What is Amazon EKS?

Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications. Amazon EKS:

- Runs and scales the Kubernetes control plane across multiple AWS Availability Zones to ensure high availability.
- Automatically scales control plane instances based on load, detects and replaces unhealthy control plane instances, and it provides automated version updates and patching for them.
- Is integrated with many AWS services to provide scalability and security for your applications, including the following capabilities:
  - Amazon ECR for container images
  - Elastic Load Balancing for load distribution
  - IAM for authentication
  - Amazon VPC for isolation
- Runs up-to-date versions of the open-source Kubernetes software, so you can use all of the existing plugins and tooling from the Kubernetes community. Applications that are running on Amazon EKS are fully compatible with applications running on any standard Kubernetes environment, no matter whether they’re running in on-premises data centers or public clouds. This means that you can easily migrate any standard Kubernetes application to Amazon EKS without any code modification.

Amazon EKS control plane architecture

Amazon EKS runs a single tenant Kubernetes control plane for each cluster. The control plane infrastructure isn't shared across clusters or AWS accounts. The control plane consists of at least two API server instances and three etcd instances that run across three Availability Zones within an AWS Region. Amazon EKS:

- Actively monitors the load on control plane instances and automatically scales them to ensure high performance.
- Automatically detects and replaces unhealthy control plane instances, restarting them across the Availability Zones within the AWS Region as needed.
- Leverages the architecture of AWS Regions in order to maintain high availability. Because of this, Amazon EKS is able to offer an SLA for API server endpoint availability.

Amazon EKS uses Amazon VPC network policies to restrict traffic between control plane components to within a single cluster. Control plane components for a cluster can't view or receive communication from other clusters or other AWS accounts, except as authorized with Kubernetes RBAC policies. This secure and highly available configuration makes Amazon EKS reliable and recommended for production workloads.
How does Amazon EKS work?

Getting started with Amazon EKS is easy:

1. Create an Amazon EKS cluster in the AWS Management Console or with the AWS CLI or one of the AWS SDKs.
2. Launch managed or self-managed Amazon EC2 nodes, or deploy your workloads to AWS Fargate.
3. When your cluster is ready, you can configure your favorite Kubernetes tools, such as kubectl, to communicate with your cluster.
4. Deploy and manage workloads on your Amazon EKS cluster the same way that you would with any other Kubernetes environment. You can also view information about your workloads using the AWS Management Console.

To create your first cluster and its associated resources, see Getting started with Amazon EKS (p. 4).
To learn about other Kubernetes deployment options, see Deployment options (p. 2).

Pricing

An Amazon EKS cluster consists of a control plane and the Amazon EC2 or AWS Fargate compute that you run pods on. For more information about pricing for the control plane, see Amazon EKS pricing. Both Amazon EC2 and Fargate provide:

- **On-Demand Instances** – Pay for the instances that you use by the second, with no long-term commitments or upfront payments. For more information, see Amazon EC2 On-Demand Pricing and AWS Fargate Pricing.
- **Savings Plans** – You can reduce your costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years. For more information, see Pricing with Savings Plans.

Deployment options

You can use Amazon EKS with any, or all, of the following deployment options:

- **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes. For more information, see What is Amazon EKS? (p. 1).
- **Amazon EKS on AWS Outposts** – AWS Outposts enables native AWS services, infrastructure, and operating models in your on-premises facilities. With Amazon EKS on AWS Outposts, you can choose to run extended or local clusters. With extended clusters, the Kubernetes control plane runs in an AWS Region, and the nodes run on AWS Outposts. With local clusters, the entire Kubernetes cluster runs
locally on Outposts, including both the Kubernetes control plane and nodes. For more information, see Amazon EKS on AWS Outposts (p. 547).

- **Amazon EKS Anywhere** – Amazon EKS Anywhere is a deployment option for Amazon EKS that enables you to easily create and operate Kubernetes clusters on-premises. Both Amazon EKS and Amazon EKS Anywhere are built on the Amazon EKS Distro. To learn more about Amazon EKS Anywhere, and its differences with Amazon EKS, see Overview and Comparing Amazon EKS Anywhere to Amazon EKS in the Amazon EKS Anywhere documentation.

- **Amazon EKS Distro** – Amazon EKS Distro is a distribution of the same open-source Kubernetes software and dependencies deployed by Amazon EKS in the cloud. Amazon EKS Distro follows the same Kubernetes version release cycle as Amazon EKS and is provided as an open-source project. To learn more, see Amazon EKS Distro. You can also view and download the source code for the Amazon EKS Distro on GitHub.

When choosing which deployment options to use for your Kubernetes cluster, consider the following:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Amazon EKS</th>

**Frequently asked questions**

- **Q:** Can I deploy Amazon EKS Anywhere in the AWS cloud?

  **A:** Amazon EKS Anywhere isn't designed to run in the AWS cloud. It doesn't integrate with the Kubernetes Cluster API Provider for AWS. If you plan to deploy Kubernetes clusters in the AWS cloud, we strongly recommend that you use Amazon EKS.

- **Q:** Can I deploy Amazon EKS Anywhere on AWS Outposts?

  **A:** Amazon EKS Anywhere isn't designed to run on AWS Outposts. If you're planning to deploy Kubernetes clusters on AWS Outposts, we strongly recommend that you use Amazon EKS on AWS Outposts.
Getting started with Amazon EKS

Many procedures of this user guide use the following command line tools:

- **kubectl** – A command line tool for working with Kubernetes clusters. For more information, see Installing or updating kubectl (p. 4).
- **eksctl** – A command line tool for working with EKS clusters that automates many individual tasks. For more information, see Installing or updating eksctl (p. 10).
- **AWS CLI** – A command line tool for working with AWS services, including Amazon EKS. For more information, see Installing, updating, and uninstalling the AWS CLI in the AWS Command Line Interface User Guide. After installing the AWS CLI, we recommend that you also configure it. For more information, see Quick configuration with aws configure in the AWS Command Line Interface User Guide.

There are two getting started guides available for creating a new Kubernetes cluster with nodes in Amazon EKS:

- **Getting started with Amazon EKS – eksctl (p. 12)** – This getting started guide helps you to install all of the required resources to get started with Amazon EKS using eksctl, a simple command line utility for creating and managing Kubernetes clusters on Amazon EKS. At the end of the tutorial, you will have a running Amazon EKS cluster that you can deploy applications to. This is the fastest and simplest way to get started with Amazon EKS.
- **Getting started with Amazon EKS – AWS Management Console and AWS CLI (p. 15)** – This getting started guide helps you to create all of the required resources to get started with Amazon EKS using the AWS Management Console and AWS CLI. At the end of the tutorial, you will have a running Amazon EKS cluster that you can deploy applications to. In this guide, you manually create each resource required for an Amazon EKS cluster. The procedures give you visibility into how each resource is created and how they interact with each other.

Installing or updating kubectl

Kubectl is a command line tool that you use to communicate with the Kubernetes API server. The kubectl binary is available in many operating system package managers. Using a package manager for your installation is often easier than a manual download and install process.

This topic helps you to download and install, or update, the kubectl binary on your device. The binary is identical to the upstream community versions. The binary is not unique to Amazon EKS or AWS.

**Note**

You must use a kubectl version that is within one minor version difference of your Amazon EKS cluster control plane. For example, a 1.22 kubectl client works with Kubernetes 1.21, 1.22, and 1.23 clusters.

**To install or update kubectl**

1. Determine whether you already have kubectl installed on your device.

```bash
kubectl version | grep Client | cut -d : -f 5
```

If you have kubectl installed in the path of your device, the example output is as follows. If you want to update the version that you currently have installed with a later version, complete the next step, making sure to install the new version in the same location that your current version is in.
"v1.22.6-eks-7d68063", GitCommit

If you receive no output, then you either don't have kubectl installed, or it's not installed in a location that's in your device's path.

2. Install or update kubectl on macOS, Linux, and Windows operating systems.

macOS

**To install or update kubectl on macOS**

1. Download the binary for your cluster's Kubernetes version from Amazon S3.
   - Kubernetes 1.23
     ```
     curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.23.7/2022-06-29/bin/darwin/amd64/kubectl
     ```
   - Kubernetes 1.22
     ```
     curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/darwin/amd64/kubectl
     ```
   - Kubernetes 1.21
     ```
     curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.21.2/2021-07-05/bin/darwin/amd64/kubectl
     ```
   - Kubernetes 1.20
     ```
     curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.20.4/2021-04-12/bin/darwin/amd64/kubectl
     ```
   - Kubernetes 1.19
     ```
     curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/darwin/amd64/kubectl
     ```

2. (Optional) Verify the downloaded binary with the SHA-256 sum for your binary.
   a. Download the SHA-256 sum for your cluster's Kubernetes version.
      - Kubernetes 1.23
        ```
        curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.23.7/2022-06-29/bin/darwin/amd64/kubectl.sha256
        ```
      - Kubernetes 1.22
        ```
        curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/darwin/amd64/kubectl.sha256
        ```
      - Kubernetes 1.21
        ```
        ```
      - Kubernetes 1.20
        ```
        curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.20.4/2021-04-12/bin/darwin/amd64/kubectl.sha256
        ```
      - Kubernetes 1.19
        ```
        curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/darwin/amd64/kubectl.sha256
        ```
Installing kubectl

- Kubernetes 1.19

```
curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/darwin/amd64/kubectl.sha256
```

b. Check the SHA-256 sum for your downloaded binary.

```
openssl sha1 -sha256 kubectl
```

c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match.

3. Apply execute permissions to the binary.

```
chmod +x ./kubectl
```

4. Copy the binary to a folder in your PATH. If you have already installed a version of kubectl, then we recommend creating a $HOME/bin/kubectl and ensuring that $HOME/bin comes first in your PATH.

```
mkdir -p $HOME/bin && cp ./kubectl $HOME/bin/kubectl && export PATH=$HOME/bin:$PATH
```

5. (Optional) Add the $HOME/bin path to your shell initialization file so that it is configured when you open a shell.

```
echo 'export PATH=$PATH:$HOME/bin' >> ~/.bash_profile
```

6. After you install kubectl, you can verify its version with the following command:

```
kubectl version --short --client
```

Linux

**To install or update kubectl on Linux**

1. Download the kubectl binary for your cluster's Kubernetes version from Amazon S3 using the command for your device's hardware platform. The first link for each version is for amd64 and the second link is for arm64.

   - Kubernetes 1.23

```
curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.23.7/2022-06-29/bin/linux/amd64/kubectl
```

```
curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.23.7/2022-06-29/bin/linux/arm64/kubectl
```

   - Kubernetes 1.22

```
curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/linux/amd64/kubectl
```

```
curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/linux/arm64/kubectl
```
curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/linux/arm64/kubectl

- Kubernetes 1.21

curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.21.2/2021-07-05/bin/linux/amd64/kubectl

curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.21.2/2021-07-05/bin/linux/arm64/kubectl

- Kubernetes 1.20

curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.20.4/2021-04-12/bin/linux/amd64/kubectl

curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.20.4/2021-04-12/bin/linux/arm64/kubectl

- Kubernetes 1.19

curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/linux/amd64/kubectl

curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/linux/arm64/kubectl

2. (Optional) Verify the downloaded binary with the SHA-256 sum for your binary.
a. Download the SHA-256 sum for your cluster's Kubernetes version from Amazon S3 using the command for your device's hardware platform. The first link for each version is for amd64 and the second link is for arm64.

- Kubernetes 1.23

curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.23.7/2022-06-29/bin/linux/amd64/kubectl.sha256

curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.23.7/2022-06-29/bin/linux/arm64/kubectl.sha256

- Kubernetes 1.22

curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/linux/amd64/kubectl.sha256

curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/linux/arm64/kubectl.sha256

- Kubernetes 1.21

curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.21.2/2021-07-05/bin/linux/amd64/kubectl.sha256
Installing kubectl

- Kubernetes 1.20

```bash
curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.21.2/2021-07-05/bin/linux/arm64/kubectl.sha256
```

- Kubernetes 1.20

```bash
curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.20.4/2021-04-12/bin/linux/amd64/kubectl.sha256
```

- Kubernetes 1.20

```bash
curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.20.4/2021-04-12/bin/linux/arm64/kubectl.sha256
```

- Kubernetes 1.19

```bash
curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/linux/amd64/kubectl.sha256
```

- Kubernetes 1.19

```bash
curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/linux/arm64/kubectl.sha256
```

b. Check the SHA-256 sum for your downloaded binary.

```bash
openssl sha1 -sha256 kubectl
```

c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match.

3. Apply execute permissions to the binary.

```bash
chmod +x ./kubectl
```

4. Copy the binary to a folder in your PATH. If you have already installed a version of kubectl, then we recommend creating a $HOME/bin/kubectl and ensuring that $HOME/bin comes first in your $PATH.

```bash
mkdir -p $HOME/bin && cp ./kubectl $HOME/bin/kubectl && export PATH=$PATH:$HOME/bin
```

5. (Optional) Add the $HOME/bin path to your shell initialization file so that it is configured when you open a shell.

**Note**

This step assumes you are using the Bash shell; if you are using another shell, change the command to use your specific shell initialization file.

```bash
echo 'export PATH=$PATH:$HOME/bin' >> ~/.bashrc
```

6. After you install kubectl, you can verify its version with the following command:

```bash
kubectl version --short --client
```

Windows

**To install or update kubectl on Windows**

1. Open a PowerShell terminal.
2. Download the `kubectl` binary for your cluster’s Kubernetes version from Amazon S3.
   - Kubernetes 1.23
     
     ```
     curl -o kubectl.exe https://s3.us-west-2.amazonaws.com/amazon-eks/1.23.7/2022-06-29/bin/windows/amd64/kubectl.exe
     ```
   - Kubernetes 1.22
     
     ```
     curl -o kubectl.exe https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/windows/amd64/kubectl.exe
     ```
   - Kubernetes 1.21
     
     ```
     curl -o kubectl.exe https://s3.us-west-2.amazonaws.com/amazon-eks/1.21.2/2021-07-05/bin/windows/amd64/kubectl.exe
     ```
   - Kubernetes 1.20
     
     ```
     curl -o kubectl.exe https://s3.us-west-2.amazonaws.com/amazon-eks/1.20.4/2021-04-12/bin/windows/amd64/kubectl.exe
     ```
   - Kubernetes 1.19
     
     ```
     curl -o kubectl.exe https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/windows/amd64/kubectl.exe
     ```
   - (Optional) Verify the downloaded binary with the SHA-256 sum for your binary.
     a. Download the SHA-256 sum for your cluster’s Kubernetes version for Windows.
       - Kubernetes 1.23
         
         ```
         curl -o kubectl.exe.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.23.7/2022-06-29/bin/windows/amd64/kubectl.exe.sha256
         ```
       - Kubernetes 1.22
         
         ```
         curl -o kubectl.exe.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/windows/amd64/kubectl.exe.sha256
         ```
       - Kubernetes 1.21
         
         ```
         curl -o kubectl.exe.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.21.2/2021-07-05/bin/windows/amd64/kubectl.exe.sha256
         ```
       - Kubernetes 1.20
         
         ```
         curl -o kubectl.exe.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.20.4/2021-04-12/bin/windows/amd64/kubectl.exe.sha256
         ```
       - Kubernetes 1.19
         
         ```
         curl -o kubectl.exe.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/windows/amd64/kubectl.exe.sha256
         ```
     b. Check the SHA-256 sum for your downloaded binary.
       ```
       Get-FileHash kubectl.exe
       ```
Installing eksctl

Installing or updating eksctl

This topic helps you install or update eksctl, a simple command line tool for creating and managing Kubernetes clusters on Amazon EKS. Eksctl provides the fastest and easiest way to create a new cluster with nodes for Amazon EKS. For more information and to see the official documentation, see https://eksctl.io/.

Prerequisite

The kubectl command line tool is installed on your device or AWS CloudShell. The version can be the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For example, if your cluster version is 1.22, you can use kubectl version 1.21, 1.22, or 1.23 with it. To install or upgrade kubectl, see Installing or updating kubectl (p. 4).

To install or update eksctl

1. Determine whether you already have eksctl installed on your device.

   eksctl version

   If you have eksctl installed in the path of your device, the example output is as follows. If you want to update the version that you currently have installed with a later version, complete the next step, making sure to install the new version in the same location that your current version is in.

   0.112.0

   If you receive no output, then you either don't have eksctl installed, or it's not installed in a location that's in your device's path.

2. You can install eksctl on macOS, Linux, or Windows

   macOS

   To install or update eksctl on macOS

   The easiest way to get started with Amazon EKS and macOS is by installing eksctl with Homebrew, an open-source tool that can be installed using these instructions. The eksctl Homebrew recipe installs eksctl and any other dependencies that are required for Amazon EKS, such as kubectl. The recipe also installs the aws-iam-authenticator (p. 396), which is required if you don’t have the AWS CLI version 1.16.156 or higher installed.
1. If you do not already have Homebrew installed on macOS, install it with the following command.

```
/bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/master/install.sh)"
```

2. Install the Weaveworks Homebrew tap.

```
brew tap weaveworks/tap
```

3. Install or upgrade eksctl.

   - Install eksctl with the following command:

   ```
brew install weaveworks/tap/eksctl
```

   - If eksctl is already installed, run the following command to upgrade:

   ```
brew upgrade eksctl && brew link --overwrite eksctl
```

4. Test that your installation was successful with the following command.

```
eksctl version
```

**Note**

The Git Tag version should be at least 0.112.0. If not, check your terminal output for any installation or upgrade errors, or manually download an archive of the release from https://github.com/weaveworks/eksctl/releases/download/v0.112.0/eksctl_Darwin_amd64.tar.gz, extract eksctl, and then run it.

**Linux**

**To install or update eksctl on Linux**

1. Download and extract the latest release of eksctl with the following command.

```
curl --silent --location "https://github.com/weaveworks/eksctl/releases/latest/download/eksctl_${(uname -s)_amd64}.tar.gz" | tar xz -C /tmp
```

2. Move the extracted binary to /usr/local/bin.

```
sudo mv /tmp/eksctl /usr/local/bin
```

3. Test that your installation was successful with the following command.

```
eksctl version
```

**Note**

The Git Tag version should be at least 0.112.0. If not, check your terminal output for any installation or upgrade errors, or replace the address in step 1 with https://github.com/weaveworks/eksctl/releases/download/v0.112.0/eksctl_Linux_amd64.tar.gz and complete steps 1-3 again.
To install or update eksctl on Windows

1. If you do not already have Chocolatey installed on your Windows system, see Installing Chocolatey.
2. Install or upgrade eksctl.
   - Install the binaries with the following command:
     
     ```
     choco install -y eksctl
     ```
   - If they are already installed, run the following command to upgrade:
     
     ```
     choco upgrade -y eksctl
     ```
3. Test that your installation was successful with the following command.

   ```
   eksctl version
   ```

   **Note**
   The GitTag version should be at least 0.112.0. If not, check your terminal output for any installation or upgrade errors, or manually download an archive of the release from https://github.com/weaveworks/eksctl/releases/download/v0.112.0/eksctl_Windows_amd64.zip, extract eksctl, and then run it.

Getting started with Amazon EKS – eksctl

This guide helps you to create all of the required resources to get started with Amazon Elastic Kubernetes Service (Amazon EKS) using eksctl, a simple command line utility for creating and managing Kubernetes clusters on Amazon EKS. At the end of this tutorial, you will have a running Amazon EKS cluster that you can deploy applications to.

The procedures in this guide create several resources for you automatically that you have to create manually when you create your cluster using the AWS Management Console. If you’d rather manually create most of the resources to better understand how they interact with each other, then use the AWS Management Console to create your cluster and compute. For more information, see Getting started with Amazon EKS – AWS Management Console and AWS CLI (p. 15).

Prerequisites

Before starting this tutorial, you must install and configure the following tools and resources that you need to create and manage an Amazon EKS cluster.

- **kubect1** – A command line tool for working with Kubernetes clusters. This guide requires that you use version 1.23 or later. For more information, see Installing or updating kubect1 (p. 4).
- **eksctl** – A command line tool for working with EKS clusters that automates many individual tasks. This guide requires that you use version 0.112.0 or later. For more information, see Installing or updating eksctl (p. 10).
- **Required IAM permissions** – The IAM security principal that you’re using must have permissions to work with Amazon EKS IAM roles and service linked roles, AWS CloudFormation, and a VPC and related resources. For more information, see Actions, resources, and condition keys for Amazon Elastic Container Service for Kubernetes and Using service-linked roles in the IAM User Guide. You must complete all steps in this guide as the same user.
Step 1: Create your Amazon EKS cluster and nodes

Important
To get started as simply and quickly as possible, this topic includes steps to create a cluster and nodes with default settings. Before creating a cluster and nodes for production use, we recommend that you familiarize yourself with all settings and deploy a cluster and nodes with the settings that meet your requirements. For more information, see Creating an Amazon EKS cluster (p. 24) and Amazon EKS nodes (p. 94). Some settings can only be enabled when creating your cluster and nodes.

You can create a cluster with one of the following node types. To learn more about each type, see Amazon EKS nodes (p. 94). After your cluster is deployed, you can add other node types.

- **Fargate – Linux** – Select this type of node if you want to run Linux applications on AWS Fargate. Fargate is a serverless compute engine that lets you deploy Kubernetes pods without managing Amazon EC2 instances.
- **Managed nodes – Linux** – Select this type of node if you want to run Amazon Linux applications on Amazon EC2 instances. Though not covered in this guide, you can also add Windows self-managed (p. 129) and Bottlerocket (p. 127) nodes to your cluster.

Create your Amazon EKS cluster with the following command. You can replace `my-cluster` with your own value. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. Replace `region-code` with any AWS Region that is supported by Amazon EKS. For a list of AWS Regions, see Amazon EKS endpoints and quotas in the AWS General Reference guide.

**Fargate – Linux**

```
eksctl create cluster --name my-cluster --region region-code --fargate
```

**Managed nodes – Linux**

```
eksctl create cluster --name my-cluster --region region-code
```

Cluster creation takes several minutes. During creation you'll see several lines of output. The last line of output is similar to the following example line.

```
...[✓]  EKS cluster "my-cluster" in "region-code" region is ready
```

`eksctl` created a kubectl config file in `~/.kube` or added the new cluster's configuration within an existing config file in `~/.kube` on your computer.

After cluster creation is complete, view the AWS CloudFormation stack named `eksctl-my-cluster-cluster` in the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation to see all of the resources that were created.

Step 2: View Kubernetes resources

1. View your cluster nodes.

```
kubectl get nodes -o wide
```

The example output is as follows.
Fargate – Linux

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
<th>INTERNAL-IP</th>
<th>EXTERNAL-IP</th>
<th>OS-IMAGE</th>
<th>KERNEL-VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>fargate-ip-192-168-141-147.region-code.compute.internal</td>
<td>Ready</td>
<td>&lt;none&gt;</td>

<td></td>
<td>5.4.156-83.273.amzn2.x86_64</td>
<td>containerd://20.10.7</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For more information about what you see in the output, see View Kubernetes resources (p. 500).

2. View the workloads running on your cluster.

```
kubectl get pods -A -o wide
```

The example output is as follows.

Fargate – Linux

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>
Step 3: Delete cluster and nodes

For more information about what you see in the output, see View Kubernetes resources (p. 500).

Step 3: Delete your cluster and nodes

After you've finished with the cluster and nodes that you created for this tutorial, you should clean up by deleting the cluster and nodes with the following command. If you want to do more with this cluster before you clean up, see Next steps (p. 15).

```
eksctl delete cluster --name my-cluster --region region-code
```

Next steps

The following documentation topics help you to extend the functionality of your cluster.

- Deploy a sample application (p. 338) to your cluster.
- The IAM entity (user or role) that created the cluster is the only IAM entity that can make calls to the Kubernetes API server with kubectl or the AWS Management Console. If you want other IAM users or roles to have access to your cluster, then you need to add them. For more information, see Enabling IAM user and role access to your cluster (p. 381) and Required permissions (p. 500).
- Before deploying a cluster for production use, we recommend familiarizing yourself with all of the settings for clusters (p. 24) and nodes (p. 94). Some settings (such as enabling SSH access to Amazon EC2 nodes) must be made when the cluster is created.
- To increase security for your cluster, configure the Amazon VPC Container Networking Interface plugin to use IAM roles for service accounts (p. 258).

Getting started with Amazon EKS – AWS Management Console and AWS CLI

This guide helps you to create all of the required resources to get started with Amazon Elastic Kubernetes Service (Amazon EKS) using the AWS Management Console and the AWS CLI. In this guide, you manually create each resource. At the end of this tutorial, you will have a running Amazon EKS cluster that you can deploy applications to.

The procedures in this guide give you complete visibility into how each resource is created and how the resources interact with each other. If you'd rather have most of the resources created for you automatically, use the eksctl CLI to create your cluster and nodes. For more information, see Getting started with Amazon EKS – eksctl (p. 12).
Prerequisites

Before starting this tutorial, you must install and configure the following tools and resources that you need to create and manage an Amazon EKS cluster.

- **AWS CLI** – A command line tool for working with AWS services, including Amazon EKS. This guide requires that you use version 2.7.32 or later or 1.25.72 or later. For more information, see Installing, updating, and uninstalling the AWS CLI in the AWS Command Line Interface User Guide. After installing the AWS CLI, we recommend that you also configure it. For more information, see Quick configuration with `aws configure` in the AWS Command Line Interface User Guide.

- **kubectl** – A command line tool for working with Kubernetes clusters. This guide requires that you use version 1.23 or later. For more information, see Installing or updating kubectl (p. 4).

- **Required IAM permissions** – The IAM security principal that you're using must have permissions to work with Amazon EKS IAM roles and service linked roles, AWS CloudFormation, and a VPC and related resources. For more information, see Actions, resources, and condition keys for Amazon Elastic Kubernetes Service and Using service-linked roles in the IAM User Guide. You must complete all steps in this guide as the same user.

Step 1: Create your Amazon EKS cluster

**Important**

To get started as simply and quickly as possible, this topic includes steps to create a cluster with default settings. Before creating a cluster for production use, we recommend that you familiarize yourself with all settings and deploy a cluster with the settings that meet your requirements. For more information, see Creating an Amazon EKS cluster (p. 24). Some settings can only be enabled when creating your cluster.

To create your cluster

1. Create an Amazon VPC with public and private subnets that meets Amazon EKS requirements. Replace `region-code` with any AWS Region that is supported by Amazon EKS. For a list of AWS Regions, see Amazon EKS endpoints and quotas in the AWS General Reference guide. You can replace `my-eks-vpc-stack` with any name you choose.

   ```bash
   aws cloudformation create-stack \
   --region region-code \
   --stack-name my-eks-vpc-stack \
   ```

   **Tip**

   For a list of all the resources the previous command creates, open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation. Choose the `my-eks-vpc-stack` stack and then choose the Resources tab.

2. Create a cluster IAM role and attach the required Amazon EKS IAM managed policy to it. Kubernetes clusters managed by Amazon EKS make calls to other AWS services on your behalf to manage the resources that you use with the service.

   a. Copy the following contents to a file named `eks-cluster-role-trust-policy.json`.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   ```
"Principal": {
    "Service": "eks.amazonaws.com"
},
"Action": "sts:AssumeRole"
}

b. Create the role.

```bash
aws iam create-role \
  --role-name myAmazonEKSClusterRole \
  --assume-role-policy-document file://"eks-cluster-role-trust-policy.json"
```

c. Attach the required Amazon EKS managed IAM policy to the role.

```bash
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::aws:policy/AmazonEKSClusterPolicy \
  --role-name myAmazonEKSClusterRole
```

3. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.

Make sure that the AWS Region shown in the upper right of your console is the AWS Region that you want to create your cluster in. If it's not, choose the dropdown next to the AWS Region name and choose the AWS Region that you want to use.

4. Choose Add cluster, and then choose Create. If you don't see this option, then choose Clusters in the left navigation pane first.

5. On the Configure cluster page, do the following:

   a. Enter a Name for your cluster, such as my-cluster. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters.

   b. For Cluster Service Role, choose myAmazonEKSClusterRole.

   c. Leave the remaining settings at their default values and choose Next.

6. On the Specify networking page, do the following:

   a. Choose the ID of the VPC that you created in a previous step from the VPC dropdown list. It is something like vpc-00x0000x000x0x000 | my-eks-vpc-stack-VPC.

   b. Leave the remaining settings at their default values and choose Next.

7. On the Configure logging page, choose Next.

8. On the Review and create page, choose Create.

To the right of the cluster's name, the cluster status is Creating for several minutes until the cluster provisioning process completes. Don't continue to the next step until the status is Active.

**Note**

You might receive an error that one of the Availability Zones in your request doesn't have sufficient capacity to create an Amazon EKS cluster. If this happens, the error output contains the Availability Zones that can support a new cluster. Retry creating your cluster with at least two subnets that are located in the supported Availability Zones for your account. For more information, see Insufficient capacity (p. 521).
Step 2: Configure your computer to communicate with your cluster

In this section, you create a `kubeconfig` file for your cluster. The settings in this file enable the `kubectl` CLI to communicate with your cluster.

To configure your computer to communicate with your cluster

1. Create or update a `kubeconfig` file for your cluster. Replace `region-code` with the AWS Region that you created your cluster in. Replace `my-cluster` with the name of your cluster.

   ```bash
   aws eks update-kubeconfig --region region-code --name my-cluster
   ```

   By default, the config file is created in `~/.kube` or the new cluster's configuration is added to an existing config file in `~/.kube`.

2. Test your configuration.

   ```bash
   kubectl get svc
   ```

   **Note**
   If you receive any authorization or resource type errors, see Unauthorized or access denied (kubectl) (p. 522) in the troubleshooting section.

   The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>svc/kubernetes</td>
<td>ClusterIP</td>
<td>10.100.0.1</td>
<td>&lt;none&gt;</td>
<td>443/TCP</td>
<td>1m</td>
</tr>
</tbody>
</table>

Step 3: Create nodes

**Important**
To get started as simply and quickly as possible, this topic includes steps to create nodes with default settings. Before creating nodes for production use, we recommend that you familiarize yourself with all settings and deploy nodes with the settings that meet your requirements. For more information, see Amazon EKS nodes (p. 94). Some settings can only be enabled when creating your nodes.

You can create a cluster with one of the following node types. To learn more about each type, see Amazon EKS nodes (p. 94). After your cluster is deployed, you can add other node types.

- **Fargate – Linux** – Choose this type of node if you want to run Linux applications on AWS Fargate. Fargate is a serverless compute engine that lets you deploy Kubernetes pods without managing Amazon EC2 instances.
- **Managed nodes – Linux** – Choose this type of node if you want to run Amazon Linux applications on Amazon EC2 instances. Though not covered in this guide, you can also add Windows self-managed (p. 129) and Bottlerocket (p. 127) nodes to your cluster.

Fargate – Linux

Create a Fargate profile. When Kubernetes pods are deployed with criteria that matches the criteria defined in the profile, the pods are deployed to Fargate.
To create a Fargate profile

1. Create an IAM role and attach the required Amazon EKS IAM managed policy to it. When your cluster creates pods on Fargate infrastructure, the components running on the Fargate infrastructure must make calls to AWS APIs on your behalf. This is so that they can do actions such as pull container images from Amazon ECR or route logs to other AWS services. The Amazon EKS pod execution role provides the IAM permissions to do this.

   a. Copy the following contents to a file named `pod-execution-role-trust-policy.json`. Replace `region-code` with the AWS Region that your cluster is in. If you want to use the same role in all AWS Regions in your account, replace `region-code` with `*`. Replace `111122223333` with your account ID and `my-cluster` with the name of your cluster. If you want to use the same role for all clusters in your account, replace `my-cluster` with `*`.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Condition": {
   "ArnLike": {
   }
   },
   "Principal": {
   "Service": "eks-fargate-pods.amazonaws.com"
   },
   "Action": "sts:AssumeRole"
   }
   ]
   }
   }
   
   b. Create a pod execution IAM role.

   ```bash
   aws iam create-role
   --role-name AmazonEKSFargatePodExecutionRole
   --assume-role-policy-document file://"pod-execution-role-trust-policy.json"
   ```
   
   c. Attach the required Amazon EKS managed IAM policy to the role.

   ```bash
   aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonEKSFargatePodExecutionRolePolicy
   --role-name AmazonEKSFargatePodExecutionRole
   ```

2. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
3. On the Clusters page, choose the my-cluster cluster.
4. On the my-cluster page, do the following:
   a. Choose the Compute tab.
   b. Under Fargate Profiles, choose Add Fargate Profile.
5. On the Configure Fargate Profile page, do the following:
   a. For Name, enter a unique name for your Fargate profile, such as `my-profile`.
   b. For Pod execution role, choose the AmazonEKSFargatePodExecutionRole that you created in a previous step.
   c. Choose the Subnets dropdown and deselect any subnet with Public in its name. Only private subnets are supported for pods that are running on Fargate.
Amazon EKS User Guide
Step 3: Create nodes

d.
6.

Choose Next.

On the Conﬁgure pod selection page, do the following:
a.

For Namespace, enter default.

b.

Choose Next.

7.

On the Review and create page, review the information for your Fargate proﬁle and choose
Create.

8.

After a few minutes, the Status in the Fargate Proﬁle conﬁguration section will change from
Creating to Active. Don't continue to the next step until the status is Active.

9.

If you plan to deploy all pods to Fargate (none to Amazon EC2 nodes), do the following to
create another Fargate proﬁle and run the default name resolver (CoreDNS) on Fargate.

Note

If you don't do this, you won't have any nodes at this time.
a.

On the Fargate Proﬁle page, choose my-profile.

b.

Under Fargate proﬁles, choose Add Fargate Proﬁle.

c.

For Name, enter CoreDNS.

d.

For Pod execution role, choose the AmazonEKSFargatePodExecutionRole that you created
in a previous step.

e.

Choose the Subnets dropdown and deselect any subnet with Public in its name. Only
private subnets are supported for pods running on Fargate.

f.

Choose Next.

g.

For Namespace, enter kube-system.

h.

Choose Match labels, and then choose Add label.

i.

Enter k8s-app for Key and kube-dns for value. This is necessary for the default name
resolver (CoreDNS) to deploy to Fargate.

j.

Choose Next.

k.

On the Review and create page, review the information for your Fargate proﬁle and choose
Create.

l.

Run the following command to remove the default eks.amazonaws.com/computetype : ec2 annotation from the CoreDNS pods.
kubectl patch deployment coredns \
-n kube-system \
--type json \
-p='[{"op": "remove", "path": "/spec/template/metadata/annotations/
eks.amazonaws.com~1compute-type"}]'

Note

The system creates and deploys two nodes based on the Fargate proﬁle label you
added. You won't see anything listed in Node Groups because they aren't applicable for
Fargate nodes, but you will see the new nodes listed in the Overview tab.
Managed nodes – Linux
Create a managed node group, specifying the subnets and node IAM role that you created in
previous steps.

20


To create your Amazon EC2 Linux managed node group

1. Create a node IAM role and attach the required Amazon EKS IAM managed policy to it. The Amazon EKS node kubelet daemon makes calls to AWS APIs on your behalf. Nodes receive permissions for these API calls through an IAM instance profile and associated policies.
   a. Copy the following contents to a file named `node-role-trust-policy.json`.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "Service": "ec2.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
       }
     ]
   }
   ```

   b. Create the node IAM role.

   ```bash
   aws iam create-role \
   --role-name myAmazonEKSNodeRole \
   --assume-role-policy-document file://"node-role-trust-policy.json"
   ```

   c. Attach the required managed IAM policies to the role.

   ```bash
   aws iam attach-role-policy \
   --policy-arn arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy \
   --role-name myAmazonEKSNodeRole
   aws iam attach-role-policy \
   --policy-arn arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly \
   --role-name myAmazonEKSNodeRole
   aws iam attach-role-policy \
   --policy-arn arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy \
   --role-name myAmazonEKSNodeRole
   ```

2. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.

3. Choose the name of the cluster that you created in Step 1: Create your Amazon EKS cluster (p. 16), such as `my-cluster`.

4. On the `my-cluster` page, do the following:
   a. Choose the Compute tab.
   b. Choose Add Node Group.

5. On the Configure Node Group page, do the following:
   a. For Name, enter a unique name for your managed node group, such as `my-nodegroup`. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters.
   b. For Node IAM role name, choose `myAmazonEKSNodeRole` role that you created in a previous step. We recommend that each node group use its own unique IAM role.
   c. Choose Next.

6. On the Set compute and scaling configuration page, accept the default values and choose Next.

7. On the Specify networking page, accept the default values and choose Next.
8. On the **Review and create** page, review your managed node group configuration and choose **Create**.

9. After several minutes, the **Status** in the **Node Group configuration** section will change from **Creating** to **Active**. Don't continue to the next step until the status is **Active**.

**Step 4: View resources**

You can view your nodes and Kubernetes workloads.

**To view your nodes and workloads**

1. In the left navigation pane, choose **Clusters**. In the list of **Clusters**, choose the name of the cluster that you created, such as **my-cluster**.
2. On the **my-cluster** page, choose the following:
   a. **Compute** tab – You see the list of **Nodes** that were deployed for the cluster. You can choose the name of a node to see more information about it.
   b. **Resources** tab – You see all of the Kubernetes resources that are deployed by default to an Amazon EKS cluster. Select any resource type in the console to learn more about it.

**Step 5: Delete resources**

After you've finished with the cluster and nodes that you created for this tutorial, you should delete the resources that you created. If you want to do more with this cluster before you delete the resources, see **Next steps (p. 23)**.

**To delete the resources that you created in this guide**

1. Delete any node groups or Fargate profiles that you created.
   b. In the left navigation pane, choose **Clusters**. In the list of clusters, choose **my-cluster**.
   c. Choose the **Compute** tab.
   d. If you created a node group, choose the **my-nodegroup** node group and then choose **Delete**. Enter **my-nodegroup**, and then choose **Delete**.
   e. For each Fargate profile that you created, choose it and then choose **Delete**. Enter the name of the profile, and then choose **Delete**.
      
      **Note**
      When deleting a second Fargate profile, you may need to wait for the first one to finish deleting.
   f. Don't continue until the node group or Fargate profiles are deleted.
2. Delete the cluster.
   a. In the left navigation pane, choose **Clusters**. In the list of clusters, choose **my-cluster**.
   b. Choose **Delete cluster**.
   c. Enter **my-cluster** and then choose **Delete**. Don't continue until the cluster is deleted.
3. Delete the VPC AWS CloudFormation stack that you created.
   b. Choose the **my-eks-vpc-stack** stack, and then choose **Delete**.
   c. In the **Delete my-eks-vpc-stack** confirmation dialog box, choose **Delete stack**.
4. Delete the IAM roles that you created.
   b. In the left navigation pane, choose Roles.
   c. Select each role you created from the list (`myAmazonEKSClusterRole`, as well as `AmazonEKSFargatePodExecutionRole` or `myAmazonEKSNodeRole`). Choose Delete, enter the requested confirmation text, then choose Delete.

Next steps

The following documentation topics help you to extend the functionality of your cluster.

- The IAM entity (user or role) that created the cluster is the only IAM entity that can make calls to the Kubernetes API server with `kubectl` or the AWS Management Console. If you want other IAM users or roles to have access to your cluster, then you need to add them. For more information, see Enabling IAM user and role access to your cluster (p. 381) and Required permissions (p. 500).
- Deploy a sample application (p. 338) to your cluster.
- Before deploying a cluster for production use, we recommend familiarizing yourself with all of the settings for clusters (p. 24) and nodes (p. 94). Some settings (such as enabling SSH access to Amazon EC2 nodes) must be made when the cluster is created.
- To increase security for your cluster, configure the Amazon VPC Container Networking Interface plugin to use IAM roles for service accounts (p. 258).
Amazon EKS clusters

An Amazon EKS cluster consists of two primary components:

- The Amazon EKS control plane
- Amazon EKS nodes that are registered with the control plane

The Amazon EKS control plane consists of control plane nodes that run the Kubernetes software, such as etcd and the Kubernetes API server. The control plane runs in an account managed by AWS, and the Kubernetes API is exposed via the Amazon EKS endpoint associated with your cluster. Each Amazon EKS cluster control plane is single-tenant and unique, and runs on its own set of Amazon EC2 instances.

All of the data stored by the etcd nodes and associated Amazon EBS volumes is encrypted using AWS KMS. The cluster control plane is provisioned across multiple Availability Zones and fronted by an Elastic Load Balancing Network Load Balancer. Amazon EKS also provisions elastic network interfaces in your VPC subnets to provide connectivity from the control plane instances to the nodes (for example, to support kubectl exec logs proxy data flows).

**Important**
In the Amazon EKS environment, etcd storage is limited to 8GB as per upstream guidance. You can monitor the `etcd_db_total_size_in_bytes` metric for the current database size.

Amazon EKS nodes run in your AWS account and connect to your cluster's control plane via the API server endpoint and a certificate file that is created for your cluster.

**Note**

- You can find out how the different components of Amazon EKS work in Amazon EKS networking (p. 238).
- For connected clusters, see Amazon EKS Connector (p. 540).

Creating an Amazon EKS cluster

This topic provides an overview of the available options and describes what to consider when you create an Amazon EKS cluster. If you need to create a cluster on an AWS Outpost, see the section called "Local clusters" (p. 549). If this is your first time creating an Amazon EKS cluster, we recommend that you follow one of our Getting started with Amazon EKS (p. 4) guides. These guides help you to create a simple, default cluster without expanding into all of the available options.

**Prerequisites**

- An existing VPC and subnets that meet Amazon EKS requirements (p. 238). Before you deploy a cluster for production use, we recommend that you have a thorough understanding of the VPC and subnet requirements. If you don't have a VPC and subnets, you can create them using an Amazon EKS provided AWS CloudFormation template (p. 241).
- The kubectl command line tool is installed on your device or AWS CloudShell. The version can be the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For example, if your cluster version is 1.22, you can use kubectl version 1.21, 1.22, or 1.23 with it. To install or upgrade kubectl, see Installing or updating kubectl (p. 4).
Creating a cluster

- Version 2.7.32 or later or 1.25.72 or later of the AWS CLI installed and configured on your device or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with `aws configure` in the AWS Command Line Interface User Guide.

- An IAM user or role with permissions to create and describe an Amazon EKS cluster. For more information, see the section called “Create a local Kubernetes cluster on an Outpost” (p. 449) and the section called “List or describe all clusters” (p. 450).

When an Amazon EKS cluster is created, the IAM entity (user or role) that creates the cluster is permanently added to the Kubernetes RBAC authorization table as the administrator. This entity has `system:masters` permissions. The identity of this entity isn't visible in your cluster configuration. So, it's important to note the entity that created the cluster and make sure that you never delete it. Initially, only the IAM entity that created the server can make calls to the Kubernetes API server using `kubectl`. If you use the console to create the cluster, you must ensure that the same IAM credentials are in the AWS SDK credential chain when you run `kubectl` commands on your cluster. After your cluster is created, you can grant other IAM entities access to your cluster.

To create an Amazon EKS cluster

1. If you already have a cluster IAM role, or you're going to create your cluster with `eksctl`, then you can skip this step. By default, `eksctl` creates a role for you.

   To create an Amazon EKS cluster IAM role

   1. Run the following command to create an IAM trust policy JSON file.

   ```
cat >eks-cluster-role-trust-policy.json <<EOF
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "eks.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
EOF
```

2. Create the Amazon EKS cluster IAM role. If necessary, preface `eks-cluster-role-trust-policy.json` with the path on your computer that you wrote the file to in the previous step. The command associates the trust policy that you created in the previous step to the role. To create an IAM role, the IAM entity (user or role) that is creating the role must be assigned the following IAM action (permission): `iam:CreateRole`.

   ```
   aws iam create-role --role-name myAmazonEKSClusterRole --assume-role-policy-document file://"eks-cluster-role-trust-policy.json"
   ```

3. Attach the Amazon EKS managed policy named `AmazonEKSClusterPolicy` to the role. To attach an IAM policy to an IAM entity (user or role), the IAM entity that is attaching the policy must be assigned one of the following IAM actions (permissions): `iam:AttachUserPolicy` or `iam:AttachRolePolicy`.

   ```
   aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/AmazonEKSClusterPolicy --role-name myAmazonEKSClusterRole
   ```

2. Create an Amazon EKS cluster.
You can create a cluster by using eksctl, the AWS Management Console, or the AWS CLI.

eksctl

**Prerequisite**

Version 0.112.0 or later of the eksctl command line tool installed on your device or AWS CloudShell. To install or update eksctl, see Installing or updating eksctl (p. 10).

**To create your cluster**

Create an Amazon EKS IPv4 cluster with the Amazon EKS default Kubernetes version in your default AWS Region. Before running command, make the following replacements:

- Replace `region-code` with the AWS Region that you want to create your cluster in.
- Replace `my-cluster` with a name for your cluster. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. The name must be unique within the AWS Region and AWS account that you're creating the cluster in.
- Replace `1.23` with any Amazon EKS supported version (p. 66).
- Change the values for `vpc-private-subnets` to meet your requirements. You can also add additional IDs. You must specify at least two subnet IDs. If you'd rather specify public subnets, you can change `--vpc-private-subnets` to `--vpc-public-subnets`. Public subnets have an associated route table with a route to an internet gateway, but private subnets don't have an associated route table. We recommend using private subnets whenever possible.

The subnets that you choose must meet the Amazon EKS subnet requirements (p. 239). Before selecting subnets, we recommend that you're familiar with all of the Amazon EKS VPC and subnet requirements and considerations (p. 238). You can't change which subnets you want to use after cluster creation.

```bash
eksctl create cluster --name my-cluster --region region-code --version 1.23 --vpc-private-subnets subnet-ExampleID1,subnet-ExampleID2 --without-nodegroup
```

Cluster provisioning takes several minutes. While the cluster is being created, several lines of output appear. The last line of output is similar to the following example line.

```
[✓]  EKS cluster "my-cluster" in "region-code" region is ready
```

**Tip**

To see the most options that you can specify when creating a cluster with eksctl, use the `eksctl create cluster --help` command. To see all the available options, you can use a config file. For more information, see Using config files and the config file schema in the eksctl documentation. You can find config file examples on GitHub.

**Optional settings**

The following are optional settings that, if required, must be added to the previous command. You can only enable these options when you create the cluster, not after. If you need to specify these options, you must create the cluster with an eksctl config file and specify the settings, rather than using the previous command.

- If you want to specify one or more security groups that Amazon EKS assigns to the network interfaces that it creates, specify the `securityGroup` option.
Whether you choose any security groups or not, Amazon EKS creates a security group that enables communication between your cluster and your VPC. Amazon EKS associates this security group, and any that you choose, to the network interfaces that it creates. For more information about the cluster security group that Amazon EKS creates, see the section called "Security group requirements" (p. 245). You can modify the rules in the cluster security group that Amazon EKS creates. If you choose to add your own security groups, you can't change the ones that you choose after cluster creation.

- If you want to specify which IPv4 Classless Inter-domain Routing (CIDR) block Kubernetes assigns service IP addresses from, specify the serviceIPv4CIDR option.

Specifying your own range can help prevent conflicts between Kubernetes services and other networks peered or connected to your VPC. Enter a range in CIDR notation. For example: 10.2.0.0/16.

The CIDR block must meet the following requirements:
- Be within one of the following ranges: 10.0.0.0/8, 172.16.0.0/12, or 192.168.0.0/16.
- Have a minimum size of /24 and a maximum size of /12.
- Not overlap with the range of the VPC for your Amazon EKS resources.

You can only specify this option when using the IPv4 address family and only at cluster creation. If you don't specify this, then Kubernetes assigns service IP addresses from either the 10.100.0.0/16 or 172.20.0.0/16 CIDR blocks.

- If you're creating cluster that's version 1.21 or later and want the cluster to assign IPv6 addresses to pods and services instead of IPv4 addresses, specify the ipFamily option.

Kubernetes assigns IPv4 addresses to pods and services, by default. Before deciding to use the IPv6 family, make sure that you're familiar with all of the considerations and requirements in the the section called "VPC requirements and considerations" (p. 238), the section called "Subnet requirements and considerations" (p. 239), the section called "Security group requirements" (p. 245), and the section called "IPv6" (p. 264) topics. If you choose the IPv6 family, you can't specify an address range for Kubernetes to assign IPv6 service addresses from like you can for the IPv4 family. Kubernetes assigns service addresses from the unique local address range (fe00::/7).

AWS Management Console

To create your cluster

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose Add cluster and then choose Create.
3. On the Configure cluster page, enter the following fields:
   - Name – A name for your cluster. It must be unique in your AWS account. The name can contain only alphanumerical characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. The name must be unique within the AWS Region and AWS account that you're creating the cluster in.
   - Kubernetes version – The version of Kubernetes to use for your cluster.
   - Cluster service role – Choose the Amazon EKS cluster IAM role that you created to allow the Kubernetes control plane to manage AWS resources on your behalf.
   - Secrets encryption – (Optional) Choose to enable secrets encryption of Kubernetes secrets using a KMS key. You can also enable this after you create your cluster. Before you enable this capability, make sure that you're familiar with the information in the section called "Enabling secret encryption" (p. 48).
• Tags – (Optional) Add any tags to your cluster. For more information, see Tagging your Amazon EKS resources (p. 412).

4. Select Next.

5. On the Specify networking page, select values for the following fields:

• VPC – Choose an existing VPC that meets Amazon EKS VPC requirements (p. 238) to create your cluster in. Before choosing a VPC, we recommend that you’re familiar with all of the requirements and considerations in the section called “VPC and subnet requirements” (p. 238). You can’t change which VPC you want to use after cluster creation. If no VPCs are listed, then you need to create one first. For more information, see the section called “Creating a VPC” (p. 241).

• Subnets – By default, all available subnets in the VPC specified in the previous field are preselected. You must select at least two.

The subnets that you choose must meet the Amazon EKS subnet requirements (p. 239). Before selecting subnets, we recommend that you’re familiar with all of the Amazon EKS VPC and subnet requirements and considerations (p. 238). You can’t change which subnets you want to use after cluster creation.

Security groups – (Optional) Specify one or more security groups that you want Amazon EKS to associate to the network interfaces that it creates.

Whether you choose any security groups or not, Amazon EKS creates a security group that enables communication between your cluster and your VPC. Amazon EKS associates this security group, and any that you choose, to the network interfaces that it creates. For more information about the cluster security group that Amazon EKS creates, see the section called “Security group requirements” (p. 245). You can modify the rules in the cluster security group that Amazon EKS creates. If you choose to add your own security groups, you can’t change the ones that you choose after cluster creation.

• Choose cluster IP address family – If the version you chose for your cluster is 1.20 or earlier, only the IPv4 option is available. If you chose 1.21 or later, then IPv4 and IPv6 are available.

Kubernetes assigns IPv4 addresses to pods and services, by default. Before deciding to use the IPv6 family, make sure that you’re familiar with all of the considerations and requirements in the the section called “VPC requirements and considerations” (p. 238), the section called “Subnet requirements and considerations” (p. 239), the section called “Security group requirements” (p. 245), and the section called “IPv6” (p. 264) topics. If you choose the IPv6 family, you can’t specify an address range for Kubernetes to assign IPv6 service addresses from like you can for the IPv4 family. Kubernetes assigns service addresses from the unique local address range (\textbf{\texttt{fc00::/7}}).

• (Optional) Choose Configure Kubernetes Service IP address range and specify a Service IPv4 range.

Specifying your own range can help prevent conflicts between Kubernetes services and other networks peered or connected to your VPC. Enter a range in CIDR notation. For example: \textbf{\texttt{10.2.0.0/16}}.

The CIDR block must meet the following requirements:

• Be within one of the following ranges: \textbf{\texttt{10.0.0.0/8}}, \textbf{\texttt{172.16.0.0/12}}, or \textbf{\texttt{192.168.0.0/16}}.

• Have a minimum size of /24 and a maximum size of /12.

• Not overlap with the range of the VPC for your Amazon EKS resources.
You can only specify this option when using the IPv4 address family and only at cluster creation. If you don't specify this, then Kubernetes assigns service IP addresses from either the 10.100.0.0/16 or 172.20.0.0/16 CIDR blocks.

- For **Cluster endpoint access**, select an option. After your cluster is created, you can change this option. Before selecting a non-default option, make sure to familiarize yourself with the options and their implications. For more information, see the section called "Configuring endpoint access" (p. 43).

6. You can accept the defaults in the **Networking add-ons** section to install the default version of the Amazon VPC CNI plugin for Kubernetes (p. 247), CoreDNS (p. 316), and kube-proxy (p. 323) Amazon EKS add-ons. Or, alternatively, you can select a different version. If you don't require the functionality of any of the add-ons, you can remove them once your cluster is created. If you need to manage Amazon EKS managed settings for any of these add-ons yourself, remove Amazon EKS management of the add-on after your cluster is created. For more information, see Amazon EKS add-ons (p. 367).

7. Select **Next**.

8. On the **Configure logging** page, you can optionally choose which log types that you want to enable. By default, each log type is **Disabled**. Before selecting a different option, familiarize yourself with the information in Amazon EKS control plane logging (p. 51). After you create the cluster, you can change this option.

9. Select **Next**.

10. On the **Review and create** page, review the information that you entered or selected on the previous pages. If you need to make changes, choose **Edit**. When you're satisfied, choose **Create**. The **Status** field shows **CREATING** while the cluster is provisioned.

**Note**

You might receive an error that one of the Availability Zones in your request doesn't have sufficient capacity to create an Amazon EKS cluster. If this happens, the error output contains the Availability Zones that can support a new cluster. Retry creating your cluster with at least two subnets that are located in the supported Availability Zones for your account. For more information, see Insufficient capacity (p. 521).

Cluster provisioning takes several minutes.

**AWS CLI**

**To create your cluster**

1. Create your cluster with the command that follows. Before running the command, make the following replacements:

   - Replace **region-code** with the AWS Region that you want to create your cluster in.
   - Replace **my-cluster** with a name for your cluster. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. The name must be unique within the AWS Region and AWS account that you're creating the cluster in.
   - Replace **1.23** with any Amazon EKS supported version (p. 66).
   - Replace **111122223333** with your account ID and **myAmazonEKSClusterRole** with the name of your cluster IAM role.
   - Replace the values for **subnetIds** with your own. You can also add additional IDs. You must specify at least two subnet IDs.

The subnets that you choose must meet the Amazon EKS subnet requirements (p. 239). Before selecting subnets, we recommend that you're familiar with all of the Amazon EKS VPC and subnet requirements and considerations (p. 238). You can't change which subnets you want to use after cluster creation.
If you don't want to specify a security group ID, remove `securityGroupIds=sg-ExampleID1` from the command. If you want to specify one or more security group IDs, replace the values for `securityGroupIds` with your own. You can also add additional IDs.

Whether you choose any security groups or not, Amazon EKS creates a security group that enables communication between your cluster and your VPC. Amazon EKS associates this security group, and any that you choose, to the network interfaces that it creates. For more information about the cluster security group that Amazon EKS creates, see the section called “Security group requirements” (p. 245). You can modify the rules in the cluster security group that Amazon EKS creates. If you choose to add your own security groups, you can't change the ones that you choose after cluster creation.

```
aws eks create-cluster --region region-code --name my-cluster --kubernetes-version 1.23
  --role-arn arn:aws:iam::111122223333:role/myAmazonEKSClusterRole
  --resources-vpc-config subnetIds=subnet-ExampleID1,subnet-ExampleID2,securityGroupIds=sg-ExampleID1
```

**Note**

You might receive an error that one of the Availability Zones in your request doesn't have sufficient capacity to create an Amazon EKS cluster. If this happens, the error output contains the Availability Zones that can support a new cluster. Retry creating your cluster with at least two subnets that are located in the supported Availability Zones for your account. For more information, see Insufficient capacity (p. 521).

**Optional settings**

The following are optional settings that, if required, must be added to the previous command. You can only enable these options when you create the cluster, not after.

- If you want to specify which IPv4 Classless Inter-domain Routing (CIDR) block Kubernetes assigns service IP addresses from, you must specify it by adding the `--kubernetes-network-config serviceIpv4Cidr=CIDR block` to the following command.

Specifying your own range can help prevent conflicts between Kubernetes services and other networks peered or connected to your VPC. Enter a range in CIDR notation. For example: 10.2.0.0/16.

The CIDR block must meet the following requirements:

- Be within one of the following ranges: 10.0.0.0/8, 172.16.0.0/12, or 192.168.0.0/16.
- Have a minimum size of /24 and a maximum size of /12.
- Not overlap with the range of the VPC for your Amazon EKS resources.

You can only specify this option when using the IPv4 address family and only at cluster creation. If you don't specify this, then Kubernetes assigns service IP addresses from either the 10.100.0.0/16 or 172.20.0.0/16 CIDR blocks.

- If you're creating a cluster of version 1.21 or later and want the cluster to assign IPv6 addresses to pods and services instead of IPv4 addresses, add `--kubernetes-network-config ipFamily=ipv6` to the following command.

Kubernetes assigns IPv4 addresses to pods and services, by default. Before deciding to use the IPv6 family, make sure that you're familiar with all of the considerations and requirements in the the section called “VPC requirements and considerations” (p. 238), the section called “Subnet requirements and considerations” (p. 239), the section called “Security group requirements” (p. 245), and the section called “IPv6” (p. 264) topics. If
you choose the IPv6 family, you can't specify an address range for Kubernetes to assign IPv6 service addresses from like you can for the IPv4 family. Kubernetes assigns service addresses from the unique local address range (fe00::/7).

2. It takes several minutes to provision the cluster. You can query the status of your cluster with the following command.

```bash
aws eks describe-cluster \
  --region region-code \
  --name my-cluster \
  --query "cluster.status"
```

Don't proceed to the next step until the output returned is `ACTIVE`.

3. If you created your cluster using `eksctl`, then you can skip this step. This is because `eksctl` already completed this step for you. Enable `kubectl` to communicate with your cluster by adding a new context to the `kubectl` config file. For more information about how to create and update the file, see the section called “Create a kubeconfig for Amazon EKS” (p. 392).

```bash
aws eks update-kubeconfig --region region-code --name my-cluster
```

The example output is as follows.

```
```

4. Confirm communication with your cluster by running the following command.

```bash
kubectl get svc
```

The example output is as follows.

```
NAME         TYPE        CLUSTER-IP   EXTERNAL-IP   PORT(S)   AGE
kubernetes   ClusterIP   10.100.0.1   <none>        443/TCP   28h
```

5. (Recommended) To use some Amazon EKS add-ons, or to enable individual Kubernetes workloads to have specific AWS Identity and Access Management (IAM) permissions, create an IAM OpenID Connect (OIDC) provider for your cluster. For instructions on how to create an IAM OIDC provider for your cluster, see Creating an IAM OIDC provider for your cluster (p. 426). You only need to create an IAM OIDC provider for your cluster once. To learn more about Amazon EKS add-ons, see Amazon EKS add-ons (p. 367). To learn more about assigning specific IAM permissions to your workloads, see the section called “IAM roles for service accounts” (p. 425).

6. (Recommended) Configure your cluster for the Amazon VPC CNI plugin for Kubernetes plugin before deploying Amazon EC2 nodes to your cluster. By default, the plugin was installed with your cluster. When you add Amazon EC2 nodes to your cluster, the plugin is automatically deployed to each Amazon EC2 node that you add. The plugin requires you to attach one of the following IAM policies to an IAM role:

- **AmazonEKS_CNI_Policy managed IAM policy** – If your cluster uses the IPv4 family
- **An IAM policy that you create (p. 262)** – If your cluster uses the IPv6 family

The IAM role that you attach the policy to can be the node IAM role, or a dedicated role used only for the plugin. We recommend attaching the policy to this role. For more information about creating the role, see the section called “Configure plugin for IAM account” (p. 258) or the section called “Node IAM role” (p. 461).
7. If you deployed your cluster using the AWS Management Console, you can skip this step. The AWS Management Console deploys the Amazon VPC CNI plugin for Kubernetes, CoreDNS, and `kube-proxy` Amazon EKS add-ons, by default.

(Optional) If you deploy your cluster using either `eksctl` or the AWS CLI, then the Amazon VPC CNI plugin for Kubernetes, CoreDNS, and `kube-proxy` self-managed add-ons are deployed. You can migrate the Amazon VPC CNI plugin for Kubernetes, CoreDNS, and `kube-proxy` self-managed add-ons that are deployed with your cluster to Amazon EKS add-ons. For more information, see Amazon EKS add-ons (p. 367).

Recommended next steps:

- The IAM user or role that created the cluster is the only IAM entity that has access to the cluster. Grant permissions to other IAM users or roles (p. 381) so they can access your cluster.
- If the IAM user or role that created the cluster only has the minimum IAM permissions referenced in the prerequisites (p. 24), then you might want to add additional Amazon EKS permissions for that IAM entity. For more information about granting Amazon EKS permissions to IAM entities, see the section called “Identity and access management” (p. 439).
- If you want the IAM entity that created the cluster, or any other IAM entities to view Kubernetes resources in the Amazon EKS console, grant the the section called “Required permissions” (p. 500) to the entities.
- If you want nodes and users to access your cluster from within your VPC, enable the private endpoint for your cluster. The public endpoint is enabled by default. You can disable the public endpoint once you've enabled the private endpoint, if desired. For more information, see the section called “Configuring endpoint access” (p. 43).
- Enable secrets encryption for your cluster (p. 48).
- Configure logging for your cluster (p. 51).
- Add nodes to your cluster (p. 94).
- If you plan to deploy workloads to your cluster that use Amazon EBS volumes, and you created a 1.23 or later cluster, then you must install the the section called “Amazon EBS CSI driver” (p. 205) to your cluster before deploying the workloads.

**Updating an Amazon EKS cluster Kubernetes version**

When a new Kubernetes version is available in Amazon EKS, you can update your Amazon EKS cluster to the latest version.

**Important**

We recommend that, before you update to a new Kubernetes version, you review the information in Amazon EKS Kubernetes versions (p. 66) and also review in the update steps in this topic. If you're updating to version 1.22, you must make the changes listed in the section called “Kubernetes version 1.22 prerequisites” (p. 37) to your cluster before updating it.

New Kubernetes versions sometimes introduce significant changes. Therefore, we recommend that you test the behavior of your applications against a new Kubernetes version before you update your production clusters. You can do this by building a continuous integration workflow to test your application behavior before moving to a new Kubernetes version.

The update process consists of Amazon EKS launching new API server nodes with the updated Kubernetes version to replace the existing ones. Amazon EKS performs standard infrastructure and readiness health checks for network traffic on these new nodes to verify that they're working as
expected. If any of these checks fail, Amazon EKS reverts the infrastructure deployment, and your cluster remains on the prior Kubernetes version. Running applications aren't affected, and your cluster is never left in a non-deterministic or unrecoverable state. Amazon EKS regularly backs up all managed clusters, and mechanisms exist to recover clusters if necessary. We're constantly evaluating and improving our Kubernetes infrastructure management processes.

To update the cluster, Amazon EKS requires up to five free IP addresses from the subnets that you specified when you created your cluster. Amazon EKS creates new cluster elastic network interfaces (network interfaces) in any of the subnets that you specified. The network interfaces may be created in different subnets than your existing network interfaces are in, so make sure that your security group rules allow required cluster communication (p. 245) for any of the subnets that you specified when you created your cluster. If any of the subnets that you specified when you created the cluster don't exist, don't have enough free IP addresses, or don't have security group rules that allows necessary cluster communication, then the update can fail.

Note
Even though Amazon EKS runs a highly available control plane, you might experience minor service interruptions during an update. For example, assume that you attempt to connect to an API server around when it's terminated and replaced by a new API server that's running the new version of Kubernetes. You might experience API call errors or connectivity issues. If this happens, retry your API operations until they succeed.

Update the Kubernetes version for your Amazon EKS cluster

To update the Kubernetes version for your cluster

1. Compare the Kubernetes version of your cluster control plane to the Kubernetes version of your nodes.
   • Get the Kubernetes version of your cluster control plane with the `kubectl version --short` command.
   ```bash
   kubectl version --short
   ```
   • Get the Kubernetes version of your nodes with the `kubectl get nodes` command. This command returns all self-managed and managed Amazon EC2 and Fargate nodes. Each Fargate pod is listed as its own node.
   ```bash
   kubectl get nodes
   ```

Before updating your control plane to a new Kubernetes version, make sure that the Kubernetes minor version of both the managed nodes and Fargate nodes in your cluster are the same as your control plane's version. For example, if your control plane is running version 1.22 and one of your nodes is running version 1.21, then you must update your nodes to version 1.22. We also recommend that you update your self-managed nodes to the same version as your control plane before updating the control plane. For more information, see Updating a managed node group (p. 107) and Self-managed node updates (p. 135). To update the version of a Fargate node, first delete the pod that's represented by the node. Then update your control plane. Any remaining pods will update to the new version after you redeploy them.

2. By default, the pod security policy admission controller is enabled on Amazon EKS clusters. Before updating your cluster, ensure that the proper pod security policies are in place. This is to avoid potential security issues. You can check for the default policy with the `kubectl get psp eks.privileged` command.
Update the Kubernetes version for your Amazon EKS cluster

```
kubectl get psp eks.privileged
```

If you receive the following error, see default pod security policy (p. 495) before proceeding.

| Error from server (NotFound): podsecuritypolicies.extensions "eks.privileged" not found |

3. If the Kubernetes version that you originally deployed your cluster with was Kubernetes 1.18 or later, skip this step.

You might need to remove a discontinued term from your CoreDNS manifest.

   a. Check to see if your CoreDNS manifest has a line that only has the word upstream.

```
kubectl get configmap coredns -n kube-system -o jsonpath='{$.data.Corefile}' | grep upstream
```

   If no output is returned, this means that your manifest doesn't have the line. If this is the case, skip to the next step. If the word upstream is returned, remove the line.

   b. Remove the line near the top of the file that only has the word upstream in the configmap file. Don't change anything else in the file. After the line is removed, save the changes.

```
kubectl edit configmap coredns -n kube-system -o yaml
```

4. Update your cluster using eksctl, the AWS Management Console, or the AWS CLI.

**Important**

- If you're updating to version 1.22, you must make the changes listed in the section called "Kubernetes version 1.22 prerequisites" (p. 37) to your cluster before updating it.

- If you're updating to version 1.23 and use Amazon EBS volumes in your cluster, then you must install the Amazon EBS CSI driver in your cluster before updating your cluster to version 1.23 to avoid workload disruptions. For more information, see the section called "Kubernetes 1.23" (p. 67) and the section called "Amazon EBS CSI driver" (p. 205).

- Because Amazon EKS runs a highly available control plane, you can update only one minor version at a time. For more information about this requirement, see Kubernetes Version and Version Skew Support Policy. Assume that your current cluster version is 1.21 and you want to update to 1.23. You must first update your cluster to 1.22 and then update your 1.22 cluster to 1.23.

- Make sure that the kubelet on your managed and Fargate nodes are at the same Kubernetes version as your control plane before you update. We recommend that your self-managed nodes are at the same version as the control plane. They can be only up to one version behind the current version of the control plane.

- If your cluster is configured with a version of the Amazon VPC CNI plugin that is earlier than 1.8.0, then we recommend that you update the plugin to version 1.11.3 before updating your cluster to version 1.21 or later. For more information, see Updating the Amazon VPC CNI plugin for Kubernetes add-on (p. 250) or Updating the Amazon VPC CNI plugin for Kubernetes self-managed add-on (p. 253).

**eksctl**

This procedure requires eksctl version 0.112.0 or later. You can check your version with the following command:
eksctl version

For instructions on how to install and update eksctl, see Installing or updating eksctl (p. 10).

Update the Kubernetes version of your Amazon EKS control plane to one minor version later than its current version with the following command. Replace my-cluster with your cluster name.

```
eksctl upgrade cluster --name my-cluster --approve
```

The update takes several minutes to complete.

AWS Management Console

a. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
b. Choose the name of the Amazon EKS cluster to update and choose Update cluster version.
c. For Kubernetes version, select the version to update your cluster to and choose Update.
d. For Cluster name, enter the name of your cluster and choose Confirm.

The update takes several minutes to complete.

AWS CLI

a. Update your Amazon EKS cluster with the following AWS CLI command. Replace the example values with your own.

```
aws eks update-cluster-version \
  --region region-code \
  --name my-cluster \
  --kubernetes-version 1.23
```

The example output is as follows.

```
{
  "update": {
    "id": "b5f0ba18-9a87-4450-b5a0-825e6e84496f",
    "status": "InProgress",
    "type": "VersionUpdate",
    "params": [
      {
        "type": "Version",
        "value": "1.23"
      },
      {
        "type": "PlatformVersion",
        "value": "eks.1"
      }
    ],
    "errors": []
  }
}
```

b. Monitor the status of your cluster update with the following command. Use the cluster name and update ID that the previous command returned. When a Successful status is displayed, the update is complete. The update takes several minutes to complete.
Update the Kubernetes version for your Amazon EKS cluster

```bash
aws eks describe-update \
  --region region-code \n  --name my-cluster \n  --update-id b5f0ba18-9a87-4450-b5a0-825e6e84496f
```

The example output is as follows.

```
{
  "update": {
    "id": "b5f0ba18-9a87-4450-b5a0-825e6e84496f",
    "status": "Successful",
    "type": "VersionUpdate",
    "params": [
      {
        "type": "Version",
        "value": "1.23"
      },
      {
        "type": "PlatformVersion",
        "value": "eks.1"
      }
    ],
    "errors": []
  }
}
```

5. After your cluster update is complete, update your nodes to the same Kubernetes minor version as your updated cluster. For more information, see Self-managed node updates (p. 135) and Updating a managed node group (p. 107). Any new pods that are launched on Fargate have a kubelet version that matches your cluster version. Existing Fargate pods aren’t changed.

6. (Optional) If you deployed the Kubernetes Cluster Autoscaler to your cluster before updating the cluster, update the Cluster Autoscaler to the latest version that matches the Kubernetes major and minor version that you updated to.
   a. Open the Cluster Autoscaler releases page in a web browser and find the latest Cluster Autoscaler version that matches your cluster's Kubernetes major and minor version. For example, if your cluster's Kubernetes version is 1.23 find the latest Cluster Autoscaler release that begins with 1.23. Record the semantic version number (<1.23.n>) for that release to use in the next step.
   b. Set the Cluster Autoscaler image tag to the version that you recorded in the previous step with the following command. If necessary, replace 1.23.n with your own value.

```bash
kubectl -n kube-system set image deployment.apps/cluster-autoscaler cluster-autoscaler=k8s.gcr.io/autoscaling/cluster-autoscaler:v1.23.n
```

7. (Clusters with GPU nodes only) If your cluster has node groups with GPU support (for example, p3.2xlarge), you must update the NVIDIA device plugin for Kubernetes DaemonSet on your cluster with the following command.

```bash
kubectl apply -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.9.0/nvidia-device-plugin.yml
```

8. Update the Amazon VPC CNI plugin for Kubernetes, CoreDNS, and kube-proxy add-ons. If you updated your cluster to version 1.21 or later, than we recommend updating the add-ons to the minimum versions listed in Service account tokens (p. 424).
If you are using Amazon EKS add-ons, select Clusters in the Amazon EKS console, then select the name of the cluster that you updated in the left navigation pane. Notifications appear in the console. They inform you that a new version is available for each addon that has an available update. To update an add-on, select the Add-ons tab. In one of the boxes for an add-on that has an update available, select Update now, select an available version, and then select Update.

Alternately, you can use the AWS CLI or eksctl to update the Amazon VPC CNI plugin for Kubernetes (p. 253), CoreDNS (p. 318), and kube-proxy (p. 325) Amazon EKS add-ons.

Kubernetes version 1.22 prerequisites

A number of deprecated beta APIs (v1beta1) have been removed in version 1.22 in favor of the GA (v1) version of those same APIs. As noted in the Kubernetes version 1.22 API and Feature removal blog and deprecated API migration guide, API changes are required for the following deployed resources before updating a cluster to version 1.22.

Before updating your cluster to Kubernetes version 1.22, make sure to do the following:

- Change your YAML manifest files and clients to reference the new APIs.
- Update custom integrations and controllers to call the new APIs.
- Make sure that you use an updated version of any third-party tools. These tools include ingress controllers, service mesh controllers, continuous delivery systems, and other tools that call the new APIs. To check for discontinued API usage in your cluster, enable audit control plane logging and specify v1beta as an event filter. Replacement APIs are available in Kubernetes for several versions.
- If you currently have the AWS Load Balancer Controller deployed to your cluster, you must update it to version 2.4.1 before updating your cluster to Kubernetes version 1.22.

**Important**

When you update clusters to version 1.22, existing persisted objects can be accessed using the new APIs. However, you must migrate manifests and update clients to use these new APIs. Updating the clusters prevents potential workload failures.

Kubernetes version 1.22 removes support from the following beta APIs. Migrate your manifests and API clients based on the following information:

<table>
<thead>
<tr>
<th>Resource</th>
<th>Beta version</th>
<th>GA version</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>ValidatingWebhookAdmission</td>

Deleting an Amazon EKS cluster

When you're done using an Amazon EKS cluster, you should delete the resources associated with it so that you don't incur any unnecessary costs.

To remove a connected cluster, see Deregistering a cluster (p. 545)

**Important**

- If you have active services in your cluster that are associated with a load balancer, you must delete those services before deleting the cluster so that the load balancers are deleted properly. Otherwise, you can have orphaned resources in your VPC that prevent you from being able to delete the VPC.
- If you receive an error because the cluster creator has been removed, see this article to resolve.

You can delete a cluster with eksctl, the AWS Management Console, or the AWS CLI. Select the tab with the name of the tool that you’d like to use to delete your cluster.

**eksctl**

**To delete an Amazon EKS cluster and nodes with eksctl**

This procedure requires eksctl version 0.112.0 or later. You can check your version with the following command:

```
eksctl version
```

For instructions on how to install or upgrade eksctl, see Installing or updating eksctl (p. 10).

1. List all services running in your cluster.

   `kubectl get svc --all-namespaces`

2. Delete any services that have an associated EXTERNAL-IP value. These services are fronted by an Elastic Load Balancing load balancer, and you must delete them in Kubernetes to allow the load balancer and associated resources to be properly released.

   `kubectl delete svc service-name`

To learn more about the API removal, see the Deprecated API migration guide.
3. Delete the cluster and its associated nodes with the following command, replacing \textit{prod} with your cluster name.

\texttt{eksctl delete cluster --name \textit{prod}}

Output:

[#] using region \textit{region-code}
[#] deleting EKS cluster "\textit{prod}"
[#] will delete stack "eksctl-\textit{prod}-nodegroup-standard-nodes"
[#] waiting for stack "eksctl-\textit{prod}-nodegroup-standard-nodes" to get deleted
[#] will delete stack "eksctl-\textit{prod}-cluster"
[#] the following EKS cluster resource(s) for "\textit{prod}" will be deleted: cluster. If in doubt, check CloudFormation console

AWS Management Console

\textbf{To delete an Amazon EKS cluster with the AWS Management Console}

1. List all services running in your cluster.

\texttt{kubectl get svc --all-namespaces}

2. Delete any services that have an associated \texttt{EXTERNAL-IP} value. These services are fronted by an Elastic Load Balancing load balancer, and you must delete them in Kubernetes to allow the load balancer and associated resources to be properly released.

\texttt{kubectl delete svc service-name}

3. Delete all node groups and Fargate profiles.

a. Open the Amazon EKS console at \url{https://console.aws.amazon.com/eks/home#/clusters}.

b. In the left navigation pane, choose Amazon EKS Clusters, and then in the tabbed list of clusters, choose the name of the cluster that you want to delete.

c. Choose the Compute tab and choose a node group to delete. Choose Delete, enter the name of the node group, and then choose Delete. Delete all node groups in the cluster.  

\textbf{Note}  
The node groups listed are managed node groups (p. 97) only.

d. Choose a Fargate Profile to delete, select Delete, enter the name of the profile, and then choose Delete. Delete all Fargate profiles in the cluster.

4. Delete all self-managed node AWS CloudFormation stacks.

a. Open the AWS CloudFormation console at \url{https://console.aws.amazon.com/cloudformation}.

b. Choose the node stack to delete, and then choose Delete.

c. In the Delete stack confirmation dialog box, choose Delete stack. Delete all self-managed node stacks in the cluster.

5. Delete the cluster.

a. Open the Amazon EKS console at \url{https://console.aws.amazon.com/eks/home#/clusters}.

b. Choose the cluster to delete and choose Delete.

c. On the delete cluster confirmation screen, choose Delete.

6. (Optional) Delete the VPC AWS CloudFormation stack.
b. Select the VPC stack to delete, and then choose Delete.
c. In the Delete stack confirmation dialog box, choose Delete stack.

AWS CLI

To delete an Amazon EKS cluster with the AWS CLI

1. List all services running in your cluster.

   kubectl get svc --all-namespaces

2. Delete any services that have an associated EXTERNAL-IP value. These services are fronted by an Elastic Load Balancing load balancer, and you must delete them in Kubernetes to allow the load balancer and associated resources to be properly released.

   kubectl delete svc service-name

3. Delete all node groups and Fargate profiles.
   a. List the node groups in your cluster with the following command.

      aws eks list-nodegroups --cluster-name my-cluster

      Note
      The node groups listed are managed node groups (p. 97) only.
   b. Delete each node group with the following command. Delete all node groups in the cluster.

      aws eks delete-nodegroup --nodegroup-name my-nodegroup --cluster-name my-cluster

c. List the Fargate profiles in your cluster with the following command.

   aws eks list-fargate-profiles --cluster-name my-cluster

d. Delete each Fargate profile with the following command. Delete all Fargate profiles in the cluster.

   aws eks delete-fargate-profile --fargate-profile-name my-fargate-profile --cluster-name my-cluster

4. Delete all self-managed node AWS CloudFormation stacks.
   a. List your available AWS CloudFormation stacks with the following command. Find the node template name in the resulting output.

      aws cloudformation list-stacks --query "StackSummaries[].StackName"

   b. Delete each node stack with the following command, replacing node-stack with your node stack name. Delete all self-managed node stacks in the cluster.

      aws cloudformation delete-stack --stack-name node-stack

5. Delete the cluster with the following command, replacing my-cluster with your cluster name.
Amazon EKS cluster endpoint access control

This topic helps you to enable private access for your Amazon EKS cluster's Kubernetes API server endpoint and limit, or completely disable, public access from the internet.

When you create a new cluster, Amazon EKS creates an endpoint for the managed Kubernetes API server that you use to communicate with your cluster (using Kubernetes management tools such as kubectl). By default, this API server endpoint is public to the internet, and access to the API server is secured using a combination of AWS Identity and Access Management (IAM) and native Kubernetes Role Based Access Control (RBAC).

You can enable private access to the Kubernetes API server so that all communication between your nodes and the API server stays within your VPC. You can limit the IP addresses that can access your API server from the internet, or completely disable internet access to the API server.

Note
Because this endpoint is for the Kubernetes API server and not a traditional AWS PrivateLink endpoint for communicating with an AWS API, it doesn't appear as an endpoint in the Amazon VPC console.

When you enable endpoint private access for your cluster, Amazon EKS creates a Route 53 private hosted zone on your behalf and associates it with your cluster's VPC. This private hosted zone is managed by Amazon EKS, and it doesn't appear in your account's Route 53 resources. In order for the private hosted zone to properly route traffic to your API server, your VPC must have enableDnsHostnames and enableDnsSupport set to true, and the DHCP options set for your VPC must include AmazonProvidedDNS in its domain name servers list. For more information, see Updating DNS support for your VPC in the Amazon VPC User Guide.

You can define your API server endpoint access requirements when you create a new cluster, and you can update the API server endpoint access for a cluster at any time.

Modifying cluster endpoint access

Use the procedures in this section to modify the endpoint access for an existing cluster. The following table shows the supported API server endpoint access combinations and their associated behavior.

API server endpoint access options

<table>
<thead>
<tr>
<th>Endpoint public access</th>
<th>Endpoint private access</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>Disabled</td>
<td>- This is the default behavior for new Amazon EKS clusters.</td>
</tr>
</tbody>
</table>
### Endpoint public access

- Kubernetes API requests that originate from within your cluster's VPC (such as node to control plane communication) leave the VPC but not Amazon's network.
- Your cluster API server is accessible from the internet. You can, optionally, limit the CIDR blocks that can access the public endpoint. If you limit access to specific CIDR blocks, then it is recommended that you also enable the private endpoint, or ensure that the CIDR blocks that you specify include the addresses that nodes and Fargate pods (if you use them) access the public endpoint from.

### Endpoint private access

- Kubernetes API requests within your cluster's VPC (such as node to control plane communication) use the private VPC endpoint.
- Your cluster API server is accessible from the internet. You can, optionally, limit the CIDR blocks that can access the public endpoint.
Modifying cluster endpoint access

<table>
<thead>
<tr>
<th>Endpoint public access</th>
<th>Endpoint private access</th>
<th>Behavior</th>
</tr>
</thead>
</table>
| Disabled                | Enabled                 | • All traffic to your cluster API server must come from within your cluster's VPC or a connected network.  
• There is no public access to your API server from the internet. Any kubectl commands must come from within the VPC or a connected network. For connectivity options, see Accessing a private only API server (p. 47).  
• The cluster’s API server endpoint is resolved by public DNS servers to a private IP address from the VPC. In the past, the endpoint could only be resolved from within the VPC.  

If your endpoint does not resolve to a private IP address within the VPC for an existing cluster, you can:  
• Enable public access and then disable it again. You only need to do so once for a cluster and the endpoint will resolve to a private IP address from that point forward.  
• Update (p. 32) your cluster. |

You can modify your cluster API server endpoint access using the AWS Management Console or AWS CLI. Select the tab with the name of the tool that you’d like to use to modify your endpoint access with.

AWS Management Console

**To modify your cluster API server endpoint access using the AWS Management Console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the name of the cluster to display your cluster information.
3. Choose the **Networking** tab and choose **Update**.
4. For **Private access**, choose whether to enable or disable private access for your cluster’s Kubernetes API server endpoint. If you enable private access, Kubernetes API requests that originate from within your cluster’s VPC use the private VPC endpoint. You must enable private access to disable public access.
5. For **Public access**, choose whether to enable or disable public access for your cluster’s Kubernetes API server endpoint. If you disable public access, your cluster’s Kubernetes API server can only receive requests from within the cluster VPC.
6. (Optional) If you've enabled **Public access**, you can specify which addresses from the internet can communicate to the public endpoint. Select **Advanced Settings**. Enter a CIDR block, such as `203.0.113.5/32`. The block cannot include reserved addresses. You can enter additional blocks by selecting **Add Source**. There is a maximum number of CIDR blocks that you can specify. For more information, see Amazon EKS service quotas (p. 416). If you specify no blocks, then the public API server endpoint receives requests from all (0.0.0.0/0) IP addresses. If you restrict access to your public endpoint using CIDR blocks, it is recommended that you also enable private endpoint access so that nodes and Fargate pods (if you use them) can communicate with the cluster. Without the private endpoint enabled, your public access endpoint CIDR sources must include the egress sources from your VPC. For example, if you have a node in a private subnet that communicates to the internet through a NAT Gateway, you will need to add the outbound IP address of the NAT gateway as part of an allowed CIDR block on your public endpoint.

7. Choose **Update** to finish.

**AWS CLI**

**To modify your cluster API server endpoint access using the AWS CLI**

Complete the following steps using the AWS CLI version 1.25.72 or later. You can check your current version with `aws --version`. To install or upgrade the AWS CLI, see Installing the AWS CLI.

1. Update your cluster API server endpoint access with the following AWS CLI command. Substitute your cluster name and desired endpoint access values. If you set `endpointPublicAccess=true`, then you can (optionally) enter single CIDR block, or a comma-separated list of CIDR blocks for `publicAccessCidrs`. The blocks cannot include reserved addresses. If you specify CIDR blocks, then the public API server endpoint will only receive requests from the listed blocks. There is a maximum number of CIDR blocks that you can specify. For more information, see Amazon EKS service quotas (p. 416). If you restrict access to your public endpoint using CIDR blocks, it is recommended that you also enable private endpoint access so that nodes and Fargate pods (if you use them) can communicate with the cluster. Without the private endpoint enabled, your public access endpoint CIDR sources must include the egress sources from your VPC. For example, if you have a node in a private subnet that communicates to the internet through a NAT Gateway, you will need to add the outbound IP address of the NAT gateway as part of an allowed CIDR block on your public endpoint. If you specify no CIDR blocks, then the public API server endpoint receives requests from all (0.0.0.0/0) IP addresses.

   **Note**
   The following command enables private access and public access from a single IP address for the API server endpoint. Replace `203.0.113.5/32` with a single CIDR block, or a comma-separated list of CIDR blocks that you want to restrict network access to.

   ```
   aws eks update-cluster-config \
   --region region-code \
   --name my-cluster \ 
   --resources-vpc-config \
   endpointPublicAccess=true,publicAccessCidrs="203.0.113.5/32",endpointPrivateAccess=true
   ```

   The example output is as follows.

   ```
   {
   "update": {
   "id": "e6f0905f-a5d4-4a2a-8c49-EXAMPLE00000",
   "status": "InProgress",
   "type": "EndpointAccessUpdate",
   "params": [
   ```
Accessing a private only API server

If you have disabled public access for your cluster's Kubernetes API server endpoint, you can only access the API server from within your VPC or a connected network. Here are a few possible ways to access the Kubernetes API server endpoint:
Connected network – Connect your network to the VPC with an AWS transit gateway or other connectivity option and then use a computer in the connected network. You must ensure that your Amazon EKS control plane security group contains rules to allow ingress traffic on port 443 from your connected network.

Amazon EC2 bastion host – You can launch an Amazon EC2 instance into a public subnet in your cluster's VPC and then log in via SSH into that instance to run kubectl commands. For more information, see Linux bastion hosts on AWS. You must ensure that your Amazon EKS control plane security group contains rules to allow ingress traffic on port 443 from your bastion host. For more information, see Amazon EKS security group requirements and considerations (p. 245).

When you configure kubectl for your bastion host, be sure to use AWS credentials that are already mapped to your cluster's RBAC configuration, or add the IAM user or role that your bastion will use to the RBAC configuration before you remove endpoint public access. For more information, see Enabling IAM user and role access to your cluster (p. 381) and Unauthorized or access denied (kubectl) (p. 522).

AWS Cloud9 IDE – AWS Cloud9 is a cloud-based integrated development environment (IDE) that lets you write, run, and debug your code with just a browser. You can create an AWS Cloud9 IDE in your cluster's VPC and use the IDE to communicate with your cluster. For more information, see Creating an environment in AWS Cloud9. You must ensure that your Amazon EKS control plane security group contains rules to allow ingress traffic on port 443 from your IDE security group. For more information, see Amazon EKS security group requirements and considerations (p. 245).

When you configure kubectl for your AWS Cloud9 IDE, be sure to use AWS credentials that are already mapped to your cluster's RBAC configuration, or add the IAM user or role that your IDE will use to the RBAC configuration before you remove endpoint public access. For more information, see Enabling IAM user and role access to your cluster (p. 381) and Unauthorized or access denied (kubectl) (p. 522).

Enabling secret encryption on an existing cluster

If you enable secrets encryption, the Kubernetes secrets are encrypted using the AWS KMS key that you select. The KMS key must meet the following conditions:

- Symmetric
- Can encrypt and decrypt data
- Created in the same AWS Region as the cluster
- If the KMS key was created in a different account, the user must have access to the KMS key.

For more information, see Allowing users in other accounts to use a KMS key in the AWS Key Management Service Developer Guide.

Warning
You can't disable secrets encryption after enabling it. This action is irreversible.

You can enable encryption in two ways:

- Add encryption to your cluster with a single command.

To automatically re-encrypt your secrets, run the following command.

```
eksctl utils enable-secrets-encryption
```
To opt-out of automatically re-encrypting your secrets, run the following command.

```bash
eksctl utils enable-secrets-encryption
  --cluster my-cluster \
  --key-arn arn:aws:kms:region-code:account:key/key
```

AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster that you want to add KMS encryption to.
3. Choose the Overview tab (this is selected by default).
4. Scroll down to the Secrets encryption section and choose Enable.
5. Select a key from the dropdown list and choose the Enable button. If no keys are listed, you must create one first. For more information, see Creating keys.
6. Choose the Confirm button to use the chosen key.

AWS CLI

1. Associate the secrets encryption configuration with your cluster using the following AWS CLI command. Replace the example values with your own.

```bash
aws eks associate-encryption-config \
  --cluster-name my-cluster \
  --encryption-config '{"resources": ["secrets"], "provider": 
  {"keyArn": "arn:aws:kms:region-code:account:key/key"}}'
```

The output is as follows.
2. You can monitor the status of your encryption update with the following command. Use the specific cluster name and update ID that was returned in the previous output. When a Successful status is displayed, the update is complete.

```bash
aws eks describe-update
   --region region-code
   --name my-cluster
   --update-id 3141b835-8103-423a-8e68-12c2521ffa4d
```

The output is as follows.

```
{
 "update": {
    "id": "3141b835-8103-423a-8e68-12c2521ffa4d",
    "status": "Successful",
    "type": "AssociateEncryptionConfig",
    "params": [
      {
        "type": "EncryptionConfig",
        "value": "{\"resources\":{\"secrets\"},\"provider\":{\"keyArn\":\
          \"arn:aws:kms:region-code:account:key/key\"}}"
      }
    ],
    "createdAt": 1613754188.734,
    "errors": []
  }
}
```

3. To verify that encryption is enabled in your cluster, run the `describe-cluster` command. The response contains an EncryptionConfig string.

```bash
aws eks describe-cluster --region region-code --name my-cluster
```

After you enabled encryption on your cluster, you must encrypt all existing secrets with the new key:

**Note**

If you use `eksctl`, running the following command is necessary only if you opt out of re-encrypting your secrets automatically.

```bash
kubectl get secrets --all-namespaces -o json | kubectl annotate --overwrite -f -  kms-encryption-timestamp="time value"
```
Warning
If you enable secrets encryption for an existing cluster and the KMS key that you use is ever
deleted, then there’s no way to recover the cluster. If you delete the KMS key, you permanently
put the cluster in a degraded state. For more information, see Deleting AWS KMS keys.

Note
By default, the create-key command creates a symmetric encryption KMS key with a key
policy that gives the account root admin access on AWS KMS actions and resources. If you want
to scope down the permissions, make sure that the kms:DescribeKey and kms:CreateGrant
actions are permitted on the policy for the principal that calls the create-cluster API.
For clusters using KMS Envelope Encryption, kms:CreateGrant permissions are required.
The condition kms:GrantIsForAWSResource is not supported for the CreateCluster action,
and should not be used in KMS policies to control kms:CreateGrant permissions for users
performing CreateCluster.

Amazon EKS control plane logging

Amazon EKS control plane logging provides audit and diagnostic logs directly from the Amazon EKS
control plane to CloudWatch Logs in your account. These logs make it easy for you to secure and run
your clusters. You can select the exact log types you need, and logs are sent as log streams to a group for
each Amazon EKS cluster in CloudWatch.

You can start using Amazon EKS control plane logging by choosing which log types you want to
enable for each new or existing Amazon EKS cluster. You can enable or disable each log type on a per-
cluster basis using the AWS Management Console, AWS CLI (version 1.16.139 or higher), or through
the Amazon EKS API. When enabled, logs are automatically sent from the Amazon EKS cluster to
CloudWatch Logs in the same account.

When you use Amazon EKS control plane logging, you’re charged standard Amazon EKS pricing for each
cluster that you run. You are charged the standard CloudWatch Logs data ingestion and storage costs for
any logs sent to CloudWatch Logs from your clusters. You are also charged for any AWS resources, such
as Amazon EC2 instances or Amazon EBS volumes, that you provision as part of your cluster.

The following cluster control plane log types are available. Each log type corresponds to a component
of the Kubernetes control plane. To learn more about these components, see Kubernetes Components in
the Kubernetes documentation.

- **Kubernetes API server component logs (api)** – Your cluster’s API server is the control plane
  component that exposes the Kubernetes API. For more information, see kube-apiserver and the audit
  policy in the Kubernetes documentation.

- **Audit (audit)** – Kubernetes audit logs provide a record of the individual users, administrators,
or system components that have affected your cluster. For more information, see Auditing in the
  Kubernetes documentation.

- **Authenticator (authenticator)** – Authenticator logs are unique to Amazon EKS. These logs
  represent the control plane component that Amazon EKS uses for Kubernetes Role Based
  Access Control (RBAC) authentication using IAM credentials. For more information, see Cluster
  management (p. 401).

- **Controller manager (controllerManager)** – The controller manager manages the core control
  loops that are shipped with Kubernetes. For more information, see kube-controller-manager in the
  Kubernetes documentation.

- **Scheduler (scheduler)** – The scheduler component manages when and where to run pods in your
  cluster. For more information, see kube-scheduler in the Kubernetes documentation.
Enabling and disabling control plane logs

By default, cluster control plane logs aren’t sent to CloudWatch Logs. You must enable each log type individually to send logs for your cluster. CloudWatch Logs ingestion, archive storage, and data scanning rates apply to enabled control plane logs. For more information, see CloudWatch pricing.

When you enable a log type, the logs are sent with a log verbosity level of 2.

To enable or disable control plane logs with the console

1. Open the Amazon EKS console.
2. Choose the name of the cluster to display your cluster information.
3. Choose the Logging tab and choose Manage logging.
4. For each individual log type, choose whether the log type should be Enabled or Disabled. By default, each log type is Disabled.
5. Choose Save changes to finish.

To enable or disable control plane logs with the AWS CLI

1. Check your AWS CLI version with the following command.
   
   ```
   aws --version
   ```

   If your AWS CLI version is earlier than 1.16.139, you must first update to the latest version. To install or upgrade the AWS CLI, see Installing the AWS Command Line Interface in the AWS Command Line Interface User Guide.

2. Update your cluster’s control plane log export configuration with the following AWS CLI command. Replace my-cluster with your cluster name and specify your desired endpoint access values.

   **Note**
   
   The following command sends all available log types to CloudWatch Logs.

   ```
   aws eks update-cluster-config \
   --region region-code \
   --name my-cluster \
   --logging '{"clusterLogging":{{"types": ["api","audit","authenticator","controllerManager","scheduler"], "enabled":true}}}'
   ```

   The example output is as follows.

   ```json
   {
   "update": {
   "id": "883405c8-65c6-4758-8cee-2a7c1340a6d9",
   "status": "InProgress",
   "type": "LoggingUpdate",
   "params": [
   {"type": "ClusterLogging",
   "value": "{"clusterLogging":{{"types":["api","audit","authenticator","controllerManager","scheduler"],"enabled":true}}}"},
   "createdAt": 1553271814.684,
   "errors": []
   }
   }
   ```
3. Monitor the status of your log configuration update with the following command, using the cluster name and the update ID that were returned by the previous command. Your update is complete when the status appears as `Successful`.

```
aws eks describe-update \
   --region region-code \
   --name my-cluster \
   --update-id 883405c8-65c6-4758-8cee-2a7c1340a6d9
```

The example output is as follows.

