East (Ohio), this solution doesn't work in that AWS Region. We recommend that if you want to back up your file system using this solution, you use your file system in one of the other supported AWS Regions.

Topics
• Performance for Amazon EFS backups using AWS Data Pipeline (p. 344)
• Considerations for Amazon EFS backup using AWS Data Pipeline (p. 345)
• Assumptions for Amazon EFS backup with AWS Data Pipeline (p. 345)
• How to back up an Amazon EFS file system with AWS Data Pipeline (p. 346)
• Additional backup resources (p. 351)

Performance for Amazon EFS backups using AWS Data Pipeline

When performing data backups and restorations, your file system performance is subject to Amazon EFS performance (p. 120), including baseline and burst throughput capacity. The throughput used by your backup solution counts toward your total file system throughput. The following table provides some recommendations for the Amazon EFS file system and Amazon EC2 instance sizes that work for this solution, assuming that your backup window is 15 minutes long.

<table>
<thead>
<tr>
<th>EFS size (30 MB average file size)</th>
<th>Daily change volume</th>
<th>Remaining burst hours</th>
<th>Minimum number of backup agents</th>
</tr>
</thead>
<tbody>

</table>

* These estimates are based on the assumption that data stored in an EFS file system that is 1 TB or larger is organized so that the backup can be spread across multiple backup nodes. The multiple-node
example scripts divide the backup load across nodes based on the contents of the first-level directory of your EFS file system.

For example, if there are two backup nodes, one node backs up all of the even files and directories located in the first-level directory. The odd node does the same for the odd files and directories. In another example, with six directories in the Amazon EFS file system and four backup nodes, the first node backs up the first and the fifth directories. The second node backs up the second and the sixth directories, and the third and fourth nodes back up the third and the fourth directories respectively.

Considerations for Amazon EFS backup using AWS Data Pipeline

Consider the following when you’re deciding whether to implement an Amazon EFS backup solution using AWS Data Pipeline:

• This approach to EFS backup involves a number of AWS resources. For this solution, you need to create the following:
  • One production file system and one backup file system that contains a full copy of the production file system. The system also contains any incremental changes to your data over the backup rotation period.
  • Amazon EC2 instances, whose lifecycles are managed by AWS Data Pipeline, that perform restorations and scheduled backups.
  • One regularly scheduled AWS Data Pipeline for backing up data.
  • An AWS Data Pipeline for restoring backups.

When this solution is implemented, it results in billing to your account for these services. For more information, see the pricing pages for Amazon EFS, Amazon EC2, and AWS Data Pipeline.

• This solution isn’t an offline backup solution. To ensure a fully consistent and complete backup, pause any file writes to the file system or unmount the file system while the backup occurs. We recommend that you perform all backups during scheduled downtime or off hours.

Assumptions for Amazon EFS backup with AWS Data Pipeline

This walkthrough makes several assumptions and declares example values as follows:

• Before you get started, this walkthrough assumes that you already completed Getting started (p. 13).
• After you've completed the Getting Started exercise, you have two security groups, a VPC subnet, and a file system mount target for the file system that you want to back up. For the rest of this walkthrough, you use the following example values:
  • The ID of the file system that you back up in this walkthrough is fs-12345678.
  • The security group for the file system that is associated with the mount target is called efs-mt-sg (sg-1111111a).
  • The security group that grants Amazon EC2 instances the ability to connect to the production EFS mount point is called efs-ec2-sg (sg-1111111b).
  • The VPC subnet has the ID value of subnet-abcd1234.
  • The source file system mount target IP address for the file system that you want to back up is 10.0.1.32:/.  
  • The example assumes that the production file system is a content management system serving media files with an average size of 30 MB.
How to back up an Amazon EFS file system with AWS Data Pipeline

Follow the steps in this section to back up or restore your Amazon EFS file system with AWS Data Pipeline.

Topics
- Step 1: Create your backup Amazon EFS file system (p. 346)
- Step 2: Download the AWS Data Pipeline template for backups (p. 347)
- Step 3: Create a data pipeline for backup (p. 347)
- Step 4: Access your Amazon EFS backups (p. 348)

Step 1: Create your backup Amazon EFS file system

In this walkthrough, you create separate security groups, file systems, and mount points to separate your backups from your data source. In this first step, you create those resources:

1. First, create two new security groups. The example security group for the backup mount target is efs-backup-mt-sg (sg-9999999a). The example security group for the EC2 instance to access the mount target is efs-backup-ec2-sg (sg-9999999b). Remember to create these security groups in the same VPC as the EFS volume that you want to back up. In this example, the VPC associated with the subnet-abcd1234 subnet. For more information about creating security groups, see Creating security groups (p. 38).

2. Next, create a backup Amazon EFS file system. In this example, the file system ID is fs-abcdefaa. For more information about creating file systems, see Creating Amazon EFS file systems (p. 20).

3. Finally, create a mount point for the EFS backup file system and assume that it has the value of 10.0.1.75:/ For more information about creating mount targets, see Creating and managing mount targets (p. 31).

After you've completed this first step, your setup should look similar to the following example diagram.
Step 2: Download the AWS Data Pipeline template for backups

AWS Data Pipeline helps you reliably process and move data between different AWS compute and storage services at specified intervals. By using the AWS Data Pipeline console, you can create preconfigured pipeline definitions, known as templates. You can use these templates to get started with AWS Data Pipeline quickly. For this walkthrough, a template is provided to make the process of setting up your backup pipeline easier.

When implemented, this template creates a data pipeline that launches a single Amazon EC2 instance on the schedule that you specify to back up data from the production file system to the backup file system. This template has a number of placeholder values. You provide the matching values for those placeholders in the Parameters section of the AWS Data Pipeline console. Download the AWS Data Pipeline template for backups at 1-Node-EFSBackupDataPipeline.json from GitHub.

Note
This template also references and runs a script to perform the backup commands. You can download the script before creating the pipeline to review what it does. To review the script, download efs-backup.sh from GitHub. This backup solution depends on running scripts that are hosted on GitHub and is subject to GitHub availability. If you'd prefer to eliminate this reliance and host the scripts in an Amazon S3 bucket instead, see Hosting the rsync scripts in an Amazon S3 bucket (p. 354).

Step 3: Create a data pipeline for backup

Use the following procedure to create your data pipeline.

To create a data pipeline for Amazon EFS backups

1. Open the AWS Data Pipeline console at https://console.aws.amazon.com/datapipeline/.

   Important
   Make sure that you're working in the same AWS Region as your Amazon EFS file systems.

2. Choose Create new pipeline.

3. Add values for Name and optionally for Description.

4. For Source, choose Import a definition, and then choose Load local file.

5. In the file explorer, navigate to the template that you saved in Step 2: Download the AWS Data Pipeline template for backups (p. 347), and then choose Open.

6. In Parameters, provide the details for both your backup and production EFS file systems.
7. Configure the options in Schedule to define your Amazon EFS backup schedule. The backup in the example runs once every day, and the backups are kept for a week. When a backup is seven days old, it is replaced with next oldest backup.

Note
We recommend that you specify a run time that occurs during your off-peak hours.

8. (Optional) Specify an Amazon S3 location for storing pipeline logs, configure a custom IAM role, or add tags to describe your pipeline.

9. When your pipeline is configured, choose Activate.

You’ve now configured and activated your Amazon EFS backup data pipeline. For more information about AWS Data Pipeline, see the AWS Data Pipeline Developer Guide. At this stage, you can perform the backup now as a test, or you can wait until the backup is performed at the scheduled time.

Step 4: Access your Amazon EFS backups

Your Amazon EFS backup has now been created, activated, and is running on the schedule you defined. This step outlines how you can access your EFS backups. Your backups are stored in the EFS backup file system that you created in the following format.
Using the values from the example scenario, the backup of the file system is located in `10.1.0.75:/fs-12345678/daily.[0-6]`, where daily.0 is the most recent backup and daily.6 is the oldest of the seven rotating backups.

Accessing your backups gives you the ability to restore data to your production file system. You can choose to restore an entire file system, or you can choose to restore individual files.

**Step 4.1: Restore an entire Amazon EFS backup**

Restoring a backup copy of an Amazon EFS file system requires another AWS Data Pipeline, similar to the one you configured in Step 3: Create a data pipeline for backup (p. 347). However, this restoration pipeline works in the reverse of the backup pipeline. Typically, these restorations aren't scheduled to begin automatically.

As with backups, restores can be done in parallel to meet your recovery time objective. Keep in mind that when you create a data pipeline, you need to schedule when you want it run. If you choose to run on activation, you start the restoration process immediately. We recommend that you only create a restoration pipeline when you need to do a restoration, or when you already have a specific window of time in mind.

Burst capacity is consumed by both the backup EFS and restoration EFS. For more information about performance, see Amazon EFS performance (p. 120). The following procedure shows you how to create and implement your restoration pipeline.

**To create a data pipeline for EFS data restoration**

1. Download the data pipeline template for restoring data from your backup EFS file system. This template launches a single Amazon EC2 instance based on the specified size. It launches only when you specify it to launch. Download the AWS Data Pipeline template for backups at 1-Node-EFSRestoreDataPipeline.json from GitHub.

   **Note**
   This template also references and runs a script to perform the restoration commands. You can download the script before creating the pipeline to review what it does. To review the script, download efs-restore.sh from GitHub.

2. Open the AWS Data Pipeline console at https://console.aws.amazon.com/datapipeline/.

   **Important**
   Make sure that you're working in the same AWS Region as your Amazon EFS file systems and Amazon EC2.

3. Choose Create new pipeline.

4. Add values for Name and optionally for Description.

5. For Source, choose Import a definition, and then choose Load local file.

6. In the file explorer, navigate to the template that you saved in Step 1: Create your backup Amazon EFS file system (p. 346), and then choose Open.