```
{
   "update": {
      "id": "883405c8-65c6-4758-8cee-2a7c1340a6d9",
      "status": "Successful",
      "type": "LoggingUpdate",
      "params": [
         {
            "type": "ClusterLogging",
            "value": "{\"clusterLogging\":[{\"types\":[{\"api\",\"audit\",\"authenticator\",\"controllerManager\",\"scheduler\"},\"enabled\":true}]}"
         }
      ],
      "createdAt": 1553271814.684,
      "errors": []
   }
}
```

**Viewing cluster control plane logs**

After you have enabled any of the control plane log types for your Amazon EKS cluster, you can view them on the CloudWatch console.

To learn more about viewing, analyzing, and managing logs in CloudWatch, see the Amazon CloudWatch Logs User Guide.

**To view your cluster control plane logs on the CloudWatch console**

1. Open the CloudWatch console. The link opens the console and displays your current available log groups and filters them with the `/aws/eks` prefix.
2. Choose the cluster that you want to view logs for. The log group name format is `/aws/eks/my-cluster/cluster`.
3. Choose the log stream to view. The following list describes the log stream name format for each log type.

   - **Kubernetes API server component logs (api)**  `kube-apiserver-<nnn...>`
   - **Audit (audit)**  `kube-apiserver-audit-<nnn...>`
   - **Authenticator (authenticator)**  `authenticator-<nnn...>`
   - **Controller manager (controllerManager)**  `kube-controller-manager-<nnn...>`
   - **Scheduler (scheduler)**  `kube-scheduler-<nnn...>`
Viewing API server flags in the Amazon CloudWatch console

You can use the control plane logging feature for Amazon EKS clusters to view the API server flags that were enabled when a cluster was created. For more information, see Amazon EKS control plane logging (p. 51). This topic shows you how to view the API server flags for an Amazon EKS cluster in the Amazon CloudWatch console.

When a cluster is first created, the initial API server logs include the flags that were used to start the API server. If you enable API server logs when you launch the cluster, or shortly thereafter, these logs are sent to CloudWatch Logs and you can view them there.

To view API server flags for a cluster

1. If you have not already done so, enable API server logs for your Amazon EKS cluster.
   a. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
   b. Choose the name of the cluster to display your cluster information.
   c. On the Logging tab, choose Manage logging.
   d. For API server, make sure that the log type is Enabled.
   e. Choose Save changes to finish.
2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/
3. Choose Logs, then Log groups in the side menu. Choose the cluster of which you want to see the logs, then choose the Log streams tab.
4. In the list of log streams, find the earliest version of the kube-apiserver-example-ID-288ec988b77a59d70ec77 log stream. Use the Last Event Time column to determine the log stream ages.
5. Scroll up to the earliest events (the beginning of the log stream). You should see the initial API server flags for the cluster.

   Note
   If you don't see the API server logs at the beginning of the log stream, then it is likely that the API server log file was rotated on the server before you enabled API server logging on the server. Any log files that are rotated before API server logging is enabled cannot be exported to CloudWatch.
   However, you can create a new cluster with the same Kubernetes version and enable the API server logging when you create the cluster. Clusters with the same platform version have the same flags enabled, so your flags should match the new cluster's flags. When you finish viewing the flags for the new cluster in CloudWatch, you can delete the new cluster.

Enabling Windows support for your Amazon EKS cluster

Before deploying Windows nodes, be aware of the following considerations.

Considerations

- Amazon EC2 instance types C3, C4, D2, I2, M4 (excluding m4.16xlarge), M6a.x, and R3 instances aren't supported for Windows workloads.
• Host networking mode is not supported for Windows workloads.
• Amazon EKS clusters must contain one or more Linux or Fargate nodes to run core system pods that only run on Linux, such as CoreDNS.
• The kubelet and kube-proxy event logs are redirected to the EKS Windows Event Log and are set to a 200 MB limit.
• You can't use Security groups for pods (p. 292) with pods running on Windows nodes.
• You can't use custom networking (p. 276) with Windows nodes.
• You can't use IP prefixes (p. 289) with Windows nodes. This is a requirement for using IPv6 (p. 264), so you can't use IPv6 with Windows nodes either.
• Windows nodes support one elastic network interface per node. The number of pods that you can run per Windows node is equal to the number of IP addresses available per elastic network interface for the node's instance type, minus one. For more information, see IP addresses per network interface per instance type in the Amazon EC2 User Guide for Windows Instances.
• In an Amazon EKS cluster, a single service with a load balancer can support up to 1024 back-end pods. Each pod has its own unique IP address. The previous limit of 64 pods is no longer the case, after a Windows Server update starting with OS Build 17763.2746.
• You can't deploy Windows managed nodes. You can only create self-managed Windows nodes. For more information, see Launching self-managed Windows nodes (p. 129).
• Windows containers aren't supported for Amazon EKS pods on Fargate.
• You can't retrieve logs from the vpc-resource-controller Pod. You previously could when you deployed the controller to the data plane.
• There is a cool down period before an IPv4 address is assigned to a new Pod. This prevents traffic from flowing to an older Pod with the same IPv4 address due to stale kube-proxy rules.
• The source for the controller is managed on GitHub. To contribute to, or file issues against the controller, visit the project on GitHub.

Prerequisites

• An existing cluster. The cluster must be running one of the Kubernetes versions and platform versions listed in the following table. Any Kubernetes and platform versions later than those listed are also supported. If your cluster or platform version is earlier than one of the following versions, you need to enable legacy Windows support (p. 58) on your cluster's data plane. Once your cluster is at one of the following Kubernetes and platform versions, or later, you can remove legacy Windows support (p. 57) and enable Windows support (p. 56) on your control plane.

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Platform version</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.23</td>
<td>eks.1</td>
</tr>
<tr>
<td>1.22</td>
<td>eks.1</td>
</tr>
<tr>
<td>1.21</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.20</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.19</td>
<td>eks.7</td>
</tr>
</tbody>
</table>

Your cluster must have at least one (we recommend at least two) Linux node or Fargate pod to run CoreDNS. If you enable legacy Windows support, you must use a Linux node (you can't use a Fargate pod) to run CoreDNS.
• An existing Amazon EKS cluster IAM role (p. 460).
Enabling Windows support

If your cluster is not at, or later, than one of the Kubernetes and platform versions listed in the Prerequisites (p. 55), you must enable legacy Windows support instead. For more information, see Enabling legacy Windows support (p. 58).

If you've never enabled Windows support on your cluster, skip to the next step.

If you enabled Windows support on a cluster that is earlier than a Kubernetes or platform version listed in the Prerequisites (p. 55), then you must first remove the vpc-resource-controller and vpc-admission-webhook from your data plane (p. 57). They're deprecated and no longer needed.

To enable Windows support for your cluster

1. If you don't have Amazon Linux nodes in your cluster and use security groups for pods, skip to the next step. Otherwise, confirm that the AmazonEKSVPCResourceController managed policy is attached to your cluster role (p. 460). Replace eksClusterRole with your cluster role name.

   ```bash
   aws iam list-attached-role-policies --role-name eksClusterRole
   ```

   The example output is as follows.

   ```json
   {
     "AttachedPolicies": [
       {
         "PolicyName": "AmazonEKSClusterPolicy",
         "PolicyArn": "arn:aws:iam::aws:policy/AmazonEKSClusterPolicy"
       },
       {
         "PolicyName": "AmazonEKSVPCResourceController",
         "PolicyArn": "arn:aws:iam::aws:policy/AmazonEKSVPCResourceController"
       }
     ]
   }
   ```

   If the policy is attached, as it is in the previous output, skip the next step.

2. Attach the AmazonEKSVPCResourceController managed policy to your Amazon EKS cluster IAM role (p. 460). Replace eksClusterRole with your cluster role name.

   ```bash
   aws iam attach-role-policy
   --role-name eksClusterRole
   --policy-arn arn:aws:iam::aws:policy/AmazonEKSVPCResourceController
   ```

3. Create a file named vpc-resource-controller-configmap.yaml with the following contents.

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: amazon-vpc-cni
     namespace: kube-system
   data:
     enable-windows-ipam: "true"
   ```

4. Apply the ConfigMap to your cluster.

   ```bash
   kubectl apply -f vpc-resource-controller-configmap.yaml
   ```
Removing legacy Windows support from your data plane

If you enabled Windows support on a cluster that is earlier than a Kubernetes or platform version listed in the Prerequisites (p. 55), then you must first remove the `vpc-resource-controller` and `vpc-admission-webhook` from your data plane. They're deprecated and no longer needed because the functionality that they provided is now enabled on the control plane.

1. Uninstall the `vpc-resource-controller` with the following command. Use this command regardless of which tool you originally installed it with. Replace `region-code` (only the instance of that text after `/manifests/`) with the AWS Region that your cluster is in.

   ```bash
   ```

2. Uninstall the `vpc-admission-webhook` using the instructions for the tool that you installed it with.

   ```bash
   eksctl
   ```
   Run the following commands.

   ```bash
   kubectl delete deployment -n kube-system vpc-admission-webhook
   kubectl delete service -n kube-system vpc-admission-webhook
   kubectl delete mutatingwebhookconfigurations.admissionregistration.k8s.io vpc-admission-webhook-cfg
   ```

   kubectl on macOS or Windows
   Run the following command. Replace `region-code` (only the instance of that text after `/manifests/`) with the AWS Region that your cluster is in.

   ```bash
   ```

3. Enable Windows support (p. 56) for your cluster on the control plane.

Disabling Windows support

To disable Windows support on your cluster

1. If your cluster contains Amazon Linux nodes and you use security groups for pods (p. 292) with them, then skip this step.

   Remove the AmazonVPCResourceController managed IAM policy from your cluster role (p. 460). Replace `eksClusterRole` with the name of your cluster role and `111122223333` with your account ID.

   ```bash
   aws iam detach-role-policy \ 
   --role-name eksClusterRole \ 
   --policy-arn arn:aws:iam::aws:policy/AmazonEKSVCPCResourceController
   ```

2. Disable Windows IPAM in the `amazon-vpc-cni` ConfigMap.
Deploying Pods

When you deploy Pods to your cluster, you need to specify the operating system that they use if you're running a mixture of node types.

For Linux pods, use the following node selector text in your manifests.

```
nodeSelector:
  kubernetes.io/os: linux
  kubernetes.io/arch: amd64
```

For Windows pods, use the following node selector text in your manifests.

```
nodeSelector:
  kubernetes.io/os: windows
  kubernetes.io/arch: amd64
```

You can deploy a sample application (p. 338) to see the node selectors in use.

Enabling legacy Windows support

If your cluster is at, or later, than one of the Kubernetes and platform versions listed in the Prerequisites (p. 55), then we recommend that you enable Windows support on your control plane instead. For more information, see Enabling Windows support (p. 56).

The following steps help you to enable legacy Windows support for your Amazon EKS cluster's data plane if your cluster or platform version are earlier than the versions listed in the Prerequisites (p. 55). Once your cluster and platform version are at, or later than a version listed in the Prerequisites (p. 55), we recommend that you remove legacy Windows support (p. 57) and enable it for your control plane (p. 56).

You can use eksctl, a Windows client, or a macOS or Linux client to enable legacy Windows support for your cluster.

```
$ eksctl
```

To enable legacy Windows support for your cluster with eksctl

**Prerequisite**

This procedure requires eksctl version 0.112.0 or later. You can check your version with the following command.

```
$ eksctl version
```

For more information about installing or upgrading eksctl, see Installing or updating eksctl (p. 10).

1. Enable Windows support for your Amazon EKS cluster with the following eksctl command. Replace **my-cluster** with the name of your cluster. This command deploys the VPC resource controller and VPC admission controller webhook that are required on Amazon EKS clusters to run Windows workloads.
Enabling legacy Windows support

```
eksctl utils install-vpc-controllers --cluster my-cluster --approve
```

**Important**
The VPC admission controller webhook is signed with a certificate that expires one year after the date of issue. To avoid down time, make sure to renew the certificate before it expires. For more information, see Renewing the VPC admission webhook certificate (p. 62).

2. After you have enabled Windows support, you can launch a Windows node group into your cluster. For more information, see Launching self-managed Windows nodes (p. 129).

Windows

**To enable legacy Windows support for your cluster with a Windows client**

In the following steps, replace `region-code` with the AWS Region that your cluster resides in.

1. Deploy the VPC resource controller to your cluster.

```
```

2. Deploy the VPC admission controller webhook to your cluster.
   a. Download the required scripts and deployment files.

```
```

   b. Install OpenSSL and jq.
   c. Set up and deploy the VPC admission webhook.

```
./Setup-VPCAdmissionWebhook.ps1 -DeploymentTemplate ".\vpc-admission-webhook-deployment.yaml"
```

**Important**
The VPC admission controller webhook is signed with a certificate that expires one year after the date of issue. To avoid down time, make sure to renew the certificate before it expires. For more information, see Renewing the VPC admission webhook certificate (p. 62).

3. Determine if your cluster has the required cluster role binding.

```
kubectl get clusterrolebinding eks:kube-proxy-windows
```

If output similar to the following example output is returned, then the cluster has the necessary role binding.
Enabling legacy Windows support

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>eks:kube-proxy-windows</td>
<td>10d</td>
</tr>
</tbody>
</table>

If the output includes `Error from server (NotFound)`, then the cluster does not have the necessary cluster role binding. Add the binding by creating a file named `eks-kube-proxy-windows-crb.yaml` with the following content.

```yaml
kind: ClusterRoleBinding
apiVersion: rbac.authorization.k8s.io/v1beta1
metadata:
  name: eks:kube-proxy-windows
labels:
  k8s-app: kube-proxy
  eks.amazonaws.com/component: kube-proxy
subjects:
  - kind: Group
    name: "eks:kube-proxy-windows"
roleRef:
  kind: ClusterRole
  name: system:node-proxier
  apiGroup: rbac.authorization.k8s.io
```

Apply the configuration to the cluster.

```bash
kubectl apply -f eks-kube-proxy-windows-crb.yaml
```

4. After you have enabled Windows support, you can launch a Windows node group into your cluster. For more information, see Launching self-managed Windows nodes (p. 129).

macOS and Linux

To enable legacy Windows support for your cluster with a macOS or Linux client

This procedure requires that the `openssl` library and `jq` JSON processor are installed on your client system.

In the following steps, replace `region-code` with the AWS Region that your cluster resides in.

1. Deploy the VPC resource controller to your cluster.

```bash
```

2. Create the VPC admission controller webhook manifest for your cluster.

   a. Download the required scripts and deployment files.

   ```bash
```

   b. Add permissions to the shell scripts so that they can be run.
Enabling legacy Windows support

```
chmod +x webhook-create-signed-cert.sh webhook-patch-ca-bundle.sh
```

c. Create a secret for secure communication.

```
./webhook-create-signed-cert.sh
```

d. Verify the secret.

```
kubectl get secret -n kube-system vpc-admission-webhook-certs
```

e. Configure the webhook and create a deployment file.

```
cat ./vpc-admission-webhook-deployment.yaml | ./webhook-patch-ca-bundle.sh > vpc-admission-webhook.yaml
```

3. Deploy the VPC admission webhook.

```
kubectl apply -f vpc-admission-webhook.yaml
```

**Important**
The VPC admission controller webhook is signed with a certificate that expires one year after the date of issue. To avoid down time, make sure to renew the certificate before it expires. For more information, see Renewing the VPC admission webhook certificate (p. 62).

4. Determine if your cluster has the required cluster role binding.

```
kubectl get clusterrolebinding eks:kube-proxy-windows
```

If output similar to the following example output is returned, then the cluster has the necessary role binding.

<table>
<thead>
<tr>
<th>NAME</th>
<th>ROLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>eks:kube-proxy-windows</td>
<td>ClusterRole/system:node-proxier</td>
<td>19h</td>
</tr>
</tbody>
</table>

If the output includes *Error from server (NotFound)*, then the cluster does not have the necessary cluster role binding. Add the binding by creating a file named `eks-kube-proxy-windows-crb.yaml` with the following content.

```
kind: ClusterRoleBinding
apiVersion: rbac.authorization.k8s.io/v1beta1
metadata:
  name: eks:kube-proxy-windows
labels:
  k8s-app: kube-proxy
  eks.amazonaws.com/component: kube-proxy
subjects:
- kind: Group
  name: "eks:kube-proxy-windows"
roleRef:
  kind: ClusterRole
  name: system:node-proxier
  apiGroup: rbac.authorization.k8s.io
```

Apply the configuration to the cluster.
Enabling legacy Windows support

```shell
ekubectl apply -f eks-kube-proxy-windows-crb.yaml
```

5. After you have enabled Windows support, you can launch a Windows node group into your cluster. For more information, see Launching self-managed Windows nodes (p. 129).

Renewing the VPC admission webhook certificate

The certificate used by the VPC admission webhook expires one year after issue. To avoid down time, it's important that you renew the certificate before it expires. You can check the expiration date of your current certificate with the following command.

```shell
ekubectl get secret \
  -n kube-system \
  vpc-admission-webhook-certs -o json | \
  jq -r '.data."cert.pem"' | \
  base64 -decode | \
  openssl x509 \
  -noout \
  -enddate | \
  cut -d= -f2
```

The example output is as follows.

May 28 14:23:00 2022 GMT

You can renew the certificate using `eksctl` or a Windows or Linux/macOS computer. Follow the instructions for the tool you originally used to install the VPC admission webhook. For example, if you originally installed the VPC admission webhook using `eksctl`, then you should renew the certificate using the instructions on the `eksctl` tab.

`eksctl`

1. Reinstall the certificate. Replace `my-cluster` with the name of your cluster.

```shell
eksctl utils install-vpc-controllers -cluster my-cluster -approve
```

2. Verify that you receive the following output.

<table>
<thead>
<tr>
<th>Time</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>2021/05/28 05:24:59</td>
<td>[INFO] generate received request</td>
</tr>
<tr>
<td>2021/05/28 05:24:59</td>
<td>[INFO] received CSR</td>
</tr>
<tr>
<td>2021/05/28 05:24:59</td>
<td>[INFO] generating key: rsa-2048</td>
</tr>
<tr>
<td>2021/05/28 05:24:59</td>
<td>[INFO] encoded CSR</td>
</tr>
</tbody>
</table>

3. Restart the webhook deployment.

```shell
kubectl rollout restart deployment -n kube-system vpc-admission-webhook
```

4. If the certificate that you renewed was expired, and you have Windows pods stuck in the `Container creating state`, then you must delete and redeploy those pods.

Windows

1. Get the script to generate new certificate.
Private cluster requirements

This topic describes how to deploy an Amazon EKS private cluster without outbound internet access. If you’re not familiar with Amazon EKS networking, see De-mystifying cluster networking for Amazon EKS worker nodes.

Requirements

The following requirements must be met to run Amazon EKS in a private cluster without outbound internet access.
Considerations

- A container image must be in or copied to Amazon Elastic Container Registry (Amazon ECR) or to a registry inside the VPC to be pulled. For more information, see Creating local copies of container images (p. 65).
- Endpoint private access is required for nodes to register with the cluster endpoint. Endpoint public access is optional. For more information, see Amazon EKS cluster endpoint access control (p. 43).
- For Linux and Windows nodes, you must include bootstrap arguments when launching self-managed nodes. This text bypasses the Amazon EKS introspection and doesn't require access to the Amazon EKS API from within the VPC. Replace `api-server-endpoint` and `certificate-authority` with the values from your Amazon EKS cluster.
  - For Linux nodes:
    ```bash
    --apiserver-endpoint <api-server-endpoint> --b64-cluster-ca <certificate-authority>
    ```
    For additional arguments, see the bootstrap script on GitHub.
  - For Windows nodes:
    ```bash
    -APIServerEndpoint <api-server-endpoint> -Base64ClusterCA <certificate-authority>
    ```
    For additional arguments, see Amazon EKS optimized Windows AMI (p. 202).
- The `aws-auth` ConfigMap must be created from within the VPC. For more information about create the `aws-auth` ConfigMap, see Enabling IAM user and role access to your cluster (p. 381).

## Considerations

Here are some things to consider when running Amazon EKS in a private cluster without outbound internet access.

- Many AWS services support private clusters, but you must use a VPC endpoint. For more information, see VPC endpoints. Some commonly-used services and endpoints include:

<table>
<thead>
<tr>
<th>Service</th>
<th>Endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Elastic Container Registry</td>
<td><code>com.amazonaws.&lt;region-code&gt;.ecr.api</code> and <code>com.amazonaws.&lt;region-code&gt;.ecr.dkr</code> and the Amazon S3 gateway endpoint</td>
</tr>
<tr>
<td>Application Load Balancers and Network Load Balancers</td>
<td><code>com.amazonaws.&lt;region-code&gt;.elasticloadbalancing</code></td>
</tr>
<tr>
<td>AWS X-Ray</td>
<td><code>com.amazonaws.&lt;region-code&gt;.xray</code></td>
</tr>
<tr>
<td>Amazon CloudWatch Logs</td>
<td><code>com.amazonaws.&lt;region-code&gt;.logs</code></td>
</tr>
<tr>
<td>IAM roles for service accounts (p. 425)</td>
<td><code>com.amazonaws.&lt;region-code&gt;.sts</code></td>
</tr>
<tr>
<td>App Mesh</td>
<td><code>com.amazonaws.&lt;region-code&gt;.appmesh-envoy-management</code></td>
</tr>
</tbody>
</table>
  - The App Mesh sidecar injector for Kubernetes is supported. For more information, see App Mesh sidecar injector on GitHub.
  - The App Mesh controller for Kubernetes isn't supported. For more information, see App Mesh controller on GitHub.
Creating local copies of container images

Because a private cluster has no outbound internet access, container images can't be pulled from external sources such as Docker Hub. Instead, container images must be copied locally to Amazon ECR or to an alternative registry accessible in the VPC. A container image can be copied to Amazon ECR from outside the private VPC. The private cluster accesses the Amazon ECR repository using the Amazon ECR VPC endpoints. You must have Docker and the AWS CLI installed on the workstation that you use to create the local copy.

To create a local copy of a container image

1. Create an Amazon ECR repository. For more information, see Creating a repository.
2. Pull the container image from the external registry using `docker pull`.
3. Tag your image with the Amazon ECR registry, repository, and the optional image tag name combination using `docker tag`.
4. Authenticate to the registry. For more information, see Registry authentication.
5. Push the image to Amazon ECR using `docker push`.

Note
Make sure to update your resource configuration to use the new image location.

The following example pulls the `amazon/aws-node-termination-handler` image, using tag `v1.3.1-linux-amd64`, from Docker Hub and creates a local copy in Amazon ECR.
aws ecr create-repository --repository-name amazon/aws-node-termination-handler
docker pull amazon/aws-node-termination-handler:v1.3.1-linux-amd64
docker tag amazon/aws-node-termination-handler | docker login region-code.amazonaws.com/amazon/aws-node-termination-handler:v1.3.1-linux-amd64
docker push region-code.amazonaws.com/amazon/aws-node-termination-handler:v1.3.1-linux-amd64

**AWS STS endpoints for IAM roles for service accounts**

Pods configured with IAM roles for service accounts (p. 425) acquire credentials from an AWS Security Token Service (AWS STS) API call. If there is no outbound internet access, you must create and use an AWS STS VPC endpoint in your VPC. Most AWS v1 SDKs use the global AWS STS endpoint by default (sts.amazonaws.com), which doesn't use the AWS STS VPC endpoint. To use the AWS STS VPC endpoint, you may need to configure the SDK to use the regional AWS STS endpoint (sts.region-code.amazonaws.com). You can do this by setting the AWS_STS_REGIONAL_ENDPOINTS environment variable with a value of regional, along with the AWS Region.

For example, in a pod spec:

```yaml
... containers:
  - env:
    - name: AWS_REGION
      value: region-code
    - name: AWS_STS_REGIONAL_ENDPOINTS
      value: regional
  ...
```

Replace `region-code` with the AWS Region that your cluster is in.

**Amazon EKS Kubernetes versions**

The Kubernetes project is continually integrating new features, design updates, and bug fixes. The community releases new Kubernetes minor versions, such as 1.23. New version updates are available on average every three months. Each minor version is supported for approximately twelve months after it's first released.

**Available Amazon EKS Kubernetes versions**

The following Kubernetes versions are currently available for new Amazon EKS clusters:

- 1.23
- 1.22
- 1.21
- 1.20

If your application doesn’t require a specific version of Kubernetes, we recommend that you use the latest available Kubernetes version that's supported by Amazon EKS for your clusters. As new Kubernetes versions become available in Amazon EKS, we recommend that you proactively update your clusters to
use the latest available version. For instructions on how to update your cluster, see Updating an Amazon EKS cluster Kubernetes version (p. 32). For more information about Kubernetes releases, see Amazon EKS Kubernetes release calendar (p. 73) and Amazon EKS version support and FAQ (p. 74).

**Note**
Starting with the Kubernetes version 1.24 launch, officially published Amazon EKS AMIs will include containerd as the only runtime. Kubernetes versions lower than 1.24 use Docker as the default runtime. However, these versions have a bootstrap flag option that you can use to test out your workloads on any supported cluster with containerd. For more information, see Amazon EKS is ending support for Dockershim (p. 165).

## Kubernetes 1.23

Kubernetes 1.23 is now available in Amazon EKS. For more information about Kubernetes 1.23, see the official release announcement.

- **Important**
  The Kubernetes in-tree to Container Storage Interface (CSI) Volume migration feature is enabled. This feature enables the replacement of existing Kubernetes in-tree storage plugins for Amazon EBS with a corresponding Amazon EBS CSI driver. For more information, see Kubernetes 1.17 Feature: Kubernetes In-Tree to CSI Volume Migration Moves to Beta on the Kubernetes blog.
  The feature translates in-tree APIs to equivalent CSI APIs and delegates operations to a replacement CSI driver. With this feature, if you use existing StorageClass, PersistentVolume, and PersistentVolumeClaim objects that belong to these workloads, there likely won’t be any noticeable change. The feature enables Kubernetes to delegate all storage management operations from the in-tree plugin to the CSI driver. If you use Amazon EBS volumes in an existing cluster, install the Amazon EBS CSI driver in your cluster before you update your cluster to version 1.23. If you don't install the driver before updating an existing cluster, interruptions to your workloads might occur. If you plan to deploy workloads that use Amazon EBS volumes in a new 1.23 cluster, install the Amazon EBS CSI driver in your cluster before deploying the workloads your cluster.
  For instructions on how to install the Amazon EBS CSI driver on your cluster, see the section called “Amazon EBS CSI driver” (p. 205). For frequently asked questions about the migration feature, see the section called “CSI migration FAQ” (p. 218).

- Kubernetes stopped supporting dockershim in version 1.20 and removed dockershim in version 1.24. For more information, see Kubernetes is Moving on From Dockershim: Commitments and Next Steps in the Kubernetes blog. Amazon EKS will end support for dockershim starting in Amazon EKS version 1.24. Starting with Amazon EKS version 1.24, Amazon EKS official AMIs will have containerd as the only runtime.

Even though Amazon EKS version 1.23 continues to support dockershim, we recommend that you start testing your applications now to identify and remove any Docker dependencies. This way, you are prepared to update your cluster to version 1.24. For more information about dockershim removal, see the section called “Dockershim deprecation” (p. 165).

- Kubernetes graduated IPv4/IPv6 dual-stack networking for pods, services, and nodes to general availability. However, Amazon EKS and the Amazon VPC CNI plugin for Kubernetes don't support dual-stack networking. Your clusters can assign IPv4 or IPv6 addresses to pods and services, but can't assign both address types.

- Kubernetes graduated the Pod Security Admission feature to beta. The feature is enabled by default. For more information, see Pod Security Admission in the Kubernetes documentation. Pod Security Admission replaces the Pod Security Policy (PSP) admission controller. The PSP admission controller isn't supported and is scheduled for removal in Kubernetes version 1.25.

  The PSP admission controller enforces pod security standards on pods in a namespace based on specific namespace labels that set the enforcement level. For more information, see Pod Security Standards (PSS) and Pod Security Admission (PSA) in the Amazon EKS best practices guide.
• The `kube-proxy` image deployed with clusters is now the minimal base image maintained by Amazon EKS Distro (EKS-D). The image contains minimal packages and doesn’t have shells or package managers.

• Kubernetes graduated ephemeral containers to beta. Ephemeral containers are temporary containers that run in the same namespace as an existing pod. You can use them to observe the state of pods and containers for troubleshooting and debugging purposes. This is especially useful for interactive troubleshooting when `kubectl exec` is insufficient because either a container has crashed or a container image doesn't include debugging utilities. An example of a container that includes a debugging utility is distroless images. For more information, see Debugging with an ephemeral debug container in the Kubernetes documentation.

• Kubernetes graduated the `HorizontalPodAutoscaler` autoscaling/v2 stable API to general availability. The `HorizontalPodAutoscaler` autoscaling/v2beta2 API is no longer supported.

For the complete Kubernetes 1.23 changelog, see https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.23.md#changelog-since-v1220.

**Kubernetes 1.22**

Kubernetes 1.22 is now available in Amazon EKS. For more information about Kubernetes 1.22, see the official release announcement.

• Kubernetes 1.22 removes a number of APIs that are no longer available. You might need to make changes to your application before you upgrade to Amazon EKS version 1.22. Follow the Kubernetes version 1.22 prerequisites (p. 37) carefully before updating your cluster.

• **Important**
  `BoundServiceAccountTokenVolume` graduated to stable and enabled by default in Kubernetes version 1.22. This feature improves security of service account tokens. It allows workloads that are running on Kubernetes to request JSON web tokens that are audience, time, and key bound. Service account tokens now have an expiration of one hour. In previous Kubernetes versions, they didn't have an expiration. This means that clients that rely on these tokens must refresh the tokens within an hour. The following Kubernetes client SDKs refresh tokens automatically within the required timeframe:
  - Go version 0.15.7 and later
  - Python version 12.0.0 and later
  - Java version 9.0.0 and later
  - JavaScript version 0.10.3 and later
  - Ruby master branch
  - Haskell version 0.3.0.0
  - C# version 7.0.5 and later

  If your workload is using an older client version, then you must update it. To enable a smooth migration of clients to the newer time-bound service account tokens, Kubernetes version 1.22 adds an extended expiry period to the service account token over the default one hour. For Amazon EKS clusters, the extended expiry period is 90 days. Your Amazon EKS cluster's Kubernetes API server rejects requests with tokens older than 90 days. We recommend that you check your applications and their dependencies to make sure that the Kubernetes client SDKs are the same or later than the versions listed previously. For instructions about how to identify pods that are using stale tokens, see Kubernetes service accounts (p. 424).

• The Ingress API versions `extensions/v1beta1` and `networking.k8s.io/v1beta1` have been removed in Kubernetes 1.22. If you're using the AWS Load Balancer Controller, you must upgrade to at least version 2.4.1 before you upgrade your Amazon EKS clusters to version 1.22. Additionally, you must modify Ingress manifests to use `apiVersion networking.k8s.io/v1`. This has been available since Kubernetes version 1.19. For more information about changes between Ingress
v1beta1 and v1, see the Kubernetes documentation. The AWS Load Balancer Controller controller sample manifest uses the v1 spec.

- The Amazon EKS legacy Windows support controllers use the admissionregistration.k8s.io/v1beta1 API that was removed in Kubernetes 1.22. If you're running Windows workloads, you must remove legacy Windows support and enable Windows support before upgrading to Amazon EKS version 1.22.

- The CertificateSigningRequest (CSR) API version certificates.k8s.io/v1beta1 was removed in Kubernetes version 1.22. You must migrate manifests and API clients to use the certificates.k8s.io/v1 CSR API. This API has been available since version 1.19. For instructions on how to use CSR in Amazon EKS, see Certificate signing (p. 422).

- The CustomResourceDefinition API version apiextensions.k8s.io/v1beta1 was removed in Kubernetes 1.22. Make sure that all custom resource definitions in your cluster are updated to v1. API version v1 custom resource definitions are required to have Open API v3 schema validation defined. For more information, see the Kubernetes documentation.

- If you're using App Mesh, you must upgrade to at least App Mesh controller v1.4.3 or later before you upgrade to Amazon EKS version 1.22. Older versions of the App Mesh controller use v1beta1 CustomResourceDefinition API version and aren't compatible with Kubernetes version 1.22 and later.

- Amazon EKS version 1.22 enables the EndpointSliceTerminatingCondition feature by default, which includes pods in terminating state within EndpointSlices. If you set enableEndpointSlices to True (the default is disabled) in the AWS Load Balancer Controller, you must upgrade to at least AWS Load Balancer Controller version 2.4.1+ before upgrading to Amazon EKS version 1.22.

- Starting with Amazon EKS version 1.22, kube-proxy is configured by default to expose Prometheus metrics outside the pod. This behavior change addresses the request made in containers roadmap issue #657.

- The initial launch of Amazon EKS version 1.22 uses etcd version 3.4 as a backend, and is not affected by the possibility of data corruption present in etcd version 3.5.

- Starting with Amazon EKS 1.22, Amazon EKS is decoupling AWS cloud specific control logic from core control plane code to the out-of-tree AWS Kubernetes Cloud Controller Manager. This is in line with the upstream Kubernetes recommendation. By decoupling the interoperability logic between Kubernetes and the underlying cloud infrastructure, the cloud-controller-manager component enables cloud providers to release features at a different pace compared to the main Kubernetes project. This change is transparent and requires no action. However, a new log stream named cloud-controller-manager now appears under the ControllerManager log type when enabled. For more information, see Amazon EKS control plane logging.

- Starting with Amazon EKS 1.22, Amazon EKS is changing the default AWS Security Token Service endpoint used by IAM roles for service accounts (IRSA) to be the regional endpoint instead of the global endpoint to reduce latency and improve reliability. You can optionally configure IRSA to use the global endpoint in the section called “Configuring AWS STS endpoint” (p. 434).

The following Kubernetes features are now supported in Kubernetes 1.22 Amazon EKS clusters:

- **Server-side Apply graduates to GA** - Server-side Apply helps users and controllers manage their resources through declarative configurations. It allows them to create or modify objects declaratively by sending their fully specified intent. After being in beta for a couple releases, Server-side Apply is now generally available.

- **Warning mechanism for use of unsupported APIs** - Use of unsupported APIs produces warnings visible to API consumers, and metrics visible to cluster administrators.

For the complete Kubernetes 1.22 changelog, see https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.22.md#changelog-since-v1210.
Kubernetes 1.21

Kubernetes 1.21 is now available in Amazon EKS. For more information about Kubernetes 1.21, see the official release announcement.

- **Important**
  - `BoundServiceAccountTokenVolume` graduated to beta and is enabled by default in Kubernetes version 1.21. This feature improves security of service account tokens by allowing workloads running on Kubernetes to request JSON web tokens that are audience, time, and key bound. Service account tokens now have an expiration of one hour. In previous Kubernetes versions, they didn't have an expiration. This means that clients that rely on these tokens must refresh the tokens within an hour. The following Kubernetes client SDKs refresh tokens automatically within the required time frame:
    - Go version 0.15.7 and later
    - Python version 12.0.0 and later
    - Java version 9.0.0 and later
    - JavaScript version 0.10.3 and later
    - Ruby `master` branch
    - Haskell version 0.3.0.0
    - C# version 7.0.5 and later

  If your workload is using an older client version, then you must update it. To enable a smooth migration of clients to the newer time-bound service account tokens, Kubernetes version 1.21 adds an extended expiry period to the service account token over the default one hour. For Amazon EKS clusters, the extended expiry period is 90 days. Your Amazon EKS cluster's Kubernetes API server rejects requests with tokens older than 90 days. We recommend that you check your applications and their dependencies to make sure that the Kubernetes client SDKs are the same or later than the versions listed previously. For instructions about how to identify pods that are using stale tokens, see Kubernetes service accounts (p. 424).

- **Dual-stack networking** support (IPv4 and IPv6 addresses) on pods, services, and nodes reached beta status. However, Amazon EKS and the Amazon VPC CNI plugin for Kubernetes don't currently support dual stack networking.

- The Amazon EKS Optimized Amazon Linux 2 AMI now contains a bootstrap flag to enable the containerd runtime as a Docker alternative. This flag allows preparation for the removal of Docker as a supported runtime in the next Kubernetes release. For more information, see Enable the containerd runtime bootstrap flag (p. 174). This can be tracked through the container roadmap on Github.

- **Managed node groups support** for Cluster Autoscaler priority expander.

  Newly created managed node groups on Amazon EKS version 1.21 clusters use the following format for the underlying Auto Scaling group name:

  `eks-managed-node-group-name-uuid`

  This enables using the priority expander feature of Cluster Autoscaler to scale node groups based on user defined priorities. A common use case is to prefer scaling spot node groups over on-demand groups. This behavior change solves the containers roadmap issue #1304.

The following Kubernetes features are now supported in Amazon EKS 1.21 clusters:

- **CronJobs** (previously ScheduledJobs) have now graduated to stable status. With this change, users perform regularly scheduled actions such as backups and report generation.
- **Immutable Secrets and ConfigMaps** have now graduated to stable status. A new, immutable field was added to these objects to reject changes. This rejection protects the cluster from updates that can unintentionally break the applications. Because these resources are immutable, kubelet
doesn't watch or poll for changes. This reduces `kube-apiserver` load and improving scalability and performance.

- **Graceful Node Shutdown** has now graduated to beta status. With this update, the `kubelet` is aware of node shutdown and can gracefully terminate that node's pods. Before this update, when a node shutdown, its pods didn’t follow the expected termination lifecycle. This caused workload problems. Now, the `kubelet` can detect imminent system shutdown through `systemd`, and inform running pods so they terminate gracefully.

- Pods with multiple containers can now use the `kubectld.kubernetes.io/default-container` annotation to have a container preselected for `kubectl` commands.

- PodSecurityPolicy is being phased out. PodSecurityPolicy will still be functional for several more releases according to Kubernetes deprecation guidelines. For more information, see PodSecurityPolicy Deprecation: Past, Present, and Future and the AWS blog.

For the complete Kubernetes 1.21 changelog, see https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.21.md.

**Kubernetes 1.20**

For more information about Kubernetes 1.20, see the official release announcement.

- 1.20 brings new default roles and users. You can find more information in Default EKS Kubernetes roles and users. Ensure that you are using a supported cert-manager version.

The following Kubernetes features are now supported in Kubernetes 1.20 Amazon EKS clusters:

- **API Priority and Fairness** has reached beta status and is enabled by default. This allows `kube-apiserver` to categorize incoming requests by priority levels.

- **RuntimeClass** has reached stable status. The `RuntimeClass` resource provides a mechanism for supporting multiple runtimes in a cluster and surfaces information about that container runtime to the control plane.

- **Process ID Limits** has now graduated to general availability.

- `kubectld debug` has reached beta status. `kubectld debug` supports common debugging workflows directly from `kubectl`.

- The Docker container runtime has been phased out. The Kubernetes community has written a blog post about this in detail with a dedicated FAQ page. Docker-produced images can continue to be used and will work as they always have. You can safely ignore the `dockershim` deprecation warning message printed in `kubelet` startup logs. Amazon EKS will eventually move to `containerd` as the runtime for the Amazon EKS optimized Amazon Linux 2 AMI. You can follow the containers roadmap issue for more details.

- Pod Hostname as FQDN has graduated to beta status. This feature allows setting a pod's hostname to its Fully Qualified Domain Name (FQDN), giving the ability to set the hostname field of the kernel to the FQDN of a pod.

- The client-go credential plugins can now be passed in the current cluster information via the `KUBERNETES_EXEC_INFO` environment variable. This enhancement allows Go clients to authenticate using external credential providers, such as a key management system (KMS).

For the complete Kubernetes 1.20 changelog, see https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.20.md.

**Kubernetes 1.19**

For more information about Kubernetes 1.19, see the official release announcement.
• Starting with 1.19, Amazon EKS no longer adds the `kubernetes.io/cluster/my-cluster` tag to subnets passed in when clusters are created. This subnet tag is only required if you want to influence where the Kubernetes service controller or AWS Load Balancer Controller places Elastic Load Balancers. For more information about the requirements of subnets passed to Amazon EKS during cluster creation, see updates to the section called “VPC and subnet requirements” (p. 238).

• Subnet tags aren't modified on existing clusters updated to 1.19.

• The AWS Load Balancer Controller version 2.1.1 and earlier required the `my-cluster` subnet tag. In version 2.1.2 and later, you can specify the tag to refine subnet discovery, but it's not required. For more information about the AWS Load Balancer Controller, see Installing the AWS Load Balancer Controller add-on (p. 308). For more information about subnet tagging when using a load balancer, see Application load balancing on Amazon EKS (p. 357) and Network load balancing on Amazon EKS (p. 351).

• You're no longer required to provide a security context for non-root containers that must access the web identity token file for use with IAM roles for service accounts. For more information, see IAM roles for service accounts (p. 425) and proposal for file permission handling in projected service account volume on GitHub.

• The pod identity webhook has been updated to address the missing startup probes GitHub issue. The webhook also now supports an annotation to control token expiration. For more information, see the GitHub pull request.

• CoreDNS version 1.8.0 is the recommended version for Amazon EKS 1.19 clusters. This version is installed by default in new Amazon EKS 1.19 clusters. For more information, see Managing the CoreDNS add-on (p. 316).

• Amazon EKS optimized Amazon Linux 2 AMIs include the Linux kernel version 5.4 for Kubernetes version 1.19. For more information, see Changelog on GitHub.

• The CertificateSigningRequest API has been promoted to stable `certificates.k8s.io/v1` with the following changes:
  • `spec.signerName` is now required. You can't create requests for `kubernetes.io/legacy-unknown` with the `certificates.k8s.io/v1` API.
  • You can continue to create CSRs with the `kubernetes.io/legacy-unknown` signer name with the `certificates.k8s.io/v1beta1` API.
  • You can continue to request that a CSR to is signed for a non-node server cert, webhooks (for example, with the `certificates.k8s.io/v1beta1` API). These CSRs aren't auto-approved.
  • To approve certificates, a privileged user requires `kubectl 1.18.8` or later.

For more information about the certificate v1 API, see Certificate Signing Requests in the Kubernetes documentation.

The following Amazon EKS Kubernetes resources are critical for the Kubernetes control plane to work. We recommend that you don't delete or edit them.

<table>
<thead>
<tr>
<th>Permission</th>
<th>Kind</th>
<th>Namespace</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>eks:certificate-controller</td>
<td>Rolebinding</td>
<td>kube-system</td>
<td>Impacts signer and approver functionality in the control plane.</td>
</tr>
<tr>
<td>eks:certificate-controller</td>
<td>Role</td>
<td>kube-system</td>
<td>Impacts signer and approver functionality in the control plane.</td>
</tr>
<tr>
<td>eks:certificate-controller</td>
<td>ClusterRolebinding</td>
<td>All</td>
<td>Impacts kubelet's ability to request server certificates, which affects certain cluster</td>
</tr>
</tbody>
</table>
The following Kubernetes features are now supported in Kubernetes 1.19 Amazon EKS clusters:

- The `ExtendedResourceToleration` admission controller is enabled. This admission controller automatically adds tolerations for taints to pods requesting extended resources, such as GPUs. This way, you don't have to manually add the tolerations. For more information, see [ExtendedResourceToleration](https://kubernetes.io/docs/reference/generated/api/admissionregistration/v1beta1#ExtendedResourceToleration) in the Kubernetes documentation.

- Elastic Load Balancers (CLB and NLB) provisioned by the in-tree Kubernetes service controller support filtering the nodes included as instance targets. This can help prevent reaching target group limits in large clusters. For more information, see the related [GitHub issue](https://github.com/kubernetes/kubernetes/issues/95167) and the `service.beta.kubernetes.io/aws-load-balancer-target-node-labels` annotation under the [Other ELB annotations](https://kubernetes.io/docs/concepts/services-networking/service/) in the Kubernetes documentation.

- Pod Topology Spread has reached stable status. You can use topology spread constraints to control how pods are spread across your cluster among failure-domains such as regions, zones, nodes, and other user-defined topology domains. This can help to achieve high availability, as well as efficient resource utilization. For more information, see [Pod Topology Spread Constraints](https://kubernetes.io/docs/concepts/workloads/pods/pod-topology-spreading-constraints/) in the Kubernetes documentation.

- The Ingress API has reached general availability. For more information, see [Ingress](https://kubernetes.io/docs/concepts/services-networking/ingress/) in the Kubernetes documentation.

- EndpointSlices are enabled by default. EndpointSlices are a new API that provides a more scalable and extensible alternative to the Endpoints API for tracking IP addresses, ports, readiness, and topology information for Pods backing a Service. For more information, see [Scaling Kubernetes Networking With EndpointSlices](https://kubernetes.io/blog/2021/08/25/endpoint-slices/) in the Kubernetes blog.

- Secret and ConfigMap volumes can now be marked as immutable. This significantly reduces load on the API server if there are many Secret and ConfigMap volumes in the cluster. For more information, see [ConfigMap](https://kubernetes.io/docs/concepts/configuration/organize-components/configmaps/) and [Secret](https://kubernetes.io/docs/concepts/configuration/organize-components/secret/) in the Kubernetes documentation.

*Note:
Dates with only a month and a year are approximate and are updated with an exact date when it's known.*
Amazon EKS version support and FAQ

In line with the Kubernetes community support for Kubernetes versions, Amazon EKS is committed to supporting at least four production-ready versions of Kubernetes at any given time. We will announce the end of support date of a given Kubernetes minor version at least 60 days before the end of support date. Because of the Amazon EKS qualification and release process for new Kubernetes versions, the end of support date of a Kubernetes version on Amazon EKS will be on or after the date that the Kubernetes project stops supporting the version upstream.

Frequently asked questions

Q: How long is a Kubernetes version supported by Amazon EKS?

A: A Kubernetes version is supported for 14 months after first being available on Amazon EKS. This is true even if upstream Kubernetes no longer support a version that's available on Amazon EKS. We backport security patches that are applicable to the Kubernetes versions that are supported on Amazon EKS.

Q: Am I notified when support is ending for a Kubernetes version on Amazon EKS?

A: Yes, if any clusters in your account are running the version nearing the end of support, Amazon EKS sends out a notice through the AWS Health Dashboard approximately 12 months after the Kubernetes version was released on Amazon EKS. The notice includes the end of support date. This is at least 60 days from the date of the notice.

Q: What happens on the end of support date?

A: On the end of support date, you can no longer create new Amazon EKS clusters with the unsupported version. Existing control planes are automatically updated by Amazon EKS to the earliest supported version through a gradual deployment process after the end of support date. After the automatic control plane update, make sure to manually update cluster add-ons and Amazon EC2 nodes. For more information, see the section called “Update the Kubernetes version for your Amazon EKS cluster” (p. 33).

Q: When exactly is my control plane automatically updated after the end of support date?

A: Amazon EKS can't provide specific time frames. Automatic updates can happen at any time after the end of support date. You won't receive any notification before the update. We recommend that you proactively update your control plane without relying on the Amazon EKS automatic update process. For more information, see the section called "Updating Kubernetes version" (p. 32).

Q: Can I leave my control plane on a Kubernetes version indefinitely?

A: No, cloud security at AWS is the highest priority. Past a certain point (usually one year), the Kubernetes community stops releasing common vulnerabilities and exposures (CVE) patches and discourages CVE submission for unsupported versions. This means that vulnerabilities specific to an older version of Kubernetes might not even be reported. This leaves clusters exposed with no notice and no remediation options in the event of a vulnerability. Given this, Amazon EKS doesn't allow control planes to stay on a version that reached end of support.

Q: Which Kubernetes features are supported by Amazon EKS?

A: Amazon EKS supports all general availability features of the Kubernetes API. It also supports all beta features, which are enabled by default. Alpha features aren't supported.

Q: Are Amazon EKS managed node groups automatically updated along with the cluster control plane version?
A: No, a managed node group creates Amazon EC2 instances in your account. These instances aren't automatically upgraded when you or Amazon EKS update your control plane. Assume that Amazon EKS automatically updates your control plane. The Kubernetes version that's on your managed node group might be more than one version earlier than your control plane. Then, assume that a managed node group contains instances that are running a version of Kubernetes that's more than one version earlier than the control plane. The node group has a health issue in the Node Groups section of the Compute tab of your cluster in the console. Last, if a node group has an available version update, Update now appears next to the node group in the console. For more information, see the section called “Updating a managed node group” (p. 107). We recommend maintaining the same Kubernetes version on your control plane and nodes.

Q: Are self-managed node groups automatically updated along with the cluster control plane version?

A: No, a self-managed node group includes Amazon EC2 instances in your account. These instances aren't automatically upgraded when you or Amazon EKS update the control plane version on your behalf. A self-managed node group doesn’t have any indication in the console that it needs updating. You can view the kubelet version installed on a node by selecting the node in the Nodes list on the Overview tab of your cluster to determine which nodes need updating. You must manually update the nodes. For more information, see the section called “Updates” (p. 135).

The Kubernetes project tests compatibility between the control plane and nodes for up to two minor versions. For example, 1.21 nodes continue to operate when orchestrated by a 1.23 control plane. However, running a cluster with nodes that are persistently two minor versions behind the control plane isn’t recommended. For more information, see Kubernetes version and version skew support policy in the Kubernetes documentation. We recommend maintaining the same Kubernetes version on your control plane and nodes.

Q: Are pods running on Fargate automatically upgraded with an automatic cluster control plane version upgrade?

Yes, Fargate pods run on infrastructure in AWS owned accounts on the Amazon EKS side of the shared responsibility model (p. 421). Amazon EKS uses the Kubernetes eviction API to attempt to gracefully drain pods that are running on Fargate. For more information, see The Eviction API in the Kubernetes documentation. If a pod can’t be evicted, Amazon EKS issues a Kubernetes delete pod command. We strongly recommend running Fargate pods as part of a replication controller such as a Kubernetes deployment. This is so that a pod is automatically rescheduled after deletion. For more information, see Deployments in the Kubernetes documentation. The new version of the Fargate pod is deployed with a kubelet version that's the same version as your updated cluster control plane version.

Important
If you update the control plane, you must still update the Fargate nodes yourself. To update Fargate nodes, delete the Fargate pod represented by the node and redeploy the pod. The new pod is deployed with a kubelet version that's the same version as your cluster.

Amazon EKS platform versions

Amazon EKS platform versions represent the capabilities of the Amazon EKS cluster control plane, such as which Kubernetes API server flags are enabled, as well as the current Kubernetes patch version. Each Kubernetes minor version has one or more associated Amazon EKS platform versions. The platform versions for different Kubernetes minor versions are independent. If you have a local cluster on AWS Outposts, see the section called “Platform versions” (p. 556) instead of this topic.

When a new Kubernetes minor version is available in Amazon EKS, such as 1.23, the initial Amazon EKS platform version for that Kubernetes minor version starts at eks-1. However, Amazon EKS releases new platform versions periodically to enable new Kubernetes control plane settings and to provide security fixes.
When new Amazon EKS platform versions become available for a minor version:

- The Amazon EKS platform version number is incremented \( (\text{eks.n+1}) \).
- Amazon EKS automatically upgrades all existing clusters to the latest Amazon EKS platform version for their corresponding Kubernetes minor version. Automatic upgrades of existing Amazon EKS platform versions are rolled out incrementally. The roll-out process might take some time. If you need the latest Amazon EKS platform version features immediately, you should create a new Amazon EKS cluster.

If your cluster is more than two platform versions behind the current platform version, then it's possible that Amazon EKS wasn't able to automatically update your cluster. For details of what may cause this, see the section called ‘Old platform version’ (p. 529).

- Amazon EKS might publish a new node AMI with a corresponding patch version. However, all patch versions are compatible between the EKS control plane and node AMIs for a given Kubernetes minor version.

New Amazon EKS platform versions don't introduce breaking changes or cause service interruptions.

Clusters are always created with the latest available Amazon EKS platform version \( (\text{eks.n}) \) for the specified Kubernetes version. If you update your cluster to a new Kubernetes minor version, your cluster receives the current Amazon EKS platform version for the Kubernetes minor version that you updated to.

The current and recent Amazon EKS platform versions are described in the following tables.

Kubernetes version 1.23

The following admission controllers are enabled for all 1.23 platform versions:

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Amazon EKS platform version</th>
<th>Release notes</th>
<th>Release date</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.23.7</td>

## Autoscaling

Autoscaling is a function that automatically scales your resources up or down to meet changing demands. This is a major Kubernetes function that would otherwise require extensive human resources to perform manually.

Amazon EKS supports two autoscaling products. The Kubernetes Cluster Autoscaler and the Karpenter open source autoscaling project. The cluster autoscaler uses AWS scaling groups, while Karpenter works directly with the Amazon EC2 fleet.

### Cluster Autoscaler

The Kubernetes Cluster Autoscaler automatically adjusts the number of nodes in your cluster when pods fail or are rescheduled onto other nodes. The Cluster Autoscaler is typically installed as a Deployment in your cluster. It uses leader election to ensure high availability, but scaling is done by only one replica at a time.

Before you deploy the Cluster Autoscaler, make sure that you're familiar with how Kubernetes concepts interface with AWS features. The following terms are used throughout this topic:

- **Kubernetes Cluster Autoscaler** – A core component of the Kubernetes control plane that makes scheduling and scaling decisions. For more information, see Kubernetes Control Plane FAQ on GitHub.

- **AWS Cloud provider implementation** – An extension of the Kubernetes Cluster Autoscaler that implements the decisions of the Kubernetes Cluster Autoscaler by communicating with AWS products and services such as Amazon EC2. For more information, see Cluster Autoscaler on AWS on GitHub.

- **Node groups** – A Kubernetes abstraction for a group of nodes within a cluster. Node groups aren't a true Kubernetes resource, but they're found as an abstraction in the Cluster Autoscaler, Cluster API, and other components. Nodes that are found within a single node group might share several common properties such as labels and taints. However, they can still consist of more than one Availability Zone or instance type.

- **Amazon EC2 Auto Scaling groups** – A feature of AWS that's used by the Cluster Autoscaler. Auto Scaling groups are suitable for a large number of use cases. Amazon EC2 Auto Scaling groups are configured to launch instances that automatically join their Kubernetes cluster. They also apply labels and taints to their corresponding node resource in the Kubernetes API.
For reference, Managed node groups (p. 97) are managed using Amazon EC2 Auto Scaling groups, and are compatible with the Cluster Autoscaler.

This topic describes how you can deploy the Cluster Autoscaler to your Amazon EKS cluster and configure it to modify your Amazon EC2 Auto Scaling groups.

Prerequisites

Before deploying the Cluster Autoscaler, you must meet the following prerequisites:

- An existing Amazon EKS cluster – If you don’t have a cluster, see Creating an Amazon EKS cluster (p. 24).
- An existing IAM OIDC provider for your cluster. To determine whether you have one or need to create one, see Creating an IAM OIDC provider for your cluster (p. 426).
- Node groups with Auto Scaling groups tags. The Cluster Autoscaler requires the following tags on your Auto Scaling groups so that they can be auto-discovered.
  - If you used eksctl to create your node groups, these tags are automatically applied.
  - If you didn’t use eksctl, you must manually tag your Auto Scaling groups with the following tags. For more information, see Tagging your Amazon EC2 resources in the Amazon EC2 User Guide for Linux Instances.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>k8s.io/cluster-autoscaler/my-cluster</td>
<td>owned</td>
</tr>
<tr>
<td>k8s.io/cluster-autoscaler/enabled</td>
<td>true</td>
</tr>
</tbody>
</table>

Create an IAM policy and role

Create an IAM policy that grants the permissions that the Cluster Autoscaler requires to use an IAM role. Replace all of the example values with your own values throughout the procedures.

1. Create an IAM policy.
   a. Save the following contents to a file that’s named cluster-autoscaler-policy.json. If your existing node groups were created with eksctl and you used the --asg-access option, then this policy already exists and you can skip to step 2.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "autoscaling:SetDesiredCapacity",
                "autoscaling:TerminateInstanceInAutoScalingGroup"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/k8s.io/cluster-autoscaler/my-cluster": "owned"
                }
            }
        },
        {
        }
    ]
}
```
b. Create the policy with the following command. You can change the value for policy-name.

```
aws iam create-policy \
  --policy-name AmazonEKSClusterAutoscalerPolicy \
  --policy-document file://cluster-autoscaler-policy.json
```

Take note of the Amazon Resource Name (ARN) that's returned in the output. You need to use it in a later step.

2. You can create an IAM role and attach an IAM policy to it using `eksctl` or the AWS Management Console. Select the desired tab for the following instructions.

**eksctl**

1. Run the following command if you created your Amazon EKS cluster with `eksctl`. If you created your node groups using the `--asg-access` option, then replace `AmazonEKSClusterAutoscalerPolicy` with the name of the IAM policy that `eksctl` created for you. The policy name is similar to `eksctl-my-cluster-nodegroup-ng-xxxxxxxx-PolicyAutoScaling`.

```
eksctl create iamserviceaccount \
  --cluster=my-cluster \
  --namespace=kube-system \
  --name=cluster-autoscaler \
  --attach-policy-arn=arn:aws:iam::111122223333:policy/AmazonEKSClusterAutoscalerPolicy \
  --override-existing-serviceaccounts \
  --approve
```

2. We recommend that, if you created your node groups using the `--asg-access` option, you detach the IAM policy that `eksctl` created and attached to the Amazon EKS node IAM role (p. 461) that `eksctl` created for your node groups. You detach the policy from the node IAM role for Cluster Autoscaler to function properly. Detaching the policy doesn't give other pods on your nodes the permissions in the policy. For more information, see Removing IAM identity permissions in the Amazon EC2 User Guide for Linux Instances.

**AWS Management Console**

b. In the left navigation pane, choose Roles. Then choose Create role.

c. In the Trusted entity type section, choose Web identity.

d. In the Web identity section:

   i. For Identity provider, choose the OpenID Connect provider URL for your cluster (as shown in the cluster Overview tab in Amazon EKS).

   ii. For Audience, choose sts.amazonaws.com.
Deploy the Cluster Autoscaler

Complete the following steps to deploy the Cluster Autoscaler. We recommend that you review Deployment considerations (p. 86) and optimize the Cluster Autoscaler deployment before you deploy it to a production cluster.

To deploy the Cluster Autoscaler

1. Download the Cluster Autoscaler YAML file.

   ```bash
curl -o cluster-autoscaler-autodiscover.yaml https://raw.githubusercontent.com/kubernetes/autoscaler/master/cluster-autoscaler/cloudprovider/aws/examples/cluster-autoscaler-autodiscover.yaml
   ```

2. Modify the YAML file and replace `<YOUR CLUSTER NAME>` with your cluster name. Also consider replacing the `cpu` and `memory` values as determined by your environment.

3. Apply the YAML file to your cluster.

   ```bash
ekubectl apply -f cluster-autoscaler-autodiscover.yaml
   ```

4. Annotate the `cluster-autoscaler` service account with the ARN of the IAM role that you created previously. Replace the `example values` with your own values.

   ```bash
ekubectl annotate serviceaccount cluster-autoscaler \
   -n kube-system \n   eks.amazonaws.com/role-arn=arn:aws:iam::ACCOUNT_ID:role/AmazonEKSClusterAutoscalerRole
   ```
5. Patch the deployment to add the `cluster-autoscaler.kubernetes.io/safe-to-evict` annotation to the Cluster Autoscaler pods with the following command.

```bash
kubectl patch deployment cluster-autoscaler \
    -n kube-system \
    -p '{"spec":{"template":{"metadata":{"annotations":{"cluster-autoscaler.kubernetes.io/safe-to-evict": "false"}}}}}'
```

6. Edit the Cluster Autoscaler deployment with the following command.

```bash
kubectl -n kube-system edit deployment.apps/cluster-autoscaler
```

Edit the `cluster-autoscaler` container command to add the following options. `--balance-similar-node-groups` ensures that there is enough available compute across all availability zones. `--skip-nodes-with-system-pods=false` ensures that there are no problems with scaling to zero.

- `--balance-similar-node-groups`
- `--skip-nodes-with-system-pods=false`

```yaml
spec:
  containers:
    - command
      - ./cluster-autoscaler
      - --v=4
      - --stderrthreshold=info
      - --cloud-provider=aws
      - --skip-nodes-with-local-storage=false
      - --expander=least-waste
      - --node-group-auto-discovery=asg:tag=k8s.io/cluster-autoscaler/enabled,k8s.io/cluster-autoscaler/my-cluster
        --balance-similar-node-groups
        --skip-nodes-with-system-pods=false
```

Save and close the file to apply the changes.

7. Open the Cluster Autoscaler releases page from GitHub in a web browser and find the latest Cluster Autoscaler version that matches the Kubernetes major and minor version of your cluster. For example, if the Kubernetes version of your cluster is `1.23`, find the latest Cluster Autoscaler release that begins with `1.23`. Record the semantic version number (`1.23.n`) for that release to use in the next step.

8. Set the Cluster Autoscaler image tag to the version that you recorded in the previous step with the following command. Replace `1.23.n` with your own value.

```bash
kubectl set image deployment cluster-autoscaler \
    -n kube-system \
    cluster-autoscaler=k8s.gcr.io/autoscaling/cluster-autoscaler:v1.23.n
```

**View your Cluster Autoscaler logs**

After you have deployed the Cluster Autoscaler, you can view the logs and verify that it's monitoring your cluster load.

View your Cluster Autoscaler logs with the following command.
kubectl -n kube-system logs -f deployment.apps/cluster-autoscaler

The example output is as follows.

```
I0926 23:15:55.166279       1 static_autoscaler.go:138] Starting main loop
I0926 23:15:55.166293       1 static_autoscaler.go:294] Filtering out schedulables
I0926 23:15:55.166330       1 static_autoscaler.go:311] No schedulable pods
I0926 23:15:55.166338       1 static_autoscaler.go:319] No unschedulable pods
I0926 23:15:55.166345       1 static_autoscaler.go:366] Calculating unneeded nodes
I0926 23:15:55.166357       1 utils.go:552] Skipping ip-192-168-3-111.region-code.compute.internal - node group min size reached
I0926 23:15:55.166365       1 utils.go:552] Skipping ip-192-168-71-83.region-code.compute.internal - node group min size reached
I0926 23:15:55.166435       1 static_autoscaler.go:393] Scale down status: unneededOnly=false lastScaleUpTime=2019-09-26 21:42:40.908059094 ...
I0926 23:15:55.166458       1 static_autoscaler.go:403] Starting scale down
I0926 23:15:55.166488       1 scale_down.go:706] No candidates for scale down
```

Deployment considerations

Review the following considerations to optimize your Cluster Autoscaler deployment.

Scaling considerations

The Cluster Autoscaler can be configured to include any additional features of your nodes. These features can include Amazon EBS volumes attached to nodes, Amazon EC2 instance types of nodes, or GPU accelerators.

Scope node groups across more than one Availability Zone

We recommend that you configure multiple node groups, scope each group to a single Availability Zone, and enable the `--balance-similar-node-groups` feature. If you only create one node group, scope that node group to span over more than one Availability Zone.

When setting `--balance-similar-node-groups` to true, make sure that the node groups you want the Cluster Autoscaler to balance have matching labels (except for automatically added zone labels). You can pass a `--balancing-ignore-label` flag to nodes with different labels to balance them regardless, but this should only be done as needed.

Optimize your node groups

The Cluster Autoscaler makes assumptions about how you’re using node groups. This includes which instance types that you use within a group. To align with these assumptions, configure your node group based on these considerations and recommendations:

- Each node in a node group must have identical scheduling properties. This includes labels, taints, and resources.
  - For `MixedInstancePolicies`, the instance types must have compatible CPU, memory, and GPU specifications.
  - The first instance type that's specified in the policy simulates scheduling.
  - If your policy has additional instance types with more resources, resources might be wasted after scale out.
  - If your policy has additional instance types with fewer resources than the original instance types, pods might fail to schedule on the instances.
• Configure a smaller number of node groups with a larger number of nodes because the opposite configuration can negatively affect scalability.

• Use Amazon EC2 features whenever both systems provide support them (for example, use Regions and MixedInstancePolicy.)

If possible, we recommend that you use Managed node groups (p. 97). Managed node groups come with powerful management features. These include features for Cluster Autoscaler such as automatic Amazon EC2 Auto Scaling group discovery and graceful node termination.

**Use EBS volumes as persistent storage**

Persistent storage is critical for building stateful applications, such as databases and distributed caches. With Amazon EBS volumes, you can build stateful applications on Kubernetes. However, you're limited to only building them within a single Availability Zone. For more information, see How do I use persistent storage in Amazon EKS?. For a better solution, consider building stateful applications that are sharded across more than one Availability Zone using a separate Amazon EBS volume for each Availability Zone. Doing so means that your application can be highly available. Moreover, the Cluster Autoscaler can balance the scaling of the Amazon EC2 Auto Scaling groups. To do this, make sure that the following conditions are met:

• Node group balancing is enabled by setting `balance-similar-node-groups=true`.

• Your node groups are configured with identical settings (outside of being in more than one Availability Zone and using different Amazon EBS volumes).

**Co-scheduling**

Machine learning distributed training jobs benefit significantly from the minimized latency of same-zone node configurations. These workloads deploy multiple pods to a specific zone. You can achieve this by setting pod affinity for all co-scheduled pods or node affinity using `topologyKey: topology.kubernetes.io/zone`. Using this configuration, the Cluster Autoscaler scales out a specific zone to match demands. Allocate multiple Amazon EC2 Auto Scaling groups, with one for each Availability Zone, to enable failover for the entire co-scheduled workload. Make sure that the following conditions are met:

• Node group balancing is enabled by setting `balance-similar-node-groups=true`.

• **Node affinity, pod preemption**, or both, are used when clusters include both Regional and Zonal node groups.
  • Use **Node Affinity** to force or encourage regional pods and avoid zonal node groups.
  • Don't schedule zonal pods onto Regional node groups. Doing so can result in imbalanced capacity for your Regional pods.
  • Configure **pod preemption** if your zonal workloads can tolerate disruption and relocation. Doing so enforces preemption and rescheduling on a less contested zone for your Regionally scaled pods.

**Accelerators and GPUs**

Some clusters use specialized hardware accelerators such as a dedicated GPU. When scaling out, the accelerator can take several minutes to advertise the resource to the cluster. During this time, the Cluster Autoscaler simulates that this node has the accelerator. However, until the accelerator becomes ready and updates the available resources of the node, pending pods can't be scheduled on the node. This can result in repeated unnecessary scale out.

Nodes with accelerators and high CPU or memory utilization aren't considered for scale down even if the accelerator is unused. However, this can be result in unnecessary costs. To avoid these costs, the Cluster Autoscaler can apply special rules to consider nodes for scale down if they have unoccupied accelerators.
To ensure the correct behavior for these cases, configure the kubelet on your accelerator nodes to label the node before it joins the cluster. The Cluster Autoscaler uses this label selector to invoke the accelerator optimized behavior. Make sure that the following conditions are met:

- The kubelet for GPU nodes is configured with --node-labels k8s.amazonaws.com/accelerator=ACCELERATOR_TYPE.
- Nodes with accelerators adhere to the identical scheduling properties rule.

**Scaling from zero**

Cluster Autoscaler can scale node groups to and from zero. This might result in a significant cost savings. The Cluster Autoscaler detects the CPU, memory, and GPU resources of an Auto Scaling group by inspecting the InstanceType that is specified in its LaunchConfiguration or LaunchTemplate. Some pods require additional resources such as WindowsENI or PrivateIPv4Address. Or they might require specific NodeSelectors or Taints. These latter two can't be discovered from the LaunchConfiguration. However, the Cluster Autoscaler can account for these factors by discovering them from the following tags on the Auto Scaling group.

| Key: k8s.io/cluster-autoscaler/node-template/resources/$RESOURCE_NAME |
| Value: 5 |
| Key: k8s.io/cluster-autoscaler/node-template/label/$LABEL_KEY |
| Value: $LABEL_VALUE |
| Key: k8s.io/cluster-autoscaler/node-template/taint/$TAINT_KEY |
| Value: NoSchedule |

**Note**

- When scaling to zero, your capacity is returned to Amazon EC2 and might become unavailable in the future.
- You can use describeNodegroup to diagnose issues with managed node groups when scaling to and from zero.

**Additional configuration parameters**

There are many configuration options that can be used to tune the behavior and performance of the Cluster Autoscaler. For a complete list of parameters, see What are the parameters to CA? on GitHub.

**Performance considerations**

There are a few key items that you can change to tune the performance and scalability of the Cluster Autoscaler. The primary ones are any resources that are provided to the process, the scan interval of the algorithm, and the number of node groups in the cluster. However, there are also several other factors that are involved in the true runtime complexity of this algorithm. These include the scheduling plugin complexity and the number of pods. These are considered to be unconfigurable parameters because they're integral to the workload of the cluster and can't easily be tuned.

*Scalability* refers to how well the Cluster Autoscaler performs as the number of pods and nodes in your Kubernetes cluster increases. If its scalability quotas are reached, the performance and functionality of the Cluster Autoscaler degrades. Additionally, when it exceeds its scalability quotas, the Cluster Autoscaler can no longer add or remove nodes in your cluster.

*Performance* refers to how quickly the Cluster Autoscaler can make and implement scaling decisions. A perfectly performing Cluster Autoscaler instantly make decisions and invoke scaling actions in response to specific conditions, such as a pod becoming unschedulable.

Be familiar with the runtime complexity of the autoscaling algorithm. Doing so makes it easier to tune the Cluster Autoscaler to operate well in large clusters (with more than 1,000 nodes).
The Cluster Autoscaler loads the state of the entire cluster into memory. This includes the pods, nodes, and node groups. On each scan interval, the algorithm identifies unschedulable pods and simulates scheduling for each node group. Know that tuning these factors in different ways comes with different tradeoffs.

**Vertical autoscaling**

You can scale the Cluster Autoscaler to larger clusters by increasing the resource requests for its deployment. This is one of the simpler methods to do this. Increase both the memory and CPU for the large clusters. Know that how much you should increase the memory and CPU depends greatly on the specific cluster size. The autoscaling algorithm stores all pods and nodes in memory. This can result in a memory footprint larger than a gigabyte in some cases. You usually need to increase resources manually. If you find that you often need to manually increase resources, consider using the Addon Resizer or Vertical Pod Autoscaler to automate the process.

**Reducing the number of node groups**

You can lower the number of node groups to improve the performance of the Cluster Autoscaler in large clusters. If you structured your node groups on an individual team or application basis, this might be challenging. Even though this is fully supported by the Kubernetes API, this is considered to be a Cluster Autoscaler anti-pattern with repercussions for scalability. There are many advantages to using multiple node groups that, for example, use both Spot or GPU instances. In many cases, there are alternative designs that achieve the same effect while using a small number of groups. Make sure that the following conditions are met:

- Isolate pods by using namespaces rather than node groups.
- You might not be able to do this in low-trust multi-tenant clusters.
- Set pod ResourceRequests and ResourceLimits properly to avoid resource contention.
- Use larger instance types for more optimal bin packing and reduced system pod overhead.
- Avoid using NodeTaints or NodeSelectors to schedule pods. Only use them on a limited basis.
- Define Regional resources as a single Amazon EC2 Auto Scaling group with more than one Availability Zone.

**Reducing the scan interval**

Using a low scan interval, such as the default setting of ten seconds, ensures that the Cluster Autoscaler responds as quickly as possible when pods become unschedulable. However, each scan results in many API calls to the Kubernetes API and Amazon EC2 Auto Scaling group or the Amazon EKS managed node group APIs. These API calls can result in rate limiting or even service unavailability for your Kubernetes control plane.

The default scan interval is ten seconds, but on AWS, launching a node takes significantly longer to launch a new instance. This means that it’s possible to increase the interval without significantly increasing overall scale up time. For example, if it takes two minutes to launch a node, don't change the interval to one minute because this might result in a trade-off of 6x reduced API calls for 38% slower scale ups.

**Sharing across node groups**

You can configure the Cluster Autoscaler to operate on a specific set of node groups. By using this functionality, you can deploy multiple instances of the Cluster Autoscaler. Configure each instance to operate on a different set of node groups. By doing this, you can use arbitrarily large numbers of node groups, trading cost for scalability. However, we only recommend that you do this as last resort for improving the performance of Cluster Autoscaler.

This configuration has its drawbacks. It can result in unnecessary scale out of multiple node groups. The extra nodes scale back in after the scale-down-delay.
Make sure that the following conditions are true.

- Each shard is configured to point to a unique set of Amazon EC2 Auto Scaling groups.
- Each shard is deployed to a separate namespace to avoid leader election conflicts.

**Cost efficiency and availability**

The primary options for tuning the cost efficiency of the Cluster Autoscaler are related to provisioning Amazon EC2 instances. Additionally, cost efficiency must be balanced with availability. This section describes strategies such as using Spot instances to reduce costs and overprovisioning to reduce latency when creating new nodes.

- **Availability** – Pods can be scheduled quickly and without disruption. This is true even for when newly created pods need to be scheduled and for when a scaled down node terminates any remaining pods scheduled to it.
- **Cost** – Determined by the decision behind scale-out and scale-in events. Resources are wasted if an existing node is underutilized or if a new node is added that is too large for incoming pods. Depending on the specific use case, there can be costs that are associated with prematurely terminating pods due to an aggressive scale down decision.

**Spot instances**

You can use Spot Instances in your node groups to save up to 90% off the on-demand price. This has the trade-off of Spot Instances possibly being interrupted at any time when Amazon EC2 needs the capacity back. **Insufficient Capacity Errors** occur whenever your Amazon EC2 Auto Scaling group can't scale up due to a lack of available capacity. Selecting many different instance families has two main benefits. First, it can increase your chance of achieving your desired scale by tapping into many Spot capacity pools. Second, it also can decrease the impact of Spot Instance interruptions on cluster availability. Mixed Instance Policies with Spot Instances are a great way to increase diversity without increasing the number of node groups. However, know that, if you need guaranteed resources, use On-Demand Instances instead of Spot Instances.

Spot instances might be terminated when demand for instances rises. For more information, see the Spot Instance Interruptions section of the Amazon EC2 User Guide for Linux Instances. The AWS Node Termination Handler project automatically alerts the Kubernetes control plane when a node is going down. The project uses the Kubernetes API to cordon the node to ensure that no new work is scheduled there, then drains it and removes any existing work.
It’s critical that all instance types have similar resource capacity when configuring Mixed instance policies. The scheduling simulator of the autoscaler uses the first instance type in the Mixed Instance Policy. If subsequent instance types are larger, resources might be wasted after a scale up. If the instances are smaller, your pods may fail to schedule on the new instances due to insufficient capacity. For example, M4, M5, M5a, and M5n instances all have similar amounts of CPU and memory and are great candidates for a Mixed Instance Policy. The Amazon EC2 Instance Selector tool can help you identify similar instance types or additional critical criteria, such as size. For more information, see Amazon EC2 Instance Selector on GitHub.

We recommend that you isolate your On-Demand and Spot instances capacity into separate Amazon EC2 Auto Scaling groups. We recommend this over using a base capacity strategy because the scheduling properties of On-Demand and Spot instances are different. Spot Instances can be interrupted at any time. When Amazon EC2 needs the capacity back, preemptive nodes are often tainted, thus requiring an explicit pod tolerance to the preemption behavior. This results in different scheduling properties for the nodes, so they should be separated into multiple Amazon EC2 Auto Scaling groups.

The Cluster Autoscaler involves the concept of Expanders. They collectively provide different strategies for selecting which node group to scale. The strategy --expander=least-waste is a good general purpose default, and if you’re going to use multiple node groups for Spot Instance diversification, as described previously, it could help further cost-optimize the node groups by scaling the group that would be best utilized after the scaling activity.

**Prioritizing a node group or Auto Scaling group**

You might also configure priority-based autoscaling by using the Priority expander. --expander=priority enables your cluster to prioritize a node group or Auto Scaling group, and if it is unable to scale for any reason, it will choose the next node group in the prioritized list. This is useful in situations where, for example, you want to use P3 instance types because their GPU provides optimal performance for your workload, but as a second option you can also use P2 instance types. For example:

```yaml
apiVersion: v1
type: ConfigMap
metadata:
  name: cluster-autoscaler-priority-expander
  namespace: kube-system
data:
  priorities: |
    10:
      - .*p2-node-group.*
    50:
      - .*p3-node-group.*
```

Cluster Autoscaler attempts to scale up the Amazon EC2 Auto Scaling group matching the name p3-node-group. If this operation doesn’t succeed within --max-node-provision-time, it then attempts to scale an Amazon EC2 Auto Scaling group matching the name p2-node-group. This value defaults to 15 minutes and can be reduced for more responsive node group selection. However, if the value is too low, unnecessary scaleout might occur.

**Overprovisioning**

The Cluster Autoscaler helps to minimize costs by ensuring that nodes are only added to the cluster when they’re needed and are removed when they’re unused. This significantly impacts deployment latency because many pods must wait for a node to scale up before they can be scheduled. Nodes can take multiple minutes to become available, which can increase pod scheduling latency by an order of magnitude.

This can be mitigated using overprovisioning, which trades cost for scheduling latency. Overprovisioning is implemented using temporary pods with negative priority. These pods occupy space in the cluster. When newly created pods are unschedulable and have a higher priority, the temporary pods are
preempted to make room. Then, the temporary pods become unschedulable, causing the Cluster Autoscaler to scale out new overprovisioned nodes.

There are other benefits to overprovisioning. Without overprovisioning, pods in a highly utilized cluster make less optimal scheduling decisions using the preferredDuringSchedulingIgnoredDuringExecution rule. A common use case for this is to separate pods for a highly available application across Availability Zones using AntiAffinity. Overprovisioning can significantly increase the chance that a node of the desired zone is available.

It's important to choose an appropriate amount of overprovisioned capacity. One way that you can make sure that you choose an appropriate amount is by taking your average scaleup frequency and dividing it by the duration of time it takes to scale up a new node. For example, if, on average, you require a new node every 30 seconds and Amazon EC2 takes 30 seconds to provision a new node, a single node of overprovisioning ensures that there's always an extra node available. Doing this can reduce scheduling latency by 30 seconds at the cost of a single additional Amazon EC2 instance. To make better zonal scheduling decisions, you can also overprovision the number of nodes to be the same as the number of Availability Zones in your Amazon EC2 Auto Scaling group. Doing this ensures that the scheduler can select the best zone for incoming pods.

**Prevent scale down eviction**

Some workloads are expensive to evict. Big data analysis, machine learning tasks, and test runners can take a long time to complete and must be restarted if they’re interrupted. The Cluster Autoscaler helps to scale down any node under the scale-down-utilization-threshold. This interrupts any remaining pods on the node. However, you can prevent this from happening by ensuring that pods that are expensive to evict are protected by a label recognized by the Cluster Autoscaler. To do this, ensure that pods that are expensive to evict have the label `cluster-autoscaler.kubernetes.io/safe-to-evict=false`.

**Karpenter**

Amazon EKS supports the Karpenter open-source autoscaling project. See the Karpenter documentation to deploy it.

**About Karpenter**

Karpenter is a flexible, high-performance Kubernetes cluster autoscaler that helps improve application availability and cluster efficiency. Karpenter launches right-sized compute resources, (for example, Amazon EC2 instances), in response to changing application load in under a minute. Through integrating Kubernetes with AWS, Karpenter can provision just-in-time compute resources that precisely meet the requirements of your workload. Karpenter automatically provisions new compute resources based on the specific requirements of cluster workloads. These include compute, storage, acceleration, and scheduling requirements. Amazon EKS supports clusters using Karpenter, although Karpenter works with any conformant Kubernetes cluster.

**How Karpenter works**

Karpenter works in tandem with the Kubernetes scheduler by observing incoming pods over the lifetime of the cluster. It launches or terminates nodes to maximize application availability and cluster utilization. When there is enough capacity in the cluster, the Kubernetes scheduler will place incoming pods as usual. When pods are launched that cannot be scheduled using the existing capacity of the cluster, Karpenter bypasses the Kubernetes scheduler and works directly with your provider’s compute service, (for example, Amazon EC2), to launch the minimal compute resources needed to fit those pods and binds the pods to the nodes provisioned. As pods are removed or rescheduled to other nodes, Karpenter looks for opportunities to terminate under-utilized nodes. Running fewer, larger nodes in your cluster reduces overhead from daemonsets and Kubernetes system components and provides more opportunities for efficient bin-packing.
Prerequisites

Before deploying Karpenter, you must meet the following prerequisites:

- An existing Amazon EKS cluster – If you don't have a cluster, see Creating an Amazon EKS cluster (p. 24).
- An existing IAM OIDC provider for your cluster. To determine whether you have one or need to create one, see Creating an IAM OIDC provider for your cluster (p. 426).
- A user or role with permission to create a cluster.
- AWS CLI
  - Installing or updating kubectl (p. 4)
  - Using Helm with Amazon EKS (p. 411)

You can deploy Karpenter using eksctl if you prefer. See Installing or updating eksctl (p. 10).
Amazon EKS nodes

Your Amazon EKS cluster can schedule pods on any combination of Self-managed nodes (p. 121), Amazon EKS Managed node groups (p. 97), and AWS Fargate (p. 142). To learn more about nodes deployed in your cluster, see View Kubernetes resources (p. 500).

**Note**
Nodes must be in the same VPC as the subnets you selected when you created the cluster. However, the nodes don’t have to be in the same subnets.

The following table provides several criteria to evaluate when deciding which options best meet your requirements. This table doesn't include connected nodes (p. 540) that were created outside of Amazon EKS, which can only be viewed.

**Note**
Bottlerocket has some specific differences from the general information in this table. For more information, see the Bottlerocket documentation on GitHub.

### Managed node groups

Amazon EKS managed node groups automate the provisioning and lifecycle management of nodes (Amazon EC2 instances) for Amazon EKS Kubernetes clusters.

With Amazon EKS managed node groups, you don't need to separately provision or register the Amazon EC2 instances that provide compute capacity to run your Kubernetes applications. You can create, automatically update, or terminate nodes for your cluster with a single operation. Node updates and terminations automatically drain nodes to ensure that your applications stay available.

Every managed node is provisioned as part of an Amazon EC2 Auto Scaling group that's managed for you by Amazon EKS. Every resource including the instances and Auto Scaling groups runs within your AWS account. Each node group runs across multiple Availability Zones that you define.

You can add a managed node group to new or existing clusters using the Amazon EKS console, `eksctl`, AWS CLI; AWS API, or infrastructure as code tools including AWS CloudFormation. Nodes launched as part of a managed node group are automatically tagged for auto-discovery by the Kubernetes cluster.

</tbody>
</table>
autoscaler. You can use the node group to apply Kubernetes labels to nodes and update them at any
time.

There are no additional costs to use Amazon EKS managed node groups, you only pay for the AWS
resources you provision. These include Amazon EC2 instances, Amazon EBS volumes, Amazon EKS cluster
hours, and any other AWS infrastructure. There are no minimum fees and no upfront commitments.

To get started with a new Amazon EKS cluster and managed node group, see Getting started with
Amazon EKS – AWS Management Console and AWS CLI (p. 15).

To add a managed node group to an existing cluster, see Creating a managed node group (p. 101).

Managed node groups concepts

• Amazon EKS managed node groups create and manage Amazon EC2 instances for you.
• Every managed node is provisioned as part of an Amazon EC2 Auto Scaling group that's managed
  for you by Amazon EKS. Moreover, every resource including Amazon EC2 instances and Auto Scaling
groups run within your AWS account.
• The Auto Scaling group of a managed node group spans every subnet that you specify when you
  create the group.
• Amazon EKS tags managed node group resources so that they are configured to use the Kubernetes
  Cluster Autoscaler (p. 81).

  Important
  If you are running a stateful application across multiple Availability Zones that is backed
  by Amazon EBS volumes and using the Kubernetes Cluster Autoscaler (p. 81), you should
  configure multiple node groups, each scoped to a single Availability Zone. In addition, you
  should enable the --balance-similar-node-groups feature.

• You can use a custom launch template for a greater level of flexibility and customization when
  deploying managed nodes. If you deploy using a launch template, you can also use a custom AMI.
  For more information, see Launch template support (p. 113). If you don't use a custom launch
  template when first creating a managed node group, there is an auto-generated launch template.
  Don't manually modify this auto-generated template or errors occur.
• Amazon EKS follows the shared responsibility model for CVEs and security patches on managed
  node groups. When managed nodes run an Amazon EKS optimized AMI, Amazon EKS is responsible
  for building patched versions of the AMI when bugs or issues are reported. We can publish a fix.
  However, you're responsible for deploying these patched AMI versions to your managed node groups.
  When managed nodes run a custom AMI, you're responsible for building patched versions of the AMI
  when bugs or issues are reported and then deploying the AMI. For more information, see Updating a
  managed node group (p. 107).
• Amazon EKS managed node groups can be launched in both public and private subnets. If you
  launch a managed node group in a public subnet on or after April 22, 2020, the subnet must have
  MapPublicIpOnLaunch set to true for the instances to successfully join a cluster. If the public subnet
  was created using eksctl or the Amazon EKS vended AWS CloudFormation templates (p. 241) on
  or after March 26, 2020, then this setting is already set to true. If the public subnets were created
  before March 26, 2020, you must change the setting manually. For more information, see Modifying
  the public IPv4 addressing attribute for your subnet.
• When using VPC endpoints in private subnets, you must create endpoints for
  com.amazonaws.region.ecr.api, com.amazonaws.region.ecr.dkr, and a gateway endpoint
  for Amazon S3. For more information, see Amazon ECR interface VPC endpoints (AWS PrivateLink).
• Managed node groups can't be deployed on AWS Outposts (p. 547) or in AWS Wavelength or AWS
  Local Zones.
• You can create multiple managed node groups within a single cluster. For example, you can create one
  node group with the standard Amazon EKS optimized Amazon Linux 2 AMI for some workloads and
  another with the GPU variant for workloads that require GPU support.
• If your managed node group encounters an Amazon EC2 instance status check failure, Amazon EKS returns an error message to help you to diagnose the issue. For more information, see Managed node group errors (p. 523).

• Amazon EKS adds Kubernetes labels to managed node group instances. These Amazon EKS provided labels are prefixed with eks.amazonaws.com.

• Amazon EKS automatically drains nodes using the Kubernetes API during terminations or updates. Updates respect the pod disruption budgets that you set for your pods.

• There are no additional costs to use Amazon EKS managed node groups. You only pay for the AWS resources that you provision.

• If you want to encrypt Amazon EBS volumes for your nodes, you can deploy the nodes using a launch template. To deploy managed nodes with encrypted Amazon EBS volumes without using a launch template, encrypt all new Amazon EBS volumes created in your account. For more information, see Encryption by default in the Amazon EC2 User Guide for Linux Instances.

Managed node group capacity types

When creating a managed node group, you can choose either the On-Demand or Spot capacity type. Amazon EKS deploys a managed node group with an Amazon EC2 Auto Scaling group that either contains only On-Demand or only Amazon EC2 Spot Instances. You can schedule pods for fault tolerant applications to Spot managed node groups, and fault intolerant applications to On-Demand node groups within a single Kubernetes cluster. By default, a managed node group deploys On-Demand Amazon EC2 instances.

On-Demand

With On-Demand Instances, you pay for compute capacity by the second, with no long-term commitments.

How it works

By default, if you don’t specify a Capacity Type, the managed node group is provisioned with On-Demand Instances. A managed node group configures an Amazon EC2 Auto Scaling group on your behalf with the following settings applied:

• The allocation strategy to provision On-Demand capacity is set to prioritized. Managed node groups use the order of instance types passed in the API to determine which instance type to use first when fulfilling On-Demand capacity. For example, you might specify three instance types in the following order: c5.large, c4.large, and c3.large. When your On-Demand Instances are launched, the managed node group fulfills On-Demand capacity by starting with c5.large, then c4.large, and then c3.large. For more information, see Amazon EC2 Auto Scaling group in the Amazon EC2 Auto Scaling User Guide.

• Amazon EKS adds the following Kubernetes label to all nodes in your managed node group that specifies the capacity type: eks.amazonaws.com/capacityType: ON_DEMAND. You can use this label to schedule stateful or fault intolerant applications on On-Demand nodes.

Spot

Amazon EC2 Spot Instances are spare Amazon EC2 capacity that offers steep discounts off of On-Demand prices. Amazon EC2 Spot Instances can be interrupted with a two-minute interruption notice when EC2 needs the capacity back. For more information, see Spot Instances in the Amazon EC2 User Guide for Linux Instances. You can configure a managed node group with Amazon EC2 Spot Instances to optimize costs for the compute nodes running in your Amazon EKS cluster.
How it works

To use Spot Instances inside a managed node group, create a managed node group by setting the capacity type as `spot`. A managed node group configures an Amazon EC2 Auto Scaling group on your behalf with the following Spot best practices applied:

- The allocation strategy to provision Spot capacity is set to `capacity-optimized` to ensure that your Spot nodes are provisioned in the optimal Spot capacity pools. To increase the number of Spot capacity pools available for allocating capacity from, configure a managed node group to use multiple instance types.
- Amazon EC2 Spot Capacity Rebalancing is enabled so that Amazon EKS can gracefully drain and rebalance your Spot nodes to minimize application disruption when a Spot node is at elevated risk of interruption. For more information, see Amazon EC2 Auto Scaling Capacity Rebalancing in the Amazon EC2 Auto Scaling User Guide.
  - When a Spot node receives a rebalance recommendation, Amazon EKS automatically attempts to launch a new replacement Spot node and waits until it successfully joins the cluster.
  - When a replacement Spot node is bootstrapped and in the `Ready` state on Kubernetes, Amazon EKS cordons and drains the Spot node that received the rebalance recommendation. Cordonning the Spot node ensures that the service controller doesn't send any new requests to this Spot node. It also removes it from its list of healthy, active Spot nodes. Draining the Spot node ensures that running pods are evicted gracefully.
  - If a Spot two-minute interruption notice arrives before the replacement Spot node is in a `Ready` state, Amazon EKS starts draining the Spot node that received the rebalance recommendation.
- Amazon EKS adds the following Kubernetes label to all nodes in your managed node group that specifies the capacity type: `eks.amazonaws.com/capacityType: SPOT`. You can use this label to schedule fault tolerant applications on Spot nodes.

Considerations for selecting a capacity type

When deciding whether to deploy a node group with On-Demand or Spot capacity, you should consider the following conditions:

- Spot Instances are a good fit for stateless, fault-tolerant, flexible applications. These include batch and machine learning training workloads, big data ETLs such as Apache Spark, queue processing applications, and stateless API endpoints. Because Spot is spare Amazon EC2 capacity, which can change over time, we recommend that you use Spot capacity for interruption-tolerant workloads. More specifically, Spot capacity is suitable for workloads that can tolerate periods where the required capacity isn't available.
- We recommend that you use On-Demand for applications that are fault intolerant. This includes cluster management tools such as monitoring and operational tools, deployments that require StatefulSets, and stateful applications, such as databases.
- To maximize the availability of your applications while using Spot Instances, we recommend that you configure a Spot managed node group to use multiple instance types. We recommend applying the following rules when using multiple instance types:
  - Within a managed node group, if you're using the Cluster Autoscaler (p. 81), we recommend using a flexible set of instance types with the same amount of vCPU and memory resources. This is to ensure that the nodes in your cluster scale as expected. For example, if you need four vCPUs and eight GiB memory, use `c3.xlarge`, `c4.xlarge`, `c5.xlarge`, `c5d.xlarge`, `c5a.xlarge`, `c5n.xlarge`, or other similar instance types.
  - To enhance application availability, we recommend deploying multiple Spot managed node groups. For this, each group should use a flexible set of instance types that have the same vCPU and memory resources. For example, if you need 4 vCPUs and 8 GiB memory, we recommend that you create one managed node group with `c3.xlarge`, `c4.xlarge`, `c5.xlarge`, `c5d.xlarge`, `c5a.xlarge`, `c5n.xlarge`, or other similar instance types, and a second managed node group with
m3.xlarge, m4.xlarge, m5.xlarge, m5d.xlarge, m5a.xlarge, m5n.xlarge or other similar instance types.

- When deploying your node group with the Spot capacity type that's using a custom launch template, use the API to pass multiple instance types. Don't pass a single instance type through the launch template. For more information about deploying a node group using a launch template, see Launch template support (p. 113).

Creating a managed node group

This topic describes how you can launch Amazon EKS managed node groups of nodes that register with your Amazon EKS cluster. After the nodes join the cluster, you can deploy Kubernetes applications to them.

If this is your first time launching an Amazon EKS managed node group, we recommend that you follow one of our Getting started with Amazon EKS (p. 4) guides instead. The guides provide walkthroughs for creating an Amazon EKS cluster with nodes.

Important

- Amazon EKS nodes are standard Amazon EC2 instances. You’re billed based on the normal Amazon EC2 prices. For more information, see Amazon EC2 Pricing.

- You can't create managed nodes in an AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled. You can create self-managed nodes in an AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled. For more information, see Launching self-managed Amazon Linux nodes (p. 122), Launching self-managed Windows nodes (p. 129), and Launching self-managed Bottlerocket nodes (p. 127). You can also create a self-managed Amazon Linux node group on an Outpost. For more information, see the section called “Launching nodes” (p. 567).

Prerequisites

- An existing Amazon EKS cluster. To deploy one, see Creating an Amazon EKS cluster (p. 24).

- (Optional, but recommended) The Amazon VPC CNI plugin for Kubernetes add-on configured with its own IAM role that has the necessary IAM policy attached to it. For more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).

- Familiarity with the considerations listed in Choosing an Amazon EC2 instance type (p. 162). Depending on the instance type you choose, there may be additional prerequisites for your cluster and VPC.

You can create a managed node group with eksctl or the AWS Management Console.

eksctl

To create a managed node group with eksctl

This procedure requires eksctl version 0.112.0 or later. You can check your version with the following command:

```
eksctl version
```

For instructions on how to install or upgrade eksctl, see Installing or updating eksctl (p. 10).

1. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy is attached to your the section called “Node IAM role” (p. 461), we recommend assigning it to an IAM role that you associate
to the Kubernetes `aws-node` service account instead. For more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).

2. Create a managed node group with or without using a custom launch template. Manually specifying a launch template allows for greater customization of a node group. For example, it can allow deploying a custom AMI or providing arguments to the `bootstrap.sh` script in an Amazon EKS optimized AMI. For a complete list of every available option and default, enter the following command.

```bash
eksctl create nodegroup --help
```

In the following command, replace `my-cluster` with the name of your cluster and replace `my-mng` with the name of your node group. The names can contain only alphanumeric characters (case-sensitive) and hyphens. The names must start with an alphabetic character and can't be longer than 100 characters. Replace the rest of the example values with your own values.

**Important**

If you don't use a custom launch template when first creating a managed node group, don't use one at a later time for the node group. If you didn't specify a custom launch template, the system auto-generates a launch template that we don't recommend that you modify manually. Manually modifying this auto-generated launch template might cause errors.

- **Without a launch template** – `eksctl` creates a default Amazon EC2 launch template in your account and deploys the node group using a launch template that it creates based on options that you specify. Before specifying a value for `--node-type`, see Choosing an Amazon EC2 instance type (p. 162).

Replace `my-key` with the name of your Amazon EC2 key pair or public key. This key is used to SSH into your nodes after they launch. If you don't already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 key pairs in the Amazon EC2 User Guide for Linux Instances.

We recommend blocking pod access to IMDS if the following conditions are true:

- You plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need.
- No pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region.

For more information, see Restrict access to the instance profile assigned to the worker node.

If you want to block pod access to IMDS, then add the `--disable-pod-imds` option to the following command.

```bash
eksctl create nodegroup \
--cluster my-cluster \
--region region-code \
--name my-mng \
--node-type m5.large \
--nodes 3 \
--nodes-min 2 \
--nodes-max 4 \
--ssh-access \
--ssh-public-key my-key
```

Your instances can optionally assign a significantly higher number of IP addresses to pods, assign IP addresses to pods from a different CIDR block than the instance's, and be deployed to a cluster without internet access. For more information, see Increase the
amount of available IP addresses for your Amazon EC2 nodes (p. 289), Tutorial: Custom networking (p. 276), and Private cluster requirements (p. 63) for additional options to add to the previous command.

Managed node groups calculates and applies a single value for the maximum number of pods that can run on each node of your node group, based on instance type. If you create a node group with different instance types, the smallest value calculated across all instance types is applied as the maximum number of pods that can run on every instance type in the node group. Managed node groups calculates the value using the script referenced in Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 163).

• **With a launch template** – The launch template must already exist and must meet the requirements specified in Launch template configuration basics (p. 113).

We recommend blocking pod access to IMDS if the following conditions are true:

• You plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need.

• No pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region.

For more information, see Restrict access to the instance profile assigned to the worker node.

If you want to block pod access to IMDS, then specify the necessary settings in the launch template.

a. Copy the following contents to your device. Replace the example values and then run the modified command to create the **eks-nodegroup.yaml** file. Several settings that you specify when deploying without a launch template are moved into the launch template. If you don't specify a version, the template's default version is used.

```yaml
cat >eks-nodegroup.yaml <<EOF
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: my-cluster
  region: region-code
managedNodeGroups:
- name: my-mng
  launchTemplate:
    id: lt-id
    version: "1"
EOF
```

For a complete list of **eksctl** config file settings, see Config file schema in the eksctl documentation. Your instances can optionally assign a significantly higher number of IP addresses to pods, assign IP addresses to pods from a different CIDR block than the instance’s, use the containerd runtime, and be deployed to a cluster without outbound internet access. For more information, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 289), Tutorial: Custom networking (p. 276), Enable the containerd runtime bootstrap flag (p. 174), and Private cluster requirements (p. 63) for additional options to add to the config file.

If you didn't specify an AMI ID in your launch template, managed node groups calculates and applies a single value for the maximum number of pods that can run on each node of your node group, based on instance type. If you create a node group with different instance types, the smallest value calculated across all instance types is applied as the maximum number of pods that can run on every instance type in the node group. Managed node groups calculates the value using the script referenced in Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 163).
If you specified an AMI ID in your launch template, specify the maximum number of pods that can run on each node of your node group if you're using custom networking (p. 276) or want to increase the number of IP addresses assigned to your instance (p. 289). For more information, see Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 163).

b. Deploy the nodegroup with the following command.