7. In Parameters, provide the details for both your backup and production EFS file systems.
8. Because you typically perform restorations only when you need them, you can schedule the restoration to run **once on pipeline activation**. Or schedule a one-time restoration at a future time of your choosing, like during an off-peak window of time.

9. (Optional) Specify an Amazon S3 location for storing pipeline logs, configure a custom IAM role, or add tags to describe your pipeline.

10. When your pipeline is configured, choose **Activate**.

You've now configured and activated your Amazon EFS restoration data pipeline. Now when you need to restore a backup to your production EFS file system, you just activate it from the AWS Data Pipeline console. For more information, see the **AWS Data Pipeline Developer Guide**.

**Step 4.2: Restore individual files from your Amazon EFS backups**

You can restore files from your Amazon EFS file system backups by launching an Amazon EC2 instance to temporarily mount both the production and backup EFS file systems. The EC2 instance must be a member of both of the EFS client security groups (in this example, **efs-ec2-sg** and **efs-backup-clients-sg**). Both EFS mount targets can be mounted by this restoration instance. For example, a recovery EC2 instance can create the following mount points. Here, the **-o ro** option is used to mount the backup EFS as read-only to prevent accidentally modifying the backup when attempting to restore from a backup.

```bash
mount -t nfs source-efs-mount-target:/ /mnt/data

mount -t nfs -o ro backup-efs-mount-target:/fs-12345678/daily.0 /mnt/backup>
```

After you've mounted the targets, you can copy files from `/mnt/backup` to the appropriate location in `/mnt/data` in the terminal using the `cp -p` command. For example, an entire home directory (with its file system permissions) can be recursively copied with the following command.

```bash
sudo cp -rp /mnt/backup/users/my_home /mnt/data/users/my_home
```

You can restore a single file by running the following command.

```bash
sudo cp -p /mnt/backup/user/my_home/.profile /mnt/data/users/my_home/.profile
```
Warning
When you are manually restoring individual data files, be careful that you don't accidentally modify the backup itself. Otherwise, you might corrupt it.

Additional backup resources

The backup solution presented in this walkthrough uses templates for AWS Data Pipeline. The templates used in Step 2: Download the AWS Data Pipeline template for backups (p. 347) and Step 4.1: Restore an entire Amazon EFS backup (p. 349) both use a single Amazon EC2 instance to perform their work. However, there's no real limit to the number of parallel instances that you can run for backing up or restoring your data in Amazon EFS file systems. In this topic, you can find links to other AWS Data Pipeline templates configured for multiple EC2 instances that you can download and use for your backup solution. You can also find instructions for how to modify the templates to include additional instances.

Topics
- Using additional templates (p. 351)
- Adding additional backup instances (p. 351)
- Adding additional restoration instances (p. 353)
- Hosting the rsync scripts in an Amazon S3 bucket (p. 354)

Using additional templates

You can download the following additional templates from GitHub:

- 2-Node-EFSBackupPipeline.json – This template starts two parallel Amazon EC2 instances to back up your production Amazon EFS file system.
- 2-Node-EFSRestorePipeline.json – This template starts two parallel Amazon EC2 instances to restore a backup of your production Amazon EFS file system.

Adding additional backup instances

You can add additional nodes to the backup templates used in this walkthrough. To add a node, modify the following sections of the 2-Node-EFSBackupDataPipeline.json template.

Important
If you're using additional nodes, you can't use spaces in file names and directories stored in the top-level directory. If you do, those files and directories aren't backed up or restored. All files and subdirectories that are at least one level below the top level are backed up and restored as expected.

- Create an additional EC2Resource for each additional node you want to create (in this example, a fourth EC2 instance).

```json
{
  "id": "EC2Resource4",
  "terminateAfter": "70 Minutes",
  "instanceType": "#{myInstanceType}"
}
```

351
• Create an additional data pipeline activity for each additional node (in this case, activity `BackupPart4`), make sure to configure the following sections:

  • Update the `runsOn` reference to point to the EC2Resource created previously (EC2Resource4 in the following example).

  • Increment the last two `scriptArgument` values to equal the backup part that each node is responsible for and the total number of nodes. For "2" and "3" in the example following, the backup part is "3" for the fourth node because in this example our modulus logic needs to count starting with 0.

```json
{
  "id": "BackupPart4",
  "name": "BackupPart4",
  "runsOn": {
    "ref": "EC2Resource4"
  },
  "command": "wget https://raw.githubusercontent.com/awslabs/data-pipeline-samples/master/samples/EFSBackup/efs-backup-rsync.sh \n  chmod a+x efs-backup-rsync.sh \n  ./efs-backup-rsync.sh $1 $2 $3 $4 $5 $6 $7",
  "scriptArgument": ["#{myEfsSource}","#{myEfsBackup}", "#{myInterval}",
    "#{myRetainedBackups}","#{myEfsID}", "3", "4"],
  "type": "ShellCommandActivity",
  "dependsOn": {
    "ref": "InitBackup"
  },
  "stage": "true"
}
```