```
eksctl create nodegroup --config-file eks-nodegroup.yaml
```

AWS Management Console

To create a managed node group using the AWS Management Console

1. Wait for your cluster status to show as ACTIVE. You can't create a managed node group for a cluster that isn't already ACTIVE.
2. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
3. Choose the name of the cluster that you want to create a managed node group in.
4. Select the Compute tab.
5. Choose Add node group.
6. On the Configure node group page, fill out the parameters accordingly, and then choose Next.

   • **Name** – Enter a unique name for your managed node group. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters.
   
   • **Node IAM role** – Choose the node instance role to use with your node group. For more information, see Amazon EKS node IAM role (p. 461).

     Important

     • You can't use the same role that is used to create any clusters.
     
     • We recommend using a role that's not currently in use by any self-managed node group. Otherwise, you plan to use with a new self-managed node group. For more information, see Deleting a managed node group (p. 120).

   • **Use launch template** – (Optional) Choose if you want to use an existing launch template. Select a Launch Template Name. Then, select a Launch template version. If you don't select a version, then Amazon EKS uses the template's default version. Launch templates allow for more customization of your node group, such as allowing you to deploy a custom AMI, assign a significantly higher number of IP addresses to pods, assign IP addresses to pods from a different CIDR block than the instance's, enable the containerd runtime for your instances, and deploying nodes to a cluster without outbound internet access. For more information, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 289), Tutorial: Custom networking (p. 276), Enable the containerd runtime bootstrap flag (p. 174), and Private cluster requirements (p. 63).

     The launch template must meet the requirements in Launch template support (p. 113).

     If you don't use your own launch template, the Amazon EKS API creates a default Amazon EC2 launch template in your account and deploys the node group using the default launch template.

     If you implement IAM roles for service accounts (p. 425), assign necessary permissions directly to every pod that requires access to AWS services, and no pods in your cluster require access to IMDS for other reasons, such as retrieving the current AWS Region, then you can also disable access to IMDS for pods that don't use host networking in a launch template. For more information, see Restrict access to the instance profile assigned to the worker node.
• **Kubernetes labels** – (Optional) You can choose to apply Kubernetes labels to the nodes in your managed node group.

• **Kubernetes taints** – (Optional) You can choose to apply Kubernetes taints to the nodes in your managed node group. The available options in the Effect menu are NoSchedule, NoExecute, and PreferNoSchedule.

• **Tags** – (Optional) You can choose to tag your Amazon EKS managed node group. These tags don't propagate to other resources in the node group, such as Auto Scaling groups or instances. For more information, see Tagging your Amazon EKS resources (p. 412).

• **node group update configuration** – (Optional) You can select the number or percentage of nodes to be updated in parallel. Select either **Number** or **Percentage** to enter a value. These nodes won't be available during the update.

7. On the **Set compute and scaling configuration** page, fill out the parameters accordingly, and then choose **Next**.

• **AMI type** – Choose **Amazon Linux 2 (AL2_x86_64)** for Linux non-GPU instances, **Amazon Linux 2 GPU Enabled (AL2_x86_64_GPU)** for Linux GPU instances, **Amazon Linux 2 Arm (AL2_ARM_64)** for Linux Arm instances, **Bottlerocket (BOTTLEROCKET_x86_64)** for Bottlerocket x86_64 instances, or **Bottlerocket Arm (BOTTLEROCKET_ARM_64)** for Bottlerocket Arm instances.

If you are deploying Arm instances, be sure to review the considerations in Amazon EKS optimized Arm Amazon Linux AMIs (p. 176) before deploying.

If you specified a launch template on the previous page, and specified an AMI in the launch template, then you can't select a value. The value from the template is displayed. The AMI specified in the template must meet the requirements in Specifying an AMI (p. 117).

• **Capacity type** – Select a capacity type. For more information about choosing a capacity type, see Managed node group capacity types (p. 99). You can't mix different capacity types within the same node group. If you want to use both capacity types, create separate node groups, each with their own capacity and instance types.

• **Instance types** – By default, one or more instance type is specified. To remove a default instance type, select the X on the right side of the instance type. Choose the instance types to use in your managed node group. For more information, see Choosing an Amazon EC2 instance type (p. 162).

The console displays a set of commonly used instance types. If you need to create a managed node group with an instance type that's not displayed, then use eksctl, the AWS CLI, AWS CloudFormation, or an SDK to create the node group. If you specified a launch template on the previous page, then you can’t select a value because the instance type must be specified in the launch template. The value from the launch template is displayed. If you selected Spot for **Capacity type**, then we recommend specifying multiple instance types to enhance availability.

• **Disk size** – Enter the disk size (in GiB) to use for your node's root volume.

If you specified a launch template on the previous page, then you can't select a value because it must be specified in the launch template.

• **Minimum size** – Specify the minimum number of nodes that the managed node group can scale in to.

• **Maximum size** – Specify the maximum number of nodes that the managed node group can scale out to.

• **Desired size** – Specify the current number of nodes that the managed node group should maintain at launch.
Note
Amazon EKS doesn't automatically scale your node group in or out. However, you can configure the Kubernetes Cluster Autoscaler (p. 81) to do this for you.

- For **Maximum unavailable**, select one of the following options and specify a **Value**:
  - **Number** – Select and specify the number of nodes in your node group that can be updated in parallel. These nodes will be unavailable during update.
  - **Percentage** – Select and specify the percentage of nodes in your node group that can be updated in parallel. These nodes will be unavailable during update. This is useful if you have a large number of nodes in your node group.

8. On the **Specify networking** page, fill out the parameters accordingly, and then choose **Next**.

- **Subnets** – Choose the subnets to launch your managed nodes into.

  **Important**
  If you are running a stateful application across multiple Availability Zones that is backed by Amazon EBS volumes and using the Kubernetes Cluster Autoscaler (p. 81), you should configure multiple node groups, each scoped to a single Availability Zone. In addition, you should enable the `--balance-similar-node-groups` feature.

  **Important**
  - If you choose a public subnet, and your cluster has only the public API server endpoint enabled, then the subnet must have `MapPublicIPOnLaunch` set to `true` for the instances to successfully join a cluster. If the subnet was created using `eksctl` or the Amazon EKS vended AWS CloudFormation templates (p. 241) on or after March 26, 2020, then this setting is already set to `true`. If the subnets were created with `eksctl` or the AWS CloudFormation templates before March 26, 2020, then you need to change the setting manually. For more information, see Modifying the public IPv4 addressing attribute for your subnet.
  - If you use a launch template and specify multiple network interfaces, Amazon EC2 won't auto-assign a public IPv4 address, even if `MapPublicIpOnLaunch` is set to `true`. For nodes to join the cluster in this scenario, you must either enable the cluster's private API server endpoint, or launch nodes in a private subnet with outbound internet access provided through an alternative method, such as a NAT Gateway. For more information, see Amazon EC2 instance IP addressing in the Amazon EC2 User Guide for Linux Instances.

9. On the **Review and create** page, review your managed node group configuration and choose **Create**.
If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 521) in the Troubleshooting guide.

10. Watch the status of your nodes and wait for them to reach the Ready status.

    **kubectl get nodes --watch**

11. (GPU nodes only) If you chose a GPU instance type and the Amazon EKS optimized accelerated AMI, then you must apply the NVIDIA device plugin for Kubernetes as a DaemonSet on your cluster with the following command.

    **kubectl apply -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.9.0/nvidia-device-plugin.yml**

12. (Optional) After you add Linux nodes to your cluster, follow the procedures in Enabling Windows support for your Amazon EKS cluster (p. 54) to add Windows support to your cluster and to add Windows worker nodes. Every Amazon EKS cluster must contain at least one Linux node, even if you only want to run Windows workloads in your cluster.

Now that you have a working Amazon EKS cluster with nodes, you're ready to start installing Kubernetes add-ons and deploying applications to your cluster. The following documentation topics help you to extend the functionality of your cluster.

- The IAM entity (user or role) that created the cluster is the only IAM entity that can make calls to the Kubernetes API server with **kubectl** or the AWS Management Console. If you want other IAM users or roles to have access to your cluster, then you need to add them. For more information, see Enabling IAM user and role access to your cluster (p. 381) and Required permissions (p. 500).

- We recommend blocking pod access to IMDS if the following conditions are true:
  - You plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need.
  - No pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region.

  For more information, see Restrict access to the instance profile assigned to the worker node.

- **Cluster Autoscaler** (p. 81) – Configure the Kubernetes Cluster Autoscaler to automatically adjust the number of nodes in your node groups.

- Deploy a sample application (p. 338) to your cluster.

- **Cluster management** (p. 401) – Learn how to use important tools for managing your cluster.

### Updating a managed node group

When you initiate a managed node group update, Amazon EKS automatically updates your nodes for you, completing the steps listed in Managed node update behavior (p. 110). If you're using an Amazon EKS optimized AMI, Amazon EKS automatically applies the latest security patches and operating system updates to your nodes as part of the latest AMI release version.

There are several scenarios where it's useful to update your Amazon EKS managed node group's version or configuration:

- You have updated the Kubernetes version for your Amazon EKS cluster and want to update your nodes to use the same Kubernetes version.

- A new AMI release version is available for your managed node group. For more information about AMI versions, see these sections:
• Amazon EKS optimized Amazon Linux AMI versions (p. 177)
• Amazon EKS optimized Bottlerocket AMIs (p. 179)
• Amazon EKS optimized Windows AMI versions (p. 196)
• You want to adjust the minimum, maximum, or desired count of the instances in your managed node group.
• You want to add or remove Kubernetes labels from the instances in your managed node group.
• You want to add or remove AWS tags from your managed node group.
• You need to deploy a new version of a launch template with configuration changes, such as an updated custom AMI.
• You have deployed version 1.9.0 or later of the Amazon VPC CNI add-on, enabled the add-on for prefix delegation, and want new AWS Nitro System instances in a node group to support a significantly increased number of pods. For more information, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 289).

If there's a newer AMI release version for your managed node group's Kubernetes version, you can update your node group's version to use the newer AMI version. Similarly, if your cluster is running a Kubernetes version that's newer than your node group, you can update the node group to use the latest AMI release version to match your cluster's Kubernetes version.

When a node in a managed node group is terminated due to a scaling operation or update, the pods in that node are drained first. For more information, see Managed node update behavior (p. 110).

**Update a node group version**

You can update a node group version with `eksctl` or the AWS Management Console. Select the tab with the name of the tool that you want to use to update your node group. The version that you update to can't be greater than the control plane's version.

**eksctl**

To update a node group version with `eksctl`

- Update a managed node group to the latest AMI release of the same Kubernetes version that's currently deployed on the nodes with the following command. Replace every `example value` with your own values.

```bash
eksctl upgrade nodegroup --name=node-group-name --cluster=my-cluster
```

**Note**

If you're upgrading a node group that's deployed with a launch template to a new launch template version, add `--launch-template-version version-number` to the preceding command. The launch template must meet the requirements described in Launch template support (p. 113). If the launch template includes a custom AMI, the AMI must meet the requirements in Specifying an AMI (p. 117). When you upgrade your node group to a newer version of your launch template, every node is recycled to match the new configuration of the launch template version that's specified.

You can't directly upgrade a node group that's deployed without a launch template to a new launch template version. Instead, you must deploy a new node group using the launch template to update the node group to a new launch template version.

You can upgrade a node group to the same version as the control plane's Kubernetes version. For example, if you have a cluster running Kubernetes 1.23, you can upgrade nodes currently running Kubernetes 1.22 to version 1.23 with the following command.
AWS Management Console

To update a node group version with the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster that contains the node group to update.
3. If at least one node group has an available update, a box appears at the top of the page notifying you of the available update. If you select the Compute tab, you'll see Update now in the AMI release version column in the Node Groups table for the node group that has an available update. To update the node group, select Update now. You won't see a notification for node groups that were deployed with a custom AMI. If your nodes are deployed with a custom AMI, complete the following steps to deploy a new updated custom AMI.
   a. Create a new version of your AMI.
   b. Create a new launch template version with the new AMI ID.
   c. Upgrade the nodes to the new version of the launch template.
4. On the Update Node Group version page, select:
   a. Update Node Group version – This option is unavailable if you deployed a custom AMI or your Amazon EKS optimized AMI is currently on the latest version for your cluster.
   b. Launch template version – This option is unavailable if the node group is deployed without a custom launch template. You can only update the launch template version for a node group that has been deployed with a custom launch template. Select the version that you want to update the node group to. If your node group is configured with a custom AMI, then the version that you select must also specify an AMI. When you upgrade to a newer version of your launch template, every node is recycled to match the new configuration of the launch template version specified.
5. For Update strategy, select one of the following options and then choose Update.
   a. Rolling update – This option respects the pod disruption budgets for your cluster. Updates fail if there's a pod disruption budget issue that causes Amazon EKS to be unable to gracefully drain the pods that are running on this node group.
   b. Force update – This option doesn't respect pod disruption budgets. Updates occur regardless of pod disruption budget issues by forcing node restarts to occur.

Edit a node group configuration

You can modify some of the configurations of a managed node group.

To edit a node group configuration

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster that contains the node group to edit.
3. Select the Compute tab.
4. Select the node group to edit, and choose Edit.
5. (Optional) On the Edit node group page, edit the Group configuration.
• **Tags** – Add tags to or remove tags from your node group resource. These tags are only applied to the Amazon EKS node group. They don't propagate to other resources, such as subnets or Amazon EC2 instances in the node group.

• **Kubernetes labels** – Add or remove Kubernetes labels to the nodes in your node group. The labels shown here are only the labels that you have applied with Amazon EKS. Other labels may exist on your nodes that aren't shown here.

• **Kubernetes taints** – Add or remove Kubernetes taints to the nodes in your node group. Added taints can have the effect of either `No_Schedule`, `Prefer_No_Schedule`, or `No_Execute`.

6. (Optional) On the **Edit node group** page, edit the **Group size**.

   • **Minimum size** – Specify the minimum number of nodes that the managed node group can scale in to.

   • **Maximum size** – Specify the maximum number of nodes that the managed node group can scale out to. For the maximum number of nodes supported in a node group, see Amazon EKS service quotas (p. 416).

   • **Desired size** – Specify the current number of nodes that the managed node group should maintain.

7. (Optional) Edit the **Node Group update configuration**. Select either **Number** or **Percentage**.

   • **Number** – Select and specify the number of nodes in your node group that can be updated in parallel. These nodes will be unavailable during update.

   • **Percentage** – Select and specify the percentage of nodes in your node group that can be updated in parallel. These nodes will be unavailable during update. This is useful if you have many nodes in your node group.

8. When you're finished editing, choose **Save changes**.

**Managed node update behavior**

The Amazon EKS managed worker node upgrade strategy has four different phases described in the following sections.

**Setup phase**

The setup phase has these steps:

1. Creates a new Amazon EC2 launch template version for the Auto Scaling group that's associated with your node group. The new launch template version uses the target AMI or customer-provided launch template version for the update.

2. Updates the Auto Scaling group to use the latest launch template version.

3. Determines the maximum quantity of nodes to upgrade in parallel using the `updateConfig` property for the node group. The maximum unavailable has a quota of 100 nodes. The default value is one node. For more information, see the `updateConfig` property in the Amazon EKS API Reference.

**Scale up phase**

When upgrading the nodes in a managed node group, the upgraded nodes are launched in the same Availability Zone as those that are being upgraded. To guarantee this placement, we use Amazon EC2's Availability Zone Rebalancing. For more information, see Availability Zone Rebalancing in the Amazon EC2 Auto Scaling User Guide. To meet this requirement, it's possible that we'd launch up to two instances per Availability Zone in your Managed Node Group.

The scale up phase has these steps:
1. Increments the Auto Scaling Group's maximum size and desired size by the larger of either:
   - Up to twice the number of Availability Zones that the Auto Scaling group is deployed in.
   - The maximum unavailable of upgrade.

   For example, if your node group has five Availability Zones and maxUnavailable as one, the upgrade process can launch a maximum of 10 nodes. However when maxUnavailable is 20 (or anything greater than 10, the process would launch 20 new nodes).

2. After scaling the Auto Scaling Group, it checks if the nodes using the latest configuration are present in the node group. This step succeeds only when it meets these criteria:
   - At least one new node is launched in every Availability Zone where the node exists.
   - Every new node should be in Ready state.
   - New nodes should have Amazon EKS applied labels.

   These are the Amazon EKS applied labels on the worker nodes in a regular node group:
   - eks.amazonaws.com/nodegroup-image=$amiName
   - eks.amazonaws.com/nodegroup=$nodeGroupName

   These are the Amazon EKS applied labels on the worker nodes in a custom launch template or AMI node group:
   - eks.amazonaws.com/nodegroup-image=$amiName
   - eks.amazonaws.com/nodegroup=$nodeGroupName
   - eks.amazonaws.com/sourceLaunchTemplateId=$launchTemplateId
   - eks.amazonaws.com/sourceLaunchTemplateVersion=$launchTemplateVersion

3. Applies an eks.amazonaws.com/nodegroup=unschedulable:NoSchedule taint on every node in the node group without the latest labels. This prevents nodes that have already been updated from a previous failed update from being tainted.

The following are known reasons which lead to a NodeCreationFailure error in this phase:

- **Insufficient capacity in the Availability Zone** – There is a possibility that the Availability Zone might not have capacity of requested instance types. It's recommended to configure multiple instance types while creating a managed node group.

- **Customers hitting EC2 instance limits in their account** – You may need to increase the number of Amazon EC2 instances your account can run simultaneously using Service Quotas. For more information, see EC2 Service Quotas in the Amazon Elastic Compute Cloud User Guide for Linux Instances.

- **Custom user data** – Custom user data can sometimes break the bootstrap process. This scenario can lead to the kubelet not starting on the node or nodes not getting expected Amazon EKS labels on them. For more information on handling custom LT/AMI, see Specifying an AMI (p. 117).

- **Any changes which make a node unhealthy or not ready** – Node disk pressure, memory pressure, and similar conditions can lead to a node not going to Ready state.

### Upgrade phase

The upgrade phase has these steps:

1. Randomly selects a node, up to the maximum unavailable configured for the node group.

2. Drains the pods from the node. If the pods don't leave the node within 15 minutes and there's no force flag, the upgrade phase fails with a PodEvictionFailure error. For this scenario, you can apply the force flag with the update-nodegroup-version request to delete the pods.
3. Cordons the node after every pod is evicted and waits for 60 seconds. This is done so that the service controller doesn’t send any new requests to this node and removes this node from its list of active nodes.

4. Sends a termination request to the Auto Scaling Group for the cordoned node.

5. Repeats the previous upgrade steps until there are no nodes in the node group that are deployed with the earlier version of the launch template.

The following are known reasons which lead to a PodEvictionFailure error in this phase:

- **Aggressive PDB** – Aggressive PDB is defined on the pod or there are multiple PDBs pointing to the same pod.

- **Deployment tolerating all the taints** – Once every pod is evicted, it's expected for the node to be empty because the node is tainted in the earlier steps. However, if the deployment tolerates every taint, then the node is more likely to be non-empty, leading to pod eviction failure.

**Scale down phase**

The scale down phase decrements the Auto Scaling group maximum size and desired size by one to return to values before the update started.

If the Upgrade workflow determines that the Cluster Autoscaler is scaling up the node group during the scale down phase of the workflow, it exits immediately without bringing the node group back to its original size.

**Node taints on managed node groups**

Amazon EKS supports configuring Kubernetes taints through managed node groups. Taints and tolerations work together to ensure that pods aren’t scheduled onto inappropriate nodes.

One or more taints can be applied to a node. This marks that the node shouldn’t accept any pods that don't tolerate the taints. Tolerations are applied to pods and allow, but don't require, the pods to schedule onto nodes with matching taints.

Kubernetes node taints can be applied to new and existing managed node groups using the AWS Management Console or through the Amazon EKS API.

The following is an example of creating a node group with a taint using the AWS CLI:

```bash
aws eks create-nodegroup \
--cli-input-json ' {
  "clusterName": "my-cluster",
  ...
  "taints": [
    {
      "key": "dedicated",
      "value": "gpuGroup",
      "effect": "NO_SCHEDULE"
    }
  ],
}
'
```

For more information on taints and tolerations, see the Kubernetes documentation. For more information and examples of usage, see the Kubernetes reference documentation.

**Note**

- Maximum of 50 taints are allowed for one node group.
Launch template support

Managed node groups are always deployed with a launch template to be used with the Amazon EC2 Auto Scaling group. The Amazon EKS API creates this launch template either by copying one you provide or by creating one automatically with default values in your account. For the highest level of customization, you can deploy managed nodes using your own launch template and a custom AMI. We don't recommend that you modify auto-generated launch templates. So, make sure to specify a custom one when first creating a managed node group if you want greater flexibility.

After you deployed a managed node group with your own launch template, update it with a different version of the same launch template. When you update your node group to a different version of your launch template, all nodes in the group are recycled to match the new configuration of the specified launch template version. Existing node groups that don't use a custom launch template can't be updated directly. Rather, you must create a new node group with a custom launch template to do so.

Launch template configuration basics

You can create an Amazon EC2 Auto Scaling launch template with the AWS Management Console, AWS CLI, or an AWS SDK. For more information, see Creating a Launch Template for an Auto Scaling group in the Amazon EC2 Auto Scaling User Guide. Some of the settings in a launch template are similar to the settings used for managed node configuration. When deploying or updating a node group with a launch template, some settings must be specified in either the node group configuration or the launch template. Don't specify a setting in both places. If a setting exists where it shouldn't, then operations such as creating or updating a node group fail.

The following table lists the settings that are prohibited in a launch template. It also lists similar settings, if any are available, that are required in the managed node group configuration. The listed settings are the settings that appear in the console. They might have similar but different names in the AWS CLI and SDK.

<table>
<thead>
<tr>
<th>Launch template – Prohibited</th>
<th>Amazon EKS node group configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAM instance profile under Advanced details</td>
<td>Node IAM role under Node group configuration on the Configure Node group page</td>
</tr>
<tr>
<td>Subnet under Network interfaces (Add network interface)</td>
<td>Subnets under Node group network configuration on the Specify networking page</td>
</tr>
<tr>
<td>Shutdown behavior and Stop - Hibernate behavior under Advanced details. Retain default Don't include in launch template setting in launch template for both settings.</td>
<td>No equivalent. Amazon EKS must control the instance lifecycle, not the Auto Scaling group.</td>
</tr>
</tbody>
</table>
The following table lists the prohibited settings in a managed node group configuration. It also lists similar settings, if any are available, which are required in a launch template. The listed settings are the settings that appear in the console. They might have similar names in the AWS CLI and SDK.

<table>
<thead>
<tr>
<th>Amazon EKS node group configuration – Prohibited</th>
<th>Launch template</th>
</tr>
</thead>
</table>
| (Only if you specified a custom AMI in a launch template) AMI type under Node group compute configuration on Set compute and scaling configuration page – Console displays Specified in launch template and the AMI ID that was specified. | Application and OS Images (Amazon Machine Image) under Launch template contents – You must specify an ID if you have either of the following requirements:  
• Using a custom AMI. If you specify an AMI that doesn't meet the requirements listed in Specifying an AMI (p. 117), the node group deployment will fail.  
• Want to provide user data to provide arguments to the bootstrap.sh file included with an Amazon EKS optimized AMI. You can enable your instances to assign a significantly higher number of IP addresses to pods, assign IP addresses to pods from a different CIDR block than the instance's, enable the containerd runtime, or deploy a private cluster without outbound internet access. For more information, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 289), Tutorial: Custom networking (p. 276), Enable the containerd runtime bootstrap flag (p. 174), Private cluster requirements (p. 63), and Specifying an AMI (p. 117). |
| Disk size under Node group compute configuration on Set compute and scaling configuration page – Console displays Specified in launch template. | Size under Storage (Volumes) (Add new volume). You must specify this in the launch template. |
| SSH key pair under Node group configuration on the Specify Networking page – The console displays the key that was specified in the launch template or displays Not specified in launch template. | Key pair name under Key pair (login). |
| You can't specify source security groups that are allowed remote access when using a launch template. | Security groups under Network settings for the instance or Security groups under Network interfaces (Add network interface), but not both. For more information, see Using custom security groups (p. 115). |

**Note**

- If you deploy a node group using a launch template, specify zero or one Instance type under Launch template contents in a launch template. Alternatively, you can specify 0–20 instance types for Instance types on the Set compute and scaling configuration page in the console. Or, you can do so using other tools that use the Amazon EKS API. If you specify an instance
type in a launch template, and use that launch template to deploy your node group, then you
can't specify any instance types in the console or using other tools that use the Amazon EKS
API. If you don't specify an instance type in a launch template, in the console, or using other
tools that use the Amazon EKS API, the t3.medium instance type is used. If your node group
is using the Spot capacity type, then we recommend specifying multiple instance types using
the console. For more information, see Managed node group capacity types (p. 99).

• If any containers that you deploy to the node group use the Instance Metadata Service Version
2, make sure to set the Metadata response hop limit to 2 in your launch template. For more
information, see Instance metadata and user data in the Amazon EC2 User Guide for Linux
Instances. If you deploy a managed node group without using a custom launch template, this
value is automatically set for the node group in the default launch template.

Tagging Amazon EC2 instances

You can use the TagSpecification parameter of a launch template to specify which tags to
apply to Amazon EC2 instances in your node group. The IAM entity calling the CreateNodegroup
or UpdateNodegroupVersion APIs must have permissions for ec2:RunInstances and
ec2:CreateTags, and the tags must be added to the launch template.

Using custom security groups

You can use a launch template to specify custom Amazon EC2 security groups to apply to instances in
your node group. This can be either in the instance level security groups parameter or as part of the
network interface configuration parameters. However, you can't create a launch template that specifies
both instance level and network interface security groups. Consider the following conditions that apply
to using custom security groups with managed node groups:

• Amazon EKS only allows launch templates with a single network interface specification.
• By default, Amazon EKS applies the cluster security group (p. 245) to the instances in your node
group to facilitate communication between nodes and the control plane. If you specify custom security
groups in the launch template using either option mentioned earlier, Amazon EKS doesn't add the
cluster security group. So, you must ensure that the inbound and outbound rules of your security
groups enable communication with the endpoint of your cluster. If your security group rules are
incorrect, the worker nodes can't join the cluster. For more information about security group rules, see
Amazon EKS security group requirements and considerations (p. 245).
• If you need SSH access to the instances in your node group, include a security group that allows that
access.

Amazon EC2 user data

The launch template includes a section for custom user data. You can specify configuration settings for
your node group in this section without manually creating individual custom AMIs. For more information
about the settings available for Bottlerocket, see Using user data on GitHub.

You can supply Amazon EC2 user data in your launch template using cloud-init when launching
your instances. For more information, see the cloud-init documentation. Your user data can be used to
perform common configuration operations. This includes the following operations:

• Including users or groups
• Installing packages

Amazon EC2 user data in launch templates that are used with managed node groups must be in the
MIME multi-part archive format for Amazon Linux AMIs and TOML format for Bottlerocket AMIs. This is
because your user data is merged with Amazon EKS user data required for nodes to join the cluster. Don’t specify any commands in your user data that starts or modifies kubelet. This is performed as part of the user data merged by Amazon EKS. Certain kubelet parameters, such as setting labels on nodes, can be configured directly through the managed node groups API.

**Note**
For more information about advanced kubelet customization, including manually starting it or passing in custom configuration parameters, see Specifying an AMI (p. 117). If a custom AMI ID is specified in a launch template, Amazon EKS doesn’t merge user data.

The following details provide more information about the user data section for Amazon Linux or Bottlerocket.

**Amazon Linux user data**
You can combine multiple user data blocks together into a single MIME multi-part file. For example, you can combine a cloud boothook that configures the Docker daemon with a user data shell script that installs a custom package. A MIME multi-part file consists of the following components:

- The content type and part boundary declaration – Content-Type: multipart/mixed; boundary="==MYBOUNDARY=="
- The MIME version declaration – MIME-Version: 1.0
- One or more user data blocks, which contain the following components:
  - The opening boundary, which signals the beginning of a user data block – --==MYBOUNDARY==--
  - The content type declaration for the block: Content-Type: text/cloud-config; charset="us-ascii". For more information about content types, see the cloud-init documentation.
  - The content of the user data (for example, a list of shell commands or cloud-init directives).
  - The closing boundary, which signals the end of the MIME multi-part file: --==MYBOUNDARY==--

The following is an example of a MIME multi-part file that you can use to create your own.

```
MIME-Version: 1.0
Content-Type: multipart/mixed; boundary="==MYBOUNDARY=="

--==MYBOUNDARY==
Content-Type: text/x-shellscript; charset="us-ascii"

#!/bin/bash
echo "Running custom user data script"

--==MYBOUNDARY==--
```

**Bottlerocket user data**
Bottlerocket structures user data in the TOML format. You can provide user data to be merged with the user data provided by Amazon EKS. For example, you can provide additional kubelet settings.

```
[settings.kubernetes.system-reserved]
cpu = "10m"
memory = "100Mi"
ephemeral-storage= "1Gi"
```

For more information about the supported settings, see Bottlerocket documentation. You can configure node labels and taints in your user data. However, we recommend that you configure these within your node group instead. Amazon EKS applies these configurations when you do so.
When user data is merged, formatting isn't preserved, but the content remains the same. The configuration that you provide in your user data overrides any settings that are configured by Amazon EKS. So, if you set `settings.kubernetes.max-pods` or `settings.kubernetes.cluster-dns-ip`, values in your user data are applied to the nodes.

Amazon EKS doesn't support all valid TOML. The following is a list of known unsupported formats:

- Quotes within quoted keys: 'quoted "value"' = "value"
- Escaped quotes in values: `str = "I'm a string. "You can quote me\""
- Mixed floats and integers: `numbers = [ 0.1, 0.2, 0.5, 1, 2, 5 ]`
- Mixed types in arrays: `contributors = ["foo@example.com", { name = "Baz", email = "baz@example.com" }]`
- Bracketed headers with quoted keys: `[foo."bar.baz"]`

### Specifying an AMI

If you have either of the following requirements, then specify an AMI ID in the `imageId` field of your launch template. Select the requirement you have for additional information.

**Provide user data to pass arguments to the `bootstrap.sh` file included with an Amazon EKS optimized AMI**

Bootstrapping is a term used to describe adding commands that can be run when an instance starts. You can pass arguments to the `bootstrap.sh` script by using `eksctl` without specifying a launch template. Or you can do so by specifying the information in the user data section of a launch template.

**eksctl without specifying a launch template**

Create a file named `my-nodegroup.yaml` with the following contents. Replace every `example value` with your own values. The `--apiserver-endpoint`, `--b64-cluster-ca`, and `--dns-cluster-ip` arguments are optional. However, defining them allows the `bootstrap.sh` script to avoid making a `describeCluster` call. This is useful in private cluster setups or clusters where you're scaling in and out nodes frequently. For more information on the `bootstrap.sh` script, see the `bootstrap.sh` file on GitHub.

- The only required argument is the cluster name (`my-cluster`).
- To retrieve your desired value for ami-1234567890abcdef0, you can use the tables in the following sections:
  - Amazon EKS optimized Amazon Linux AMIs (p. 165)
  - Amazon EKS optimized Bottlerocket AMIs (p. 179)
  - Amazon EKS optimized Windows AMIs (p. 185)
- This example provides a `kubelet` argument to set a custom `max-pods` value using the `bootstrap.sh` script included with the Amazon EKS optimized AMI. For help with selecting `my-max-pods-value`, see Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 163).
- To retrieve the `certificate-authority` for your cluster, run the following command.

  ```
  aws eks describe-cluster --query "cluster.certificateAuthority.data" --output text --name my-cluster --region region-code
  ```

- To retrieve the `api-server-endpoint` for your cluster, run the following command.

  ```
  aws eks describe-cluster --query "cluster.endpoint" --output text --name my-cluster --region region-code
  ```
• The value for --dns-cluster-ip is your service CIDR with .10 at the end. To retrieve the service-cidr for your cluster, run the following command. For example, if the returned value for is ipv4 10.100.0.0/16, then your value is 10.100.0.10.

```
aws eks describe-cluster --query "cluster.kubernetesNetworkConfig.serviceIpv4Cidr" --output text --name my-cluster --region region-code
```

• This example creates a node group using containerd as the runtime, but you can modify it as needed.

```yaml
---
apiversion: eksctl.io/v1alpha5
type: ClusterConfig

metadata:
  name: my-cluster
  region: region-code

managedNodeGroups:
- name: my-nodegroup
  ami: ami-1234567890abcdef0
  instanceType: m5.large
  privateNetworking: true
  disableIMDSv1: true
  labels: { x86-al2-specified-mng }
  overrideBootstrapCommand: |
  #!/bin/bash
  /etc/eks/bootstrap.sh my-cluster 
  --kubecfg-extra-args '--max-pods=my-max-pods-value' 
  --b64-cluster-ca certificate-authority 
  --apiserver-endpoint api-server-endpoint 
  --dns-cluster-ip service-cidr.10 
  --use-max-pods false 
  --container-runtime containerd
```

For every available eksctl config file option, see Config file schema in the eksctl documentation. The eksctl utility still creates a launch template for you and populates its user data with the data that you provide in the config file.

Create a node group with the following command.

```
eksctl create nodegroup --config-file=my-nodegroup.yaml
```

User data in a launch template

Specify the following information in the user data section of your launch template. Replace every example value with your own values. The --apiserver-endpoint, --b64-cluster-ca, and --dns-cluster-ip arguments are optional. However, defining them allows the bootstrap.sh script to avoid making a describeCluster call. This is useful in private cluster setups or clusters where you're scaling in and out nodes frequently. For more information on the bootstrap.sh script, see the bootstrap.sh file on GitHub.

• The only required argument is the cluster name (my-cluster).
• This example provides a kubelet argument to set a custom max-pods value using the bootstrap.sh script included with the Amazon EKS optimized AMI. For help with selecting my-max-pods-value, see Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 163).
• To retrieve the certificate-authority for your cluster, run the following command.
To retrieve the `api-server-endpoint` for your cluster, run the following command.

```
aws eks describe-cluster --query "cluster.endpoint" --output text --name my-cluster --region region-code
```

The value for `--dns-cluster-ip` is your service CIDR with .10 at the end. To retrieve the `service-cidr` for your cluster, run the following command. For example, if the returned value for is ipv4 10.100.0.0/16, then your value is 10.100.0.10.

```
aws eks describe-cluster --query "cluster.kubernetesNetworkConfig.serviceIpv4Cidr" --output text --name my-cluster --region region-code
```

This example creates a node group using `containerd` as the runtime, but you can modify it as needed.

```
#!/bin/bash
set -ex
/etc/eks/bootstrap.sh my-cluster \
  --kubelet-extra-args '--max-pods=my-max-pods-value' \
  --b64-cluster-ca certificate-authority \
  --apiserver-endpoint api-server-endpoint \
  --dns-cluster-ip service-cidr.10 \
  --use-max-pods false \
  --container-runtime containerd
```

**Run a custom AMI due to specific security, compliance, or internal policy requirements**

For more information, see Amazon Machine Images (AMI) in the *Amazon EC2 User Guide for Linux Instances*. The Amazon EKS AMI build specification contains resources and configuration scripts for building a custom Amazon EKS AMI based on Amazon Linux 2. For more information, see *Amazon EKS AMI Build Specification* on GitHub. To build custom AMIs installed with other operating systems, see *Amazon EKS Sample Custom AMIs* on GitHub.

**Important**

When specifying an AMI, Amazon EKS doesn't merge any user data. Rather, you're responsible for supplying the required bootstrap commands for nodes to join the cluster. If your nodes fail to join the cluster, the Amazon EKS `CreateNodegroup` and `UpdateNodegroupVersion` actions also fail.

**The following are the limits and conditions involved with specifying an AMI ID with managed node groups:**

- You must create a new node group to switch between specifying an AMI ID in a launch template and not specifying an AMI ID.
• You aren't notified in the console when a newer AMI version is available. To update your node group to a newer AMI version, you need to create a new version of your launch template with an updated AMI ID. Then, you need to update the node group with the new launch template version.

• The following fields can't be set in the API if you specify an AMI ID:
  • amiType
  • releaseVersion
  • version

• You can't specify a Windows AMI ID because Windows can't be used in managed node groups.

Deleting a managed node group

This topic describes how you can delete an Amazon EKS managed node group.

When you delete a managed node group, Amazon EKS first sets the minimum, maximum, and desired size of your Auto Scaling group to zero. This then causes your node group to scale down. Before each instance is terminated, Amazon EKS sends a signal to drain the pods from that node and then waits a few minutes. If the pods haven't drained after a few minutes, Amazon EKS lets Auto Scaling continue the termination of the instance. After every instance is terminated, the Auto Scaling group is deleted.

Important
If you delete a managed node group that uses a node IAM role that isn't used by any other managed node group in the cluster, the role is removed from the `aws-auth` ConfigMap (p. 381). If any of the self-managed node groups in the cluster are using the same node IAM role, the self-managed nodes move to the NotReady status. Additionally, the cluster operation are also disrupted. You can add the mapping back to the ConfigMap to minimize disruption.

You can delete a managed node group with `eksctl` or the AWS Management Console.

`eksctl`

To delete a managed node group with `eksctl`

• Enter the following command. Replace every *example value* with your own values.

```
  eksctl delete nodegroup \
  --cluster my-cluster \
  --region region-code \
  --name my-mng
```

AWS Management Console

To delete your managed node group using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#clusters.
2. Choose the cluster that contains the node group to delete.
3. Select the Compute tab.
4. Select the node group to delete, and choose Delete.
5. On the Delete node group: *my-mng* page, enter the name of the node group in the text field and choose Delete.
Self-managed nodes

A cluster contains one or more Amazon EC2 nodes that pods are scheduled on. Amazon EKS nodes run in your AWS account and connect to the control plane of your cluster through the cluster API server endpoint. You deploy one or more nodes into a node group. A node group is one or more Amazon EC2 instances that are deployed in an Amazon EC2 Auto Scaling group.

All instances in a node group must have the following characteristics:

- Be the same instance type
- Be running the same Amazon Machine Image (AMI)
- Use the same Amazon EKS node IAM role (p. 461)

Note
You can't use the same role that is used to create any clusters.

A cluster can contain several node groups. If each node group meets the previous requirements, the cluster can contain node groups that contain different instance types and host operating systems. Each node group can contain several nodes.

Amazon EKS nodes are standard Amazon EC2 instances. You're billed for them based on EC2 prices. For more information, see Amazon EC2 pricing.

Amazon EKS provides specialized Amazon Machine Images (AMI) that are called Amazon EKS optimized AMIs. The AMIs are configured to work with Amazon EKS and include Docker, kubelet, and the AWS IAM Authenticator. The AMIs also contain a specialized bootstrap script that allows it to discover and connect to your cluster's control plane automatically.

If you restrict access to the public endpoint of your cluster using CIDR blocks, we recommend that you also enable private endpoint access. This is so that nodes can communicate with the cluster. Without the private endpoint enabled, the CIDR blocks that you specify for public access must include the egress sources from your VPC. For more information, see Amazon EKS cluster endpoint access control (p. 43).

To add self-managed nodes to your Amazon EKS cluster, see the topics that follow. If you launch self-managed nodes manually, add the following tag to each node. For more information, see Adding and deleting tags on an individual resource. If you follow the steps in the guides that follow, the required tag is automatically added to nodes for you.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/cluster/my-cluster</td>
<td>owned</td>
</tr>
</tbody>
</table>

For more information about nodes from a general Kubernetes perspective, see Nodes in the Kubernetes documentation.

Topics

- Launching self-managed Amazon Linux nodes (p. 122)
- Launching self-managed Bottlerocket nodes (p. 127)
- Launching self-managed Windows nodes (p. 129)
- Self-managed node updates (p. 135)
Launching self-managed Amazon Linux nodes

This topic describes how you can launch Auto Scaling groups of Linux nodes that register with your Amazon EKS cluster. After the nodes join the cluster, you can deploy Kubernetes applications to them. You can also launch self-managed Amazon Linux 2 nodes with eksctl or the AWS Management Console. If you need to launch nodes on AWS Outposts, see the section called “Launching nodes” (p. 567).

Prerequisites

- An existing Amazon EKS cluster. To deploy one, see Creating an Amazon EKS cluster (p. 24). If you have subnets in the AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled, those subnets must not have been passed in when you created your cluster.
- (Optional, but recommended) The Amazon VPC CNI plugin for Kubernetes add-on configured with its own IAM role that has the necessary IAM policy attached to it. For more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).
- Familiarity with the considerations listed in Choosing an Amazon EC2 instance type (p. 162). Depending on the instance type you choose, there may be additional prerequisites for your cluster and VPC.

eksctl

Prerequisite

Version 0.112.0 or later of the eksctl command line tool installed on your device or AWS CloudShell. To install or update eksctl, see Installing or updating eksctl (p. 10).

To launch self-managed Linux nodes using eksctl

1. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy is attached to your the section called "Node IAM role" (p. 461), we recommend assigning it to an IAM role that you associate to the Kubernetes aws-node service account instead. For more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).
2. The following command creates a node group in an existing cluster. Replace al-nodes with a name for your node group. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. Replace my-cluster with the name of your cluster. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. Replace the remaining example value with your own values. The nodes are created with the same Kubernetes version as the control plane, by default.

Before choosing a value for --node-type, review Choosing an Amazon EC2 instance type (p. 162).

Replace my-key with the name of your Amazon EC2 key pair or public key. This key is used to SSH into your nodes after they launch. If you don't already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 key pairs in the Amazon EC2 User Guide for Linux Instances.

Create your node group with the following command.

**Important**

If you want to deploy a node group to AWS Outposts, Wavelength, or Local Zone subnets, there are additional considerations:

- The subnets must not have been passed in when you created the cluster.
• You must create the node group with a config file that specifies the subnets and
volumeType: gp2. For more information, see Create a nodegroup from a config file
and Config file schema in the eksctl documentation.

```
$ eksctl create nodegroup \
  --cluster my-cluster \
  --name al-nodes \
  --node-type t3.medium \
  --nodes 3 \
  --nodes-min 1 \
  --nodes-max 4 \
  --ssh-access \
  --managed=false \
  --ssh-public-key my-key
```

To deploy a node group that:
• can assign a significantly higher number of IP addresses to pods than the default
configuration, see Increase the amount of available IP addresses for your Amazon EC2
nodes (p. 289).
• can assign IPv4 addresses to pods from a different CIDR block than that of the instance, see
Tutorial: Custom networking (p. 276).
• can assign IPv6 addresses to pods and services, see the section called “IPv6” (p. 264).
• use the containerd runtime, you must deploy the node group using a config file. For more
information, see Enable the containerd runtime bootstrap flag (p. 174).
• don't have outbound internet access, see Private cluster requirements (p. 63).

For a complete list of all available options and defaults, enter the following command.

```
$ eksctl create nodegroup --help
```

If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 521) in the
Troubleshooting guide.

The example output is as follows. Several lines are output while the nodes are created. One of
the last lines of output is the following example line.

```
[✓]  created 1 nodegroup(s) in cluster "my-cluster"
```

3. We recommend blocking pod access to IMDS if the following conditions are true:
• You plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have
the minimum permissions that they need.
• No pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for
other reasons, such as retrieving the current AWS Region.

For more information, see Restrict access to the instance profile assigned to the worker node.

AWS Management Console

**Step 1: To launch self-managed Linux nodes using the AWS Management Console**

1. Download the latest version of the AWS CloudFormation template.
2. Wait for your cluster status to show as **ACTIVE**. If you launch your nodes before the cluster is active, the nodes fail to register with the cluster and you will have to relaunch them.

4. Choose **Create stack** and then select **With new resources (standard)**.

5. For **Specify template**, select **Upload a template file** and then select **Choose file**. Select the `amazon-eks-nodegroup.yaml` file that you downloaded in step 2 and then select **Next**.

6. On the **Specify stack details** page, enter the following parameters accordingly, and then choose **Next**:

   - **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it `my-cluster-nodes`. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters.
   - **ClusterName**: Enter the name that you used when you created your Amazon EKS cluster. This name must equal the cluster name or your nodes can't join the cluster.
   - **ClusterControlPlaneSecurityGroup**: Choose the **SecurityGroups** value from the AWS CloudFormation output that you generated when you created your VPC (p. 241).

   The following steps show one operation to retrieve the applicable group.
   1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
   2. Choose the name of the cluster.
   3. Choose the **Networking** tab.
   4. Use the **Additional security groups** value as a reference when selecting from the **ClusterControlPlaneSecurityGroup** dropdown list.
   - **NodeGroupName**: Enter a name for your node group. This name can be used later to identify the Auto Scaling node group that's created for your nodes.
   - **NodeAutoScalingGroupMinSize**: Enter the minimum number of nodes that your node Auto Scaling group can scale in to.
   - **NodeAutoScalingGroupDesiredCapacity**: Enter the desired number of nodes to scale to when your stack is created.
   - **NodeAutoScalingGroupMaxSize**: Enter the maximum number of nodes that your node Auto Scaling group can scale out to.
   - **NodeInstanceType**: Choose an instance type for your nodes. For more information, see Choosing an Amazon EC2 instance type (p. 162).
   - **NodeImageIdSSMParam**: Pre-populated with the Amazon EC2 Systems Manager parameter of a recent Amazon EKS optimized Amazon Linux AMI ID for a Kubernetes version. To use a different Kubernetes minor version supported with Amazon EKS, replace `1.x` with a different supported version (p. 66). We recommend specifying the same Kubernetes version as your cluster.

   To use the Amazon EKS optimized accelerated AMI, replace `amazon-linux-2` with `amazon-linux-2-gpu`. To use the Amazon EKS optimized Arm AMI, replace `amazon-linux-2` with `amazon-linux-2-arm64`.

   **Note**
   The Amazon EKS node AMI is based on Amazon Linux 2. You can track security or privacy events for Amazon Linux 2 at the Amazon Linux Security Center or subscribe to the associated RSS feed. Security and privacy events include an overview of the issue, what packages are affected, and how to update your instances to correct the issue.
- **NodeImageId**: (Optional) If you're using your own custom AMI (instead of the Amazon EKS optimized AMI), enter a node AMI ID for your AWS Region. If you specify a value here, it overrides any values in the `NodeImageIdSSMParam` field.

- **NodeVolumeSize**: Specify a root volume size for your nodes, in GiB.

- **KeyName**: Enter the name of an Amazon EC2 SSH key pair that you can use to connect using SSH into your nodes with after they launch. If you don't already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 key pairs in the Amazon EC2 User Guide for Linux Instances.

  **Note**
  
  If you don't provide a key pair here, the AWS CloudFormation stack creation fails.

- **BootstrapArguments**: Specify any optional arguments to pass to the node bootstrap script, such as extra `kubelet` arguments. For more information, view the bootstrap script usage information on GitHub.

To deploy a node group that:

- can assign a significantly higher number of IP addresses to pods than the default configuration, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 289).

- can assign IPv4 addresses to pods from a different CIDR block than that of the instance, see Tutorial: Custom networking (p. 276).

- can assign IPv6 addresses to pods and services, see the section called “IPv6” (p. 264).

- use the `containerd` runtime, you must deploy the node group using a `config` file. For more information, see Enable the `containerd` runtime bootstrap flag (p. 174).

- don't have outbound internet access, see Private cluster requirements (p. 63).

- **DisableIMDSv1**: By default, each node supports the Instance Metadata Service Version 1 (IMDSv1) and IMDSv2. You can disable IMDSv1. To prevent future nodes and pods in the node group from using MDSv1, set `DisableIMDSv1` to true. For more information about IMDS, see Configuring the instance metadata service. For more information about restricting access to it on your nodes, see Restrict access to the instance profile assigned to the worker node.

- **VpcId**: Enter the ID for the VPC (p. 241) that you created.

- **Subnets**: Choose the subnets that you created for your VPC. If you created your VPC using the steps that are described in Creating a VPC for your Amazon EKS cluster (p. 241), specify only the private subnets within the VPC for your nodes to launch into. You can see which subnets are private by opening each subnet link from the Networking tab of your cluster.

  **Important**

  - If any of the subnets are public subnets, then they must have the automatic public IP address assignment setting enabled. If the setting isn't enabled for the public subnet, then any nodes that you deploy to that public subnet won't be assigned a public IP address and won't be able to communicate with the cluster or other AWS services. If the subnet was deployed before March 26, 2020 using either of the Amazon EKS AWS CloudFormation VPC templates (p. 241), or by using `eksctl`, then automatic public IP address assignment is disabled for public subnets. For information about how to enable public IP address assignment for a subnet, see Modifying the public IPv4 addressing attribute for your subnet. If the node is deployed to a private subnet, then it's able to communicate with the cluster and other AWS services through a NAT gateway.

  - If the subnets don't have internet access, make sure that you're aware of the considerations and extra steps in Private cluster requirements (p. 63).

  - If you select AWS Outposts, Wavelength, or Local Zone subnets, the subnets must not have been passed in when you created the cluster.

7. Select your desired choices on the Configure stack options page, and then choose Next.
8. Select the check box to the left of I acknowledge that AWS CloudFormation might create IAM resources, and then choose Create stack.

9. When your stack has finished creating, select it in the console and choose Outputs.

10. Record the NodelInstanceRole for the node group that was created. You need this when you configure your Amazon EKS nodes.

**Step 2: To enable nodes to join your cluster**

*Note*
If you launched nodes inside a private VPC without outbound internet access, make sure to enable nodes to join your cluster from within the VPC.

1. Download, edit, and apply the AWS IAM Authenticator configuration map.
   
a. Download the configuration map using the following command.

```
curl -o aws-auth-cm.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/cloudformation/2020-10-29/aws-auth-cm.yaml
```

b. In the `aws-auth-cm.yaml` file, set the `rolearn` to the value that you recorded in the previous procedure. You can do this with a text editor, or by replacing `my-node-instance-role` and running the following command:

```
sed -i.bak -e 's|<ARN of instance role (not instance profile)>|my-node-instance-role|' aws-auth-cm.yaml
```

c. Apply the configuration. This command may take a few minutes to finish.

```
kubectl apply -f aws-auth-cm.yaml
```

*Note*
If you receive any authorization or resource type errors, see Unauthorized or access denied (kubectl) (p. 522) in the troubleshooting section.

If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 521) in the Troubleshooting guide.

2. Watch the status of your nodes and wait for them to reach the Ready status.

```
kubectl get nodes --watch
```

Enter Ctrl+C to return to a shell prompt.

3. (GPU nodes only) If you chose a GPU instance type and the Amazon EKS optimized accelerated AMI, you must apply the NVIDIA device plugin for Kubernetes as a DaemonSet on your cluster with the following command.

```
kubectl apply -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.9.0/nvidia-device-plugin.yml
```

4. (Optional) Deploy a sample application (p. 338) to test your cluster and Linux nodes.

5. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy (if you have an IPv4 cluster) or the AmazonEKS_CNI_IPv6_Policy (that you created yourself (p. 262) if you have an IPv6 cluster) is attached to your the section called “Node IAM role” (p. 461), we recommend assigning it to an IAM role that you associate to the Kubernetes `aws-node` service account instead. For more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).
6. We recommend blocking pod access to IMDS if the following conditions are true:

- You plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need.
- No pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region.

For more information, see Restrict access to the instance profile assigned to the worker node.

Launching self-managed Bottlerocket nodes

Note
Managed node groups might offer some advantages for your use case. For more information, see Managed node groups (p. 97).

This topic describes how to launch Auto Scaling groups of Bottlerocket nodes that register with your Amazon EKS cluster. Bottlerocket is a Linux-based open-source operating system from AWS that you can use for running containers on virtual machines or bare metal hosts. After the nodes join the cluster, you can deploy Kubernetes applications to them. For more information about Bottlerocket, see Using a Bottlerocket AMI with Amazon EKS on GitHub and Custom AMI support in the eksctl documentation.

For information about in-place upgrades, see Bottlerocket Update Operator on GitHub.

Important

- Amazon EKS nodes are standard Amazon EC2 instances, and you are billed for them based on normal Amazon EC2 instance prices. For more information, see Amazon EC2 pricing.
- You can launch Bottlerocket nodes in Amazon EKS extended clusters on AWS Outposts, but you can't launch them in local clusters on AWS Outposts. For more information, see Amazon EKS on AWS Outposts (p. 547).
- You can deploy to Amazon EC2 instances with x86 or Arm processors. However, you can't deploy to instances that have Inferentia chips.
- There is no AWS CloudFormation template to deploy nodes with.
- Bottlerocket images don't come with an SSH server or a shell. You can use out-of-band access methods to allow SSH enabling the admin container and to pass some bootstrapping configuration steps with user data. For more information, see these sections in the bottlerocket README.md on GitHub:
  - Exploration
  - Admin container
  - Kubernetes settings

To launch Bottlerocket nodes using eksctl

This procedure requires eksctl version 0.112.0 or later. You can check your version with the following command:

```
eksctl version
```

For instructions on how to install or upgrade eksctl, see Installing or updating eksctl (p. 10).

Note
This procedure only works for clusters that were created with eksctl.

1. Copy the following contents to your device. Replace `my-cluster` with the name of your cluster. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with
an alphabetic character and can’t be longer than 100 characters. Replace ng-bottlerocket with
a name for your node group. The name can contain only alphanumeric characters (case-sensitive)
and hyphens. It must start with an alphabetic character and can’t be longer than 100 characters.
To deploy on Arm instances, replace m5.large with an Arm instance type. Replace my-ec2-
keypair-name with the name of an Amazon EC2 SSH key pair that you can use to connect using
SSH into your nodes with after they launch. If you don’t already have an Amazon EC2 key pair, you
can create one in the AWS Management Console. For more information, see Amazon EC2 key pairs
in the Amazon EC2 User Guide for Linux Instances. Replace all remaining example values
with your own values. Once you’ve made the replacements, run the modified command to create the
bottlerocket.yaml file.

If specifying an Arm Amazon EC2 instance type, then review the considerations in Amazon EKS
optimized Arm Amazon Linux AMIs (p. 176) before deploying. For instructions on how to deploy
using a custom AMI, see Building Bottlerocket on GitHub and Custom AMI support in the eksctl
documentation. To deploy a managed node group, deploy a custom AMI using a launch template.
For more information, see Launch template support (p. 113).

Important
To deploy a node group to AWS Outposts, AWS Wavelength, or AWS Local Zone subnets,
don’t pass AWS Outposts, AWS Wavelength, or AWS Local Zone subnets when you
create the cluster. You must specify the subnets in the following example. For more
information see Create a nodegroup from a config file and Config file schema in the
eksctl documentation. Replace region-code with the AWS Region that your cluster is in.

```
cat >bottlerocket.yaml <<EOF
---
apiversion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: my-cluster
  region: region-code
  version: '1.23'
iam:
  withOIDC: true
nodeGroups:
  - name: ng-bottlerocket
    instanceType: m5.large
    desiredCapacity: 3
    amiFamily: Bottlerocket
    ami: auto-ssm
    iam:
      attachPolicyARNs:
        - arn:aws:iam::aws:policy/AmazonEKSServerPolicy
        - arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly
        - arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
        - arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy
    ssh:
      allow: true
      publicKeyName: my-ec2-keypair-name
EOF
```

2. Deploy your nodes with the following command.

```
eksctl create nodegroup --config-file=bottlerocket.yaml
```

The example output is as follows.
Several lines are output while the nodes are created. One of the last lines of output is the following example line.

```
[✓] created 1 nodegroup(s) in cluster "my-cluster"
```

3. **(Optional)** Create a Kubernetes persistent volume on a Bottlerocket node using the Amazon EBS CSI Plugin. The default Amazon EBS driver relies on file system tools that aren't included with Bottlerocket. For more information about creating a storage class using the driver, see Amazon EBS CSI driver (p. 205).

4. **(Optional)** By default, `kube-proxy` sets the `nf_conntrack_max` kernel parameter to a default value that may differ from what Bottlerocket originally sets at boot. To keep Bottlerocket's default setting, edit the `kube-proxy` configuration with the following command.

```
kubectl edit -n kube-system daemonset kube-proxy
```

Add `--conntrack-max-per-core` and `--conntrack-min` to the `kube-proxy` arguments that are in the following example. A setting of 0 implies no change.

```yaml
containers:
  - command:
    - kube-proxy
    - --v=2
    - --config=/var/lib/kube-proxy-config/config
    - --conntrack-max-per-core=0
    - --conntrack-min=0
```

5. **(Optional)** Deploy a sample application (p. 338) to test your Bottlerocket nodes.

6. **We recommend blocking pod access to IMDS if the following conditions are true:**

   - You plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need.
   - No pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region.

   For more information, see Restrict access to the instance profile assigned to the worker node.

**Launching self-managed Windows nodes**

This topic describes how to launch Auto Scaling groups of Windows nodes that register with your Amazon EKS cluster. After the nodes join the cluster, you can deploy Kubernetes applications to them.

**Important**

- Amazon EKS nodes are standard Amazon EC2 instances, and you are billed for them based on normal Amazon EC2 instance prices. For more information, see Amazon EC2 pricing.
- You can launch Windows nodes in Amazon EKS extended clusters on AWS Outposts, but you can't launch them in local clusters on AWS Outposts. For more information, see Amazon EKS on AWS Outposts (p. 547).

Enable Windows support for your cluster. We recommend that you review important considerations before you launch a Windows node group. For more information, see Enabling Windows support (p. 56).

You can launch self-managed Windows nodes with `eksctl` or the AWS Management Console.
eksctl

To launch self-managed Windows nodes using eksctl

This procedure requires that you have installed eksctl, and that your eksctl version is at least 0.112.0. You can check your version with the following command.

```
eksctl version
```

For instructions on how to install or upgrade eksctl, see Installing or updating eksctl (p. 10).

**Note**

This procedure only works for clusters that were created with eksctl.

1. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy (if you have an IPv4 cluster) or the AmazonEKS_CNI_IPv6_Policy (that you created yourself (p. 262) if you have an IPv6 cluster) is attached to your the section called "Node IAM role" (p. 461), we recommend assigning it to an IAM role that you associate to the Kubernetes aws-node service account instead. For more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).

2. This procedure assumes that you have an existing cluster. If you don't already have an Amazon EKS cluster and an Amazon Linux 2 node group to add a Windows node group to, we recommend that you follow the Getting started with Amazon EKS – eksctl (p. 12) guide. The guide provides a complete walkthrough for how to create an Amazon EKS cluster with Amazon Linux nodes.

Create your node group with the following command. Replace `my-cluster` with your cluster name. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. Replace `ng-windows` with a name for your node group. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. Replace the rest of the example values with your own values.

```
Important
To deploy a node group to AWS Outposts, AWS Wavelength, or AWS Local Zone subnets, don't pass the AWS Outposts, Wavelength, or Local Zone subnets when you create the cluster. Create the node group with a config file, specifying the AWS Outposts, Wavelength, or Local Zone subnets. For more information, see Create a nodegroup from a config file and Config file schema in the eksctl documentation.

Note
Amazon EKS optimized Windows AMIs can be configured to use containerd as a runtime. When using eksctl for launching Windows nodes, specify containerRuntime as containerd in the node group configuration. For more information, see Enable the containerd runtime bootstrap flag (p. 195) in this user guide or Define container runtime in the eksctl documentation. Replace `region-code` with the AWS Region that your cluster is in.

```
```
Note

- If nodes fail to join the cluster, see Nodes fail to join cluster (p. 521) in the Troubleshooting guide.
- To see the available options for eksctl commands, enter the following command.

```
eksctl command -help
```

The example output is as follows. Several lines are output while the nodes are created. One of the last lines of output is the following example line.

```
[✓]  created 1 nodegroup(s) in cluster "my-cluster"
```

3. (Optional) Deploy a sample application (p. 338) to test your cluster and Windows nodes.
4. We recommend blocking pod access to IMDS if the following conditions are true:
   - You plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need.
   - No pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region.

For more information, see Restrict access to the instance profile assigned to the worker node.

AWS Management Console

Prerequisites

- An existing Amazon EKS cluster and a Linux node group. If you don't have these resources, we recommend that you follow one of our Getting started with Amazon EKS (p. 4) guides to create them. The guides describe how to create an Amazon EKS cluster with Linux nodes.
- An existing VPC and security group that meet the requirements for an Amazon EKS cluster. For more information, see Amazon EKS VPC and subnet requirements and considerations (p. 238) and Amazon EKS security group requirements and considerations (p. 245). The Getting started with Amazon EKS (p. 4) guide creates a VPC that meets the requirements. Alternatively, you can also follow Creating a VPC for your Amazon EKS cluster (p. 241) to create one manually.
- An existing Amazon EKS cluster that uses a VPC and security group that meets the requirements of an Amazon EKS cluster. For more information, see Creating an Amazon EKS cluster (p. 24). If you have subnets in the AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled, those subnets must not have been passed in when you created the cluster.

Step 1: To launch self-managed Windows nodes using the AWS Management Console

1. Wait for your cluster status to show as ACTIVE. If you launch your nodes before the cluster is active, the nodes fail to register with the cluster and you need to relaunch them.
2. Open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation
3. Choose Create stack.
4. For Specify template, select Amazon S3 URL, copy the following URL, paste it into Amazon S3 URL, and select Next twice.

```
```
5. On the **Quick create stack** page, enter the following parameters accordingly:

- **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it `my-cluster-nodes`.
- **ClusterName**: Enter the name that you used when you created your Amazon EKS cluster.
  
  **Important**
  
  This name must exactly match the name that you used in **Step 1: Create your Amazon EKS cluster** (p. 16). Otherwise, your nodes can't join the cluster.

- **ClusterControlPlaneSecurityGroup**: Choose the security group from the AWS CloudFormation output that you generated when you created your VPC (p. 241).

  The following steps show one method to retrieve the applicable group.
  1. Open the Amazon EKS console at [https://console.aws.amazon.com/eks/home#/clusters](https://console.aws.amazon.com/eks/home#/clusters).
  2. Choose the name of the cluster.
  3. Choose the **Networking** tab.
  4. Use the **Additional security groups** value as a reference when selecting from the **ClusterControlPlaneSecurityGroup** dropdown list.

- **NodeGroupName**: Enter a name for your node group. This name can be used later to identify the Auto Scaling node group that's created for your nodes. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters.

- **NodeAutoScalingGroupMinSize**: Enter the minimum number of nodes that your node Auto Scaling group can scale in to.

- **NodeAutoScalingGroupDesiredCapacity**: Enter the desired number of nodes to scale to when your stack is created.

- **NodeAutoScalingGroupMaxSize**: Enter the maximum number of nodes that your node Auto Scaling group can scale out to.

- **NodeInstanceType**: Choose an instance type for your nodes. For more information, see **Choosing an Amazon EC2 instance type** (p. 162).
  
  **Note**
  
  The supported instance types for the latest version of the Amazon VPC CNI plugin for Kubernetes are listed in `vpc_ip_resource_limit.go` on GitHub. You might need to update your CNI version to use the latest supported instance types. For more information, see **Updating the Amazon VPC CNI plugin for Kubernetes self-managed add-on** (p. 253).

- **NodeImageIdSSMParam**: Pre-populated with the Amazon EC2 Systems Manager parameter of the current recommended Amazon EKS optimized Windows Core AMI ID. To use the full version of Windows, replace `Core` with `Full`.

- **NodeImageId**: (Optional) If you're using your own custom AMI (instead of the Amazon EKS optimized AMI), enter a node AMI ID for your AWS Region. If you specify a value for this field, it overrides any values in the **NodeImageIdSSMParam** field.

- **NodeVolumeSize**: Specify a root volume size for your nodes, in GiB.

- **KeyName**: Enter the name of an Amazon EC2 SSH key pair that you can use to connect using SSH into your nodes with after they launch. If you don't already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see **Amazon EC2 key pairs** in the **Amazon EC2 User Guide for Windows Instances**.
  
  **Note**
  
  If you don't provide a key pair here, the AWS CloudFormation stack fails to be created.

- **BootstrapArguments**: Specify any optional arguments to pass to the node bootstrap script, such as extra kubelet arguments using `kubeletExtraArgs`. 

132
Note
You can configure Amazon EKS optimized Windows AMIs to use containerd as a runtime. When using an AWS CloudFormation template to create Windows nodes, specify `-ContainerRuntime containerd` in a bootstrap argument to enable the containerd runtime. For more information, see Enable the containerd runtime bootstrap flag (p. 195).

- **DisableIMDSv1**: By default, each node supports the Instance Metadata Service Version 1 (IMDSv1) and IMDSv2. You can disable IMDSv1. To prevent future nodes and pods in the node group from using MDSv1, set **DisableIMDSv1** to **true**. For more information about IMDS, see Configuring the instance metadata service.

- **VpcId**: Select the ID for the VPC (p. 241) that you created.

- **NodeSecurityGroups**: Select the security group that was created for your Linux node group when you created your VPC (p. 241). If your Linux nodes have more than one security group attached to them, specify all of them. This for, for example, if the Linux node group was created with eksctl.

- **Subnets**: Choose the subnets that you created. If you created your VPC using the steps in Creating a VPC for your Amazon EKS cluster (p. 241), then specify only the private subnets within the VPC for your nodes to launch into.

Important
- If any of the subnets are public subnets, then they must have the automatic public IP address assignment setting enabled. If the setting isn't enabled for the public subnet, then any nodes that you deploy to that public subnet won't be assigned a public IP address and won't be able to communicate with the cluster or other AWS services. If the subnet was deployed before March 26, 2020 using either of the Amazon EKS AWS CloudFormation VPC templates (p. 241), or by using eksctl, then automatic public IP address assignment is disabled for public subnets. For information about how to enable public IP address assignment for a subnet, see Modifying the public IPv4 addressing attribute for your subnet. If the node is deployed to a private subnet, then it's able to communicate with the cluster and other AWS services through a NAT gateway.

- If the subnets don't have internet access, then make sure that you're aware of the considerations and extra steps in Private cluster requirements (p. 63).

- If you select AWS Outposts, Wavelength, or Local Zone subnets, then the subnets must not have been passed in when you created the cluster.

6. Acknowledge that the stack might create IAM resources, and then choose **Create stack**.

7. When your stack has finished creating, select it in the console and choose **Outputs**.

8. Record the **NodeInstanceRole** for the node group that was created. You need this when you configure your Amazon EKS Windows nodes.

**Step 2: To enable nodes to join your cluster**

1. Download, edit, and apply the AWS IAM Authenticator configuration map.

   a. Download the configuration map:

   ```bash
curl -o aws-auth-cm-windows.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/cloudformation/2020-10-29/aws-auth-cm-windows.yaml
   ```

   b. Open the file using your preferred text editor. Replace the **ARN of instance role (not instance profile) of **Linux** node** and **ARN of instance role (not instance profile) of **Windows** node** snippets with the **NodeInstanceRole** values that you recorded for your Linux and Windows nodes, and save the file.
Important

- Don't modify any other lines in this file.
- Don't use the same IAM role for both Windows and Linux nodes.

```yaml
apiVersion: v1
class: ConfigMap
metadata:
  name: aws-auth
  namespace: kube-system
data:
  mapRoles: |
    - rolearn: ARN of instance role (not instance profile) of **Linux** node
      username: system:node:{{EC2PrivateDNSName}}
      groups:
        - system:bootstrappers
        - system:nodes
    - rolearn: ARN of instance role (not instance profile) of **Windows** node
      username: system:node:{{EC2PrivateDNSName}}
      groups:
        - system:bootstrappers
        - system:nodes
        - eks:kube-proxy-windows
```

c. Apply the configuration. This command might take a few minutes to finish.

```
kubectl apply -f aws-auth-cm-windows.yaml
```

Note

If you receive any authorization or resource type errors, see Unauthorized or access denied (kubectl) (p. 522) in the troubleshooting section.

If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 521) in the Troubleshooting guide.

2. Watch the status of your nodes and wait for them to reach the **Ready** status.

```
kubectl get nodes --watch
```

3. (Optional) Deploy a sample application (p. 338) to test your cluster and Windows nodes.

4. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy (if you have an IPv4 cluster) or the AmazonEKS_CNI_IPv6_Policy (that you created yourself (p. 262) if you have an IPv6 cluster) is attached to your the section called "Node IAM role" (p. 461), we recommend assigning it to an IAM role that you associate to the Kubernetes aws-node service account instead. For more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).

5. We recommend blocking pod access to IMDS if the following conditions are true:

   - You plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need.
   - No pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region.

For more information, see Restrict access to the instance profile assigned to the worker node.
Self-managed node updates

When a new Amazon EKS optimized AMI is released, consider replacing the nodes in your self-managed node group with the new AMI. Likewise, if you have updated the Kubernetes version for your Amazon EKS cluster, update the nodes to use nodes with the same Kubernetes version.

**Important**
This topic covers node updates for self-managed nodes. If you are using Managed node groups (p. 97), see Updating a managed node group (p. 107).

There are two basic ways to update self-managed node groups in your clusters to use a new AMI:

- **Migrating to a new node group (p. 135)** – Create a new node group and migrate your pods to that group. Migrating to a new node group is more graceful than simply updating the AMI ID in an existing AWS CloudFormation stack. This is because the migration process taints the old node group as `NoSchedule` and drains the nodes after a new stack is ready to accept the existing pod workload.
- **Updating an existing self-managed node group (p. 140)** – Update the AWS CloudFormation stack for an existing node group to use the new AMI. This method isn't supported for node groups that were created with `eksctl`.

## Migrating to a new node group

This topic describes how you can create a new node group, gracefully migrate your existing applications to the new group, and remove the old node group from your cluster. You can migrate to a new node group using `eksctl` or the AWS Management Console.

**To migrate your applications to a new node group with eksctl**

This procedure requires `eksctl` version 0.112.0 or later. You can check your version with the following command:

```
eksctl version
```

For instructions on how to install or upgrade `eksctl`, see Installing or updating `eksctl` (p. 10).

**Note**
This procedure only works for clusters and node groups that were created with `eksctl`.

1. Retrieve the name of your existing node groups, replacing `my-cluster` with your cluster name.

   ```
   eksctl get nodegroups --cluster=my-cluster
   ```

   The example output is as follows:

<table>
<thead>
<tr>
<th>CLUSTER</th>
<th>NODEGROUP</th>
<th>CREATED</th>
<th>MIN SIZE</th>
<th>MAX SIZE</th>
</tr>
</thead>
<tbody>
<tr>
<td>t3.medium</td>
<td>ami-05a71d034119fffc12</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2. Launch a new node group with `eksctl` with the following command. In the command, replace every `example value` with your own values. The version number can't be later than the Kubernetes version for your control plane. Also, it can't be more than two minor versions earlier than the Kubernetes version for your control plane. We recommend that you use the same version as your control plane.

   ```
   We recommend blocking pod access to IMDS if the following conditions are true:
   ```
• You plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need.

• No pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region.

For more information, see Restrict access to the instance profile assigned to the worker node.

To block pod access to IMDS, add the `--disable-pod-imds` option to the following command.

```
Note
For more available flags and their descriptions, see https://eksctl.io/.
```

```
eksctl create nodegroup \
  --cluster my-cluster \
  --version 1.23 \
  --name standard-nodes-new \
  --node-type t3.medium \
  --nodes 3 \
  --nodes-min 1 \
  --nodes-max 4 \
  --node-ami auto
```

3. When the previous command completes, verify that all of your nodes have reached the Ready state with the following command:

```
kubectl get nodes
```

4. Delete the original node group with the following command. In the command, replace every example value with your cluster and node group names:

```
eksctl delete nodegroup --cluster my-cluster --name standard-nodes
```

To migrate your applications to a new node group with the AWS Management Console and AWS CLI

1. Launch a new node group by following the steps that are outlined in Launching self-managed Amazon Linux nodes (p. 122).

2. When your stack has finished creating, select it in the console and choose Outputs.

3. Record the NodeInstanceRole for the node group that was created. You need this to add the new Amazon EKS nodes to your cluster.

Note
If you attached any additional IAM policies to your old node group IAM role, attach those same policies to your new node group IAM role to maintain that functionality on the new group. This applies to you if you added permissions for the Kubernetes Cluster Autoscaler, for example.

4. Update the security groups for both node groups so that they can communicate with each other. For more information, see Amazon EKS security group requirements and considerations (p. 245).

   a. Record the security group IDs for both node groups. This is shown as the NodeSecurityGroup value in the AWS CloudFormation stack outputs.

      You can use the following AWS CLI commands to get the security group IDs from the stack names. In these commands, oldNodes is the AWS CloudFormation stack name for your older

```
```

136
node stack, and `newNodes` is the name of the stack that you are migrating to. Replace every example value with your own values.

```bash
oldNodes="old_node_CFN_stack_name"
newNodes="new_node_CFN_stack_name"

oldSecGroup=$(aws cloudformation describe-stack-resources --stack-name $oldNodes
  --query 'StackResources[?ResourceType==`AWS::EC2::SecurityGroup`].PhysicalResourceId'
  --output text)
newSecGroup=$(aws cloudformation describe-stack-resources --stack-name $newNodes
  --query 'StackResources[?ResourceType==`AWS::EC2::SecurityGroup`].PhysicalResourceId'
  --output text)
```

b. Add ingress rules to each node security group so that they accept traffic from each other.

The following AWS CLI commands add inbound rules to each security group that allow all traffic on all protocols from the other security group. This configuration allows pods in each node group to communicate with each other while you’re migrating your workload to the new group.

```bash
aws ec2 authorize-security-group-ingress --group-id $oldSecGroup
  --source-group $newSecGroup --protocol -1
aws ec2 authorize-security-group-ingress --group-id $newSecGroup
  --source-group $oldSecGroup --protocol -1
```

5. Edit the `aws-auth` configmap to map the new node instance role in RBAC.

```bash
kubectl edit configmap -n kube-system aws-auth
```

Add a new mapRoles entry for the new node group. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

```yaml
apiVersion: v1
data:
  mapRoles: |
    - rolearn: ARN of instance role (not instance profile)
      username: system:node:{{EC2PrivateDNSName}}
      groups:
        - system:bootstrappers
        - system:nodes
    - rolearn: arn:aws:iam::11112223333:role/nodes-1-16-NodeInstanceRole-U11V27W93CX5
      username: system:node:{{EC2PrivateDNSName}}
      groups:
        - system:bootstrappers
        - system:nodes
```

Replace the ARN of instance role (not instance profile) snippet with the NodInstanceRole value that you recorded in a previous step (p. 136). Then, save and close the file to apply the updated configmap.

6. Watch the status of your nodes and wait for your new nodes to join your cluster and reach the Ready status.

```bash
kubectl get nodes --watch
```

7. (Optional) If you’re using the Kubernetes Cluster Autoscaler, scale the deployment down to zero (0) replicas to avoid conflicting scaling actions.
8. Use the following command to taint each of the nodes that you want to remove with NoSchedule. This is so that new pods aren't scheduled or rescheduled on the nodes that you're replacing.

```
kubectl taint nodes node_name key=value:NoSchedule
```

If you're upgrading your nodes to a new Kubernetes version, you can identify and taint all of the nodes of a particular Kubernetes version (in this case, 1.21) with the following code snippet. The version number can't be later than the Kubernetes version of your control plane. It also can't be more than two minor versions earlier than the Kubernetes version of your control plane. We recommend that you use the same version as your control plane.

```
K8S_VERSION=1.21
nodes=$(kubectl get nodes -o jsonpath="{.items[?(@.status.nodeInfo.kubeletVersion=="v$K8S_VERSION")].metadata.name}")
for node in ${nodes[@]}
do
  echo "Tainting $node"
  kubectl taint nodes $node key=value:NoSchedule
done
```

9. Determine your cluster's DNS provider.

```
kubectl get deployments -l k8s-app=kube-dns -n kube-system
```

The following is the output. This cluster is using CoreDNS for DNS resolution, but your cluster can return kube-dns instead:

```
NAME  DESIRED  CURRENT  UP-TO-DATE  AVAILABLE  AGE
coredns 1 1 1 1 31m
```

10. If your current deployment is running fewer than two replicas, scale out the deployment to two replicas. Replace `coredns` with `kubedns` if your previous command output returned that instead.

```
kubectl scale deployments/coredns --replicas=2 -n kube-system
```

11. Drain each of the nodes that you want to remove from your cluster with the following command:

```
kubectl drain node_name --ignore-daemonsets --delete-local-data
```

If you're upgrading your nodes to a new Kubernetes version, identify and drain all of the nodes of a particular Kubernetes version (in this case, 1.21) with the following code snippet.

```
K8S_VERSION=1.21
nodes=$(kubectl get nodes -o jsonpath="{.items[?(@.status.nodeInfo.kubeletVersion=="v$K8S_VERSION")].metadata.name}")
for node in ${nodes[@]}
do
  echo "Draining $node"
  kubectl drain $node --ignore-daemonsets --delete-local-data
done
```

12. After your old nodes finished draining, revoke the security group inbound rules you authorized earlier. Then, delete the AWS CloudFormation stack to terminate the instances.
Note
If you attached any additional IAM policies to your old node group IAM role, such as adding permissions for the Kubernetes Cluster Autoscaler), detach those additional policies from the role before you can delete your AWS CloudFormation stack.

a. Revoke the inbound rules that you created for your node security groups earlier. In these commands, oldNodes is the AWS CloudFormation stack name for your older node stack, and newNodes is the name of the stack that you are migrating to.

```bash
oldNodes="old_node_CFN_stack_name"
newNodes="new_node_CFN_stack_name"
oldSecGroup=$(aws cloudformation describe-stack-resources --stack-name $oldNodes --query 'StackResources[? ResourceType==`AWS::EC2::SecurityGroup`].PhysicalResourceId' --output text)
newSecGroup=$(aws cloudformation describe-stack-resources --stack-name $newNodes --query 'StackResources[? ResourceType==`AWS::EC2::SecurityGroup`].PhysicalResourceId' --output text)
aws ec2 revoke-security-group-ingress --group-id $oldSecGroup --source-group $newSecGroup --protocol -1
aws ec2 revoke-security-group-ingress --group-id $newSecGroup --source-group $oldSecGroup --protocol -1
```

c. Select your old node stack.
d. Choose Delete.
e. In the Delete stack confirmation dialog box, choose Delete stack.

13. Edit the aws-auth configmap to remove the old node instance role from RBAC.

```bash
kubectl edit configmap -n kube-system aws-auth
```

Delete the mapRoles entry for the old node group. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace arn:aws: with arn:aws-us-gov:

```yaml
apiVersion: v1
data:
mapRoles:
- rolearn: arn:aws:iam::11112223333:role/nodes-1-16-NodeInstanceRole-W70725MZQFF8
  username: system:node:{{EC2PrivateDNSName}}
groups:
  - system:bootstrappers
  - system:nodes
  username: system:node:{{EC2PrivateDNSName}}
groups:
  - system:bootstrappers
  - system:nodes>
```

Save and close the file to apply the updated configmap.

14. (Optional) If you are using the Kubernetes Cluster Autoscaler, scale the deployment back to one replica.

Note
You must also tag your new Auto Scaling group appropriately (for example, k8s.io/cluster-autoscaler/enabled,k8s.io/cluster-autoscaler/my-cluster) and
update the command for your Cluster Autoscaler deployment to point to the newly tagged Auto Scaling group. For more information, see Cluster Autoscaler on AWS.

```
kubectl scale deployments/cluster-autoscaler --replicas=1 -n kube-system
```

15. (Optional) Verify that you’re using the latest version of the Amazon VPC CNI plugin for Kubernetes. You might need to update your CNI version to use the latest supported instance types. For more information, see Updating the Amazon VPC CNI plugin for Kubernetes self-managed add-on (p. 253).

16. If your cluster is using `kube-dns` for DNS resolution (see previous step (p. 138)), scale in the `kube-dns` deployment to one replica.

```
kubectl scale deployments/kube-dns --replicas=1 -n kube-system
```

### Updating an existing self-managed node group

This topic describes how you can update an existing AWS CloudFormation self-managed node stack with a new AMI. You can use this procedure to update your nodes to a new version of Kubernetes following a cluster update. Otherwise, you can update to the latest Amazon EKS optimized AMI for an existing Kubernetes version.

**Important**

This topic covers node updates for self-managed nodes. For information about using Managed node groups (p. 97), see Updating a managed node group (p. 107).

The latest default Amazon EKS node AWS CloudFormation template is configured to launch an instance with the new AMI into your cluster before removing an old one, one at a time. This configuration ensures that you always have your Auto Scaling group’s desired count of active instances in your cluster during the rolling update.

**Note**

This method isn’t supported for node groups that were created with `eksctl`. If you created your cluster or node group with `eksctl`, see Migrating to a new node group (p. 135).

**To update an existing node group**

1. Determine the DNS provider for your cluster.

```
kubectl get deployments -l k8s-app=kube-dns -n kube-system
```

The example output is as follows. This cluster is using CoreDNS for DNS resolution, but your cluster might return `kube-dns` instead.

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESIRED</th>
<th>CURRENT</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>coredns</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>31m</td>
</tr>
</tbody>
</table>

2. If your current deployment is running fewer than two replicas, scale out the deployment to two replicas. Replace `coredns` with `kube-dns` if your previous command output returned that instead.

```
kubectl scale deployments/coredns --replicas=2 -n kube-system
```

3. (Optional) If you’re using the Kubernetes Cluster Autoscaler, scale the deployment down to zero (0) replicas to avoid conflicting scaling actions.

```
kubectl scale deployments/cluster-autoscaler --replicas=0 -n kube-system
```
4. Determine the instance type and desired instance count of your current node group. You enter these values later when you update the AWS CloudFormation template for the group.
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. In the left navigation pane, choose Launch Configurations, and note the instance type for your existing node launch configuration.
   c. In the left navigation pane, choose Auto Scaling Groups, and note the Desired instance count for your existing node Auto Scaling group.

6. Select your node group stack, and then choose Update.

7. Select Replace current template and select Amazon S3 URL.

8. For Amazon S3 URL, paste the following URL into the text area to ensure that you're using the latest version of the node AWS CloudFormation template. Then, choose Next:

9. On the Specify stack details page, fill out the following parameters, and choose Next:

   - **NodeAutoScalingGroupDesiredCapacity** – Enter the desired instance count that you recorded in a previous step (p. 141). Or, enter your new desired number of nodes to scale to when your stack is updated.
   - **NodeAutoScalingGroupMaxSize** – Enter the maximum number of nodes to which your node Auto Scaling group can scale out. This value must be at least one node more than your desired capacity. This is so that you can perform a rolling update of your nodes without reducing your node count during the update.
   - **NodeType** – Choose the instance type your recorded in a previous step (p. 141). Alternatively, choose a different instance type for your nodes. Before choosing a different instance type, review Choosing an Amazon EC2 instance type (p. 162). Each Amazon EC2 instance type supports a maximum number of elastic network interfaces (network interface) and each network interface supports a maximum number of IP addresses. Because each worker node and pod is assigned its own IP address, it's important to choose an instance type that will support the maximum number of pods that you want to run on each Amazon EC2 node. For a list of the number of network interfaces and IP addresses supported by instance types, see IP addresses per network interface per instance type. For example, the m5.large instance type supports a maximum of 30 IP addresses for the worker node and pods.

   **Note**
   The supported instance types for the latest version of the Amazon VPC CNI plugin for Kubernetes are shown in vpc_ip_resource_limit.go on GitHub. You might need to update your CNI version to use the latest supported instance types. For more information, see Updating the Amazon VPC CNI plugin for Kubernetes self-managed add-on (p. 253).

   **Important**
   Some instance types might not be available in all AWS Regions.

   - **NodeImageIdSSMParam** – The Amazon EC2 Systems Manager parameter of the AMI ID that you want to update to. The following value uses the latest Amazon EKS optimized AMI for Kubernetes version 1.23.

     /aws/service/eks/optimized-ami/1.23/amazon-linux-2/recommended/image_id

     You can replace 1.23 with a supported Kubernetes version (p. 75) that's the same. Or, it should be up to one version earlier than the Kubernetes version running on your control plane. We recommend that you keep your nodes at the same version as your control plane. If you want to
use the Amazon EKS optimized accelerated AMI, then replace `amazon-linux-2` with `amazon-linux-2-gpu`.

**Note**
Using the Amazon EC2 Systems Manager parameter enables you to update your nodes in the future without having to look up and specify an AMI ID. If your AWS CloudFormation stack is using this value, any stack update always launches the latest recommended Amazon EKS optimized AMI for your specified Kubernetes version. This is even the case even if you don't change any values in the template.

- **NodeImageId** – To use your own custom AMI, enter the ID for the AMI to use.

  **Important**
This value overrides any value specified for `NodeImageIdSSMParam`. If you want to use the `NodeImageIdSSMParam` value, ensure that the value for `NodeImageId` is blank.

- **DisableIMDSv1** – By default, each node supports the Instance Metadata Service Version 1 (IMDSv1) and IMDSv2. However, you can disable IMDSv1. Select `true` if you don't want any nodes or any pods scheduled in the node group to use IMDSv1. For more information about IMDS, see Configuring the instance metadata service. If you've implemented IAM roles for service accounts, assign necessary permissions directly to all pods that require access to AWS services. This way, no pods in your cluster require access to IMDS for other reasons, such as retrieving the current AWS Region. Then, you can also disable access to IMDSv2 for pods that don't use host networking. For more information, see Restrict access to the instance profile assigned to the worker node.

10. (Optional) On the **Options** page, tag your stack resources. Choose **Next**.
11. On the **Review** page, review your information, acknowledge that the stack might create IAM resources, and then choose **Update stack**.

  **Note**
The update of each node in the cluster takes several minutes. Wait for the update of all nodes to complete before performing the next steps.

12. If your cluster's DNS provider is `kube-dns`, scale in the `kube-dns` deployment to one replica.

```
kubectl scale deployments/kube-dns --replicas=1 -n kube-system
```

13. (Optional) If you are using the Kubernetes **Cluster Autoscaler**, scale the deployment back to your desired amount of replicas.

```
kubectl scale deployments/cluster-autoscaler --replicas=1 -n kube-system
```

14. (Optional) Verify that you're using the latest version of the **Amazon VPC CNI plugin for Kubernetes**. You might need to update your CNI version to use the latest supported instance types. For more information, see Updating the Amazon VPC CNI plugin for Kubernetes self-managed add-on (p. 253).

### AWS Fargate

This topic discusses using Amazon EKS to run Kubernetes pods on AWS Fargate.

AWS Fargate is a technology that provides on-demand, right-sized compute capacity for containers. With AWS Fargate, you don't have to provision, configure, or scale groups of virtual machines on your own to run containers. You also don't need to choose server types, decide when to scale your node groups, or optimize cluster packing. You can control which pods start on Fargate and how they run with Fargate profiles (p. 147). Fargate profiles are defined as part of your Amazon EKS cluster.

Amazon EKS integrates Kubernetes with AWS Fargate by using controllers that are built by AWS using the upstream, extensible model provided by Kubernetes. These controllers run as part of the Amazon EKS managed Kubernetes control plane and are responsible for scheduling native Kubernetes pods onto
Fargate controllers include a new scheduler that runs alongside the default Kubernetes scheduler in addition to several mutating and validating admission controllers. When you start a pod that meets the criteria for running on Fargate, the Fargate controllers that are running in the cluster recognize, update, and schedule the pod onto Fargate.

This topic describes the different components of pods that run on Fargate, and calls out special considerations for using Fargate with Amazon EKS.

AWS Fargate considerations

Here are some things to consider about using Fargate on Amazon EKS.

- AWS Fargate with Amazon EKS is available in all Amazon EKS Regions except AWS GovCloud (US-East) and AWS GovCloud (US-West).
- Each pod that runs on Fargate has its own isolation boundary. They don't share the underlying kernel, CPU resources, memory resources, or elastic network interface with another pod.
- Network Load Balancers and Application Load Balancers (ALBs) can be used with Fargate with IP targets only. For more information, see Create a network load balancer (p. 353) and Application load balancing on Amazon EKS (p. 357).
- Fargate exposed services only run on target type IP mode, and not on node IP mode. The recommended way to check the connectivity from a service running on a managed node and a service running on Fargate is to connect via service name.
- Pods must match a Fargate profile at the time that they're scheduled to run on Fargate. Pods that don't match a Fargate profile might be stuck as Pending. If a matching Fargate profile exists, you can delete pending pods that you have created to reschedule them onto Fargate.
- Daemonsets aren't supported on Fargate. If your application requires a daemon, reconfigure that daemon to run as a sidecar container in your pods.
- Privileged containers aren't supported on Fargate.
- Pods running on Fargate can't specify HostPort or HostNetwork in the pod manifest.
- The default nofile and nproc soft limit is 1024 and the hard limit is 65535 for Fargate pods.
- GPUs aren't currently available on Fargate.
- Pods that run on Fargate are only supported on private subnets (with NAT gateway access to AWS services, but not a direct route to an Internet Gateway), so your cluster's VPC must have private subnets available. For clusters without outbound internet access, see Private cluster requirements (p. 63).
- You can use the Vertical Pod Autoscaler (p. 345) to set the initial correct size of CPU and memory for your Fargate pods, and then use the Horizontal Pod Autoscaler (p. 349) to scale those pods. If you want the Vertical Pod Autoscaler to automatically re-deploy pods to Fargate with larger CPU and memory combinations, set the mode for the Vertical Pod Autoscaler to either Auto or Recreate to ensure correct functionality. For more information, see the Vertical Pod Autoscaler documentation on GitHub.
- DNS resolution and DNS hostnames must be enabled for your VPC. For more information, see Viewing and updating DNS support for your VPC.
- Amazon EKS Fargate adds defense-in-depth for Kubernetes applications by isolating each Pod within a Virtual Machine (VM). This VM boundary prevents access to host-based resources used by other Pods in the event of a container escape, which is a common method of attacking containerized applications and gain access to resources outside of the container.

Using Amazon EKS doesn't change your responsibilities under the shared responsibility model (p. 421). You should carefully consider the configuration of cluster security and governance controls. The safest way to isolate an application is always to run it in a separate cluster.

- Fargate profiles support specifying subnets from VPC secondary CIDR blocks. You might want to specify a secondary CIDR block. This is because there's a limited number of IP addresses available in a subnet. As a result, there's also a limited number of pods that can be created in the cluster. By
using different subnets for pods, you can increase the number of available IP addresses. For more information, see Adding IPv4 CIDR blocks to a VPC.

- The Amazon EC2 instance metadata service (IMDS) isn't available to pods that are deployed to Fargate nodes. If you have pods that are deployed to Fargate that need IAM credentials, assign them to your pods using IAM roles for service accounts (p. 425). If your pods need access to other information available through IMDS, then you must hard code this information into your pod spec. This includes the AWS Region or Availability Zone that a pod is deployed to.
- You can't deploy Fargate pods to AWS Outposts, AWS Wavelength or AWS Local Zones.
- Amazon EKS must periodically patch AWS Fargate pods to keep them secure. We attempt the updates in a way that reduces impact, but there are times when pods must be deleted if they aren't successfully evicted. There are some actions you can take to minimize disruption. For more information, see Fargate pod patching (p. 153).
- The Amazon VPC CNI plugin for Amazon EKS is installed on Fargate nodes. You can't use the section called "Alternate compatible CNI plugins" (p. 308) with Fargate nodes.

**Getting started with AWS Fargate using Amazon EKS**

This topic describes how to get started running pods on AWS Fargate with your Amazon EKS cluster.

If you restrict access to the public endpoint of your cluster using CIDR blocks, we recommend that you also enable private endpoint access. This way, Fargate pods can communicate with the cluster. Without the private endpoint enabled, the CIDR blocks that you specify for public access must include the outbound sources from your VPC. For more information, see Amazon EKS cluster endpoint access control (p. 43).

**Prerequisite**

An existing cluster. AWS Fargate with Amazon EKS is available in all Amazon EKS Regions except AWS GovCloud (US-East) and AWS GovCloud (US-West). If you don't already have an Amazon EKS cluster, see Getting started with Amazon EKS (p. 4).

**Ensure that existing nodes can communicate with Fargate pods**

If you're working with a new cluster with no nodes, or a cluster with only managed node groups (p. 97), you can skip to Create a Fargate pod execution role (p. 145).

Assume that you're working with an existing cluster that already has nodes that are associated with it. Make sure that pods on these nodes can communicate freely with the pods that are running on Fargate. Pods that are running on Fargate are automatically configured to use the cluster security group for the cluster that they're associated with. Ensure that any existing nodes in your cluster can send and receive traffic to and from the cluster security group. Managed node groups (p. 97) are automatically configured to use the cluster security group as well, so you don't need to modify or check them for this compatibility.

For existing node groups that were created with `eksctl` or the Amazon EKS managed AWS CloudFormation templates, you can add the cluster security group to the nodes manually. Or, alternatively, you can modify the Auto Scaling group launch template for the node group to attach the cluster security group to the instances. For more information, see Changing an instance's security groups in the Amazon VPC User Guide.

You can check for a security group for your cluster in the AWS Management Console under the Networking section for the cluster. Or, you can do this using the following AWS CLI command. When using this command, replace `my-cluster` with the name of your cluster.

```
aws eks describe-cluster --name my-cluster --query cluster.resourcesVpcConfig.clusterSecurityGroupId
```
Create a Fargate pod execution role

When your cluster creates pods on AWS Fargate, the components that run on the Fargate infrastructure must make calls to AWS APIs on your behalf. The Amazon EKS pod execution role provides the IAM permissions to do this. To create an AWS Fargate pod execution role, see Amazon EKS pod execution IAM role (p. 465).

Note
If you created your cluster with eksctl using the --fargate option, your cluster already has a pod execution role that you can find in the IAM console with the pattern eksctl-my-cluster-FargatePodExecutionRole-ABCDEFGHIJKL. Similarly, if you use eksctl to create your Fargate profiles, eksctl creates your pod execution role if one isn't already created.

Create a Fargate profile for your cluster

Before you can schedule pods that are running on Fargate in your cluster, you must define a Fargate profile that specifies which pods use Fargate when they're launched. For more information, see AWS Fargate profile (p. 147).

Note
If you created your cluster with eksctl using the --fargate option, then a Fargate profile is already created for your cluster with selectors for all pods in the kube-system and default namespaces. Use the following procedure to create Fargate profiles for any other namespaces you would like to use with Fargate.

You can create a Fargate profile using eksctl or the AWS Management Console.

eksctl

This procedure requires eksctl version 0.112.0 or later. You can check your version with the following command:

```bash
eksctl version
```

For instructions on how to install or upgrade eksctl, see Installing or updating eksctl (p. 10).

To create a Fargate profile with eksctl

Create your Fargate profile with the following eksctl command, replacing every example value with your own values. You're required to specify a namespace. However, the --labels option isn't required.

```bash
eksctl create fargateprofile
  --cluster my-cluster
  --name my-fargate-profile
  --namespace my-kubernetes-namespace
  --labels key=value
```

You can use certain wildcards for my-kubernetes-namespace and key=value labels. For more information, see Fargate profile wildcards (p. 148).

AWS Management Console

To create a Fargate profile for a cluster with the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster to create a Fargate profile for.
3. Choose the Compute tab.
4. Under Fargate profiles, choose Add Fargate profile.
5. On the **Configure Fargate profile** page, do the following:
   a. For **Name**, enter a name for your Fargate profile. The name must be unique.
   b. For **Pod execution role**, choose the pod execution role to use with your Fargate profile. Only the IAM roles with the `eks-fargate-pods.amazonaws.com` service principal are shown. If you don’t see any roles listed, you must create one. For more information, see [Amazon EKS pod execution IAM role](#).
   c. Choose the **Subnets** dropdown and deselect any subnet with `Public` in its name. Only private subnets are supported for pods that are running on Fargate.
   d. For **Tags**, you can optionally tag your Fargate profile. These tags don’t propagate to other resources that are associated with the profile such as pods.
   e. Choose **Next**.

6. On the **Configure pod selection** page, do the following:
   a. For **Namespace**, enter a namespace to match for pods.
      - You can use specific namespaces to match, such as `kube-system` or `default`.
      - You can use certain wildcards (for example, `prod-*`) to match multiple namespaces (for example, `prod-deployment` and `prod-test`). For more information, see [Fargate profile wildcards](#).
   b. (Optional) Add Kubernetes labels to the selector. Specifically add them to the one that the pods in the specified namespace need to match.
      - You can add the label `infrastructure: fargate` to the selector so that only pods in the specified namespace that also have the `infrastructure: fargate` Kubernetes label match the selector.
      - You can use certain wildcards (for example, `key?: value?`) to match multiple namespaces (for example, `keya: valuea` and `keyb: valueb`). For more information, see [Fargate profile wildcards](#).
   c. Choose **Next**.

7. On the **Review and create** page, review the information for your Fargate profile and choose **Create**.

### Update CoreDNS

By default, CoreDNS is configured to run on Amazon EC2 infrastructure on Amazon EKS clusters. If you want to only run your pods on Fargate in your cluster, complete the following steps.

**Note**
- If you created your cluster with `eksctl` using the `--fargate` option, then you can skip to Next steps (p. 147).