• Increment the last value in all existing `scriptArgument` values to the number of nodes (in this example, "4").

```json
{
  "id": "BackupPart1",
  ...
  "scriptArgument": ["#{myEfsSource}","#{myEfsBackup}", "#{myInterval}",
    "#{myRetainedBackups}","#{myEfsID}", "1", "4"],
  ...
},
{
  "id": "BackupPart2",
  ...
  "scriptArgument": ["#{myEfsSource}","#{myEfsBackup}", "#{myInterval}",
    "#{myRetainedBackups}","#{myEfsID}", "2", "4"],
  ...
},
{
  "id": "BackupPart3",
  ...
  "scriptArgument": ["#{myEfsSource}","#{myEfsBackup}", "#{myInterval}",
    "#{myRetainedBackups}","#{myEfsID}", "0", "4"],
  ...
},
```

• Update `FinalizeBackup` activity and add the new backup activity to the `dependsOn` list (BackupPart4 in this case).

```json
{
  "id": "FinalizeBackup",
  "name": "FinalizeBackup",
  "runsOn": {
    "ref": "EC2Resource1"
  },
  "command": "wget https://raw.githubusercontent.com/awslabs/data-pipeline-samples/master/samples/EFSBackup/efs-backup-end.sh \n  chmod a+x efs-backup-end.sh \n  efs-backup-end.sh \n  ./efs-backup-end.sh $1 $2",
  "scriptArgument": ["#{myInterval}", "#{myEfsID}"],
  "type": "ShellCommandActivity",
  "dependsOn": [
    {"ref": "BackupPart1"}
  ]
}
```
Adding additional restoration instances

You can add nodes to the restoration templates used in this walkthrough. To add a node, modify the following sections of the 2-Node-EFSRestorePipeline.json template.

- Create an additional EC2Resource for each additional node you want to create (in this case, a third EC2 instance called EC2Resource3).

```json
{
  "id": "EC2Resource3",
  "terminateAfter": "70 Minutes",
  "instanceType": "#{myInstanceType}",
  "name": "EC2Resource3",
  "type": "Ec2Resource",
  "securityGroupIds": [ "#{mySrcSecGroupID}" , "#{myBackupSecGroupID}" ],
  "subnetId": "#{mySubnetID}",
  "associatePublicIpAddress": "true"
},
```

- Create an additional data pipeline activity for each additional node (in this case, Activity RestorePart3). Make sure to configure the following sections:
  - Update the runsOn reference to point to the EC2Resource created previously (in this example, EC2Resource3).
  - Increment the last two scriptArgument values to equal the backup part that each node is responsible for and the total number of nodes. For "2" and "3" in the example following, the backup part is "3" for the fourth node because in this example our modulus logic needs to count starting with 0.

```json
{
  "id": "RestorePart3",
  "name": "RestorePart3",
  "runsOn": {
    "ref": "EC2Resource3"
  },
  "command": "wget https://raw.githubusercontent.com/awslabs/data-pipeline-samples/master/samples/EFSBackup/efs-restore-rsync.sh\nchmod a+x efs-restore-rsync.sh\n./efs-backup-rsync.sh $1 $2 $3 $4 $5 $6 $7",
  "scriptArgument": [ "#{myEfsSource}" , "#{myEfsBackup}" , "#{myInterval}" ,
    "#{myBackup}" , "#{myEfsID}" , "2" , "3" ],
  "type": "ShellCommandActivity",
  "dependsOn": {
    "ref": "InitBackup"
  },
  "stage": "true"
},
```

- Increment the last value in all existing scriptArgument values to the number of nodes (in this example, "3").

```json
{
  "id": "RestorePart1",
  ...
  "scriptArgument": [ "#{myEfsSource}" , "#{myEfsBackup}" , "#{myInterval}" ,
    "#{myBackup}" , "#{myEfsID}" , "1" , "3" ],
  ...
}
```
Hosting the rsync scripts in an Amazon S3 bucket

This backup solution is dependent on running rsync scripts that are hosted in a GitHub repository on the internet. Therefore, this backup solution is subject to the GitHub repository being available. This requirement means that if the GitHub repository removes these scripts, or if the GitHub website goes offline, the backup solution as implemented preceding doesn't function.

If you'd prefer to eliminate this GitHub dependency, you can choose to host the scripts in an Amazon S3 bucket that you own instead. Following, you can find the steps necessary to host the scripts yourself.