1. Create a Fargate profile for CoreDNS with the following command. Replace `my-cluster` with your cluster name, `111122223333` with your account ID, `AmazonEKSFargatePodExecutionRole` with the name of your pod execution role, and `0000000000000001,0000000000000002, and 0000000000000003` with the IDs of your private subnets. If you don’t have a pod execution role, you must create one (p. 145) first. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

   **Important**
   - The role ARN can’t include a path. The format of the role ARN must be `arn:aws:iam::111122223333:role/role-name`. For more information, see [aws-auth ConfigMap](#) does not grant access to the cluster (p. 532).

```bash
aws eks create-fargate-profile
```
AWS Fargate profile

Before you schedule pods on Fargate in your cluster, you must define at least one Fargate profile that specifies which pods use Fargate when launched.

As an administrator, you can use a Fargate profile to declare which pods run on Fargate. You can do this through the profile’s selectors. You can add up to five selectors to each profile. Each selector contains a namespace and optional labels. For every selector, you must define a namespace for every selector. The label field consists of multiple optional key-value pairs. Pods that match a selector are scheduled on Fargate. Pods are matched using a namespace and the labels that are specified in the selector. If a namespace selector is defined without labels, Amazon EKS attempts to schedule all the pods that run in that namespace onto Fargate using the profile. If a to-be-scheduled pod matches any of the selectors in the Fargate profile, then that pod is scheduled on Fargate.

If a pod matches multiple Fargate profiles, you can specify which profile a pod uses by adding the following Kubernetes label to the pod specification: eks.amazonaws.com/fargate-profile:
my-fargate-profile. The pod must match a selector in that profile to be scheduled onto Fargate. Kubernetes affinity/anti-affinity rules do not apply and aren't necessary with Amazon EKS Fargate pods.

When you create a Fargate profile, you must specify a pod execution role. This execution role is for the Amazon EKS components that run on the Fargate infrastructure using the profile. It's added to the cluster's Kubernetes Role Based Access Control (RBAC) for authorization. That way, the kubelet that runs on the Fargate infrastructure can register with your Amazon EKS cluster and appear in your cluster as a node. The pod execution role also provides IAM permissions to the Fargate infrastructure to allow read access to Amazon ECR image repositories. For more information, see Amazon EKS pod execution IAM role (p. 465).

Fargate profiles can't be changed. However, you can create a new updated profile to replace an existing profile, and then delete the original.

Note
Any pods that are running using a Fargate profile are stopped and put into a pending state when the profile is deleted.

If any Fargate profiles in a cluster are in the DELETING status, you must wait until after the Fargate profile is deleted before you create other profiles in that cluster.

Amazon EKS and Fargate spread pods across each of the subnets that's defined in the Fargate profile. However, you might end up with an uneven spread. If you must have an even spread, use two Fargate profiles. Even spread is important in scenarios where you want to deploy two replicas and don't want any downtime. We recommend that each profile has only one subnet.

Fargate profile components

The following components are contained in a Fargate profile.

- **Pod execution role** – When your cluster creates pods on AWS Fargate, the kubelet that's running on the Fargate infrastructure must make calls to AWS APIs on your behalf. For example, it needs to make calls to pull container images from Amazon ECR. The Amazon EKS pod execution role provides the IAM permissions to do this.

When you create a Fargate profile, you must specify a pod execution role to use with your pods. This role is added to the cluster's Kubernetes Role-based access control (RBAC) for authorization. This is so that the kubelet that's running on the Fargate infrastructure can register with your Amazon EKS cluster and appear in your cluster as a node. For more information, see Amazon EKS pod execution IAM role (p. 465).

- **Subnets** – The IDs of subnets to launch pods into that use this profile. At this time, pods that are running on Fargate aren't assigned public IP addresses. Therefore, only private subnets with no direct route to an Internet Gateway are accepted for this parameter.

- **Selectors** – The selectors to match for pods to use this Fargate profile. You might specify up to five selectors in a Fargate profile. The selectors have the following components:
  - **Namespace** – You must specify a namespace for a selector. The selector only matches pods that are created in this namespace. However, you can create multiple selectors to target multiple namespaces.
  - **Labels** – You can optionally specify Kubernetes labels to match for the selector. The selector only matches pods that have all of the labels that are specified in the selector.

Fargate profile wildcards

In addition to characters allowed by Kubernetes, you're allowed to use * and ? in the selector criteria for namespaces, label keys, and label values:
• * represents none, one, or multiple characters. For example, prod* can represent prod and prod-metrics.
• ? represents a single character (for example, value? can represent valuea). However, it can’t represent value and value-a, because ? can only represent exactly one character.

These wildcard characters can be used in any position and in combination (for example, prod*, *dev, and frontend*?). Other wildcards and forms of pattern matching, such as regular expressions, aren’t supported.

If there are multiple matching profiles for the namespace and labels in the pod spec, Fargate picks up the profile based on alphanumeric sorting by profile name. For example, if both profile A (with the name beta-workload) and profile B (with the name prod-workload) have matching selectors for the pods to be launched, Fargate picks profile A (beta-workload) for the pods. The pods have labels with profile A on the pods (for example, eks.amazonaws.com/fargate-profile=beta-workload).

If you want to migrate existing Fargate pods to new profiles that use wildcards, there are two ways to do so:

• Create a new profile with matching selectors, then delete the old profiles. Pods labeled with old profiles are rescheduled to new matching profiles.
• If you want to migrate workloads but aren’t sure what Fargate labels are on each Fargate pod, you can use the following method. Create a new profile with a name that sorts alphanumerically first among the profiles on the same cluster. Then, recycle the Fargate pods that need to be migrated to new profiles.

Creating a Fargate profile

This topic describes how to create a Fargate profile. AWS Fargate with Amazon EKS is available in all Amazon EKS Regions except AWS GovCloud (US-East) and AWS GovCloud (US-West). You also must have created a pod execution role to use for your Fargate profile. For more information, see Amazon EKS pod execution IAM role (p. 465). Pods that are running on Fargate are only supported on private subnets with NAT gateway access to AWS services, but not a direct route to an Internet Gateway. This is so that your cluster's VPC must have private subnets available. You can create a profile with eksctl or the AWS Management Console. Select the tab with the name of the tool that you want to create your Fargate profile with.

This procedure requires eksctl version 0.112.0 or later. You can check your version with the following command:

```bash
eksctl version
```

For instructions on how to install or upgrade eksctl, see Installing or updating eksctl (p. 10).

eksctl

To create a Fargate profile with eksctl

Create your Fargate profile with the following eksctl command, replacing every example value with your own values. You’re required to specify a namespace. However, the --labels option isn’t required.

```bash
eksctl create fargateprofile \
--cluster my-cluster \
--name my-fargate-profile \
--namespace my-kubernetes-namespace \
--labels key=value
```
You can use certain wildcards for `my-kubernetes-namespace` and `key=value` labels. For more information, see Fargate profile wildcards (p. 148).

AWS Management Console

To create a Fargate profile for a cluster with the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster to create a Fargate profile for.
3. Choose the Compute tab.
4. Under Fargate profiles, choose Add Fargate profile.
5. On the Configure Fargate profile page, do the following:
   a. For Name, enter a unique name for your Fargate profile, such as `my-profile`.
   b. For Pod execution role, choose the pod execution role to use with your Fargate profile. Only the IAM roles with the `eks-fargate-pods.amazonaws.com` service principal are shown. If you don't see any roles listed, you must create one. For more information, see Amazon EKS pod execution IAM role (p. 465).
   c. Choose the Subnets dropdown and deselect any subnet with Public in its name. Only private subnets are supported for pods that are running on Fargate.
   d. For Tags, you can optionally tag your Fargate profile. These tags don't propagate to other resources that are associated with the profile, such as pods.
   e. Choose Next.
6. On the Configure pod selection page, do the following:
   a. For Namespace, enter a namespace to match for pods.
      • You can use specific namespaces to match, such as `kube-system` or `default`.
      • You can use certain wildcards (for example, `prod-*`) to match multiple namespaces (for example, `prod-deployment` and `prod-test`). For more information, see Fargate profile wildcards (p. 148).
   b. (Optional) Add Kubernetes labels to the selector. Specifically, add them to the one that the pods in the specified namespace need to match.
      • You can add the label `infrastructure: fargate` to the selector so that only pods in the specified namespace that also have the `infrastructure: fargate` Kubernetes label match the selector.
      • You can use certain wildcards (for example, `key?: value?`) to match multiple namespaces (for example, `keya: valuea` and `keyb: valueb`). For more information, see Fargate profile wildcards (p. 148).
   c. Choose Next.
7. On the Review and create page, review the information for your Fargate profile and choose Create.

Deleting a Fargate profile

This topic describes how to delete a Fargate profile.

When you delete a Fargate profile, any pods that were scheduled onto Fargate with the profile are deleted. If those pods match another Fargate profile, then they're scheduled on Fargate with that profile. If they no longer match any Fargate profiles, then they aren't scheduled onto Fargate and might remain as pending.

Only one Fargate profile in a cluster can be in the DELETING status at a time. Wait for a Fargate profile to finish deleting before you can delete any other profiles in that cluster.
You can delete a profile with `eksctl`, the AWS Management Console, or the AWS CLI. Select the tab with the name of the tool that you want to use to delete your profile.

**eksctl**

To delete a Fargate profile with `eksctl`

Use the following command to delete a profile from a cluster. Replace every `example value` with your own values.

```
eksctl delete fargateprofile --name my-profile --cluster my-cluster
```

**AWS Management Console**

To delete a Fargate profile from a cluster with the AWS Management Console

1. Open the Amazon EKS console at [https://console.aws.amazon.com/eks/home#/clusters](https://console.aws.amazon.com/eks/home#/clusters).
2. In the left navigation pane, choose Clusters. In the list of clusters, choose the cluster that you want to delete the Fargate profile from.
3. Choose the Compute tab.
4. Choose the Fargate profile to delete, and then choose Delete.
5. On the Delete Fargate profile page, enter the name of the profile, and then choose Delete.

**AWS CLI**

To delete a Fargate profile with AWS CLI

Use the following command to delete a profile from a cluster. Replace every `example value` with your own values.

```
aws eks delete-fargate-profile --fargate-profile-name my-profile --cluster-name my-cluster
```

**Fargate pod configuration**

This section describes some of the unique pod configuration details for running Kubernetes pods on AWS Fargate.

**Pod CPU and memory**

With Kubernetes, you can define requests, a minimum vCPU amount, and memory resources that are allocated to each container in a pod. Pods are scheduled by Kubernetes to ensure that at least the requested resources for each pod are available on the compute resource. For more information, see Managing compute resources for containers in the Kubernetes documentation.

**Note**

Since Amazon EKS Fargate runs only one pod per node, the scenario of evicting pods in case of fewer resources doesn't occur. All Amazon EKS Fargate pods run with guaranteed priority, so the requested CPU and memory must be equal to the limit for all of the containers. For more information, see Configure Quality of Service for Pods in the Kubernetes documentation.

When pods are scheduled on Fargate, the vCPU and memory reservations within the pod specification determine how much CPU and memory to provision for the pod.

- The maximum request out of any Init containers is used to determine the Init request vCPU and memory requirements.
• Requests for all long-running containers are added up to determine the long-running request vCPU and memory requirements.
• The larger of the previous two values is chosen for the vCPU and memory request to use for your pod.
• Fargate adds 256 MB to each pod's memory reservation for the required Kubernetes components (kubelet, kube-proxy, and containerd).

Fargate rounds up to the following compute configuration that most closely matches the sum of vCPU and memory requests in order to ensure pods always have the resources that they need to run.

If you don't specify a vCPU and memory combination, then the smallest available combination is used (.25 vCPU and 0.5 GB memory).

The following table shows the vCPU and memory combinations that are available for pods running on Fargate.

<table>
<thead>
<tr>
<th>vCPU value</th>
<th>Memory value</th>
</tr>
</thead>
<tbody>
<tr>
<td>.25 vCPU</td>
<td>0.5 GB, 1 GB, 2 GB</td>
</tr>
<tr>
<td>.5 vCPU</td>
<td>1 GB, 2 GB, 3 GB, 4 GB</td>
</tr>
<tr>
<td>1 vCPU</td>
<td>2 GB, 3 GB, 4 GB, 5 GB, 6 GB, 7 GB, 8 GB</td>
</tr>
<tr>
<td>2 vCPU</td>
<td>Between 4 GB and 16 GB in 1-GB increments</td>
</tr>
<tr>
<td>4 vCPU</td>
<td>Between 8 GB and 30 GB in 1-GB increments</td>
</tr>
<tr>
<td>8 vCPU</td>
<td>Between 16 GB and 60 GB in 4-GB increments</td>
</tr>
<tr>
<td>16 vCPU</td>
<td>Between 32 GB and 120 GB in 8-GB increments</td>
</tr>
</tbody>
</table>

The additional memory reserved for the Kubernetes components can cause a Fargate task with more vCPUs than requested to be provisioned. For example, a request for 1 vCPU and 8 GB memory will have 256 MB added to its memory request, and will provision a Fargate task with 2 vCPUs and 9 GB memory, since no task with 1 vCPU and 9 GB memory is available.

There is no correlation between the size of the pod running on Fargate and the node size reported by Kubernetes with `kubectl get nodes`. The reported node size is often larger than the pod's capacity. You can verify pod capacity with the following command. Replace `pod-name` with the name of your pod.

```
kubectl describe pod pod-name
```

The example output is as follows.

```
... annotations:
  CapacityProvisioned: 0.25vCPU 0.5GB
...
```

The `CapacityProvisioned` annotation represents the enforced pod capacity and it determines the cost of your pod running on Fargate. For pricing information for the compute configurations, see AWS Fargate Pricing.

**Fargate storage**

When provisioned, each pod running on Fargate receives 20 GB of container image layer storage. Pod storage is ephemeral. After a pod stops, the storage is deleted. New pods launched onto Fargate on
or after May 28, 2020, have encryption of the ephemeral storage volume enabled by default. The ephemeral pod storage is encrypted with an AES-256 encryption algorithm using AWS Fargate managed keys.

**Note**
The usable storage for Amazon EKS pods that run on Fargate is less than 20 GB because some space is used by the kubelet and other Kubernetes modules that are loaded inside the pod.

## Fargate pod patching

Amazon EKS must periodically patch AWS Fargate pods to keep them secure. Updates are attempted in a way that creates the least impact on your services. However, if pods aren't successfully evicted, there are times when they must be deleted. The following are actions that you can take to minimize potential disruptions:

- Set appropriate pod disruption budgets (PDBs) to control the number of pods that are down simultaneously.
- Create event rules to react to failed evictions before the pods are deleted.

Amazon EKS works closely with the Kubernetes community to make bug fixes and security patches available as quickly as possible. New patch versions of Kubernetes are made available as part of Fargate platform versions. All Fargate pods start on the most recent Kubernetes patch version, which is available from Amazon EKS for the Kubernetes version of your cluster. If you have a pod with an older patch version, Amazon EKS might restart it to update it to the latest version. This ensures that your pods are equipped with the latest security updates. That way, if there's a critical Common Vulnerabilities and Exposures (CVE) issue, you're kept up to date to reduce security risks.

To limit the number of pods that are down at one time when pods are patched, you can set pod disruption budgets (PDBs). You can use PDBs to define minimum availability based on the requirements of each of your applications while still allowing updates to occur. For more information, see Specifying a Disruption Budget for your Application in the Kubernetes Documentation.

Amazon EKS uses the Eviction API to safely drain the pod while respecting the PDBs that you set for the application. Pods are evicted by Availability Zone to minimize impact. If the eviction succeeds, the new pod gets the latest patch and no further action is required.

When the eviction for a pod fails, Amazon EKS sends an event to your account with details about the pods that failed eviction. You can act on the message before the scheduled termination time. The specific time varies based on the urgency of the patch. When it's time, Amazon EKS attempts to evict the pods again. However, this time a new event isn’t sent if the eviction fails. If the eviction fails again, your existing pods are deleted periodically so that the new pods can have the latest patch.

The following is a sample event received when the pod eviction fails. It contains details about the cluster, pod name, pod namespace, Fargate profile, and the scheduled termination time.

```json
{
    "version": "0",
    "id": "12345678-90ab-cdef-0123-4567890abcde",
    "detail-type": "EKS Fargate Pod Scheduled Termination",
    "source": "aws.eks",
    "account": "111122223333",
    "time": "2021-06-27T12:52:44Z",
    "region": "region-code",
    "resources": [
        "default/my-database-deployment"
    ],
    "detail": {
        "clusterName": "my-cluster",
        "fargateProfileName": "my-fargate-profile",
```
Fargate metrics

You can collect system metrics and CloudWatch usage metrics for AWS Fargate.

Application metrics

For applications running on Amazon EKS and AWS Fargate, you can use the AWS Distro for OpenTelemetry (ADOT). ADOT allows you to collect system metrics and send them to CloudWatch Container Insights dashboards. To get started with ADOT for applications running on Fargate, see Using CloudWatch Container Insights with AWS Distro for OpenTelemetry in the ADOT documentation.

Usage metrics

You can use CloudWatch usage metrics to provide visibility into your account's usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

AWS Fargate usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about Fargate service quotas, see Amazon EKS service quotas (p. 416).

AWS Fargate publishes the following metrics in the AWS/Usage namespace.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourceCount</td>
<td>The total number of the specified resource running on your account. The resource is defined by the dimensions associated with the metric.</td>
</tr>
</tbody>
</table>
The following dimensions are used to refine the usage metrics that are published by AWS Fargate.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service</td>
<td>The name of the AWS service containing the resource. For AWS Fargate usage metrics, the value for this dimension is Fargate.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of entity that's being reported. Currently, the only valid value for AWS Fargate usage metrics is Resource.</td>
</tr>
<tr>
<td>Resource</td>
<td>The type of resource that's running. Currently, AWS Fargate returns information on your Fargate On-Demand usage. The resource value for Fargate On-Demand usage is OnDemand. <strong>Note</strong> Fargate On-Demand usage combines Amazon EKS pods using Fargate, Amazon ECS tasks using the Fargate launch type and Amazon ECS tasks using the FARGATE capacity provider.</td>
</tr>
<tr>
<td>Class</td>
<td>The class of resource being tracked. Currently, AWS Fargate doesn't use the class dimension.</td>
</tr>
</tbody>
</table>

**Creating a CloudWatch alarm to monitor Fargate resource usage metrics**

AWS Fargate provides CloudWatch usage metrics that correspond to the AWS service quotas for Fargate On-Demand resource usage. In the Service Quotas console, you can visualize your usage on a graph. You can also configure alarms that alert you when your usage approaches a service quota. For more information, see Fargate metrics (p. 154).

Use the following steps to create a CloudWatch alarm based on the Fargate resource usage metrics.

**To create an alarm based on your Fargate usage quotas (AWS Management Console)**

2. In the left navigation pane, choose AWS services.
3. From the AWS services list, search for and select AWS Fargate.
4. In the Service quotas list, choose the Fargate usage quota you want to create an alarm for.
5. In the Amazon CloudWatch alarms section, choose Create.
6. For Alarm threshold, choose the percentage of your applied quota value that you want to set as the alarm value.
7. For Alarm name, enter a name for the alarm and then choose Create.

**Fargate logging**

Amazon EKS on Fargate offers a built-in log router based on Fluent Bit. This means that you don't explicitly run a Fluent Bit container as a sidecar, but Amazon runs it for you. All that you have to do is configure the log router. The configuration happens through a dedicated ConfigMap that must meet the following criteria:

- Named aws-logging
- Created in a dedicated namespace called aws-observability
Once you've created the ConfigMap, Amazon EKS on Fargate automatically detects it and configures the log router with it. Fargate uses a version of AWS for Fluent Bit, an upstream compliant distribution of Fluent Bit managed by AWS. For more information, see AWS for Fluent Bit on GitHub.

The log router allows you to use the breadth of services at AWS for log analytics and storage. You can stream logs from Fargate directly to Amazon CloudWatch, Amazon OpenSearch Service. You can also stream logs to destinations such as Amazon S3, Amazon Kinesis Data Streams, and partner tools through Amazon Kinesis Data Firehose.

**Prerequisites**

- An existing Fargate profile that specifies an existing Kubernetes namespace that you deploy Fargate pods to. For more information, see Create a Fargate profile for your cluster (p. 145).
- An existing Fargate pod execution role. For more information, see Create a Fargate pod execution role (p. 145).

**Log router configuration**

**To configure the log router**

In the following steps, replace every *example value* with your own values.

1. Create a dedicated Kubernetes namespace named `aws-observability`.
   a. Save the following contents to a file named `aws-observability-namespace.yaml` on your computer. The value for `name` must be `aws-observability` and the `aws-observability: enabled` label is required.

   ```yaml
   kind: Namespace
   apiVersion: v1
   metadata:
     name: aws-observability
     labels:
       aws-observability: enabled
   ```
   b. Create the namespace.

   ```sh
   kubectl apply -f aws-observability-namespace.yaml
   ```

2. Create a ConfigMap with a Fluent Conf data value to ship container logs to a destination. Fluent Conf is Fluent Bit, which is a fast and lightweight log processor configuration language that's used to route container logs to a log destination of your choice. For more information, see Configuration File in the Fluent Bit documentation.

   **Important**
   The main sections included in a typical Fluent Conf are Service, Input, Filter, and Output. The Fargate log router however, only accepts:

   - The Filter and Output sections and manages the Service and Input sections itself.
   - A Parser section.

   If you provide any sections other than Filter, Output, and Parser, the sections are rejected.

   When creating the ConfigMap, take into account the following rules that Fargate uses to validate fields:
• [FILTER], [OUTPUT], and [PARSER] are supposed to be specified under each corresponding key. For example, [FILTER] must be under filters.conf. You can have one or more [FILTER]s under filters.conf. The [OUTPUT] and [PARSER] sections should also be under their corresponding keys. By specifying multiple [OUTPUT] sections, you can route your logs to different destinations at the same time.

• Fargate validates the required keys for each section. Name and match are required for each [FILTER] and [OUTPUT]. Name and format are required for each [PARSER]. The keys are case-insensitive.

• Environment variables such as ${ENV_VAR} aren't allowed in the ConfigMap.

• The indentation has to be the same for either directive or key-value pair within each filters.conf, output.conf, and parsers.conf. Key-value pairs have to be indented more than directives.

• Fargate validates against the following supported filters: grep, parser, record_modifier, rewrite_tag, throttle, nest, modify, and kubernetes.

• Fargate validates against the following supported output: es, firehose, kinesis_firehose, cloudwatch, cloudwatch_logs, and kinesis.

• At least one supported Output plugin has to be provided in the ConfigMap to enable logging. Filter and Parser aren't required to enable logging.

You can also run Fluent Bit on Amazon EC2 using the desired configuration to troubleshoot any issues that arise from validation. Create your ConfigMap using one of the following examples.

**Important**

Amazon EKS Fargate logging doesn't support dynamic configuration of ConfigMaps. Any changes to ConfigMaps are applied to new pods only. Changes aren't applied to existing pods.

Create a ConfigMap using the example for your desired log destination.

CloudWatch

**To create a ConfigMap for CloudWatch**

You have two output options when using CloudWatch:

• An output plugin written in C
• An output plugin written in Golang

The following example shows you how to use the cloudwatch_logs plugin to send logs to CloudWatch.

1. Save the following contents to a file named `aws-logging-cloudwatch-configmap.yaml`. Replace `region-code` with the AWS Region that your cluster is in. The parameters under [OUTPUT] are required.

```yaml
kind: ConfigMap
apiversion: v1
metadata:
  name: aws-logging
  namespace: aws-observability
data:
  output.conf:
    [OUTPUT]
    Name cloudwatch_logs
    Match *
    region region-code
```
log_group_name fluent-bit-cloudwatch
log_stream_prefix from-fluent-bit-
auto_create_group true
log_key log

parsers.conf: |
[PARSER]
Name crio
Format Regex
Regex ^(?<time>[^ ]+) (?<stream>stdout|stderr) (?<logtag>P|F) (?<log>.*)$
Time_Key    time
Time_Format %Y-%m-%dT%H:%M:%S.%L%z

filters.conf: |
[FILTER]
Name parser
Match *
Key_name log
Parser crio

2. Apply the manifest to your cluster.

```bash
kubectl apply -f aws-logging-cloudwatch-configmap.yaml
```

3. Download the CloudWatch IAM policy to your computer. You can also view the policy on GitHub.

```bash
curl -o permissions.json https://raw.githubusercontent.com/aws-samples/amazon-eks-fluent-logging-examples/mainline/examples/fargate/cloudwatchlogs/permissions.json
```

Amazon OpenSearch Service

**To create a ConfigMap for Amazon OpenSearch Service**

If you want to send logs to Amazon OpenSearch Service, you can use es output, which is a plugin written in C. The following example shows you how to use the plugin to send logs to OpenSearch.

1. Save the following contents to a file named `aws-logging-opensearch-configmap.yaml`. Replace every `example value` with your own values.

```yaml
kind: ConfigMap
apiVersion: v1
metadata:
  name: aws-logging
  namespace: aws-observability
data:
  output.conf: |
  [OUTPUT]
    Name es
    Match *
    Host search-example-gjxdctilogiprbglq42jst66y.region-code.es.amazonaws.com
    Port 443
    Index example
    Type example_type
    AWS_Auth On
    AWS_Region region-code
tls On
```
2. Apply the manifest to your cluster.

```bash
kubectl apply -f aws-logging-opensearch-configmap.yaml
```

3. Download the OpenSearch IAM policy to your computer. You can also view the policy on GitHub.

```bash
curl -o permissions.json https://raw.githubusercontent.com/aws-samples/amazon-eks-fluent-logging-examples/mainline/examples/fargate/amazon-elasticsearch/permissions.json
```

Make sure that OpenSearch Dashboards' access control is configured properly. The all_access role in OpenSearch Dashboards needs to have the Fargate pod execution role and the IAM role mapped. The same mapping must be done for the security_manager role. You can add the previous mappings by selecting Menu, then Security, then Roles, and then select the respective roles. For more information, see How do I troubleshoot CloudWatch Logs so that it streams to my Amazon ES domain?.

Kinesis Data Firehose

**To create a ConfigMap for Kinesis Data Firehose**

You have two output options when sending logs to Kinesis Data Firehose:

- **kinesis_firehose** – An output plugin written in C.
- **firehose** – An output plugin written in Golang.

The following example shows you how to use the kinesis_firehose plugin to send logs to Kinesis Data Firehose.

1. Save the following contents to a file named `aws-logging-firehose-configmap.yaml`. Replace `region-code` with the AWS Region that your cluster is in.

```yaml
kind: ConfigMap
apiVersion: v1
metadata:
  name: aws-logging
  namespace: aws-observability
data:
  output.conf: |
  [OUTPUT]
  Name kinesis_firehose
  Match *
  region region-code
  delivery_stream my-stream-firehose
```

2. Apply the manifest to your cluster.

```bash
kubectl apply -f aws-logging-firehose-configmap.yaml
```

3. Download the Kinesis Data Firehose IAM policy to your computer. You can also view the policy on GitHub.

```bash
```
3. Create an IAM policy from the policy file you downloaded in a previous step.

```bash
aws iam create-policy --policy-name eks-fargate-logging-policy --policy-document file://permissions.json
```

4. Attach the IAM policy to the pod execution role specified for your Fargate profile with the following command. Replace `111122223333` with your account ID. Replace `AmazonEKSFargatePodExecutionRole` with your pod execution role (for more information, see Create a Fargate pod execution role (p. 145)). If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:` with `arn:aws-us-gov:`.

```bash
aws iam attach-role-policy --policy-arn arn:aws::111122223333:policy/eks-fargate-logging-policy --role-name AmazonEKSFargatePodExecutionRole
```

## Kubernetes filter support

This feature requires the following minimum Kubernetes version and platform level, or later.

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Platform level</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.22 and later</td>
<td>eks.1</td>
</tr>
<tr>
<td>1.21</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.20</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.19</td>
<td>eks.7</td>
</tr>
</tbody>
</table>

The Fluent Bit Kubernetes filter allows you to add Kubernetes metadata to your log files. For more information about the filter, see Kubernetes in the Fluent Bit documentation. You can apply a filter using the API server endpoint.

```conf
filters.conf: |
[FILTER]         | kubernetes
Name             | kube.*
Match            | On
Buffer_Size      | 0
Kube_Meta_Cache_TTL | 300s
```

### Important

- `Kube_URL`, `Kube_CA_File`, `Kube_Token_Command`, and `Kube_Token_File` are service owned configuration parameters and must not be specified. Amazon EKS Fargate populates these values.
- `Kube_Meta_Cache_TTL` is the time Fluent Bit waits until it communicates with the API server for the latest metadata. If `Kube_Meta_Cache_TTL` isn't specified, Amazon EKS Fargate appends a default value of 30 minutes to lessen the load on the API server.

### To ship Fluent Bit process logs to your account

You can ship Fluent Bit process logs to Amazon CloudWatch using the following ConfigMap. Replace `region-code` with the AWS Region that your cluster is in.
kind: ConfigMap
apiVersion: v1
metadata:
  name: aws-logging
  namespace: aws-observability
labels:
data:
  # Configuration files: server, input, filters and output
  # ======================================================
  flb_log_cw: "true"  #ships fluent-bit process logs to CloudWatch
  output.conf: |
    [OUTPUT]
    Name cloudwatch
    Match kube.*
    region $region-code
    log_group_name fluent-bit-cloudwatch
    log_stream_prefix from-fluent-bit-
    auto_create_group true

The logs are in the AWS Region that the cluster resides in under CloudWatch. The log group name is `my-cluster-fluent-bit-logs` and the Fluent Bit logstream name is `fluent-bit-podname-pod-namespace`.

Note

- The process logs are shipped only when the Fluent Bit process successfully starts. If there is a failure while starting Fluent Bit, the process logs are missed. You can only ship process logs to CloudWatch.
- To debug shipping process logs to your account, you can apply the previous ConfigMap to get the process logs. Fluent Bit failing to start is usually due to your ConfigMap not being parsed or accepted by Fluent Bit while starting.

**Test application**

1. Deploy a sample pod.

   a. Save the following contents to a file named `sample-app.yaml` on your computer.
b. Apply the manifest to the cluster.

```bash
kubectl apply -f sample-app.yaml
```

2. View the NGINX logs using the destination(s) that you configured in the ConfigMap.

### Size considerations

We suggest that you plan for up to 50 MB of memory for the log router. If you expect your application to generate logs at very high throughput then you should plan for up to 100 MB.

### Troubleshooting

To confirm whether the logging feature is enabled or disabled for some reason, such as an invalid ConfigMap, and why it’s invalid, check your pod events with `kubectl describe pod pod_name`. The output might include pod events that clarify whether logging is enabled or not, such as the following example output.

```
... Annotations:          CapacityProvisioned: 0.25vCPU 0.5GB
                      Logging: LoggingDisabled: LOGGING_CONFIGMAP_NOT_FOUND
                      kubernetes.io/psp: eks.privileged
...

Events:    Type        Reason                Age                  From                                   Message
----        ------                ----                  ----                                   -------
Warning     LoggingDisabled  <unknown> fargate-scheduler
             Disabled logging because aws-logging configmap was not found. configmap "aws-logging" not found
```

The pod events are ephemeral with a time period depending on the settings. You can also view a pod’s annotations using `kubectl describe pod pod-name`. In the pod annotation, there is information about whether the logging feature is enabled or disabled and the reason.

### Choosing an Amazon EC2 instance type

Amazon EC2 provides a wide selection of instance types for worker nodes. Each instance type offers different compute, memory, storage, and network capabilities. Each instance is also grouped in an instance family based on these capabilities. For a list, see [Available instance types](#) in the Amazon EC2 User Guide for Linux Instances and [Available instance types](#) in the Amazon EC2 User Guide for Windows Instances. Amazon EKS releases several variations of Amazon EC2 AMIs to enable support. To make sure that the instance type you select is compatible with Amazon EKS, consider the following criteria.

- All Amazon EKS AMIs don’t currently support the g5g and mac families.
- Arm and non-accelerated Amazon EKS AMIs don’t support the g3, g4, inf, and p families.
- Accelerated Amazon EKS AMIs don’t support the a, c, hpc, m, and t families.

When choosing between instance types that are supported by Amazon EKS, consider the following capabilities of each type.

- **Number of instances in a node group** – In general, fewer, larger instances are better, especially if you have a lot of Daemonsets. Each instance requires API calls to the API server, so the more instances you have, the more load on the API server.
• **Operating system** – Review the supported instance types for **Linux**, **Windows**, and **Bottlerocket**. Before creating Windows instances, review the section called “Enabling Windows support” (p. 54).

• **Hardware architecture** – Do you need x86 or Arm? You can only deploy Linux on Arm. Before deploying Arm instances, review the section called “Arm” (p. 176). Do you need instances built on the Nitro System (**Linux** or **Windows**) or that have Accelerated capabilities? If you need accelerated capabilities, you can only use Linux with Amazon EKS.

• **Maximum number of pods** – Since each pod is assigned its own IP address, the number of IP addresses supported by an instance type is a factor in determining the number of pods that can run on the instance. To manually determine how many pods an instance type supports, see Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 163).

  **Note**
  If you're using an Amazon EKS optimized Amazon Linux 2 AMI that's `v20220406` or newer, you can use a new instance type without upgrading to the latest AMI. For these AMIs, the AMI auto-calculates the necessary `max-pods` value if it isn't listed in the `eni-max-pods.txt` file. Instance types that are currently in preview may not be supported by Amazon EKS by default. Values for `max-pods` for such types still need to be added to `eni-max-pods.txt` in our AMI.

AWS Nitro System instance types optionally support significantly more IP addresses than non-Nitro System instance types. However, not all IP addresses assigned for an instance are available to pods. To assign a significantly larger number of IP addresses to your instances, you must have version 1.9.0 or later of the Amazon VPC CNI add-on installed in your cluster and configured appropriately. For more information, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 289). To assign the largest number of IP addresses to your instances, you must have version 1.10.1 or later of the Amazon VPC CNI add-on installed in your 1.21 or later cluster and deploy the cluster with the IPv6 family.

• **IP family** – You can use any supported instance type when using the IPv4 family for a cluster, which allows your cluster to assign private IPv4 addresses to your pods and Services. But if you want to use the IPv6 family for your cluster, then you must use AWS Nitro System instance types or bare metal instance types. Only IPv4 is supported for Windows instances. Your cluster must be a new 1.21 or later cluster running version 1.10.1 or later of the Amazon VPC CNI add-on. For more information about using IPv6, see Tutorial: Assigning IPv6 addresses to pods and services (p. 264).

• **Version of the Amazon VPC CNI add-on that you're running** – The latest version of the Amazon VPC CNI plugin for Kubernetes supports these instance types. You may need to update your Amazon VPC CNI add-on version to take advantage of the latest supported instance types. For more information, see the section called “Updating the self-managed add-on” (p. 253). The latest version supports the latest features for use with Amazon EKS. Earlier versions don't support all features. You can view features supported by different versions in the Changelog on GitHub.

• **AWS Region that you're creating your nodes in** – Not all instance types are available in all AWS Regions.

• **Whether you're using security groups for pods** – If you're using security groups for pods, only specific instance types are supported. For more information, see Security groups for pods (p. 292).

---

### Amazon EKS recommended maximum pods for each Amazon EC2 instance type

Since each pod is assigned its own IP address, the number of IP addresses supported by an instance type is a factor in determining the number of pods that can run on the instance. Amazon EKS provides a script that you can download and run to determine the Amazon EKS recommended maximum number of pods to run on each instance type. The script uses hardware attributes of each instance, and configuration options, to determine the maximum pods number. You can use the number returned in these steps to enable capabilities such as assigning IP addresses to pods from a different subnet than the instance's (p. 276) and significantly increasing the number of IP addresses for your instance (p. 289).
If you’re using a managed node group with multiple instance types, use a value that would work for all instance types.

1. Download a script that you can use to calculate the maximum number of pods for each instance type.

   ```bash
   ```

2. Mark the script as executable on your computer.

   ```bash
   chmod +x max-pods-calculator.sh
   ```

3. Run the script, replacing `m5.large` with the instance type that you plan to deploy and `1.9.0-eksbuild.1` with your Amazon VPC CNI add-on version. To determine your add-on version, see the update procedures in Managing the Amazon VPC CNI plugin for Kubernetes (p. 247).

   ```bash
   ./max-pods-calculator.sh --instance-type m5.large --cni-version 1.9.0-eksbuild.1
   ```

   The example output is as follows.

   ```
   29
   ```

   You can add the following options to the script to see the maximum pods supported when using optional capabilities.

   - `--cni-custom-networking-enabled` – Use this option when you want to assign IP addresses from a different subnet than your instance’s. For more information, see the section called “Custom networking” (p. 276). Adding this option to the previous script with the same example values yields 20.

   - `--cni-prefix-delegation-enabled` – Use this option when you want to assign significantly more IP addresses to each elastic network interface. This capability requires an Amazon Linux instance that run on the Nitro System and version 1.9.0 or later of the Amazon VPC CNI add-on. For more information, see the section called “Increase available IP addresses” (p. 289). Adding this option to the previous script with the same example values yields 110.

   You can also run the script with the `--help` option to see all available options.

### Amazon EKS optimized AMIs

You can deploy nodes with pre-built Amazon EKS optimized Amazon Machine Images (AMIs), or your own custom AMIs. For more information about each type of Amazon EKS optimized AMI, see one of the following topics. For instructions on how to create your own custom AMI, see Amazon EKS optimized Amazon Linux AMI build script (p. 177).

#### Topics

- Amazon EKS is ending support for Dockershim (p. 165)
- Amazon EKS optimized Amazon Linux AMIs (p. 165)
- Amazon EKS optimized Ubuntu Linux AMIs (p. 179)
- Amazon EKS optimized Bottlerocket AMIs (p. 179)
- Amazon EKS optimized Windows AMIs (p. 185)
Amazon EKS is ending support for Dockershim

Kubernetes no longer supports Dockershim. The Kubernetes team completely removed the runtime in Kubernetes version 1.24. Amazon EKS will be ending support for Dockershim starting with the Kubernetes version 1.24 launch. Amazon EKS AMIs that are officially published will have containerd as the only runtime starting with version 1.24.

There's a kubectl plugin you can use to see which of your Kubernetes workloads are mounting the Docker socket volume. For more information, see Detector for Docker Socket (DDS) on GitHub. Amazon EKS AMIs that run Kubernetes versions lower than 1.24 use Docker as the default runtime, but have a bootstrap flag option that you can use to test out your workloads on any supported cluster today with containerd. For more information, see Enable the containerd runtime bootstrap flag (p. 174).

We will continue to publish AMIs for existing Kubernetes versions until the end of their support date. For more information, see Amazon EKS Kubernetes release calendar (p. 73). If you require more time to test your workloads on containerd, you can stay on a supported version before 1.24 and still be fully supported. But, when version 1.24 is made available and you want to upgrade official Amazon EKS AMIs to that version or higher, make sure to validate that your workloads run on containerd.

If you will be upgrading to version 1.24 or higher but you still want to use Dockershim, build your own AMI with Docker installed. However, when Kubernetes removes Dockershim support, make sure that you migrate to containerd to remain on a supported version. For more information, see Kubernetes is Moving on From Dockershim: Commitments and Next Steps on the Kubernetes Blog.

The containerd runtime provides more reliable performance and security, and it's the runtime we're standardizing on across Amazon EKS (Fargate and Bottlerocket already use containerd only). containerd helps to minimize the number of Amazon EKS AMI releases that are required to address Dockershim Common Vulnerabilities and Exposures (CVEs). As Dockershim already uses containerd internally, you might not need to make any changes. However, there are some situations where changes might or must be required:

- You must make changes for any application that mounts the Docker socket. For example, building container images using a container are impacted. Many monitoring tools also mount the Docker socket. You may have to wait for updates or re-deploy workloads for runtime monitoring.
- You might need to make changes for any application that's reliant on specific Docker settings. For example, using HTTPS_PROXY can require changes. For more information, see dockerd in the Docker Docs.
- If you're using the Amazon ECR credential helper to pull images, you must switch to the kubelet image credential provider. For more information, see Configure a kubelet image credential provider in the Kubernetes documentation.

Amazon EKS optimized Amazon Linux AMIs

The Amazon EKS optimized Amazon Linux AMI is built on top of Amazon Linux 2, and is configured to serve as the base image for Amazon EKS nodes. The AMI is configured to work with Amazon EKS and it includes Docker, kubelet, and the AWS IAM Authenticator.

Note

- You can track security or privacy events for Amazon Linux 2 at the Amazon Linux security center or subscribe to the associated RSS feed. Security and privacy events include an overview of the issue, what packages are affected, and how to update your instances to correct the issue.
- Before deploying an accelerated or Arm AMI, review the information in Amazon EKS optimized accelerated Amazon Linux AMIs (p. 175) and Amazon EKS optimized Arm Amazon Linux AMIs (p. 176).
Amazon EKS optimized Amazon Linux 2 contains an optional bootstrap flag to enable the containerd runtime. This feature provides a clear path to migrate to containerd. Amazon EKS is ending support for Docker starting with the Kubernetes version 1.24 launch. The containerd runtime is widely adopted in the Kubernetes community and is a graduated project with the CNCF. You can test it by adding a node group to a new or existing cluster. For more information, see Enable the containerd runtime bootstrap flag (p. 174). When bootstrapped in Amazon EKS optimized accelerated Amazon Linux AMIs for version 1.21, AWS Inferentia workloads aren't supported.

In the following tables, choose View AMI ID for the Kubernetes version, AWS Region, and processor type that are specific to your Amazon Linux instance. You can also retrieve the IDs with an AWS Systems Manager parameter. For more information, see Retrieving Amazon EKS optimized Amazon Linux AMI IDs (p. 177).

**Important**

These AMIs require the latest AWS CloudFormation node template. You can’t use these AMIs with a previous version of the node template. If you do, they fail to join your cluster. Make sure that you update any existing AWS CloudFormation node stacks with the latest template before you attempt to use these AMIs.

The AWS CloudFormation node template launches your nodes with Amazon EC2 user data that triggers a specialized bootstrap script. This script allows your nodes to discover and connect to your cluster's control plane automatically. For more information, see Launching self-managed Amazon Linux nodes (p. 122).

Enable the containerd runtime bootstrap flag

The Amazon EKS optimized Amazon Linux 2 AMI contains an optional bootstrap flag to enable the containerd runtime. This feature provides a clear path to migrate to containerd. Amazon EKS is ending support for Docker starting with the Kubernetes version 1.24 launch. For more information, see Amazon EKS is ending support for Dockershim (p. 165).

You can enable the bootstrap flag by creating one of the following types of node groups.

- **Self-managed** – Create the node group using the instructions in Launching self-managed Amazon Linux nodes (p. 122). Specify an Amazon EKS optimized AMI and the following text for the BootstrapArguments parameter.

  ```
  --container-runtime containerd
  ```

- **Managed** – If you use eksctl, create a file named `my-nodegroup.yaml` with the following contents. Replace every `example value` with your own values. To retrieve your desired value for `ami-1234567890abcdef0`, you can use the previous AMI tables.

  ```yaml
  apiVersion: eksctl.io/v1alpha5
  kind: ClusterConfig
  metadata:
    name: my-cluster
    region: region-code
  managedNodeGroups:
    - name: my-nodegroup
      ami: ami-1234567890abcdef0
      overrideBootstrapCommand: |
        #!/bin/bash
        /etc/eks/bootstrap.sh my-cluster --container-runtime containerd
  ```

  **Note**
  If you launch many nodes simultaneously, you may also want to specify values for the `--apiserver-endpoint`, `--b64-cluster-ca`, and `--dns-cluster-ip bootstrap` arguments to avoid errors. For more information, see Specifying an AMI (p. 117).

Run the following command to create the node group.

```bash
eksctl create nodegroup -f my-nodegroup.yaml --version 1.23
```

If you prefer to use a different tool to create your managed node group, you must deploy the node group using a launch template. In your launch template, specify an Amazon EKS optimized AMI ID, then deploy the node group using a launch template (p. 113) and provide the following user data. This user data passes arguments into the `bootstrap.sh` file. For more information about the bootstrap file, see bootstrap.sh on GitHub.

```bash
/etc/eks/bootstrap.sh my-cluster \
--container-runtime containerd
```
Amazon EKS optimized accelerated Amazon Linux AMIs

The Amazon EKS optimized accelerated Amazon Linux AMI is built on top of the standard Amazon EKS optimized Amazon Linux AMI. It's configured to serve as an optional image for Amazon EKS nodes to support GPU and Inferentia based workloads.

In addition to the standard Amazon EKS optimized AMI configuration, the accelerated AMI includes the following:

• NVIDIA drivers
• The `nvidia-container-runtime` (as the default runtime)
• AWS Neuron container runtime

Note

• The Amazon EKS optimized accelerated AMI only supports GPU and Inferentia based instance types. Make sure to specify these instance types in your node AWS CloudFormation template. By using the Amazon EKS optimized accelerated AMI, you agree to NVIDIA's user license agreement (EULA).
• The Amazon EKS optimized accelerated AMI was previously referred to as the Amazon EKS optimized AMI with GPU support.
• Previous versions of the Amazon EKS optimized accelerated AMI installed the `nvidia-docker` repository. The repository is no longer included in Amazon EKS AMI version v20200529 and later.

To enable GPU based workloads

The following procedure describes how to run a workload on a GPU based instance with the Amazon EKS optimized accelerated AMI. For more information about using Inferentia based workloads, see Machine learning inference using AWS Inferentia (p. 376).

1. After your GPU nodes join your cluster, you must apply the NVIDIA device plugin for Kubernetes as a DaemonSet on your cluster with the following command.

   ```sh
ekubectl apply -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.9.0/nvidia-device-plugin.yml
```

2. You can verify that your nodes have allocatable GPUs with the following command.

   ```sh
   kubectl get nodes "-o=custom-columns=NAME:.metadata.name,GPU:.status.allocatable.nvidia.com/gpu"
   ```

To deploy a pod to test that your GPU nodes are configured properly

1. Create a file named `nvidia-smi.yaml` with the following contents. This manifest launches a Cuda container that runs `nvidia-smi` on a node.

   ```yaml
   apiVersion: v1
   kind: Pod
   metadata:
     name: nvidia-smi
   spec:
     restartPolicy: OnFailure
   containers:
   ```

175
2. Apply the manifest with the following command.

```
kubectl apply -f nvidia-smi.yaml
```

3. After the pod has finished running, view its logs with the following command.

```
kubectl logs nvidia-smi
```

The output as follows.

```
Mon Aug  6 20:23:31 2018

```

### Amazon EKS optimized Arm Amazon Linux AMIs

Arm instances deliver significant cost savings for scale-out and Arm-based applications such as web servers, containerized microservices, caching fleets, and distributed data stores. When adding Arm nodes to your cluster, review the following considerations.

#### Considerations

- If your cluster was deployed before August 17, 2020, you must do a one-time upgrade of critical cluster add-on manifests. This is so that Kubernetes can pull the correct image for each hardware architecture in use in your cluster. For more information about updating cluster add-ons, see Update the Kubernetes version for your Amazon EKS cluster (p. 33). If you deployed your cluster on or after August 17, 2020, then your CoreDNS, kube-proxy, and Amazon VPC CNI plugin for Kubernetes add-ons are already multi-architecture capable.
- Applications deployed to Arm nodes must be compiled for Arm.
- You can't use the Amazon FSx for Lustre CSI driver (p. 232) with Arm.
- If you have DaemonSets that are deployed in an existing cluster, or you want to deploy them to a new cluster that you also want to deploy Arm nodes in, then verify that your DaemonSet can run on all hardware architectures in your cluster.
- You can run Arm node groups and x86 node groups in the same cluster. If you do, consider deploying multi-architecture container images to a container repository such as Amazon Elastic Container
Registry and then adding node selectors to your manifests so that Kubernetes knows what hardware architecture a pod can be deployed to. For more information, see Pushing a multi-architecture image in the Amazon ECR User Guide and the Introducing multi-architecture container images for Amazon ECR blog post.

Amazon EKS optimized Amazon Linux AMI versions

Amazon EKS optimized Amazon Linux AMIs are versioned by Kubernetes version and the release date of the AMI in the following format:

```
k8s_major_version.k8s_minor_version.k8s_patch_version-release_date
```

In the past, this page included details about each AMI version release. The details included the versions of kubelet, Docker, the Linux kernel, containerd, and the NVIDIA driver available in each new AMI version. You can now find this information in the Changelog on GitHub.

Retrieving Amazon EKS optimized Amazon Linux AMI IDs

You can programmatically retrieve the Amazon Machine Image (AMI) ID for Amazon EKS optimized AMIs by querying the AWS Systems Manager Parameter Store API. This parameter eliminates the need for you to manually look up Amazon EKS optimized AMI IDs. For more information about the Systems Manager Parameter Store API, see GetParameter. Your user account must have the `ssm:GetParameter` IAM permission to retrieve the Amazon EKS optimized AMI metadata.

You can retrieve the AMI ID with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon EKS optimized Amazon Linux AMI with the following command by using the sub-parameter `image_id`. Replace 1.23 with a supported version (p. 75). Replace `region-code` with the AWS Region that your cluster is in. Replace `amazon-linux-2` with `amazon-linux-2-gpu` to see the accelerated AMI ID and `amazon-linux-2-arm64` to see the Arm ID.

  ```
  aws ssm get-parameter --name /aws/service/eks/optimized-ami/1.23/amazon-linux-2/recommended/image_id --region region-code --query "Parameter.Value" --output text
  ```

  The example output is as follows.

  ```
  ami-1234567890abcdef0
  ```

- **AWS Management Console** – You can query for the recommended Amazon EKS optimized AMI ID using a URL. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, replace 1.23 with a supported version (p. 75) and `region-code` with an Amazon EKS Supported Region for which you want the AMI ID. Replace `amazon-linux-2` with `amazon-linux-2-gpu` to see the accelerated AMI ID and `amazon-linux-2-arm64` to see the Arm ID.

  ```
  ```

Amazon EKS optimized Amazon Linux AMI build script

Amazon Elastic Kubernetes Service (Amazon EKS) has open-source scripts that are used to build the Amazon EKS optimized AMI. These build scripts are available on GitHub.
The Amazon EKS optimized Amazon Linux AMI is built on top of Amazon Linux 2, specifically for use as a node in Amazon EKS clusters. You can use this repository to view the specifics of how the Amazon EKS team configures `kubelet`, Docker, the AWS IAM Authenticator for Kubernetes, and more.

The build scripts repository includes a HashiCorp `packer` template and build scripts to generate an AMI. These scripts are the source of truth for Amazon EKS optimized AMI builds, so you can follow the GitHub repository to monitor changes to our AMIs. For example, perhaps you want your own AMI to use the same version of Docker that the Amazon EKS team uses for the official AMI.

The GitHub repository also contains the specialized bootstrap script that runs at boot time to configure your instance's certificate data, control plane endpoint, cluster name, and more.

Additionally, the GitHub repository contains our Amazon EKS node AWS CloudFormation templates. These templates make it easier to spin up an instance running the Amazon EKS optimized AMI and register it with a cluster.

For more information, see the repositories on GitHub at https://github.com/awslabs/amazon-eks-ami.

Amazon EKS optimized Amazon Linux 2 contains an optional bootstrap flag to enable the containerd runtime. When bootstrapped in Amazon EKS optimized accelerated Amazon Linux AMIs for version 1.21, AWSInferentia workloads are not supported.

**Configuring VT1 for your custom Amazon Linux AMI**

Custom Amazon Linux AMIs in Amazon EKS can support the VT1 video transcoding instance family for Amazon Linux 2, Ubuntu 18, and Ubuntu 20. VT1 supports the Xilinx U30 media transcoding cards with accelerated H.264/AVC and H.265/HEVC codecs. To get the benefit of these accelerated instances, you must follow these steps:

1. Create and launch a base AMI from Amazon Linux 2, Ubuntu 18, or Ubuntu 20.
2. After the based AMI is launched, Install the XRT driver and runtime on the node.
3. Create a cluster.
4. Install the Kubernetes FPGA plugin on your cluster.

```
kubectl apply -f fpga-device-plugin.yml
```

The plugin will now advertise Xilinx U30 devices per node on your Amazon EKS cluster. You can use the FFMPEG docker image to run example video transcoding workloads on your Amazon EKS cluster.

**Configuring DL1 for your custom Amazon Linux 2 AMI**

Custom Amazon Linux 2 AMIs in Amazon EKS can support deep learning workloads at scale through additional configuration and Kubernetes add-ons. This document describes the components required to set up a generic Kubernetes solution for an on-premise setup or as a baseline in a larger cloud configuration. To support this function, you will have to perform the following steps in your custom environment:

- SynapaseAI® Software drivers loaded on the system – These are included in the AMIs available on Github.

  The Habana device plugin -- A Daemonset that allows you to automatically enable the registration of Habana devices in your Kubernetes cluster and track device health.

- Kubernetes version up to 1.21 (confirmed through testing).
- Helm 3.x
• Helm chart to install MPI Operator.
• MPI Operator

1. Create and launch a base AMI from Amazon Linux 2, Ubuntu 18, or Ubuntu 20.
2. Follow these instructions to set up the environment for DL1.

**Amazon EKS optimized Ubuntu Linux AMIs**

Canonical has partnered with Amazon EKS to create node AMIs that you can use in your clusters.

Canonical delivers a built-for-purpose Kubernetes Node OS image. This minimized Ubuntu image is optimized for Amazon EKS and includes the custom AWS kernel that is jointly developed with AWS. For more information, see Ubuntu and Amazon Elastic Kubernetes Service and Optimized support for Amazon EKS on Ubuntu 18.04.

**Amazon EKS optimized Bottlerocket AMIs**

The Amazon EKS optimized Bottlerocket AMI is built on top of Bottlerocket. Bottlerocket is a Linux based open-source operating system that is purpose built by AWS for running containers on virtual machines or bare metal hosts. It's secure and only includes the bare minimum packages required to run containers. This reduces the attack surface and impact of vulnerabilities. It also requires less effort to meet node compliance requirements. For more information about Bottlerocket, see the documentation and releases on GitHub.

The AMI is configured to work with Amazon EKS and it includes containerd and kubelet.

The following points are some considerations when using Bottlerocket for your AMI type:

• You can deploy to Amazon EC2 instances with x86 or Arm processors, but not to instances that have Inferentia chips.
• There is no AWS CloudFormation template to deploy nodes with.
• Bottlerocket images don’t come with an SSH server or a shell. You can use out-of-band access methods to allow SSH enabling the admin container and to pass some bootstrapping configuration steps with user data. For more information, see these sections in the bottlerocket README.md on GitHub:
  • Exploration
  • Admin container
  • Kubernetes settings
• By default, Bottlerocket has a control container that's enabled. This container runs the AWS Systems Manager agent that you can use to run commands or start shell sessions on Amazon EC2 Bottlerocket instances. For more information, see Setting up Session Manager in the AWS Systems Manager User Guide.
• Bottlerocket also has an admin container that's enabled if an SSH key is given when creating the node group. We recommend using the admin container only for development and testing scenarios. We don’t recommend using it for production environments.

Select a link in one of the following tables to view the latest Amazon EKS optimized Bottlerocket AMI ID for a region and Kubernetes version. You can also retrieve the IDs with an AWS Systems Manager parameter using different tools. For more information, see Retrieving Amazon EKS optimized Bottlerocket AMI IDs (p. 185).

1.19
Retrieving Amazon EKS optimized Bottlerocket AMI IDs

You can retrieve the Amazon Machine Image (AMI) ID for Amazon EKS optimized AMIs by querying the AWS Systems Manager Parameter Store API. Using this parameter, you don’t need to manually look up Amazon EKS optimized AMI IDs. For more information about the Systems Manager Parameter Store API, see GetParameter. Your user account must have the ssm:GetParameter IAM permission to retrieve the Amazon EKS optimized AMI metadata.

You can retrieve the AMI ID with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon EKS optimized Bottlerocket AMI with the following AWS CLI command by using the sub-parameter `image_id`.
  Replace **1.23** with a supported version (p. 75) and `region-code` with an Amazon EKS supported Region for which you want the AMI ID.

  ```bash
  aws ssm get-parameter --name /aws/service/bottlerocket/aws-k8s-1.23/x86_64/latest/image_id --region region-code --query "Parameter.Value" --output text
  
  The example output is as follows.
  
  ami-1234567890abcdef0
  ```

- **AWS Management Console** – You can query for the recommended Amazon EKS optimized AMI ID using a URL in the AWS Management Console. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, replace **1.23** with a supported version (p. 75) and `region-code` with an Amazon EKS supported Region for which you want the AMI ID.

  ```plaintext
  ```

Amazon EKS optimized Windows AMIs

Windows Amazon EKS optimized AMIs are built on top of Windows Server 2019. They are configured to serve as the base image for Amazon EKS nodes. By default, the AMIs include the following components:

- **kubelet**
- **kube-proxy**
- **AWS IAM Authenticator**
- **CSI proxy**
• Docker (Amazon EKS version 1.22 and earlier)
• Containerd (Amazon EKS version 1.21 and later)

**Note**
You can track security or privacy events for Windows Server with the [Microsoft security update guide](https://docs.microsoft.com).

Amazon EKS offers AMIs that are optimized for Windows containers in the following variants:

• Amazon EKS-optimized Windows Server 2019 Core AMI
• Amazon EKS-optimized Windows Server 2019 Full AMI

**Important**
The Amazon EKS-optimized Windows Server 20H2 Core AMI is deprecated. No new versions of this AMI will be released.

The latest Amazon EKS optimized AMI IDs are in the following tables. You can also retrieve the IDs with an AWS Systems Manager parameter using different tools. For more information, see [Retrieving Amazon EKS optimized Windows AMI IDs](https://docs.aws.amazon.com/eks/latest/user-guide/security-update-tracking.html) (p. 201).

Windows Server 2019 is a Long-Term Servicing Channel (LTSC) release, whereas Versions 20H2 is a Semi-Annual Channel (SAC) release. We no longer support SAC releases. For more information about these release types, see [Windows Server release information](https://docs.microsoft.com) in the Microsoft documentation. For more information about Windows OS version support, see [Intro to Windows support in Kubernetes](https://kubernetes.io/docs/admin/).

Bootstrap script configuration parameters

When you create a Windows node, there’s a script on the node that allows for configuring different parameters. Depending on your setup, this script can be found on the node at a location similar to: C:\Program Files\Amazon\EKS\Start-EKSBootstrap.ps1. The script includes the following parameters:

- `-EKSClusterName` – Specifies the Amazon EKS cluster name for this worker node to join.
- `-KubeletExtraArgs` – Specifies extra arguments for `kubelet` (optional).
- `-KubeProxyExtraArgs` – Specifies extra arguments for `kube-proxy` (optional).
- `-APIServerEndpoint` – Specifies the Amazon EKS cluster API server endpoint (optional). Only valid when used with `-Base64ClusterCA`. Bypasses calling Get-EKSCluster.
- `-Base64ClusterCA` – Specifies the base64 encoded cluster CA content (optional). Only valid when used with `-APIServerEndpoint`. Bypasses calling Get-EKSCluster.
- `--DNSClusterIP` – Overrides the IP address to use for DNS queries within the cluster (optional). Defaults to `10.100.0.10` or `172.20.0.10` based on the IP address of the primary interface.
- `--ContainerRuntime` – Specifies the container runtime to be used on the node.

### Enable the containerd runtime bootstrap flag

The Amazon EKS optimized Windows AMI contains an optional bootstrap flag to enable the containerd runtime. This feature gives you a clear path to migrate to containerd. Amazon EKS is ending support for Docker starting with the Kubernetes version 1.24 launch. For more information, see Amazon EKS is ending support for Dockershim (p. 165).

Until Kubernetes version 1.24, the supported values for the container runtime are `docker` and `containerd`, specified when launching the Windows nodes using either `eksctl` or the AWS Management Console.

- If the specified value is `docker` and the Amazon EKS version is 1.23 or earlier, then Docker is used as the runtime on the node.
- If the specified value is `containerd` and the Amazon EKS version is later than 1.20, then `containerd` is selected as the runtime. If the Amazon EKS version is earlier than 1.21, then the bootstrap fails and nodes are unable to join the cluster.
- If any other value is specified, then the bootstrap fails and the node isn’t able to join the cluster.
- If this flag isn’t specified, then the default value of the container runtime is selected. For Amazon EKS version 1.23 and earlier, the default is Docker. For 1.24 and later clusters, it will be `containerd`.

When launching Windows nodes in your Amazon EKS cluster, follow the steps in Launching self-managed Windows nodes (p. 129). Windows self-managed nodes with the `containerd` runtime can be launched using `eksctl` or the AWS Management Console.

**eksctl**

To enable the containerd runtime with `eksctl`

For Windows self-managed nodes, the container runtime can be specified in the configuration while creating new node groups. You can use the following `test-windows-with-containerd.yaml` as reference.

**Note**

You must use `eksctl` version `0.95.0` or later to use the `containerRuntime` setting in the configuration file.

```yaml
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: windows-containerd-cluster
  region: us-west-2
  version: '1.21'
nodeGroups:
- name: windows-ng
  instanceType: m5.2xlarge
  amiFamily: WindowsServer2019FullContainer
  volumeSize: 100
  minSize: 2
  maxSize: 3
  containerRuntime: containerd
- name: linux-ng
  amiFamily: AmazonLinux2
```
The node groups can then be created using the following command.

```
eksctl create cluster -f test-windows-with-containerd.yaml
```

Alternatively, you can also specify the `EKS_CONTAINER_RUNTIME` environment variable as a pre-bootstrap command in the `eksctl` configuration file.

```
preBootstrapCommands:
  - Invoke-Expression -Command
    '[[Environment]::SetEnvironmentVariable("EKS_CONTAINER_RUNTIME", "containerd", [System.EnvironmentVariableTarget]::Machine)'
```

For more information, see Creating a nodegroup from a config file, defining containerd runtime, and Config file schema in the `eksctl` documentation.

AWS Management Console

**To enable the containerd runtime with the AWS Management Console**

In the AWS CloudFormation template, there's a parameter named `BootstrapArguments` which can be used to pass in additional arguments to the bootstrap script. A parameter named `ContainerRuntime` can be used to select a particular runtime on the node.

Specify the following in `BootstrapArguments` to enable the containerd runtime:

```
-ContainerRuntime containerd
```

## Amazon EKS optimized Windows AMI versions

This topic lists versions of the Amazon EKS optimized Windows AMIs and their corresponding versions of kubelet, Docker, containerd, and csi-proxy.

The Amazon EKS optimized AMI metadata, including the AMI ID, for each variant can be retrieved programmatically. For more information, see Retrieving Amazon EKS optimized Windows AMI IDs (p. 201).

AMIs are versioned by Kubernetes version and the release date of the AMI in the following format:

```
k8s_major_version.k8s_minor_version-release_date
```

### Amazon EKS optimized Windows Server 2019 Core AMI

Retrieving Amazon EKS optimized Windows AMI IDs

You can programmatically retrieve the Amazon Machine Image (AMI) ID for Amazon EKS optimized AMIs by querying the AWS Systems Manager Parameter Store API. This parameter eliminates the need for you to manually look up Amazon EKS optimized AMI IDs. For more information about the Systems Manager Parameter Store API, see `GetParameter`. Your user account must have the `ssm:GetParameter` IAM permission to retrieve the Amazon EKS optimized AMI metadata.

You can retrieve the AMI ID with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon EKS optimized Windows AMI with the following command by using the sub-parameter `image_id`. You can replace `1.23` with
any supported Amazon EKS version and can replace `region-code` with an Amazon EKS supported Region for which you want the AMI ID. Replace `Core` with `Full` to see the Windows Server full AMI ID.

```bash
```

The example output is as follows.

`ami-1234567890abcdef0`

- **AWS Management Console** – You can query for the recommended Amazon EKS optimized AMI ID using a URL. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, you can replace `1.22` with any supported Amazon EKS version and can replace `region-code` with an Amazon EKS supported Region for which you want the AMI ID. Replace `Core` with `Full` to see the Windows Server full AMI ID.

  ```text
  ```

### Amazon EKS optimized Windows AMI

You can use Amazon EC2 Image Builder to create custom Amazon EKS optimized Windows AMIs. You must create your own Image Builder recipe. For more information, see Create image recipes and versions in the EC2 Image Builder User Guide. When creating a recipe and selecting a Source image, you have the following options:

- **Select managed images** – If you select this option, you can choose one of the following options for Image origin.
  - **Quick start (Amazon-managed)** – In the Image name dropdown, select an Amazon EKS supported Windows Server version (p. 185).
  - **Images owned by me** – For Image name, select the ARN of your own image with your own license. The image that you provide can’t already have Amazon EKS components installed.
  - **Enter custom AMI ID** – For AMI ID, enter the ID for your AMI with your own license. The image that you provide can’t already have Amazon EKS components installed.

In the search box under **Build components - Windows**, select **Amazon-managed** in the dropdown list and then search on eks. Select the `eks-optimized-ami-windows` search result, even though the result returned may not be the version that you want. Under **Selected components**, select **Versioning options**, then select **Specify component version**. Enter `version.x`, replacing `version` with a supported Kubernetes version (p. 66). If you enter `1.23.x` as the component version, your Image Builder pipeline builds an AMI with the latest `1.23.x` kubelet version.

To determine which kubelet and Docker versions are installed with the component, select **Components** in the left navigation. Under **Components**, change **Owned by me** to **Quick start (Amazon-managed)**. In the **Find components by name** box, enter `eks`. The search results show the kubelet and Docker version in the component returned for each supported Kubernetes version. The components go through functional testing on the Amazon EKS supported Windows versions. Any other Windows versions are not supported and might not be compatible with the component.

Also include the `update-windows` component for the latest Windows patches for the operating system.
Storage

This chapter covers storage options for Amazon EKS clusters.

The Storage classes (p. 203) topic uses the in-tree Amazon EBS storage provisioner.

Note
The existing in-tree Amazon EBS plugin is still supported, but by using a CSI driver, you benefit from the decoupling of Kubernetes upstream release cycle and CSI driver release cycle. Eventually, the in-tree plugin will be discontinued in favor of the CSI driver. However, the CSI driver isn't supported on Fargate.

Topics
- Storage classes (p. 203)
- Amazon EBS CSI driver (p. 205)
- Amazon EFS CSI driver (p. 220)
- Amazon FSx for Lustre CSI driver (p. 232)
- Amazon FSx for NetApp ONTAP CSI driver (p. 237)

Storage classes

Amazon EKS clusters that were created prior to Kubernetes version 1.11 weren't created with any storage classes. You must define storage classes for your cluster to use and you should define a default storage class for your persistent volume claims. For more information, see Storage classes in the Kubernetes documentation.

Note
This topic uses the in-tree Amazon EBS storage provisioner. The existing in-tree Amazon EBS plugin is still supported, but by using a CSI driver, you benefit from the decoupling of Kubernetes upstream release cycle and CSI driver release cycle. Eventually, the in-tree plugin will be discontinued in favor of the CSI driver. However, the CSI driver isn't supported on Fargate.

To create an AWS storage class for your Amazon EKS cluster

1. Determine which storage classes your cluster already has.

```
kubectl get storageclass
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>PROVISIONER</th>
<th>RECLAIMPOLICY</th>
<th>VOLUMEBINDINGMODE</th>
</tr>
</thead>
<tbody>
<tr>
<td>gp2 (default)</td>
<td>kubernetes.io/aws-ebs</td>
<td>Delete</td>
<td>WaitForFirstConsumer</td>
</tr>
<tr>
<td>34m</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If your cluster returns the previous output, then it already has the storage class defined in the remaining steps. You can define other storage classes using the steps for deploying any of the CSI drivers in the Storage (p. 203) chapter. Once deployed, you can set one of the storage classes as your default (p. 204) storage class.
2. Create an AWS storage class manifest file for your storage class. The following `gp2-storage-class.yaml` example defines a storage class called `gp2` that uses the Amazon EBS `gp2` volume type.

For more information about the options available for AWS storage classes, see AWS EBS in the Kubernetes documentation.

```yaml
kind: StorageClass
apiVersion: storage.k8s.io/v1
metadata:
  name: gp2
  annotations:
    storageclass.kubernetes.io/is-default-class: "true"
provisioner: kubernetes.io/aws-ebs
parameters:
  type: gp2
  fsType: ext4
```

3. Use `kubectl` to create the storage class from the manifest file.

```bash
kubectl create -f gp2-storage-class.yaml
```

The example output is as follows.

```
storageclass "gp2" created
```

To define a default storage class

1. List the existing storage classes for your cluster. A storage class must be defined before you can set it as a default.

```bash
kubectl get storageclass
```

The example output is as follows.

```
NAME      PROVISIONER             AGE
gp2       kubernetes.io/aws-ebs   8m
```

2. Choose a storage class and set it as your default by setting the `storageclass.kubernetes.io/is-default-class=true` annotation.

```bash
kubectl annotate storageclass gp2 storageclass.kubernetes.io/is-default-class=true
```

The example output is as follows.

```
storageclass "gp2" patched
```

3. Verify that the storage class is now set as default.

```bash
kubectl get storageclass
```

The example output is as follows.

```
gp2 (default) kubernetes.io/aws-ebs 12m
```
Amazon EBS CSI driver

The Amazon Elastic Block Store (Amazon EBS) Container Storage Interface (CSI) driver allows Amazon Elastic Kubernetes Service (Amazon EKS) clusters to manage the lifecycle of Amazon EBS volumes for persistent volumes.

Here are some things to consider about using the Amazon EBS CSI driver.

• The Amazon EBS CSI plugin requires IAM permissions to make calls to AWS APIs on your behalf. For more information, see Creating the Amazon EBS CSI driver IAM role for service accounts (p. 205).

• You can run the Amazon EBS CSI controller on Fargate, but you can't mount volumes to Fargate pods.

• Alpha features of the Amazon EBS CSI driver aren't supported on Amazon EKS clusters.

  Important
  If you have a 1.22 or earlier cluster that you currently run pods on that use Amazon EBS volumes, and you don't currently have this driver installed on your cluster, then be sure to install this driver to your cluster before updating the cluster to 1.23. If you don't install this driver before updating your cluster to 1.23, you might experience workload interruption. For more information or to get answers to frequently asked questions about this requirement, see the section called “Kubernetes 1.23” (p. 67) or the section called “CSI migration FAQ” (p. 218).

The Amazon EBS CSI driver isn't installed when you first create a cluster. To use the driver, you must add it as an Amazon EKS add-on or as a self-managed add-on.

• For instructions on how to add it as an Amazon EKS add-on, see Managing the Amazon EBS CSI driver as an Amazon EKS add-on (p. 211).

• For instructions on how to add it as a self-managed add-on, see the Amazon EBS Container Storage Interface (CSI) driver project on GitHub.

After you installed the CSI driver with either method, you can test the functionality with a sample application. For more information, see Deploy a sample application and verify that the CSI driver is working (p. 216).

Creating the Amazon EBS CSI driver IAM role for service accounts

The Amazon EBS CSI plugin requires IAM permissions to make calls to AWS APIs on your behalf. For more information, see Set up driver permission on GitHub.

When the plugin is deployed, it creates and is configured to use a service account that's named ebs-csi-controller-sa. The service account is bound to a Kubernetes clusterrole that's assigned the required Kubernetes permissions.

  Note
  No matter if you configure the Amazon EBS CSI plugin to use IAM roles for service accounts, the pods have access to the permissions that are assigned to the IAM role. This is the case except when you block access to IMDS. For more information, see Security best practices for Amazon EKS (p. 495).

Prerequisites

• An existing cluster.

  • 1.19 requires eks.7 or later.
To create your Amazon EBS CSI plugin IAM role with `eksctl`

1. Create an IAM role and attach the required AWS managed policy with the following command. Replace `my-cluster` with the name of your cluster. The command deploys an AWS CloudFormation stack that creates an IAM role, attaches the IAM policy to it, and annotates the existing `ebs-csi-controller-sa` service account with the Amazon Resource Name (ARN) of the IAM role. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

   ```bash
   eksctl create iamserviceaccount \\
   --name ebs-csi-controller-sa \\
   --namespace kube-system \\
   --cluster my-cluster \\
   --attach-policy-arn arn:aws:iam::aws:policy/service-role/AmazonEBSCSIDriverPolicy \\
   --approve \\
   --role-only \\
   --role-name AmazonEKS_EBS_CSI_DriverRole
   ```

2. If you use a custom KMS key for encryption on your Amazon EBS volumes, customize the IAM role as needed. For example, do the following:
   a. Copy and paste the following code into a new `kms-key-for-encryption-on-ebs.json` file. Replace `custom-key-id` with the custom KMS key ID.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": [
           "kms:CreateGrant",
           "kms:ListGrants",
           "kms:RevokeGrant"
         ],
         "Resource": ["custom-key-id"],
         "Condition": {
           "Bool": {
             "kms:GrantIsForAWSResource": "true"
           }
         }
       },
       {
         "Effect": "Allow",
         "Action": [
           "kms:Encrypt",
           "kms:Decrypt",
           "kms:ReEncrypt*",
           "kms:GenerateDataKey*",
           "kms:ReEncryptTo*",
           "kms:ReEncryptFrom*",
           "kms:ListGrants",
           "kms:CreateGrant",
           "kms:TagResource",
           "kms:RemoveTags"
         ],
         "Resource": ["arn:aws:iam::aws:policy/service-role/AmazonEBSCSIDriverPolicy"]
       }
     ]
   }
   ```
Create an IAM policy and role

b. Create the policy. You can change `KMS_Key_For_Encryption_On_EBS_Policy` to a different name. However, if you do, make sure to change it in later steps, too.

```bash
aws iam create-policy
  --policy-name KMS_Key_For_Encryption_On_EBS_Policy
  --policy-document file://kms-key-for-encryption-on-ebs.json
```

c. Attach the IAM policy to the role with the following command. Replace `111122223333` with your account ID. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

```bash
aws iam attach-role-policy
  --policy-arn arn:aws:iam::111122223333:policy/KMS_Key_For_Encryption_On_EBS_Policy
  --role-name AmazonEKS_EBS_CSI_DriverRole
```

AWS Management Console

To create your Amazon EBS CSI plugin IAM role with the AWS Management Console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Roles.
3. On the Roles page, choose Create role.
4. On the Select trusted entity page, do the following:
   a. In the Trusted entity type section, choose Web identity.
   b. For Identity provider, choose the OpenID Connect provider URL for your cluster (as shown under Overview in Amazon EKS).
   c. For Audience, choose sts.amazonaws.com.
   d. Choose Next.
5. On the Add permissions page, do the following:
   a. In the Filter policies box, enter AmazonEBSCSIDriverPolicy.
   b. Select the check box to the left of the AmazonEBSCSIDriverPolicy returned in the search.
   c. Choose Next.
6. On the Name, review, and create page, do the following:
   a. For Role name, enter a unique name for your role, such as AmazonEKS_EBS_CSI_DriverRole.
   b. Under Add tags (Optional), add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM Entities in the IAM User Guide.
   c. Choose Create role.
7. After the role is created, choose the role in the console to open it for editing.
8. Choose the Trust relationships tab, and then choose Edit trust policy.
9. Find the line that looks similar to the following line:
Create an IAM policy and role

"oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:aud": "sts.amazonaws.com"

Add a comma to the end of the previous line, and then add the following line after the previous line. Replace `region-code` with the AWS Region that your cluster is in. Replace `EXAMPLED539D4633E53DE1B71EXAMPLE` with your cluster's OIDC provider ID.

10. Choose **Update policy** to finish.

11. If you use a custom KMS key for encryption on your Amazon EBS volumes, customize the IAM role as needed. For example, do the following:
   a. In the left navigation pane, choose Policies.
   b. On the Policies page, choose **Create Policy**.
   c. On the Create policy page, choose the JSON tab.
   d. Copy and paste the following code into the editor, replacing `custom-key-id` with the custom KMS key ID:

   ```json
   { 
   "Version": "2012-10-17",
   "Statement": [
   { 
   "Effect": "Allow",
   "Action": [ 
   "kms:CreateGrant",
   "kms:ListGrants",
   "kms:RevokeGrant"
   ],
   "Resource": ["custom-key-id"],
   "Condition": { 
   "Bool": { 
   "kms:GrantIsForAWSResource": "true"
   }
   }
   },
   { 
   "Effect": "Allow",
   "Action": [ 
   "kms:Encrypt",
   "kms:Decrypt",
   "kms:ReEncrypt*",
   "kms:GenerateDataKey*",
   "kms:DescribeKey"
   ],
   "Resource": ["custom-key-id"]
   }
   ]
   }
   
   e. Choose **Next: Tags**.
   f. On the Add tags (Optional) page, choose **Next: Review**.
   g. For Name, enter a unique name for your policy (for example, `KMS_Key_For_Encryption_On_EBS_Policy`).
   h. Choose **Create policy**.
   i. In the left navigation pane, choose Roles.
j. Choose the **AmazonEKS_EBS_CSI_DriverRole** in the console to open it for editing.
k. From the **Add permissions** drop-down list, choose **Attach policies**.
l. In the **Filter policies** box, enter **KMS Key For Encryption On EBS Policy**.
m. Select the check box to the left of the **KMS Key For Encryption On EBS Policy** that was returned in the search.
n. Choose **Attach policies**.

AWS CLI

**To create your Amazon EBS CSI plugin IAM role with the AWS CLI**

1. View your cluster's OIDC provider URL. Replace *my-cluster* with your cluster name. If the output from the command is None, review the **Prerequisites**.

   ```bash
   aws eks describe-cluster \
   --name my-cluster \
   --query "cluster.identity.oidc.issuer" \
   --output text
   ```

   The example output is as follows.

   ```bash
   https://oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE
   ```

2. Create the IAM role.

   a. Copy the following contents to a file that's named **aws-ebs-csi-driver-trust-policy.json**. Replace *111122223333* with your account ID, *region-code* with your AWS Region, and *EXAMPLED539D4633E53DE1B71EXAMPLE* with the value that was returned in the previous step. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace arn:aws with arn:aws-us-gov:

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Principal": {
   "Federated": "arn:aws:iam::111122223333:oidc-provider/oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE"
   },
   "Action": "sts:AssumeRoleWithWebIdentity",
   "Condition": {
   "StringEquals": {
   "oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:aud": "sts.amazonaws.com",
   }},
   }
]
}
```

   b. Create the role. You can change **AmazonEKS_EBS_CSI_DriverRole** to a different name. If you change it, make sure to change it in later steps.

   ```bash
   aws iam create-role \
   ```
3. Attach the required AWS managed policy to the role with the following command. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

```bash
aws iam attach-role-policy \
--policy-arn arn:aws:iam::aws:policy/service-role/AmazonEBSCSIDriverPolicy \
--role-name AmazonEKS_EBS_CSI_DriverRole
```

4. If you use a custom KMS key for encryption on your Amazon EBS volumes, customize the IAM role as needed. For example, do the following:

a. Copy and paste the following code into a new `kms-key-for-encryption-on-ebs.json` file. Replace `custom-key-id` with the custom KMS key ID.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:CreateGrant",
        "kms:ListGrants",
        "kms:RevokeGrant"
      ],
      "Resource": ["custom-key-id"],
      "Condition": {
        "Bool": {
          "kms:GrantIsForAWSResource": "true"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:DescribeKey"
      ],
      "Resource": ["custom-key-id"]
    }
  ]
}
```

b. Create the policy. You can change `KMS_Key_For_Encryption_On_EBS_Policy` to a different name. However, if you do, make sure to change it in later steps, too.

```bash
aws iam create-policy \
--policy-name KMS_Key_For_Encryption_On_EBS_Policy \
--policy-document file://kms-key-for-encryption-on-ebs.json
```

c. Attach the IAM policy to the role with the following command. Replace `111122223333` with your account ID. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

```bash
aws iam attach-role-policy \
--policy-arn arn:aws:iam::111122223333:policy/KMS_Key_For_Encryption_On_EBS_Policy \
--role-name AmazonEKS_EBS_CSI_DriverRole
```
Managing the Amazon EBS CSI driver as an Amazon EKS add-on

To improve security and reduce the amount of work, you can manage the Amazon EBS CSI driver as an Amazon EKS add-on. For information about Amazon EKS add-ons, see Amazon EKS add-ons (p. 367). You can add the Amazon EBS CSI add-on by following the steps in Adding the Amazon EBS CSI add-on (p. 211).

If you added the Amazon EBS CSI add-on, you can manage it by following the steps in the Updating the Amazon EBS CSI driver as an Amazon EKS add-on (p. 213) and Removing the Amazon EBS CSI add-on (p. 215) sections.

Prerequisites

- An existing cluster. To see the required platform version, run the following command.

  ```
  aws eks describe-addon-versions --addon-name aws-ebs-csi-driver
  ```

- An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Creating an IAM OIDC provider for your cluster (p. 426).

- An Amazon EBS CSI driver IAM role. For more information, see Creating the Amazon EBS CSI driver IAM role for service accounts (p. 205).

  **Important**

  To use the snapshot functionality of the Amazon EBS CSI driver, you must install the external snapshotter before the installation of the add-on. The external snapshotter components must be installed in the following order:

  - CustomResourceDefinition (CRD) for volumesnapshotclasses, volumesnapshots, and volumesnapshotcontents
  - RBAC (ClusterRole, ClusterRoleBinding, and so on)
  - controller deployment

  For more information, see CSI Snapshotter on GitHub.

Adding the Amazon EBS CSI add-on

  **Important**

  Before adding the Amazon EBS CSI add-on, confirm that you don't self-manage any settings that Amazon EKS will start managing. To determine which settings Amazon EKS manages, see Amazon EKS add-on configuration (p. 368).
You can use `eksctl`, the AWS Management Console, or the AWS CLI to add the Amazon EBS CSI add-on to your cluster.

`eksctl`

To add the Amazon EBS CSI add-on using `eksctl`

Run the following command. Replace `my-cluster` with the name of your cluster, `111122223333` with your account ID, and `AmazonEKS_EBS_CSI_DriverRole` with the name of the IAM role created earlier (p. 205). If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

```
  eksctl create addon --name aws-ebs-csi-driver --cluster my-cluster --service-account-role-arn arn:aws:iam::111122223333:role/AmazonEKS_EBS_CSI_DriverRole --force
```

If you remove the `--force` option and there's a conflict with your existing settings, the command fails. You can use the resulting error message to troubleshoot the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage. This is because those settings are overwritten with this option. For more information about managing Amazon EKS add-ons, see Amazon EKS add-on configuration (p. 368).

AWS Management Console

To add the Amazon EBS CSI add-on using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Clusters.
3. Choose the name of the cluster that you want to configure the Amazon EBS CSI add-on for.
4. Choose the Add-ons tab.
5. Choose Add new.
   a. Select Amazon EBS CSI Driver for Name.
   b. Select the Version you'd like to use.
   c. For Service account role, select the name of an IAM role that you attached the IAM policy to.
   d. If you select Override existing configuration for this add-on on the cluster, one or more of the settings for the existing add-on can be overwritten with the Amazon EKS add-on settings. If you don't enable this option and there's a conflict with your existing settings, the operation fails. You can use the resulting error message to troubleshoot the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage. For more information about managing Amazon EKS add-ons, see Amazon EKS add-on configuration (p. 368).
   e. Choose Add.

AWS CLI

To add the Amazon EBS CSI add-on using the AWS CLI

Run the following command. Replace `my-cluster` with the name of your cluster, `111122223333` with your account ID, and `AmazonEKS_EBS_CSI_DriverRole` with the name of the role that was created earlier. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

```
  aws eks create-addon \ 
  --cluster-name my-cluster 
```
Updating the Amazon EBS CSI driver as an Amazon EKS add-on

Amazon EKS doesn't automatically update Amazon EBS CSI for your cluster when new versions are released or after you update your cluster (p. 32) to a new Kubernetes minor version. To update Amazon EBS CSI on an existing cluster, you must initiate the update and then Amazon EKS updates the add-on for you.

**Important**
Update your cluster and nodes to a new Kubernetes minor version before you update Amazon EBS CSI to the same minor version.

### eksctl

**To update the Amazon EBS CSI add-on using eksctl**

1. Check the current version of your Amazon EBS CSI add-on. Replace `my-cluster` with your cluster name.

   ```bash
   eksctl get addon --name aws-ebs-csi-driver --cluster my-cluster
   ```

   The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>STATUS</th>
<th>ISSUES</th>
<th>IAMROLE UPDATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws-ebs-csi-driver</td>
<td>v1.4.0-eksbuild.preview</td>
<td>ACTIVE</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>v1.5.1-eksbuild.1</td>
<td>v1.5.1-eksbuild.1</td>
<td>ACTIVE</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

2. Update the add-on to the version returned under `UPDATE AVAILABLE` in the output of the previous step.

   ```bash
   eksctl update addon --name aws-ebs-csi-driver --version v1.5.1-eksbuild.1 --cluster my-cluster --force
   ```

   If you remove the `--force` option and there's a conflict with your existing settings, the command fails. You can use the resulting error message to troubleshoot the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage. This is because those settings are overwritten with this option. For more information about managing Amazon EKS add-ons, see Amazon EKS add-on configuration (p. 368).

### AWS Management Console

**To update the Amazon EBS CSI add-on using the AWS Management Console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Clusters.
3. Choose the name of the cluster that you want to update the Amazon EBS CSI add-on for.
4. Choose the Add-ons tab.
5. Select the radio button in the upper right of the \texttt{aws-ebs-csi-driver} box.
6. Choose \texttt{Edit}.
   a. Select the \texttt{Version} of the Amazon EKS add-on that you want to use.
   b. For \texttt{Service account role}, select the name of the IAM role that you've attached the Amazon EBS CSI driver IAM policy to.
   c. If you select \texttt{Override existing configuration for this add-on on the cluster.}, then one or more of the settings for the existing add-on can be overwritten with the Amazon EKS add-on settings. If you don't enable this option and there's a conflict with your existing settings, the operation fails with an error message to help you resolve the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage. For more information about managing Amazon EKS add-ons, see \textit{Amazon EKS add-on configuration} (p. 368).
   d. Select \texttt{Update}.

\textbf{AWS CLI}

\textbf{To update the Amazon EBS CSI add-on using the AWS CLI}

1. Check the current version of your Amazon EBS CSI add-on. Replace \texttt{my-cluster} with your cluster name.

   \begin{verbatim}
   aws eks describe-addon \  
   --cluster-name my-cluster \  
   --addon-name aws-ebs-csi-driver \  
   --query "addon.addonVersion" \  
   --output text
   \end{verbatim}

   The example output is as follows.

   \texttt{v1.4.0-eksbuild.preview}

2. Determine which versions of the Amazon EBS CSI add-on are available for your cluster version.

   \begin{verbatim}
   aws eks describe-addon-versions \  
   --addon-name aws-ebs-csi-driver \  
   --kubernetes-version 1.20 \  
   --query "addons[].addonVersions[].[addonVersion, \  
   compatibilities[].defaultVersion]" \  
   --output text
   \end{verbatim}

   The example output is as follows.

   \begin{verbatim}
   v1.5.1-eksbuild.1
   False
   v1.4.0-eksbuild.preview
   True
   \end{verbatim}

   The version with \texttt{True} underneath is the default version deployed with new clusters with the version that you specified.

3. Update the add-on to the version with \texttt{True} that was returned in the output of the previous step. If it was returned in the output, you can also update to a later version.

   \begin{verbatim}
   aws eks update-addon \  
   --cluster-name my-cluster \  
   \end{verbatim}
Remove the Amazon EBS CSI add-on

You have two options for removing an Amazon EKS add-on.

- **Preserve add-on software on your cluster** – This option removes Amazon EKS management of any settings. It also removes the ability for Amazon EKS to notify you of updates and automatically update the Amazon EKS add-on after you initiate an update. However, it preserves the add-on software on your cluster. This option makes the add-on a self-managed add-on, rather than an Amazon EKS add-on. With this option, there's no downtime for the add-on. The commands in this procedure use this option.

- **Remove add-on software entirely from your cluster** – We recommend that you remove the Amazon EKS add-on from your cluster only if there are no resources on your cluster that are dependent on it. To do this option, delete **--preserve** from the command you use in this procedure.

If the add-on has an IAM account associated with it, the IAM account isn't removed.

You can use eksctl, the AWS Management Console, or the AWS CLI to remove the Amazon EBS CSI add-on.

**eksctl**

To remove the Amazon EBS CSI add-on using eksctl

Replace `my-cluster` with the name of your cluster, and then run the following command.

```
eksctl delete addon --cluster my-cluster --name aws-ebs-csi-driver --preserve
```

**AWS Management Console**

To remove the Amazon EBS CSI add-on using the AWS Management Console

1. Open the Amazon EKS console at [https://console.aws.amazon.com/eks/home#/clusters](https://console.aws.amazon.com/eks/home#/clusters).
2. In the left navigation pane, choose **Clusters**.
3. Choose the name of the cluster that you want to remove the Amazon EBS CSI add-on for.
4. Choose the **Add-ons** tab.
5. Select the radio button in the upper right of the **aws-ebs-csi-driver** box.
6. Choose **Remove**.
7. Select **Preserve on cluster** if you want Amazon EKS to stop managing settings for the add-on. Do this if you want to retain the add-on software on your cluster. This is so that you can manage all of the settings of the add-on on your own.
8. Enter **aws-ebs-csi-driver**.
9. Select Remove.

AWS CLI

To remove the Amazon EBS CSI add-on using the AWS CLI

Replace `my-cluster` with the name of your cluster, and then run the following command.

```bash
aws eks delete-addon --cluster-name my-cluster --addon-name aws-ebs-csi-driver --preserve
```

Deploy a sample application and verify that the CSI driver is working

You can test the CSI driver functionality with a sample application. This topic shows one example, but you can also do the following:

- Deploy a sample application that uses the external snapshotter to create volume snapshots. For more information, see Volume Snapshots on GitHub.
- Deploy a sample application that uses volume resizing. For more information, see Volume Resizing on GitHub.

This procedure uses the Dynamic volume provisioning example from the Amazon EBS Container Storage Interface (CSI) driver GitHub repository to consume a dynamically provisioned Amazon EBS volume.

1. Clone the Amazon EBS Container Storage Interface (CSI) driver GitHub repository to your local system.

   ```bash
git clone https://github.com/kubernetes-sigs/aws-ebs-csi-driver.git
```

2. Navigate to the dynamic-provisioning example directory.

   ```bash
cd aws-ebs-csi-driver/examples/kubernetes/dynamic-provisioning/
```

3. Deploy the `ebs-sc` storage class, `ebs-claim` persistent volume claim, and `app` sample application from the manifests directory.

   ```bash
kubectl apply -f manifests/
```

4. Describe the `ebs-sc` storage class.

   ```bash
kubectl describe storageclass ebs-sc
```

The example output is as follows.

```
Name: ebs-sc
IsDefaultClass: No
Annotations: Kubectl.kubernetes.io/last-applied-configuration={"apiVersion":"storage.k8s.io/v1","kind":"StorageClass","metadata":{"annotations":{},"name":"ebs-sc"},"provisioner":"ebs.csi.aws.com","volumeBindingMode":"WaitForFirstConsumer"}
Provisioner: ebs.csi.aws.com
```
Parameters: <none>
AllowVolumeExpansion: <unset>
MountOptions: <none>
ReclaimPolicy: Delete
VolumeBindingMode: WaitForFirstConsumer
Events: <none>

Note
The storage class uses the WaitForFirstConsumer volume binding mode. This means that volumes aren't dynamically provisioned until a pod makes a persistent volume claim. For more information, see Volume Binding Mode in the Kubernetes documentation.

5. Watch the pods in the default namespace. After a few minutes, the app pod's status changes to Running.

    kubectl get pods --watch

Enter Ctrl+C to return to a shell prompt.

6. List the persistent volumes in the default namespace. Look for a persistent volume with the default/ebs-claim claim.

    kubectl get pv

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>CAPACITY</th>
<th>ACCESS MODES</th>
<th>RECLAIM POLICY</th>
</tr>
</thead>
<tbody>
<tr>
<td>pvc-3771cd6-d0dc-11e9-b17f-06fad4858a5a</td>
<td>4Gi</td>
<td>RWO</td>
<td>Delete</td>
</tr>
</tbody>
</table>

7. Describe the persistent volume. Replace pvc-3771cd6-d0dc-11e9-b17f-06fad4858a5a with the value from the output in the previous step.

    kubectl describe pv pvc-3771cd6-d0dc-11e9-b17f-06fad4858a5a

The example output is as follows.

Name: pvc-3771cd6-d0dc-11e9-b17f-06fad4858a5a
Labels: <none>
Annotations: pv.kubernetes.io/provisioned-by: ebs.csi.aws.com
Finalizers: [kubernetes.io/pv-protection external-attacher/ebs-csi-aws-com]
StorageClass: ebs-sc
Status: Bound
Claim: default/ebs-claim
Reclaim Policy: Delete
Access Modes: RWO
VolumeMode: Filesystem
Capacity: 4Gi
Node Affinity: Required Terms:
  Term 0: topology.ebs.csi.aws.com/zone in [region-code]
Message: Source:
  Type: CSI (a Container Storage Interface (CSI) volume source)
  Driver: ebs.csi.aws.com
  VolumeHandle: vol-0d651e157c6d93445
  ReadOnly: false
  VolumeAttributes: storage.kubernetes.io/csiProvisionerIdentity=1567792483192-8081-ebs.csi.aws.com
The Amazon EBS volume ID is the value for `VolumeHandle` in the previous output.

8. Verify that the pod is writing data to the volume.

```bash
kubectl exec -it app -- cat /data/out.txt
```

The example output is as follows.

```plaintext
Wed May 5 16:17:03 UTC 2021
Wed May 5 16:17:08 UTC 2021
Wed May 5 16:17:13 UTC 2021
Wed May 5 16:17:18 UTC 2021
...
```

9. After you're done, delete the resources for this sample application.

```bash
kubectl delete -f manifests/
```

---

### Amazon EBS CSI migration frequently asked questions

The Amazon EBS container storage interface (CSI) migration feature is enabled by default in Amazon EKS 1.23 and later clusters. **If you have pods running on a version 1.22 or earlier cluster, then you must install the Amazon EBS driver (p. 205) before updating your cluster to version 1.23 to avoid service interruption.** Select any frequently asked question to learn about the answer to it.

**What are CSI drivers?**

CSI drivers:

- replace the Kubernetes "in-tree" storage drivers that exist in the Kubernetes project source code.
- work with storage providers, such as Amazon EBS.
- provide a simplified plug-in model that make it easier for storage providers like AWS to release features and maintain support without depending on the Kubernetes release cycle.

For more information, see **Introduction** in the Kubernetes CSI documentation.

**What is CSI migration?**

The Kubernetes CSI Migration feature moves responsibility for handling storage operations from the existing in-tree storage plugins, such as `kubernetes.io/aws-ebs`, to corresponding CSI drivers. Existing `StorageClass`, `PersistentVolume` and `PersistentVolumeClaim` (PVC) objects continue to work, as long as the corresponding CSI driver is installed. When the feature is enabled:

- Existing workloads that utilize PVCs continue to function as they always have.
- Kubernetes passes control of all storage management operations to CSI drivers.

For more information, see **Kubernetes 1.23: Kubernetes In-Tree to CSI Volume Migration Status Update** on the Kubernetes blog.

To help you migrate from the in-tree plugin to CSI drivers, the `CSIMigration` and `CSIMigrationAWS` flags are enabled by default on Amazon EKS version 1.23 and later clusters. These flags enable your
cluster to translate the in-tree APIs to their equivalent CSI APIs. These flags are set on the Kubernetes control plane managed by Amazon EKS and in the kubelet settings configured in Amazon EKS optimized AMIs. If you have pods using Amazon EBS volumes in your cluster, you must install the Amazon EBS CSI driver before updating your cluster to version 1.23. If you don't, volume operations such as provisioning and mounting might not work as expected. For more information, see Amazon EBS CSI driver (p. 205).

Note
The in-tree StorageClass provisioner is named kubernetes.io/aws-ebs. The Amazon EBS CSI StorageClass provisioner is named ebs.csi.aws.com.

Can I mount kubernetes.io/aws-ebsStorageClass volumes in version 1.23 and later clusters?
Yes, as long as the Amazon EBS CSI driver (p. 205) is installed. For newly created version 1.23 and later clusters, we recommend installing the Amazon EBS CSI driver as part of your cluster creation process. We also recommend only using StorageClasses based on the ebs.csi.aws.com provisioner.

If you've updated your cluster control plane to version 1.23 and haven't yet updated your nodes to 1.23, then the CSIMigration and CSIMigrationAWS kubelet flags aren't enabled. In this case, the in-tree driver is used to mount kubernetes.io/aws-ebs based volumes. The Amazon EBS CSI driver must still be installed however, to ensure that pods using kubernetes.io/aws-ebs based volumes can be scheduled. The driver is also required for other volume operations to succeed.

Can I provision kubernetes.io/aws-ebsStorageClass volumes on Amazon EKS 1.23 and later clusters?
Yes, as long as the Amazon EBS CSI driver (p. 205) is installed.

Will the kubernetes.io/aws-ebsStorageClass provisioner ever be removed from Amazon EKS?
No. The StorageClass provisioner kubernetes.io/aws-ebs and volume type awsElasticBlockStore are treated as a part of the Kubernetes API. These resources are no longer supported, but there are no plans to remove them.

How do I install the Amazon EBS CSI driver?
If you want to manage the driver yourself, you can install it using the open source Helm chart. Alternatively, you can install the Amazon EBS CSI driver Amazon EKS add-on (p. 205). When an update is required to the Amazon EKS add-on, you initiate the update and Amazon EKS updates the add-on for you.

Important
The Kubernetes in-tree Amazon EBS driver runs on the Kubernetes control plane. It uses IAM permissions assigned to the the section called “Cluster IAM role” (p. 460) to provision Amazon EBS volumes. The Amazon EBS CSI driver runs on nodes. The driver needs IAM permissions to provision volumes. For more information, see the section called “Create an IAM policy and role” (p. 205).

How can I check whether the Amazon EBS CSI driver is installed in my cluster?
Use helm list -A to determine whether the open source Helm chart is installed. Use aws eks list-addons to determine whether the Amazon EKS add-on is installed.

Will Amazon EKS prevent a cluster update to version 1.23 if I haven't already installed the Amazon EBS CSI driver?
No.
What if I forget to install the Amazon EBS CSI driver before I update my cluster to version 1.23? Can I install the driver after updating my cluster?

Yes, but volume operations requiring the Amazon EBS CSI driver will fail after your cluster update until the driver is installed.

What is the default StorageClass applied in newly created Amazon EKS version 1.23 and later clusters?

The default StorageClass behavior remains unchanged. With each new cluster, Amazon EKS applies a kubernetes.io/aws-ebs based StorageClass named gp2. We don't plan to ever remove this StorageClass from newly created clusters. Though subject to change, we are currently targeting version 1.25 to remove the default annotation from the StorageClass applied to newly created clusters. Separate from the cluster default StorageClass, if you create an ebs.csi.aws.com based StorageClass without specifying a volume type, the Amazon EBS CSI driver will default to using gp3.

Will Amazon EKS make any changes to StorageClasses already present in my existing cluster when I update my cluster to version 1.23?

No.

How do I migrate a persistent volume from the kubernetes.io/aws-ebsStorageClass to ebs.csi.aws.com using snapshots?

To migrate a persistent volume, see Migrating Amazon EKS clusters from gp2 to gp3 EBS volumes on the AWS blog.

Is migration supported for Windows workloads?

Yes. If you're installing the Amazon EBS CSI driver using the open source Helm chart, set node.enableWindows to true. This is set by default if installing the Amazon EBS CSI driver as an Amazon EKS add-on. When creating StorageClasses, set the fsType to a Windows file system, such as ntfs. Volume operations for Windows workloads are then migrated to the Amazon EBS CSI driver the same as they are for Linux workloads. An exception is file system resize operations, which are not supported for kubernetes.io/aws-ebs persistent volumes using Windows file systems.

Amazon EFS CSI driver

The Amazon EFS Container Storage Interface (CSI) driver provides a CSI interface that allows Kubernetes clusters running on AWS to manage the lifecycle of Amazon EFS file systems.

This topic shows you how to deploy the Amazon EFS CSI Driver to your Amazon EKS cluster and verify that it works.

Note

Alpha features of the Amazon EFS CSI Driver aren't supported on Amazon EKS clusters.

For detailed descriptions of the available parameters and complete examples that demonstrate the driver's features, see the Amazon EFS Container Storage Interface (CSI) driver project on GitHub.

Considerations

- The Amazon EFS CSI Driver isn't compatible with Windows-based container images.
- You can't use dynamic persistent volume provisioning with Fargate nodes, but you can use static provisioning.
• Dynamic provisioning requires 1.2 or later of the driver. You can statically provision persistent volumes using version 1.1 of the driver on any supported Amazon EKS cluster version (p. 66).

• Version 1.3.2 or later of this driver supports the Arm64 architecture, including Amazon EC2 Graviton-based instances.

Prerequisites

• An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Creating an IAM OIDC provider for your cluster (p. 426).

• Version 2.7.32 or later or 1.25.72 or later of the AWS CLI installed and configured on your device or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with aws configure in the AWS Command Line Interface User Guide.

• The kubectl command line tool is installed on your device or AWS CloudShell. The version can be the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For example, if your cluster version is 1.22, you can use kubectl version 1.21, 1.22, or 1.23 with it. To install or upgrade kubectl, see Installing or updating kubectl (p. 4).

Note
A pod running on AWS Fargate automatically mounts an Amazon EFS file system, without needing the manual driver installation steps described on this page.

Create an IAM policy and role

Create an IAM policy and assign it to an IAM role. The policy will allow the Amazon EFS driver to interact with your file system.

To deploy the Amazon EFS CSI driver to an Amazon EKS cluster

1. Create an IAM policy that allows the CSI driver's service account to make calls to AWS APIs on your behalf.
   a. Download the IAM policy document from GitHub. You can also view the policy document.

   ```bash
   curl -o iam-policy-example.json https://raw.githubusercontent.com/kubernetes-sigs/aws-efs-csi-driver/master/docs/iam-policy-example.json
   ```

   b. Create the policy. You can change `AmazonEKS_EFS_CSI_Driver_Policy` to a different name, but if you do, make sure to change it in later steps too.

   ```bash
   aws iam create-policy \
   --policy-name AmazonEKS_EFS_CSI_Driver_Policy \
   --policy-document file://iam-policy-example.json
   ```

2. Create an IAM role and attach the IAM policy to it. Annotate the Kubernetes service account with the IAM role ARN and the IAM role with the Kubernetes service account name. You can create the role using eksctl or the AWS CLI.
   ```bash
   eksctl
   ```

   Run the following command to create the IAM role and Kubernetes service account. It also attaches the policy to the role, annotates the Kubernetes service account with the IAM role ARN, and adds the Kubernetes service account name to the trust policy for the IAM role. Replace `my-cluster` with your cluster name and `111122223333` with your account ID. Replace `region-code` with the AWS Region that your cluster is in. If your cluster is in the AWS GovCloud (US-
Create an IAM policy and role

East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

```
eksctl create iamserviceaccount \
  --cluster my-cluster \
  --namespace kube-system \
  --name efs-csi-controller-sa \
  --attach-policy-arn arn:aws:iam::111122223333:policy/A...Policy \
  --approve \
  --region region-code
```

AWS CLI

1. Determine your cluster's OIDC provider URL. Replace `my-cluster` with your cluster name. If the output from the command is `None`, review the Prerequisites.

```
aws eks describe-cluster --name my-cluster --query "cluster.identity.oidc.issuer" --output text
```

The example output is as follows.

```
https://oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE
```

2. Create the IAM role, granting the Kubernetes service account the AssumeRoleWithWebIdentity action.

   a. Copy the following contents to a file named `trust-policy.json`. Replace `111122223333` with your account ID. Replace `EXAMPLED539D4633E53DE1B71EXAMPLE` and `region-code` with the values returned in the previous step. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

   ```
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Principal": {
   "Federated": "arn:aws:iam::111122223333:oidc-provider/oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE"
   },
   "Action": "sts:AssumeRoleWithWebIdentity",
   "Condition": {
   "StringEquals": {
   }
   }
   }
   ]
   }
   ```

   b. Create the role. You can change `AmazonEKS_EFS_CSI_DriverRole` to a different name, but if you do, make sure to change it in later steps too.

```
aws iam create-role \
  --role-name AmazonEKS_EFS_CSI_DriverRole \
  --assume-role-policy-document file://"trust-policy.json"
```
Install the Amazon EKS User Guide

Install the Amazon EFS driver

3. Attach the IAM policy to the role with the following command. Replace 111122223333 with your account ID. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace arn:aws: with arn:aws-us-gov:

```
aws iam attach-role-policy \
--policy-arn arn:aws:iam::111122223333:policy/AmazonEKS_EFS_CSI_Driver_Policy \
--role-name AmazonEKS_EFS_CSI_DriverRole
```

4. Create a Kubernetes service account that’s annotated with the ARN of the IAM role that you created.

a. Save the following contents to a file named `efs-service-account.yaml`. Replace 111122223333 with your account ID. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace arn:aws: with arn:aws-us-gov:

```
---
apiversion: v1
kind: ServiceAccount
metadata:
  labels:
    app.kubernetes.io/name: aws-efs-csi-driver
  name: efs-csi-controller-sa
  namespace: kube-system
  annotations:
    eks.amazonaws.com/role-arn:
      arn:aws:iam::111122223333:role/AmazonEKS_EFS_CSI_DriverRole
```

b. Create the Kubernetes service account on your cluster. The Kubernetes service account named `efs-csi-controller-sa` is annotated with the IAM role that you created named `AmazonEKS_EFS_CSI_DriverRole`.

```
kubectl apply -f efs-service-account.yaml
```

Install the Amazon EFS driver

Install the Amazon EFS CSI driver using Helm or a manifest.

**Important**

Encryption of data in transit using TLS is enabled by default. Using encryption in transit, data is encrypted during its transition over the network to the Amazon EFS service. To disable it and mount volumes using NFSv4, set the `volumeAttributes` field `encryptInTransit` to "false" in your persistent volume manifest. For an example manifest, see Encryption in Transit example on GitHub.

Helm

This procedure requires Helm V3 or later. To install or upgrade Helm, see Using Helm with Amazon EKS (p. 411).

**To install the driver using Helm**

1. Add the Helm repo.

```
```

2. Update the repo.
Install the Amazon EFS driver

3. Install a release of the driver using the Helm chart. Replace the repository address with the cluster's container image address (p. 365).

```
helm repo update
```

```
helm upgrade -i aws-efs-csi-driver aws-efs-csi-driver/aws-efs-csi-driver \
  --namespace kube-system \
  --set image.repository=602401143452.dkr.ecr.region-code.amazonaws.com/eks/aws-efs-csi-driver \
  --set controller.serviceAccount.create=false \
  --set controller.serviceAccount.name=efs-csi-controller-sa
```

Manifest (private registry)

If you want to download the image with a manifest, we recommend first trying these steps to pull secured images from the private Amazon ECR registry.

To install the driver using images stored in the private Amazon ECR registry

1. Download the manifest.

```
kubectl kustomize \
```

2. In the following command, replace `region-code` with the AWS Region that your cluster is in and then run the modified command to replace `us-west-2` in the file with your AWS Region.

```
sed -i.bak -e 's|us-west-2|region-code|' private-ecr-driver.yaml
```

3. Replace `account` in the following command with the account from Amazon container image registries (p. 365) for the AWS Region that your cluster is in and then run the modified command to replace `602401143452` in the file.

```
sed -i.bak -e 's|602401143452|account|' private-ecr-driver.yaml
```

4. Edit the `private-ecr-driver.yaml` file and remove the following lines that create a Kubernetes service account. These lines aren't needed because the service account was created in a previous step.

```
apiVersion: v1
kind: ServiceAccount
metadata:
  labels:
    app.kubernetes.io/name: aws-efs-csi-driver
    name: efs-csi-controller-sa
    namespace: kube-system
```

5. Apply the manifest.

```
kubectl apply -f private-ecr-driver.yaml
```
Manifest (public registry)

For some situations, you may not be able to add the necessary IAM permissions to pull from the private Amazon ECR registry. One example of this scenario is if your IAM user or role isn’t allowed to authenticate with someone else’s account. When this is true, you can use the public Amazon ECR registry.

To install the driver using images stored in the public Amazon ECR registry

1. Download the manifest.

```bash
kubectl kustomize \
  "github.com/kubernetes-sigs/aws-efs-csi-driver/deploy/kubernetes/overlays/stable/?ref=release-" > public-ecr-driver.yaml
```

2. Edit the file and remove the following lines that create a Kubernetes service account. This isn't necessary because the service account was created in a previous step.

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  labels:
    app.kubernetes.io/name: aws-efs-csi-driver
    name: efs-csi-controller-sa
    namespace: kube-system
---
```

3. Apply the manifest.

```bash
kubectl apply -f public-ecr-driver.yaml
```

Create an Amazon EFS file system

The Amazon EFS CSI driver supports Amazon EFS access points, which are application-specific entry points into an Amazon EFS file system that make it easier to share a file system between multiple pods. Access points can enforce a user identity for all file system requests that are made through the access point, and enforce a root directory for each pod. For more information, see Amazon EFS access points on GitHub.

**Important**

You must complete the following steps in the same terminal because variables are set and used across the steps.

To create an Amazon EFS file system for your Amazon EKS cluster

1. Retrieve the VPC ID that your cluster is in and store it in a variable for use in a later step. Replace `my-cluster` with your cluster name.

   ```bash
   vpc_id=$(aws eks describe-cluster \
     --name my-cluster \n     --query "cluster.resourcesVpcConfig.vpcId" \n     --output text)
   ```

2. Retrieve the CIDR range for your cluster’s VPC and store it in a variable for use in a later step.

   ```bash
cidr_range=$(aws ec2 describe-vpcs \
     --vpc-ids $vpc_id \n     --query "Vpcs[0].CidrBlock" \n```
3. Create a security group with an inbound rule that allows inbound NFS traffic for your Amazon EFS mount points.
   a. Create a security group. Replace the example values with your own.

   ```bash
   security_group_id=$(aws ec2 create-security-group
   --group-name MyEfsSecurityGroup
   --description "My EFS security group"
   --vpc-id $vpc_id
   --output text)
   
   b. Create an inbound rule that allows inbound NFS traffic from the CIDR for your cluster's VPC.

   ```bash
   aws ec2 authorize-security-group-ingress
   --group-id $security_group_id
   --protocol tcp
   --port 2049
   --cidr $cidr_range
   ```

   Important
   To further restrict access to your file system, you can use the CIDR for your subnet instead of the VPC.

4. Create an Amazon EFS file system for your Amazon EKS cluster.
   a. Create a file system. Replace region-code with the AWS Region that your cluster is in.

   ```bash
   file_system_id=$(aws efs create-file-system
   --region region-code
   --performance-mode generalPurpose
   --query 'FileSystemId'
   --output text)
   
   b. Create mount targets.
      i. Determine the IP address of your cluster nodes.

      ```bash
      kubectl get nodes
      ```
      The example output is as follows.

      | NAME                                         | STATUS   | ROLES    | AGE     | VERSION          |
      |----------------------------------------------|----------|----------|---------|------------------|
      | ip-192-168-56-0.region-code.compute.internal | Ready    | <none>   | 19m     | v1.19.6-eks-49a6c0 |

      ii. Determine the IDs of the subnets in your VPC and which Availability Zone the subnet is in.

      ```bash
      aws ec2 describe-subnets
      --filters "Name=vpc-id,Values=$vpc_id"
      --query 'Subnets[*].{SubnetId,AvailabilityZone:CidrBlock}'
      --output table
      ```

      The example output is as follows.

      | AvailabilityZone | CidrBlock | SubnetId |
      |------------------|-----------|----------|
      |                  |           |          |
iii. Add mount targets for the subnets that your nodes are in. From the output in the previous two steps, the cluster has one node with an IP address of 192.168.56.0. That IP address is within the CidrBlock of the subnet with the ID subnet-EXAMPLEe2ba886490. As a result, the following command creates a mount target for the subnet the node is in. If there were more nodes in the cluster, you’d run the command once for a subnet in each AZ that you had a node in, replacing subnet-EXAMPLEe2ba886490 with the appropriate subnet ID.

```bash
aws efs create-mount-target
  --file-system-id $file_system_id
  --subnet-id subnet-EXAMPLEe2ba886490
  --security-groups $security_group_id
```

### Deploy a sample application

You can deploy a sample app that dynamically creates a persistent volume, or you can manually create a persistent volume. You can replace the examples given in this section with a different application.

**Dynamic**

**Important**

You can't use dynamic provisioning with Fargate nodes.

**Prerequisite**

You must use version 1.2x or later of the Amazon EFS CSI driver.

#### To deploy a sample application that uses a persistent volume that the controller creates

This procedure uses the Dynamic Provisioning example from the Amazon EFS Container Storage Interface (CSI) driver GitHub repository. It dynamically creates a persistent volume through Amazon EFS access points and a Persistent Volume Claim (PVC) that's consumed by a pod.

1. Create a storage class for EFS. For all parameters and configuration options, see Amazon EFS CSI Driver on GitHub.
   a. Retrieve your Amazon EFS file system ID. You can find this in the Amazon EFS console, or use the following AWS CLI command.

   ```bash
   aws efs describe-file-systems --query "FileSystems[*].FileSystemId" --output text
   ```

   The example output is as follows.

   ```
   fs-582a03f3
   ```

   b. Download a StorageClass manifest for Amazon EFS.

   ```bash
curl -o storageclass.yaml https://raw.githubusercontent.com/kubernetes-sigs/aws-efs-csi-driver/master/examples/kubernetes/dynamic_provisioning/specs/storageclass.yaml
   ```

   c. Edit the file. Find the following line, and replace the value for `fileSystemId` with your file system ID.
d. Deploy the storage class.

```
kubectl apply -f storageclass.yaml
```

2. Test automatic provisioning by deploying a Pod that makes use of the PersistentVolumeClaim:
   a. Download a manifest that deploys a pod and a PersistentVolumeClaim.

```
```

b. Deploy the pod with a sample app and the PersistentVolumeClaim used by the pod.

```
kubectl apply -f pod.yaml
```

3. Determine the names of the pods running the controller.

```
kubectl get pods -n kube-system | grep efs-csi-controller
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>CAPACITY</th>
<th>ACCESS MODES</th>
<th>RECLAIM POLICY</th>
</tr>
</thead>
<tbody>
<tr>
<td>efs-csi-controller-74ccf9f566-q5989</td>
<td>3/3</td>
<td>Running</td>
<td>40m</td>
</tr>
<tr>
<td>efs-csi-controller-74ccf9f566-wswg9</td>
<td>3/3</td>
<td>Running</td>
<td>40m</td>
</tr>
</tbody>
</table>

4. After few seconds, you can observe the controller picking up the change (edited for readability). Replace `74ccf9f566-q5989` with a value from one of the pods in your output from the previous command.

```
kubectl logs efs-csi-controller-74ccf9f566-q5989 \
  -n kube-system \
  -c csi-provisioner \
  --tail 10
```

The example output is as follows.

```
... 1 controller.go:737] successfully created PV pvc-5983ffec-96cf-40c1-9cd6-e5686ca84eca for PVC efs-claim and csi volume name fs-95bcec92::fsap-02a88145b865d3a87
```

If you don't see the previous output, run the previous command using one of the other controller pods.

5. Confirm that a persistent volume was created with a status of Bound to a PersistentVolumeClaim:

```
kubectl get pv
```

The example output is as follows.
6. View details about the PersistentVolumeClaim that was created.

```
kubectl get pvc
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>VOLUME</th>
<th>CAPACITY</th>
<th>ACCESS</th>
</tr>
</thead>
<tbody>
<tr>
<td>efs-claim</td>
<td>Bound</td>
<td>pvc-5983ffec-96cf-40c1-9cd6-e5686ca84eca</td>
<td>20Gi</td>
<td>RWX</td>
</tr>
<tr>
<td>efs-sc</td>
<td></td>
<td></td>
<td>9m7s</td>
<td></td>
</tr>
</tbody>
</table>

7. View the sample app pod's status until the STATUS becomes Running.

```
kubectl get pods -o wide
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
<th>IP</th>
<th>NODE</th>
<th>NOMINATED NODE</th>
<th>READINESS GATES</th>
</tr>
</thead>
<tbody>
<tr>
<td>efs-example</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>10m</td>
<td>192.168.78.156</td>
<td>ip-192-168-73-191.region-code.compute.internal</td>
<td>&lt;none&gt;</td>
<td>&lt;none&gt;</td>
</tr>
</tbody>
</table>

**Note**

If a pod doesn't have an IP address listed, make sure that you added a mount target for the subnet that your node is in (as described at the end of *Create an Amazon EFS file system* (p. 225)). Otherwise the pod won't leave ContainerCreating status. When an IP address is listed, it may take a few minutes for a pod to reach the Running status.

8. Confirm that the data is written to the volume.

```
kubectl exec efs-app -- bash -c "cat data/out"
```

The example output is as follows.

```
...  
Tue Mar 23 14:29:16 UTC 2021
Tue Mar 23 14:29:21 UTC 2021
Tue Mar 23 14:29:26 UTC 2021
Tue Mar 23 14:29:31 UTC 2021
...  
```

9. (Optional) Terminate the Amazon EKS node that your pod is running on and wait for the pod to be re-scheduled. Alternately, you can delete the pod and redeploy it. Complete the previous step again, confirming that the output includes the previous output.

### Static

**To deploy a sample application that uses a persistent volume that you create**

This procedure uses the Multiple Pods Read Write Many example from the Amazon EFS Container Storage Interface (CSI) driver GitHub repository to consume a statically provisioned Amazon EFS persistent volume and access it from multiple pods with the ReadWriteMany access mode.
1. Clone the Amazon EFS Container Storage Interface (CSI) driver GitHub repository to your local system.

```bash
git clone https://github.com/kubernetes-sigs/aws-efs-csi-driver.git
```

2. Navigate to the `multiple_pods` example directory.

```bash
cd aws-efs-csi-driver/examples/kubernetes/multiple_pods/
```

3. Retrieve your Amazon EFS file system ID. You can find this in the Amazon EFS console, or use the following AWS CLI command.

```bash
aws efs describe-file-systems --query "FileSystems[*].FileSystemId" --output text
```

The example output is as follows.

```
fs-582a03f3
```

4. Edit the `specs/pv.yaml` file and replace the `volumeHandle` value with your Amazon EFS file system ID.

```yaml
apiVersion: v1
classKind: PersistentVolume
metadata:
  name: efs-pv
spec:
  capacity:
    storage: 5Gi
  volumeMode: Filesystem
  accessModes:
    - ReadWriteMany
  persistentVolumeReclaimPolicy: Retain
  storageClassName: efs-sc
  csi:
    driver: efs.csi.aws.com
    volumeHandle: fs-582a03f3
```

**Note**
Because Amazon EFS is an elastic file system, it doesn't enforce any file system capacity limits. The actual storage capacity value in persistent volumes and persistent volume claims isn't used when creating the file system. However, because storage capacity is a required field in Kubernetes, you must specify a valid value, such as, 5Gi in this example. This value doesn't limit the size of your Amazon EFS file system.

5. Deploy the `efs-sc` storage class, `efs-claim` persistent volume claim, and `efs-pv` persistent volume from the `specs` directory.

```bash
kubectl apply -f specs/pv.yaml
kubectl apply -f specs/claim.yaml
kubectl apply -f specs/storageclass.yaml
```

6. List the persistent volumes in the default namespace. Look for a persistent volume with the `default/efs-claim` claim.

```bash
kubectl get pv -w
```

The example output is as follows.
Don’t proceed to the next step until the STATUS is Bound.

7. Deploy the app1 and app2 sample applications from the specs directory.

```bash
kubectl apply -f specs/pod1.yaml
kubectl apply -f specs/pod2.yaml
```

8. Watch the pods in the default namespace and wait for the app1 and app2 pods' STATUS to become Running.

```bash
kubectl get pods --watch
```

**Note**
It may take a few minutes for the pods to reach the Running status.

9. Describe the persistent volume.

```bash
kubectl describe pv efs-pv
```

The example output is as follows.

<table>
<thead>
<tr>
<th>Name:</th>
<th>efs-pv</th>
</tr>
</thead>
<tbody>
<tr>
<td>Labels:</td>
<td>none</td>
</tr>
<tr>
<td>Annotations:</td>
<td>kubectl.kubernetes.io/last-applied-configuration:</td>
</tr>
</tbody>
</table>
|                  | {
|                  |   "apiVersion":"v1","kind":"PersistentVolume","metadata": |
|                  |   {"annotations":{},"name":"efs-pv"},"spec":{"accessModes": |
|                  |   ["ReadWriteMany"],"capacity":null,"volumeAttributes":null, |
|                  |   "pv.kubernetes.io/bound-by-controller": "yes"} |
| Finalizers:      | [kubernetes.io/pv-protection] |
| StorageClass:    | efs-sc       |
| Status:         | Bound        |
| Claim:          | default/efs-claim |
| Reclaim Policy: | Retain       |
| Access Modes:   | RWX          |
| VolumeMode:     | Filesystem   |
| Capacity:       | 5Gi          |
| Node Affinity:  | none         |
| Message:        |              |
| Source:         | CSI (a Container Storage Interface (CSI) volume source) |
|                 | Driver: efs.csi.aws.com |
|                 | VolumeHandle: fs-582a03f3 |
|                 | ReadOnly: false |
|                 | VolumeAttributes: none |
|                 | Events: none |

The Amazon EFS file system ID is listed as the VolumeHandle.

10. Verify that the app1 pod is successfully writing data to the volume.

```bash
kubectl exec -ti app1 -- tail /data/out1.txt
```

The example output is as follows.
11. Verify that the `app2` pod shows the same data in the volume that `app1` wrote to the volume.

```
kubectl exec -ti app2 -- tail /data/out1.txt
```

The example output is as follows.

```
... Mon Mar 22 18:18:22 UTC 2021
Mon Mar 22 18:18:27 UTC 2021
Mon Mar 22 18:18:32 UTC 2021
Mon Mar 22 18:18:37 UTC 2021
...  
```

12. When you finish experimenting, delete the resources for this sample application to clean up.

```
kubectl delete -f specs/
```

You can also manually delete the file system and security group that you created.

---

**Amazon FSx for Lustre CSI driver**

The [FSx for Lustre Container Storage Interface (CSI) driver](https://docs.aws.amazon.com/fsx/latest/ultralightvolume/user-guide/index.html) provides a CSI interface that allows Amazon EKS clusters to manage the lifecycle of FSx for Lustre file systems. For more information, see the [FSx for Lustre User Guide](https://docs.aws.amazon.com/fsx/latest/ultralightvolume/user-guide/index.html).

This topic shows you how to deploy the FSx for Lustre CSI Driver to your Amazon EKS cluster and verify that it works. We recommend using version 0.4.0 of the driver.

**Note**

This driver is supported on Kubernetes version 1.23 and later Amazon EKS clusters and nodes. The driver isn't supported on Fargate. Alpha features of the FSx for Lustre CSI Driver aren't supported on Amazon EKS clusters. The driver is in Beta release. It is well tested and supported by Amazon EKS for production use. Support for the driver will not be dropped, though details may change. If the schema or schematics of the driver changes, instructions for migrating to the next version will be provided.

For detailed descriptions of the available parameters and complete examples that demonstrate the driver's features, see the [FSx for Lustre Container Storage Interface (CSI) driver](https://github.com/aws/efs-csi-driver) project on GitHub.

**Prerequisites**

You must have:

- Version 2.7.32 or later or 1.25.72 or later of the AWS CLI installed and configured on your device or AWS CloudShell. For more information, see [Installing, updating, and uninstalling the AWS CLI](https://docs.aws.amazon.com/cli/latest/userguide/cli-install-uninstall.html) and [Quick configuration with `aws configure` in the AWS Command Line Interface User Guide](https://docs.aws.amazon.com/cli/latest/userguide/cli-configure.html).
- Version 0.112.0 or later of the `eksctl` command line tool installed on your device or AWS CloudShell. To install or update `eksctl`, see [Installing or updating `eksctl`](https://docs.aws.amazon.com/eks/latest/user-guide/install-eksctl.html).
The kubectl command line tool is installed on your device or AWS CloudShell. The version can be the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For example, if your cluster version is 1.22, you can use kubectl version 1.21, 1.22, or 1.23 with it. To install or upgrade kubectl, see Installing or updating kubectl (p. 4).

The following procedures help you create a simple test cluster and configure custom networking for it so that you can see how it works. We don't recommend using the testing cluster for production workloads. For this tutorial, we recommend using the example values, except where it's noted to replace them. You can replace any example value when completing the steps for your production cluster. We recommend completing all steps in the same terminal because variables are set and used throughout the steps and won't exist in different terminals.

To deploy the FSx for Lustre CSI driver to an Amazon EKS cluster

1. Set a few variables to use in the remaining steps. Replace my-csi-fsx-cluster with the name of the test cluster you want to create and region-code with the AWS Region that you want to create your test cluster in.

   ```
   export cluster_name=my-csi-fsx-cluster
   export region_code=region-code
   ```

2. Create a test cluster.

   ```
   eksctl create cluster \
   --name $cluster_name \
   --region $region_code \
   --with-oidc \
   --ssh-access \
   --ssh-public-key my-key
   ```

   Cluster provisioning takes several minutes. During cluster creation, you'll see several lines of output. The last line of output is similar to the following example line.

   ```
   [✓]  EKS cluster "my-csi-fsx-cluster" in "region-code" region is ready
   ```

3. Create a Kubernetes service account for the driver and attach the AmazonFSxFullAccess AWS-managed policy to the service account with the following command. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace arn:aws: with arn:aws-us-gov:

   ```
   eksctl create iamserviceaccount \
   --name fsx-csi-controller-sa \
   --namespace kube-system \
   --cluster $cluster_name \
   --attach-policy-arn arn:aws:iam::aws:policy/AmazonFSxFullAccess \
   --approve \
   --role-name AmazonEKSFSxLustreCSIDriverFullAccess \
   --region $region_code
   ```

   The example output is as follows.

   You'll see several lines of output as the service account is created. The last lines of output are similar to the following.

   ```
   [✓]  1 task: { 
   2 sequential sub-tasks: { 
   create IAM role for serviceaccount "kube-system/fsx-csi-controller-sa",
   ```
create serviceaccount "kube-system/fsx-csi-controller-sa",
{
} }

[#] building iamserviceaccount stack "eksctl-my-csi-fsx-cluster-addon-iamserviceaccount-kube-system-fsx-csi-controller-sa"
[#] deploying stack "eksctl-my-csi-fsx-cluster-addon-iamserviceaccount-kube-system-fsx-csi-controller-sa"
[#] waiting for CloudFormation stack "eksctl-my-csi-fsx-cluster-addon-iamserviceaccount-kube-system-fsx-csi-controller-sa"
[#] created serviceaccount "kube-system/fsx-csi-controller-sa"

Note the name of the AWS CloudFormation stack that was deployed. In the previous example output, the stack is named eksctl-my-csi-fsx-cluster-addon-iamserviceaccount-kube-system-fsx-csi-controller-sa.

4. Deploy the driver with the following command.

   Note
   You can view the content being applied in aws-fsx-csi-driver on GitHub.

   kubectl apply -k "github.com/kubernetes-sigs/aws-fsx-csi-driver/deploy/kubernetes/overlays/stable/?ref=master"

   The example output is as follows.

   serviceaccount/fsx-csi-controller-sa created
   serviceaccount/fsx-csi-node-sa created
   clusterrole.rbac.authorization.k8s.io/fsx-csi-external-provisioner-role created
   clusterrole.rbac.authorization.k8s.io/fsx-csi-external-resizer-role created
   clusterrolebinding.rbac.authorization.k8s.io/fsx-csi-external-provisioner-binding created
   clusterrolebinding.rbac.authorization.k8s.io/fsx-csi-external-resizer-binding created
   deployment.apps/fsx-csi-controller created
   daemonset.apps/fsx-csi-node created
   csidriver.storage.k8s.io/fsx.csi.aws.com created

5. Note the ARN for the role that was created. If you didn't note it earlier and don't have it available anymore in the AWS CLI output, you can do the following to see it in the AWS Management Console.

   b. Ensure that the console is set to the AWS Region that you created your IAM role in and then select Stacks.
   d. Select the Outputs tab. The Role1 ARN is listed on the Outputs (1) page.

6. Patch the driver deployment to add the service account that you created earlier with the following command. Replace the ARN with the ARN that you noted. Replace 111122223333 with your account ID. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace arn:aws: with arn:aws-us-gov:.

   kubectl annotate serviceaccount -n kube-system fsx-csi-controller-sa "
   eks.amazonaws.com/role-arn=arn:aws:iam::111122223333:role/AmazonEKSFSxLustreCSIDriverFullAccess --overwrite=true"

   The example output is as follows.

   serviceaccount/fsx-csi-controller-sa annotated
To deploy a Kubernetes storage class, persistent volume claim, and sample application to verify that the CSI driver is working

This procedure uses the FSx for Lustre Container Storage Interface (CSI) driver GitHub repository to consume a dynamically-provisioned FSx for Lustre volume.

1. Note the security group for your cluster. You can see it in the AWS Management Console under the Networking section or by using the following AWS CLI command.

   ```bash
   aws eks describe-cluster --name $cluster_name --query cluster.resourcesVpcConfig.clusterSecurityGroupId
   ```

2. Create a security group for your Amazon FSx file system according to the criteria shown in Amazon VPC Security Groups in the Amazon FSx for Lustre User Guide. For the VPC, select the VPC of your cluster as shown under the Networking section. For "the security groups associated with your Lustre clients", use your cluster security group. You can leave the outbound rules alone to allow All traffic.

3. Download the storage class manifest with the following command.

   ```bash
   curl -o storageclass.yaml https://raw.githubusercontent.com/kubernetes-sigs/aws-fsx-csi-driver/master/examples/kubernetes/dynamic_provisioning/specs/storageclass.yaml
   ```

4. Edit the parameters section of the storageclass.yaml file. Replace every example value with your own values.

   ```yaml
   parameters:
   subnetId: subnet-0eabfaa81fb22bcaf
   securityGroupIds: sg-068000ccf82dfba88
   deploymentType: PERSISTENT_1
   automaticBackupRetentionDays: "1"
   dailyAutomaticBackupStartTime: "00:00"
   copyTagsToBackups: "true"
   perUnitStorageThroughput: "200"
   dataCompressionType: "NONE"
   weeklyMaintenanceStartTime: "7:09:00"
   fileSystemTypeVersion: "2.12"
   ```

   - **subnetId** – The subnet ID that the Amazon FSx for Lustre file system should be created in. Amazon FSx for Lustre isn't supported in all Availability Zones. Open the Amazon FSx for Lustre console at https://console.aws.amazon.com/fsx/ to confirm that the subnet that you want to use is in a supported Availability Zone. The subnet can include your nodes, or can be a different subnet or VPC:
     - You can check for the node subnets in the AWS Management Console by selecting the node group under the Compute section.
     - If the subnet that you specify isn't the same subnet that you have nodes in, then your VPCs must be connected, and you must ensure that you have the necessary ports open in your security groups.

   - **securityGroupIds** – The ID of the security group you created for the file system.

   - **deploymentType (optional)** – The file system deployment type. Valid values are SCRATCH_1, SCRATCH_2, PERSISTENT_1, and PERSISTENT_2. For more information about deployment types, see Create your Amazon FSx for Lustre file system.

   - **other parameters (optional)** – For information about the other parameters, see Edit StorageClass on GitHub.

5. Create the storage class manifest.

   ```bash
   kubectl apply -f storageclass.yaml
   ```
The example output is as follows.

```
storageclass.storage.k8s.io/fsx-sc created
```

6. Download the persistent volume claim manifest.

```
curl -o claim.yaml https://raw.githubusercontent.com/kubernetes-sigs/aws-fsx-csi-driver/master/examples/kubernetes/dynamic_provisioning/specs/claim.yaml
```

7. (Optional) Edit the `claim.yaml` file. Change `1200Gi` to one of the following increment values, based on your storage requirements and the deploymentType that you selected in a previous step.

```
storage: 1200Gi
```

- SCRATCH_2 and PERSISTENT – 1.2 TiB, 2.4 TiB, or increments of 2.4 TiB over 2.4 TiB.
- SCRATCH_1 – 1.2 TiB, 2.4 TiB, 3.6 TiB, or increments of 3.6 TiB over 3.6 TiB.

8. Create the persistent volume claim.

```
kubectl apply -f claim.yaml
```

The example output is as follows.

```
persistentvolumeclaim/fsx-claim created
```

9. Confirm that the file system is provisioned.

```
kubectl describe pvc
```

The example output is as follows.

```
Name:          fsx-claim
Namespace:     default
StorageClass:  fsx-sc
Status:        Bound
...  
```

**Note**

The Status may show as Pending for 5-10 minutes, before changing to Bound. Don't continue with the next step until the Status is Bound. If the Status shows Pending for more than 10 minutes, use warning messages in the Events as reference for addressing any problems.

10. Deploy the sample application.

```
```

11. Verify that the sample application is running.

```
kubectl get pods
```

The example output is as follows.

```
NAME     READY   STATUS     RESTARTS   AGE
--------- -------- -------- --------- -----
```
12. Verify that the file system is mounted correctly by the application.

```
kubectl exec -ti fsx-app -- df -h
```

The example output is as follows.

<table>
<thead>
<tr>
<th>Filesystem</th>
<th>Size</th>
<th>Used</th>
<th>Avail</th>
<th>Use%</th>
<th>Mounted on</th>
</tr>
</thead>
<tbody>
<tr>
<td>overlay</td>
<td>80G</td>
<td>4.0G</td>
<td>77G</td>
<td>5%</td>
<td>/</td>
</tr>
<tr>
<td>tmpfs</td>
<td>64M</td>
<td>0</td>
<td>64M</td>
<td>0%</td>
<td>/dev</td>
</tr>
<tr>
<td>tmpfs</td>
<td>3.8G</td>
<td>0</td>
<td>3.8G</td>
<td>0%</td>
<td>/sys/fs/cgroup</td>
</tr>
<tr>
<td>192.0.2.0@tcp:abcde</td>
<td>1.1T</td>
<td>7.8M</td>
<td>1.1T</td>
<td>1%</td>
<td>/data</td>
</tr>
<tr>
<td>/dev/nvme0n1p1</td>
<td>80G</td>
<td>4.0G</td>
<td>77G</td>
<td>5%</td>
<td>/etc/hosts</td>
</tr>
<tr>
<td>shm</td>
<td>64M</td>
<td>0</td>
<td>64M</td>
<td>0%</td>
<td>/dev/shm</td>
</tr>
<tr>
<td>tmpfs</td>
<td>6.9G</td>
<td>12K</td>
<td>6.9G</td>
<td>1%</td>
<td>/run/secrets/kubernetes.io/serviceaccount</td>
</tr>
<tr>
<td>tmpfs</td>
<td>3.8G</td>
<td>0</td>
<td>3.8G</td>
<td>0%</td>
<td>/proc/acpi</td>
</tr>
<tr>
<td>tmpfs</td>
<td>3.8G</td>
<td>0</td>
<td>3.8G</td>
<td>0%</td>
<td>/sys/firmware</td>
</tr>
</tbody>
</table>

13. Verify that data was written to the FSx for Lustre file system by the sample app.

```
kubectl exec -it fsx-app -- ls /data
```

The example output is as follows.

```
out.txt
```

This example output shows that the sample app successfully wrote the `out.txt` file to the file system.

**Note**
Before deleting the cluster, make sure to delete the FSx for Lustre file system. For more information, see Clean up resources in the FSx for Lustre User Guide.

Amazon FSx for NetApp ONTAP CSI driver

NetApp's Astra Trident provides dynamic storage orchestration using a Container Storage Interface (CSI) compliant driver. This allows Amazon EKS clusters to manage the lifecycle of persistent volumes (PVs) backed by Amazon FSx for NetApp ONTAP file systems. To get started, see Use Astra Trident with Amazon FSx for NetApp ONTAP in the Astra Trident documentation.

Amazon FSx for NetApp ONTAP is a storage service that allows you to launch and run fully managed ONTAP file systems in the cloud. ONTAP is NetApp's file system technology that provides a widely adopted set of data access and data management capabilities. Amazon FSx for NetApp ONTAP provides the features, performance, and APIs of on-premises NetApp file systems with the agility, scalability, and simplicity of a fully managed AWS service. For more information, see the FSx for ONTAP User Guide.
Amazon EKS networking

Your Amazon EKS cluster is created in a VPC. Pod networking is provided by the Amazon VPC Container Network Interface (CNI) plugin. This chapter includes the following topics for learning more about networking for your cluster.

**Topics**

- Amazon EKS VPC and subnet requirements and considerations (p. 238)
- Creating a VPC for your Amazon EKS cluster (p. 241)
- Amazon EKS security group requirements and considerations (p. 245)
- Pod networking in Amazon EKS using the Amazon VPC CNI plugin for Kubernetes (p. 247)
- Installing the AWS Load Balancer Controller add-on (p. 308)
- Managing the CoreDNS add-on (p. 316)
- Managing the kube-proxy add-on (p. 323)
- Installing the Calico add-on (p. 329)

Amazon EKS VPC and subnet requirements and considerations

When you create a cluster, you specify a VPC and at least two subnets that are in different Availability Zones. This topic provides an overview of Amazon EKS specific requirements and considerations for the VPC and subnets that you use with your cluster. If you don’t have a VPC to use with Amazon EKS, you can create one using an Amazon EKS provided AWS CloudFormation template (p. 241). If you’re creating a local or extended cluster on AWS Outposts, see the section called “VPC and subnet requirements” (p. 557) instead of this topic.

**VPC requirements and considerations**

When you create a cluster, the VPC that you specify must meet the following requirements and considerations:

- The VPC must have a sufficient number of IP addresses available for the cluster, any nodes, and other Kubernetes resources that you want to create. If the VPC that you want to use doesn’t have a sufficient number of IP addresses, try to increase the number of available IP addresses. You can do this by associating additional Classless Inter-Domain Routing (CIDR) blocks with your VPC. You can associate private (RFC 1918) and public (non-RFC 1918) CIDR blocks to your VPC either before or after you create your cluster. It can take a cluster up to five hours for a CIDR block that you associated with a VPC to be recognized.

You can conserve IP address utilization by using a transit gateway with a shared services VPC. For more information, see Isolated VPCs with shared services and Amazon EKS VPC routable IP address conservation patterns in a hybrid network.

- If you want Kubernetes to assign IPv6 addresses to pods and services, associate an IPv6 CIDR block with your VPC. For more information, see Associate an IPv6 CIDR block with your VPC in the Amazon VPC User Guide.

You can conserve IP address utilization by using a transit gateway with a shared services VPC. For more information, see Isolated VPCs with shared services and Amazon EKS VPC routable IP address conservation patterns in a hybrid network.

- The VPC must have DNS hostname and DNS resolution support. Otherwise, nodes can’t register to your cluster. For more information, see DNS attributes for your VPC in the Amazon VPC User Guide.

- The VPC might require VPC endpoints using AWS PrivateLink. For more information, see the section called “Subnet requirements and considerations” (p. 239).
If you created a cluster with Kubernetes 1.14 or earlier, Amazon EKS added the following tag to your VPC:

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/cluster/my-cluster</td>
<td>owned</td>
</tr>
</tbody>
</table>

This tag was only used by Amazon EKS. You can remove the tag without impacting your services. It's not used with clusters that are version 1.15 or later.

Subnet requirements and considerations

When you create a cluster, Amazon EKS creates 2–4 elastic network interfaces in the subnets that you specify. These network interfaces enable communication between your cluster and your VPC. These network interfaces also enable Kubernetes features such as `kubectl exec` and `kubectl logs`. Each Amazon EKS created network interface has the text `Amazon EKS cluster-name` in its description.

Amazon EKS can create its network interfaces in any subnet that you specify when you create a cluster. You can't change which subnets Amazon EKS creates its network interfaces in after your cluster is created. When you update the Kubernetes version of a cluster, Amazon EKS deletes the original network interfaces that it created, and creates new network interfaces. These network interfaces might be created in the same subnets as the original network interfaces or in different subnets than the original network interfaces. To control which subnets network interfaces are created in, you can limit the number of subnets you specify to only two when you create a cluster.

The subnets that you specify when you create a cluster must meet the following requirements:

- The subnets must each have at least six IP addresses for use by Amazon EKS. However, we recommend at least 16 IP addresses.
- The subnets can't reside in AWS Outposts, AWS Wavelength, or an AWS Local Zone. However, if you have them in your VPC, you can deploy self-managed nodes (p. 121) and Kubernetes resources to these types of subnets.
- The subnets must use IP address-based naming. Amazon EC2 resource-based naming isn't supported with Amazon EKS.
- The subnets can be a public or private. However, we recommend that you specify private subnets, if possible. A public subnet is a subnet with a route table that includes a route to an internet gateway, whereas a private subnet is a subnet with a route table that doesn't include a route to an internet gateway.

You can deploy nodes and Kubernetes resources to the same subnets that you specify when you create your cluster. However, this isn't necessary. This is because you can also deploy nodes and Kubernetes resources to subnets that you didn't specify when you created the cluster. If you deploy nodes to different subnets, Amazon EKS doesn't create cluster network interfaces in those subnets. Any subnet that you deploy nodes and Kubernetes resources to must meet the following requirements:

- The subnets must have enough available IP addresses to deploy all of your nodes and Kubernetes resources to.
- The subnets must use IP address-based naming. Amazon EC2 resource-based naming isn't supported with Amazon EKS.
- If you want Kubernetes to assign IPv6 addresses to pods and services, then you must have one IPv6 CIDR block and one IPv4 CIDR block that are associated with your subnet. For more information, see Associate an IPv6 CIDR block with your subnet in the Amazon VPC User Guide. The route tables that are associated with the subnets must include routes to IPv4 and IPv6 addresses. For more
information, see Routes in the Amazon VPC User Guide. Pods are assigned only an IPv6 address. However the network interfaces that Amazon EKS creates for your cluster and your nodes are assigned an IPv4 and an IPv6 address.

- If you need inbound access from the internet to your pods, make sure to have at least one public subnet with enough available IP addresses to deploy load balancers and ingresses to. You can deploy load balancers to public subnets. Load balancers can load balance to pods in private or public subnets. We recommend deploying your nodes to private subnets, if possible.

- If you plan to deploy nodes to a public subnet, the subnet must auto-assign IPv4 public addresses or IPv6 addresses. If you deploy nodes to a private subnet that has an associated IPv6 CIDR block, the private subnet must also auto-assign IPv6 addresses. If you used an Amazon EKS AWS CloudFormation template (p. 241) to deploy your VPC after March 26, 2020, this setting is enabled. If you used the templates to deploy your VPC before this date or you use your own VPC, you must enable this setting manually. For more information, see Modify the public IPv4 addressing attribute for your subnet and Modify the IPv6 addressing attribute for your subnet in the Amazon VPC User Guide.

- If the subnet that you deploy a node to is a private subnet and its route table doesn't include a route to a network address translation (NAT) device (IPv4) or an egress-only gateway (IPv6), add VPC endpoints using AWS PrivateLink to your VPC. VPC endpoints are needed for all the AWS services that your nodes and pods need to communicate with. Examples include Amazon ECR, Elastic Load Balancing, Amazon CloudWatch, AWS Security Token Service, and Amazon Simple Storage Service (Amazon S3). The endpoint must include the subnet that the nodes are in. Not all AWS services support VPC endpoints. For more information, see What is AWS PrivateLink? and AWS services that integrate with AWS PrivateLink. For a list of more Amazon EKS requirements, see the section called “Private cluster requirements” (p. 63).

- If you want to deploy load balancers to a subnet, the subnet must have the following tag:

  - Private subnets

    | Key                              | Value |
    |----------------------------------|-------|
    | kubernetes.io/role/internal-elb  | 1     |

  - Public subnets

    | Key                              | Value |
    |----------------------------------|-------|
    | kubernetes.io/role/elb           | 1     |

When a Kubernetes cluster that’s version 1.18 and earlier was created, Amazon EKS added the following tag to all of the subnets that were specified.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/cluster/my-cluster</td>
<td>shared</td>
</tr>
</tbody>
</table>

When you create a new Kubernetes cluster now, Amazon EKS doesn't add the tag to your subnets. If the tag was on subnets that were used by a cluster that was previously a version earlier than 1.19, the tag wasn't automatically removed from the subnets when the cluster was updated to a newer version. Version 2.1.1 or earlier of the AWS Load Balancer Controller (p. 308) requires this tag. If you are using a newer version of the Load Balancer Controller, you can remove the tag without interrupting your services.

If you deployed a VPC by using eksctl or any of the Amazon EKS AWS CloudFormation VPC templates, the following applies:
• **On or after March 26, 2020** – Public IPv4 addresses are automatically assigned by public subnets to new nodes that are deployed to public subnets.

• **Before March 26, 2020** – Public IPv4 addresses aren't automatically assigned by public subnets to new nodes that are deployed to public subnets.

This change impacts new node groups that are deployed to public subnets in the following ways:

• **Managed node groups (p. 101)** – If the node group is deployed to a public subnet on or after April 22, 2020, automatic assignment of public IP addresses must be enabled for the public subnet. For more information, see Modifying the public IPv4 addressing attribute for your subnet.

• **Linux (p. 122), Windows (p. 129), or Arm (p. 176) self-managed node groups** – If the node group is deployed to a public subnet on or after March 26, 2020, automatic assignment of public IP addresses must be enabled for the public subnet. Otherwise, the nodes must be launched with a public IP address instead. For more information, see Modifying the public IPv4 addressing attribute for your subnet or Assigning a public IPv4 address during instance launch.

---

**Creating a VPC for your Amazon EKS cluster**

You can use Amazon Virtual Private Cloud (Amazon VPC) to launch AWS resources into a virtual network that you've defined. This virtual network closely resembles a traditional network that you might operate in your own data center. However, it comes with the benefits of using the scalable infrastructure of Amazon Web Services. For more information, see the Amazon VPC User Guide.

An Amazon EKS cluster, nodes, and Kubernetes resources are deployed to a VPC. If you want to use an existing VPC with Amazon EKS, that VPC must meet the requirements that are described in the section called “VPC and subnet requirements” (p. 238). This topic describes how to create a VPC that meets Amazon EKS requirements using an Amazon EKS provided AWS CloudFormation template.

**Prerequisite**

To create a VPC for Amazon EKS, you must have the necessary IAM permissions to create Amazon VPC resources. These resources are VPCs, subnets, security groups, route tables and routes, and internet and NAT gateways. For more information, see Create a VPC with a public subnet example policy in the Amazon VPC User Guide and the full list of Actions, resources, and condition keys for Amazon EC2 in the Service Authorization Reference.

You can create a VPC with public and private subnets, only public subnets, or only private subnets.

**Public and private subnets**

This VPC has two public and two private subnets. A public subnet's associated route table has a route to an internet gateway. However, the route table of a private subnet doesn't have a route to an internet gateway. One public and one private subnet are deployed to the same Availability Zone. The other public and private subnets are deployed to a second Availability Zone in the same AWS Region. We recommend this option for most deployments.

With this option, you can deploy your nodes to private subnets. This option allows Kubernetes to deploy load balancers to the public subnets that can load balance traffic to pods that run on nodes in the private subnets. Public IPv4 addresses are automatically assigned to nodes that are deployed to public subnets, but public IPv4 addresses aren't assigned to nodes deployed to private subnets.

You can also assign IPv6 addresses to nodes in public and private subnets. The nodes in private subnets can communicate with the cluster and other AWS services. Pods can communicate to the internet through a NAT gateway using IPv4 addresses or outbound-only Internet gateway using...
IPv6 addresses deployed in each Availability Zone. A security group is deployed that has rules that deny all inbound traffic from sources other than the cluster or nodes but allows all outbound traffic. The subnets are tagged so that Kubernetes can deploy load balancers to them.

To create your VPC

2. From the navigation bar, select an AWS Region that supports Amazon EKS.
3. Choose Create stack, With new resources (standard).
4. Under Prerequisite - Prepare template, make sure that Template is ready is selected and then under Specify template, select Amazon S3 URL.
5. You can create a VPC that supports only IPv4, or a VPC that supports IPv4 and IPv6. Paste one of the following URLs into the text area under Amazon S3 URL and choose Next:
   - IPv4
     
   - IPv4 and IPv6
     
6. On the Specify stack details page, enter the parameters, and then choose Next.
   - Stack name: Choose a stack name for your AWS CloudFormation stack. For example, you can use the template name you used in the previous step. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can’t be longer than 100 characters.
   - VpcBlock: Choose an IPv4 CIDR range for your VPC. Each node, pod, and load balancer that you deploy is assigned an IPv4 address from this block. The default IPv4 values provide enough IP addresses for most implementations, but if it doesn’t, then you can change it. For more information, see VPC and subnet sizing in the Amazon VPC User Guide. You can also add additional CIDR blocks to the VPC once it’s created. If you’re creating an IPv6 VPC, IPv6 CIDR ranges are automatically assigned for you from Amazon’s Global Unicast Address space.
   - PublicSubnet01Block: Specify an IPv4 CIDR block for public subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn’t, then you can change it. If you’re creating an IPv6 VPC, this block is specified for you within the template.
   - PublicSubnet02Block: Specify an IPv4 CIDR block for public subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn’t, then you can change it. If you’re creating an IPv6 VPC, this block is specified for you within the template.
   - PrivateSubnet01Block: Specify an IPv4 CIDR block for private subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn’t, then you can change it. If you’re creating an IPv6 VPC, this block is specified for you within the template.
   - PrivateSubnet02Block: Specify an IPv4 CIDR block for private subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn’t, then you can change it. If you’re creating an IPv6 VPC, this block is specified for you within the template.
7. (Optional) On the Configure stack options page, tag your stack resources and then choose Next.
9. When your stack is created, select it in the console and choose Outputs.
10. Record the VpcId for the VPC that was created. You need this when you create your cluster and nodes.
11. Record the SubnetIds for the subnets that were created and whether you created them as public or private subnets. You need at least two of these when you create your cluster and nodes.

12. If you created an IPv4 VPC, skip this step. If you created an IPv6 VPC, you must enable the auto-assign IPv6 address option for the public subnets that were created by the template. That setting is already enabled for the private subnets. To enable the setting, complete the following steps:
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. In the left navigation pane, choose Subnets
   c. Select one of your public subnets (stack-name/SubnetPublic01 or stack-name/SubnetPublic02 contains the word public) and choose Actions, Edit subnet settings.
   d. Choose the Enable auto-assign IPv6 address check box and then choose Save.
   e. Complete the previous steps again for your other public subnet.

Only public subnets

This VPC has three public subnets that are deployed into different Availability Zones in an AWS Region. All nodes are automatically assigned public IPv4 addresses and can send and receive internet traffic through an internet gateway. A security group is deployed that denies all inbound traffic and allows all outbound traffic. The subnets are tagged so that Kubernetes can deploy load balancers to them.

To create your VPC

2. From the navigation bar, select an AWS Region that supports Amazon EKS.
3. Choose Create stack, With new resources (standard).
4. Under Prepare template, make sure that Template is ready is selected and then under Template source, select Amazon S3 URL.
5. Paste the following URL into the text area under Amazon S3 URL and choose Next:

6. On the Specify Details page, enter the parameters, and then choose Next.
   - **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it amazon-eks-vpc-sample. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters.
   - **VpcBlock**: Choose a CIDR block for your VPC. Each node, pod, and load balancer that you deploy is assigned an IPv4 address from this block. The default IPv4 values provide enough IP addresses for most implementations, but if it doesn't, then you can change it. For more information, see VPC and subnet sizing in the Amazon VPC User Guide. You can also add additional CIDR blocks to the VPC once it's created.
   - **Subnet01Block**: Specify a CIDR block for subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
   - **Subnet02Block**: Specify a CIDR block for subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
   - **Subnet03Block**: Specify a CIDR block for subnet 3. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
7. (Optional) On the Options page, tag your stack resources. Choose Next.
9. When your stack is created, select it in the console and choose Outputs.
10. Record the VpcId for the VPC that was created. You need this when you create your cluster and nodes.
11. Record the SubnetIds for the subnets that were created. You need at least two of these when you create your cluster and nodes.
12. (Optional) Any cluster that you deploy to this VPC can assign private IPv4 addresses to your pods and services. If you want to deploy clusters to this VPC to assign private IPv6 addresses to your pods and services, make updates to your VPC, subnet, route tables, and security groups. For more information, see Migrate existing VPCs from IPv4 to IPv6 in the Amazon VPC User Guide. Amazon EKS requires that your subnets have the Auto-assign IPv6 addresses option enabled. By default, it's disabled.

Only private subnets

This VPC has three private subnets that are deployed into different Availability Zones in the AWS Region. Resources that are deployed to the subnets can't access the internet, nor can the internet access resources in the subnets. The template creates VPC endpoints using AWS PrivateLink for several AWS services that nodes typically need to access. If your nodes need outbound internet access, you can add a public NAT gateway in the Availability Zone of each subnet after the VPC is created. A security group is created that denies all inbound traffic, except from resources deployed into the subnets. A security group also allows all outbound traffic. The subnets are tagged so that Kubernetes can deploy internal load balancers to them. If you're creating a VPC with this configuration, see the section called “Private cluster requirements” (p. 63) for additional requirements and considerations.

To create your VPC

2. From the navigation bar, select an AWS Region that supports Amazon EKS.
3. Choose Create stack, With new resources (standard).
4. Under Prepare template, make sure that Template is ready is selected and then under Template source, select Amazon S3 URL.
5. Paste the following URL into the text area under Amazon S3 URL and choose Next:

6. On the Specify Details page, enter the parameters and then choose Next.

   • Stack name: Choose a stack name for your AWS CloudFormation stack. For example, you can call it amazon-eks-fully-private-vpc. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters.
   • VpcBlock: Choose a CIDR block for your VPC. Each node, pod, and load balancer that you deploy is assigned an IPv4 address from this block. The default IPv4 values provide enough IP addresses for most implementations, but if it doesn't, then you can change it. For more information, see VPC and subnet sizing in the Amazon VPC User Guide. You can also add additional CIDR blocks to the VPC once it's created.
   • PrivateSubnet01Block: Specify a CIDR block for subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
   • PrivateSubnet02Block: Specify a CIDR block for subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
   • PrivateSubnet03Block: Specify a CIDR block for subnet 3. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
7. (Optional) On the Options page, tag your stack resources. Choose Next.
9. When your stack is created, select it in the console and choose Outputs.
10. Record the VpcId for the VPC that was created. You need this when you create your cluster and nodes.
11. Record the SubnetIds for the subnets that were created. You need at least two of these when you create your cluster and nodes.
12. (Optional) Any cluster that you deploy to this VPC can assign private IPv4 addresses to your pods and services. If you want deploy clusters to this VPC to assign private IPv6 addresses to your pods and services, make updates to your VPC, subnet, route tables, and security groups. For more information, see Migrate existing VPCs from IPv4 to IPv6 in the Amazon VPC User Guide. Amazon EKS requires that your subnets have the Auto-assign IPv6 addresses option enabled (it’s disabled by default).

Amazon EKS security group requirements and considerations

This topic describes the security group requirements of an Amazon EKS cluster.

When you create a cluster, Amazon EKS creates a security group that’s named eks-cluster-sg-my-cluster-uniqueID. This security group has the following default rules:

<table>
<thead>
<tr>
<th>Rule type</th>
<th>Protocol</th>
<th>Ports</th>
<th>Source</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inbound</td>
<td>All</td>
<td>All</td>
<td>Self</td>
<td></td>
</tr>
<tr>
<td>Outbound</td>
<td>All</td>
<td>All</td>
<td>0.0.0.0/0 (IPv4) or ::/0 (IPv6)</td>
<td>0.0.0.0/0 (IPv4) or ::/0 (IPv6)</td>
</tr>
</tbody>
</table>

Amazon EKS tags this security group with the following tags:

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/cluster/my-cluster</td>
<td>owned</td>
</tr>
<tr>
<td>aws:eks:cluster-name</td>
<td>my-cluster</td>
</tr>
</tbody>
</table>

Amazon EKS automatically associates this security group to the following resources that it also creates:

- 2–4 elastic network interfaces (referred to for the rest of this document as network interface) that are created when you create your cluster.
- Network interfaces of the nodes in any managed node group that you create.

The default rules allow all traffic to flow freely between your cluster and nodes, and allows all outbound traffic to any destination. When you create a cluster, you can (optionally) specify your own security groups. If you do, then Amazon EKS also associates the security groups that you specify to the network interfaces that it creates for your cluster. However, it doesn’t associate them to any node groups that you create.
You can determine the ID of your cluster security group in the AWS Management Console under the cluster’s Networking section. Or, you can do so by running the following AWS CLI command.

```
aws eks describe-cluster --name my-cluster --query
cluster.resourcesVpcConfig.clusterSecurityGroupId
```

Restricting cluster traffic

If you need to limit the open ports between the cluster and nodes, you can remove the default rules and add the following minimum rules that are required for the cluster:

<table>
<thead>
<tr>
<th>Rule type</th>
<th>Protocol</th>
<th>Port</th>
<th>Source</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inbound</td>
<td>TCP</td>
<td>443</td>
<td>Cluster security group</td>
<td></td>
</tr>
<tr>
<td>Inbound</td>
<td>TCP</td>
<td>10250</td>
<td>Cluster security group</td>
<td></td>
</tr>
<tr>
<td>Inbound (CoreDNS)</td>
<td>TCP and UDP</td>
<td>53</td>
<td>Cluster security group</td>
<td></td>
</tr>
<tr>
<td>Outbound</td>
<td>TCP</td>
<td>443</td>
<td>Cluster security group</td>
<td></td>
</tr>
<tr>
<td>Outbound</td>
<td>TCP</td>
<td>10250</td>
<td>Cluster security group</td>
<td></td>
</tr>
<tr>
<td>Outbound (DNS)</td>
<td>TCP and UDP</td>
<td>53</td>
<td>Cluster security group</td>
<td></td>
</tr>
</tbody>
</table>

You must also add rules for the following traffic:

- Any protocol and ports that you expect your nodes to use for inter-node communication.
- Outbound internet access so that nodes can access the Amazon EKS APIs for cluster introspection and node registration at launch time. If your nodes don’t have internet access, review Private cluster requirements (p. 63) for additional considerations.
- Node access to pull container images from Amazon ECR or other container registries APIs that they need to pull images from, such as DockerHub. For more information, see AWS IP address ranges in the AWS General Reference.
- Node access to Amazon S3.
- Separate rules are required for IPv4 and IPv6 addresses.

If you’re considering limiting the rules, we recommend that you thoroughly test all of your pods before you apply your changed rules to a production cluster.

If you originally deployed a cluster with Kubernetes 1.14 and a platform version of eks.3 or earlier, then consider the following:

- You might also have control plane and node security groups. When these groups were created, they included the restricted rules listed in the previous table. These security groups are no longer required and can be removed. However, you need to make sure your cluster security group contains the rules that those groups contain.
- If you deployed the cluster using the API directly or you used a tool such as the AWS CLI or AWS CloudFormation to create the cluster and you didn’t specify a security group at cluster creation, then...
the default security group for the VPC was applied to the cluster network interfaces that Amazon EKS created.

Pod networking in Amazon EKS using the Amazon VPC CNI plugin for Kubernetes

Amazon EKS supports native Amazon VPC networking using the Amazon VPC Container Network Interface (CNI) plugin for Kubernetes. This plugin:

• creates elastic network interfaces (network interfaces) and attaches them to your Amazon EC2 nodes.
• assigns a private IPv4 or IPv6 address from your VPC to each pod and service.

The plugin is an open-source project that is maintained on GitHub. We recommend familiarizing yourself with the plugin by reading amazon-vpc-cni-k8s and Proposal: CNI plugin for Kubernetes networking over Amazon VPC on GitHub. Several of the CNI configuration variables in amazon-vpc-cni-k8s are expanded on in the section called “Use cases” (p. 263). The plugin is fully supported for use on Amazon EKS and self-managed Kubernetes clusters on AWS.

Topics

• Managing the Amazon VPC CNI plugin for Kubernetes (p. 247)
• Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258)
• Choosing pod networking use cases (p. 263)
• Metrics helper (p. 303)
• Alternate compatible CNI plugins (p. 308)

Managing the Amazon VPC CNI plugin for Kubernetes

Amazon EKS supports native VPC networking with the Amazon VPC Container Network Interface (CNI) plugin for Kubernetes. This plugin allows Kubernetes pods to have the same IP address inside the pod as they do on the VPC network. For more information, see Pod networking in Amazon EKS using the Amazon VPC CNI plugin for Kubernetes (p. 247).

Recommended version of the Amazon VPC CNI add-on for each cluster version

<table>
<thead>
<tr>
<th>Add-on version</th>
<th>1.23</th>
<th>1.22</th>
<th>1.21</th>
<th>1.20</th>
<th>1.19</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add-on version</td>
<td>1.11.3-eksbuild.1</td>
<td>1.11.3-eksbuild.1</td>
<td>1.11.3-eksbuild.1</td>
<td>1.11.3-eksbuild.1</td>
<td>1.11.3-eksbuild.1</td>
</tr>
</tbody>
</table>

If you created a 1.18 or later cluster using the AWS Management Console, then Amazon EKS installed the plugin for you as an Amazon EKS add-on. If you originally created a 1.17 or earlier cluster using any tool, or you created a 1.18 or later cluster using any tool other than the AWS Management Console, then Amazon EKS installed the plugin as a self-managed add-on for you. You can migrate the self-managed add-on to the Amazon EKS add-on using the procedure in Adding the Amazon VPC CNI Amazon EKS add-on (p. 248). If you have a cluster that you’ve already added the Amazon VPC CNI plugin for Kubernetes add-on to, you can manage it using the procedures in the Updating the Amazon VPC CNI plugin for Kubernetes add-on (p. 250) and Removing the Amazon VPC CNI plugin for Kubernetes add-on (p. 252) sections. For more information about Amazon EKS add-ons, see Amazon EKS add-ons (p. 367).
To update your Amazon EKS add-on version, see Updating the Amazon VPC CNI plugin for Kubernetes add-on (p. 250). To update your self-managed add-on version using container images in the Amazon EKS Amazon Elastic Container Registry or your own repository, see Updating the Amazon VPC CNI plugin for Kubernetes self-managed add-on (p. 253).

**Important**
The version of the add-on that was deployed when you created your cluster may be earlier than the recommended version. If you’ve updated the self-managed add-on using a manifest, then the version doesn’t include -eksbuild.1.

**Prerequisites**

- An existing Amazon EKS cluster. To deploy one, see Getting started with Amazon EKS (p. 4).
- If your cluster is 1.21 or later, make sure that your kube-proxy and CoreDNS add-ons are at the minimum versions listed in Service account tokens (p. 424).
- An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Creating an IAM OIDC provider for your cluster (p. 426).
- An IAM role with the AmazonEKS_CNI_Policy IAM policy (if your cluster uses the IPv4 family) or an IPv6 policy (p. 262) (if your cluster uses the IPv6 family) attached to it. For more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).
- If you are using version 1.7.0 or later of the CNI plugin and you use custom pod security policies, see the section called “Delete default policy” (p. 496)Pod security policy (p. 495).

**Adding the Amazon VPC CNI Amazon EKS add-on**

You can add the Amazon VPC CNI Amazon EKS add-on to your cluster with eksctl, the AWS Management Console, or the AWS CLI.

**Important**
Before adding the Amazon VPC CNI Amazon EKS add-on, confirm that you do not self-manage any settings that Amazon EKS will start managing. To determine which settings Amazon EKS manages, see Amazon EKS add-on configuration (p. 368).

**eksctl**

To add the recommended version (p. 247) of the Amazon EKS add-on using eksctl

Replace `my-cluster` with the name of your cluster and `arn:aws:iam::111122223333:role/AmazonEKSVPCCNIRole` with your existing IAM role (see Prerequisites (p. 248)).

```
eksctl create addon \
  --name vpc-cni \
  --version v1.11.3-eksbuild.1 \
  --cluster my-cluster \
  --service-account-role-arn arn:aws:iam::111122223333:role/AmazonEKSVPCCNIRole \
  --force
```

If any of the Amazon EKS add-on settings conflict with the existing settings for the self-managed add-on, then adding the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict.

If you want to add a different version of the add-on instead, then you can view all versions available for the add-on and your cluster’s version with the following command. Replace 1.23 with your cluster’s version.

```
```
Managing the Amazon VPC CNI plugin for Kubernetes

```
eksctl utils describe-addon-versions --name vpc-cni --kubernetes-version 1.23 | grep AddonVersion:
```

Replace `v1.11.3-eksbuild.1` in the `create addon` command with the version returned in the output that you want to add and then run the `create addon` command.

AWS Management Console

To add the **recommended version (p. 247)** of the Amazon EKS add-on using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, select **Clusters**, and then select the name of the cluster that you want to configure the Amazon VPC CNI plugin for Kubernetes add-on for.
3. Choose the **Add-ons** tab.
4. Select **Add new**.
   - Select `vpc-cni` for **Name**.
   - Select the **Version** you'd like to use. We recommend the `1.11.3-eksbuild.1` version, but you can select a different version if necessary.
   - For **Service account role**, select the name of an IAM role that you've attached the `AmazonEKS_CNI_Policy` IAM policy to (see Prerequisites (p. 248)).
   - Select **Override existing configuration for this add-on on the cluster**. If any of the Amazon EKS add-on settings conflict with the existing settings for the self-managed add-on, then adding the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict.
   - Select **Add**.

AWS CLI

To add the **recommended version (p. 247)** of the Amazon EKS add-on using the AWS CLI, replace `my-cluster` with the name of your cluster, `arn:aws:iam::111122223333:role/AmazonEKS_CMPNIRole` with the ARN of an IAM role that you've attached the `AmazonEKS_CMPNI_Policy` IAM policy to (see Prerequisites (p. 248)), and then run the command.

```
aws eks create-addon \
  --cluster-name my-cluster \
  --addon-name vpc-cni \
  --addon-version v1.11.3-eksbuild.1 \
  --service-account-role-arn arn:aws:iam::111122223333:role/AmazonEKS_CMPNIRole \
  --resolve-conflicts OVERWRITE
```

If any of the Amazon EKS add-on settings conflict with the existing settings for the self-managed add-on, then adding the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict.

If you want to add a different version of the add-on instead, then you can view all versions available for the add-on and your cluster's version with the following command. Replace `1.23` with your cluster's version.

```
aws eks describe-addon-versions \
  --addon-name vpc-cni \
  --kubernetes-version 1.23 \
  --query "addons[] .addonVersions[].addonVersion, compatibilities[].Version" \
  --output text
```
Replacing v1.11.3-eksbuild.1 in the create-addon command with the version returned in the output that you want to add and then run the create-addon command.

## Updating the Amazon VPC CNI plugin for Kubernetes add-on

**Important**
Before updating the Amazon VPC CNI plugin for Kubernetes add-on, confirm that you do not self-manage any settings that Amazon EKS manages. To determine which settings Amazon EKS manages, see [Amazon EKS add-on configuration](#p.368).

This procedure is for updating the Amazon VPC CNI plugin for Kubernetes add-on. If you haven't added the Amazon VPC CNI plugin for Kubernetes add-on, complete the procedure in [Updating the Amazon VPC CNI plugin for Kubernetes self-managed add-on](#p.253) instead. Amazon EKS does not automatically update the add-on when new versions are released or after you update your cluster (p. 32) to a new Kubernetes minor version. To update the add-on for an existing cluster, you must initiate the update and then Amazon EKS updates the add-on for you.

We recommend that you update one minor version at a time. For example, if your current minor version is 1.9 and you want to update to 1.11, you should update to the latest patch version of 1.10 first, then update to the latest patch version of 1.11.

You can update the Amazon VPC CNI plugin for Kubernetes add-on on to your cluster using `eksctl`, the AWS Management Console, or the AWS CLI.

**eksctl**

**To update the Amazon EKS add-on to the recommended version (p. 247) using eksctl**

1. Check the current version of your add-on. Replace `my-cluster` with your cluster name.

   ```bash
eksctl get addon --name vpc-cni --cluster my-cluster
   ```

   The example output is as follows.

   ```
   NAME    VERSION                 STATUS  ISSUES  IAMROLE
   vpc-cni v1.7.5-eksbuild.2     ACTIVE  0        arn:aws:iam::111122223333:role/AmazonEKSVPCCNIRole
   ```

   v1.11.3-eksbuild.1

2. Update the add-on to the recommended version (p. 247).

   ```bash
   eksctl update addon \
   --name vpc-cni \n   --version 1.11.3-eksbuild.1 \n   --cluster my-cluster \n   --force
   ```

   If you want to update to a different version of the add-on instead, then you can view all versions available for the add-on and your cluster's version with the following command. Replace 1.23 with your cluster's version.

   ```bash
   eksctl utils describe-addon-versions --name vpc-cni --kubernetes-version 1.23 | grep AddonVersion:
   ```

   Replace `v1.11.3-eksbuild.1` in the `update addon` command with the version returned in the output that you want to add and then run the `update addon` command.
AWS Management Console

To update the Amazon EKS add-on to the recommended version (p. 247) using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, select Clusters, and then select the name of the cluster that you want to update the Amazon VPC CNI plugin for Kubernetes add-on for.
3. Choose the Add-ons tab.
4. Select the box in the top right of the vpc-cni box and then choose Edit.
   • Select the Version of the Amazon EKS add-on that you want to use. We recommend the 1.11.3-eksbuild.1 version, but you can select a different version if necessary.
   • For Service account role, select the name of an IAM role that you’ve attached the AmazonEKS_CNI_Policy IAM policy to (see Prerequisites (p. 248)), if one isn’t already selected.
   • Select Override existing configuration for this add-on on the cluster.
   • Select Update.

AWS CLI

To update the Amazon EKS add-on to the recommended version (p. 247) using the AWS CLI

1. Check the current version of your add-on. Replace my-cluster with your cluster name.

```bash
aws eks describe-addon
  --cluster-name my-cluster
  --addon-name vpc-cni
  --query "addon.addonVersion"
  --output text
```

The example output is as follows.

```
v1.7.5-eksbuild.2
```

The version returned for you may be different.

2. Update the add-on to the latest recommended version. Replace my-cluster with your cluster name.

```bash
aws eks update-addon
  --cluster-name my-cluster
  --addon-name vpc-cni
  --addon-version v1.11.3-eksbuild.1
  --resolve-conflicts OVERWRITE
```

If you want to update to a different version of the add-on instead, then you can view all versions available for the add-on and your cluster’s version with the following command. Replace 1.23 with your cluster’s version.

```bash
aws eks describe-addon-versions
  --addon-name vpc-cni
  --kubernetes-version 1.23
  --query "addons[].addonVersions[].addonVersion, compatibilities[].Version"
```
Replace v1.11.3-eksbuild.1 in the update-addon command with the version returned in the output that you want to add and then run the update-addon command.

Removing the Amazon VPC CNI plugin for Kubernetes add-on

You have two options when removing an Amazon EKS add-on:

- **Preserve the add-on’s software on your cluster** – This option removes Amazon EKS management of any settings and the ability for Amazon EKS to notify you of updates and automatically update the Amazon EKS add-on after you initiate an update, but preserves the add-on’s software on your cluster. This option makes the add-on a self-managed add-on, rather than an Amazon EKS add-on. There is no downtime for the add-on.

- **Removing the add-on software entirely from your cluster** – You should only remove the Amazon EKS add-on from your cluster if there are no resources on your cluster that are dependent on the functionality that the add-on provides. After removing the Amazon EKS add-on, you can add it again if you want to.

If the add-on has an IAM account associated with it, the IAM account is not removed.

You can remove the Amazon VPC CNI plugin for Kubernetes add-on from your cluster with eksctl, the AWS Management Console, or the AWS CLI.

**eksctl**

To remove the Amazon EKS add-on using eksctl

Replace `my-cluster` with the name of your cluster and then run the following command. Removing --preserve removes the add-on software from your cluster.

```
eksctl delete addon --cluster my-cluster --name vpc-cni --preserve
```

**AWS Management Console**

To remove the Amazon EKS add-on using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, select Clusters, and then select the name of the cluster that you want to remove the Amazon VPC CNI plugin for Kubernetes add-on for.
3. Choose the Add-ons tab.
4. Select the check box in the top right of the vpc-cni box and then choose Remove. Select Preserve on cluster if you want Amazon EKS to stop managing settings for the add-on, but want to retain the add-on software on your cluster so that you can self-managed all of the add-on’s settings. Type `vpc-cni` and then select Remove.

**AWS CLI**

To remove the Amazon EKS add-on using the AWS CLI

Replace `my-cluster` with the name of your cluster and then run the following command. Removing --preserve removes the add-on software from your cluster.

```
aws eks delete-addon --cluster-name my-cluster --addon-name vpc-cni --preserve
```
Updating the Amazon VPC CNI plugin for Kubernetes self-managed add-on

If you have a cluster that you haven't added the Amazon VPC CNI plugin for Kubernetes add-on to, or need to manage the add-on yourself, then complete the following steps to update the add-on. If you've added the Amazon VPC CNI plugin for Kubernetes Amazon EKS add-on, complete the procedure in Updating the Amazon VPC CNI plugin for Kubernetes add-on (p. 250) instead.

Important

- Versions are specified as major-version.minor-version.patch-version
- You should only update one minor version at a time. For example, if your current minor version is 1.9 and you want to update to 1.11, then you should update to 1.10 first, then update to 1.11.
- All versions work with all Amazon EKS supported Kubernetes versions, though not all features of each release work with all Kubernetes versions. When using different Amazon EKS features, if a specific version of the add-on is required, then it's noted in the feature documentation.
- We recommend that you update to version 1.11.3, though you can update to any release version, if necessary.

To update the self-managed add-on

1. View releases on GitHub to see the available versions and familiarize yourself with the changes in the version that you want to update to.
2. Use the following command to determine your cluster's current Amazon VPC CNI plugin for Kubernetes add-on version:

   ```bash
ekubectl describe daemonset aws-node --namespace kube-system | grep Image | cut -d "/" - f 2
```

   The example output is as follows.

   ```plaintext
   amazon-k8s-cni-init:v1.7.5-eksbuild.1
   amazon-k8s-cni:v1.7.5-eksbuild.1
   ```

   Your output might look different than the example output. In this example output, the Amazon VPC CNI plugin for Kubernetes add-on version is 1.7.5-eksbuild.1. The current recommended version is 1.11.3. The version that Amazon EKS originally deployed with your cluster looks similar to the previous output. If you've already updated the add-on at least once using a manifest however, your output might not include -eksbuild.1.
3. Update the DaemonSet using Helm V3 (p. 411) or later, or by using a manifest.

   Helm
   a. Add the eks-charts repository to Helm.

   ```bash
   helm repo add eks https://aws.github.io/eks-charts
   ```

   b. Update your local repository to make sure that you have the most recent charts.

   ```bash
   helm repo update
   ```

   c. Backup your current settings so that you can determine which settings you need to specify values for in a later step.
d. If you installed the existing Amazon VPC CNI plugin for Kubernetes DaemonSet using Helm, then skip to the next step.

Complete one of the following options so that Helm can manage the DaemonSet resources:

- Add the Helm annotations and labels to your existing resources.
  
i. Copy the following contents to your device. Replace `aws-vpc-cni` if you want to use a different release name. Run the command to create the `helm-cni.sh` file.

```bash
cat >helm-cni.sh <<EOF
#!/usr/bin/env bash
set -euo pipefail
for kind in daemonSet clusterRole clusterRoleBinding serviceAccount; do
echo "setting annotations and labels on $kind/aws-node"
kubectl -n kube-system annotate --overwrite $kind aws-node meta.helm.sh/release-name=aws-vpc-cni
kubectl -n kube-system annotate --overwrite $kind aws-node meta.helm.sh/release-namespace=kube-system
kubectl -n kube-system label --overwrite $kind aws-node app.kubernetes.io/managed-by=Helm
done
EOF

ii. Make the script executable.

```chmod +x helm-cni.sh```

iii. Run the script

```.:/helm-cni.sh```

- Remove the existing DaemonSet resources.

  **Important**
  
  Your cluster will experience downtime between completing this step and the next step.

```bash
kubectl delete serviceaccount aws-node -n kube-system
kubectl delete customresourcedefinition eniconfigs.crd.k8s.amazonaws.com
kubectl delete clusterrole aws-node
kubectl delete clusterrolebinding aws-node
kubectl delete daemonset aws-node -n kube-system
```

e. Install the chart using one of the following options. Before running the installation, review the backup you made of the settings for your DaemonSet in a previous step and then review the configuration settings to determine if you need to set any of them.

If you have an existing IAM role to use with the DaemonSet, then add the following line at the end of the install options that follow. If you don't have an IAM role associated to the `aws-node` Kubernetes service account, then we recommend creating one. Replace `111122223333` with your account ID and `AmazonEKSVPCCNIRole` with the name of your role. To create a role, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).
If you added the Helm annotations and labels in the previous step, then add the following settings to any of the following options.

```bash
--set originalMatchLabels=true
--set crd.create=false
```

- If your nodes have access to the Amazon EKS Amazon ECR repositories and are in the us-west-2 AWS Region, then install the chart with the release name aws-vpc-cni and default configuration.

```bash
helm upgrade -i aws-vpc-cni eks/aws-vpc-cni \\
--namespace kube-system \\
--set image.tag=v1.11.3 \\
--set init.image.tag=v1.11.3
```

- If your nodes have access to the Amazon EKS Amazon ECR repositories and are in an AWS Region other than us-west-2, then install the chart with the release name aws-vpc-cni. Replace `eks-ecr-account` with the value from the section called “Amazon container image registries” (p. 365) for the AWS Region that your cluster is in. Replace `region-code` with the AWS Region that your cluster is in.

```bash
helm upgrade -i aws-vpc-cni eks/aws-vpc-cni \\
--namespace kube-system \\
--set image.account=eks-ecr-account \\
--set image.region=region-code \\
--set image.tag=v1.11.3 \\
--set init.image.account=eks-ecr-account \\
--set init.image.region=region-code \\
--set init.image.tag=v1.11.3
```

- If your nodes don’t have access to the Amazon EKS Amazon ECR repositories

1. Pull the following container images and push them to a repository that your nodes have access to. For more information on how to pull, tag, and push an image to your own repository, see Copy a container image from one repository to another repository (p. 363). We recommend using the version in the following commands, but if necessary, you can replace it with any release version. Replace `602401143452` and `region-code` with values from the section called “Amazon container image registries” (p. 365) for the AWS Region that your cluster is in.

   ```bash
   602401143452.dkr.ecr.region-code.amazonaws.com/amazon-k8s-cni-init:v1.11.3
   602401143452.dkr.ecr.region-code.amazonaws.com/amazon-k8s-cni:v1.11.3
   ```

2. Install the chart with the release name aws-vpc-cni and default configuration. Before running the installation, review the backup you made of the settings for your DaemonSet in a previous step and then review the configuration settings to determine if you need to set any of them. Replace `registry/repo:tag` with your registry, repository, and tag.

```bash
helm upgrade -i aws-vpc-cni eks/aws-vpc-cni \\
--namespace kube-system \\
--set image.override=registry/repo:tag \\
--set init.image.override=registry/repo:tag
```
Manifest

a. If you've changed any default settings for your current Amazon VPC CNI plugin for Kubernetes DaemonSet, or you need to pull the container images from your own repository to update the DaemonSet, or your cluster is in a region other than us-west-2, or you need to update to a specific patch version for version 1.7 or earlier, then skip to the next step.

Run the following command to update your Amazon VPC CNI plugin for Kubernetes add-on. You can change 1.11.3 to 1.7.0 or later. Regardless of the patch version that you specify for 1.7, such as 1.7.5, the latest patch version of the image (1.7.10) is pulled.

```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.11.3/config/master/aws-k8s-cni.yaml
```

If you need to update to a version earlier than 1.7.0, then pull the manifest with the following URL. You can change 1.6 to an earlier version, if necessary. The manifest pulls the latest patch version of the image for the version that you specify.

```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/release-1.6/config/v1.6/aws-k8s-cni.yaml
```

Skip to the View the status of the DaemonSet (p. 258) step.

b. If your nodes have access to the Amazon EKS Amazon ECR image repositories, then skip to the next step.

Pull the following container images and push them to a repository that your nodes have access to. For more information on how to pull, tag, and push an image to your own repository, see Copy a container image from one repository to another repository (p. 363). We recommend using the version in the following commands, but if necessary, you can replace it with any release version. Replace 602401143452 and region-code with values from the section called “Amazon container image registries” (p. 365) for the AWS Region that your cluster is in.

```
602401143452.dkr.ecr.region-code.amazonaws.com/amazon-k8s-cni-init:v1.11.3
602401143452.dkr.ecr.region-code.amazonaws.com/amazon-k8s-cni:v1.11.3
```

c. If you haven't changed any of the default settings for the DaemonSet, skip to the next step.

Backup your current settings so that you can compare your settings to the default settings in the new manifest.

```
kubectl get daemonset aws-node -n kube-system -o yaml > aws-k8s-cni-old.yaml
```

d. Download the manifest for the Amazon VPC CNI plugin for Kubernetes add-on. You can change 1.11.3 to 1.7.0 or later. Regardless of the patch version that you specify for 1.7, such as 1.7.5, the latest patch version of the image (1.7.10) is pulled.

```
curl -o aws-k8s-cni.yaml https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.11.3/config/master/aws-k8s-cni.yaml
```

If you need to update to a version earlier than 1.7.0, then pull the manifest with the following URL. You can change 1.6 to an earlier version, if necessary. The manifest pulls the latest patch version of the image for the version that you specify.
curl -o aws-k8s-cni.yaml https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/release-1.6/config/v1.6/aws-k8s-cni.yaml

If you need a specific patch version of 1.7 or earlier, open the file in a text editor and change \texttt{v1.11.3} in the following two lines to the specific patch version that you want. Depending on which version of the file that you downloaded, \texttt{v1.11.3} may be a different version number, or may be \texttt{latest}. After you've made the changes, save the file.

\begin{Verbatim}
image: "602401143452.dkr.ecr.us-west-2.amazonaws.com/amazon-k8s-cni-init:v1.11.3"
image: "602401143452.dkr.ecr.us-west-2.amazonaws.com/amazon-k8s-cni:v1.11.3"
\end{Verbatim}

e. If you didn't copy the container images to your own repository in a previous step, then skip to the next step.

Replace the registry, repository, and tag in the file with your own.

i. Replace \texttt{your-registry} in the following command with your registry and then run the modified command to replace \texttt{602401143452.dkr.ecr.us-west-2.amazonaws.com} in the file.

\begin{Verbatim}
\texttt{sed -i.bak -e 's|602401143452.dkr.ecr.us-west-2.amazonaws.com|your-registry|' aws-k8s-cni.yaml}
\end{Verbatim}

ii. Replace \texttt{your-repository} and \texttt{tag} in the following command with your repository and tag and then run the modified command to replace \texttt{amazon-k8s-cni-init:v1.11.3} in the file. Replace \texttt{1.11.3} with the version of the manifest that you downloaded.

\begin{Verbatim}
\texttt{sed -i.bak -e 's|amazon-k8s-cni-init:v1.11.3|your-repository:tag|' aws-k8s-cni.yaml}
\end{Verbatim}

iii. Replace \texttt{your-repository} and \texttt{tag} in the following command with your repository and tag and then run the modified command to replace \texttt{amazon-k8s-cni:v1.11.3} in the file. Replace \texttt{1.11.3} with the version of the manifest that you downloaded.

\begin{Verbatim}
\texttt{sed -i.bak -e 's|amazon-k8s-cni:v1.11.3|your-repository:tag|' aws-k8s-cni.yaml}
\end{Verbatim}

iv. Skip to the Compare settings (p. 258) step.

f. Run the following command to replace information in the file with information for the AWS Region that your cluster is in.

i. Replace \texttt{us-west-2} in the file with the AWS Region that your cluster is in.

AWS GovCloud (US-East)

\begin{Verbatim}
\texttt{sed -i.bak -e 's|us-west-2|us-gov-east-1|' aws-k8s-cni.yaml}
\end{Verbatim}

AWS GovCloud (US-West)

\begin{Verbatim}
\texttt{sed -i.bak -e 's|us-west-2|us-gov-west-1|' aws-k8s-cni.yaml}
\end{Verbatim}

All other AWS Regions – Replace \texttt{region-code} with the AWS Region that your cluster is in.

\begin{Verbatim}
\texttt{sed -i.bak -e 's|us-west-2|region-code|' aws-k8s-cni.yaml}
\end{Verbatim}
ii. Replace 602401143452 in the file with the account for the AWS Region that your cluster is in.

AWS GovCloud (US-East)

```bash
sed -i.bak -e 's|602401143452|151742754352|' aws-k8s-cni.yaml
```

AWS GovCloud (US-West)

```bash
sed -i.bak -e 's|602401143452|013241004608|' aws-k8s-cni.yaml
```

All other AWS Regions – Replace account with the value from Amazon container image registries (p. 365) for the AWS Region that your cluster is in.

```bash
sed -i.bak -e 's|602401143452|account|' aws-k8s-cni.yaml
```

g. If you’ve changed any default settings for your current Amazon VPC CNI plugin for Kubernetes DaemonSet then compare the settings in the new manifest to the backup file that you made in a previous step.

```bash
diff aws-k8s-cni.yaml aws-k8s-cni-old.yaml -u
```

Edit the new manifest file and make changes to any setting values so that they match the settings in your backup file.

h. Apply the manifest file to your cluster.

```bash
kubectl apply -f aws-k8s-cni.yaml
```

4. View the status of the DaemonSet.

```bash
kubectl get daemonset aws-node -n kube-system
```

The example output is as follows.

```
NAME       DESIRED   CURRENT   READY   UP-TO-DATE   AVAILABLE   NODE SELECTOR   AGE
aws-node   2         2         2       2            2           <none>          4h39m
```

Once the numbers in the READY, UP-TO-DATE, and AVAILABLE columns are the same, then your update is complete. Your numbers may be different than those in the previous output.

5. View the DaemonSet to confirm the changes that you made.

```bash
kubectl get daemonset aws-node -n kube-system -o yaml
```

### Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts

The Amazon VPC CNI plugin for Kubernetes is the networking plugin for pod networking in Amazon EKS clusters. The plugin is responsible for allocating VPC IP addresses to Kubernetes nodes and configuring the necessary networking for pods on each node. The plugin:
• Requires AWS Identity and Access Management (IAM) permissions. If your cluster uses the IPv4 family, the permissions are specified in the AmazonEKS_CNI_Policy AWS managed policy. If your cluster uses the IPv6 family, then the permissions must be added to an IAM policy that you create (p. 262). You can attach the policy to the Amazon EKS node IAM role (p. 461), or to a separate IAM role. We recommend that you assign it to a separate role, as detailed in this topic.

• Creates and is configured to use a Kubernetes service account named aws-node when it’s deployed. The service account is bound to a Kubernetes clusterrole named aws-node, which is assigned the required Kubernetes permissions.

Note
The pods for the Amazon VPC CNI plugin for Kubernetes have access to the permissions assigned to the Amazon EKS node IAM role (p. 461), unless you block access to IMDS. For more information, see Restrict access to the instance profile assigned to the worker node.

Prerequisites
• An existing Amazon EKS cluster. To deploy one, see Getting started with Amazon EKS (p. 4).
• An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Creating an IAM OIDC provider for your cluster (p. 426).

Step 1: Create the Amazon VPC CNI plugin for Kubernetes IAM role

To create the IAM role

1. Determine the IP family of your cluster.

   ```
   aws eks describe-cluster --name my-cluster | grep ipFamily
   ```

   The example output is as follows.

   "ipFamily": "ipv4"

   The output may return ipv6 instead.

2. Create the IAM role. You can use eksctl or kubectl and the AWS CLI to create your IAM role.

   eksctl

   Create an IAM role and attach the IAM policy to the role with the command that matches the IP family of your cluster. The command creates and deploys an AWS CloudFormation stack that creates an IAM role, attaches the policy that you specify to it, and annotates the existing aws-node Kubernetes service account with the ARN of the IAM role that is created.

   • IPv4

   Replace my-cluster with your own value.

   ```
   eksctl create iamserviceaccount \
   --name aws-node \
   --namespace kube-system \
   --cluster my-cluster \
   --role-name "AmazonEKSVPCCNIRole" \
   --attach-policy-arn arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy \
   ```
Configure plugin for IAM account

```
--override-existing-serviceaccounts \
--approve
```

- IPv6

Replace `my-cluster` with your own value. Replace `111122223333` with your account ID and replace `AmazonEKS_CNI_IPv6_Policy` with the name of your IPv6 policy. If you don't have an IPv6 policy, see [Create IAM policy for clusters that use the IPv6 family (p. 262)](#) to create one. To use IPv6 with your cluster, it must meet several requirements. For more information, see [Tutorial: Assigning IPv6 addresses to pods and services (p. 264)](#).

```
eksctl create iamserviceaccount \
  --name aws-node \ 
  --namespace kube-system \ 
  --cluster my-cluster \ 
  --role-name "AmazonEKSVPCCNIRole" \ 
  --attach-policy-arn \ 
arwn:aws:iam::111122223333:policy/AmazonEKS_CNI_IPv6_Policy \ 
  --override-existing-serviceaccounts \ 
  --approve
```

**kubectl and the AWS CLI**

1. View your cluster's OIDC provider URL.

```
aws eks describe-cluster --name my-cluster --query "cluster.identity.oidc.issuer" --output text
```

The example output is as follows.

`https://oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE`

If no output is returned, then you must create an IAM OIDC provider for your cluster (p. 426).

2. Copy the following contents to a file named `vpc-cni-trust-policy.json`. Replace `111122223333` with your account ID and `EXAMPLED539D4633E53DE1B71EXAMPLE` with the output returned in the previous step. Replace `region-code` with the AWS Region that your cluster is in.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
        "StringEquals": {
          "oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:aud": "sts.amazonaws.com",
          "oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:sub": "system:serviceaccount:kube-system:aws-node"
        }
      }
    }
  ]
}
```
3. Create the role. You can replace `AmazonEKSVPCCNIRole` with any name that you choose.

```bash
aws iam create-role 
  --role-name AmazonEKSVPCCNIRole 
  --assume-role-policy-document file://"vpc-cni-trust-policy.json"
```

4. Attach the required IAM policy to the role. Run the command that matches the IP family of your cluster.

- **IPv4**

```bash
aws iam attach-role-policy 
  --policy-arn arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy 
  --role-name AmazonEKSVPCCNIRole
```

- **IPv6**

Replace `111122223333` with your account ID and `AmazonEKS_CNI_IPv6_Policy` with the name of your IPv6 policy. If you don't have an IPv6 policy, see Create IAM policy for clusters that use the IPv6 family (p. 262) to create one. To use IPv6 with your cluster, it must meet several requirements. For more information, see Tutorial: Assigning IPv6 addresses to pods and services (p. 264).

```bash
aws iam attach-role-policy 
  --policy-arn arn:aws:iam::111122223333:policy/AmazonEKS_CNI_IPv6_Policy 
  --role-name AmazonEKSVPCCNIRole
```

5. Run the following command to annotate the `aws-node` service account with the ARN of the IAM role that you created previously. Replace the example values with your own values.

```bash
kubectl annotate serviceaccount 
  -n kube-system aws-node 
  eks.amazonaws.com/role-arn=arn:aws:iam::111122223333:role/AmazonEKSVPCCNIRole
```

3. (Optional) Configure the AWS Security Token Service endpoint type used by your Kubernetes service account. For more information, see Configuring the AWS Security Token Service endpoint for a service account (p. 434).

### Step 2: Re-deploy Amazon VPC CNI plugin for Kubernetes pods

1. Delete and re-create any existing pods that are associated with the service account to apply the credential environment variables. The annotation is not applied to pods that are currently running without the annotation. The following command deletes the existing `aws-node` DaemonSet pods and deploys them with the service account annotation.

```bash
kubectl delete pods -n kube-system -l k8s-app=aws-node
```

2. Confirm that the pods all restarted.

```bash
kubectl get pods -n kube-system -l k8s-app=aws-node
```

3. Describe one of the pods and verify that the `AWS_WEB_IDENTITY_TOKEN_FILE` and `AWS_ROLE_ARN` environment variables exist. Replace `9rgzw` with the name of one of your pods returned in the output of the previous step.
Configure plugin for IAM account

```bash
kubectl exec -n kube-system aws-node-9rgzw -c aws-node -- env | grep AWS
```

The example output is as follows.

```bash
... AWS_WEB_IDENTITY_TOKEN_FILE=/var/run/secrets/eks.amazonaws.com/serviceaccount/token ...
AWS_ROLE_ARN=arn:aws:iam::111122223333:role/AmazonEKSVPCCNIRole ...
```

If your pod is using the AWS Regional endpoint, then the following line is also returned in the previous output.

```
AWS_STS_REGIONAL_ENDPOINTS=regional
```

**Step 3: Remove the CNI policy from the node IAM role**

If your Amazon EKS node IAM role (p. 461) currently has the AmazonEKS_CNI_Policy IAM (IPv4) policy or an IPv6 policy (p. 262) attached to it, and you've created a separate IAM role, attached the policy to it instead, and assigned it to the `aws-node` Kubernetes service account, then we recommend that you remove the policy from your node role with the the AWS CLI command that matches the IP family of your cluster. Replace `AmazonEKSNodeRole` with the name of your node role.