To host the rsync scripts in your own Amazon S3 bucket

1. **Sign Up for AWS** – If you already have an AWS account, go ahead and skip to the next step. Otherwise, see [Sign up for AWS](#) (p. 11).
2. **Create an AWS Identity and Access Management User** – If you already have an IAM user, go ahead and skip to the next step. Otherwise, see [Create an IAM User](#) (p. 11).
3. **Create an Amazon S3 bucket** – If you already have a bucket that you want to host the rsync scripts in, go ahead and skip to the next step. Otherwise, see [Create a Bucket](#) in the Amazon Simple Storage Service User Guide.
4. **Download the rsync scripts and templates** – Download all of the rsync scripts and templates in the EFSBackup folder from GitHub. Make a note of the location on your computer where you downloaded these files.
5. **Upload the rsync scripts to your S3 bucket** – For instructions on how to upload objects into your S3 bucket, see [Add an Object to a Bucket](#) in the Amazon Simple Storage Service User Guide.
6. **Change the permissions on the uploaded rsync scripts to allow Everyone to Open/Download them.** For instructions on how to change the permissions on an object in your S3 bucket, see [Editing Object Permissions](#) in the Amazon Simple Storage Service User Guide.
7. **Update your templates** – Modify the `wget` statement in the `shellCmd` parameter to point to the Amazon S3 bucket where you put the startup script. Save the updated template, and use that template when you're following the procedure in Step 3: Create a data pipeline for backup (p. 347).

   **Note**
   We recommend that you limit access to your Amazon S3 bucket to include the IAM account that activates the AWS Data Pipeline for this backup solution. For more information, see Editing Bucket Permissions in the *Amazon Simple Storage Service User Guide*.

You are now hosting the rsync scripts for this backup solution, and your backups are no longer dependent on GitHub availability.

### Mounting file systems without the EFS mount helper

**Note**
In this section, you can learn how to mount your Amazon EFS file system without the `amazon-efs-utils` package. To use encryption of data in transit with your file system, you must mount your file system with Transport Layer Security (TLS). To do so, we recommend using the `amazon-efs-utils` package. For more information, see Using the `amazon-efs-utils` Tools (p. 47).

Following, you can learn how to install the Network File System (NFS) client and how to mount your Amazon EFS file system on an Amazon EC2 instance. You also can find an explanation of the `mount`
command and the available options for specifying your file system's Domain Name System (DNS) name in the `mount` command. In addition, you can find how to use the file `/etc/fstab` to automatically remount your file system after any system restarts.

**Note**
Before you can mount a file system, you must create, configure, and launch your related AWS resources. For detailed instructions, see Getting started with Amazon Elastic File System (p. 13).

**Topics**
- NFS support (p. 356)
- Installing the NFS client (p. 357)
- Recommended NFS mount options (p. 358)
- Mounting on Amazon EC2 with a DNS name (p. 359)
- Mounting with an IP address (p. 361)

## NFS support

Amazon EFS supports the Network File System versions 4.0 and 4.1 (NFSv4) protocols when mounting your file systems on Amazon EC2 instances. Although NFSv4.0 is supported, we recommend that you use NFSv4.1. Mounting your Amazon EFS file system on your Amazon EC2 instance also requires an NFS client that supports your chosen NFSv4 protocol. Amazon EC2 Mac instances running macOS Big Sur only support NFS v4.0.

Amazon EFS does not support the `nconnect` mount option.

**Note**
For Linux kernel versions 5.4.*, the Linux NFS client uses a default `read_ahead_kb` value of 128 KB. We recommend increasing this value to 15 MB. For more information, see Optimizing the NFS `read_ahead_kb` size (p. 128).

For optimal performance and to avoid a variety of known NFS client bugs, we recommend working with a recent Linux kernel. If you are using an enterprise Linux distribution, we recommend the following:

- Amazon Linux 2
- Amazon Linux 2017.09 or newer
- Red Hat Enterprise Linux (and derivatives such as CentOS) version 7 and newer
- Ubuntu 16.04 LTS and newer
- SLES 12 Sp2 or later

If you are using another distribution or a custom kernel, we recommend kernel version 4.3 or newer.

**Note**
RHEL 6.9 might be suboptimal for certain workloads due to Poor Performance When Opening Many Files in Parallel (p. 219).

**Note**
Using Amazon EFS with Amazon EC2 instances based on Microsoft Windows is not supported.

## Troubleshooting AMI and kernel versions

To troubleshoot issues related to certain AMI or kernel versions when using Amazon EFS from an EC2 instance, see Troubleshooting AMI and Kernel Issues (p. 222).
Installing the NFS client

To mount your Amazon EFS file system on your Amazon EC2 instance, first you need to install an NFS client. To connect to your EC2 instance and install an NFS client, you need the public DNS name of the EC2 instance and a user name to log in. That user name for your instance is typically `ec2-user`.

To connect your EC2 instance and install the NFS client

1. Connect to your EC2 instance. Note the following about connecting to the instance:
   - To connect to your instance from a computer running macOS or Linux, specify the .pem file to your Secure Shell (SSH) client with the `-i` option and the path to your private key.
   - To connect to your instance from a computer running Windows, you can use either MindTerm or PuTTY. If you plan to use PuTTY, you need to install it and use the following procedure to convert the .pem file to a .ppk file.

   For more information, see the following topics in the *Amazon EC2 User Guide for Linux Instances*:
   - Connecting to Your Linux Instance from Windows Using PuTTY
   - Connecting to Your Linux Instance Using SSH

   The key file cannot be publicly viewable for SSH. You can use the `chmod 400 filename.pem` command to set these permissions. For more information, see Create a Key Pair.