- **IPv4**

```bash
aws iam detach-role-policy --role-name AmazonEKSNodeRole --policy-arn arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy
```

- **IPv6**

Replace `111122223333` with your account ID and `AmazonEKS_CNI_IPv6_Policy` with the name of your IPv6 policy.

```bash
aws iam detach-role-policy --role-name AmazonEKSNodeRole --policy-arn arn:aws:iam::111122223333:policy/AmazonEKS_CNI_IPv6_Policy
```

**Create IAM policy for clusters that use the IPv6 family**

If you created a 1.21 or later cluster that uses the IPv6 family and the cluster has version 1.10.1 or later of the Amazon VPC CNI plugin for Kubernetes add-on configured, then you need to create an IAM policy that you can assign to an IAM role. If you have an existing 1.21 or later cluster that you didn’t configure with the IPv6 family when you created it, then to use IPv6, you must create a new cluster. For more information about using IPv6 with your cluster, see the section called “IPv6” (p. 264).

1. Copy the following text and save it to a file named `vpc-cni-ipv6-policy.json`.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ec2:AssignIPv6Addresses",
```
Use cases

```
"ec2:DescribeInstances",
"ec2:DescribeTags",
"ec2:DescribeNetworkInterfaces",
"ec2:DescribeInstanceTypes"
],
"Resource": "**
},
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateTags"
  ],
  "Resource": [
    "arn:aws:ec2:*:*:network-interface/**
  ]
}
```

2. Create the IAM policy.

```
aws iam create-policy --policy-name AmazonEKS_CNI_IPv6_Policy --policy-document file:///vpc-cni-ipv6-policy.json
```

Choosing pod networking use cases

The Amazon VPC CNI plugin provides networking for pods. The following table helps you understand which networking use cases you can use together and the capabilities and Amazon VPC CNI plugin settings that you can use with different Amazon EKS node types. All information in the table applies to Linux IPv4 nodes only.

<table>
<thead>
<tr>
<th>Amazon EKS node type (p. 94)</th>
<th>Amazon EC2</th>
<th>Fargate</th>
</tr>

</tr>
</tbody>
</table>

Note

- You can't use IPv6 with custom networking.
- IPv6 addresses are not translated, so SNAT doesn't apply.
- You can use Calico network policy with IPv6.
- Traffic flow to and from pods with associated security groups are not subjected to Calico network policy enforcement and are limited to Amazon VPC security group enforcement only.
- IP prefixes and IP addresses are associated with standard Amazon EC2 elastic network interfaces. Pods requiring specific security groups are assigned the primary IP address of a branch network interface. You can mix pods getting IP addresses, or IP addresses from IP prefixes with pods getting branch network interfaces on the same node.

Windows nodes

Each Windows node only supports one network interface and secondary IPv4 addresses for pods. As a result, you can't use IP address prefixes or IPv6 with Windows nodes. The maximum number of pods for each node is equal to the number of IP addresses that you can assign to each Elastic network interface, minus one. Calico network policies are supported on Windows. For more information, see Open Source Calico for Windows Containers on Amazon EKS. You can't use security groups for pods (p. 292) on Windows.

Tutorial: Assigning IPv6 addresses to pods and services

By default, Kubernetes assigns IPv4 addresses to your pods and services. Instead of assigning IPv4 addresses to your pods and services, you can configure your cluster to assign IPv6 addresses to them. Amazon EKS doesn't support dual-stacked pods or services, even though Kubernetes does in version 1.23 and later. As a result, you can't assign both IPv4 and IPv6 addresses to your pods and services.

You select which IP family you want to use for your cluster when you create it. You can't change the family after you create the cluster.
Considerations for using the IPv6 family for your cluster:

- You must create a new cluster that's version 1.21 or later and specify that you want to use the IPv6 family for that cluster. You can't enable the IPv6 family for a cluster that you updated from a previous version. For instructions on how to create a new cluster, see Creating an Amazon EKS cluster (p. 24).

- The version of the Amazon VPC CNI add-on that you deploy to your cluster must be version 1.10.1 or later. This version or later is deployed by default with a new 1.21 or later cluster. After you deploy the add-on, you can't downgrade your Amazon VPC CNI add-on to a version lower than 1.10.1 without first removing all nodes in all node groups in your cluster.

- Windows pods and services aren't supported.

- If you use Amazon EC2 nodes, you must configure the Amazon VPC CNI add-on with IP prefix delegation and IPv6. If you choose the IPv6 family when creating your cluster, the 1.10.1 version of the add-on defaults to this configuration. This is the case for both a self-managed or Amazon EKS add-on. For more information about IP prefix delegation, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 289).

- When you create a cluster, the VPC and subnets that you specify must have an IPv6 CIDR block that's assigned to the VPC and subnets that you specify. They must also have an IPv4 CIDR block assigned to them. This is because, even if you only want to use IPv6, a VPC still requires an IPv4 CIDR block to function. For more information, see Associate an IPv6 CIDR block with your VPC in the Amazon VPC User Guide.

- When you create your cluster and nodes, you must specify subnets that are configured to auto-assign IPv6 addresses. Otherwise, you can't deploy your cluster and nodes. By default, this configuration is disabled. For more information, see Modify the IPv6 addressing attribute for your subnet in the Amazon VPC User Guide.

- The route tables that are assigned to your subnets must have routes for IPv6 addresses. For more information, see Migrate to IPv6 in the Amazon VPC User Guide.

- Your security groups must allow IPv6 addresses. For more information, see Migrate to IPv6 in the Amazon VPC User Guide.

- You can only use IPv6 with AWS Nitro-based Amazon EC2 or Fargate nodes.

- You can't use IPv6 with Security groups for pods (p. 292) with Amazon EC2 nodes. However, you can use it with Fargate nodes. If you need separate security groups for individual pods, continue using the IPv4 family with Amazon EC2 nodes, or use Fargate nodes instead.

- If you previously used custom networking (p. 276) to help alleviate IP address exhaustion, you can use IPv6 instead. You can't use custom networking with IPv6. If you use custom networking for network isolation, then you might need to continue to use custom networking and the IPv4 family for your clusters.

- You can't use IPv6 with AWS Outposts (p. 547).

- Pods and services are only assigned an IPv6 address. They aren't assigned an IPv4 address. Because pods are able to communicate to IPv4 endpoints through NAT on the instance itself, DNS54 and NAT64 aren't needed. If the traffic needs a public IP address, the traffic is then source network address translated to a public IP.

- The source IPv6 address of a pod isn't source network address translated to the IPv6 address of the node when communicating outside of the VPC. It is routed using an internet gateway or egress-only internet gateway.

- All nodes are assigned an IPv4 and IPv6 address.

- The Amazon FSx for Lustre CSI driver (p. 232) is not supported.

- You can use version 2.3.1 or later of the AWS Load Balancer Controller to load balance application (p. 357) or network (p. 351) traffic to IPv6 pods in IP mode, but not instance mode. For more information, see Installing the AWS Load Balancer Controller add-on (p. 308).

- You must attach an IPv6 IAM policy to your node IAM or CNI IAM role. Between the two, we recommend that you attach it to a CNI IAM role. For more information, see Create IAM policy for
clusters that use the IPv6 family (p. 262) and Step 1: Create the Amazon VPC CNI plugin for Kubernetes IAM role (p. 259).

- Each Fargate pod receives an IPv6 address from the CIDR that’s specified for the subnet that it's deployed in. The underlying hardware unit that runs Fargate pods gets a unique IPv4 and IPv6 address from the CIDRs that are assigned to the subnet that the hardware unit is deployed in.
- We recommend that you perform a thorough evaluation of your applications, Amazon EKS add-ons, and AWS services that you integrate with before deploying IPv6 clusters. This is to ensure that everything works as expected with IPv6.
- You can't use IPv6 with AWS App Mesh.
- Use of the Amazon EC2 Instance Metadata Service IPv6 endpoint is not supported with Amazon EKS.
- When creating a self-managed node group in a cluster that uses the IPv6 family, user-data must include the following BootstrapArguments for the bootstrap.sh file that runs at node start up. Replace your-cidr with the IPv6 CIDR range of your cluster’s VPC.

```
--ip-family ipv6 --service-ipv6-cidr your-cidr
```

If you don't know the IPv6 CIDR range for your cluster, you can see it with the following command (requires the AWS CLI version 2.4.9 or later).

```
aws eks describe-cluster --name my-cluster --query
  cluster.kubernetesNetworkConfig.serviceIpv6Cidr --output text
```

### Deploy an IPv6 cluster and managed Amazon Linux nodes

In this tutorial, you deploy an IPv6 Amazon VPC, an Amazon EKS cluster with the IPv6 family, and a managed node group with Amazon EC2 Amazon Linux nodes. You can't deploy Amazon EC2 Windows nodes in an IPv6 cluster. You can also deploy Fargate nodes to your cluster, though those instructions aren't provided in this topic for simplicity.

Before creating a cluster for production use, we recommend that you familiarize yourself with all settings and deploy a cluster with the settings that meet your requirements. For more information, see Creating an Amazon EKS cluster (p. 24), Managed node groups (p. 97) and the considerations (p. 264) for this topic. You can only enable some settings when creating your cluster.

### Prerequisites

Before starting this tutorial, you must install and configure the following tools and resources that you need to create and manage an Amazon EKS cluster.

- The kubectl command line tool is installed on your device or AWS CloudShell. The version can be the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For example, if your cluster version is 1.22, you can use kubectl version 1.21,1.22, or 1.23 with it. To install or upgrade kubectl, see Installing or updating kubectl (p. 4). For this tutorial, the version must be 1.21 or later.
- The IAM security principal that you're using must have permissions to work with Amazon EKS IAM roles and service linked roles, AWS CloudFormation, and a VPC and related resources. For more information, see Actions, resources, and condition keys for Amazon Elastic Kubernetes Service and Using service-linked roles in the IAM User Guide.

Procedures are provided to create the resources with either eksctl or the AWS CLI. You can also deploy the resources using the AWS Management Console, but those instructions aren't provided in this topic for simplicity.
Prerequisite

`eksctl` version 0.112.0 or later installed on your computer. To install or update to it, see the section called “Installing `eksctl`” (p. 10).

To deploy an IPv6 cluster with `eksctl`

1. Copy the following contents to your device. Replace the `example values` with your own. Replace `region-code` with any AWS Region that is supported by Amazon EKS. For a list of AWS Regions, see Amazon EKS endpoints and quotas in the AWS General Reference guide. You can replace `t3.medium` with any AWS Nitro System instance type. The value for `version` must be 1.21 or a later supported Amazon EKS Kubernetes version (p. 66). The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. After you've replaced the values, run the modified command to create the `ipv6-cluster.yaml` file.

```
cat >ipv6-cluster.yaml <<EOF
---
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig

metadata:
  name: my-cluster
  region: region-code
  version: "1.21"

kubernetesNetworkConfig:
  ipFamily: IPv6

addons:
- name: vpc-cni
  version: latest
- name: coredns
  version: latest
- name: kube-proxy
  version: latest

iam:
  withOIDC: true

managedNodeGroups:
- name: my-nodegroup
  instanceType: t3.medium
EOF
```

2. Create your cluster.

```
eksctl create cluster -f ipv6-cluster.yaml
```

Cluster creation takes several minutes. Don't proceed until you see the last line of output, which looks similar to the following output.

```
[✓] EKS cluster "my-cluster" in "region-code" region is ready
```

3. Confirm that default pods are assigned IPv6 addresses.

```
kubectl get pods -n kube-system -o wide
```
The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
<th>IP</th>
<th>NOMINATED</th>
</tr>
</thead>
<tbody>
<tr>
<td>node</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>aws-node-rs1ts</td>
<td>1/1</td>
<td>Running</td>
<td>1</td>
<td>5m36s</td>
<td>ip-192-168-34-75.region-code.compute.internal</td>
<td></td>
</tr>
<tr>
<td>2600:1f13:b66:8200:11a5:ode0:c590:6ac8</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>aws-node-t74jh</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>5m32s</td>
<td>ip-192-168-253-70.region-code.compute.internal</td>
<td></td>
</tr>
<tr>
<td>coredns=85d5b445ac-cw7w2</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>56m</td>
<td>ip-192-168-253-70.region-code.compute.internal</td>
<td></td>
</tr>
<tr>
<td>2600:1f13:b66:8203:34e5:1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>kube-proxy-btpbk</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>5m36s</td>
<td>ip-192-168-34-75.region-code.compute.internal</td>
<td></td>
</tr>
<tr>
<td>2600:1f13:b66:8200:11a5:ode0:c590:6ac8</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>kube-proxy-jjk2g</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>5m33s</td>
<td>ip-192-168-253-70.region-code.compute.internal</td>
<td></td>
</tr>
</tbody>
</table>

4. Confirm that default services are assigned IPv6 addresses.

```
kubectl get services -n kube-system -o wide
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>kube-dns</td>
<td>ClusterIP</td>
<td>fd30:3087:b6c2::a</td>
<td>&lt;none&gt;</td>
<td>53/UDP, 53/TCP</td>
<td>57m</td>
</tr>
<tr>
<td>app=kube-dns</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. **(Optional)** Deploy a sample application (p. 338) or deploy the AWS Load Balancer Controller (p. 308) and a sample application to load balance application (p. 357) or network (p. 351) traffic to IPv6 pods.

6. After you've finished with the cluster and nodes that you created for this tutorial, you should clean up the resources that you created with the following command.

```
eksctl delete cluster my-cluster
```

**AWS CLI**

**Prerequisite**

Version 2.7.32 or later or 1.25.72 or later of the AWS CLI installed and configured on your device or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with aws configure in the AWS Command Line Interface User Guide. If you use the AWS CloudShell, you may need to install version 2.7.32 or later or 1.25.72 or later of the AWS CLI, because the default AWS CLI version installed in the AWS CloudShell may be an earlier version.

**Important**

- You must complete all steps in this procedure as the same user.
Amazon EKS User Guide
Use cases

- You must complete all steps in this procedure in the same shell. Several steps use variables set in previous steps. Steps that use variables won’t function properly if the variable values are set in a different shell. If you use the AWS CloudShell to complete the following procedure, remember that if you don’t interact with it using your keyboard or pointer for approximately 20–30 minutes, your shell session ends. Running processes do not count as interactions.
- The instructions are written for the Bash shell, and may need adjusting in other shells.

**To create your cluster with the AWS CLI**

Replace all *example values* in the steps of this procedure with your own values.

1. Run the following commands to set some variables used in later steps. Replace `region-code` with the AWS Region that you want to deploy your resources in. The value can be any AWS Region that is supported by Amazon EKS. For a list of AWS Regions, see Amazon EKS endpoints and quotas in the AWS General Reference guide. Replace `my-cluster` with a name for your cluster. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. Replace `my-nodegroup` with a name for your node group. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. Replace `111122223333` with your account ID.

```bash
export region_code=
export cluster_name=
export nodegroup_name=
export account_id=
```

2. Create an Amazon VPC with public and private subnets that meets Amazon EKS and IPv6 requirements.

   a. Run the following command to set a variable for your AWS CloudFormation stack name. You can replace `my-eks-ipv6-vpc` with any name you choose.

   ```bash
   export vpc_stack_name=
   ```

   b. Create an IPv6 VPC using an AWS CloudFormation template.

   ```bash
   aws cloudformation create-stack --region $region_code --stack-name $vpc_stack_name \
   ```

   The stack takes a few minutes to create. Run the following command. Don't continue to the next step until the output of the command is `CREATE_COMPLETE`.

   ```bash
   aws cloudformation describe-stacks --region $region_code --stack-name $vpc_stack_name --query Stacks[].StackStatus --output text
   ```

   c. Retrieve the IDs of the public subnets that were created.

   ```bash
   aws cloudformation describe-stacks --region $region_code --stack-name $vpc_stack_name \
   --query='Stacks[].Outputs[?OutputKey==`SubnetsPublic`].OutputValue' --output text
   ```

   The example output is as follows.
d. Enable the auto-assign IPv6 address option for the public subnets that were created.

```bash
aws ec2 modify-subnet-attribute --region $region_code --subnet-id subnet-0a1a56c486EXAMPLE --assign-ipv6-address-on-creation
aws ec2 modify-subnet-attribute --region $region_code --subnet-id subnet-099e6ca77aEXAMPLE --assign-ipv6-address-on-creation
```

e. Retrieve the names of the subnets and security groups created by the template from the deployed AWS CloudFormation stack and store them in variables for use in a later step.

```bash
security_groups=$(aws cloudformation describe-stacks --region $region_code --stack-name $vpc_stack_name --query='Stacks[].Outputs[?OutputKey==`SecurityGroups`].OutputValue' --output text)
public_subnets=$(aws cloudformation describe-stacks --region $region_code --stack-name $vpc_stack_name --query='Stacks[].Outputs[?OutputKey==`SubnetsPublic`].OutputValue' --output text)
private_subnets=$(aws cloudformation describe-stacks --region $region_code --stack-name $vpc_stack_name --query='Stacks[].Outputs[?OutputKey==`SubnetsPrivate`].OutputValue' --output text)
subnets=${public_subnets},${private_subnets}
```

3. Create a cluster IAM role and attach the required Amazon EKS IAM managed policy to it. Kubernetes clusters managed by Amazon EKS make calls to other AWS services on your behalf to manage the resources that you use with the service.

a. Run the following command to create the eks-cluster-role-trust-policy.json file.

```bash
cat >eks-cluster-role-trust-policy.json <<EOF
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "eks.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
EOF
```

b. Run the following command to set a variable for your role name. You can replace `myAmazonEKSClusterRole` with any name you choose.

```bash
export cluster_role_name=myAmazonEKSClusterRole
```

c. Create the role.
Use cases

d. Retrieve the ARN of the IAM role and store it in a variable for a later step.

```
cluster_iam_role=$(aws iam get-role --role-name $cluster_role_name --query="Role.Arn" --output text)
```

e. Attach the required Amazon EKS managed IAM policy to the role.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/AmazonEKSClusterPolicy --role-name $cluster_role_name
```

4. Create your cluster.

a. The version must be **1.21** or a later supported Amazon EKS Kubernetes version (p. 66).

```
aws eks create-cluster --region $region_code --name $cluster_name --kubernetes-version 1.21 \ 
--role-arn $cluster_iam_role --resources-vpc-config subnetIds=\ $subnets,securityGroupIds=$security_groups \ 
--kubernetes-network-config ipFamily=ipv6
```

**Note**
You might receive an error that one of the Availability Zones in your request doesn't have sufficient capacity to create an Amazon EKS cluster. If this happens, retry creating your cluster with at least two subnets that are located in the supported Availability Zones for your account. For more information, see *Insufficient capacity* (p. 521).

b. The cluster takes several minutes to create. Run the following command. Don't continue to the next step until the output from the command is **ACTIVE**.

```
aws eks describe-cluster --region $region_code --name $cluster_name --query cluster.status
```

5. Create or update a **kubeconfig** file for your cluster so that you can communicate with your cluster.

```
aws eks update-kubeconfig --region $region_code --name $cluster_name
```

By default, the **config** file is created in `~/.kube` or the new cluster's configuration is added to an existing **config** file in `~/.kube`.

6. Create a node IAM role.

a. Run the following command to create the **vpc-cni-ipv6-policy.json** file.

```
cat >vpc-cni-ipv6-policy <<EOF
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ec2:AssignIpv6Addresses", "ec2:DescribeInstances"],
```
b. Create the IAM policy.

```bash
aws iam create-policy --policy-name AmazonEKS_CNI_IPv6_Policy --policy-document file://vpc-cni-ipv6-policy.json
```

c. Run the following command to create the node-role-trust-relationship.json file.

```bash
cat >node-role-trust-relationship.json <<EOF
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "ec2.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
EOF
```

d. Run the following command to set a variable for your role name. You can replace AmazonEKSNodeRole with any name you choose.

```bash
export node_role_name=AmazonEKSNodeRole
```

e. Create the IAM role.

```bash
aws iam create-role --role-name $node_role_name --assume-role-policy-document file://"node-role-trust-relationship.json"
```

f. Attatch the IAM policy to the IAM role.

```bash
aws iam attach-role-policy --policy-arn arn:aws:iam::$account_id:policy/AmazonEKS_CNI_IPv6_Policy $node_role_name
```

**Important**

For simplicity in this tutorial, the policy is attached to this IAM role. In a production cluster however, we recommend attaching the policy to a separate IAM role. For
more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).

g. Attach two required IAM managed policies to the IAM role.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy --role-name $node_role_name
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly --role-name $node_role_name
```

h. Retrieve the ARN of the IAM role and store it in a variable for a later step.

```
node_iam_role=$(aws iam get-role --role-name $node_role_name --query="Role.Arn" --output text)
```

7. Create a managed node group.

a. View the IDs of the subnets that you created in a previous step.

```
echo $subnets
```

The example output is as follows.

```
subnet-0a1a56c486EXAMPLE,subnet-099e6ca77aEXAMPLE,subnet-0377963d69EXAMPLE,subnet-0c05f819d5EXAMPLE
```

b. Create the node group. Replace `0a1a56c486EXAMPLE, 099e6ca77aEXAMPLE, 0377963d69EXAMPLE, and 0c05f819d5EXAMPLE` with the values returned in the output of the previous step. Be sure to remove the commas between subnet IDs from the previous output in the following command. You can replace `t3.medium` with any AWS Nitro System instance type.

```
aws eks create-nodegroup --region $region_code --cluster-name $cluster_name --nodegroup-name $nodegroup_name --subnets subnet-0a1a56c486EXAMPLE subnet-099e6ca77aEXAMPLE subnet-0377963d69EXAMPLE subnet-0c05f819d5EXAMPLE --instance-types t3.medium --node-role $node_iam_role
```

The node group takes a few minutes to create. Run the following command. Don't proceed to the next step until the output returned is `ACTIVE`.

```
aws eks describe-nodegroup --region $region_code --cluster-name $cluster_name --nodegroup-name $nodegroup_name --query nodegroup.status --output text
```

8. Confirm that the default pods are assigned IPv6 addresses in the IP column.

```
kubectl get pods -n kube-system -o wide
```

The example output is as follows.

```
NAME                       READY   STATUS    RESTARTS   AGE     IP NODE   NOMINATED
NODE  READINESS GATES
```

273
9. Confirm that the default services are assigned IPv6 addresses in the IP column.

```
kubectl get services -n kube-system -o wide
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>kube-dns</td>
<td>ClusterIP</td>
<td>fd30:3087:b6c2::a</td>
<td>&lt;none&gt;</td>
<td>53/UDP,53/TCP</td>
<td>57m</td>
</tr>
</tbody>
</table>

10. (Optional) Deploy a sample application (p. 338) or deploy the AWS Load Balancer Controller (p. 308) and a sample application to load balance application (p. 357) or network (p. 351) traffic to IPv6 pods.

11. After you've finished with the cluster and nodes that you created for this tutorial, you should clean up the resources that you created with the following commands. Make sure that you're not using any of the resources outside of this tutorial before deleting them.

   a. If you're completing this step in a different shell than you completed the previous steps in, set the values of all the variables used in previous steps, replacing the example values with the values you specified when you completed the previous steps. If you're completing this step in the same shell that you completed the previous steps in, skip to the next step.

   ```
   export region_code=region-code
   export vpc_stack_name=my-eks-ipv6-vpc
   export cluster_name=my-cluster
   export nodegroup_name=my-nodegroup
   export account_id=111122223333
   export node_role_name=AmazonEKSNodeRole
   export cluster_role_name=myAmazonEKSClusterRole
   ```

   b. Delete your node group.

   ```
   aws eks delete-nodegroup --region $region_code --cluster-name $cluster_name --nodegroup-name $nodegroup_name
   ```

   Deletion takes a few minutes. Run the following command. Don't proceed to the next step if any output is returned.
Use cases

```bash
aws eks list-nodegroups --region $region_code --cluster-name $cluster_name --query nodegroups --output text
```

c. Delete the cluster.

```bash
aws eks delete-cluster --region $region_code --name $cluster_name
```

The cluster takes a few minutes to delete. Before continuing make sure that the cluster is deleted with the following command.

```bash
aws eks describe-cluster --region $region_code --name $cluster_name
```

Don't proceed to the next step until your output is similar to the following output.

```
An error occurred (ResourceNotFoundException) when calling the DescribeCluster operation: No cluster found for name: my-cluster.
```

d. Delete the IAM resources that you created. Replace AmazonEKS_CNI_IPv6_Policy with the name you chose, if you chose a different name than the one used in previous steps.

```bash
aws iam detach-role-policy --role-name $cluster_role_name --policy-arn arn:aws:iam::<account_id>:policy/AmazonEKS_CNI_IPv6_Policy
aws iam detach-role-policy --role-name $node_role_name --policy-arn arn:aws:iam::<account_id>:policy/AmazonEKSClusterPolicy
aws iam detach-role-policy --role-name $node_role_name --policy-arn arn:aws:iam::<account_id>:policy/AmazonEKSWorkerNodePolicy
aws iam detach-role-policy --role-name $node_role_name --policy-arn arn:aws:iam::<account_id>:policy/AmazonEC2ContainerRegistryReadOnly
aws iam delete-policy --policy-arn arn:aws:iam::<account_id>:policy/AmazonEKS_CNI_IPv6_Policy
aws iam delete-role --role-name $cluster_role_name
aws iam delete-role --role-name $node_role_name
```

e. Delete the AWS CloudFormation stack that created the VPC.

```bash
aws cloudformation delete-stack --region $region_code --stack-name $vpc_stack_name
```

**SNAT for pods**

If you deployed your cluster using the IPv6 family, then the information in this topic isn’t applicable to your cluster, because IPv6 addresses are not network translated. For more information about using IPv6 with your cluster, see the section called “IPv6” (p. 264).

By default, each pod in your cluster is assigned a private IPv4 address from a classless inter-domain routing (CIDR) block that is associated with the VPC that the pod is deployed in. Pods in the same VPC communicate with each other using these private IP addresses as end points. When a pod communicates to any IPv4 address that isn’t within a CIDR block that’s associated to your VPC, the **Amazon VPC CNI plugin for Kubernetes** translates the pod’s IPv4 address to the primary private IPv4 address of the primary elastic network interface of the node that the pod is running on, by default *p. 276*.

Due to this behavior:
• Resources that are in networks or VPCs that are connected to your cluster VPC using VPC peering, a transit VPC, or Direct Connect can't initiate communication to your pods. Your pods can initiate communication to those resources and receive responses from them though.

• Your pods can communicate bi-directionally with internet resources only if the node that they're running on has a public or elastic IP address assigned to it and is in a public subnet. A public subnet’s associated route table has a route to an internet gateway. A private subnet’s associated route table doesn't have a route to an internet gateway. We recommend deploying nodes to private subnets, whenever possible.

If you have either of the following requirements, then you need to change the default configuration of the Amazon VPC CNI plugin for Kubernetes:

• You have resources in networks or VPCs that are connected to your cluster VPC using VPC peering, a transit VPC, or Direct Connect that need to initiate communication with your pods using an IPv4 address.

• Your nodes are in private subnets.

Change the default configuration with the following command.

```
kubectl set env daemonset -n kube-system aws-node AWS_VPC_K8S_CNI_EXTERNALSNAT=true
```

If you want pods to communicate to the internet after you've changed the setting, then the route table that's associated with the private subnet must contain a route to a public NAT gateway. Resources on the internet can't initiate communication to pods in private subnets, unless you've deployed a load balancer or ingress to a public subnet in your VPC. The load balancer or ingress can route traffic to the private IP address of the pods. For more information about creating network load balancers and ingress (application load balancers), see the section called “Network load balancing” (p. 351) and the section called “Application load balancing” (p. 357).

*If a pod's spec contains hostNetwork=true (default is false), then its IP address isn't translated to a different address. This is the case for the kube-proxy and Amazon VPC CNI plugin for Kubernetes pods that run on your cluster, by default. For these pods, the IP address is the same as the node's primary IP address, so the pod's IP address isn't translated. For more information about a pod's hostNetwork setting, see PodSpec v1 core in the Kubernetes API reference.

**Tutorial: Custom networking**

By default, when the Amazon VPC CNI plugin for Kubernetes creates secondary elastic network interfaces (network interfaces) for your Amazon EC2 node, it creates them in the same subnet as the node's primary network interface. It also associates the same security groups to the secondary network interface that are associated to the primary network interface. For one or more of the following reasons, you might want the plugin to create secondary network interfaces in a different subnet or want to associate different security groups to the secondary network interfaces, or both:

• There's a limited number of IPv4 addresses that are available in the subnet that the primary network interface is in. This might limit the number of pods that you can create in the subnet. By using a different subnet for secondary network interfaces, you can increase the number of available IPv4 addresses available for pods.

• For security reasons, your pods might need to use a different subnet or security groups than the node's primary network interface.

• The nodes are configured in public subnets, and you want to place the pods in private subnets. The route table associated to a public subnet includes a route to an internet gateway. The route table associated to a private subnet doesn't include a route to an internet gateway.
Considerations

• With custom networking enabled, no IP addresses assigned to the primary network interface are assigned to pods. Only IP addresses from secondary network interfaces are assigned to pods.

• If your cluster uses the IPv6 family, you can't use custom networking.

• If you plan to use custom networking only to help alleviate IPv4 address exhaustion, you can create a cluster using the IPv6 family instead. For more information, see Tutorial: Assigning IPv6 addresses to pods and services (p. 264).

• Even though pods deployed to subnets specified for secondary network interfaces can use different subnet and security groups than the node's primary network interface, the subnets and security groups must be in the same VPC as the node.

Prerequisites

• Familiarity with how the Amazon VPC CNI plugin for Kubernetes creates secondary network interfaces and assigns IP addresses to pods. For more information, see ENI Allocation on GitHub.

• Version 2.7.32 or later or 1.25.72 or later of the AWS CLI installed and configured on your device or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with aws configure in the AWS Command Line Interface User Guide.

• The kubectl command line tool is installed on your device or AWS CloudShell. The version can be the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For example, if your cluster version is 1.22, you can use kubectl version 1.21, 1.22, or 1.23 with it. To install or upgrade kubectl, see Installing or updating kubectl (p. 4).

• We recommend that you complete the steps in this topic in a Bash shell. If you aren't using a Bash shell, some script commands such as line continuation characters and the way variables are set and used require adjustment for your shell.

For this tutorial, we recommend using the example values, except where it's noted to replace them. You can replace any example value when completing the steps for a production cluster. We recommend completing all steps in the same terminal. This is because variables are set and used throughout the steps and won't exist in different terminals.

Step 1: Create a test VPC and cluster

To create a cluster

The following procedures help you create a test VPC and cluster and configure custom networking for that cluster. We don't recommend using the test cluster for production workloads because several unrelated features that you might use on your production cluster aren't covered in this topic. For more information, see the section called “Creating a cluster” (p. 24).

When you want to deploy custom networking to your production cluster, skip to the section called “Step 2: Configure your VPC” (p. 279).

1. Define a few variables to use in the remaining steps. Replace region-code with the AWS Region that you want to create your cluster in.

   ```bash
   export cluster_name=my-custom-networking-cluster
   export region_code=region-code
   account_id=$(aws sts get-caller-identity --query Account --output text)
   ```

2. Create a VPC.

   1. Create a VPC using an Amazon EKS AWS CloudFormation template.
aws cloudformation create-stack --region $region_code --stack-name my-eks-custom-networking-vpc  
   --parameters ParameterKey=VpcBlock,ParameterValue=192.168.0.0/24 
   ParameterKey=PrivateSubnet01Block,ParameterValue=192.168.0.64/27 
   ParameterKey=PrivateSubnet02Block,ParameterValue=192.168.0.96/27 
   ParameterKey=PublicSubnet01Block,ParameterValue=192.168.0.0/27 
   ParameterKey=PublicSubnet02Block,ParameterValue=192.168.0.32/27

The AWS CloudFormation stack takes a few minutes to create. To check on the stack's deployment status, run the following command.

aws cloudformation describe-stacks --region $region_code --stack-name my-eks-custom-networking-vpc 
   --query Stacks[].StackStatus --output text

Don't continue to the next step until the output of the command is CREATE_COMPLETE.

2. Define variables with the values of the private subnet IDs created by the template.

   subnet_id_1=$(aws cloudformation describe-stack-resources --stack-name my-eks-custom-networking-vpc --region $region_code 
   --query "StackResources[?LogicalResourceId=='PrivateSubnet01'].PhysicalResourceId" --output text)

   subnet_id_2=$(aws cloudformation describe-stack-resources --stack-name my-eks-custom-networking-vpc --region $region_code 
   --query "StackResources[?LogicalResourceId=='PrivateSubnet02'].PhysicalResourceId" --output text)

3. Define variables with the Availability Zones of the subnets retrieved in the previous step.

   az_1=$(aws ec2 describe-subnets --subnet-ids $subnet_id_1 --region $region_code --query 'Subnets[*].AvailabilityZone' --output text)

   az_2=$(aws ec2 describe-subnets --subnet-ids $subnet_id_2 --region $region_code --query 'Subnets[*].AvailabilityZone' --output text)

3. Create a cluster IAM role.
   a. Run the following command to create an IAM trust policy JSON file.

   cat >eks-cluster-role-trust-policy.json <<EOF
   "Version": "2012-10-17",
   "Statement": [
     { "Effect": "Allow",
       "Principal": { "Service": "eks.amazonaws.com" },
       "Action": "sts:AssumeRole" }
   ]
   EOF

   b. Create the Amazon EKS cluster IAM role. If necessary, preface eks-cluster-role-trust-policy.json with the path on your computer that you wrote the file to in the previous step. The command associates the trust policy that you created in the previous step to the role. To
create an IAM role, the IAM entity (user or role) that is creating the role must be assigned the following IAM action (permission): iam:CreateRole.

```
aws iam create-role --role-name myCustomNetworkingAmazonEKSClusterRole --assume-role-policy-document file://"eks-cluster-role-trust-policy.json"
```

c. Attach the Amazon EKS managed policy named AmazonEKSClusterPolicy to the role. To attach an IAM policy to an IAM entity (user or role), the IAM entity that is attaching the policy must be assigned one of the following IAM actions (permissions): iam:AttachUserPolicy or iam:AttachRolePolicy.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/AmazonEKSClusterPolicy --role-name myCustomNetworkingAmazonEKSClusterRole
```

4. Create an Amazon EKS cluster and configure your device to communicate with it.

a. Create a cluster.

```
aws eks create-cluster --region $region_code --name my-custom-networking-cluster --role-arn arn:aws:iam::$account_id:role/myCustomNetworkingAmazonEKSClusterRole --resources-vpc-config subnetIds=$subnet_id_1","$subnet_id_2
```

Note
You might receive an error that one of the Availability Zones in your request doesn't have sufficient capacity to create an Amazon EKS cluster. If this happens, the error output contains the Availability Zones that can support a new cluster. Retry creating your cluster with at least two subnets that are located in the supported Availability Zones for your account. For more information, see Insufficient capacity (p. 521).

b. The cluster takes several minutes to create. To check on the cluster's deployment status, run the following command.

```
aws eks describe-cluster --region $region_code --name my-custom-networking-cluster --query cluster.status
```

Don't continue to the next step until the output of the command is ACTIVE.

c. Configure kubectl to communicate with your cluster.

```
aws eks update-kubeconfig --region $region_code --name my-custom-networking-cluster
```

Step 2: Configure your VPC

This tutorial requires the VPC created in the section called “Step 1: Create a test VPC and cluster” (p. 277). For a production cluster, adjust the steps accordingly for your VPC by replacing all of the example values with your own.

1. Confirm that your currently-installed Amazon VPC CNI plugin is version 1.6.3-eksbuild.2 or later by running the following command.

```
kubectl describe daemonset aws-node -n kube-system | grep amazon-k8s-cni: | cut -d "/" -f 2
```

The example output is as follows.
If your version is earlier than `1.6.3-eksbuild.2`, then you must update it. For more information, see the updating sections of Managing the Amazon VPC CNI plugin for Kubernetes (p. 247).

2. Retrieve the ID of your cluster VPC and store it in a variable for use in later steps. For a production cluster, replace `my-custom-networking-cluster` with the name of your cluster.

   ```
vpc_id=$(aws eks describe-cluster --name my-custom-networking-cluster --region $region_code --query "cluster.resourcesVpcConfig.vpcId" --output text)
   ```

3. Associate an additional Classless Inter-Domain Routing (CIDR) block with your cluster's VPC. The CIDR block can't overlap with any existing associated CIDR blocks.

   1. View the current CIDR blocks associated to your VPC.

      ```
      aws ec2 describe-vpcs --vpc-ids $vpc_id --region $region_code --query 'Vpcs[*].CidrBlockAssociationSet[*].{CIDRBlock: CidrBlock, State: CidrBlockState.State}.' --out table
      ```

      The example output is as follows.

      | DescribeVpcs | |
      | +-----------------+--------------+|
      | CIDRBlock | State | |
      | +-----------------+--------------+|
      | 192.168.0.0/24 | associated | |
      +-----------------+--------------+

   2. Associate an additional CIDR block to your VPC. For more information, see Associate additional IPv4 CIDR blocks with your VPC in the Amazon VPC User Guide.

      ```
      aws ec2 associate-vpc-cidr-block --vpc-id $vpc_id --region $region_code --cidr-block 192.168.1.0/24
      ```

   3. Confirm that the new block is associated.

      ```
      aws ec2 describe-vpcs --vpc-ids $vpc_id --region $region_code --query 'Vpcs[*].CidrBlockAssociationSet[*].{CIDRBlock: CidrBlock, State: CidrBlockState.State}.' --out table
      ```

      The example output is as follows.

      | DescribeVpcs | |
      | +-----------------+--------------+|
      | CIDRBlock | State | |
      | +-----------------+--------------+|
      | 192.168.0.0/24 | associated | |
      | 192.168.1.0/24 | associated | |
      +-----------------+--------------+

   Don't proceed to the next step until your new CIDR block's State is associated.
4. Create as many subnets as you want to use in each Availability Zone that your existing subnets are in. Specify a CIDR block that's within the CIDR block that you associated with your VPC in a previous step.

1. Create new subnets. The subnets must be created in a different VPC CIDR block than your existing subnets are in, but in the same Availability Zones as your existing subnets. In this example, one subnet is created in the new CIDR block in each Availability Zone that the current private subnets exist in. The IDs of the subnets created are stored in variables for use in later steps. The Name values match the values assigned to the subnets created using the Amazon EKS VPC template in a previous step. Names aren't required. You can use different names.

```
new_subnet_id_1=$(aws ec2 create-subnet --vpc-id $vpc_id --region $region_code --availability-zone $az_1 --cidr-block 192.168.1.0/27
  --tag-specifications 'ResourceType=subnet,Tags=[{Key=Name,Value=my-eks-custom-networking-vpc-PrivateSubnet01},{Key=kubernetes.io/role/internal-elb,Value=1}]'
  --query Subnet.SubnetId --output text)
new_subnet_id_2=$(aws ec2 create-subnet --vpc-id $vpc_id --region $region_code --availability-zone $az_2 --cidr-block 192.168.1.32/27
  --tag-specifications 'ResourceType=subnet,Tags=[{Key=Name,Value=my-eks-custom-networking-vpc-PrivateSubnet02},{Key=kubernetes.io/role/internal-elb,Value=1}]'
  --query Subnet.SubnetId --output text)
```

**Important**

By default, your new subnets are implicitly associated with your VPC's main route table. This route table allows communication between all the resources that are deployed in the VPC. However, it doesn't allow communication with resources that have IP addresses that are outside the CIDR blocks that are associated with your VPC. You can associate your own route table to your subnets to change this behavior. For more information, see Subnet route tables in the Amazon VPC User Guide.

2. View the current subnets in your VPC.

```
aws ec2 describe-subnets --region $region_code --filters "Name=vpc-id,Values=$vpc_id"
  --query 'Subnets[*].{SubnetId: SubnetId,AvailabilityZone: AvailabilityZone,CidrBlock: CidrBlock}'
  --output table
```

The example output is as follows.

```
| DescribeSubnets |
|-----------------|-----------------|-----------------|
| AvailabilityZone | CidrBlock | SubnetId |
| us-west-2d | 192.168.0.0/27 | subnet-example1 |
| us-west-2a | 192.168.0.32/27 | subnet-example2 |
| us-west-2a | 192.168.0.64/27 | subnet-example3 |
| us-west-2d | 192.168.0.96/27 | subnet-example4 |
| us-west-2a | 192.168.1.0/27 | subnet-example5 |
| us-west-2d | 192.168.1.32/27 | subnet-example6 |
```

You can see the subnets in the `192.168.1.0` CIDR block that you created are in the same Availability Zones as the subnets in the `192.168.0.0` CIDR block.
Step 3: Configure Kubernetes resources

To configure Kubernetes resources

1. Set the `AWS_VPC_K8S_CNI_CUSTOM_NETWORK_CFG` environment variable to `true` in the `aws-node` DaemonSet.

   ```bash
   kubectl set env daemonset aws-node -n kube-system AWS_VPC_K8S_CNI_CUSTOM_NETWORK_CFG=true
   ```

2. Retrieve the ID of your cluster security group (p. 245) and store it in a variable for use in the next step. Amazon EKS automatically creates this security group when you create your cluster.

   ```bash
   cluster_security_group_id=$(aws eks describe-cluster --name $cluster_name --query cluster.resourcesVpcConfig.clusterSecurityGroupId --output text)
   ```

3. Create an ENIConfig custom resource for each subnet that you want to deploy pods in.
   a. Create a unique file for each network interface configuration.

      The following commands create separate ENIConfig files for the two subnets that were created in a previous step. The value for `name` must be unique. The name is the same as the Availability Zone that the subnet is in. The cluster security group is assigned to the ENIConfig.

      ```bash
      cat >$az_1.yaml <<EOF
      apiVersion: crd.k8s.amazonaws.com/v1alpha1
      kind: ENIConfig
      metadata:
        name: $az_1
      spec:
        securityGroups:
        - $cluster_security_group_id
        subnet: $new_subnet_id_1
      EOF
      
      cat >$az_2.yaml <<EOF
      apiVersion: crd.k8s.amazonaws.com/v1alpha1
      kind: ENIConfig
      metadata:
        name: $az_2
      spec:
        securityGroups:
        - $cluster_security_group_id
        subnet: $new_subnet_id_2
      EOF
      ```

   For a production cluster, you can make the following changes to the previous commands:

   - Replace `$cluster_security_group_id` with the ID of an existing security group that you want to use for each ENIConfig.
   - We recommend naming your ENIConfigs the same as the Availability Zone that you'll use the ENIConfig for, whenever possible. You might need to use different names for your ENIConfigs than the names of the Availability Zones for a variety of reasons. For example, if you have more than two subnets in the same Availability Zone and want to use them both with custom networking, then you need multiple ENIConfigs for the same Availability Zone. Since each ENIConfig requires a unique name, you can’t name more than one of your ENIConfigs using the Availability Zone name.
If your ENIConfig names aren't all the same as Availability Zone names, then replace $az_1$ and $az_2$ with your own names in the previous commands and annotate your nodes with the ENIConfig (p. 286) later in this tutorial.

**Note**
If you don't specify a valid security group for use with a production cluster and you're using:

- version 1.8.0 or later of the Amazon VPC CNI plugin for Kubernetes, then the security groups associated with the node's primary elastic network interface are used.
- a version of the Amazon VPC CNI plugin for Kubernetes that's earlier than 1.8.0, then the default security group for the VPC is assigned to secondary network interfaces.

**Important**

- AWS_VPC_K8S_CNI_EXTERNALSNAT=false is a default setting in the configuration for the Amazon VPC CNI plugin for Kubernetes. If you're using the default setting, then traffic that is destined for IP addresses that aren't within one of the CIDR blocks associated with your VPC use the security groups and subnets of your node's primary network interface. The subnets and security groups defined in your ENIConfigs that are used to create secondary network interfaces aren't used for this traffic. For more information about this setting, see SNAT for pods (p. 275).
- If you also use security groups for pods, the security group that's specified in a SecurityGroupPolicy is used instead of the security group that's specified in the ENIConfigs. For more information, see Security groups for pods (p. 292).

b. Apply each custom resource file that you created to your cluster with the following commands.

```bash
kubectl apply -f $az_1.yaml
kubectl apply -f $az_2.yaml
```

4. Confirm that your ENIConfigs were created.

```bash
kubectl get ENIConfigs
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-west-2a</td>
<td>175s</td>
</tr>
<tr>
<td>us-west-2d</td>
<td>105s</td>
</tr>
</tbody>
</table>

5. If you're enabling custom networking on a production cluster and named your ENIConfigs something other than the Availability Zone that you're using them for, then skip to the next step (p. 284) to deploy Amazon EC2 nodes.

Enable Kubernetes to automatically apply the ENIConfig for an Availability Zone to any new Amazon EC2 nodes created in your cluster.

1. For the test cluster in this tutorial, skip to the next step (p. 284).

For a production cluster, check to see if an annotation with the key k8s.amazonaws.com/eniConfig for the ENI_CONFIG_ANNOTATION_DEF environment variable exists in the container spec for the aws-node DaemonSet.
kubectl describe daemonset aws-node -n kube-system | grep ENI_CONFIG_ANNOTATION_DEF

If output is returned, the annotation exists. If no output is returned, then the variable is not set. For a production cluster, you can use either this setting or the setting in the following step. If you use this setting, it overrides the setting in the following step. In this tutorial, the setting in the next step is used.

2. Update your `aws-node` DaemonSet to automatically apply the ENIConfig for an Availability Zone to any new Amazon EC2 nodes created in your cluster.

```bash
kubectl set env daemonset aws-node -n kube-system
ENI_CONFIG_LABEL_DEF=topology.kubernetes.io/zone
```

## Step 4: Deploy Amazon EC2 nodes

To deploy Amazon EC2 nodes

1. Create a node IAM role.
   a. Run the following command to create an IAM trust policy JSON file.

   ```bash
   cat > node-role-trust-relationship.json <<EOF
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Principal": {
   "Service": "ec2.amazonaws.com"
   },
   "Action": "sts:AssumeRole"
   }
   ]
   EOF
   
   b. Run the following command to set a variable for your role name. You can replace `myCustomNetworkingAmazonEKSNodeRole` with any name you choose.

   ```bash
   export node_role_name=myCustomNetworkingAmazonEKSNodeRole
   ```
   c. Create the IAM role and store its returned Amazon Resource Name (ARN) in a variable for use in a later step.

   ```bash
   node_role_arn=$(aws iam create-role --role-name $node_role_name --assume-role-policy-document file://"node-role-trust-relationship.json" \ 
   --query Role.Arn --output text)
   ```
   d. Attach three required IAM managed policies to the IAM role.

   ```bash
   aws iam attach-role-policy \
   --policy-arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy \ 
   --role-name $node_role_name
   aws iam attach-role-policy \
   --policy-arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly \ 
   --role-name $node_role_name
   aws iam attach-role-policy \
   --policy-arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy
   ```
2. Create one of the following types of node groups. To determine the instance type that you want to deploy, see Choosing an Amazon EC2 instance type (p. 162). For this tutorial, complete the Managed, Without a launch template or with a launch template without an AMI ID specified option. If you're going to use the node group for production workloads, then we recommend that you familiarize yourself with all of the managed (p. 101) and self-managed (p. 121) node group options before deploying the node group.

- Managed – Deploy your node group using one of the following options:
  - Without a launch template or with a launch template without an AMI ID specified – Run the following command. For this tutorial, use the example values. For a production node group, replace all example values with your own.

    ```bash
    aws eks create-nodegroup --region $region_code --cluster-name $cluster_name --nodegroup-name my-nodegroup \
    --subnets $subnet_id_1 $subnet_id_2 --instance-types t3.medium --node-role $node_role_arn
    ```

2. In your launch template, specify an Amazon EKS optimized AMI ID, or a custom AMI built off the Amazon EKS optimized AMI, then deploy the node group using a launch template (p. 113) and provide the following user data in the launch template. This user data passes arguments into the bootstrap.sh file. For more information about the bootstrap file, see bootstrap.sh on GitHub. You can replace 20 with either the value from the previous step (recommended) or your own value.

    ```bash
    /etc/eks/bootstrap.sh my-cluster --use-max-pods false --kubelet-extra-args '--max-pods=20'
    ```

If you've created a custom AMI that is not built off the Amazon EKS optimized AMI, then you need to custom create the configuration yourself.

- Self-managed
  1. Determine the Amazon EKS recommended number of maximum pods for your nodes. Follow the instructions in Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 163), adding --cni-custom-networking-enabled to step 3 in that topic. Note the output for use in the next step.

  2. Deploy the node group using the instructions in Launching self-managed Amazon Linux nodes (p. 122). Specify the following text for the BootstrapArguments parameter. You can replace 20 with either the value from the previous step (recommended) or your own value.

    ```bash
    --use-max-pods false --kubelet-extra-args '--max-pods=20'
    ```
Note
If you want nodes in a production cluster to support a significantly higher number of pods, run the script in Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 163) again. Also, add the `--cni-prefix-delegation-enabled` option to the command. For example, 110 is returned for an m5.large instance type. For instructions on how to enable this capability, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 289). You can use this capability with custom networking.

Node group creation takes several minutes. You can check the status of the creation of a managed node group with the following command.

```
aws eks describe-nodegroup --cluster-name $cluster_name --nodegroup-name my-nodegroup
--query nodegroup.status --output text
```

Don't continue to the next step until the output returned is `ACTIVE`.

3. For the tutorial, you can skip this step.

For a production cluster, if you didn't name your ENIConfigs the same as the Availability Zone that you're using them for, then you must annotate your nodes with the ENIConfig name that should be used with the node. This step isn't necessary if you only have one subnet in each Availability Zone and you named your ENIConfigs with the same names as your Availability Zones. This is because the Amazon VPC CNI plugin for Kubernetes automatically associates the correct ENIConfig with the node for you when you enabled it to do so in a previous step (p. 284).

a. Get the list of nodes in your cluster.

```
kubectl get nodes
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip-192-168-0-126.us-west-2.compute.internal.eks-810597c</td>
<td>Ready</td>
<td>&lt;none&gt;</td>
<td>8m49s</td>
<td>v1.22.9-eks-810597c</td>
</tr>
<tr>
<td>ip-192-168-0-92.us-west-2.compute.internal.eks-810597c</td>
<td>Ready</td>
<td>&lt;none&gt;</td>
<td>8m34s</td>
<td>v1.22.9-eks-810597c</td>
</tr>
</tbody>
</table>

b. Determine which Availability Zone each node is in. Run the following command for each node that was returned in the previous step.

```
aws ec2 describe-instances --filters Name=network-interface.private-dns-name,Values=ip-192-168-0-126.us-west-2.compute.internal \ --query 'Reservations[].Instances[].{AvailabilityZone: Placement.AvailabilityZone, SubnetId: SubnetId}'
```

The example output is as follows.

```json
[
  {
    "AvailabilityZone": "us-west-2d",
    "SubnetId": "subnet-Example5"
  }
]
```
c. Annotate each node with the ENIConfig that you created for the subnet ID and Availability Zone. You can only annotate a node with one ENIConfig, though multiple nodes can be annotated with the same ENIConfig. Replace the example values with your own.

<table>
<thead>
<tr>
<th>Command 1</th>
<th>Command 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubectl annotate node ip-192-168-0-126.us-west-2.compute.internal k8s.amazonaws.com/eniConfig=EniConfigName1</td>
<td>kubectl annotate node ip-192-168-0-92.us-west-2.compute.internal k8s.amazonaws.com/eniConfig=EniConfigName2</td>
</tr>
</tbody>
</table>

4. If you had nodes in a production cluster with running pods before you switched to using the custom networking feature, complete the following tasks:

a. Make sure that you have available nodes that are using the custom networking feature.

b. Cordon and drain the nodes to gracefully shut down the pods. For more information, see Safely Drain a Node in the Kubernetes documentation.

c. Terminate the nodes. If the nodes are in an existing managed node group, you can delete the node group. Replace the example values with your own.

   aws eks delete-nodegroup --cluster-name my-cluster --nodegroup-name my-nodegroup

Only new nodes that are registered with the k8s.amazonaws.com/eniConfig label use the custom networking feature.

5. Confirm that pods are assigned an IP address from a CIDR block that's associated to one of the subnets that you created in a previous step.

   kubectl get pods -A -o wide

The example output is as follows.

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

You can see that the coredns pods are assigned IP addresses from the 192.168.1.0 CIDR block that you added to your VPC. Without custom networking, they would have been assigned addresses from the 192.168.0.0 CIDR block, because it was the only CIDR block originally associated with the VPC.

If a pod's spec contains hostNetwork=true, it's assigned the primary IP address of the node. It isn't assigned an address from the subnets that you added. By default, this value is set to false. This value is set to true for the kube-proxy and Amazon VPC CNI plugin for Kubernetes (aws-node) pods that run on your cluster. This is why the kube-proxy and the plugin's aws-node pods aren't assigned 192.168.1.x addresses in the previous output. For more information about a pod's hostNetwork setting, see PodSpec v1 core in the Kubernetes API reference.
Step 5: Delete tutorial resources

After you complete the tutorial, we recommend that you delete the resources that you created. You can then adjust the steps to enable custom networking for a production cluster.

To delete the tutorial resources

1. If the node group that you created was just for testing, then delete it.

   ```
   aws eks delete-nodegroup --region $region_code --cluster-name $cluster_name --nodegroup-name my-nodegroup
   ```

   Even after the AWS CLI output says that the cluster is deleted, the delete process might not actually be complete. The delete process takes a few minutes. Confirm that it's complete by running the following command.

   ```
   aws eks describe-nodegroup --region $region_code --cluster-name $cluster_name --nodegroup-name my-nodegroup --query nodegroup.status --output text
   ```

   Don't continue until the returned output is similar to the following output.

   ```
   An error occurred (ResourceNotFoundException) when calling the DescribeNodegroup operation: No node group found for name: my-nodegroup.
   ```

2. If the node group that you created was just for testing, then delete the node IAM role.

   a. Detach the policies from the role.

      ```
      aws iam detach-role-policy --role-name myCustomNetworkingAmazonEKSNodeRole --policy-arn arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy
      aws iam detach-role-policy --role-name myCustomNetworkingAmazonEKSNodeRole --policy-arn arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly
      aws iam detach-role-policy --role-name myCustomNetworkingAmazonEKSNodeRole --policy-arn arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy
      ```

   b. Delete the role.

      ```
      aws iam delete-role --role-name myCustomNetworkingAmazonEKSNodeRole
      ```

3. Delete the cluster.

   ```
   aws eks delete-cluster --region $region_code --name $cluster_name
   ```

   Confirm the cluster is deleted with the following command.

   ```
   aws eks describe-cluster --region $region_code --name $cluster_name --query cluster.status --output text
   ```

   When output similar to the following is returned, the cluster is successfully deleted.

   ```
   An error occurred (ResourceNotFoundException) when calling the DescribeCluster operation: No cluster found for name: my-cluster.
   ```

4. Delete the cluster IAM role.

   a. Detach the policies from the role.

      ```
      ```

288
Increase the amount of available IP addresses for your Amazon EC2 nodes

By default, the number of IP addresses available to assign to pods is based on the number of IP addresses assigned to Elastic network interfaces, and the number of network interfaces attached to your Amazon EC2 node. You can configure version 1.9.0 or later of the Amazon VPC CNI add-on to assign /28 IPv4 address prefixes. With 1.10.1 or later of the add-on, you can still assign /28 IPv4 address prefixes, but if your cluster is version 1.21 or later, and you've configured it for IPv6 (p. 264), you can assign /80 IPv6 address prefixes instead.

When configured for prefix assignment, the CNI add-on can assign significantly more IP addresses to a network interface than it can when you assign individual IP addresses. The node can then assign significantly more available IP addresses to pods. For more information about the Amazon EC2 capability that enables the add-on to do this, see Assigning prefixes to Amazon EC2 network interfaces in the Amazon EC2 User Guide for Linux Instances.

Without enabling this capability, the add-on must make more Amazon EC2 application programming interface (API) calls to configure the network interfaces and IP addresses necessary for pod connectivity. The frequency of these API calls combined with a high number of network interfaces in each VPC can lead to longer pod and instance launch times as clusters grow to larger sizes. This results in scaling delays to meet the demand of large and spiky workloads, and adds cost and management overhead because you need to provision additional clusters and VPCs to meet scaling requirements. See the Kubernetes scalability thresholds for more information.

Considerations

- AWS Nitro-based nodes use this capability. Instances that aren't Nitro-based continue to allocate individual secondary IP addresses, but have a significantly lower number of IP addresses to assign to pods than Nitro-based instances.
- Once you configure the add-on to assign prefixes to network interfaces, you can't downgrade your Amazon VPC CNI add-on to a version lower than 1.9.0 (or 1.10.1) without removing all nodes in all node groups in your cluster.
- Your VPC must have enough available contiguous /28 IPv4 address blocks to support this capability.
- Each instance type supports a maximum number of pods. If your managed node group consists of multiple instance types, the smallest number of maximum pods for an instance in the cluster is applied to all nodes in the cluster.
Prerequisites

• An existing cluster. To deploy one, see Creating an Amazon EKS cluster (p. 24).

• Version 1.9.0 or later (for version 1.20 or earlier clusters or 1.21 or later clusters configured for IPv4) or 1.10.1 or later (for version 1.21 or later clusters configured for IPv6) of the Amazon VPC CNI plugin for Kubernetes add-on deployed to your cluster.

To increase the amount of available IP addresses for your Amazon EC2 nodes

1. Confirm that your currently-installed Amazon VPC CNI plugin for Kubernetes version is 1.9.0 or 1.10.1 or later.

```bash
kubectl describe daemonset aws-node --namespace kube-system | grep Image | cut -d "/" - f 2
```

The example output is as follows.

```bash
amazon-k8s-cni:v1.10.1-eksbuild.1
```

If your version is earlier than 1.9.0, then you must update it. For more information, see the updating sections of Managing the Amazon VPC CNI plugin for Kubernetes (p. 247).

2. Enable the parameter to assign prefixes to network interfaces for the Amazon VPC CNI DaemonSet. When you deploy a 1.21 or later cluster, version 1.10.1 or later of the Amazon VPC CNI plugin for Kubernetes add-on is deployed with it. If you created the cluster with the IPv6 family, this setting was set to true by default. If you created the cluster with the IPv4 family, this setting was set to false by default.

```bash
kubectl set env daemonset aws-node -n kube-system ENABLE_PREFIX_DELEGATION=true
```

Important

Even if your subnet has free IP addresses, if the subnet does not have any contiguous /28 blocks available, you will see the following error in the Amazon VPC CNI plugin for Kubernetes logs:

```
"failed to allocate a private IP/Prefix address: InsufficientCidrBlocks: The specified subnet does not have enough free cidr blocks to satisfy the request"
```

This can happen due to fragmentation of existing secondary IP addresses spread out across a subnet. To resolve this error, either create a new subnet and launch pods there, or use an Amazon EC2 subnet CIDR reservation to reserve space within a subnet for use with prefix assignment. For more information, see Subnet CIDR reservations in the Amazon VPC User Guide.

3. If you plan to deploy a managed node group without a launch template, or with a launch template that you haven't specified an AMI ID in, and you're using a version of the Amazon VPC CNI plugin for Kubernetes at or later than the versions listed in the prerequisites, then skip to the next step. Managed node groups automatically calculates the maximum number of pods for you.

If you're deploying a self-managed node group or a managed node group with a launch template that you have specified an AMI ID in, then you must determine the Amazon EKS recommend number
of maximum pods for your nodes. Follow the instructions in Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 163), adding --cni-prefix-delegation-enabled to step 3. Note the output for use in a later step.

**Important**
Managed node groups enforces a maximum number on the value of `maxPods`. For instances with less than 30 vCPUs the maximum number is 110 and for all other instances the maximum number is 250. This maximum number is applied whether prefix delegation is enabled or not.

4. If you're using a 1.21 or later cluster configured for IPv6, skip to the next step.

Specify the parameters in one of the following options. To determine which option is right for you and what value to provide for it, see WARM_PREFIX_TARGET, WARM_IP_TARGET, and MINIMUM_IP_TARGET on GitHub.

You can replace the example values with a value greater than zero.

- **WARM_PREFIX_TARGET**

```bash
kubectl set env ds aws-node -n kube-system WARM_PREFIX_TARGET=1
```

- **WARM_IP_TARGET** or **MINIMUM_IP_TARGET** – If either value is set, it overrides any value set for WARM_PREFIX_TARGET.

```bash
kubectl set env ds aws-node -n kube-system WARM_IP_TARGET=5
```

```bash
kubectl set env ds aws-node -n kube-system MINIMUM_IP_TARGET=2
```

5. Create one of the following types of node groups with at least one Amazon EC2 Nitro Amazon Linux 2 instance type. For a list of Nitro instance types, see Instances built on the Nitro System in the Amazon EC2 User Guide for Linux Instances. This capability is not supported on Windows. For the options that include 110, replace it with either the value from step 3 (recommended), or your own value.

- **Self-managed** – Deploy the node group using the instructions in Launching self-managed Amazon Linux nodes (p. 122). Specify the following text for the BootstrapArguments parameter.

```bash
--use-max-pods false --kubelet-extra-args '--max-pods=110'
```

If you're using eksctl to create the node group, you can use the following command.

```bash
eksctl create nodegroup --cluster my-cluster --managed=false --max-pods-per-node 110
```

- **Managed** – Deploy your node group using one of the following options:

  - **Without a launch template or with a launch template without an AMI ID specified** – Complete the procedure in Creating a managed node group (p. 101). Managed node groups automatically calculates the Amazon EKS recommended `max-pods` value for you.

  - **With a launch template with a specified AMI ID** – In your launch template, specify an Amazon EKS optimized AMI ID, or a custom AMI built off the Amazon EKS optimized AMI, then deploy the node group using a launch template (p. 113) and provide the following user data in the launch template. This user data passes arguments into the bootstrap.sh file. For more information about the bootstrap file, see bootstrap.sh on GitHub.

```bash
/etc/eks/bootstrap.sh my-cluster
  --use-max-pods false
```
Use cases

If you're using eksctl to create the node group, you can use the following command.

```
eksctl create nodegroup --cluster my-cluster --max-pods-per-node 110
```

If you've created a custom AMI that is not built off the Amazon EKS optimized AMI, then you need to custom create the configuration yourself.

**Note**
If you also want to assign IP addresses to pods from a different subnet than the instance's, then you need to enable the capability in this step. For more information, see Tutorial: Custom networking (p. 276).

6. Once your nodes are deployed, view the nodes in your cluster.

```
kubectl get nodes
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip-192-168-22-103.region-code.compute.internal</td>
<td>Ready</td>
<td>&lt;none&gt;</td>
<td>19m</td>
<td>v1.20.4-eks-6b7464</td>
</tr>
<tr>
<td>ip-192-168-97-94.region-code.compute.internal</td>
<td>Ready</td>
<td>&lt;none&gt;</td>
<td>19m</td>
<td>v1.20.4-eks-6b7464</td>
</tr>
</tbody>
</table>

7. Describe one of the nodes to determine the max-pods for the node.

```
kubectl describe node node-name ip-192-168-22-103.region-code.compute.internal
```

The example output is as follows.

```
...  
Allocatable: 
  attachable-volumes-aws-ebs: 25
  cpu: 1930m
  ephemeral-storage: 76224326324
  hugepages-1Gi: 0
  hugepages-2Mi: 0
  memory: 7244720Ki
  pods: 110
...
```

In the previous output, 110 is the maximum number of pods that Kubernetes will deploy to the node.

**Security groups for pods**

Security groups for pods integrate Amazon EC2 security groups with Kubernetes pods. You can use Amazon EC2 security groups to define rules that allow inbound and outbound network traffic to and from pods that you deploy to nodes running on many Amazon EC2 instance types and Fargate. For a detailed explanation of this capability, see the Introducing security groups for pods blog post.

**Considerations**

Before deploying security groups for pods, consider the following limits and conditions:
Amazon EKS User Guide
Use cases

- Security groups for pods can’t be used with Windows nodes.
- Security groups for pods can’t be used with clusters configured for the IPv6 family that contain Amazon EC2 nodes. You can however, use security groups for pods with clusters configured for the IPv6 family that contain only Fargate nodes. For more information, see Tutorial: Assigning IPv6 addresses to pods and services (p. 264).
- Security groups for pods are supported by most Nitro-based Amazon EC2 instance families, including the m5, c5, r5, p3, m6g, c6g, and r6g instance families. The t3 instance family is not supported. For a complete list of supported instances, see the limits.go file on Github. Your nodes must be one of the listed instance types that have IsTrunkingCompatible: true in that file.
- If you’re also using pod security policies to restrict access to pod mutation, then the eks-vpc-resource-controller and vpc-resource-controller Kubernetes service accounts must be specified in the Kubernetes ClusterRoleBinding for the role that your psp is assigned to. If you’re using the default Amazon EKS psp, role, and ClusterRoleBinding (p. 495), this is the eks:podsecuritypolicy:authenticated ClusterRoleBinding. For example, you add the service accounts to the subjects: section, as shown in the following example:

```
...
subjects:
  - kind: Group
    apiGroup: rbac.authorization.k8s.io
    name: system:authenticated
  - kind: ServiceAccount
    name: vpc-resource-controller
  - kind: ServiceAccount
    name: eks-vpc-resource-controller
```

- If you’re using custom networking (p. 276) and security groups for pods together, the security group specified by security groups for pods is used instead of the security group specified in the ENIconfig.
- If you’re using version 1.10.2 or earlier of the Amazon VPC CNI plugin and you include the terminationGracePeriodSeconds setting in your pod spec, the value for the setting can’t be zero.
- If you’re using version 1.10 or earlier of the Amazon VPC CNI plugin, or version 1.11 with POD_SECURITY_GROUP_ENFORCING_MODE=strict, which is the default setting, then Kubernetes services of type NodePort and LoadBalancer using instance targets with an externalTrafficPolicy set to Local are not supported with pods that you assign security groups to. For more information about using a load balancer with instance targets, see Network load balancing on Amazon EKS (p. 351). If you’re using version 1.11 or later of the plugin with POD_SECURITY_GROUP_ENFORCING_MODE=standard, then instance targets with an externalTrafficPolicy set to Local are supported.
- If you’re using version 1.10 or earlier of the Amazon VPC CNI plugin or version 1.11 with POD_SECURITY_GROUP_ENFORCING_MODE=strict, which is the default setting, source NAT is disabled for outbound traffic from pods with assigned security groups so that outbound security group rules are applied. To access the internet, pods with assigned security groups must be launched on nodes that are deployed in a private subnet configured with a NAT gateway or instance. Pods with assigned security groups deployed to public subnets are not able to access the internet.

If you’re using version 1.11 or later of the plugin with 
POD_SECURITY_GROUP_ENFORCING_MODE=standard, then pod traffic destined for outside of the VPC is translated to the IP address of the instance's primary network interface. For this traffic, the rules in the security groups for the primary network interface are used, rather than the rules in the pod's security groups.

- To use Calico network policy with pods that have associated security groups, you must use version 1.11.0 or later of the Amazon VPC CNI plugin and set POD_SECURITY_GROUP_ENFORCING_MODE=standard. Otherwise, traffic flow to and from pods with associated security groups are not subjected to Calico network policy (p. 329) enforcement and are limited to Amazon EC2 security group enforcement only. To update your Amazon VPC CNI version, see Managing the Amazon VPC CNI plugin for Kubernetes (p. 247).
• Pods running on Amazon EC2 nodes that use security groups in clusters that use Nodelocal DNSCache are only supported with version 1.11.0 or later of the Amazon VPC CNI plugin and with POD_SECURITY_GROUP_ENFORCING_MODE=standard. To update your Amazon VPC CNI plugin version, see Managing the Amazon VPC CNI plugin for Kubernetes (p. 247).

• Security groups for pods might lead to higher pod startup latency for pods with high churn. This is due to rate limiting in the resource controller.

Configure the Amazon VPC CNI add-on for security groups for pods

To deploy security groups for pods

If you’re using security groups for Fargate pods only, and don’t have any Amazon EC2 nodes in your cluster, skip to Deploy an example application (p. 298).

1. Check your current CNI plugin version with the following command:

```bash
kubectl describe daemonset aws-node --namespace kube-system | grep Image | cut -d "/" -f 2
```

The example output is as follows.

```
amazon-k8s-cni-init:1.7.5-eksbuild.1
amazon-k8s-cni:1.7.5-eksbuild.1
```

If your CNI plugin version is earlier than 1.7.7, then update your CNI plugin to version 1.7.7 or later. For more information, see Updating the Amazon VPC CNI plugin for Kubernetes add-on (p. 250).

2. Add the AmazonEKSVPCResourceController managed policy to the cluster role (p. 461) that is associated with your Amazon EKS cluster. The policy allows the role to manage network interfaces, their private IP addresses, and their attachment and detachment to and from network instances.

   a. Determine the ARN of your cluster IAM role. Replace `my-cluster` with the name of your cluster.

   ```bash
   aws eks describe-cluster --name my-cluster --query cluster.roleArn --output text
   ```

   The example output is as follows.

   ```
arnc:aws:iam::111122223333:role/eksClusterRole
   ```

   b. The following command adds the policy to a cluster role named `eksClusterRole`. Replace `eksClusterRole` with the name of your role.

   ```bash
   aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonEKSVPCResourceController
   --role-name eksClusterRole
   ```

3. Enable the Amazon VPC CNI add-on to manage network interfaces for pods by setting the ENABLE_POD_ENI variable to true in the aws-node DaemonSet. Once this setting is set to true, for each node in the cluster the add-on adds a label with the value vpc.amazonaws.com/has-trunk-attached=true. The VPC resource controller creates and attaches one special network interface called a `trunk network interface` with the description aws-k8s-trunk-eni.

   ```bash
   kubectl set env daemonset aws-node -n kube-system ENABLE_POD_ENI=true
   ```
Note
The trunk network interface is included in the maximum number of network interfaces supported by the instance type. For a list of the maximum number of network interfaces supported by each instance type, see IP addresses per network interface per instance type in the Amazon EC2 User Guide for Linux Instances. If your node already has the maximum number of standard network interfaces attached to it then the VPC resource controller will reserve a space. You will have to scale down your running pods enough for the controller to detach and delete a standard network interface, create the trunk network interface, and attach it to the instance.

You can see which of your nodes have aws-k8s-trunk-eni set to true with the following command. If No resources found is returned, then wait several seconds and try again. The previous step requires restarting the CNI pods, which takes several seconds.

```
kubectl get nodes -o wide -l vpc.amazonaws.com/has-trunk-attached=true
```

Once the trunk network interface is created, pods are assigned secondary IP addresses from the trunk or standard network interfaces. The trunk interface is automatically deleted if the node is deleted.

When you deploy a security group for a pod in a later step, the VPC resource controller creates a special network interface called a branch network interface with a description of aws-k8s-branch-eni and associates the security groups to it. Branch network interfaces are created in addition to the standard and trunk network interfaces attached to the node. If you are using liveness or readiness probes, then you also need to disable TCP early demux, so that the kubelet can connect to pods on branch network interfaces using TCP. To disable TCP early demux, run the following command:

```
kubectl patch daemonset aws-node \
  -n kube-system \
  -p '{"spec": {"template": {"spec": {"initContainers": [{"env": [{"name":"DISABLE_TCP_EARLY_DEMUX","value":"true"}],"name":"aws-vpc-cni-init"}]}}}}'}
```

Note
If you're using 1.11.0 or later of the Amazon VPC CNI plugin for Kubernetes add-on and set POD_SECURITY_GROUP_ENFORCING_MODE=standard, as described in the next step, then you don't need to run the previous command.

4. If your cluster uses NodeLocal DNSCache, or you want to use Calico network policy with your pods that have their own security groups, or you have Kubernetes services of type NodePort and LoadBalancer using instance targets with an externalTrafficPolicy set to Local for pods that you want to assign security groups to, then you must be using version 1.11.0 or later of the Amazon VPC CNI plugin for Kubernetes add-on, and you must enable the following setting:

```
kubectl set env daemonset aws-node -n kube-system 
POD_SECURITY_GROUP_ENFORCING_MODE=standard
```

Important
- Pod security group rules aren't applied to traffic between pods or between pods and services, such as kubelet or nodeLocalDNS, that are on the same node.
- Outbound traffic from pods to addresses outside of the VPC is network address translated to the IP address of the instance's primary network interface (unless you've also set AWS_VPC_K8S_CNI_EXTERNALSNAT=true). For this traffic, the rules in the security groups for the primary network interface are used, rather than the rules in the pod's security groups.
• For this setting to apply to existing pods, you must restart the pods or the nodes that the pods are running on.

5. Create a namespace to deploy resources to.

```bash
kubectl create namespace my-namespace
```

6. Deploy an Amazon EKS SecurityGroupPolicy to your cluster.

   a. Save the following example security policy to a file named `my-security-group-policy.yaml`. You can replace `podSelector` with `serviceAccountSelector` if you’d rather select pods based on service account labels. You must specify one selector or the other. An empty `podSelector` (example: `podSelector: {}`) selects all pods in the namespace. An empty `serviceAccountSelector` selects all service accounts in the namespace. You must specify 1-5 security group IDs for `groupIds`. If you specify more than one ID, then the combination of all the rules in all the security groups are effective for the selected pods.

```yaml
apiVersion: vpcresources.k8s.aws/v1beta1
kind: SecurityGroupPolicy
metadata:
  name: my-security-group-policy
  namespace: my-namespace
spec:
  podSelector:
    matchLabels:
      role: my-role
  securityGroups:
    groupIds:
    - sg-abc123
```

**Important**

• The security groups that you specify in the policy must exist. If they don’t exist, then, when you deploy a pod that matches the selector, your pod remains stuck in the creation process. If you describe the pod, you’ll see an error message similar to the following one: An error occurred (InvalidSecurityGroupID.NotFound) when calling the CreateNetworkInterface operation: The securityGroup ID 'sg-abc123' does not exist.

• The security group must allow inbound communication from the cluster security group (for `kubelet`) over any ports you’ve configured probes for.

• The security group must allow outbound communication to a security group that allows inbound TCP and UDP port 53 (for CoreDNS pods) from it.

• If you’re using the security group policy with Fargate, make sure that your security group has rules that allow the pods to communicate with the Kubernetes control plane. The easiest way to do this is to specify the cluster security group as one of the security groups.

• Security group policies only apply to newly scheduled pods. They do not affect running pods.

   b. Deploy the policy.

```bash
kubectl apply -f my-security-group-policy.yaml
```

7. Deploy a sample application with a label that matches the `my-role` value for `podselector` that you specified in the previous step.

   a. Save the following contents to a file.
Use cases

```yaml
apiVersion: apps/v1
type: Deployment
metadata:
  name: my-deployment
  namespace: my-namespace
  labels:
    app: my-app
spec:
  replicas: 1
  selector:
    matchLabels:
      app: my-app
  template:
    metadata:
      labels:
        app: my-app
        role: my-role
    spec:
      containers:
      - name: my-container
        image: my-image
        ports:
          - containerPort: 80
```

b. Deploy the application with the following command. When you deploy the application, the Amazon VPC CNI plugin for Kubernetes matches the role label and the security groups that you specified in the previous step are applied to the pod.

```
kubectl apply -f my-security-group-policy.yaml
```

**Note**

- If your pod is stuck in the Waiting state and you see Insufficient permissions: Unable to create Elastic Network Interface. when you describe the pod, confirm that you added the IAM policy to the IAM cluster role in a previous step.

- If your pod is stuck in the Pending state, confirm that your node instance type has IsTrunkingCompatible: true in limits.go on Github and that the maximum number of branch network interfaces supported by the instance type multiplied times the number of nodes in your node group hasn't already been met. For example, an m5.large instance supports nine branch network interfaces. If your node group has five nodes, then a maximum of 45 branch network interfaces can be created for the node group. The 46th pod that you attempt to deploy will sit in Pending state until another pod that has associated security groups is deleted.

If you run kubectl describe pod my-deployment-xxxxxxxxxx-xxxxx -n my-namespace and see a message similar to the following message, then it can be safely ignored. This message might appear when the CNI plugin tries to set up host networking and fails while the network interface is being created. The Amazon VPC CNI plugin for Kubernetes logs this event until the network interface is created.

```
Failed to create pod sandbox: rpc error: code = Unknown desc = failed to set up sandbox container 
"e24268322e55c818b572f52df6493684f6c2c3bf4d59c9c121fd4cda493f" network for pod 
"my-deployment-59f5f68b58-c89wx" networkPlugin cni failed to set up pod 
"my-deployment-59f5f68b58-c89wx_my-namespace" network: add cmd: failed to assign an IP address to container
```
You cannot exceed the maximum number of pods that can be run on the instance type. For a list of the maximum number of pods that you can run on each instance type, see eni-max-pods.txt on GitHub. When you delete a pod that has associated security groups, or delete the node that the pod is running on, the VPC resource controller deletes the branch network interface. If you delete a cluster with pods using pods for security groups, then the controller does not delete the branch network interfaces, so you'll need to delete them yourself.

**Deploy an example application**

To use security groups for pods, you must have an existing security group and Deploy an Amazon EKS SecurityGroupPolicy (p. 299) to your cluster, as described in the following procedure. The following steps show you how to use the security group policy for a pod. Unless otherwise noted, complete all steps from the same terminal because variables are used in the following steps that don't persist across terminals.

**To deploy an example pod with a security group**

1. Create a security group to use with your pod. The steps that follow help you create a simple security group for illustrative purposes only. In a production cluster, your rules will likely be different.
   a. Retrieve the IDs of your cluster's VPC and cluster security group. Replace `my-cluster` with the name of your cluster.

   ```bash
   my_cluster_name=my-cluster
   my_cluster_vpc_id=$(aws eks describe-cluster
   --name $my_cluster_name
   --query cluster.resourcesVpcConfig.vpcId
   --output text)
   my_cluster_security_group_id=$(aws eks describe-cluster
   --name $my_cluster_name
   --query cluster.resourcesVpcConfig.clusterSecurityGroupId
   --output text)
   ```
   b. Create the security group for your pod. Replace `my-pod-security-group` with your own. Note the ID of the security group returned in the output after running the commands. You'll use it in a later step.

   ```bash
   my_pod_security_group_name=my-pod-security-group
   aws ec2 create-security-group
   --vpc-id $my_cluster_vpc_id
   --group-name $my_pod_security_group_name
   --description "My pod security group"
   my_pod_security_group_id=$(aws ec2 describe-security-groups
   --filters Name=group-name,Values=$my_pod_security_group_name
   --query 'SecurityGroups[].GroupId'
   --output text)
   echo $my_pod_security_group_id
   ```
   c. Allow TCP and UDP port 53 traffic from the pod security group that you created in the previous step to your cluster security group. If you want the DNS traffic from your pod to flow to a different security group than your cluster security group, then replace `my_cluster_security_group_id` with your own security group ID. Note the value returned for SecurityGroupRuleId in the output returned for each of the commands. You'll use them in a later step.

   ```bash
   aws ec2 authorize-security-group-ingress
   --group-id $my_cluster_security_group_id
   --protocol tcp --port 53 --source-group $my_pod_security_group_id
   ```
Use cases

AWS EC2 authorize-security-group-ingress
  --group-id $my_cluster_security_group_id
  --protocol udp --port 53 --source-group $my_pod_security_group_id

**d.** Allow inbound traffic to your pod security group from any pod the security group is associated to over any protocol and port. The security group has a default outbound rule that allows outbound traffic from the pods that your security group is associated with to any destination over any protocol and port.

AWS EC2 authorize-security-group-ingress
  --group-id $my_pod_security_group_id
  --protocol -1 --port -1 --source-group $my_pod_security_group_id

2. Create a Kubernetes namespace to deploy resources to.

```
kubectl create namespace my-namespace
```

3. Deploy an Amazon EKS SecurityGroupPolicy to your cluster.

**a.** Save the following example security policy to a file named `my-security-group-policy.yaml`. You can replace `podSelector` with `serviceAccountSelector` if you'd rather select pods based on service account labels. You must specify one selector or the other. An empty `podSelector` (example: `podSelector: {}`) selects all pods in the namespace. An empty `serviceAccountSelector` selects all service accounts in the namespace. You must specify 1-5 security group IDs for `groupIds`. If you specify more than one ID, then the combination of all the rules in all the security groups are effective for the selected pods. Replace `sg-05b1d815d1EXAMPLE` with the ID of the security group that you noted in a previous step when you created the security group for your pod.

```
apiVersion: vpcresources.k8s.aws/v1beta1
kind: SecurityGroupPolicy
metadata:
  name: my-security-group-policy
  namespace: my-namespace
spec:
  podSelector:
    matchLabels:
      role: my-role
  securityGroups:
    groupIds:
    - sg-05b1d815d1EXAMPLE
```

**Important**

The security group or groups that you specify for your pods must meet the following criteria:

- They must exist. If they don't exist, then, when you deploy a pod that matches the selector, your pod remains stuck in the creation process. If you describe the pod, you'll see an error message similar to the following one: An error occurred (InvalidSecurityGroupId.NotFound) when calling the CreateNetworkInterface operation: The securityGroupId 'sg-05b1d815d1EXAMPLE' does not exist.
- They must allow inbound communication from the cluster security group (p. 245) (for kubelet) over any ports that you've configured probes for.
- They must allow outbound communication over TCP and UDP ports 53 to a security group assigned to pods running CoreDNS. The security group for your CoreDNS pods must allow inbound TCP and UDP port 53 traffic from your security group.
They must have necessary inbound and outbound rules to communicate with other pods that they need to communicate with.

They must have rules that allow the pods to communicate with the Kubernetes control plane if you're using the security group with Fargate. The easiest way to do this is to specify the cluster security group as one of the security groups.

Security group policies only apply to newly scheduled pods. They do not affect running pods.

b. Deploy the policy.

```bash
kubectl apply -f my-security-group-policy.yaml
```

4. Deploy a sample application with a label that matches the `my-role` value for `podSelector` that you specified in the previous step.

a. Save the following contents to a file named `sample-application.yaml`.

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: my-deployment
  namespace: my-namespace
  labels:
    app: my-app
spec:
  replicas: 4
  selector:
    matchLabels:
      app: my-app
  template:
    metadata:
      labels:
        app: my-app
        role: my-role
    spec:
      terminationGracePeriodSeconds: 120
    containers:
      - name: nginx
        image: public.ecr.aws/nginx/nginx:1.21
        ports:
          - containerPort: 80

---
apiVersion: v1
kind: Service
metadata:
  name: my-app
  namespace: my-namespace
  labels:
    app: my-app
spec:
  selector:
    app: my-app
    role: my-role
  ports:
    - protocol: TCP
      port: 80
      targetPort: 80
```

b. Deploy the application with the following command. When you deploy the application, the Amazon VPC CNI plugin for Kubernetes matches the `role` label and the security groups that you specified in the previous step are applied to the pod.
Amazon EKS User Guide

Use cases

```
kubectl apply -f sample-application.yaml
```

**Note**

- If your pod is stuck in the **Waiting** state and you see **Insufficient permissions**: Unable to create Elastic Network Interface. when you describe the pod, confirm that you added the IAM policy to the IAM cluster role in a previous step.

- If your pod is stuck in the **Pending** state, confirm that your node instance type is listed in `limits.go` and that the maximum number of branch network interfaces supported by the instance type multiplied times the number of nodes in your node group hasn’t already been met. For example, an `m5.large` instance supports nine branch network interfaces. If your node group has five nodes, then a maximum of 45 branch network interfaces can be created for the node group. The 46th pod that you attempt to deploy will sit in **Pending** state until another pod that has associated security groups is deleted.

If you run `kubectl describe pod my-deployment-xxxxxxxxxx-xxxxx -n my-namespace` and see a message similar to the following message, then it can be safely ignored. This message might appear when the CNI plugin tries to set up host networking and fails while the network interface is being created. The CNI plugin logs this event until the network interface is created.

```
Failed to create pod sandbox: rpc error: code = Unknown desc = failed to set up sandbox container "e24268322e55c8185721f52df6f6493684f6c2c3bf4fd59c9c121fd4cd894579f" network for pod "my-deployment-5df6f7687b-4fbjm": networkPlugin cni failed to set up pod "my-deployment-5df6f7687b-4fbjm-c89wx_my-namespace" network: add cmd: failed to assign an IP address to container
```

You can’t exceed the maximum number of pods that can be run on the instance type. For a list of the maximum number of pods that you can run on each instance type, see `eni-max-pods.txt` on GitHub. When you delete a pod that has associated security groups, or delete the node that the pod is running on, the VPC resource controller deletes the branch network interface. If you delete a cluster with pods using pods for security groups, then the controller does not delete the branch network interfaces, so you’ll need to delete them yourself.

5. View the pods deployed with the sample application. For the remainder of this topic, this terminal is referred to as **TerminalA**.

```
kubectl get pods -n my-namespace -o wide
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
<th>IP</th>
<th>NODE</th>
<th>NOMINATED NODE</th>
<th>READINESS GATES</th>
</tr>
</thead>
<tbody>
<tr>

<td>7m51s</td>
<td>192.168.63.27</td>
<td>ip-192-168-33-28.region-code.compute.internal</td>
<td>&lt;none&gt;</td>
<td></td>
</tr>
<tr>
<td>ip-192-168-33-28.region-code.compute.internal</td>
<td>&lt;none&gt;</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
6. In a separate terminal, shell into one of the pods. For the remainder of this topic, this terminal is referred to as TerminalB. Replace `5df6f7687b-4fbjm` with the ID of one of the pods returned in your output from the previous step.

   ```
kubectl exec -it -n my-namespace my-deployment-5df6f7687b-4fbjm -- /bin/bash
   ```

7. From the shell in TerminalB, confirm that the sample application works.

   ```
curl my-app
   ```

   The example output is as follows.

   ```
   <!DOCTYPE html>
   <html>
   <head>
   <title>Welcome to nginx!</title>
   ...
   You received the output because all pods running the application are associated with the security group that you created. That group contains a rule that allows all traffic between all pods that the security group is associated to. DNS traffic is allowed outbound from that security group to the cluster security group, which is associated with your nodes. The nodes are running the CoreDNS pods, which your pods did a name lookup to.

8. From TerminalA, remove the security group rules that allow DNS communication to the cluster security group from your security group. If you didn't add the DNS rules to the cluster security group in a previous step, then replace `$my_cluster_security_group_id` with the ID of the security group that you created the rules in. Replace `sgr-0407e21efdEXAMPLE` and `sgr-04dedf9701EXAMPLE` with the IDs of the security group rules that you noted in a previous step.

   ```
aws ec2 revoke-security-group-ingress --group-id $my_cluster_security_group_id --security-group-rule-ids sgr-0407e21efdEXAMPLE
aws ec2 revoke-security-group-ingress --group-id $my_cluster_security_group_id --security-group-rule-ids sgr-04dedf9701EXAMPLE
   ```

9. From TerminalB, attempt to access the application again.

   ```
curl my-app
   ```

   The attempt fails because the pod is no longer able to access the CoreDNS pods, which have the cluster security group associated to them. The cluster security group no longer has the security group rules that allow DNS communication from the security group associated to your pod.

   If you attempt to access the application using the IP addresses returned for one of the pods in a previous step, you still receive a response because all ports are allowed between pods that have the security group associated to them and a name lookup isn't required.

10. Once you've finished experimenting, you can remove the sample security group policy, application, and security group that you created with the following commands.

    ```
kubectl delete namespace my-namespace
aws ec2 delete-security-group --group-id $my_pod_security_group_id
   ```
Multiple network interfaces for pods

Multus CNI is a container network interface (CNI) plugin for Amazon EKS that enables attaching multiple network interfaces to a pod. For more information, see the Multus-CNI documentation on GitHub.

In Amazon EKS, each pod has one network interface assigned by the Amazon VPC CNI plugin. With Multus, you can create a multi-homed pod that has multiple interfaces. This is accomplished by Multus acting as a "meta-plugin"; a CNI plugin that can call multiple other CNI plugins. AWS support for Multus comes configured with the Amazon VPC CNI plugin as the default delegate plugin.

Considerations

- Amazon EKS won't be building and publishing single root I/O virtualization (SR-IOV) and Data Plane Development Kit (DPDK) CNI plugins. However, you can achieve packet acceleration by connecting directly to Amazon EC2 Elastic Network Adapters (ENA) through Multus managed host-device and ipvlan plugins.
- Amazon EKS is supporting Multus, which provides a generic process that enables simple chaining of additional CNI plugins. Multus and the process of chaining is supported, but AWS won't provide support for all compatible CNI plugins that can be chained, or issues that may arise in those CNI plugins that are unrelated to the chaining configuration.
- Amazon EKS is providing support and life cycle management for the Multus plugin, but isn't responsible for any IP address or additional management associated with the additional network interfaces. The IP address and management of the default network interface utilizing the Amazon VPC CNI plugin remains unchanged.
- Only the Amazon VPC CNI plugin is officially supported as the default delegate plugin. You need to modify the published Multus installation manifest to reconfigure the default delegate plugin to an alternate CNI if you choose not to use the Amazon VPC CNI plugin for primary networking.
- Multus is only supported when using the Amazon VPC CNI as the primary CNI. We do not support the Amazon VPC CNI when used for higher order interfaces, secondary or otherwise.
- To prevent the Amazon VPC CNI plugin from trying to manage additional network interfaces assigned to pods, add the following tag to the network interface:

```
key: node.k8s.amazonaws.com/no_manage
value: true
```
- Multus is compatible with network policies, but the policy has to be enriched to include ports and IP addresses that may be part of additional network interfaces attached to pods.

For an implementation walk through, see the Multus Setup Guide on GitHub.

Metrics helper

The CNI metrics helper is a tool that you can use to scrape network interface and IP address information, aggregate metrics at the cluster level, and publish the metrics to Amazon CloudWatch. To learn more about the metrics helper, see cni-metrics-helper on GitHub.

When managing an Amazon EKS cluster, you may want to know how many IP addresses have been assigned and how many are available. The CNI metrics helper helps you to:

- Track these metrics over time
- Troubleshoot and diagnose issues related to IP assignment and reclamation
- Provide insights for capacity planning
When a node is provisioned, the CNI plugin automatically allocates a pool of secondary IP addresses from the node’s subnet to the primary network interface (eth0). This pool of IP addresses is known as the warm pool, and its size is determined by the node’s instance type. For example, a `c4.large` instance can support three network interfaces and nine IP addresses per interface. The number of IP addresses available for a given pod is one less than the maximum (of ten) because one of the IP addresses is reserved for the elastic network interface itself. For more information, see IP Addresses Per Network Interface Per Instance Type in the Amazon EC2 User Guide for Linux Instances.

As the pool of IP addresses is depleted, the plugin automatically attaches another elastic network interface to the instance and allocates another set of secondary IP addresses to that interface. This process continues until the node can no longer support additional elastic network interfaces.

The following metrics are collected for your cluster and exported to CloudWatch:

- The maximum number of network interfaces that the cluster can support
- The number of network interfaces have been allocated to pods
- The number of IP addresses currently assigned to pods
- The total and maximum numbers of IP addresses available
- The number of ipamD errors

**Prerequisites**

- An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Creating an IAM OIDC provider for your cluster (p. 426).
- Version 2.7.32 or later or 1.25.72 or later of the AWS CLI installed and configured on your device or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with `aws configure` in the AWS Command Line Interface User Guide.
- The `kubectl` command line tool is installed on your device or AWS CloudShell. The version can be the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For example, if your cluster version is 1.22, you can use `kubectl` version 1.21.1.22, or 1.23 with it. To install or upgrade `kubectl`, see Installing or updating `kubectl` (p. 4).
- If your cluster is 1.21 or later, make sure that your Amazon VPC CNI plugin for Kubernetes, `kube-proxy`, and CoreDNS add-ons are at the minimum versions listed in Service account tokens (p. 424).

**Deploy the CNI metrics helper**

Create an IAM policy and role and deploy the metrics helper.

**To deploy the CNI metrics helper**

1. Create an IAM policy that grants the CNI metrics helper `cloudwatch:PutMetricData` permissions to send metric data to CloudWatch.
   a. Run the following command to create a file named `cni-metrics-helper-policy.json`.

```
cat >cni-metrics-helper-policy.json <<EOF
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
            "cloudwatch:PutMetricData"
            ],
```
b. Create an IAM policy named `AmazonEKSVPCCNIMetricsHelperPolicy`.

```bash
aws iam create-policy --policy-name AmazonEKSVPCCNIMetricsHelperPolicy \
--description "Grants permission to write metrics to CloudWatch" \
--policy-document file://cni-metrics-helper-policy.json
```

2. Create an IAM role and attach the IAM policy to it. Create a Kubernetes service account. Annotate the Kubernetes service account with the IAM role ARN and the IAM role with the Kubernetes service account name. You can create the role using `eksctl` or the AWS CLI.

**eksctl**

Run the following command to create the IAM role. Replace `my-cluster` with your cluster name, `111122223333` with your account ID, and `region-code` with the AWS Region that your cluster is in.

```bash
eksctl create iamserviceaccount \
--name cni-metrics-helper \
--namespace kube-system \
--cluster my-cluster \
--role-name "AmazonEKSVPCCNIMetricsHelperRole" \
--attach-policy-arn arn:aws:iam::111122223333:policy/AmazonEKSVPCCNIMetricsHelperPolicy \
--approve
```

**AWS CLI**

1. Determine your cluster’s OIDC provider URL. Replace `my-cluster` with your cluster name. If the output from the command is `None`, review the Prerequisites.

```bash
aws eks describe-cluster --name my-cluster --query "cluster.identity.oidc.issuer" --output text
```

The example output is as follows.

```bash
oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE
```

2. Create the IAM role, granting the Kubernetes service account the `AssumeRoleWithWebIdentity` action.

   a. Copy the following contents to your device. Replace `111122223333` with your account ID. Replace `EXAMPLED539D4633E53DE1B71EXAMPLE` and `region-code` with the values returned in the previous step. After replacing the values, run the command to create a file named `trust-policy.json`.

   ```bash
cat >trust-policy.json <<EOF
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Principal": {
   "Federated": "arn:aws:iam::111122223333:oidc-provider/oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE"
   }
   }
   ]
   EOF
   ```
b. Create the role.

```
aws iam create-role \
  --role-name AmazonEKSVPCCNIMetricsHelperRole \
  --assume-role-policy-document file://"trust-policy.json"
```

3. Attach the IAM policy to the role. Replace 111122223333 with your account ID.

```
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::111122223333:policy/AmazonEKSVPCCNIMetricsHelperPolicy \
  --role-name AmazonEKSVPCCNIMetricsHelperRole
```

3. Use the following command for the AWS Region that your cluster is in to add the recommended version of the CNI metrics helper to your cluster.

**Important**
You should only update one minor version at a time. For example, if your current minor version is 1.9 and you want to update to 1.11, you should update to 1.10 first, then update to 1.11 by changing the version number in one of the following commands.
The recommended and latest version work with all Amazon EKS supported Kubernetes versions.

AWS GovCloud (US-East) (us-gov-east-1)

```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.11.3/config/master/cni-metrics-helper-us-gov-east-1.yaml
```

AWS GovCloud (US-West) (us-gov-west-1)

```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.11.3/config/master/cni-metrics-helper-us-gov-west-1.yaml
```

All other AWS Regions

1. Download the manifest file.

```
```

2. If your cluster isn't in us-west-2, then replace region-code in the following command with the AWS Region that your cluster is in and then run the modified command to replace us-west-2 in the file with your AWS Region.
3. If your cluster isn't in us-west-2, then replace 602401143452 in the following command with the account from Amazon container image registries (p. 365) for the AWS Region that your cluster is in and then run the modified command to replace 602401143452 in the file.

```
sed -i.bak -e 's/us-west-2/region-code/' cni-metrics-helper.yaml
```

4. Apply the manifest file to your cluster.

```
kubectl apply -f cni-metrics-helper.yaml
```

4. Annotate the cni-metrics-helper Kubernetes service account created in a previous step with the ARN of the IAM role that you created previously. Replace 111122223333 with your account ID, my-cluster with your cluster name, and AmazonEKSVPCCNIMetricsHelperRole with the name of the IAM role that you created in a previous step.

```
kubectl annotate serviceaccount cni-metrics-helper \
  -n kube-system \
  eks.amazonaws.com/role-arn=arn:aws:iam::111122223333:role/AmazonEKSVPCCNIMetricsHelperRole
```

5. (Optional) Configure the AWS Security Token Service endpoint type used by your Kubernetes service account. For more information, see Configuring the AWS Security Token Service endpoint for a service account (p. 434).