2. (Optional) Get updates and reboot.

   ```
   # sudo yum -y update
   # sudo reboot
   ```

3. After the reboot, reconnect to your EC2 instance.

4. Install the NFS client.

   If you're using an Amazon Linux AMI or Red Hat Linux AMI, install the NFS client with the following command.

   ```
   # sudo yum -y install nfs-utils
   ```

   If you're using an Ubuntu Amazon EC2 AMI, install the NFS client with the following command.

   ```
   # sudo apt-get -y install nfs-common
   ```

5. Start the NFS service using the following commands. For RHEL 7:

   ```
   # sudo service nfs start
   ```

   For RHEL 8:

   ```
   # sudo service nfs-server start
   ```

6. Verify that the NFS service started, as follows.

   ```
   # sudo service nfs status
   Redirecting to /bin/systemctl status nfs.service
   # nfs-server.service - NFS server and services
   Loaded: loaded (/usr/lib/systemd/system/nfs-server.service; disabled; vendor preset: disabled)
   ```
If you use a custom kernel (that is, if you build a custom AMI), you need to include at least the following:

- NFSv4.1 client kernel module
- The right NFS4 userspace mount helper

**Note**
If you choose Amazon Linux AMI 2016.03.0 or Amazon Linux AMI 2016.09.0 when launching your Amazon EC2 instance, you don’t need to install nfs-utils because it’s already included in the AMI by default.

**Next: Mount your file system**

Use one of the following procedures to mount your file system.

- Mounting on Amazon EC2 with a DNS name (p. 359)
- Mounting with an IP address (p. 361)
- Mounting your Amazon EFS file system automatically (p. 68)

**Recommended NFS mount options**

We recommend the following default values for mount options on Linux:

- **rsize=1048576** – Sets the maximum number of bytes of data that the NFS client can receive for each network READ request. This value applies when reading data from a file on an EFS file system. We recommend that you use the largest size possible (up to 1048576) to avoid diminished performance.

- **wsize=1048576** – Sets the maximum number of bytes of data that the NFS client can send for each network WRITE request. This value applies when writing data to a file on an EFS file system. We recommend that you use the largest size possible (up to 1048576) to avoid diminished performance.

- **hard** – Sets the recovery behavior of the NFS client after an NFS request times out, so that NFS requests are retried indefinitely until the server replies. We recommend that you use the hard mount option (hard) to ensure data integrity. If you use a soft mount, set the timeo parameter to at least 150 deciseconds (15 seconds). Doing so helps minimize the risk of data corruption that is inherent with soft mounts.

- **timeo=600** – Sets the timeout value that the NFS client uses to wait for a response before it retries an NFS request to 600 deciseconds (60 seconds). If you must change the timeout parameter (timeo), we recommend that you use a value of at least 150, which is equivalent to 15 seconds. Doing so helps avoid diminished performance.

- **retrans=2** – Sets to 2 the number of times the NFS client retries a request before it attempts further recovery action.

- **noresvport** – Tells the NFS client to use a new Transmission Control Protocol (TCP) source port when a network connection is reestablished. Doing this helps make sure that the EFS file system has uninterrupted availability after a network recovery event.

- **_netdev** – When present in /etc/fstab, prevents the client from attempting to mount the EFS file system until the network has been enabled.

- **nofail** – If your EC2 instance needs to start regardless of the status of your mounted EFS file system, add the nofail option to your file system’s entry in your /etc/fstab file.
If you don’t use the preceding defaults, be aware of the following:

- In general, avoid setting any other mount options that are different from the defaults, which can cause reduced performance and other issues. For example, changing read or write buffer sizes or disabling attribute caching can result in reduced performance.
- Amazon EFS ignores source ports. If you change Amazon EFS source ports, it doesn’t have any effect.
- Amazon EFS does not support the `nconnect` mount option.
- Amazon EFS doesn’t support any of the Kerberos security variants. For example, the following mount command fails.

```
$ mount -t nfs4 -o krb5p <DNS_NAME>:/ /efs/
```

- We recommend that you mount your file system using its DNS name. This name resolves to the IP address of the Amazon EFS mount target in the same Availability Zone as your Amazon EC2 instance. If you use a mount target in an Availability Zone different from that of your Amazon EC2 instance, you incur standard EC2 charges for data sent across Availability Zones. You also might see increased latencies for file system operations.
- For more mount options, and detailed explanations of the defaults, see the `man fstab` and `man nfs` pages in the Linux documentation.

### Mounting on Amazon EC2 with a DNS name

- **File system DNS name** – Using the file system's DNS name is your simplest mounting option. The file system DNS name automatically resolves to the mount target’s IP address in the Availability Zone of the connecting Amazon EC2 instance. You can get this DNS name from the console, or if you have the file system ID, you can construct it using the following convention.

```
file-system-id.efs.aws-region.amazonaws.com
```

**Note**

DNS resolution for file system DNS names requires that the Amazon EFS file system has a mount target in the same Availability Zone as the client instance.