6. Restart the cni-metrics-helper deployment.

```
kubectl rollout restart \
  deployment cni-metrics-helper \
  -n kube-system
```

### Creating a metrics dashboard

After you have deployed the CNI metrics helper, you can view the CNI metrics in the CloudWatch console. This topic helps you to create a dashboard for viewing your cluster’s CNI metrics.

**To create a CNI metrics dashboard**

2. In the left navigation pane, choose Metrics and then select All metrics.
3. Under Custom Namespaces, select Kubernetes.
4. Select CLUSTER_ID.
5. On the Metrics tab, select the metrics you want to add to the dashboard.
6. At the upper right of the console, select Actions, and then Add to dashboard.
7. In the Select a dashboard section, select Create new, enter a name for your dashboard, such as EKS-CNI-metrics, and then select Create.
8. In the Widget type section, select Number.
9. In the Customize widget title section, enter a logical name for your dashboard title, such as EKS CNI metrics.
10. Select Add to dashboard to finish. Now your CNI metrics are added to a dashboard that you can monitor.
Alternate compatible CNI plugins

Amazon EKS only officially supports the Amazon VPC CNI plugin for Kubernetes (p. 247). Amazon EKS runs upstream Kubernetes and is certified Kubernetes however, so you can install alternate CNI plugins to Amazon EC2 nodes in your cluster. Your cluster will fail to install an alternate CNI plugin to Fargate nodes, if you have them in your cluster. The Amazon VPC CNI plugin for Amazon EKS is already on your Fargate nodes, but it's the only plugin that you can use with Fargate nodes. If you plan to use an alternate CNI plugin in production, then we strongly recommend that you either obtain commercial support, or have the in-house expertise to troubleshoot and contribute fixes to the open source CNI plugin project.

Amazon EKS maintains relationships with a network of partners that offer support for alternate compatible CNI plugins. See the following partners' documentation for details on supported Kubernetes versions and qualifications and testing performed.

<table>
<thead>
<tr>
<th>Partner</th>
<th>Product</th>
<th>Documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tigera</td>

</tbody>
</table>

Amazon EKS aims to give you a wide selection of options to cover all use cases. If you develop a commercially supported Kubernetes CNI plugin that is not listed here, then please contact our partner team at aws-container-partners@amazon.com for more information.

Installing the AWS Load Balancer Controller add-on

The AWS Load Balancer Controller manages AWS Elastic Load Balancers for a Kubernetes cluster. The controller provisions the following resources:

- An AWS Application Load Balancer (ALB) when you create a Kubernetes Ingress.
- An AWS Network Load Balancer (NLB) when you create a Kubernetes service of type LoadBalancer. In the past, the Kubernetes network load balancer was used for instance targets, but the AWS Load
balancer Controller was used for IP targets. With the AWS Load Balancer Controller version 2.3.0 or later, you can create NLBs using either target type. For more information about NLB target types, see Target type in the User Guide for Network Load Balancers.

The AWS Load Balancer Controller controller was formerly named the AWS ALB Ingress Controller. It’s an open-source project managed on GitHub. This topic describes how to install the controller using default options. You can view the full documentation for the controller on GitHub. Before deploying the controller, we recommend that you review the prerequisites and considerations in Application load balancing on Amazon EKS (p. 357) and Network load balancing on Amazon EKS (p. 351). Those topics also include steps on how to deploy a sample application that require the AWS Load Balancer Controller to provision AWS Application Load Balancers and Network Load Balancers.

**Prerequisites**

- An existing Amazon EKS cluster. To deploy one, see Getting started with Amazon EKS (p. 4).
- An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Creating an IAM OIDC provider for your cluster (p. 426).
- If your cluster is 1.21 or later, make sure that your Amazon VPC CNI plugin for Kubernetes, kube-proxy, and CoreDNS add-ons are at the minimum versions listed in Service account tokens (p. 424).

**To deploy the AWS Load Balancer Controller to an Amazon EKS cluster**

In the following steps, replace the example values with your own values.

1. Create an IAM policy.
   a. Download an IAM policy for the AWS Load Balancer Controller that allows it to make calls to AWS APIs on your behalf.
      - AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions
        ```bash
        ```
      - All other AWS Regions
        ```bash
        curl -o iam_policy.json https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.4.3/docs/install/iam_policy.json
        ```
   b. Create an IAM policy using the policy downloaded in the previous step. If you downloaded iam_policy_us-gov.json, change iam_policy.json to iam_policy_us-gov.json before running the command.
      ```bash
      aws iam create-policy \
      --policy-name AWSLoadBalancerControllerIAMPolicy \
      --policy-document file://iam_policy.json
      ```

   **Note**
   If you view the policy in the AWS Management Console, you may see warnings for ELB. These can be safely ignored because some of the actions only exist for ELB v2. You do not see warnings for ELB v2.

2. Create an IAM role. Create a Kubernetes service account named aws-load-balancer-controller in the kube-system namespace for the AWS Load Balancer Controller and annotate the Kubernetes service account with the name of the IAM role.
You can use `eksctl` or the AWS CLI and `kubectl` to create the IAM role and Kubernetes service account.

**`eksctl`**

Replace `my-cluster` with the name of your cluster, `111122223333` with your account ID, and then run the command. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

```
eksctl create iamserviceaccount \
  --cluster=my-cluster \
  --namespace=kube-system \
  --name=aws-load-balancer-controller \
  --role-name "AmazonEKSLoadBalancerControllerRole" \
  --attach-policy-arn=arn:aws:iam::111122223333:policy/AWSLoadBalancerControllerIAMPolicy \
  --approve
```

**AWS CLI and `kubectl`**

**Using the AWS CLI and `kubectl`**

a. View your cluster's OIDC provider URL.

```
aws eks describe-cluster --name my-cluster --query "cluster.identity.oidc.issuer" --output text
```

The example output is as follows.

```
oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE
```

If no output is returned, then you must create an IAM OIDC provider for your cluster (p. 426).

b. Copy the following contents to your device. Replace `111122223333` with your account ID. Replace `EXAMPLED539D4633E53DE1B71EXAMPLE` with the output returned in the previous step. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`. After replacing the text, run the modified command to create the `load-balancer-role-trust-policy.json` file.

```
cat >load-balancer-role-trust-policy.json <<EOF
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::111122223333:oidc-provider/
oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE",
        "Action": "sts:AssumeRoleWithWebIdentity",
        "Condition": {
          "StringEquals": {
            "oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:aud": "sts.amazonaws.com",
            "oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:sub": "system:serviceaccount:kube-system:aws-load-balancer-controller"
          }
        }
      }
    }
  ]
}
```

310
c. Create the IAM role.

```bash
aws iam create-role \
  --role-name AmazonEKSLoadBalancerControllerRole \
  --assume-role-policy-document file://"load-balance-role-trust-policy.json"
```

d. Attach the required Amazon EKS managed IAM policy to the IAM role. Replace 111122223333 with your account ID.

```bash
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::111122223333:policy/AWSLoadBalancerControllerIAMPolicy \
  --role-name AmazonEKSLoadBalancerControllerRole
```

e. Copy the following contents to your device. Replace 111122223333 with your account ID. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace arn:aws: with arn:aws-us-gov:. After replacing the text, run the modified command to create the `aws-load-balancer-controller-service-account.yaml` file.

```bash
cat >aws-load-balancer-controller-service-account.yaml <<EOF
apiVersion: v1
kind: ServiceAccount
metadata:
  labels:
    app.kubernetes.io/component: controller
    app.kubernetes.io/name: aws-load-balancer-controller
    name: aws-load-balancer-controller
    namespace: kube-system
  annotations:
    eks.amazonaws.com/role-arn:
      arn:aws:iam::111122223333:role/AmazonEKSLoadBalancerControllerRole
EOF
```

f. Create the Kubernetes service account on your cluster. The Kubernetes service account named `aws-load-balancer-controller` is annotated with the IAM role that you created named `AmazonEKSLoadBalancerControllerRole`.

```bash
cubectl apply -f aws-load-balancer-controller-service-account.yaml
```

3. (Optional) Configure the AWS Security Token Service endpoint type used by your Kubernetes service account. For more information, see Configuring the AWS Security Token Service endpoint for a service account (p. 434).

4. If you don’t currently have the AWS ALB Ingress Controller for Kubernetes installed, or don’t currently have the 0.1.x version of the AWS Load Balancer Controller installed with Helm, then skip to the next step.

Uninstall the AWS ALB Ingress Controller or 0.1.x version of the AWS Load Balancer Controller (only if installed with Helm). Complete the procedure using the tool that you originally installed it with. The AWS Load Balancer Controller replaces the functionality of the AWS ALB Ingress Controller for Kubernetes.
Helm

a. If you installed the incubator/aws-alb-ingress-controller Helm chart, uninstall it.

```
helm delete aws-alb-ingress-controller -n kube-system
```

b. If you have version 0.1.x of the eks-charts/aws-load-balancer-controller chart installed, uninstall it. The upgrade from 0.1.x to version 1.0.0 doesn't work due to incompatibility with the webhook API version.

```
helm delete aws-load-balancer-controller -n kube-system
```

Kubernetes manifest

a. Check to see if the controller is currently installed.

```
kubectl get deployment -n kube-system alb-ingress-controller
```

This is the output if the controller isn't installed. Skip to the install controller (p. 313) step.

```
Error from server (NotFound): deployments.apps "alb-ingress-controller" not found
```

This is the output if the controller is installed.

```
NAME                   READY UP-TO-DATE AVAILABLE AGE
alb-ingress-controller 1/1   1          1         122d
```

b. Enter the following commands to remove the controller.

```
kubectl delete -f https://raw.githubusercontent.com/kubernetes-sigs/aws-alb-ingress-controller/v1.1.8/docs/examples/rbac-role.yaml
```

c. Add the following IAM policy to the IAM role created in a previous step (p. 309). The policy allows the AWS Load Balancer Controller access to the resources that were created by the ALB Ingress Controller for Kubernetes.

1. Download the IAM policy. You can also view the policy.

```
curl -o iam_policy_v1_to_v2_additional.json https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.4.3/docs/install/iam_policy_v1_to_v2_additional.json
```

2. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace arn:aws: with arn:aws-us-gov:

```
sed -i.bak -e 's|arn:aws:|arn:aws-us-gov:' iam_policy_v1_to_v2_additional.json
```

3. Create the IAM policy and note the ARN that is returned.

```
aws iam create-policy
   --policy-name AWSLoadBalancerControllerAdditionalIAMPolicy
   --policy-document file://iam_policy_v1_to_v2_additional.json
```
4. Attach the IAM policy to the IAM role that you created in a previous step (p. 309). Replace `your-role-name` with the name of the role. If you created the role using `eksctl`, then to find the role name that was created, open the AWS CloudFormation console and select the `eksctl-my-cluster-addon-iamserviceaccount-kube-system-aws-load-balancer-controller` stack. Select the Resources tab. The role name is in the Physical ID column. If you used the AWS Management Console to create the role, then the role name is whatever you named it, such as `AmazonEKSLoadBalancerControllerRole`. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

```bash
aws iam attach-role-policy
  --role-name your-role-name
  --policy-arn arn:aws:iam::111122223333:policy/AWSLoadBalancerControllerAdditionalIAMPolicy
```

5. Install the AWS Load Balancer Controller using Helm V3 (p. 411) or later by applying a Kubernetes manifest. If you want to deploy the controller on Fargate, use the Helm procedure because it doesn’t depend on `cert-manager`.

**Helm**

a. Add the `eks-charts` repository.

```bash
helm repo add eks https://aws.github.io/eks-charts
```

b. Update your local repo to make sure that you have the most recent charts.

```bash
helm repo update
```

c. If your nodes don’t have access to Amazon EKS Amazon ECR image repositories, then you need to pull the following container image and push it to a repository that your nodes have access to. For more information on how to pull, tag, and push an image to your own repository, see Copy a container image from one repository to another repository (p. 363). Replace `602401143452` and `region-code` with the values for your AWS Region listed in Amazon container image registries (p. 365).

```plaintext
602401143452.dkr.ecr.region-code.amazonaws.com/amazon/aws-load-balancer-controller:v2.4.3
```

d. Install the AWS Load Balancer Controller. If you’re deploying the controller to Amazon EC2 nodes that have restricted access to the Amazon EC2 instance metadata service (IMDS), or if you’re deploying to Fargate, then add the following flags to the `helm` command that follows:

- `--set region=region-code`
- `--set vpcId=vpc-xxxxxxxx`

If you’re deploying to any AWS Region other than `us-west-2`, then add the following flag to the `helm` command, replacing `602401143452` and `region-code` with the values for your AWS Region listed in Amazon container image registries (p. 365). If you pulled the image and pushed it to your own repository, then replace the full registry and repository with your own.

```bash
--set image.repository=602401143452.dkr.ecr.region-code.amazonaws.com/amazon/aws-load-balancer-controller
```

Replace `my-cluster` with your own. In the following command, `aws-load-balancer-controller` is the Kubernetes service account that you created in a previous step.
**helm** install aws-load-balancer-controller eks/aws-load-balancer-controller 
   -n kube-system 
   --set clusterName=my-cluster 
   --set serviceAccount.create=false 
   --set serviceAccount.name=aws-load-balancer-controller

**Important**
The deployed chart doesn't receive security updates automatically. You need to manually upgrade to a newer chart when it becomes available. When upgrading, change **install** to **upgrade** in the previous command, but run the following command to install the TargetGroupBinding custom resource definitions before running the previous command.

```bash
```

**Kubernetes manifest**

a. Install **cert-manager** using one of the following methods to inject certificate configuration into the webhooks.
   - If your nodes have access to the **quay.io** container registry, install **cert-manager** to inject certificate configuration into the webhooks.

   ```bash
   kubectl apply \
   --validate=false \
   -f https://github.com/jetstack/cert-manager/releases/download/v1.5.4/cert-manager.yaml
   ```

   - If your nodes don't have access to the **quay.io** container registry, then complete the following tasks:

     i. Download the manifest.

        ```bash
curl -Lo cert-manager.yaml https://github.com/jetstack/cert-manager/releases/download/v1.5.4/cert-manager.yaml
        ```

     ii. Pull the following images and push them to a repository that your nodes have access to. For more information on how to pull, tag, and push the images to your own repository, see Copy a container image from one repository to another repository (p. 363).

        ```bash
        quay.io/jetstack/cert-manager-cainjector:v1.5.4
        quay.io/jetstack/cert-manager-controller:v1.5.4
        quay.io/jetstack/cert-manager-webhook:v1.5.4
        ```

     iii. Replace **quay.io** in the manifest for the three images with your own registry name. The following command assumes that your private repository's name is the same as the source repository. Replace `11112223333.dkr.ecr.region-code.amazonaws.com` with your private registry.

        ```bash
        sed -i.bak -e 's|quay.io|11112223333.dkr.ecr.region-code.amazonaws.com|' ./cert-manager.yaml
        ```

     iv. Apply the manifest.

        ```bash
        kubectl apply \
        --validate=false \
        ```

---

314
b. Install the controller.
   i. Download the controller specification. For more information about the controller, see the documentation on GitHub.

   ```bash
   curl -Lo v2_4_3_full.yaml https://github.com/kubernetes-sigs/aws-load-balancer-controller/releases/download/v2.4.3/v2_4_3_full.yaml
   ```

   ii. Make the following edits to the file.

   • If you downloaded the `v2_4_3_full.yaml` file, run the following command to remove the ServiceAccount section in the manifest. If you don’t remove this section, the required annotation that you made to the service account in a previous step is overwritten. Removing this section also preserves the service account that you created in a previous step if you delete the controller.

   ```bash
   sed -i.bak -e '480,488d' ./v2_4_3_full.yaml
   ```

   If you downloaded a different file version, then open the file in an editor and remove the following lines.

   ```yaml
   apiVersion: v1
   kind: ServiceAccount
   metadata:
     labels:
       app.kubernetes.io/component: controller
       app.kubernetes.io/name: aws-load-balancer-controller
       name: aws-load-balancer-controller
       namespace: kube-system
     ---
   ```

   • Replace `your-cluster-name` in the Deployment spec section of the file with the name of your cluster by replacing `my-cluster` with the name of your cluster.

   ```bash
   sed -i.bak -e 's|your-cluster-name|my-cluster|' ./v2_4_3_full.yaml
   ```

   • If your nodes don’t have access to the Amazon EKS Amazon ECR image repositories, then you need to pull the following image and push it to a repository that your nodes have access to. For more information on how to pull, tag, and push an image to your own repository, see Copy a container image from one repository to another repository (p. 363).

   ```bash
   amazon/aws-alb-ingress-controller:v2.4.3
   ```

   Add your registry’s name to the manifest. The following command assumes that your private repository’s name is the same as the source repository and adds your private registry’s name to the file. In the source file there is no registry specified because Kubernetes pulls from docker.io, by default. Replace `111122223333.dkr.ecr.region-code.amazonaws.com` with your registry. This line assumes that you named your private repository the same as the source repository. If not, change the `amazon/aws-alb-ingress-controller` text after your private registry name to your repository name.

   ```bash
   sed -i.bak -e 's|amazon/aws-alb-ingress-controller|111122223333.dkr.ecr.region-code.amazonaws.com/amazon/aws-alb-ingress-controller|' ./v2_4_3_full.yaml
   ```
• If you're deploying the controller to Amazon EC2 nodes that have restricted access to the Amazon EC2 instance metadata service (IMDS), or if you're deploying to Fargate, then add the following parameters under `--args`:

```yaml
... spec:
  containers:
    - args:
      - --cluster-name=your-cluster-name
      - --ingress-class=alb
      - --aws-vpc-id=vpc-xxxxxxx
      - --aws-region=region-code
...```

iii. Apply the file.

```bash
kubectl apply -f v2_4_3_full.yaml
```

iv. Apply the `IngressClass` and `IngressClassParams` manifest to your cluster.

```bash
curl -Lo v2_4_3_ingclass.yaml https://github.com/kubernetes-sigs/aws-load-balancer-controller/releases/download/v2.4.3/v2_4_3_ingclass.yaml
```

v. Apply the manifest to your cluster.

```bash
kubectl apply -f v2_4_3_ingclass.yaml
```

6. Verify that the controller is installed.

```bash
kubectl get deployment -n kube-system aws-load-balancer-controller
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws-load-balancer-controller</td>
<td>2/2</td>
<td>2</td>
<td>2</td>
<td>84s</td>
</tr>
</tbody>
</table>

You receive the previous output if you deployed using Helm. If you deployed using the Kubernetes manifest, you only have one replica.

7. Before using the controller to provision AWS resources, your cluster must meet specific requirements. For more information, see Application load balancing on Amazon EKS (p. 357) and Network load balancing on Amazon EKS (p. 351).

### Managing the CoreDNS add-on

CoreDNS is a flexible, extensible DNS server that can serve as the Kubernetes cluster DNS. When you launch an Amazon EKS cluster with at least one node, two replicas of the CoreDNS image are deployed by default, regardless of the number of nodes deployed in your cluster. The CoreDNS pods provide name resolution for all pods in the cluster. The CoreDNS pods can be deployed to Fargate nodes if your cluster includes an AWS Fargate profile (p. 147) with a namespace that matches the namespace for the CoreDNS deployment. For more information about CoreDNS, see Using CoreDNS for Service Discovery in the Kubernetes documentation.

The following table lists the version of the CoreDNS add-on that is deployed with each Amazon EKS cluster version.
CoreDNS version deployed with each Amazon EKS supported cluster version

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>1.23</th>
<th>1.22</th>
<th>1.21</th>
<th>1.20</th>
<th>1.19</th>
</tr>
</thead>
<tbody>
<tr>
<td>CoreDNS</td>
<td>1.8.7-eksbuild.2</td>
<td>1.8.7</td>
<td>1.8.4</td>
<td>1.8.3</td>
<td>1.8.0</td>
</tr>
</tbody>
</table>

If you created a 1.18 or later cluster using the AWS Management Console, then Amazon EKS installed the add-on for you as an Amazon EKS add-on. If you originally created a 1.17 or earlier cluster using any tool, or you created a 1.18 or later cluster using any tool other than the AWS Management Console, then Amazon EKS installed the plugin as a self-managed add-on for you.

You can migrate the self-managed add-on to the Amazon EKS add-on using the procedure in Adding the CoreDNS Amazon EKS add-on (p. 317). If you have a cluster that you’ve already added the CoreDNS add-on to, you can manage it using the procedures in the Updating the CoreDNS Amazon EKS add-on (p. 318) and Removing the CoreDNS Amazon EKS add-on (p. 320) sections. For more information about Amazon EKS add-ons, see Amazon EKS add-ons (p. 367).

If you have not added the CoreDNS Amazon EKS add-on, the CoreDNS self-managed add-on is still running on your cluster. You can update the CoreDNS self-managed add-on using the procedure in Updating the CoreDNS self-managed add-on (p. 321).

**Prerequisites**

- An existing Amazon EKS cluster. To deploy one, see Getting started with Amazon EKS (p. 4).
- If your cluster is 1.21 or later, make sure that your Amazon VPC CNI plugin for Kubernetes and kube-proxy add-ons are at the minimum versions listed in Service account tokens (p. 424).

**Adding the CoreDNS Amazon EKS add-on**

Select the tab with the name of the tool that you want to use to add the CoreDNS Amazon EKS add-on to your cluster with.

**Important**

Before adding the CoreDNS Amazon EKS add-on, confirm that you do not self-manage any settings that Amazon EKS will start managing. To determine which settings Amazon EKS manages, see Amazon EKS add-on configuration (p. 368).

**eksctl**

To add the CoreDNS Amazon EKS add-on using eksctl

Replace my-cluster with the name of your cluster and then run the following command.

```
eksctl create addon --name coredns --cluster my-cluster --force
```

If you remove the --force option and any of the Amazon EKS add-on settings conflict with your existing settings, then adding the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn’t manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 368).

**AWS Management Console**

To add the CoreDNS Amazon EKS add-on using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Clusters, and then select the name of the cluster that you want to configure the CoreDNS Amazon EKS add-on for.

3. Choose the Add-ons tab.

4. Select Add new.
   a. Select CoreDNS for Name.
   b. Select the Version you'd like to use.
   c. If you select Override existing configuration for this add-on on the cluster, then any setting for the existing add-on can be overwritten with the Amazon EKS add-on's settings. If you don't enable this option and any of the Amazon EKS add-on settings conflict with your existing settings, then adding the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 368).
   d. Select Add.

AWS CLI

To add the CoreDNS Amazon EKS add-on using the AWS CLI

Replace my-cluster with the name of your cluster and then run the following command.

```
aws eks create-addon \
  --cluster-name my-cluster \
  --addon-name coredns \
  --resolve-conflicts OVERWRITE
```

If you remove the --resolve-conflicts OVERWRITE option and any of the Amazon EKS add-on settings conflict with your existing settings, then creating the add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 368).

Updating the CoreDNS Amazon EKS add-on

This procedure is for updating the CoreDNS Amazon EKS add-on. If you haven't added the CoreDNS Amazon EKS add-on, complete the procedure in Updating the CoreDNS self-managed add-on (p. 321) instead, or add the CoreDNS Amazon EKS add-on (p. 317). Amazon EKS does not automatically update CoreDNS on your cluster when new versions are released or after you update your cluster (p. 32) to a new Kubernetes minor version. To update CoreDNS on an existing cluster, you must initiate the update and then Amazon EKS updates the Amazon EKS add-on for you.

eksctl

To update the CoreDNS Amazon EKS add-on using eksctl

1. Check the current version of your coredns Amazon EKS add-on. Replace my-cluster with your cluster name.

   ```
   eksctl get addon --name coredns --cluster my-cluster
   ```

   The example output is as follows.
2. Update the add-on to the version returned under **UPDATE AVAILABLE** in the output of the previous step.

   ```bash
   eksctl update addon \
   --name coredns \
   --version v1.8.3-eksbuild.1 \
   --cluster my-cluster \
   --force
   ```

   If you remove the `--force` option and any of the Amazon EKS add-on settings conflict with your existing settings, then updating the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 368).

**AWS Management Console**

**To update the CoreDNS Amazon EKS add-on using the AWS Management Console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose **Clusters**, and then select the name of the cluster that you want to update the CoreDNS Amazon EKS add-on for.
3. Choose the **Add-ons** tab.
4. Select the radio button in the upper right of the **coredns** box and then choose **Edit**.
   a. Select the **Version** of the Amazon EKS add-on that you want to use.
   b. If you select **Override existing configuration for this add-on on the cluster**, then any setting for the existing add-on can be overwritten with the Amazon EKS add-on's settings. If you don't enable this option and any of the Amazon EKS add-on settings conflict with your existing settings, then updating the add-on to an Amazon EKS add-on fail, and you receive an error message to help you resolve the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 368).
   c. Select **Update**.

**AWS CLI**

**To update the CoreDNS Amazon EKS add-on using the AWS CLI**

1. Check the current version of your CoreDNS add-on. Replace `my-cluster` with your cluster name.

   ```bash
   aws eks describe-addon \
   --cluster-name my-cluster \
   --addon-name coredns \
   --query "addon.addonVersion" \
   --output text
   ```

   The example output is as follows.
Removing the Amazon EKS add-on

2. Determine which versions of the CoreDNS add-on are available for your cluster's version.

```bash
aws eks describe-addon-versions \
  --addon-name coredns \
  --kubernetes-version 1.19 \
  --query "addons[].addonVersions[].[addonVersion, \n  compatibilities[].defaultVersion]" \
  --output text
```

The example output is as follows.

```
1.8.0
  True
1.7.0
  False
```

The version with `True` underneath is the default version deployed with new clusters.

3. Update the add-on to the version with `True` returned in the output of the previous step. You can also update to a later version, if returned in the output.

```bash
aws eks update-addon \
  --cluster-name my-cluster \
  --addon-name coredns \
  --addon-version 1.8.0 \
  --resolve-conflicts OVERWRITE
```

If you remove the `--resolve-conflicts OVERWRITE` option and any of the Amazon EKS add-on settings conflict with your existing settings, then updating the add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 368).

Removing the CoreDNS Amazon EKS add-on

You have two options when removing an Amazon EKS add-on:

- **Preserve the add-on's software on your cluster** – This option removes Amazon EKS management of any settings and the ability for Amazon EKS to notify you of updates and automatically update the Amazon EKS add-on after you initiate an update, but preserves the add-on's software on your cluster. This option makes the add-on a self-managed add-on, rather than an Amazon EKS add-on. There is no downtime for the add-on.

- **Removing the add-on software entirely from your cluster** – You should only remove the Amazon EKS add-on from your cluster if there are no resources on your cluster that are dependent on the functionality that the add-on provides. After removing the Amazon EKS add-on, you can add it again if you want to.

If the add-on has an IAM account associated with it, the IAM account is not removed.

Select the tab with the name of the tool that you want to use for removing the CoreDNS Amazon EKS add-on.
**Updating the self-managed add-on**

To remove the CoreDNS Amazon EKS add-on using `eksctl`

Replace `my-cluster` with the name of your cluster and then run the following command. Removing `--preserve` removes the add-on software from your cluster.

```
  eksctl delete addon --cluster my-cluster --name coredns --preserve
```

To remove the CoreDNS Amazon EKS add-on using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Clusters, and then select the name of the cluster that you want to remove the CoreDNS Amazon EKS add-on for.
3. Choose the Add-ons tab.
4. Select the radio button in the upper right of the coredns box and then choose Remove. Type coredns and then select Remove.

To remove the CoreDNS Amazon EKS add-on using the AWS CLI

Replace `my-cluster` with the name of your cluster and then run the following command. Removing `--preserve` removes the add-on software from your cluster.

```
  aws eks delete-addon --cluster-name my-cluster --addon-name coredns --preserve
```

**Updating the CoreDNS self-managed add-on**

If you have a cluster that you have not added the CoreDNS Amazon EKS add-on to, complete the following steps to update the add-on. If you've added the CoreDNS Amazon EKS add-on, complete the procedure in Updating the CoreDNS Amazon EKS add-on (p. 318) instead.

To update the CoreDNS self-managed add-on using `kubectl`

1. Check the current version of your CoreDNS add-on.

```
  kubectl describe deployment coredns 
  --namespace kube-system 
  | grep Image 
  | cut -d "/" -f 3
```

The example output is as follows.

```
coredns:v1.8.0
```

2. If your current CoreDNS version is 1.5.0 or later, but earlier than the version listed in the CoreDNS versions (p. 316) table, then skip this step. If your current version is earlier than 1.5.0, then you need to modify the ConfigMap for CoreDNS to use the forward add-on, rather than the proxy add-on.

   a. Open the configmap with the following command.
Updating the self-managed add-on

```bash
kubectl edit configmap coredns -n kube-system
```

b. Replace `proxy` in the following line with `forward`. Save the file and exit the editor.

```bash
proxy /etc/resolv.conf
```

3. If you originally deployed your cluster on Kubernetes 1.17 or earlier, then you may need to remove a discontinued term from your CoreDNS manifest.

**Important**
You must complete this before upgrading to CoreDNS version 1.7.0, but it’s recommended that you complete this step even if you’re upgrading to an earlier version.

a. Check to see if your CoreDNS manifest has the line.

```bash
kubectl get configmap coredns -n kube-system -o jsonpath='{$.data.Corefile}' | grep upstream
```

If no output is returned, your manifest doesn’t have the line and you can skip to the next step to update CoreDNS. If output is returned, then you need to remove the line.

b. Edit the ConfigMap with the following command, removing the line in the file that has the word `upstream` in it. Do not change anything else in the file. Once the line is removed, save the changes.

```bash
kubectl edit configmap coredns -n kube-system -o yaml
```

4. Retrieve your current CoreDNS image:

```bash
kubectl get deployment coredns --namespace kube-system -o=jsonpath='{$.spec.template.spec.containers[:1].image}'
```

5. If you’re updating to CoreDNS 1.8.3 or later, then you need to add the `endpointslices` permission to the `system:coredns` Kubernetes clusterrole.

```bash
kubectl edit clusterrole system:coredns -n kube-system
```

Add the following lines under the existing permissions lines in the `rules` section of the file.

```yaml
...  
- apiGroups:  
  - discovery.k8s.io  
  resources:  
  - endpointslices  
  verbs:  
    - list  
    - watch  
...
```

6. Update the CoreDNS add-on by replacing `602401143452` and `region-code` with the values from the output returned in a previous step. Replace `1.8.7-eksbuild.2` with your cluster’s recommended CoreDNS version (p. 316) or later:

```bash
kubectl set image --namespace kube-system deployment.apps/coredns \
  coredns=602401143452.dkr.ecr.region-code.amazonaws.com/eks/coredns:v1.8.7-eksbuild.2
```
Managing the kube-proxy add-on

Kube-proxy maintains network rules on each Amazon EC2 node. It enables network communication to your pods. Kube-proxy is not deployed to Fargate nodes. For more information, see kube-proxy in the Kubernetes documentation. There are two types of the kube-proxy image available for each Kubernetes version:

- **Default** – This type is deployed by default with new clusters. This is the only type that you can use with the Amazon EKS add-on for version 1.22 and earlier clusters.
- **Minimal** – Unlike the default type, this image type is based on a minimal base image maintained by Amazon EKS Distro, which contains minimal packages and doesn’t have shells. For more information, see Amazon EKS Distro. This type is available as a self-managed add-on. It is also available as an Amazon EKS add-on for version 1.23 and later clusters, but isn’t available as an Amazon EKS add-on for version 1.22 and earlier clusters. If you choose to install this type as a self-managed add-on, for version 1.22 and earlier clusters, complete the steps in the section called “Updating the self-managed add-on” (p. 328), specifying the latest version for the minimal type in the following table. This type is added by default to any new 1.23 and later clusters. If you update an existing cluster to version 1.23, you can add (p. 324) the Amazon EKS add-on to your cluster, or update (p. 325) your existing Amazon EKS add-on to this type. Even though the v1.23.7-eksbuild.1 version doesn’t include minimal in the version (as previous versions do), the image is still based on the minimal base image.

<table>
<thead>
<tr>
<th>Image type</th>
<th>1.23</th>
<th>1.22</th>
<th>1.21</th>
<th>1.20</th>
<th>1.19</th>
</tr>
</thead>
<tbody>
<tr>
<td>kube-proxy (default type)</td>
<td>Not available</td>
<td>v1.22.11-eksbuild.2</td>
<td>v1.21.14-eksbuild.2</td>
<td>v1.20.15-eksbuild.2</td>
<td>v1.19.16-eksbuild.2</td>
</tr>
<tr>
<td>kube-proxy (minimal type)</td>
<td>v1.23.7-eksbuild.1</td>
<td>v1.22.11-minimal-eksbuild.2</td>
<td>v1.21.14-minimal-eksbuild.2</td>
<td>v1.20.15-minimal-eksbuild.3</td>
<td>v1.19.16-minimal-eksbuild.3</td>
</tr>
</tbody>
</table>

If you created a 1.18 or later cluster using the AWS Management Console, then Amazon EKS installed the plugin for you as an Amazon EKS add-on. If you originally created a 1.17 or earlier cluster using any tool, or you created a 1.18 or later cluster using any tool other than the AWS Management Console, then Amazon EKS installed the plugin as a self-managed add-on for you. You can migrate the self-managed add-on to the Amazon EKS add-on using the procedure in Adding the kube-proxy Amazon EKS add-on (p. 324). If you have a cluster that you’ve already added the kube-proxy add-on to, you can manage it using the procedures in the Updating the kube-proxy Amazon EKS add-on (p. 325) and Removing the kube-proxy Amazon EKS add-on (p. 327) sections. For more information about Amazon EKS add-ons, see Amazon EKS add-ons (p. 367).

If you haven’t added the kube-proxy Amazon EKS add-on, the kube-proxy self-managed add-on is still running on your cluster. You can manually update the kube-proxy self-managed add-on using the procedure in Updating the kube-proxy self-managed add-on (p. 328).

Amazon EKS has the same compatibility and skew policy as Kubernetes for kube-proxy. Kube-proxy must meet the following requirements:

- It must be the same minor version as kubelet on the node.
- It must not be newer than the version of your cluster’s control plane.
- It’s version can’t be earlier than two minor versions from your control plane. For example, if your control plane is running Kubernetes 1.23, then the kube-proxy minor version can’t be earlier than 1.21.
Prerequisites

- An existing Amazon EKS cluster. To deploy one, see Getting started with Amazon EKS (p. 4).
- If your cluster is 1.21 or later, make sure that your Amazon VPC and CoreDNS add-ons are at the minimum versions listed in Service account tokens (p. 424).

Adding the kube-proxy Amazon EKS add-on

You can add the kube-proxy Amazon EKS add-on to your cluster using eksctl, the AWS Management Console, or the AWS CLI.

Important
Before adding the kube-proxy Amazon EKS add-on, confirm that you do not self-manage any settings that Amazon EKS will start managing. To determine which settings Amazon EKS manages, see Amazon EKS add-on configuration (p. 368).

eksctl

To add the kube-proxy Amazon EKS add-on using eksctl

Replace my-cluster with the name of your cluster and then run the following command. Eksctl adds the latest version of the add-on that's available for your cluster version.

```
eksctl create addon --name kube-proxy --cluster my-cluster --force
```

If you remove the --force option and any of the Amazon EKS add-on settings conflict with your existing settings, then adding the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 368).

AWS Management Console

To add the kube-proxy Amazon EKS add-on using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, select Clusters, and then select the name of the cluster that you want to configure the kube-proxy Amazon EKS add-on for.
3. Choose the Add-ons tab.
4. Select Add new.
   a. Select kube-proxy for Name.
   b. Select the Version you'd like to use. Select the version marked as Latest.
   c. If you select Override existing configuration for this add-on on the cluster., then any setting for the existing add-on can be overwritten with the Amazon EKS add-on's settings. If you don't enable this option and any of the Amazon EKS add-on settings conflict with your existing settings, then adding the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 368).
   d. Select Add.
AWS CLI

To add the kube-proxy Amazon EKS add-on using the AWS CLI

Create the add-on. Replace `my-cluster` with the name of your cluster and `v1.23.7-minimal-eksbuild.1` with the latest version for your cluster from the latest versions table (p. 323).

```
aws eks create-addon --cluster-name my-cluster --addon-name kube-proxy --addon-version v1.23.7-minimal-eksbuild.1 --resolve-conflicts OVERWRITE
```

If you remove the `--resolve-conflicts OVERWRITE` option and any of the Amazon EKS add-on settings conflict with your existing settings, then creating the add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 368).

Updating the kube-proxy Amazon EKS add-on

This procedure is for updating the kube-proxy Amazon EKS add-on. If you haven't added the kube-proxy Amazon EKS add-on, complete the procedure in Updating the kube-proxy self-managed add-on (p. 328) instead. Amazon EKS does not automatically update kube-proxy on your cluster when new versions are released or after you update your cluster (p. 32) to a new Kubernetes minor version. To update kube-proxy on an existing cluster, you must initiate the update and then Amazon EKS updates the add-on for you.

**Important**
Update your cluster and nodes to a new Kubernetes minor version before updating kube-proxy to the same minor version as your updated cluster's minor version.

**eksctl**

To update the kube-proxy Amazon EKS add-on using eksctl

1. Check the current version of your kube-proxy Amazon EKS add-on. Replace `my-cluster` with your cluster name.

```
eksctl get addon --name kube-proxy --cluster my-cluster
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>STATUS</th>
<th>ISSUES</th>
<th>IAMROLE</th>
<th>UPDATE AVAILABLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>kube-proxy</td>
<td>v1.22.11-eksbuild.2</td>
<td>ACTIVE</td>
<td>0</td>
<td></td>
<td>v1.23.7-minimal-eksbuild.1</td>
</tr>
</tbody>
</table>

2. Update the add-on to the version returned under UPDATE AVAILABLE in the output of the previous step.

```
eksctl update addon \
  --name kube-proxy \
  --version v1.23.7-minimal-eksbuild.1 \
  --cluster my-cluster \
  --force
```

If you remove the `--force` option and any of the Amazon EKS add-on settings conflict with your existing settings, then updating the add-on fails, and you receive an error message to help
you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 368).

AWS Management Console

To update the `kube-proxy` Amazon EKS add-on using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, select Clusters, and then select the name of the cluster that you want to update the `kube-proxy` Amazon EKS add-on for.
3. Choose the Add-ons tab.
4. Select the box in the top right of the `kube-proxy` box and then choose Edit.
   a. Select the Version marked as Latest.
   b. If you select Override existing configuration for this add-on on the cluster, then any setting for the existing add-on can be overwritten with the Amazon EKS add-on's settings. If you don't enable this option and any of the Amazon EKS add-on settings conflict with your existing settings, then updating the add-on to an Amazon EKS add-on fail, and you receive an error message to help you resolve the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 368).
   c. Select Update.

AWS CLI

To update the `kube-proxy` Amazon EKS add-on using the AWS CLI

1. Check the current version of your `kube-proxy` Amazon EKS add-on. Replace `my-cluster` with your cluster name.

```
aws eks describe-addon --cluster-name my-cluster --addon-name kube-proxy --query "addon.addonVersion" --output text
```

The example output is as follows.

```
v1.22.11-eksbuild.2
```

2. Determine which versions of the `kube-proxy` add-on are available for your cluster version. Replace 1.23 with your cluster's version.

```
aws eks describe-addon-versions --addon-name kube-proxy --kubernetes-version 1.23 \ --query "addons[].addonVersions[].[addonVersion, compatibilities[].defaultVersion]" --output text
```

The example output is as follows.

```
v1.23.7-minimal-eksbuild.1 False
v1.22.11-eksbuild.2 True
...```
The version with True underneath is the default version deployed with new clusters with the Kubernetes version that you specified.

3. Update the add-on to the latest version returned in the output of the previous step.

   ```
   aws eks update-addon --cluster-name my-cluster --addon-name kube-proxy --addon-version v1.23.7-minimal-eksbuild.1 --resolve-conflicts OVERWRITE
   ```

If you remove the `--resolve-conflicts OVERWRITE` option and any of the Amazon EKS add-on settings conflict with your existing settings, then updating the add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 368).

### Removing the kube-proxy Amazon EKS add-on

You have two options when removing an Amazon EKS add-on:

- **Preserve the add-on's software on your cluster** – This option removes Amazon EKS management of any settings and the ability for Amazon EKS to notify you of updates and automatically update the Amazon EKS add-on after you initiate an update, but preserves the add-on's software on your cluster. This option makes the add-on a self-managed add-on, rather than an Amazon EKS add-on. There is no downtime for the add-on.

- **Removing the add-on software entirely from your cluster** – You should only remove the Amazon EKS add-on from your cluster if there are no resources on your cluster are dependent on the functionality that the add-on provides. After removing the Amazon EKS add-on, you can add it again if you want to.

If the add-on has an IAM account associated with it, the IAM account is not removed.

You can use eksctl, the AWS Management Console or the AWS CLI to remove the kube-proxy Amazon EKS add-on from your cluster.

**eksctl**

   **To remove the kube-proxy Amazon EKS add-on using eksctl**

   Replace `my-cluster` with the name of your cluster and then run the following command. Removing `--preserve` removes the add-on software from your cluster.

   ```
   eksctl delete addon --cluster my-cluster --name kube-proxy --preserve
   ```

**AWS Management Console**

   **To remove the kube-proxy Amazon EKS add-on using the AWS Management Console**

   1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
   2. In the left navigation pane, select **Clusters**, and then select the name of the cluster that you want to remove the **kube-proxy** Amazon EKS add-on for.
   3. Choose the **Add-ons** tab.
   4. Select the check box in the top right of the **kube-proxy** box and then choose **Remove**. Type **kube-proxy** and then select **Remove**.
AWS CLI

To remove the kube-proxy Amazon EKS add-on using the AWS CLI

Replace `my-cluster` with the name of your cluster and then run the following command. Removing `--preserve` removes the add-on software from your cluster.

```
aws eks delete-addon --cluster-name my-cluster --addon-name kube-proxy --preserve
```

Updating the kube-proxy self-managed add-on

If you have a cluster that you have not added the kube-proxy Amazon EKS add-on to, complete the following steps to update the self-managed add-on. If you've added the kube-proxy Amazon EKS add-on, complete the procedure in Updating the kube-proxy Amazon EKS add-on (p. 325) instead.

**Important**

Update your cluster and nodes to a new Kubernetes minor version before updating kube-proxy to the same minor version as your updated cluster's minor version.

To update the kube-proxy self-managed add-on using kubectl

1. Check the current version of your kube-proxy deployment.

   ```
   kubectl get daemonset kube-proxy --namespace kube-system -o=jsonpath='{$.spec.template.spec.containers[0:1].image}'
   ```

   The example output is as follows.

   ```
   602401143452.dkr.ecr.region-code.amazonaws.com/eks/kube-proxy:v1.22.11-eksbuild.2
   ```

2. Update the kube-proxy add-on by replacing `602401143452` and `region-code` with the values from your output. Replace `1.22.11-eksbuild.2` with the kube-proxy version listed in the Latest available kube-proxy version for each Amazon EKS cluster version (p. 323) table for your cluster version. You can specify a version number for the default or minimal image type.

   ```
   kubectl set image daemonset.apps/kube-proxy -n kube-system kube-proxy=602401143452.dkr.ecr.region-code.amazonaws.com/eks/kube-proxy:v1.23.7-minimal-eksbuild.1
   ```

3. If you're using x86 and Arm nodes in the same cluster and your cluster was deployed before August 17, 2020. Then, edit your kube-proxy manifest to include a node selector for multiple hardware architectures with the following command. This is a one-time operation. After you've added the selector to your manifest, you don't need to add it each time you update. If your cluster was deployed on or after August 17, 2020, then kube-proxy is already multi-architecture capable.

   ```
   kubectl edit -n kube-system daemonset/kube-proxy
   ```

   Add the following node selector to the file in the editor and then save the file. For an example of where to include this text in the editor, see the CNI manifest file on GitHub. This enables Kubernetes to pull the correct hardware image based on the node's hardware architecture.

   ```
   - key: "kubernetes.io/arch"
     operator: In
     values:
     - amd64
   ```
4. If your cluster was originally created with Kubernetes version 1.14 or later, then you can skip this step because kube-proxy already includes this Affinity Rule. If you originally created an Amazon EKS cluster with Kubernetes version 1.13 or earlier and intend to use Fargate nodes, then edit your kube-proxy manifest to include a NodeAffinity rule to prevent kube-proxy pods from scheduling on Fargate nodes. This is a one-time edit. Once you've added the Affinity Rule to your manifest, you don't need to add it each time you upgrade your cluster. Edit your kube-proxy DaemonSet.

```
kubectl edit -n kube-system daemonset/kube-proxy
```

Add the following Affinity Rule to the DaemonSet spec section of the file in the editor and then save the file. For an example of where to include this text in the editor, see the CNI manifest file on GitHub.

```
- key: eks.amazonaws.com/compute-type
  operator: NotIn
  values:
  - fargate
```

## Installing the Calico add-on

**Project Calico** is a network policy engine for Kubernetes. With Calico network policy enforcement, you can implement network segmentation and tenant isolation. This is useful in multi-tenant environments where you must isolate tenants from each other or when you want to create separate environments for development, staging, and production. Network policies are similar to AWS security groups in that you can create network ingress and egress rules. Instead of assigning instances to a security group, you assign network policies to pods using pod selectors and labels.

### Considerations

- Calico is not supported when using Fargate with Amazon EKS.
- Calico adds rules to `iptables` on the node that may be higher priority than existing rules that you've already implemented outside of Calico. Consider adding existing `iptables` rules to your Calico policies to avoid having rules outside of Calico policy overridden by Calico.
- If you're using the Amazon VPC CNI add-on version 1.10 or earlier, [security groups for pods](p. 292) traffic flow to pods on branch network interfaces is not subjected to Calico network policy enforcement and is limited to Amazon EC2 security group enforcement only. If you're using 1.11.0 or later of the Amazon VPC CNI add-on, traffic flow to pods on branch network interfaces is subject to Calico network policy enforcement if you set `POD_SECURITY_GROUP_ENFORCING_MODE=standard` for the Amazon VPC CNI add-on.

### Prerequisites

- An existing Amazon EKS cluster. To deploy one, see [Getting started with Amazon EKS](p. 4).
- The `kubectl` command line tool is installed on your device or AWS CloudShell. The version can be the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For example, if your cluster version is 1.22, you can use `kubectl` version 1.21, 1.22, or 1.23 with it. To install or upgrade `kubectl`, see [Installing or updating kubectl](p. 4).

The following procedure shows you how to install Calico on Linux nodes in your Amazon EKS cluster. To install Calico on Windows nodes, see [Using Calico on Amazon EKS Windows Containers](p. 4).
Install Calico on your Amazon EKS Linux nodes

**Important**
Amazon EKS doesn't maintain the manifests or charts used in the following procedures. The recommended way to install Calico on Amazon EKS is by using the Calico Operator instead of these charts or manifests. For more information, see Important Announcement: Amazon EKS will no longer maintain and update Calico charts in this repository on GitHub. If you encounter issues during installation and usage of Calico, submit issues to Calico Operator and the Calico project directly. You should always contact Tigera for compatibility of any new Calico operator and Calico versions before installing them on your cluster.

You can install Calico using the procedure for Helm or manifests.

Helm

**Prerequisite**
Helm version 3.0 or later installed on your computer. To install or upgrade Helm, see Using Helm with Amazon EKS (p. 411).

**To install Calico with Helm**

1. Add Project Calico into your Helm repository.

   ```bash
   helm repo add projectcalico https://docs.projectcalico.org/charts
   ```

2. If you already have Calico added, you may want to update it to get the latest released version.

   ```bash
   helm repo update
   ```

3. Install version 3.21.4 or later of the Tigera Calico operator and custom resource definitions.

   ```bash
   helm install calico projectcalico/tigera-operator --version v3.21.4
   ```

4. View the resources in the tigera-operator namespace.

   ```bash
   kubectl get all -n tigera-operator
   ```

   The example output is as follows.

   ```
   NAME                                  READY   STATUS    RESTARTS   AGE
   pod/tigera-operator-c4b9549c7-h4zp5   1/1     Running   0          110m
   ...
   ```

5. View the resources in the calico-system namespace.

   ```bash
   kubectl get all -n calico-system
   ```

   The example output is as follows.

   ```
   NAME                                        DESIRED   CURRENT   READY   AGE
   replicaset.apps/tigera-operator-c4b9549c7   1         1         1      2m35s
   ```
Install Calico

6. Confirm that the logs for one of your calico-node, calico-typha, and tigera-operator pods don’t contain ERROR. Replace the values in the following commands with the values returned in your output for the previous steps.

```bash
kubectl logs tigera-operator-c4b9549c7-h4zp5 -n tigera-operator | grep ERROR
kubectl logs calico-node-v9dhf -n calico-system | grep ERROR
kubectl logs calico-typha-6f9c6786d-f2mc7 -n calico-system | grep ERROR
```

If no output is returned from the previous commands, then ERROR doesn’t exist in your logs and everything should be running correctly.

Manifests

**To install Calico using manifests**

1. Apply the Calico manifests to your cluster. These manifests create a DaemonSet in the calico-system namespace.

```bash
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/master/config/master/calico-operator.yaml
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/master/config/master/calico-crs.yaml
```

2. View the resources in the calico-system namespace.

```bash
kubectl get daemonset calico-node --namespace calico-system
```

The example output is as follows.

The values in the DESIRED and READY columns should match. The values returned for you are different than the values in the following output.

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESIRED</th>
<th>CURRENT</th>
<th>READY</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>calico-node</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>100m</td>
</tr>
<tr>
<td>os=linux</td>
<td></td>
<td></td>
<td></td>
<td>26m</td>
</tr>
</tbody>
</table>
Stars policy demo

This section walks through the Stars policy demo provided by the Project Calico documentation and isn’t necessary for Calico functionality on your cluster. The demo creates a front-end, back-end, and client service on your Amazon EKS cluster. The demo also creates a management graphical user interface that shows the available ingress and egress paths between each service. We recommend that you complete the demo on a cluster that you don’t run production workloads on.

Before you create any network policies, all services can communicate bidirectionally. After you apply the network policies, you can see that the client can only communicate with the front-end service, and the back-end only accepts traffic from the front-end.

To run the Stars policy demo

1. Apply the front-end, back-end, client, and management user interface services:

   ```
   kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/00-namespace.yaml
   kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/01-management-ui.yaml
   kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/02-backend.yaml
   kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/03-frontend.yaml
   kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/04-client.yaml
   ```

2. View all pods on the cluster.

   ```
   kubectl get pods -A
   ```

   The example output is as follows.

   In your output, you should see pods in the namespaces shown in the following output. Your pod NAMES and the number of pods in the READY column are different than those in the following output. Don’t continue until you see pods with similar names and they all have Running in the STATUS column.

3. To connect to the management user interface, forward your local port 9001 to the management-ui service running on your cluster:

   ```
   kubectl port-forward service/management-ui -n management-ui 9001
   ```

4. Open a browser on your local system and point it to http://localhost:9001/. You should see the management user interface. The C node is the client service, the F node is the front-end service, and
the B node is the back-end service. Each node has full communication access to all other nodes, as indicated by the bold, colored lines.

5. Apply the following network policies to isolate the services from each other:

   kubectl apply -n stars -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/policies/default-deny.yaml
   kubectl apply -n client -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/policies/default-deny.yaml

6. Refresh your browser. You see that the management user interface can no longer reach any of the nodes, so they don’t show up in the user interface.

7. Apply the following network policies to allow the management user interface to access the services:

   kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/policies/allow-ui.yaml
   kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/policies/allow-ui-client.yaml

8. Refresh your browser. You see that the management user interface can reach the nodes again, but the nodes cannot communicate with each other.
9. Apply the following network policy to allow traffic from the front-end service to the back-end service:

```
kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/policies/backend-policy.yaml
```

10. Refresh your browser. You see that the front-end can communicate with the back-end.
11. Apply the following network policy to allow traffic from the client to the front-end service.

```bash
kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/policies/frontend-policy.yaml
```

12. Refresh your browser. You see that the client can communicate to the front-end service. The front-end service can still communicate to the back-end service.
13. (Optional) When you are done with the demo, you can delete its resources.

```
kubectl delete -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/04-client.yaml
kubectl delete -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/03-frontend.yaml
kubectl delete -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/02-backend.yaml
kubectl delete -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/01-management-ui.yaml
kubectl delete -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/00-namespace.yaml
```

Even after deleting the resources, there can still be `iptables` rules on the nodes that might interfere in unexpected ways with networking in your cluster. The only sure way to remove Calico is to terminate all of the nodes and recycle them. To terminate all nodes, either set the Auto Scaling Group desired count to 0, then back up to the desired number, or just terminate the nodes. If you are unable to recycle the nodes, then see Disabling and removing Calico Policy in the Calico GitHub repository for a last resort procedure.
Remove Calico

Remove Calico using the method that you installed Calico with.

Helm

Remove Calico from your cluster.

```
helm uninstall calico
```

Manifests

Remove Calico from your cluster.

```
kubectl delete -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/master/config/master/calico-crs.yaml
kubectl delete -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/master/config/master/calico-operator.yaml
```
Workloads

Your workloads are deployed in containers, which are deployed in pods in Kubernetes. A pod includes one or more containers. Typically, one or more pods that provide the same service are deployed in a Kubernetes service. Once you've deployed multiple pods that provide the same service, you can:

- View information about the workloads (p. 500) running on each of your clusters using the AWS Management Console.
- Vertically scale pods up or down with the Kubernetes Vertical Pod Autoscaler (p. 345).
- Horizontally scale the number of pods needed to meet demand up or down with the Kubernetes Horizontal Pod Autoscaler (p. 349).
- Create an external (for internet-accessible pods) or an internal (for private pods) network load balancer (p. 351) to balance network traffic across pods. The load balancer routes traffic at Layer 4 of the OSI model.
- Create an Application load balancing on Amazon EKS (p. 357) to balance application traffic across pods. The application load balancer routes traffic at Layer 7 of the OSI model.
- If you're new to Kubernetes, this topic helps you Deploy a sample application (p. 338).
- You can restrict IP addresses that can be assigned to a service (p. 361) with `externalIPs`.

Deploy a sample application

In this topic, you deploy a sample application to your cluster.

Prerequisites

- An existing Kubernetes cluster with at least one node. If you don't have an existing Amazon EKS cluster, you can deploy one using one of the Getting started with Amazon EKS (p. 4) guides. If you're deploying a Windows application, then you must have Windows support (p. 54) enabled for your cluster and at least one Amazon EC2 Windows node.
- `kubectl` installed on your computer. For more information, see Installing or updating `kubectl` (p. 4).
- `kubectl` configured to communicate with your cluster. For more information, see Create a `kubeconfig` for Amazon EKS (p. 392).
- If you plan to deploy your sample workload to Fargate, then you must have an existing Fargate profile (p. 147) that includes the same namespace created in this tutorial, which is `eks-sample-app`, unless you change the name. If you used one of the getting started guides (p. 4) to create your cluster, then you'll have to create a new profile, or add the namespace to your existing profile, because the profile created in the getting started guides doesn't specify the namespace used in this tutorial. Your VPC must also have at least one private subnet.

To deploy a sample application

Though many variables are changeable in the following steps, we recommend only changing variable values where specified. Once you have a better understanding of Kubernetes pods, deployments, and services, you can experiment with changing other values.

1. Create a namespace. A namespace allows you to group resources in Kubernetes. For more information, see Namespaces in the Kubernetes documentation. If you plan to deploy your sample application to AWS Fargate (p. 142), make sure that the value for `namespace` in your AWS Fargate profile (p. 147) is `eks-sample-app`. 
2. Create a Kubernetes deployment. This sample deployment pulls a container image from a public repository and deploys three replicas (individual pods) of it to your cluster. To learn more, see Deployments in the Kubernetes documentation. You can deploy the application to Linux or Windows nodes. If you're deploying to Fargate, then you can only deploy a Linux application.

   a. Save the following contents to a file named eks-sample-deployment.yaml. The containers in the sample application don't use network storage, but you might have applications that need to. For more information, see Storage (p. 203).

```
apiVersion: apps/v1
kind: Deployment
metadata:
  name: eks-sample-linux-deployment
  namespace: eks-sample-app
  labels:
    app: eks-sample-linux-app
spec:
  replicas: 3
  selector:
    matchLabels:
      app: eks-sample-linux-app
  template:
    metadata:
      labels:
        app: eks-sample-linux-app
    spec:
      affinity:
        nodeAffinity:
          requiredDuringSchedulingIgnoredDuringExecution:
            nodeSelectorTerms:
              - matchExpressions:
                - key: kubernetes.io/arch
                  operator: In
                  values:
                    - amd64
                    - arm64
      containers:
        - name: nginx
          image: public.ecr.aws/nginx/nginx:1.21
          ports:
            - name: http
              containerPort: 80
          imagePullPolicy: IfNotPresent
```

The `amd64` or `arm64` values under the `kubernetes.io/arch` key mean that the application can be deployed to either hardware architecture (if you have both in your cluster). This is possible because this image is a multi-architecture image, but not all are. You can determine the hardware architecture that the image is supported on by viewing the image details in the repository that you're pulling it from. When deploying images that don't support a hardware architecture type, or that you don't want the image deployed to, remove that type from the manifest. For more information, see Well-Known Labels, Annotations and Taints in the Kubernetes documentation.

The `kubernetes.io/os: linux` nodeSelector means that if you had Linux and Windows nodes (for example) in your cluster, the image would only be deployed to Linux nodes. For more information, see Well-Known Labels, Annotations and Taints in the Kubernetes documentation.
Windows

The `kubernetes.io/os: windows` nodeSelector means that if you had Windows and Linux nodes (for example) in your cluster, the image would only be deployed to Windows nodes. For more information, see Well-Known Labels, Annotations and Taints in the Kubernetes documentation.

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: eks-sample-windows-deployment
  namespace: eks-sample-app
  labels:
    app: eks-sample-windows-app
spec:
  replicas: 3
  selector:
    matchLabels:
      app: eks-sample-windows-app
  template:
    metadata:
      labels:
        app: eks-sample-windows-app
    spec:
      affinity:
        nodeAffinity:
          requiredDuringSchedulingIgnoredDuringExecution:
            nodeSelectorTerms:
              - matchExpressions:
                  - key: beta.kubernetes.io/arch
                    operator: In
                    values:
                      - amd64
        containers:
          - name: windows-server-iis
            image: mcr.microsoft.com/windows/servercore:ltsc2019
            ports:
              - name: http
                containerPort: 80
            imagePullPolicy: IfNotPresent
            command:
              - powershell.exe
            - "Add-WindowsFeature Web-Server; Invoke-WebRequest -UseBasicParsing -Uri 'https://dotnetbinaries.blob.core.windows.net/servicemonitor/2.0.1.6/ServiceMonitor.exe' -OutFile 'C:\ServiceMonitor.exe'; echo '<html><body><br/><br/><marquee><H1>Hello EKS!!!</H1><marquee></body><html>' > C:\inetpub\wwwroot\\default.html; C:\ServiceMonitor.exe 'w3svc'; "
      nodeSelector:
        kubernetes.io/os: windows
```

b. Apply the deployment manifest to your cluster.

```
kubectl apply -f eks-sample-deployment.yaml
```

3. Create a service. A service allows you to access all replicas through a single IP address or name. For more information, see Service in the Kubernetes documentation. Though not implemented in the sample application, if you have applications that need to interact with other AWS services, we recommend that you create Kubernetes service accounts for your pods, and associate them to AWS...
IAM accounts. By specifying service accounts, your pods have only the minimum permissions that you specify for them to interact with other services. For more information, see IAM roles for service accounts (p. 425).

a. Save the following contents to a file named eks-sample-service.yaml. Kubernetes assigns the service its own IP address that is accessible only from within the cluster. To access the service from outside of your cluster, deploy the AWS Load Balancer Controller (p. 308) to load balance application (p. 357) or network (p. 351) traffic to the service.

**Linux**

```yaml
apiVersion: v1
kind: Service
metadata:
  name: eks-sample-linux-service
  namespace: eks-sample-app
labels:
  app: eks-sample-linux-app
spec:
  selector:
    app: eks-sample-linux-app
  ports:
    - protocol: TCP
      port: 80
      targetPort: 80
```

**Windows**

```yaml
apiVersion: v1
kind: Service
metadata:
  name: eks-sample-windows-service
  namespace: eks-sample-app
labels:
  app: eks-sample-windows-app
spec:
  selector:
    app: eks-sample-windows-app
  ports:
    - protocol: TCP
      port: 80
      targetPort: 80
```

b. Apply the service manifest to your cluster.

```
kubectl apply -f eks-sample-service.yaml
```

4. View all resources that exist in the eks-sample-app namespace.

```
kubectl get all -n eks-sample-app
```

The example output is as follows.

If you deployed Windows resources, then all instances of *linux* in the following output are *windows*. The other *example values* may be different from your output.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>pod/eks-sample-linux-deployment-65b7669776-m6qxz</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>27m</td>
</tr>
<tr>
<td>pod/eks-sample-linux-deployment-65b7669776-mmxxvd</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>27m</td>
</tr>
<tr>
<td>pod/eks-sample-linux-deployment-65b7669776-qzn22</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>27m</td>
</tr>
</tbody>
</table>
In the output, you see the service and deployment that were specified in the sample manifests deployed in previous steps. You also see three pods. This is because 3 replicas were specified in the sample manifest. For more information about pods, see Pods in the Kubernetes documentation. Kubernetes automatically creates the replicaset resource, even though it isn’t specified in the sample manifests. For more information about ReplicaSets, see ReplicaSet in the Kubernetes documentation.

**Note**
Kubernetes maintains the number of replicas that are specified in the manifest. If this were a production deployment and you wanted Kubernetes to horizontally scale the number of replicas or vertically scale the compute resources for the pods, use the Horizontal Pod Autoscaler (p. 349) and the Vertical Pod Autoscaler (p. 345) to do so.

5. View the details of the deployed service. If you deployed a Windows service, replace `linux` with `windows`.

```
kubectl -n eks-sample-app describe service eks-sample-linux-service
```

The example output is as follows.

If you deployed Windows resources, then all instances of `linux` in the following output are `windows`. The other `example values` may be different from your output.

<table>
<thead>
<tr>
<th>Name:</th>
<th>eks-sample-linux-service</th>
</tr>
</thead>
<tbody>
<tr>
<td>Namespace:</td>
<td>eks-sample-app</td>
</tr>
<tr>
<td>Labels:</td>
<td>app=eks-sample-linux-app</td>
</tr>
<tr>
<td>Annotations:</td>
<td>&lt;none&gt;</td>
</tr>
<tr>
<td>Selector:</td>
<td>app=eks-sample-linux-app</td>
</tr>
<tr>
<td>Type:</td>
<td>ClusterIP</td>
</tr>
<tr>
<td>IP Families:</td>
<td>&lt;none&gt;</td>
</tr>
<tr>
<td>IP:</td>
<td>10.100.74.8</td>
</tr>
<tr>
<td>IPs:</td>
<td>10.100.74.8</td>
</tr>
<tr>
<td>Port:</td>
<td>&lt;unset&gt; 80/TCP</td>
</tr>
<tr>
<td>TargetPort:</td>
<td>80/TCP</td>
</tr>
<tr>
<td>Session Affinity:</td>
<td>None</td>
</tr>
<tr>
<td>Events:</td>
<td>&lt;none&gt;</td>
</tr>
</tbody>
</table>

In the previous output, the value for IP: is a unique IP address that can be reached from any node or pod within the cluster, but it can't be reached from outside of the cluster. The values for Endpoints are IP addresses assigned from within your VPC to the pods that are part of the service.

6. View the details of one of the pods listed in the output when you viewed the namespace (p. 341) in a previous step. If you deployed a Windows app, replace `linux` with `windows` and replace `776d8f8fd8-78w66` with the value returned for one of your pods.
Abbreviated output

If you deployed Windows resources, then all instances of `linux` in the following output are `windows`. The other example values may be different from your output.

```bash
kubectl -n eks-sample-app describe pod eks-sample-linux-deployment-65b7669776-m6qxz
```

**Name:** eks-sample-linux-deployment-65b7669776-m6qxz  
**Namespace:** eks-sample-app  
**Priority:** 0  
**Node:** ip-192-168-45-132.us-west-2.compute.internal/192.168.45.132  
**IP:** 192.168.63.93  
**IPs:** 192.168.63.93  
**Controlled By:** ReplicaSet/eks-sample-linux-deployment-65b7669776  
**Conditions:**

<table>
<thead>
<tr>
<th>Type</th>
<th>Status</th>
</tr>
</thead>

</thead>
<tbody>
<tr>
<td>Normal</td>
<td>Scheduled</td>
<td>3m20s</td>
<td>default-scheduler</td>
<td>Successfully assigned eks-sample-app/eks-sample-linux-deployment-65b7669776 to ip-192-168-45-132.us-west-2.compute.internal</td>
</tr>
</tbody>
</table>

In the previous output, the value for `IP:` is a unique IP that's assigned to the pod from the CIDR block assigned to the subnet that the node is in. If you prefer to assign pods IP addresses from different CIDR blocks, you can change the default behavior. For more information, see Tutorial: Custom networking (p. 276). You can also see that the Kubernetes scheduler scheduled the pod on the Node with the IP address `192.168.45.132`.

**Tip**  
Rather than using the command line, you can view many details about pods, services, deployments, and other Kubernetes resources in the AWS Management Console. For more information, see View Kubernetes resources (p. 500).

7. Run a shell on the pod that you described in the previous step, replacing `65b7669776-m6qxz` with the ID of one of your pods.

**Linux**

```bash
kubectl exec -it eks-sample-linux-deployment-65b7669776-m6qxz -n eks-sample-app -- /bin/bash
```

**Windows**

```bash
kubectl exec -it eks-sample-windows-deployment-65b7669776-m6qxz -n eks-sample-app -- powershell.exe
```
8. From the pod shell, view the output from the web server that was installed with your deployment in a previous step. You only need to specify the service name. It is resolved to the service's IP address by CoreDNS, which is deployed with an Amazon EKS cluster, by default.

Linux

```bash
curl eks-sample-linux-service
```

The example output is as follows.

```html
<!DOCTYPE html>
<html>
<head>
<title>Welcome to nginx!</title>
</head>
<body>
<marquee>
H1> Hello EKS !!! <H1> <marquee>
</body>
</html>
```

Windows

```bash
Invoke-WebRequest -uri eks-sample-windows-service/default.html -UseBasicParsing
```

The example output is as follows.

```plaintext
StatusCode        : 200
StatusDescription : OK
Content           : <html> <body> <br/> <br/> <marquee> <h1> Hello EKS !!! <h1> <marquee> </body> </html>
```

9. From the pod shell, view the DNS server for the pod.

Linux

```bash
cat /etc/resolv.conf
```

The example output is as follows.

```plaintext
nameserver 10.100.0.10
search eks-sample-app.svc.cluster.local svc.cluster.local cluster.local us-west-2.compute.internal
options ndots:5
```

In the previous output, 10.100.0.10 is automatically assigned as the nameserver for all pods deployed to the cluster.

Windows

```bash
Get-NetIPConfiguration
```

Abbreviated output

```plaintext
InterfaceAlias : vEthernet
... IPv4Address : 192.168.63.14
... DNSServer : 10.100.0.10
```
In the previous output, 10.100.0.10 is automatically assigned as the DNS server for all pods deployed to the cluster.

10. Disconnect from the pod by typing `exit`.

11. Once you're finished with the sample application, you can remove the sample namespace, service, and deployment with the following command:

```
kubectl delete namespace eks-sample-app
```

---

## Vertical Pod Autoscaler

The Kubernetes [Vertical Pod Autoscaler](https://kubernetes.io/docs/tasks/run-application/configure-horizontal-pod-autoscaler/) automatically adjusts the CPU and memory reservations for your pods to help "right size" your applications. This adjustment can improve cluster resource utilization and free up CPU and memory for other pods. This topic helps you to deploy the Vertical Pod Autoscaler to your cluster and verify that it is working.

### Prerequisites

- You have an existing Amazon EKS cluster. If you don't, see [Getting started with Amazon EKS](p. 4).
- You have the Kubernetes Metrics Server installed. For more information, see [Installing the Kubernetes Metrics Server](p. 407).
- You are using a `kubectl` client that is configured to communicate with your Amazon EKS cluster (p. 18).
- OpenSSL 1.1.1 or later installed on your device.

### Deploy the Vertical Pod Autoscaler

In this section, you deploy the Vertical Pod Autoscaler to your cluster.

#### To deploy the Vertical Pod Autoscaler

1. Open a terminal window and navigate to a directory where you would like to download the Vertical Pod Autoscaler source code.
2. Clone the `kubernetes/autoscaler` GitHub repository.

   ```
git clone https://github.com/kubernetes/autoscaler.git
```

3. Change to the `vertical-pod-autoscaler` directory.

   ```
cd autoscaler/vertical-pod-autoscaler/
```

4. (Optional) If you have already deployed another version of the Vertical Pod Autoscaler, remove it with the following command.

   ```
./hack/vpa-down.sh
```

5. If your nodes don't have internet access to the `k8s.gcr.io` container registry, then you need to pull the following images and push them to your own private repository. For more information about how to pull the images and push them to your own private repository, see [Copy a container image from one repository to another repository](p. 363).

   ```
k8s.gcr.io/autoscaling/vpa-admission-controller:0.10.0
```
Test your Vertical Pod Autoscaler installation

In this section, you deploy a sample application to verify that the Vertical Pod Autoscaler is working.

To test your Vertical Pod Autoscaler installation

1. Deploy the hamster.yaml Vertical Pod Autoscaler example with the following command.

   ```sh
ekubectl apply -f examples/hamster.yaml
   ```

2. Get the pods from the hamster example application.

   ```sh
   kubectl get pods -l app=hamster
   ```

   The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>metrics-server-8459fc497-kfj8w</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>83m</td>
</tr>
<tr>
<td>vpa-admission-controller-68c748777d-ppspd</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>7s</td>
</tr>
<tr>
<td>vpa-recommender-6fc8c67d85-gljpl</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>8s</td>
</tr>
<tr>
<td>vpa-updater-7b6b96955c-bgp9d</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>8s</td>
</tr>
</tbody>
</table>

3. Describe one of the pods to view its cpu and memory reservation. Replace `c7d89d6db-rglf5` with one of the IDs returned in your output from the previous step.
Test your Vertical Pod Autoscaler installation

```bash
kubectl describe pod hamster-c7d89d6db-rglf5
```

The example output is as follows.

```
... Containers:
  hamster: 
    Container ID: docker://
e76c2413fc720ac395c33b64888c82094fc8e5d50e373d5f818f3978577e24
    Image: k8s.gcr.io/ubuntu-slim:0.1
    Image ID: docker-pullable://k8s.gcr.io/ubuntu-slim@sha256:b6f8c3885f5880a4f1a7cf717c07242eb485fdd5a84b5f8e35b1cf680ea17b1
    Port: <none>
    Host Port: <none>
    Command: /bin/sh
    Args: -c
      while true; do timeout 0.5s yes >/dev/null; sleep 0.5s; done
    State: Running
    Started: Fri, 27 Sep 2019 10:35:16 -0700
    Ready: True
    Restart Count: 0
    Requests: cpu: 100m
    memory: 50Mi
...
```

You can see that the original pod reserves 100 milliCPU of CPU and 50 mebibytes of memory. For this example application, 100 milliCPU is less than the pod needs to run, so it is CPU-constrained. It also reserves much less memory than it needs. The Vertical Pod Autoscaler vpa-recommender deployment analyzes the hamster pods to see if the CPU and memory requirements are appropriate. If adjustments are needed, the vpa-updater relaunches the pods with updated values.

4. Wait for the vpa-updater to launch a new hamster pod. This should take a minute or two. You can monitor the pods with the following command.

   **Note** If you are not sure that a new pod has launched, compare the pod names with your previous list. When the new pod launches, you will see a new pod name.

```bash
kubectl get --watch pods -l app=hamster
```

5. When a new hamster pod is started, describe it and view the updated CPU and memory reservations.

```bash
kubectl describe pod hamster-c7d89d6db-jxgfv
```

The example output is as follows.

```
... Containers:
  hamster: 
    Container ID: docker://2c3e7b6fb7ce0d8c86444334df654af6fb3fc8a8aad4c5d710eacb1e7c58f7db
    Image: k8s.gcr.io/ubuntu-slim:0.1
    Image ID: docker-pullable://k8s.gcr.io/ubuntu-slim@sha256:b6f8c3885f5880a4f1a7cf717c07242eb485fdd5a84b5f8e35b1cf680ea17b1
    Port: <none>
```
Host Port: <none>
Command: /bin/sh
Args:
- c
  while true; do timeout 0.5s yes >/dev/null; sleep 0.5s; done
State: Running
Started: Fri, 27 Sep 2019 10:37:08 -0700
Ready: True
Restart Count: 0
Requests:
  cpu: 587m
  memory: 262144k

In the previous output, you can see that the cpu reservation increased to 587 millicpu, which is over five times the original value. The memory increased to 262,144 Kilobytes, which is around 250 mebibytes, or five times the original value. This pod was under-resourced, and the Vertical Pod Autoscaler corrected the estimate with a much more appropriate value.

6. Describe the hamster-vpa resource to view the new recommendation.

```bash
cubectl describe vpa/hamster-vpa
```

The example output is as follows.

```
Name:         hamster-vpa
Namespace:    default
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:
               {
                   "apiVersion":"autoscaling.k8s.io/v1beta2",
                   "kind":"VerticalPodAutoscaler",
                   "metadata":{
                       "annotations":{},

```
Horizontal Pod Autoscaler

The Kubernetes Horizontal Pod Autoscaler automatically scales the number of pods in a deployment, replication controller, or replica set based on that resource's CPU utilization. This can help your applications scale out to meet increased demand or scale in when resources are not needed, thus freeing up your nodes for other applications. When you set a target CPU utilization percentage, the Horizontal Pod Autoscaler scales your application in or out to try to meet that target.

The Horizontal Pod Autoscaler is a standard API resource in Kubernetes that simply requires that a metrics source (such as the Kubernetes metrics server) is installed on your Amazon EKS cluster to work. You do not need to deploy or install the Horizontal Pod Autoscaler on your cluster to begin scaling your applications. For more information, see Horizontal Pod Autoscaler in the Kubernetes documentation.

Use this topic to prepare the Horizontal Pod Autoscaler for your Amazon EKS cluster and to verify that it is working with a sample application.

**Note**
This topic is based on the Horizontal pod autoscaler walkthrough in the Kubernetes documentation.

**Prerequisites**

- You have an existing Amazon EKS cluster. If you don't, see Getting started with Amazon EKS (p. 4).
- You have the Kubernetes Metrics Server installed. For more information, see Installing the Kubernetes Metrics Server (p. 407).
- You are using a `kubectl` client that is configured to communicate with your Amazon EKS cluster (p. 18).

**Run a Horizontal Pod Autoscaler test application**

In this section, you deploy a sample application to verify that the Horizontal Pod Autoscaler is working.

**Note**
This example is based on the Horizontal pod autoscaler walkthrough in the Kubernetes documentation.

**To test your Horizontal Pod Autoscaler installation**

1. Deploy a simple Apache web server application with the following command.

```bash
kubectl apply -f https://k8s.io/examples/application/php-apache.yaml
```

This Apache web server pod is given a 500 millicpu CPU limit and it is serving on port 80.
2. Create a Horizontal Pod Autoscaler resource for the php-apache deployment.

```bash
kubectl autoscale deployment php-apache --cpu-percent=50 --min=1 --max=10
```

This command creates an autoscaler that targets 50 percent CPU utilization for the deployment, with a minimum of one pod and a maximum of ten pods. When the average CPU load is lower than 50 percent, the autoscaler tries to reduce the number of pods in the deployment, to a minimum of one. When the load is greater than 50 percent, the autoscaler tries to increase the number of pods in the deployment, up to a maximum of ten. For more information, see How does a HorizontalPodAutoscaler work? in the Kubernetes documentation.

3. Describe the autoscaler with the following command to view its details.

```bash
kubectl get hpa
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS</th>
<th>MINPODS</th>
<th>MAXPODS</th>
<th>REPLICAS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>0%/50%</td>
<td>1</td>
<td>10</td>
<td>1</td>
<td>51s</td>
</tr>
</tbody>
</table>

As you can see, the current CPU load is 0%, because there's no load on the server yet. The pod count is already at its lowest boundary (one), so it cannot scale in.

4. Create a load for the web server by running a container.

```bash
kubectl run -i --tty load-generator --rm --image=busybox --restart=Never -- /bin/sh -c "while sleep 0.01; do wget -q -O- http://php-apache; done"
```

5. To watch the deployment scale out, periodically run the following command in a separate terminal from the terminal that you ran the previous step in.

```bash
kubectl get hpa php-apache
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS</th>
<th>MINPODS</th>
<th>MAXPODS</th>
<th>REPLICAS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>250%/50%</td>
<td>1</td>
<td>10</td>
<td>5</td>
<td>4m44s</td>
</tr>
</tbody>
</table>

It may take over a minute for the replica count to increase. As long as actual CPU percentage is higher than the target percentage, then the replica count increases, up to 10. In this case, it's 250%, so the number of REPLICA continues to increase.

**Note**
It may take a few minutes before you see the replica count reach its maximum. If only 6 replicas, for example, are necessary for the CPU load to remain at or under 50%, then the load won't scale beyond 6 replicas.

6. Stop the load. In the terminal window you're generating the load in, stop the load by holding down the Ctrl+C keys. You can watch the replicas scale back to 1 by running the following command again in the terminal that you're watching the scaling in.

```bash
kubectl get hpa
```

The example output is as follows.
Network load balancing on Amazon EKS

Network traffic is load balanced at L4 of the OSI model. To load balance application traffic at L7, you deploy a Kubernetes ingress, which provisions an AWS Application Load Balancer. For more information, see Application load balancing on Amazon EKS (p. 357). To learn more about the differences between the two types of load balancing, see Elastic Load Balancing features on the AWS website.

When you create a Kubernetes Service of type LoadBalancer, the AWS cloud provider load balancer controller creates AWS Classic Load Balancers by default, but can also create AWS Network Load Balancers. This controller is only receiving critical bug fixes in the future. For more information about using the AWS cloud provider load balancer, see AWS cloud provider load balancer controller in the Kubernetes documentation. Its use is not covered in this topic.

We recommend that you use version 2.4.3 or later of the AWS Load Balancer Controller (p. 308) instead of the AWS cloud provider load balancer controller. The AWS Load Balancer Controller creates AWS Network Load Balancers, but doesn't create AWS Classic Load Balancers. The remainder of this topic is about using the AWS Load Balancer Controller.

An AWS Network Load Balancer can load balance network traffic to pods deployed to Amazon EC2 IP and instance targets or to AWS Fargate IP targets. For more information, see AWS Load Balancer Controller on GitHub.

Prerequisites

Before you can load balance network traffic using the AWS Load Balancer Controller, you must meet the following requirements.

- Have an existing cluster. If you don't have an existing cluster, see Getting started with Amazon EKS (p. 4). If you need to update the version of an existing cluster, see Updating an Amazon EKS cluster Kubernetes version (p. 32).
- Have the AWS Load Balancer Controller deployed on your cluster. For more information, see Installing the AWS Load Balancer Controller add-on (p. 308). We recommend version 2.4.3 or later.
- At least one subnet. If multiple tagged subnets are found in an Availability Zone, the controller chooses the first subnet whose subnet ID comes first lexicographically. The subnet must have at least eight available IP addresses.
- If you're using the AWS Load Balancer Controller version 2.1.1 or earlier, subnets must be tagged as follows. If using version 2.1.2 or later, this tag is optional. You might want to tag a subnet if you have multiple clusters running in the same VPC, or multiple AWS services sharing subnets in a VPC, and want more control over where load balancers are provisioned for each cluster. If you explicitly specify subnet IDs as an annotation on a service object, then Kubernetes and the AWS Load Balancer
Controller use those subnets directly to create the load balancer. Subnet tagging isn't required if you choose to use this method for provisioning load balancers and you can skip the following private and public subnet tagging requirements. Replace my-cluster with your cluster name.

- **Key** – kubernetes.io/cluster/my-cluster
- **Value** – shared or owned

Your public and private subnets must meet the following requirements, unless you explicitly specify subnet IDs as an annotation on a service or ingress object. If you provision load balancers by explicitly specifying subnet IDs as an annotation on a service or ingress object, then Kubernetes and the AWS Load Balancer Controller use those subnets directly to create the load balancer and the following tags aren't required.

- **Private subnets** – Must be tagged in the following format. This is so that Kubernetes and the AWS Load Balancer Controller know that the subnets can be used for internal load balancers. If you use eksctl or an Amazon EKS AWS AWS CloudFormation template to create your VPC after March 26, 2020, then the subnets are tagged appropriately when they're created. For more information about the Amazon EKS AWS AWS CloudFormation VPC templates, see Creating a VPC for your Amazon EKS cluster (p. 241).
  - **Key** – kubernetes.io/role/internal-elb
  - **Value** – 1

- **Public subnets** – Must be tagged in the following format. This is so that Kubernetes knows to use only those subnets for external load balancers instead of choosing a public subnet in each Availability Zone (based on the lexicographical order of the subnet IDs). If you use eksctl or an Amazon EKS AWS AWS CloudFormation template to create your VPC after March 26, 2020, then the subnets are tagged appropriately when they're created. For more information about the Amazon EKS AWS AWS CloudFormation VPC templates, see Creating a VPC for your Amazon EKS cluster (p. 241).
  - **Key** – kubernetes.io/role/elb
  - **Value** – 1

If the subnet role tags aren't explicitly added, the Kubernetes service controller examines the route table of your cluster VPC subnets to determine if the subnet is private or public. We recommend that you don't rely on this behavior, and instead explicitly add the private or public role tags. The AWS Load Balancer Controller doesn't examine route tables, and requires the private and public tags to be present for successful auto discovery.

**Considerations**

- The configuration of your load balancer is controlled by annotations that are added to the manifest for your service. Service annotations are different when using the AWS Load Balancer Controller than they are when using the AWS cloud provider load balancer controller. Make sure to review the annotations for the AWS Load Balancer Controller before deploying services.
- When using the Amazon VPC CNI plugin for Kubernetes (p. 247), the AWS Load Balancer Controller can load balance to Amazon EC2 IP or instance targets and Fargate IP targets. When using Alternate compatible CNI plugins (p. 308), the controller can only load balance to instance targets. For more information about Network Load Balancer target types, see Target type in the User Guide for Network Load Balancers.
- If you want to add tags to the load balancer when or after it's created, add the following annotation in your service specification. For more information, see AWS Resource Tags in the AWS Load Balancer Controller documentation.
  
  `service.beta.kubernetes.io/aws-load-balancer-additional-resource-tags`

- You can assign Elastic IP addresses to the Network Load Balancer by adding the following annotation. Replace the example values with the Allocation IDs of your Elastic IP addresses. The number of Allocation IDs must match the number of subnets that are used for the load balancer. For more information, see the AWS Load Balancer Controller documentation.
Create a network load balancer

You can create a network load balancer with IP or instance targets.

**IP targets**

You can use IP targets with pods deployed to Amazon EC2 nodes or Fargate. Your Kubernetes service must be created as type `LoadBalancer`. For more information, see Type LoadBalancer in the Kubernetes documentation.

To create a load balancer that uses IP targets, add the following annotations to a service manifest and deploy your service. The external value for `aws-load-balancer-type` is what causes the AWS Load Balancer Controller, rather than the AWS cloud provider load balancer controller, to create the Network Load Balancer. You can view a sample service manifest (p. 356) with the annotations.

```

```

**Note**

If you're load balancing to IPv6 pods, add the following annotation. You can only load balance over IPv6 to IP targets, not instance targets. Without this annotation, load balancing is over IPv4.

```

```

Amazon EKS adds one inbound rule to the node's security group for client traffic and one rule for each load balancer subnet in the VPC for health checks for each Network Load Balancer that you create. Deployment of a service of type `LoadBalancer` can fail if Amazon EKS attempts to create rules that exceed the quota for the maximum number of rules allowed for a security group. For more information, see Security groups in Amazon VPC quotas in the Amazon VPC User Guide. Consider the following options to minimize the chances of exceeding the maximum number of rules for a security group:

- Request an increase in your rules per security group quota. For more information, see Requesting a quota increase in the Service Quotas User Guide.
- Use IP targets, rather than instance targets. With IP targets, you can share rules for the same target ports. You can manually specify load balancer subnets with an annotation. For more information, see Annotations on GitHub.
- Use an ingress, instead of a service of type `LoadBalancer`, to send traffic to your service. The AWS Application Load Balancer requires fewer rules than Network Load Balancers. You can share an ALB across multiple ingresses. For more information, see Application load balancing on Amazon EKS (p. 357). You can't share a Network Load Balancer across multiple services.
- Deploy your clusters to multiple accounts.
- If your pods run on Windows in an Amazon EKS cluster, a single service with a load balancer can support up to 1024 back-end pods. Each pod has its own unique IP address.
- We recommend only creating new Network Load Balancers with the AWS Load Balancer Controller. Attempting to replace existing Network Load Balancers created with the AWS cloud provider load balancer controller can result in multiple Network Load Balancers that might cause application downtime.
Network Load Balancers are created with the `internal aws-load-balancer-scheme`, by default. You can launch Network Load Balancers in any subnet in your cluster’s VPC, including subnets that weren’t specified when you created your cluster.

Kubernetes examines the route table for your subnets to identify whether they are public or private. Public subnets have a route directly to the internet using an internet gateway, but private subnets do not.

If you want to create a Network Load Balancer in a public subnet to load balance to Amazon EC2 nodes (Fargate can only be private), specify `internet-facing` with the following annotation:

```
service.beta.kubernetes.io/aws-load-balancer-scheme: "internet-facing"
```

**Note**
The `service.beta.kubernetes.io/aws-load-balancer-type: "nlb-ip"` annotation is still supported for backwards compatibility. However, we recommend using the previous annotations for new load balancers instead of `service.beta.kubernetes.io/aws-load-balancer-type: "nlb-ip"`.

**Important**
Do not edit the annotations after creating your service. If you need to modify it, delete the service object and create it again with the desired value for this annotation.

**Instance targets**

The AWS cloud provider load balancer controller creates Network Load Balancers with instance targets only. Version 2.2.0 and later of the AWS Load Balancer Controller also creates Network Load Balancers with instance targets. We recommend using it, rather than the AWS cloud provider load balancer controller, to create new Network Load Balancers. You can use Network Load Balancer instance targets with pods deployed to Amazon EC2 nodes, but not to Fargate. To load balance network traffic across pods deployed to Fargate, you must use IP targets.

To deploy a Network Load Balancer to a private subnet, your service specification must have the following annotations. You can view a sample service manifest (p. 356) with the annotations. The external value for `aws-load-balancer-type` is what causes the AWS Load Balancer Controller, rather than the AWS cloud provider load balancer controller, to create the Network Load Balancer.

```
service.beta.kubernetes.io/aws-load-balancer-type: "external"
service.beta.kubernetes.io/aws-load-balancer-nlb-target-type: "instance"
```

Network Load Balancers are created with the `internal aws-load-balancer-scheme`, by default. For internal Network Load Balancers, your Amazon EKS cluster must be configured to use at least one private subnet in your VPC. Kubernetes examines the route table for your subnets to identify whether they are public or private. Public subnets have a route directly to the internet using an internet gateway, but private subnets do not.

If you want to create an Network Load Balancer in a public subnet to load balance to Amazon EC2 nodes, specify `internet-facing` with the following annotation:

```
service.beta.kubernetes.io/aws-load-balancer-scheme: "internet-facing"
```

**Important**
Do not edit the annotations after creating your service. If you need to modify it, delete the service object and create it again with the desired value for this annotation.
(Optional) Deploy a sample application

Prerequisites

- At least one public or private subnet in your cluster VPC.
- Have the AWS Load Balancer Controller deployed on your cluster. For more information, see Installing the AWS Load Balancer Controller add-on (p. 308). We recommend version 2.4.3 or later.

To deploy a sample application

1. If you’re deploying to Fargate, make sure you have an available private subnet in your VPC and create a Fargate profile. If you’re not deploying to Fargate, skip this step. You can create the profile by running the following command or in the AWS Management Console (p. 149) using the same values for name and namespace that are in the command. Replace the example values with your own.

   ```bash
   eksctl create fargateprofile \
   --cluster my-cluster \
   --region region-code \
   --name nlb-sample-app \
   --namespace nlb-sample-app
   ```

2. Deploy a sample application.
   a. Create a namespace for the application.

   ```bash
   kubectl create namespace nlb-sample-app
   ```

   b. Save the following contents to a file named `sample-deployment.yaml` file on your computer.

   ```yaml
   apiVersion: apps/v1
   kind: Deployment
   metadata:
     name: nlb-sample-app
     namespace: nlb-sample-app
   spec:
     replicas: 3
     selector:
       matchLabels:
         app: nginx
     template:
       metadata:
         labels:
           app: nginx
     spec:
       containers:
       - name: nginx
         image: public.ecr.aws/nginx/nginx:1.21
         ports:
           - name: tcp
             containerPort: 80
   ```

   c. Apply the manifest to the cluster.

   ```bash
   kubectl apply -f sample-deployment.yaml
   ```

3. Create a service with an internet-facing Network Load Balancer that load balances to IP targets.
a. Save the following contents to a file named `sample-service.yaml` file on your computer. If you're deploying to Fargate nodes, remove the `service.beta.kubernetes.io/aws-load-balancer-scheme: internet-facing` line.

```yaml
apiVersion: v1
kind: Service
metadata:
  name: nlb-sample-service
  namespace: nlb-sample-app
  annotations:
    service.beta.kubernetes.io/aws-load-balancer-type: external
    service.beta.kubernetes.io/aws-load-balancer-nlb-target-type: ip
    service.beta.kubernetes.io/aws-load-balancer-scheme: internet-facing
spec:
  ports:
  - port: 80
    targetPort: 80
    protocol: TCP
  type: LoadBalancer
  selector:
    app: nginx
```

b. Apply the manifest to the cluster.

```
kubectl apply -f sample-service.yaml
```

4. Verify that the service was deployed.

```
kubectl get svc nlb-sample-service -n nlb-sample-app
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>sample-service</td>
<td>LoadBalancer</td>
<td>10.100.240.137</td>
<td></td>
<td>80:32400/TCP</td>
<td>16h</td>
</tr>
<tr>
<td>k8s-nlbsampli-nlbsampl-xxxxxxxx-xxxxxxxxxxxxxxxx.elb.region-code.amazonaws.com</td>
<td></td>
<td>xxxxxxxxxx-xxxxxxx</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note**
The values for `10.100.240.137` and `xxxxxxxxxxxx-xxxxxxxxxxxxxxx` will be different than the example output (they will be unique to your load balancer) and `us-west-2` may be different for you, depending on which AWS Region that your cluster is in.

5. Open the Amazon EC2 AWS Management Console. Select **Target Groups** (under **Load Balancing**) in the left navigation pane. In the **Name** column, select the target group's name where the value in the **Load balancer** column matches a portion of the name in the **EXTERNAL-IP** column of the output in the previous step. For example, you'd select the target group named `k8s-default-samplese-xxxxxxxxxx` if your output were the same as the previous output. The **Target type** is **IP** because that was specified in the sample service manifest.

6. Select the **Target group** and then select the **Targets** tab. Under **Registered targets**, you should see three IP addresses of the three replicas deployed in a previous step. Wait until the status of all targets is **healthy** before continuing. It might take several minutes before all targets are healthy. The targets might be in an unhealthy state before changing to a healthy state.

7. Send traffic to the service replacing `xxxxxxxxxxx-xxxxxxxxxxxxxxxxxx` and `us-west-2` with the values returned in the output for a previous step (p. 356) for **EXTERNAL-IP**. If you deployed to a private subnet, then you'll need to view the page from a device within your VPC, such as a bastion host. For more information, see Linux Bastion Hosts on AWS.
Application load balancing on Amazon EKS

When you create a Kubernetes ingress, an AWS Application Load Balancer (ALB) is provisioned that load balances application traffic. To learn more, see What is an Application Load Balancer? in the Application Load Balancers User Guide and Ingress in the Kubernetes documentation. ALBs can be used with pods that are deployed to nodes or to AWS Fargate. You can deploy an ALB to public or private subnets.

Application traffic is balanced at L7 of the OSI model. To load balance network traffic at L4, you deploy a Kubernetes service of the LoadBalancer type. This type provisions an AWS Network Load Balancer. For more information, see Network load balancing on Amazon EKS (p. 351). To learn more about the differences between the two types of load balancing, see Elastic Load Balancing features on the AWS website.

Prerequisites

Before you can load balance application traffic to an application, you must meet the following requirements.

- Have an existing cluster. If you don't have an existing cluster, see Getting started with Amazon EKS (p. 4). If you need to update the version of an existing cluster, see Updating an Amazon EKS cluster Kubernetes version (p. 32).
- Have the AWS Load Balancer Controller deployed on your cluster. For more information, see Installing the AWS Load Balancer Controller add-on (p. 308). We recommend version 2.4.3 or later.
- At least two subnets in different Availability Zones. The AWS Load Balancer Controller chooses one subnet from each Availability Zone. When multiple tagged subnets are found in an Availability Zone, the controller chooses the subnet whose subnet ID comes first lexicographically. Each subnet must have at least eight available IP addresses.

If you're using multiple security groups attached to worker node, exactly one security group must be tagged as follows. Replace my-cluster with your cluster name.

- **Key** – kubernetes.io/cluster/my-cluster
- **Value** – shared or owned

- If you're using the AWS Load Balancer Controller version 2.1.1 or earlier, subnets must be tagged in the format that follows. If you're using version 2.1.2 or later, tagging is optional. However, we recommend that you tag a subnet if any of the following is the case. You have multiple clusters that are running in the same VPC, or have multiple AWS services that share subnets in a VPC. Or, you want more control over where load balancers are provisioned for each cluster. Replace my-cluster with your cluster name.
• **Key** – kubernetes.io/cluster/my-cluster
  • **Value** – shared or owned

Your public and private subnets must meet the following requirements. This is unless you explicitly specify subnet IDs as an annotation on a service or ingress object. Assume that you provision load balancers by explicitly specifying subnet IDs as an annotation on a service or ingress object. In this situation, Kubernetes and the AWS load balancer controller use those subnets directly to create the load balancer and the following tags aren't required.

• **Private subnets** – Must be tagged in the following format. This is so that Kubernetes and the AWS load balancer controller know that the subnets can be used for internal load balancers. If you use eksctl or an Amazon EKS AWS CloudFormation template to create your VPC after March 26, 2020, the subnets are tagged appropriately when created. For more information about the Amazon EKS AWS CloudFormation VPC templates, see Creating a VPC for your Amazon EKS cluster (p. 241).
  • **Key** – kubernetes.io/role/internal-elb
  • **Value** – 1

• **Public subnets** – Must be tagged in the following format. This is so that Kubernetes knows to use only the subnets that were specified for external load balancers. This way, Kubernetes doesn't choose a public subnet in each Availability Zone (lexicographically based on their subnet ID). If you use eksctl or an Amazon EKS AWS CloudFormation template to create your VPC after March 26, 2020, the subnets are tagged appropriately when created. For more information about the Amazon EKS AWS CloudFormation VPC templates, see Creating a VPC for your Amazon EKS cluster (p. 241).
  • **Key** – kubernetes.io/role/elb
  • **Value** – 1

If the subnet role tags aren't explicitly added, the Kubernetes service controller examines the route table of your cluster VPC subnets. This is to determine if the subnet is private or public. We recommend that you don't rely on this behavior. Rather, explicitly add the private or public role tags. The AWS Load Balancer Controller doesn't examine route tables. It also requires the private and public tags to be present for successful auto discovery.

### Considerations

• The **AWS Load Balancer Controller** creates ALBs and the necessary supporting AWS resources whenever a Kubernetes ingress resource is created on the cluster with the `kubernetes.io/ingress.class: alb` annotation. The ingress resource configures the ALB to route HTTP or HTTPS traffic to different pods within the cluster. To ensure that your ingress objects use the AWS Load Balancer Controller, add the following annotation to your Kubernetes ingress specification. For more information, see Ingress specification on GitHub.

```yaml
annotations:
  kubernetes.io/ingress.class: alb
```

**Note**

If you're load balancing to IPv6 pods, add the following annotation to your ingress spec. You can only load balance over IPv6 to IP targets, not instance targets. Without this annotation, load balancing is over IPv4.

```yaml
alb.ingress.kubernetes.io/ip-address-type: dualstack
```

• The AWS Load Balancer Controller supports the following traffic modes:

  • **Instance** – Registers nodes within your cluster as targets for the ALB. Traffic reaching the ALB is routed to NodePort for your service and then proxied to your pods. This is the default traffic mode. You can also explicitly specify it with the `alb.ingress.kubernetes.io/target-type: instance` annotation.
Note
Your Kubernetes service must specify the NodePort or "LoadBalancer" type to use this traffic mode.