- Using the file system DNS name, you can mount a file system on your Amazon EC2 Linux instance with the following command.

```
sudo mount -t nfs -o nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport file-system-id.efs.aws-region.amazonaws.com:/ efs-mount-point
```

- Using the file system DNS name, you can mount a file system on your Amazon EC2 Mac instance running macOS Big Sur with the following command.

```
sudo mount -t nfs -o nfsvers=4.0,rsize=65536,wsize=65536,hard,timeo=600,retrans=2,noresvport,mountport=2049 file-system-id.efs.aws-region.amazonaws.com:/ efs
```

**Important**

You must use `mountport=2049` in order to successfully connect to the EFS file system when mounting on EC2 Mac instances running macOS Big Sur.

- **Mount target DNS name** – In December 2016, we introduced file system DNS names. We continue to provide a DNS name for each Availability Zone mount target for backward compatibility. The generic form of a mount target DNS name is as follows.
Mounting on Amazon EC2 with a DNS name

availability-zone.file-system-id.efs.aws-region.amazonaws.com

**Note**
Mount target DNS name resolution across Availability Zones is supported.

In some cases, you might delete a mount target and then create a new one in the same Availability Zone. In such a case, the DNS name for that new mount target in that Availability Zone is the same as the DNS name for the old mount target.

You can view and copy the exact commands to mount your file system in the Attach dialog box.

**To view the mount commands for your file system**

1. In the Amazon EFS console, choose the file system that you want to mount to display its details page.
2. To display the mount commands to use for this file system, choose Attach in the upper right.

The Attach screen displays the exact commands to use for mounting the file system.

3. The default Mount via DNS view displays the command to mount the file system using the file system's DNS name when mounting with the EFS mount helper or an NFS client.

For a list of AWS Regions that support Amazon EFS, see Amazon Elastic File System in the AWS General Reference.

To be able to use a DNS name in the `mount` command, the following must be true:

- The connecting EC2 instance must be inside a VPC and must be configured to use the DNS server provided by Amazon. For information about Amazon DNS server, see DHCP Options Sets in the Amazon VPC User Guide.
- The VPC of the connecting EC2 instance must have both DNS Resolution and DNS Hostnames enabled. For more information, see Viewing DNS Hostnames for Your EC2 Instance in the Amazon VPC User Guide.
- The connecting EC2 instance must be inside the same VPC as the EFS file system. For more information on accessing and mounting a file system from another location or from a different VPC, see Walkthrough: Create and mount a file system on-premises with AWS Direct Connect and VPN (p. 153) and Walkthrough: Mount a File System from a Different VPC (p. 160).
Note
We recommend that you wait 90 seconds after creating a mount target before you mount your file system. This wait lets the DNS records propagate fully in the AWS Region where the file system is.

Mounting with an IP address

As an alternative to mounting your Amazon EFS file system with the DNS name, Amazon EC2 instances can mount a file system using a mount target’s IP address. Mounting by IP address works in environments where DNS is disabled, such as VPCs with DNS hostnames disabled, and EC2-Classic instances mounting using ClassicLink. For more information on ClassicLink, see ClassicLink in the Amazon EC2 User Guide for Linux Instances.

You can also configure mounting a file system using the mount target IP address as a fallback option for applications configured to mount the file system using its DNS name by default. When connecting to a mount target IP address, EC2 instances should mount using the mount target IP address in the same Availability Zone as the connecting instance.

You can view and copy the exact commands to mount your file system in the Attach dialog box.

To view and copy the exact commands to mount your EFS file system using the mount target IP address

2. In the Amazon EFS console, choose the file system that you want to mount to display its details page.
3. To display the mount commands to use for this file system, choose Attach in the upper right.

The Attach screen displays the exact commands to use for mounting the file system.

Choose Mount via IP to display the command to mount the file system using the mount target IP address in the selected Availability Zone with an NFS client.

- Using the IP address of a mount target in the mount command, you can mount a file system on your Amazon EC2 Linux instance with the following command.

```
sudo mount -t nfs -o nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport mount-target-IP:/ efs
```

- Using the IP address of a mount target in the mount command, you can mount a file system on your Amazon EC2 Mac instance running macOS Big Sur with the following command.

```
Mounting with an IP address

```
sudo mount -t nfs -o
    nfsvers=4.0,rsize=65536,wsize=65536,hard,timeo=600,retrans=2,noresvport,mountport=2049
    mount-target-IP:/efs
```

**Important**
You must use `mountport=2049` in order to successfully connect to the EFS file system when mounting on EC2 Mac instances running macOS Big Sur.

Mounting with an IP address in AWS CloudFormation

You can also mount your file system using an IP address in an AWS CloudFormation template. For more information, see `storage-efs-mountfilesystem-ip-addr.config` in the `awsdocs/elastic-beanstalk-samples` repository for community-provided configuration files on GitHub.
### Document History

- **API version**: 2015-02-01
- **Latest documentation update**: October 22, 2021

The following table describes important changes to the *Amazon Elastic File System User Guide* after July 2018. For notifications about documentation updates, you can subscribe to the RSS feed.

<table>
<thead>
<tr>
<th>update-history-change</th>
<th>update-history-description</th>
<th>update-history-date</th>
</tr>
</thead>
<tbody>
<tr>
<td>File system and mount target resources use 17-character resource ID format (p. 363)</td>
<td>New Amazon EFS file system and mount target resources are now assigned 17-character IDs. For more information, see Resource IDs.</td>
<td>October 22, 2021</td>
</tr>
<tr>
<td>Support added for EFS Intelligent-Tiering (p. 363)</td>
<td>EFS Intelligent-Tiering uses EFS Lifecycle Management to monitor file access patterns and is designed to automatically transition files to and from your corresponding Infrequent Access (IA) storage classes. For more information, see EFS Intelligent-Tiering and Lifecycle Management</td>
<td>September 2, 2021</td>
</tr>
<tr>
<td>Support added for testing 17-character resource ID format (p. 363)</td>
<td>Amazon EFS is transitioning from using 8-character IDs to 17-character IDs for file systems and mount targets on October 1, 2021. During this transition, you can opt-in and start using 17-characters resource IDs on a per AWS Region basis. For more information, see Resource IDs.</td>
<td>May 5, 2021</td>
</tr>
<tr>
<td>Support added for mounting One Zone file systems from a different Availability Zone to Amazon EFS mount helper (p. 363)</td>
<td>You can now use the EFS mount helper to mount an Amazon EFS file system that uses One Zone storage classes to an EC2 instance that is in a different Availability Zone by using the new az option to specify the Availability Zone of the Amazon EFS file system. For more information, see Mounting file systems with One Zone storage classes.</td>
<td>April 6, 2021</td>
</tr>
<tr>
<td>Support added for EFS One Zone storage classes (p. 363)</td>
<td>Amazon EFS One Zone storage classes store data redundantly within a single Availability Zone in an AWS Region. EFS One Zone storage classes are designed to provide high durability and availability.</td>
<td>March 9, 2021</td>
</tr>
</tbody>
</table>
Zone and One Zone-Infrequent Access (One Zone-IA) storage classes are a cost effective option for storing data that doesn't require the multi-AZ resilience of EFS Standard and Standard-IA storage classes. For more information, see Using EFS storage classes.

Amazon EFS is now available to all users in the Asia Pacific (Osaka) AWS Region.

You can now mount your Amazon EFS file system from EC2 Mac instances running macOS Big Sur using the EFS mount helper or using the NFS mount command. For more information, see Mounting with the EFS mount helper or Mounting file systems without the EFS mount helper.

The new Amazon EFS management console is now available in the AWS GovCloud (US) Region

You can use MeteredIOBytes to measure the number of metered bytes for each file system operation, including data read, data write, and metadata operations, with read operations metered at one-third the rate of other operations. For more information, see Amazon CloudWatch metrics for Amazon EFS.

Amazon EFS file systems now meter read requests at one-third the rate of other requests. For more information, see Understanding metered throughput.

You can use StorageBytes to measure and monitor the size of the file system in bytes, including the amount of data stored in the Standard and Infrequent Access storage classes. For more information, see Amazon CloudWatch metrics for Amazon EFS.

Amazon Elastic File System User Guide

EFS File Sync is now part of the new AWS DataSync service. (p. 363)

AWS DataSync is a managed data transfer service that simplifies synchronizing large amounts of data between on-premises storage systems and AWS storage services. For more information, see Transfer Files from On-Premises File Systems to Amazon EFS Using AWS DataSync. November 26, 2018

VPN and inter-region VPC peering connection support added (p. 363)

Amazon EFS are now accessible over VPN connections and inter-region VPC peering connections. For more information, see Transfer Files from On-Premises File Systems to Amazon EFS Using AWS DataSync. October 23, 2018

VPN and Inter-region VPC Peering connection support added (p. 363)

Amazon EFS file systems are now accessible over VPN connections and inter-region VPC peering connections. For more information, see Mounting from Another Account or VPC and How Amazon EFS Works with Direct Connect and VPNs. October 23, 2018

Additional AWS Region support added (p. 363)

Amazon EFS is now available to all users in the Asia Pacific (Singapore) AWS Region. July 13, 2018

Introducing Provisioned Throughput mode (p. 363)

You can now provision throughput for new or existing file systems with the new Provisioned Throughput mode. For more information, see Throughput Modes. July 12, 2018

Additional AWS Region support added (p. 363)

Amazon EFS is now available to all users in the Asia Pacific (Tokyo) AWS Region. July 11, 2018

The following table describes important changes to the Amazon Elastic File System User Guide before July 2018.

<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Date Changed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Additional AWS Region support added</td>
<td>Amazon EFS is now available to all users in the Asia Pacific (Seoul) AWS Region.</td>