- **IP** – Registers pods as targets for the ALB. Traffic reaching the ALB is directly routed to pods for your service. You must specify the `alb.ingress.kubernetes.io/target-type: ip` annotation to use this traffic mode. The IP target type is required when target pods are running on Fargate.

- To tag ALBs created by the controller, add the following annotation to the controller:
  
  `alb.ingress.kubernetes.io/tags`. For a list of all available annotations supported by the AWS Load Balancer Controller, see [Ingress annotations on GitHub](#).

- Upgrading or downgrading the ALB controller version can introduce breaking changes for features that rely on it. For more information about the breaking changes that are introduced in each release, see [the ALB controller release notes on GitHub](#).

To share an application load balancer across multiple service resources using **IngressGroups**

To join an ingress to a group, add the following annotation to a Kubernetes ingress resource specification.

```
alb.ingress.kubernetes.io/group.name: my-group
```

The group name must:

- Be 63 or fewer characters in length.
- Consist of lower case letters, numbers, -, and .
- Start and end with a letter or number.

The controller automatically merges ingress rules for all ingresses in the same ingress group. It supports them with a single ALB. Most annotations that are defined on an ingress only apply to the paths defined by that ingress. By default, ingress resources don't belong to any ingress group.

**Warning**

**Potential security risk**: Specify an ingress group for an ingress only when all the Kubernetes users that have RBAC permission to create or modify ingress resources are within the same trust boundary. If you add the annotation with a group name, other Kubernetes users might create or modify their ingresses to belong to the same ingress group. Doing so can cause undesirable behavior, such as overwriting existing rules with higher priority rules.

You can add an order number of your ingress resource.

```
alb.ingress.kubernetes.io/group.order: '10'
```

The number can be 1-1000. The lowest number for all ingresses in the same ingress group is evaluated first. All ingresses without this annotation are evaluated with a value of zero. Duplicate rules with a higher number can overwrite rules with a lower number. By default, the rule order between ingresses within the same ingress group is determined lexicographically based namespace and name.

**Important**

Ensure that each ingress in the same ingress group has a unique priority number. You can't have duplicate order numbers across ingresses.

**(Optional) Deploy a sample application**

**Prerequisites**

- At least one public or private subnet in your cluster VPC.
• Have the AWS Load Balancer Controller deployed on your cluster. For more information, see Install the AWS Load Balancer Controller add-on (p. 308). We recommend version 2.4.3 or later.

To deploy a sample application

You can run the sample application on a cluster that has Amazon EC2 nodes, Fargate pods, or both.

1. If you're not deploying to Fargate, skip this step. If you're deploying to Fargate, create a Fargate profile. You can create the profile by running the following command or in the AWS Management Console (p. 149) using the same values for name and namespace that are in the command. Replace the example values with your own.

   ```
   eksctl create fargateprofile \
   --cluster my-cluster \
   --region region-code \
   --name alb-sample-app \
   --namespace game-2048
   ```

2. Deploy the game 2048 as a sample application to verify that the AWS Load Balancer Controller creates an AWS ALB as a result of the ingress object. Complete the steps for the type of subnet you're deploying to.

   a. If you're deploying to pods in a cluster that you created with the IPv6 family, skip to the next step.

      • Public

      ```
      kubectl apply -f https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.4.3/docs/examples/2048/2048_full.yaml
      ```

      • Private

      1. Download the manifest.

      ```
      curl -o 2048_full.yaml https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.4.3/docs/examples/2048/2048_full.yaml
      ```

      2. Edit the file and find the line that says `alb.ingress.kubernetes.io/scheme: internet-facing`.

      3. Change `internet-facing` to `internal` and save the file.

      4. Apply the manifest to your cluster.

      ```
      kubectl apply -f 2048_full.yaml
      ```

   b. If you're deploying to pods in a cluster that you created with the IPv6 family (p. 264), complete the following steps.

      1. Download the manifest.

      ```
      curl -o 2048_full.yaml https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.4.3/docs/examples/2048/2048_full.yaml
      ```

      2. Open the file in an editor and add the following line to the annotations in the ingress spec.

      ```
      alb.ingress.kubernetes.io/ip-address-type: dualstack
      ```
3. If you’re load balancing to internal pods, rather than internet facing pods, change the line that says `alb.ingress.kubernetes.io/scheme:` to `internet-facing` to `internal`
4. Save the file.
5. Apply the manifest to your cluster.
   ```bash
   kubectl apply -f 2048_full.yaml
   ```
3. After a few minutes, verify that the ingress resource was created with the following command.
   ```bash
   kubectl get ingress/ingress-2048 -n game-2048
   ```

   The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>CLASS</th>
<th>HOSTS</th>
<th>ADDRESS</th>
</tr>
</thead>
<tbody>
<tr>
<td>ingress-2048</td>
<td>&lt;none&gt;</td>
<td>*</td>
<td>k8s-game2048-ingress2-xxxxxxxxxx-yyyyyyyyyy.region-code.elb.amazonaws.com</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>80</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>2m32s</td>
</tr>
</tbody>
</table>

   **Note**
   If you created the load balancer in a private subnet, the value under ADDRESS in the previous output is prefaced with `internal-`.
   If your ingress wasn’t successfully created after several minutes, run the following command to view the AWS Load Balancer Controller logs. These logs might contain error messages that you can use to diagnose issues with your deployment.
   ```bash
   kubectl logs -n kube-system deployment.apps/aws-load-balancer-controller
   ```
4. If you deployed to a public subnet, open a browser and navigate to the ADDRESS URL from the previous command output to see the sample application. If you don't see anything, refresh your browser and try again. If you deployed to a private subnet, then you’ll need to view the page from a device within your VPC, such as a bastion host. For more information, see Linux Bastion Hosts on AWS.
5. When you finish experimenting with your sample application, delete it by running one of the following commands.
   - If you applied the manifest, rather than applying a copy that you downloaded, use the following command.
     ```bash
     kubectl delete -f https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.4.3/docs/examples/2048/2048_full.yaml
     ```
   - If you downloaded and edited the manifest, use the following command.
     ```bash
     kubectl delete -f 2048_full.yaml
     ```

**Restricting external IP addresses that can be assigned to services**

Kubernetes services can be reached from inside of a cluster through:

- A cluster IP address that is assigned automatically by Kubernetes
• Any IP address that you specify for the `externalIPs` property in a service spec. External IP addresses are not managed by Kubernetes and are the responsibility of the cluster administrator. External IP addresses specified with `externalIPs` are different than the external IP address assigned to a service of type `LoadBalancer` by a cloud provider.

To learn more about Kubernetes services, see Service in the Kubernetes documentation. You can restrict the IP addresses that can be specified for `externalIPs` in a service spec.

**To restrict the IP addresses that can be specified for `externalIPs` in a service spec**

1. Deploy cert-manager to manage webhook certificates. For more information, see the cert-manager documentation.

   ```bash
   kubectl apply -f https://github.com/jetstack/cert-manager/releases/download/v1.5.4/cert-manager.yaml
   ```

2. Verify that the cert-manager pods are running.

   ```bash
   kubectl get pods -n cert-manager
   ```

   The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>cert-manager-58c8844bd8-nlx7q</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>15s</td>
</tr>
<tr>
<td>cert-manager-cainjector-745768f6ff-696h5</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>15s</td>
</tr>
<tr>
<td>cert-manager-webhook-67cc76975b-4v4nk</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>14s</td>
</tr>
</tbody>
</table>

3. Review your existing services to ensure that none of them have external IP addresses assigned to them that aren’t contained within the CIDR block you want to limit addresses to.

   ```bash
   kubectl get services -A
   ```

   The example output is as follows.

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>PORT(S)</th>
<th>AGE</th>
<th>TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLUSTER-IP</td>
<td>cert-manager</td>
<td>9402/TCP</td>
<td>20m</td>
<td>ClusterIP</td>
</tr>
<tr>
<td>10.100.102.137</td>
<td>&lt;none&gt;</td>
<td>9402/TCP</td>
<td>20m</td>
<td>ClusterIP</td>
</tr>
<tr>
<td>cert-manager-webhook-67cc76975b-4v4nk</td>
<td>443/TCP</td>
<td>20m</td>
<td>ClusterIP</td>
<td></td>
</tr>
<tr>
<td>default</td>
<td>kubernetes</td>
<td>443/TCP</td>
<td>2d1h</td>
<td>ClusterIP</td>
</tr>
<tr>
<td>10.100.0.1</td>
<td>&lt;none&gt;</td>
<td>443/TCP</td>
<td>2d1h</td>
<td>ClusterIP</td>
</tr>
<tr>
<td>externalip-validation-system</td>
<td>externalip-validation-webhook-service</td>
<td>443/TCP</td>
<td>16s</td>
<td>ClusterIP</td>
</tr>
<tr>
<td>10.100.234.179</td>
<td>&lt;none&gt;</td>
<td>443/TCP</td>
<td>16s</td>
<td>ClusterIP</td>
</tr>
<tr>
<td>kube-system</td>
<td>kube-dns</td>
<td>53/UDP,53/TCP</td>
<td>2d1h</td>
<td>ClusterIP</td>
</tr>
<tr>
<td>my-namespace</td>
<td>my-service</td>
<td>80/TCP</td>
<td>149m</td>
<td>ClusterIP</td>
</tr>
<tr>
<td>10.100.128.10</td>
<td>192.168.1.1</td>
<td>80/TCP</td>
<td>149m</td>
<td>ClusterIP</td>
</tr>
</tbody>
</table>

   If any of the values are IP addresses that are not within the block you want to restrict access to, you’ll need to change the addresses to be within the block, and redeploy the services. For example, the `my-service` service in the previous output has an external IP address assigned to it that isn’t within the CIDR block example in step 5.

4. Download the external IP webhook manifest. You can also view the source code for the webhook on GitHub.
Copy a container image from one repository to another repository

This topic describes how to pull a container image from a repository that your nodes don’t have access to and push the image to a repository that your nodes have access to. You can push the image to Amazon ECR or an alternative repository that your nodes have access to.

Prerequisites

- The Docker engine installed and configured on your computer. For instructions, see Install Docker Engine in the Docker documentation.
- Version 2.7.32 or later or 1.25.72 or later of the AWS CLI installed and configured on your device or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with aws configure in the AWS Command Line Interface User Guide.
- An interface VPC endpoint for Amazon ECR if you want your nodes to pull container images from or push container images to a private Amazon ECR repository over Amazon's network. For more information, see Create the VPC endpoints for Amazon ECR in the Amazon Elastic Container Registry User Guide.

Complete the following steps to pull a container image from a repository and push it to your own repository. In the following examples that are provided in this topic, the image for the Metrics helper (p. 303) is pulled. When you follow these steps, make sure to replace the example values with your own values.
To copy a container image from one repository to another repository

1. If you don’t already have an Amazon ECR repository or another repository, then create one that your nodes have access to. The following command creates an Amazon ECR private repository. An Amazon ECR private repository name must start with a letter. It can only contain lowercase letters, numbers, hyphens (-), underscores (_), and forward slashes (/). For more information, see Creating a private repository in the Amazon Elastic Container Registry User Guide.

You can replace cni-metrics-helper with whatever you choose. As a best practice, create a separate repository for each image. We recommend this because image tags must be unique within a repository. Replace region-code with an AWS Region supported by Amazon ECR.

```
aws ecr create-repository --region region-code --repository-name cni-metrics-helper
```

2. Determine the registry, repository, and tag (optional) of the image that your nodes need to pull. This information is in the registry/repository[:tag] format.

Many of the Amazon EKS topics about installing images require that you apply a manifest file or install the image using a Helm chart. However, before you apply a manifest file or install a Helm chart, first view the contents of the manifest or chart’s values.yaml file. That way, you can determine the registry, repository, and tag to pull.

For example, you can find the following line in the manifest file for the Metrics helper (p. 303). The registry is 602401143452.dkr.ecr.us-west-2.amazonaws.com, which is an Amazon ECR private registry. The repository is cni-metrics-helper.

```
image: "602401143452.dkr.ecr.us-west-2.amazonaws.com/cni-metrics-helper:v1.11.3"
```

You may see the following variations for an image location:

- Only repository-name:tag. In this case, docker.io is usually the registry, but not specified since Kubernetes prepends it to a repository name by default if no registry is specified.
- repository-name/repository-namespace/repository:tag. A repository namespace is optional, but is sometimes specified by the repository owner for categorizing images. For example, all Amazon EC2 images in the Amazon ECR Public Gallery use the aws-ec2 namespace.

Before installing an image with Helm, view the Helm values.yaml file to determine the image location. For example, the values.yaml file for the Metrics helper (p. 303) includes the following lines.

```
image:
  region: us-west-2
  tag: v1.11.3
  account: "602401143452"
  domain: "amazonaws.com"
```

3. Pull the container image specified in the manifest file.

   a. If you’re pulling from a public registry, such as the Amazon ECR Public Gallery, you can skip to the next sub-step, because authentication isn’t required. In this example, you authenticate to an Amazon ECR private registry that contains the repository for the CNI metrics helper image. Amazon EKS maintains the image in each registry listed in Amazon container image registries (p. 365). You can authenticate to any of the registries by replacing 602401143452 and region-code with the information for a different registry. A separate registry exists for each AWS Region that Amazon EKS is supported in.
Amazon EKS User Guide

Amazon container image registries

When you deploy add-ons such as the Installing the AWS Load Balancer Controller add-on (p. 308), the Amazon VPC CNI plugin for Kubernetes (p. 253), kube-proxy (p. 328), or storage drivers (p. 203) to your cluster, your nodes might pull the container image from an Amazon EKS Amazon ECR private repository. The image's registry, repository, and tag are specified in a manifest or Helm values.yaml file referenced in the topics for each add-on that you deploy.

Amazon EKS replicates the images to a repository in each Amazon EKS supported AWS Region. Your nodes can pull the container image over the internet from any of the following registries. Alternatively, your nodes can pull the image over Amazon's network if you created an interface VPC endpoint for Amazon ECR (AWS PrivateLink) in your VPC. The registries require authentication with an AWS IAM account. Your nodes authenticate using the Amazon EKS node IAM role (p. 461), which has the permissions in the AmazonEC2ContainerRegistryReadOnly managed IAM policy associated to it.

</table>
### Amazon EKS add-ons

An add-on is software that provides supporting operational capabilities to Kubernetes applications, but is not specific to the application. This includes software like observability agents or Kubernetes drivers that allow the cluster to interact with underlying AWS resources for networking, compute, and storage. Add-on software is typically built and maintained by the Kubernetes community, cloud providers like AWS, or third-party vendors. Amazon EKS automatically installs self-managed add-ons such as the Amazon VPC CNI plugin for Kubernetes, `kube-proxy`, and CoreDNS for every cluster. You can change the default configuration of the add-ons and update them when desired.

Amazon EKS add-ons provide installation and management of a curated set of add-ons for Amazon EKS clusters. All Amazon EKS add-ons include the latest security patches, bug fixes, and are validated by AWS to work with Amazon EKS. Amazon EKS add-ons allow you to consistently ensure that your Amazon EKS clusters are secure and stable and reduce the amount of work that you need to do in order to install, configure, and update add-ons. If a self-managed add-on, such as `kube-proxy` is already running on your cluster and is available as an Amazon EKS add-on, then you can install the `kube-proxy` Amazon EKS add-on to start benefiting from the capabilities of Amazon EKS add-ons.

You can update specific Amazon EKS managed configuration fields for Amazon EKS add-ons through the Amazon EKS API. You can also modify configuration fields not managed by Amazon EKS directly within the Kubernetes cluster once the add-on starts. This includes defining specific configuration fields for an add-on where applicable. These changes are not overridden by Amazon EKS once they are made. This is made possible using the Kubernetes server-side apply feature. For more information, see Amazon EKS add-on configuration (p. 368).

You can use Amazon EKS add-ons with any Amazon EKS node type (p. 94).

### Considerations

- To configure add-ons for the cluster your IAM user must have IAM permissions to work with add-ons. For more information, see the actions with `Addon` in their name in Actions defined by Amazon Elastic Kubernetes Service.
- Amazon EKS add-ons run on the nodes that you provision or configure for your cluster. Node types include Amazon EC2 instances and Fargate.
- You can modify fields that aren't managed by Amazon EKS to customize the installation of an Amazon EKS add-on. For more information, see Amazon EKS add-on configuration (p. 368).
- If you create a cluster with the AWS Management Console, the Amazon EKS `kube-proxy`, Amazon VPC CNI plugin for Kubernetes, and CoreDNS Amazon EKS add-ons are automatically added to your cluster. If you use `eksctl` to create your cluster with a config file, `eksctl` can also create the cluster with Amazon EKS add-ons. If you create your cluster using `eksctl` without a config file or with any other tool, the self-managed `kube-proxy`, Amazon VPC CNI plugin for Kubernetes, and CoreDNS add-ons are installed, rather than the Amazon EKS add-ons. You can either manage them yourself or add the Amazon EKS add-ons manually after cluster creation.
You can add, update, or delete Amazon EKS add-ons using the Amazon EKS API, AWS Management Console, AWS CLI, and eksctl. For detailed steps when using the AWS Management Console, AWS CLI, and eksctl, see the topics for the following add-ons:

- Amazon VPC CNI plugin for Kubernetes (p. 247)
- CoreDNS (p. 316)
- kube-proxy (p. 323)
- ADOT (p. 510)
- Amazon EBS CSI (p. 211)

You can also create Amazon EKS add-ons using AWS CloudFormation.

Amazon EKS add-on configuration

Amazon EKS add-ons are installed to your cluster using standard, best practice configurations. For more information about adding an Amazon EKS add-on to your cluster, see Amazon EKS add-ons (p. 367).

You may want to customize the configuration of an Amazon EKS add-on to enable advanced features. Amazon EKS uses the Kubernetes server-side apply feature to enable management of an add-on by Amazon EKS without overwriting your configuration for settings that aren’t managed by Amazon EKS. For more information, see Server-Side Apply in the Kubernetes documentation. To achieve this, Amazon EKS manages a minimum set of fields for every add-on that it installs. You can modify all fields that aren’t managed by Amazon EKS, or another Kubernetes control plane process such as kube-controller-manager, without issue.

**Important**
Modifying a field managed by Amazon EKS prevents Amazon EKS from managing the add-on and may result in your changes being overwritten when an add-on is updated.

View field management status

You can use kubectl to see which fields are managed by Amazon EKS for any Amazon EKS add-on.

**To see the management status of a field**

1. Determine which add-on that you want to examine. To see all of the deployments and DaemonSets deployed to your cluster, see View Kubernetes resources (p. 500).
2. View the managed fields for an add-on by running the following command:

```
kubectl get type/add-on-name -n add-on-namespace -o yaml
```

For example, you can see the managed fields for the CoreDNS add-on with the following command.

```
kubectl get deployment/coredns -n kube-system -o yaml
```

Field management is listed in the following section in the returned output.

```yaml
... managedFields:  - apiVersion: apps/v1   fieldsType: FieldsV1   fieldsV1:
...```
Note
If you don't see `managedFields` in the output, add `--show-managed-fields` to the command and run it again. The version of `kubectl` that you're using determines whether managed fields are returned by default.

Understanding field management syntax in the Kubernetes API

When you view details for a Kubernetes object, both managed and unmanaged fields are returned in the output. Managed fields can be either of the following types:

- **Fully managed** – All keys for the field are managed by Amazon EKS. Modifications to any value causes a conflict.
- **Partially managed** – Some keys for the field are managed by Amazon EKS. Only modifications to the keys explicitly managed by Amazon EKS cause a conflict.

Both types of fields are tagged with `manager: eks`.

Each key is either a . representing the field itself, which always maps to an empty set, or a string that represents a sub-field or item. The output for field management consists of the following types of declarations:

- `f: name`, where `name` is the name of a field in a list.
- `k: keys`, where `keys` is a map of a list item's fields.
- `v: value`, where `value` is the exact JSON formatted value of a list item.
- `i: index`, where `index` is position of an item in the list.

For more information, see FieldsV1 v1 meta in the Kubernetes documentation.

The following portions of output for the CoreDNS add-on illustrate the previous declarations:

- **Fully managed fields** – If a managed field has an `f: (field)` specified, but no `k: (key)`, then the entire field is managed. Modifications to any values in this field cause a conflict.

  In the following output, you can see that the container named `coredns` is managed by `eks`. The `args`, `image`, and `imagePullPolicy` sub-fields are also managed by `eks`. Modifications to any values in these fields cause a conflict.

  ```yaml
  ...
  f:containers:
    k: {"name":"coredns":
    .: {}  
f:args: {}  
f:image: {}  
f:imagePullPolicy: {}  
...
manager: eks
...
```

- **Partially managed fields** – If a managed key has a value specified, the declared keys are managed for that field. Modifying the specified keys cause a conflict.

  In the following output, you can see that `eks` manages the `config-volume` and `tmp` volumes set with the name key.

  ```yaml
  ...
  ```
Machine learning training using Elastic Fabric Adapter

This topic describes how to integrate Elastic Fabric Adapter (EFA) with pods deployed in your Amazon EKS cluster. Elastic Fabric Adapter (EFA) is a network interface for Amazon EC2 instances that enables you to run applications requiring high levels of inter-node communications at scale on AWS. Its custom-built operating system bypass hardware interface enhances the performance of inter-instance communications, which is critical to scaling these applications. With EFA, High Performance Computing (HPC) applications using the Message Passing Interface (MPI) and Machine Learning (ML) applications using NVIDIA Collective Communications Library (NCCL) can scale to thousands of CPUs or GPUs. As a result, you get the application performance of on-premises HPC clusters with the on-demand elasticity and flexibility of the AWS cloud. Integrating EFA with applications running on Amazon EKS clusters can reduce the time to complete large scale distributed training workloads without having to add additional instances to your cluster. For more information about EFA, Elastic Fabric Adapter.

The EFA plugin described in this topic fully supports Amazon EC2 P4d instances, which represent the current state of the art in distributed machine learning in the cloud. Each p4d.24xlarge instance has eight NVIDIA A100 GPUs, and 400 Gbps GPUDirectRDMA over EFA. GPUDirectRDMA enables you to have direct GPU-to-GPU communication across nodes with CPU bypass, increasing collective communication bandwidth and lowering latency. Amazon EKS and EFA integration with P4d instances provides a seamless method to take advantage of the highest performing Amazon EC2 computing instance for distributed machine learning training.
Prerequisites

- An existing Amazon EKS cluster. If you don't have an existing cluster, use one of our Getting started with Amazon EKS (p. 4) guides to create one. Your cluster must be deployed in a VPC that has at least one private subnet with enough available IP addresses to deploy nodes in. The private subnet must have outbound internet access provided by an external device, such as a NAT gateway.

If you plan to use eksctl to create your node group, eksctl can also create a cluster for you.

- Version 2.7.32 or later or 1.25.72 or later of the AWS CLI installed and configured on your device or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with aws configure in the AWS Command Line Interface User Guide.

- The kubectl command line tool is installed on your device or AWS CloudShell. The version can be the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For example, if your cluster version is 1.22, you can use kubectl version 1.21, 1.22, or 1.23 with it. To install or upgrade kubectl, see Installing or updating kubectl (p. 4).

- You must have the Amazon VPC CNI plugin for Kubernetes version 1.7.10 or later installed before launching worker nodes that support multiple Elastic Fabric Adapters, such as the p4d.24xlarge. For more information about updating your CNI version, see Updating the Amazon VPC CNI plugin for Kubernetes self-managed add-on (p. 253).

Create node group

The following procedure helps you create a node group with a p4d.24xlarge backed node group with EFA interfaces and GPUDirect RDMA, and run an example NVIDIA Collective Communications Library (NCCL) test for multi-node NCCL Performance using EFAs. The example can be used as a template for distributed deep learning training on Amazon EKS using EFAs.

1. Determine which Amazon EC2 instance types that support EFA are available in the AWS Region that you want to deploy nodes in. Replace region-code with the AWS Region that you want to deploy your node group in.

   ```bash
   aws ec2 describe-instance-types --region region-code --filters Name=network-info.efa-supported,Values=true \ 
   --query "InstanceTypes[*].[InstanceType]" --output text
   ```

   When you deploy nodes, the instance type that you want to deploy must be available in the AWS Region that your cluster is in.

2. Determine which Availability Zones that the instance type that you want to deploy is available in. In this tutorial, the p4d.24xlarge instance type is used and must be returned in the output for the AWS Region that you specified in the previous step. When you deploy nodes in a production cluster, replace p4d.24xlarge with any instance type returned in the previous step.

   ```bash
   aws ec2 describe-instance-type-offerings --region region-code --location-type availability-zone --filters Name=instance-type,Values=p4d.24xlarge \ 
   --query 'InstanceTypeOfferings[*].Location' --output text
   ```

   The example output is as follows.

   ```bash
   us-west-2a  us-west-2b  us-west-2c
   ```

   Note the Availability Zones returned for use in later steps. When you deploy nodes to a cluster, your VPC must have subnets with available IP addresses in one of the Availability Zones returned in the output.
3. Create a node group using either `eksctl` or the AWS CLI and AWS CloudFormation.

**Prerequisite**

Version 0.112.0 or later of the `eksctl` command line tool installed on your device or AWS CloudShell. To install or update `eksctl`, see Installing or updating `eksctl` (p. 10).

1. Copy the following contents to a file named `efa-cluster.yaml`. Replace the example values with your own. You can replace `p4d.24xlarge` with a different instance, but if you do, make sure that the values for `availabilityZones` are Availability Zones that were returned for the instance type in step 1.

```yaml
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig

metadata:
  name: my-efa-cluster
  region: region-code
  version: "1.19"

iam:
  withOIDC: true

availabilityZones: ["us-west-2a", "us-west-2c"]

managedNodeGroups:
  - name: my-efa-ng
    instanceType: p4d.24xlarge
    minSize: 1
    desiredCapacity: 2
    maxSize: 3
    availabilityZones: ["us-west-2a"]
    volumeSize: 300
    privateNetworking: true
    efaEnabled: true
```

2. Create a managed node group in an existing cluster.

   `eksctl create nodegroup -f efa-cluster.yaml`

   If you don't have an existing cluster, you can run the following command to create a cluster and the node group.

   `eksctl create cluster -f efa-cluster.yaml`

**Note**

Because the instance type used in this example has GPUs, `eksctl` automatically installs the NVIDIA Kubernetes device plugin on each instance for you.

**AWS CLI and AWS CloudFormation**

There are several requirements for EFA networking, including creating an EFA specific security group, creating an Amazon EC2 placement group, and creating a launch template that specifies one or more EFA interfaces, and includes EFA driver installation as part of Amazon EC2 user data. To learn more about EFA requirements, see Get started with EFA and MPI in the Amazon EC2 User Guide for Linux Instances. The following steps create all of this for you. Replace all example values with your own.
1. Set a few variables used in later steps. Replace all of the example values with your own. Replace my-cluster with the name of your existing cluster. The value for node_group_resources_name is later used to create an AWS CloudFormation stack. The value for node_group_name is later used to create the node group in your cluster.

```plaintext
cluster_name="my-cluster"
cluster_region="region-code"
node_group_resources_name="my-efa-nodegroup-resources"
node_group_name="my-efa-nodegroup"
```

2. Identify a private subnet in your VPC that is in the same Availability Zone as the instance type that you want to deploy is available in.
   a. Retrieve the version of your cluster and store it in a variable for use in a later step.

   ```bash
   cluster_version=$(aws eks describe-cluster
   --name $cluster_name
   --query "cluster.version"
   --output text)
   ```

   b. Retrieve the VPC ID that your cluster is in and store it in a variable for use in a later step.

   ```bash
   vpc_id=$(aws eks describe-cluster
   --name $cluster_name
   --query "cluster.resourcesVpcConfig.vpcId"
   --output text)
   ```

   c. Retrieve the ID of the control plane security group for your cluster and store it in a variable for use in a later step.

   ```bash
   control_plane_security_group=$(aws eks describe-cluster
   --name $cluster_name
   --query "cluster.resourcesVpcConfig.clusterSecurityGroupId"
   --output text)
   ```

   d. Get the list of subnet IDs in your VPC that are in an Availability Zone returned in step 1.

   ```bash
   aws ec2 describe-subnets
   --filters "Name=vpc-id,Values=$vpc_id" "Name=availability-zone,Values=us-west-2a"
   --query 'Subnets[*].SubnetId'
   --output text
   ```

   If no output is returned, try a different Availability Zone returned in step 1. If none of your subnets are in an Availability Zone returned in step 1, then you need to create a subnet in an Availability Zone returned in step 1. If you have no room in your VPC to create another subnet, then you may need to create a new cluster in a new VPC.

   e. Determine whether the subnet is a private subnet by checking the route table for the subnet.

   ```bash
   aws ec2 describe-route-tables
   --filter Name=association.subnet-id,Values=subnet-0d403852a65210a29
   --query "RouteTables[].Routes[].GatewayId"
   --output text
   ```

   The example output is as follows.
Create node group

If the output is local igw-02adc64e1b72722e2, then the subnet is a public subnet. You must select a private subnet in an Availability Zone returned in step 1. Once you've identified a private subnet, note its ID for use in a later step.

f. Set a variable with the private subnet ID from the previous step for use in later steps.

```
subnet_id=your-subnet-id
```

3. Download the AWS CloudFormation template.

```
```

4. Copy the following text to your computer. Replace `p4d.24xlarge` with an instance type from step 1. Replace `subnet-0d403852a65210a29` with the ID of the private subnet that you identified in step 2.b.v. Replace `path-to-downloaded-cfn-template` with the path to the efa-p4d-managed-nodegroup.yaml that you downloaded in the previous step. Replace `your-public-key-name` with the name of your public key. Once you've made the replacements, run the modified command.

```
aws cloudformation create-stack \
--stack-name ${node_group_resources_name} \
--capabilities CAPABILITY_IAM \
--template-body file://path-to-downloaded-cfn-template \
--parameters \n  ParameterKey=ClusterName,ParameterValue=${cluster_name} \
  ParameterKey=ClusterControlPlaneSecurityGroup,ParameterValue=${control_plane_security_group} \
  ParameterKey=VpcId,ParameterValue=${vpc_id} \
  ParameterKey=SubnetId,ParameterValue=${subnet_id} \
  ParameterKey=NodeGroupName,ParameterValue=${node_group_name} \
  ParameterKey=NodeImageIdSSMParam,ParameterValue=/aws/service/eks/optimized-ami/${cluster_version}/amazon-linux-2-gpu/recommended/image_id \
  ParameterKey=KeyName,ParameterValue=your-public-key-name \
  ParameterKey=NodeInstanceType,ParameterValue=p4d.24xlarge
```

5. Determine when the stack that you deployed in the previous step is deployed.

```
aws cloudformation wait stack-create-complete --stack-name $node_group_resources_name
```

There is no output from the previous command, but your shell prompt doesn't return until the stack is created.

6. Create your node group using the resources created by the AWS CloudFormation stack in the previous step.

a. Retrieve information from the deployed AWS CloudFormation stack and store it in variables.

```
node_instance_role=$(aws cloudformation describe-stacks \
  --stack-name $node_group_resources_name \
  --query='Stacks[].Outputs[?OutputKey==`NodeInstanceRole`].OutputValue' \
  --output text)
launch_template=$(aws cloudformation describe-stacks \
  --stack-name $node_group_resources_name \
  --query='Stacks[].Outputs[?OutputKey==`LaunchTemplateID`].OutputValue'
```
(Optional) Deploy a sample EFA compatible application

Deploy the Kubeflow MPI Operator

For the NCCL tests you can apply the Kubeflow MPI Operator. The MPI Operator makes it easy to run Allreduce-style distributed training on Kubernetes. For more information, see MPI Operator on GitHub.

```
kubectl apply -f https://raw.githubusercontent.com/kubeflow/mpi-operator/master/deploy/v1alpha2/mpi-operator.yaml
```

Run the multi-node NCCL Performance Test to verify GPUDirectRDMA/EFA

To verify NCCL Performance with GPUDirectRDMA over EFA, run the standard NCCL Performance test. For more information, see the official NCCL-Tests repo on GitHub. You can use the sample Dockerfile that comes with this test already built for both CUDA 11.2 and the latest version of EFA.

Alternately, you can download an AWS Docker image available from an Amazon ECR repo.
Important
An important consideration required for adopting EFA with Kubernetes is configuring and managing Huge Pages as a resource in the cluster. For more information, see Manage Huge Pages in the Kubernetes documentation. Amazon EC2 instances with the EFA driver installed pre-allocate 5128 2M Huge Pages, which you can request as resources to consume in your job specifications.

Complete the following steps to run a two node NCCL Performance Test. In the example NCCL test job, each worker requests eight GPUs, 5210Mi of hugepages-2Mi, four EFAs, and 8000Mi of memory, which effectively means each worker consumes all the resources of a p4d.24xlarge instance.

1. Create the NCCL-tests job.

```
kubectl apply -f https://raw.githubusercontent.com/aws-samples/aws-efa-eks/main/examples/simple/nccl-efa-tests.yaml
```

The example output is as follows.

`mpijob.kubeflow.org/nccl-tests-efa created`

2. View your running pods.

```
kubectl get pods
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>nccl-tests-efa-launcher-nbql9</td>
<td>0/1</td>
<td>Init:0/1</td>
<td>0</td>
<td>2m49s</td>
</tr>
<tr>
<td>nccl-tests-efa-worker-0</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>2m49s</td>
</tr>
<tr>
<td>nccl-tests-efa-worker-1</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>2m49s</td>
</tr>
</tbody>
</table>

The MPI Operator creates a launcher pod and 2 worker pods (one on each node).

3. View the log for the efa-launcher pod. Replace wzr8j with the value from your output.

```
kubectl logs -f nccl-tests-efa-launcher-nbql9
```

For more examples, see the Amazon EKS EFA samples repository on GitHub.

### Machine learning inference using AWS Inferentia

This topic describes how to create an Amazon EKS cluster with nodes running Amazon EC2 Inf1 instances and (optionally) deploy a sample application. Amazon EC2 Inf1 instances are powered by AWS Inferentia chips, which are custom built by AWS to provide high performance and lowest cost inference in the cloud. Machine learning models are deployed to containers using AWS Neuron, a specialized software development kit (SDK) consisting of a compiler, runtime, and profiling tools that optimize the machine learning inference performance of Inferentia chips. AWS Neuron supports popular machine learning frameworks such as TensorFlow, PyTorch, and MXNet.

**Note**
Neuron device logical IDs must be contiguous. If a pod requesting multiple Neuron devices is scheduled on an inf1.6xlarge or inf1.24xlarge instance type (which have more than one Neuron device), that pod will fail to start if the Kubernetes scheduler selects non-contiguous device IDs. For more information, see Device logical IDs must be contiguous on GitHub.
Prerequisites

- Have `eksctl` installed on your computer. If you don’t have it installed, see Installing or updating `eksctl` (p. 10) for installation instructions.
- Have `kubectl` installed on your computer. For more information, see Installing or updating `kubectl` (p. 4).
- (Optional) Have `python3` installed on your computer. If you don’t have it installed, then see Python downloads for installation instructions.

Create a cluster

To create a cluster with Inf1 Amazon EC2 instance nodes

1. Create a cluster with Inf1 Amazon EC2 instance nodes. You can replace `inf1.2xlarge` with any Inf1 instance type. The `eksctl` utility detects that you are launching a node group with an Inf1 instance type and will start your nodes using one of the Amazon EKS optimized accelerated Amazon Linux AMIs.

   **Note**
   You can’t use IAM roles for service accounts (p. 425) with TensorFlow Serving.

   ```
   eksctl create cluster \
   --name inferentia \
   --region region-code \
   --nodegroup-name ng-inf1 \
   --node-type inf1.2xlarge \
   --nodes 2 \
   --nodes-min 1 \
   --nodes-max 4 \
   --ssh-access \
   --ssh-public-key your-key \
   --with-oidc
   ```

   **Note**
   Note the value of the following line of the output. It’s used in a later (optional) step.

   ```
   eksctl-inferentia-nodegroup-ng-inf1-NodeInstanceRole-FI7HIYS3BS09" to auth
   ConfigMap
   ```

   When launching a node group with Inf1 instances, `eksctl` automatically installs the AWS Neuron Kubernetes device plugin. This plugin advertises Neuron devices as a system resource to the Kubernetes scheduler, which can be requested by a container. In addition to the default Amazon EKS node IAM policies, the Amazon S3 read only access policy is added so that the sample application, covered in a later step, can load a trained model from Amazon S3.

2. Make sure that all pods have started correctly.

   ```
   kubectl get pods -n kube-system
   ```

   Abbreviated output:

   ```
   NAME                               READY   STATUS    RESTARTS   AGE
   ...                               ...     ...       ...        ...
   neuron-device-plugin-daemonset-6djhp 1/1     Running   0          5m
   ```
(Optional) Deploy a TensorFlow Serving application image

A trained model must be compiled to an Inferentia target before it can be deployed on Inferentia instances. To continue, you will need a Neuron optimized TensorFlow model saved in Amazon S3. If you don’t already have a SavedModel, please follow the tutorial for creating a Neuron compatible ResNet50 model and upload the resulting SavedModel to S3. ResNet-50 is a popular machine learning model used for image recognition tasks. For more information about compiling Neuron models, see The AWS Inferentia Chip With DLAMI in the AWS Deep Learning AMI Developer Guide.

The sample deployment manifest manages a pre-built inference serving container for TensorFlow provided by AWS Deep Learning Containers. Inside the container is the AWS Neuron Runtime and the TensorFlow Serving application. A complete list of pre-built Deep Learning Containers optimized for Neuron is maintained on GitHub under Available Images. At start-up, the DLC will fetch your model from Amazon S3, launch Neuron TensorFlow Serving with the saved model, and wait for prediction requests.

The number of Neuron devices allocated to your serving application can be adjusted by changing the `aws.amazon.com/neuron` resource in the deployment yaml. Please note that communication between TensorFlow Serving and the Neuron runtime happens over GRPC, which requires passing the `IPC_LOCK` capability to the container.

1. Add the `AmazonS3ReadOnlyAccess` IAM policy to the node instance role that was created in step 1 of Create a cluster (p. 377). This is necessary so that the sample application can load a trained model from Amazon S3.

```
aws iam attach-role-policy \
--policy-arn arn:aws:iam::aws:policy/AmazonS3ReadOnlyAccess \
--role-name eksctl-inferentia-nodegroup-ng-inNodeInstanceRole-FI7HIYS3BS09
```

2. Create a file named `rn50_deployment.yaml` with the following contents. Update the region-code and model path to match your desired settings. The model name is for identification purposes when a client makes a request to the TensorFlow server. This example uses a model name to match a sample ResNet50 client script that will be used in a later step for sending prediction requests.

```
aws ecr list-images --repository-name neuron-rtd --registry-id 790709498068 --region us-west-2
```

```yaml
kind: Deployment
apiVersion: apps/v1
metadata:
  name: eks-neuron-test
labels:
  app: eks-neuron-test
  role: master
spec:
  replicas: 2
  selector:
    matchLabels:
      app: eks-neuron-test
      role: master
  template:
    metadata:
      labels:
        app: eks-neuron-test
        role: master
```

378
spec:
  containers:
  - name: eks-neuron-test
    image: 763104351884.dkr.ecr.us-east-1.amazonaws.com/tensorflow-inference-neuron:1.15.4-neuron-py37-ubuntu18.04
    command:
      - /usr/local/bin/entrypoint.sh
    args:
      - --port=8500
      - --rest_api_port=9000
      - --model_name=resnet50_neuron
      - --model_base_path=s3://your-bucket-of-models/resnet50_neuron/
    ports:
      - containerPort: 8500
      - containerPort: 9000
    imagePullPolicy: IfNotPresent
    env:
      - name: AWS_REGION
        value: "us-east-1"
      - name: S3_USE_HTTPS
        value: "1"
      - name: S3_VERIFY_SSL
        value: "0"
      - name: S3_ENDPOINT
        value: s3.us-east-1.amazonaws.com
      - name: AWS_LOG_LEVEL
        value: "3"
    resources:
      limits:
        cpu: 4
        memory: 4Gi
        aws.amazon.com/neuron: 1
      requests:
        cpu: "1"
        memory: 1Gi
    securityContext:
      capabilities:
        add:
          - IPC_LOCK

3. Deploy the model.

```bash
kubectl apply -f rn50_deployment.yaml
```

4. Create a file named `rn50_service.yaml` with the following contents. The HTTP and gRPC ports are opened for accepting prediction requests.

```yaml
kind: Service
apiVersion: v1
metadata:
  name: eks-neuron-test
  labels:
    app: eks-neuron-test
spec:
  type: ClusterIP
  ports:
  - name: http-tf-serving
    port: 8500
    targetPort: 8500
  - name: grpc-tf-serving
    port: 9000
    targetPort: 9000
  selector:
    app: eks-neuron-test
```
5. Create a Kubernetes service for your TensorFlow model Serving application.

```bash
kubectl apply -f rn50_service.yaml
```

(Optional) Make predictions against your TensorFlow Serving service

1. To test locally, forward the gRPC port to the eks-neuron-test service.

```bash
kubectl port-forward service/eks-neuron-test 8500:8500 &
```

2. Create a Python script called `tensorflow-model-server-infer.py` with the following content. This script runs inference via gRPC, which is service framework.

```python
import numpy as np
import grpc
import tensorflow as tf
from tensorflow.keras.preprocessing import image
from tensorflow.keras.applications.resnet50 import preprocess_input
from tensorflow_serving.apis import predict_pb2
from tensorflow_serving.apis import prediction_service_pb2_grpc
from tensorflow.keras.applications.resnet50 import decode_predictions

if __name__ == '__main__':
    channel = grpc.insecure_channel('localhost:8500')
    stub = prediction_service_pb2_grpc.PredictionServiceStub(channel)
    img_file = tf.keras.utils.get_file(
        "./kitten_small.jpg",
        "https://raw.githubusercontent.com/awslabs/mxnet-model-server/master/docs/images/kitten_small.jpg")
    img_array = preprocess_input(image.img_to_array(img)[None, ...])
    request = predict_pb2.PredictRequest()
    request.model_spec.name = 'resnet50_inf1'
    request.inputs['input'].CopyFrom(
        tf.make_tensor_proto(img_array, shape=img_array.shape))
    result = stub.Predict(request)
    prediction = tf.make_ndarray(result.outputs['output'])
    print(decode_predictions(prediction))
```

3. Run the script to submit predictions to your service.

```bash
python3 tensorflow-model-server-infer.py
```

The example output is as follows.

```plaintext
[['u'n02123045', u'tabby', 0.68817204], ['u'n02127052', u'lynx', 0.12701613], ['u'n02123159', u'tiger_cat', 0.08736559], ['u'n02124075', u'Egyptian_cat', 0.063844085], ['u'n02128757', u'snow_leopard', 0.009240591]]
```
Amazon EKS uses IAM to provide authentication to your Kubernetes cluster (through the `aws eks get-token` command, available in version 1.16.156 or later of the AWS CLI, or the AWS IAM Authenticator for Kubernetes), but it still relies on native Kubernetes Role Based Access Control (RBAC) for authorization. This means that IAM is only used for authentication of valid IAM entities. All permissions for interacting with your Amazon EKS cluster’s Kubernetes API is managed through the native Kubernetes RBAC system. The following picture shows this relationship.

**Note**
Amazon EKS uses the authentication token to make the `sts:GetCallerIdentity` call. As a result, AWS CloudTrail events with the name `GetCallerIdentity` from the source `sts.amazonaws.com` can have Amazon EKS service IP addresses for their source IP address.

**Topics**
- Enabling IAM user and role access to your cluster (p. 381)
- Authenticating users for your cluster from an OpenID Connect identity provider (p. 388)
- Create a kubeconfig for Amazon EKS (p. 392)
- Installing aws-iam-authenticator (p. 396)
- Default Amazon EKS Kubernetes roles and users (p. 399)

### Enabling IAM user and role access to your cluster

Access to your cluster using AWS Identity and Access Management (IAM); entities is enabled by the AWS IAM Authenticator for Kubernetes, which runs on the Amazon EKS control plane. The authenticator gets its configuration information from the `aws-auth` ConfigMap. For all `aws-auth` ConfigMap settings, see Full Configuration Format on GitHub.
Add IAM users or roles to your Amazon EKS cluster

When you create an Amazon EKS cluster, the AWS Identity and Access Management (IAM) entity user or role, such as a federated user that creates the cluster, is automatically granted system:masters permissions in the cluster's role-based access control (RBAC) configuration in the Amazon EKS control plane. This IAM entity doesn't appear in any visible configuration, so make sure to keep track of which IAM entity originally created the cluster. To grant additional AWS users or roles the ability to interact with your cluster, you must edit the `aws-auth` ConfigMap within Kubernetes and create a Kubernetes rolebinding or clusterrolebinding with the name of a group that you specify in the `aws-auth` ConfigMap.

**Note**
For more information about different IAM identities, see Identities (Users, Groups, and Roles) in the IAM User Guide. For more information on Kubernetes role-based access control (RBAC) configuration, see Using RBAC Authorization.

**To add an IAM user or role to an Amazon EKS cluster**

1. Determine which credentials `kubectl` is using to access your cluster. On your computer, you can see which credentials `kubectl` uses with the following command. Replace `~/.kube/config` with the path to your `kubeconfig` file if you don't use the default path.

   ```bash
cat ~/.kube/config
   ``

   The example output is as follows.

   ```
   ...
   contexts:
   - context:
     cluster: my-cluster.region-code.eksctl.io
     user: admin@my-cluster.region-code.eksctl.io
     name: admin@my-cluster.region-code.eksctl.io
     current-context: admin@my-cluster.region-code.eksctl.io
   ...
   ```

   In the previous example output, the credentials for a user named `admin` are configured for a cluster named `my-cluster`. If this is the user that created the cluster, then it already has access to your cluster. If it's not the user that created the cluster, then you need to complete the remaining steps to enable cluster access for other users. You can see which other roles or users currently have access to your cluster with the following command:

   ```bash
   kubectl describe -n kube-system configmap/aws-auth
   ``

   The example output is as follows.

   ```
   Name:         aws-auth
   Namespace:    kube-system
   Labels:       <none>
   Annotations:  <none>
   Data
   ====
   mapRoles:
   ----
   - groups:
     - system:bootstrappers
     - system:nodes
     rolearn: arn:aws:iam::11112223333:role/my-node-role
   ```
Add users or roles

username: system:node:{{EC2PrivateDNSName}}

BinaryData

Events: <none>

The previous example is a default aws-auth ConfigMap. Only the node instance role has access to the cluster.

1. View your existing Kubernetes roles or clusterroles. Roles are scoped to a namespace, but clusterroles are scoped to the cluster.

   kubectl get roles -A

   kubectl get clusterroles

2. View the details of any role or clusterrole returned in the previous output and confirm that it has the permissions (rules) that you want your IAM users to have in your cluster.

   Replace role-name with a role name returned in the output from the previous command. Replace kube-system with the namespace of the role.

   kubectl describe role role-name -n kube-system

   Replace cluster-role-name with a clusterrole name returned in the output from the previous command.

   kubectl describe clusterrole cluster-role-name

3. View your existing Kubernetes rolebindings or clusterrolebindings. Rolebindings are scoped to a namespace, but clusterrolebindings are scoped to the cluster.

   kubectl get rolebindings -A

   kubectl get clusterrolebindings

4. View the details of any rolebinding or clusterrolebinding and confirm that it has a role or clusterrole from the previous step listed as a roleRef and a group name listed for subjects.

   Replace role-binding-name with a rolebinding name returned in the output from the previous command. Replace kube-system with the namespace of the rolebinding.

   kubectl describe rolebinding role-binding-name -n kube-system

The example output is as follows.

```yaml
apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
```
Add users or roles

- **name**: eks-console-dashboard-restricted-access-role-binding
  - **namespace**: default
  - **subjects**:
    - **kind**: Group
    - **name**: eks-console-dashboard-restricted-access-group
    - **apiGroup**: rbac.authorization.k8s.io
    - **roleRef**:
      - **kind**: Role
      - **name**: eks-console-dashboard-restricted-access-role
      - **apiGroup**: rbac.authorization.k8s.io

Replace `cluster-role-binding-name` with a clusterrolebinding name returned in the output from the previous command.

```bash
kubectl describe clusterrolebinding cluster-role-binding-name
```

The example output is as follows.

```yaml
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: eks-console-dashboard-full-access-binding
subjects:
  - kind: Group
    name: eks-console-dashboard-full-access-group
    apiGroup: rbac.authorization.k8s.io
roleRef:
  kind: ClusterRole
  name: eks-console-dashboard-full-access-clusterrole
  apiGroup: rbac.authorization.k8s.io
```

3. Edit the `aws-auth` ConfigMap. You can use a tool such as eksctl to update the ConfigMap or you can update it manually by editing it.

**Important**
We recommend using eksctl, or another tool, to edit the ConfigMap. For information about other tools you can use, see Use tools to make changes to the `aws-auth`ConfigMap in the Amazon EKS best practices guides. An improperly formatted `aws-auth`ConfigMap can cause you to lose access to your cluster.

**eksctl**

**Prerequisite**
Version 0.112.0 or later of the eksctl command line tool installed on your device or AWS CloudShell. To install or update eksctl, see Installing or updating eksctl (p. 10).

1. View the current mappings in the ConfigMap. Replace `my-cluster` with the name of your cluster. Replace `region-code` with the AWS Region that your cluster is in.

```bash
eksctl get iamidentitymapping --cluster my-cluster --region=region-code
```

The example output is as follows.

<table>
<thead>
<tr>
<th>ARN</th>
<th>USERNAME</th>
<th>GROUPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCOUNT</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Add users or roles

2. Add a mapping for a role. Replace `my-role` with your role name. Replace `eks-console-dashboard-full-access-group` with the name of the group specified in your Kubernetes rolebinding or clusterrolebinding. Replace `111122223333` with your account ID.

   ```bash
   eksctl create iamidentitymapping \
   --cluster my-cluster \
   --region=region-code \
   --arn arn:aws:iam::111122223333:role/my-role \
   --group eks-console-dashboard-full-access-group \
   --no-duplicate-arns
   ```

   **Important**
   The role ARN can't include a path such as `role/my-team/developers/my-role`. The format of the ARN must be `arn:aws:iam::111122223333:role/my-role`. In this example, `my-team/developers/` needs to be removed.

   The example output is as follows.

   ```
   2022-05-09 14:51:20 [✓]  adding identity "arn:aws:iam::111122223333:role/my-role" to auth ConfigMap
   ```

3. Add a mapping for a user. Replace `my-user` with your user name. Replace `eks-console-dashboard-restricted-access-group` with the name of the group specified in your Kubernetes rolebinding or clusterrolebinding. Replace `111122223333` with your account ID.

   ```bash
   eksctl create iamidentitymapping \
   --cluster my-cluster \
   --region=region-code \
   --arn arn:aws:iam::111122223333:user/my-user \
   --group eks-console-dashboard-restricted-access-group \
   --no-duplicate-arns
   ```

   The example output is as follows.

   ```
   2022-05-09 14:53:48 [✓]  adding identity "arn:aws:iam::111122223333:user/my-user" to auth ConfigMap
   ```

4. View the mappings in the ConfigMap again.

   ```bash
   eksctl get iamidentitymapping --cluster my-cluster --region=region-code
   ```

   The example output is as follows.

<table>
<thead>
<tr>
<th>ARN</th>
<th>USERNAME</th>
<th>ACCOUNT</th>
<th>GROUPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>arn:aws:iam::111122223333:role/eksctl-my-cluster-my-nodegroup-NodeInstanceRole-1XLS7754U3ZPA</td>
<td>system:nodes</td>
<td>system:node:{{EC2PrivateDNSName}}</td>
<td></td>
</tr>
</tbody>
</table>
Edit ConfigMap manually

1. Open the ConfigMap for editing.

   ```
kubectl edit -n kube-system configmap/aws-auth
   ```

   **Note**
   If you receive an error stating "Error from server (NotFound): configmaps "aws-auth" not found", then use the procedure in Apply the aws-authConfigMap to your cluster (p. 387) to apply the stock ConfigMap.

2. Add your IAM users, roles, or AWS accounts to the ConfigMap. You can't add IAM groups to the ConfigMap.

   - **To add an IAM role (for example, for federated users):** Add the role details to the mapRoles section of the ConfigMap, under data. Add this section if it does not already exist in the file. Each entry supports the following parameters:

     - **rolearn**: The ARN of the IAM role to add. This value can't include a path. For example, you can't specify an ARN such as `arn:aws:iam::111122223333:role/my-team/developers/role-name`. The ARN needs to be `arn:aws:iam::111122223333:role/role-name` instead.

     - **username**: The user name within Kubernetes to map to the IAM role.

     - **groups**: The group or list of Kubernetes groups to map the role to. The group can be a default group, or a group specified in a clusterrolebinding or rolebinding. For more information, see Default Roles and Role Bindings in the Kubernetes documentation.

   - **To add an IAM user**: Add the user details to the mapUsers section of the ConfigMap, under data. Add this section if it does not already exist in the file. Each entry supports the following parameters:

     - **userarn**: The ARN of the IAM user to add.

     - **username**: The user name within Kubernetes to map to the IAM user.

     - **groups**: The group, or list of Kubernetes groups to map the user to. The group can be a default group, or a group specified in a clusterrolebinding or rolebinding. For more information, see Default Roles and Role Bindings in the Kubernetes documentation.

For example, the following YAML block contains:

- A mapRoles section that maps the IAM node instance to Kubernetes groups so that nodes can register themselves with the cluster and the my-console-viewer-role IAM role that is mapped to a Kubernetes group that can view all Kubernetes resources for all clusters. For a list of the IAM and Kubernetes group permissions required for the my-console-viewer-role IAM role, see Required permissions (p. 500).

- A mapUsers section that maps the admin IAM user from the default AWS account to the system:masters Kubernetes group and the my-user user from a different AWS account that is mapped to a Kubernetes group that can view Kubernetes resources for a specific namespace. For a list of the IAM and Kubernetes group permissions required for the my-user IAM user, see Required permissions (p. 500).

Add or remove lines as necessary and replace all example values with your own values.
# Please edit the object below. Lines beginning with a '#' will be ignored, # and an empty file will abort the edit. If an error occurs while saving this # file will be # reopened with the relevant failures.
#
apiVersion: v1
data:
  mapRoles: |
    - groups:
      - system:bootstrappers
        rolearn: arn:aws:iam::<ARNSystemRole>role/my-role
        username: system:node:{{EC2PrivateDNSName}}
      - groups:
        - eks-console-dashboard-full-access-group
        rolearn: arn:aws:iam::<ARNConsoledashboardrole>role/my-console-viewer-role
        username: my-console-viewer-role
  mapUsers: |
    - groups:
      - system:masters
        userarn: arn:aws:iam::<ARNsystemMasters>user/admin
        username: admin
      - groups:
        - eks-console-dashboard-restricted-access-group
        userarn: arn:aws:iam::<ARNConsoledashboardSwitcher>user/my-user
        username: my-user

3. Save the file and exit your text editor.

Apply the aws-authConfigMap to your cluster

The aws-auth ConfigMap is automatically created and applied to your cluster when you create a managed node group or when you create a node group using eksctl. It is initially created to allow nodes to join your cluster, but you also use this ConfigMap to add role-based access control (RBAC) access to IAM users and roles. If you have not launched self-managed nodes and applied the aws-auth ConfigMap to your cluster, you can do so with the following procedure.

To apply the aws-authConfigMap to your cluster

1. Check to see if you have already applied the aws-auth ConfigMap.

```bash
kubectl describe configmap -n kube-system aws-auth
```

If you receive an error stating "Error from server (NotFound): configmaps "aws-auth" not found", then proceed with the following steps to apply the stock ConfigMap.

2. Download, edit, and apply the AWS authenticator configuration map.

   a. Download the configuration map.

```bash
curl -o aws-auth-cm.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/cloudformation/2020-10-29/aws-auth-cm.yaml
```

   b. Open the file with a text editor. Replace <ARN of instance role (not instance profile)> with the Amazon Resource Name (ARN) of the IAM role associated with your nodes, and save the file. Do not modify any other lines in this file.
Important
The role ARN can't include a path such as `role/my-team/developers/my-role`. The format of the ARN must be `arn:aws:iam::111122223333:role/my-role`. In this example, `my-team/developers/` needs to be removed.

```yaml
apiVersion: v1
class: ConfigMap
metadata:
  name: aws-auth
  namespace: kube-system
data:
  mapRoles: |
    - rolearn: <ARN of instance role (not instance profile)>
      username: system:node:{{EC2PrivateDNSName}}
    groups:
      - system:bootstrappers
      - system:nodes
```

You can inspect the AWS CloudFormation stack outputs for your node groups and look for the following values:

- **InstanceRoleARN** – For node groups that were created with `eksctl`
- **NodeInstanceRole** – For node groups that were created with Amazon EKS vended AWS CloudFormation templates in the AWS Management Console

c. Apply the configuration. This command may take a few minutes to finish.

```
kubectl apply -f aws-auth-cm.yaml
```

**Note**
If you receive any authorization or resource type errors, see Unauthorized or access denied (`kubectl`) (p. 522) in the troubleshooting section.

3. Watch the status of your nodes and wait for them to reach the Ready status.

```
kubectl get nodes --watch
```

### Authenticating users for your cluster from an OpenID Connect identity provider

Amazon EKS supports using OpenID Connect (OIDC) identity providers as a method to authenticate users to your cluster. OIDC identity providers can be used with, or as an alternative to AWS Identity and Access Management (IAM). For more information about using IAM, see Enabling IAM user and role access to your cluster (p. 381). After configuring authentication to your cluster, you can create Kubernetes roles and clusterroles to assign permissions to the roles, and then bind the roles to the identities using Kubernetes rolebindings and clusterrolebindings. For more information, see Using RBAC Authorization in the Kubernetes documentation.

**Considerations**

- You can associate one OIDC identity provider to your cluster.
- Kubernetes doesn't provide an OIDC identity provider. You can use an existing public OIDC identity provider, or you can run your own identity provider. For a list of certified providers, see OpenID Certification on the OpenID site.
• The issuer URL of the OIDC identity provider must be publicly accessible, so that Amazon EKS can
discover the signing keys. Amazon EKS does not support OIDC identity providers with self-signed
certificates.
• You can’t disable the AWS IAM authenticator on your cluster, because it is still required for joining
nodes to a cluster. For more information, see AWS IAM Authenticator for Kubernetes on GitHub.
• An Amazon EKS cluster must still be created by an AWS IAM user, rather than an OIDC identity
provider user. This is because the cluster creator interacts with the Amazon EKS APIs, rather than the
Kubernetes APIs.
• OIDC identity provider-authenticated users are listed in the cluster’s audit log if CloudWatch logs
are turned on for the control plane. For more information, see Enabling and disabling control plane
logs (p. 52).
• You can’t sign in to the AWS Management Console with an account from an OIDC provider. You can
only view Kubernetes resources (p. 500) in the console by signing into the AWS Management Console
with an AWS Identity and Access Management account.

Associate an OIDC identity provider

Before you can associate an OIDC identity provider with your cluster, you need the following information
from your provider:

• **Issuer URL** – The URL of the OIDC identity provider that allows the API server to discover public
signing keys for verifying tokens. The URL must begin with https:// and should correspond to the
iss claim in the provider’s OIDC ID tokens. In accordance with the OIDC standard, path components
are allowed but query parameters are not. Typically the URL consists of only a host name, like
https://server.example.org or https://example.com. This URL should point to the level
below .well-known/openid-configuration and must be publicly accessible over the internet.
• **Client ID (also known as audience)** – The ID for the client application that makes authentication
requests to the OIDC identity provider.

You can associate an identity provider using eksctl or the AWS Management Console.

**eksctl**

**To associate an OIDC identity provider to your cluster using eksctl**

1. Create a file named `associate-identity-provider.yaml` with the following contents. Replace the `example values` with your own. The values in the `identityProviders` section are obtained from your OIDC identity provider. Values are only required for the name, type, issuerUrl, and clientId settings under `identityProviders`.

```yaml
---
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig

metadata:
  name: my-cluster
  region: your-region-code

identityProviders:
- name: my-provider
  type: oidc
  issuerUrl: https://example.com
  clientId: kubernetes
  usernameClaim: email
  usernamePrefix: my-username-prefix
  groupsClaim: my-claim
```

389
Important
Don't specify `system:`, or any portion of that string, for `groupsPrefix` or `usernamePrefix`.

2. Create the provider.

    ```bash
    eksctl associate identityprovider -f associate-identity-provider.yaml
    ```

3. To use `kubectl` to work with your cluster and OIDC identity provider, see Using `kubectl` in the Kubernetes documentation.

AWS Management Console

To associate an OIDC identity provider to your cluster using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Select your cluster.
3. Select the Configuration tab, and then select the Authentication tab.
4. On the OIDC Identity Providers page, select Associate Identity Provider.
5. On the Associate OIDC Identity Provider page, enter or select the following options, and then select Associate.
   - For Name, enter a unique name for the provider.
   - For Issuer URL, enter the URL for your provider. This URL must be accessible over the internet.
   - For Client ID, enter the OIDC identity provider's client ID (also known as audience).
   - For Username claim, enter the claim to use as the username.
   - For Groups claim, enter the claim to use as the user's group.
   - (Optional) Select Advanced options, enter or select the following information.
     - **Username prefix** – Enter a prefix to prepend to username claims. The prefix is prepended to username claims to prevent clashes with existing names. If you do not provide a value, and the username is a value other than `email`, the prefix defaults to the value for Issuer URL. You can use the value `-` to disable all prefixing. Don't specify `system:` or any portion of that string.
     - **Groups prefix** – Enter a prefix to prepend to groups claims. The prefix is prepended to group claims to prevent clashes with existing names (such as `system: groups`). For example, the value `oidc:` creates group names like `oidc:engineering` and `oidc:infra`. Don't specify `system:` or any portion of that string.
     - **Required claims** – Select Add claim and enter one or more key value pairs that describe required claims in the client ID token. The pairs describe required claims in the ID Token. If set, each claim is verified to be present in the ID token with a matching value.
6. To use `kubectl` to work with your cluster and OIDC identity provider, see Using `kubectl` in the Kubernetes documentation.
Disassociate an OIDC identity provider from your cluster

If you disassociate an OIDC identity provider from your cluster, users included in the provider can no longer access the cluster. However, you can still access the cluster with AWS IAM users.

To disassociate an OIDC identity provider from your cluster using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the OIDC Identity Providers section, select Disassociate, enter the identity provider name, and then select Disassociate.

Example IAM policy

If you want to prevent an OIDC identity provider from being associated with a cluster, create and associate the following IAM policy to the IAM accounts of your Amazon EKS administrators. For more information, see Creating IAM policies and Adding IAM identity permissions in the IAM User Guide and Actions, resources, and condition keys for Amazon Elastic Kubernetes Service in the Service Authorization Reference.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "denyOIDC",
         "Effect": "Deny",
         "Action": "eks:AssociateIdentityProviderConfig",
      },
      {
         "Sid": "eksAdmin",
         "Effect": "Allow",
         "Action": "eks:*",
         "Resource": "*"
      }
   ]
}
```

The following example policy allows OIDC identity provider association if the clientID is kubernetes and the issuerUrl is https://cognito-idp.us-west-2.amazonaws.com/*.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowCognitoOnly",
         "Effect": "Deny",
         "Action": "eks:AssociateIdentityProviderConfig",
         "Condition": {
            "StringNotLikeIfExists": {}
         }
      }
   ]
}
```
Create a kubeconfig for Amazon EKS

In this section, you create a kubeconfig file for your cluster (or update an existing one).

This section offers two procedures to create or update your kubeconfig file. You can quickly create or update a kubeconfig file with the AWS CLI update-kubeconfig command automatically by using the AWS CLI, or you can create a kubeconfig file manually using the AWS CLI or the aws-iam-authenticator.

Amazon EKS uses the aws eks get-token command, available in version 1.16.156 or later of the AWS CLI or the AWS IAM Authenticator for Kubernetes with kubectl for cluster authentication. If you have installed the AWS CLI on your system, then by default the AWS IAM Authenticator for Kubernetes uses the same credentials that are returned with the following command:

```bash
aws sts get-caller-identity
```

For more information, see Configuring the AWS CLI in the AWS Command Line Interface User Guide.

Create kubeconfig file automatically

To create your kubeconfig file with the AWS CLI

1. Make sure that you have version 1.25.72 or 2.7.32 or later installed. To install or upgrade the AWS CLI, see Installing the AWS CLI in the AWS Command Line Interface User Guide.

   **Note**
   Your system's Python version must be 2.7.9 or later. Otherwise, you receive hostname doesn't match errors with AWS CLI calls to Amazon EKS.

You can check your AWS CLI version with the following command:

```bash
aws --version
```
Create kubeconfig file manually

1. Set values for a few variables by replacing the example values with your own and then running the modified commands.

```bash
export region_code=region-code
export cluster_name=my-cluster
export account_id=111122223333
```

2. Retrieve the endpoint for your cluster and store the value in a variable.

```bash
cluster_endpoint=$(aws eks describe-cluster \
  --region $region_code \
  --name $cluster_name \
  --query "cluster.endpoint"
)
```

3. Test your configuration.

```bash
kubectl get svc
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>svc/kubernetes</td>
<td>ClusterIP</td>
<td>10.100.0.1</td>
<td>&lt;none&gt;</td>
<td>443/TCP</td>
<td>1m</td>
</tr>
</tbody>
</table>

Create kubeconfig file manually

To create your kubeconfig file manually

1. Set values for a few variables by replacing the example values with your own and then running the modified commands.

```bash
export region_code=region-code
export cluster_name=my-cluster
export account_id=111122223333
```

2. Retrieve the endpoint for your cluster and store the value in a variable.

```bash
cluster_endpoint=$(aws eks describe-cluster \
  --region $region_code \
  --name $cluster_name \
  --query "cluster.endpoint"
)
```
3. Retrieve the Base64-encoded certificate data required to communicate with your cluster and store the value in a variable.

```bash
certificate_data=$(aws eks describe-cluster \
  --region $region_code \
  --name $cluster_name \
  --query "cluster.certificateAuthority.data" \
  --output text)
```

4. Create the default `~/.kube` directory if it doesn't already exist.

```bash
mkdir -p ~/.kube
```

5. Run the command for your preferred client token method (AWS CLI or AWS IAM authenticator for Kubernetes) to create the `config` file in the `~/.kube` directory. You can specify the following before running one of the commands by modifying the command to include the following:

- **An IAM role** – Remove the # at the start of the lines under `args:`. Replace `my-role` with the name of the IAM role that you want to perform cluster operations with instead of the default AWS credential provider chain. For more information, see Set up `kubectl` to use authentication tokens provided by AWS IAM Authenticator for Kubernetes on GitHub.

- **An AWS CLI named profile** – Remove the # at the start of the `env:` line, and remove # at the start of the lines under it. Replace `aws-profile` with the name of the profile to use. If you don't specify a profile, then the default profile is used. For additional information, see Specifying Credentials & Using AWS Profiles on GitHub.

**AWS CLI**

**Prerequisite**

Version 1.16.156 or later of the AWS CLI must be installed on your device.

```
#!/bin/bash
read -r -d '' KUBECONFIG <<EOF
apiVersion: v1
clusters:
- cluster:
  certificate-authority-data: $certificate_data
  server: $cluster_endpoint
  name: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
contexts:
- context:
  cluster: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
  user: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
  name: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
  current-context: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
kind: Config
preferences: {}
users:
- name: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
  user:
    exec:
      apiVersion: client.authentication.k8s.io/v1beta1
      command: aws
      args:
        - --region
        - $region_code
        - eks
EOF
```
Create kubeconfig file manually

```
- get-token
- --cluster-name
- $cluster_name
  # - "--role-arn"
  # - "arn:aws:iam::$account_id:role/my-role"
  # env:
  # - name: "AWS_PROFILE"
  # value: "aws-profile"
EOF
```

```
echo "${KUBECONFIG}" > ~/.kube/config
```

AWS IAM Authenticator for Kubernetes

Prerequisite

The AWS IAM Authenticator for Kubernetes must be installed on your device. To install it, see Installing aws-iam-authenticator (p. 396).

```
#!/bin/bash
read -r -d '' KUBECONFIG <<EOF
apiVersion: v1
clusters:
- cluster:
    server: $cluster_endpoint
certificate-authority-data: $certificate_data
    name: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
contexts:
- context:
    cluster: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
    user: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
    name: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
    current-context: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
kind: Config
preferences: {}
users:
- name: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
  user:
    exec:
      apiVersion: client.authentication.k8s.io/v1beta1
      command: aws-iam-authenticator
      args:
        - "token"
        - "-i"
        - "$cluster_name"
        # - "--role-arn"
        # - "arn:aws:iam::$account_id:role/my-role"
        # env:
        # - name: "AWS_PROFILE"
        # value: "aws-profile"
EOF
echo "${KUBECONFIG}" > ~/.kube/config
```

6. Add the file path to your KUBECONFIG environment variable so that kubectl knows where to look for your cluster configuration.

   • For Bash shells on macOS or Linux:

     ```
     export KUBECONFIG=$KUBECONFIG:~/.kube/config
     ```

   • For PowerShell on Windows:

     ```
     $ENV:KUBECONFIG="(0);(1)" -f $ENV:KUBECONFIG, "$ENV:userprofile\.kube\config"
     ```
7. (Optional) Add the configuration to your shell initialization file so that it is configured when you open a shell.

- For Bash shells on macOS:
  ```bash
echo 'export KUBECONFIG=$KUBECONFIG:~/.kube/config' >> ~/.bash_profile
  ```

- For Bash shells on Linux:
  ```bash
echo 'export KUBECONFIG=$KUBECONFIG:~/.kube/config' >> ~/.bashrc
  ```

- For PowerShell on Windows:
  ```powershell
[System.Environment]::SetEnvironmentVariable('KUBECONFIG', $ENV:KUBECONFIG, 'Machine')
  ```

8. Test your configuration.

```
kubectl get svc
```

**Note**
If you receive any authorization or resource type errors, see Unauthorized or access denied (kubectl) (p. 522) in the troubleshooting section.

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>svc/kubernetes</td>
<td>ClusterIP</td>
<td>10.100.0.1</td>
<td>&lt;none&gt;</td>
<td>443/TCP</td>
<td>1m</td>
</tr>
</tbody>
</table>

---

**Installing aws-iam-authenticator**

Amazon EKS uses IAM to provide authentication to your Kubernetes cluster through the AWS IAM authenticator for Kubernetes. You can configure the stock `kubectl` client to work with Amazon EKS by installing the AWS IAM authenticator for Kubernetes and modifying your `kubectl` configuration file (p. 392) to use it for authentication.

**Note**
If you're running the AWS CLI version 1.16.156 or later, then you don't need to install the authenticator. Instead, you can use the `aws eks get-token` command. For more information, see Create `kubeconfig` file manually (p. 393).

If you're unable to use the AWS CLI version 1.16.156 or later to create the `kubeconfig` file, then you can install the AWS IAM authenticator for Kubernetes on macOS, Linux, or Windows.

**macOS**

**To install aws-iam-authenticator with Homebrew**

The easiest way to install the `aws-iam-authenticator` is with Homebrew.

1. If you do not already have Homebrew installed on your Mac, install it with the following command.

```
/bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/master/install.sh)"
```

2. Install the `aws-iam-authenticator` with the following command.
brew install aws-iam-authenticator

3. Test that the `aws-iam-authenticator` binary works.

   `aws-iam-authenticator help`

**To install `aws-iam-authenticator` on macOS**

You can also install the AWS-vended version of the `aws-iam-authenticator` by following these steps.

1. Download the Amazon EKS vended `aws-iam-authenticator` binary from Amazon S3.

   ```bash
   ```

2. (Optional) Verify the downloaded binary with the SHA-256 sum provided in the same bucket prefix.
   a. Download the SHA-256 sum for your system.

      ```bash
   ```
   b. Check the SHA-256 sum for your downloaded binary.

      ```bash
openssl sha1 -sha256 aws-iam-authenticator
   ```
   c. Compare the generated SHA-256 sum in the command output against your downloaded `aws-iam-authenticator.sha256` file. The two should match.

3. Apply execute permissions to the binary.

   ```bash
chmod +x ./aws-iam-authenticator
   ```

4. Copy the binary to a folder in your `PATH`. We recommend creating a `HOME/bin/aws-iam-authenticator` and ensuring that `HOME/bin` comes first in your `PATH`.

   ```bash
mkdir -p $HOME/bin && cp ./aws-iam-authenticator $HOME/bin/aws-iam-authenticator && export PATH=$PATH:$HOME/bin
   ```

5. Add `$HOME/bin` to your `PATH` environment variable.

   ```bash
echo 'export PATH=$PATH:$HOME/bin' >> ~/.bash_profile
   ```

6. Test that the `aws-iam-authenticator` binary works.

   `aws-iam-authenticator help`

**To install `aws-iam-authenticator` on Linux**

1. Download the Amazon EKS vended `aws-iam-authenticator` binary from Amazon S3 for your hardware platform.
Installing `aws-iam-authenticator`

2. (Optional) Verify the downloaded binary with the SHA-256 sum provided in the same bucket prefix for your hardware platform.
   a. Download the SHA-256 sum for your system.

   ```

```

   b. Check the SHA-256 sum for your downloaded binary.

   ```
openssl sha1 -sha256 `aws-iam-authenticator`
```

   c. Compare the generated SHA-256 sum in the command output against your downloaded `aws-iam-authenticator.sha256` file. The two should match.

3. Apply execute permissions to the binary.

   ```
chmod +x `./aws-iam-authenticator`
```

4. Copy the binary to a folder in your `$PATH`. We recommend creating a `$HOME/bin/aws-iam-authenticator` and ensuring that `$HOME/bin` comes first in your `$PATH`.

   ```
mkdir -p $HOME/bin && cp `./aws-iam-authenticator` $HOME/bin/aws-iam-authenticator && export PATH=$PATH:$HOME/bin
```

5. Add `$HOME/bin` to your `PATH` environment variable.

   ```
echo 'export PATH=$PATH:$HOME/bin' >> ~/.bashrc
```

6. Test that the `aws-iam-authenticator` binary works.

   ```
aws-iam-authenticator help
```

Windows

To install `aws-iam-authenticator` on Windows with Chocolatey

1. If you do not already have Chocolatey installed on your Windows system, see Installing chocolatey.

2. Open a PowerShell terminal window and install the `aws-iam-authenticator` package with the following command:

   ```
choco install -y aws-iam-authenticator
```

3. Test that the `aws-iam-authenticator` binary works.
To install `aws-iam-authenticator` on Windows

1. Open a PowerShell terminal window and download the Amazon EKS vended `aws-iam-authenticator` binary from Amazon S3.

   ```bash
   ```

2. (Optional) Verify the downloaded binary with the SHA-256 sum provided in the same bucket prefix.
   a. Download the SHA-256 sum for your system.

      ```bash
      ```
   b. Check the SHA-256 sum for your downloaded binary.

      ```bash
      Get-FileHash aws-iam-authenticator.exe
      ```
   c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match, although the PowerShell output will be uppercase.

3. Copy the binary to a folder in your `PATH`. If you have an existing directory in your `PATH` that you use for command line utilities, copy the binary to that directory. Otherwise, complete the following steps.
   a. Create a new directory for your command line binaries, such as `C:\bin`.
   b. Copy the `aws-iam-authenticator.exe` binary to your new directory.
   c. Edit your user or system `PATH` environment variable to add the new directory to your `PATH`.
   d. Close your PowerShell terminal and open a new one to pick up the new `PATH` variable.

4. Test that the `aws-iam-authenticator` binary works.

   ```bash
   aws-iam-authenticator help
   ```

If you have an existing Amazon EKS cluster, create a `kubeconfig` file for that cluster. For more information, see Create a `kubeconfig` for Amazon EKS (p. 392). Otherwise, see Creating an Amazon EKS cluster (p. 24) to create a new Amazon EKS cluster.

### Default Amazon EKS Kubernetes roles and users

Amazon EKS creates identities for each of the Kubernetes components in 1.20 and later clusters. The following objects have been created by the Amazon EKS team to provide RBAC permissions for the components:

**Roles**

- `eks:authenticator`
- `eks:certificate-controller-approver`
Default Amazon EKS roles and users

- eks:certificate-controller
- eks:cluster-event-watcher
- eks:fargate-scheduler
- eks:k8s-metrics
- eks:nodewatcher
- eks:pod-identity-mutating-webhook

RoleBindings

- eks:authenticator
- eks:certificate-controller-approver
- eks:certificate-controller
- eks:cluster-event-watcher
- eks:fargate-scheduler
- eks:k8s-metrics
- eks:nodewatcher
- eks:pod-identity-mutating-webhook

Users

- eks:authenticator
- eks:certificate-controller
- eks:cluster-event-watcher
- eks:fargate-scheduler
- eks:k8s-metrics
- eks:nodewatcher
- eks:pod-identity-mutating-webhook

In addition to these objects, Amazon EKS uses a special user identity eks:cluster-bootstrap for kubectl operations during cluster bootstrap. Amazon EKS also uses a special user identity eks:support-engineer for cluster management operations. All the user identities will appear in the kube audit logs available to customers through CloudWatch.

Run kubectl describe clusterrole rolename to see the permissions for each role.
Cluster management

This chapter includes the following topics to help you manage your cluster. You can also view information about your Kubernetes resources (p. 500) with the AWS Management Console.

- **Tutorial: Deploy the Kubernetes Dashboard (web UI) (p. 401)** – Learn how to install the dashboard, a web-based user interface for your Kubernetes cluster and applications.
- **Installing the Kubernetes Metrics Server (p. 407)** – The Kubernetes Metrics Server is an aggregator of resource usage data in your cluster. It is not deployed by default in your cluster, but is used by Kubernetes add-ons, such as the Kubernetes Dashboard and Horizontal Pod Autoscaler (p. 349). In this topic you learn how to install the Metrics Server.
- **Control plane metrics with Prometheus (p. 408)** – The Kubernetes API server exposes a number of metrics that are useful for monitoring and analysis. This topic explains how to deploy Prometheus and some of the ways that you can use it to view and analyze what your cluster is doing.
- **Using Helm with Amazon EKS (p. 411)** – The Helm package manager for Kubernetes helps you install and manage applications on your Kubernetes cluster. This topic helps you install and run the Helm binaries so that you can install and manage charts using the Helm CLI on your local computer.
- **Tagging your Amazon EKS resources (p. 412)** – To help you manage your Amazon EKS resources, you can assign your own metadata to each resource in the form of tags. This topic describes tags and shows you how to create them.
- **Amazon EKS service quotas (p. 416)** – Your AWS account has default quotas, formerly referred to as limits, for each AWS service. Learn about the quotas for Amazon EKS and how to increase them.

**Tutorial: Deploy the Kubernetes Dashboard (web UI)**

This tutorial guides you through deploying the Kubernetes Dashboard to your Amazon EKS cluster, complete with CPU and memory metrics. It also helps you to create an Amazon EKS administrator service account that you can use to securely connect to the dashboard to view and control your cluster. If you have issues using the dashboard, you can create an issue or pull request in the project's GitHub repository.

**Prerequisites**

This tutorial assumes the following:

- You have created an Amazon EKS cluster by following the steps in Getting started with Amazon EKS (p. 4).
- You have the Kubernetes Metrics Server installed. For more information, see Installing the Kubernetes Metrics Server (p. 407).
- The security groups for your control plane elastic network interfaces and nodes follow the recommended settings in Amazon EKS security group requirements and considerations (p. 245).
- You are using a kubectl client that is configured to communicate with your Amazon EKS cluster (p. 18).

**Step 1: Deploy the Kubernetes dashboard**

Apply the dashboard manifest to your cluster using the command for the version of your cluster.
Step 2: Create an eks-admin service account and cluster role binding

By default, the Kubernetes Dashboard user has limited permissions. In this section, you create an eks-admin service account and cluster role binding that you can use to securely connect to the dashboard with admin-level permissions. For more information, see Managing Service Accounts in the Kubernetes documentation.

To create the eks-admin service account and cluster role binding

Important
The example service account created with this procedure has full cluster-admin (superuser) privileges on the cluster. For more information, see Using RBAC authorization in the Kubernetes documentation.

1. Run the following command to create a file named eks-admin-service-account.yaml with the following text. This manifest defines a service account and cluster role binding named eks-admin.

```yaml
cat >eks-admin-service-account.yaml <<EOF
apiVersion: v1
kind: ServiceAccount
metadata:
  name: eks-admin
  namespace: kube-system
---
apiVersion: rbac.authorization.k8s.io/v1
```
Step 3: Connect to the dashboard

Now that the Kubernetes Dashboard is deployed to your cluster, and you have an administrator service account that you can use to view and control your cluster, you can connect to the dashboard with that service account.

To connect to the Kubernetes dashboard

1. Retrieve an authentication token for the eks-admin service account.

   ```
kubectl -n kube-system describe secret $(kubectl -n kube-system get secret | grep eks-admin | awk '{print $1}')
   ```

   The example output is as follows.

   ```
Name:         eks-admin-token-b5zv4
Namespace:    kube-system
Labels:       <none>
Annotations:  kubernetes.io/service-account.name=eks-admin
               kubernetes.io/service-account.uid=bcfe66ac-39be-11e8-97e8-026dce96b6e8
Type:  kubernetes.io/service-account-token

Data
====
c.a.crt:     1025 bytes
namespace:  11 bytes
token:  authentication-token
   ```

   Copy the `authentication-token` value from the output. You use this token to connect to the dashboard in a later step.

2. Start the `kubectl` proxy.

   ```
kubectl proxy
   ```
3. To access the dashboard endpoint, open the following link with a web browser: http://localhost:8001/api/v1/namespaces/kubernetes-dashboard/services/https:kubernetes-dashboard:/proxy/#!/login.

4. Choose **Token**, paste the **authentication-token** output from the previous command into the **Token** field, and choose **SIGN IN**.

After signing in, you see the dashboard in your web browser.

![Kubernetes Dashboard](image)

For more information about using the dashboard, see Deploy and Access the Kubernetes Dashboard in the Kubernetes documentation.

**Cost monitoring**

Amazon EKS supports Kubecost, which you can use to monitor your costs broken down by Kubernetes resources including pods, nodes, namespaces, and labels. As a Kubernetes platform administrator and finance leader, you can use Kubecost to visualize a breakdown of Amazon EKS charges, allocate costs, and charge back organizational units such as application teams. You can provide your internal teams and business units with transparent and accurate cost data based on their actual AWS bill. Moreover, you can also get customized recommendations for cost optimization based on their infrastructure environment and usage patterns within their clusters. For more information about Kubecost, see the Kubecost documentation.

Amazon EKS provides an AWS optimized bundle of Kubecost for cluster cost visibility. You can use your existing AWS support agreements to obtain support.

**Prerequisites**

- An existing Amazon EKS cluster. To deploy one, see Getting started with Amazon EKS (p. 4).
- The `kubectl` command line tool is installed on your device or AWS CloudShell. The version can be the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For example, if your cluster version is 1.22, you can use `kubectl` version 1.21, 1.22, or 1.23 with it. To install or upgrade `kubectl`, see Installing or updating kubectl (p. 4).
To install Kubecost

1. Install Kubecost with the following command. You can replace 1.96.0 with a later version. You can see the available versions at kubecost/cost-analyzer in the Amazon ECR Public Gallery.

   ```bash
   helm upgrade -i kubecost oci://public.ecr.aws/kubecost/cost-analyzer --version 1.96.0 \
   --namespace kubecost --create-namespace \
   ```

   Kubecost releases new versions regularly. You can update your version using `helm upgrade`. The installation includes a local Prometheus server and `kube-state-metrics`. If your environment already meets some of the prerequisites, you can customize your deployment. For more information, see the sample configuration file on GitHub.

2. Make sure the required pods are running.

   ```bash
   kubectl get pods -n kubecost
   ```

   The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubecost-cost-analyzer-b9788c99f-5vj5b</td>
<td>2/2</td>
<td>Running</td>
<td>0</td>
<td>3h27m</td>
</tr>
<tr>
<td>kubecost-kube-state-metrics-99bb8c55b-bn2br</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>3h27m</td>
</tr>
<tr>
<td>kubecost-prometheus-server-7d9967bfc8-9c8p7</td>
<td>2/2</td>
<td>Running</td>
<td>0</td>
<td>3h27m</td>
</tr>
</tbody>
</table>

3. On your device, enable port-forwarding to expose the Kubecost dashboard.

   ```bash
   kubectl port-forward --namespace kubecost deployment/kubecost-cost-analyzer 9090
   ```

   Alternatively, you can use the AWS Load Balancer Controller (p. 308) to expose Kubecost and use Amazon Cognito for authentication, authorization, and user management. For more information, see How to use Application Load Balancer and Amazon Cognito to authenticate users for your Kubernetes web apps.

4. On the same device that you completed the previous step on, open a web browser and enter the following address.

   ```
   http://localhost:9090
   ```

   You see the Kubecost Overview page in your browser. It might take 5–10 minutes for Kubecost to gather metrics. You can see your Amazon EKS spend, including cumulative cluster costs, associated Kubernetes asset costs, and monthly aggregated spend.
5. To track costs at a cluster level, tag your Amazon EKS resources for billing. For more information, see the section called “Tagging your resources for billing” (p. 414).

You can also view the following information by selecting it in the left pane of the dashboard:

- **Cost allocation** – View monthly Amazon EKS costs and cumulative costs for each of your namespaces and other dimensions over the past seven days. This is helpful for understanding which parts of your application are contributing to Amazon EKS spend.
- **Assets** – View the costs of the AWS infrastructure assets that are associated with your Amazon EKS resources.

**Additional features**

- **Export cost metrics** – Amazon EKS optimized cost monitoring is deployed with Kubecost and Prometheus, which is an open-source monitoring system and time series database. Kubecost reads metric from Prometheus and then performs cost allocation calculations and writes the metrics back to Prometheus. The Kubecost front-end reads metrics from Prometheus and shows them on the Kubecost user interface. The architecture is illustrated in the following diagram.
With Prometheus pre-installed, you can write queries to ingest Kubecost data into your current business intelligence system for further analysis. You can also use it as a data source for your current Grafana dashboard to display Amazon EKS cluster costs that your internal teams are familiar with. To learn more about how to write Prometheus queries, see the Prometheus Configuration readme file on GitHub or use the example Grafana JSON models in the Kubecost Github repository as references.

- **AWS Cost and Usage Report integration** – To perform cost allocation calculations for your Amazon EKS cluster, Kubecost retrieves the public pricing information of AWS services and AWS resources from the AWS Price List API. You can also integrate Kubecost with AWS Cost and Usage Report to enhance the accuracy of the pricing information specific to your AWS account. This information includes enterprise discount programs, reserved instance usage, savings plans, and spot usage. To learn more about how the AWS Cost and Usage Report integration works, see AWS Cloud Integration in the Kubecost documentation.

## Remove Kubecost

You can remove Kubecost from your cluster with the following commands.

```
helm uninstall kubecost --namespace kubecost
kubectl delete ns kubecost
```

## Installing the Kubernetes Metrics Server

The Kubernetes Metrics Server is an aggregator of resource usage data in your cluster, and it is not deployed by default in Amazon EKS clusters. For more information, see Kubernetes Metrics Server on
GitHub. The Metrics Server is commonly used by other Kubernetes add ons, such as the Horizontal Pod Autoscaler (p. 349) or the Kubernetes Dashboard (p. 401). For more information, see Resource metrics pipeline in the Kubernetes documentation. This topic explains how to deploy the Kubernetes Metrics Server on your Amazon EKS cluster.

**Important**
Don't use Metrics Server when you need an accurate source of resource usage metrics or as a monitoring solution.

### Deploy the Metrics Server

1. Deploy the Metrics Server with the following command:

   ```bash
   kubectl apply -f https://github.com/kubernetes-sigs/metrics-server/releases/latest/download/components.yaml
   ```

2. Verify that the `metrics-server` deployment is running the desired number of pods with the following command.

   ```bash
   kubectl get deployment metrics-server -n kube-system
   ```

   The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>metrics-server</td>
<td>1/1</td>
<td>1</td>
<td>1</td>
<td>6m</td>
</tr>
</tbody>
</table>

### Control plane metrics with Prometheus

The Kubernetes API server exposes a number of metrics that are useful for monitoring and analysis. These metrics are exposed internally through a metrics endpoint that refers to the `/metrics` HTTP API. Like other endpoints, this endpoint is exposed on the Amazon EKS control plane. This topic explains some of the ways you can use this endpoint to view and analyze what your cluster is doing.

### Viewing the raw metrics

To view the raw metrics output, use `kubectl` with the `--raw` flag. This command allows you to pass any HTTP path and returns the raw response.

```bash
kubectl get --raw /metrics
```

The example output is as follows.

```
...# HELP rest_client_requests_total Number of HTTP requests, partitioned by status code, method, and host.
# TYPE rest_client_requests_total counter
rest_client_requests_total{code=“200”,host=“127.0.0.1:21362”,method=“POST”} 4994
rest_client_requests_total{code=“200”,host=“127.0.0.1:443”,method=“DELETE”} 1
rest_client_requests_total{code=“200”,host=“127.0.0.1:443”,method=“GET”} 1.326086e+06
rest_client_requests_total{code=“200”,host=“127.0.0.1:443”,method=“PUT”} 862173
rest_client_requests_total{code=“404”,host=“127.0.0.1:443”,method=“GET”} 2
rest_client_requests_total{code=“409”,host=“127.0.0.1:443”,method=“POST”} 3
rest_client_requests_total{code=“409”,host=“127.0.0.1:443”,method=“PUT”} 8
# HELP ssh_tunnel_open_count Counter of ssh tunnel total open attempts
```
This raw output returns verbatim what the API server exposes. These metrics are represented in a Prometheus format. This format allows the API server to expose different metrics broken down by line. Each line includes a metric name, tags, and a value.

```
metric_name{"tag"="value",...} value
```

While this endpoint is useful if you are looking for a specific metric, you typically want to analyze these metrics over time. To do this, you can deploy Prometheus into your cluster. Prometheus is a monitoring and time series database that scrapes exposed endpoints and aggregates data, allowing you to filter, graph, and query the results.

## Deploying Prometheus

This topic helps you deploy Prometheus into your cluster with Helm V3. If you already have Helm installed, you can check your version with the `helm version` command. Helm is a package manager for Kubernetes clusters. For more information about Helm and how to install it, see Using Helm with Amazon EKS (p. 411).

After you configure Helm for your Amazon EKS cluster, you can use it to deploy Prometheus with the following steps.

### To deploy Prometheus using Helm

1. Create a Prometheus namespace.

   ```
kubectl create namespace prometheus
   ```

2. Add the `prometheus-community` chart repository.

   ```
   helm repo add prometheus-community https://prometheus-community.github.io/helm-charts
   ```

3. Deploy Prometheus.

   ```
   helm upgrade -i prometheus prometheus-community/prometheus
   --namespace prometheus
   --set
   alertmanager.persistentVolume.storageClass="gp2",server.persistentVolume.storageClass="gp2"
   ```

   **Note**
   If you get the error `Error: failed to download "stable/prometheus" (hint: running `helm repo update` may help)` when executing this command, run `helm repo update`, and then try running the Step 2 command again.
   If you get the error `Error: rendered manifests contain a resource that already exists`, run `helm uninstall your-release-name -n namespace`, then try running the Step 3 command again.

4. Verify that all of the pods in the `prometheus` namespace are in the READY state.

   ```
kubectl get pods -n prometheus
   ```
The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>prometheus-alertmanager-59b4c8c744-r7bgp</td>
<td>1/2</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-kube-state-metrics-7cfd87cf99-jkz2f</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-node-exporter-jejg2</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-node-exporter-jxv2h</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-node-exporter-vbdks</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-pushgateway-76c444b68c-82tnw</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-server-775957f748-mmht9</td>
<td>1/2</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
</tbody>
</table>

5. Use **kubectl** to port forward the Prometheus console to your local machine.

```bash
kubectl --namespace=prometheus port-forward deploy/prometheus-server 9090
```

6. Point a web browser to **localhost:9090** to view the Prometheus console.

7. Choose a metric from the `- insert metric at cursor` menu, then choose **Execute**. Choose the **Graph** tab to show the metric over time. The following image shows `container_memory_usage_bytes` over time.

8. From the top navigation bar, choose **Status**, then **Targets**.
All of the Kubernetes endpoints that are connected to Prometheus using service discovery are displayed.

### Store your Prometheus metrics in Amazon Managed Service for Prometheus

Amazon Managed Service for Prometheus is a Prometheus-compatible monitoring and alerting service that makes it easy to monitor containerized applications and infrastructure at scale. It is a fully-managed service that automatically scales the ingestion, storage, querying, and alerting of your metrics. It also integrates with AWS security services to enable fast and secure access to your data. You can use the open-source PromQL query language to query your metrics and alert on them.

For more information, see [Getting started with Amazon Managed Service for Prometheus](#).

### Using Helm with Amazon EKS

The Helm package manager for Kubernetes helps you install and manage applications on your Kubernetes cluster. For more information, see the [Helm documentation](#). This topic helps you install and run the Helm binaries so that you can install and manage charts using the Helm CLI on your local system.

**Important**

Before you can install Helm charts on your Amazon EKS cluster, you must configure `kubectl` to work for Amazon EKS. If you have not already done this, see [Create a `kubectl` config for Amazon EKS](#) before proceeding. If the following command succeeds for your cluster, you're properly configured.

```
kubectl get svc
```
To install the Helm binaries on your local system

1. Run the appropriate command for your client operating system.
   - If you're using macOS with Homebrew, install the binaries with the following command.
     ```bash
     brew install helm
     ```
   - If you're using Windows with Chocolatey, install the binaries with the following command.
     ```bash
     choco install kubernetes-helm
     ```
   - If you're using Linux, install the binaries with the following commands.
     ```bash
     chmod 700 get_helm.sh
     ./get_helm.sh
     ```
   **Note**
   If you get a message that `openssl` must first be installed, you can install it with the following command.
   ```bash
   sudo yum install openssl
   ```

2. To pick up the new binary in your `PATH`, close your current terminal window and open a new one.
3. See the version of Helm that you installed.
   ```bash
   helm version --short | cut -d + -f 1
   ```
   The example output is as follows.
   ```
   v3.9.0
   ```

4. At this point, you can run any Helm commands (such as `helm install chart-name`) to install, modify, delete, or query Helm charts in your cluster. If you're new to Helm and don't have a specific chart to install, you can:
   - Experiment by installing an example chart. See Install an example chart in the Helm Quickstart guide.
   - Create an example chart and push it to Amazon ECR. For more information, see Pushing a Helm chart in the Amazon Elastic Container Registry User Guide.
   - Install an Amazon EKS chart from the eks-charts GitHub repo or from ArtifactHub.

Tagging your Amazon EKS resources

You can use tags to help you manage your Amazon EKS resources. This topic provides an overview of the tags function and shows how you can create tags.

Topics
- Tag basics (p. 413)
- Tagging your resources (p. 413)
- Tag restrictions (p. 414)
Tag basics

A tag is a label that you assign to an AWS resource. Each tag consists of a key and an optional value. You define both.

With tags, you can categorize your AWS resources. For example, you can categorize resources by purpose, owner, or environment. When you have many resources of the same type, you can use the tags that you assigned to a specific resource to quickly identify that resource. For example, you can define a set of tags for your Amazon EKS clusters to help you track each cluster’s owner and stack level. We recommend that you devise a consistent set of tag keys for each resource type. You can then search and filter the resources based on the tags that you add.

After you add a tag, you can edit tag keys and values or remove tags from a resource at any time. If you delete a resource, any tags for the resource are also deleted.

Tags don’t have any semantic meaning to Amazon EKS and are interpreted strictly as a string of characters. You can set the value of a tag to an empty string. However, you can’t set the value of a tag to null. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the earlier value.

If you use AWS Identity and Access Management (IAM), you can control which users in your AWS account have permission to manage tags.

Tagging your resources

The following Amazon EKS resources support tags:

- clusters
- managed node groups
- Fargate profiles

You can tag these resources using the following:

- If you’re using the Amazon EKS console, you can apply tags to new or existing resources at any time. You can do this by using theTags tab on the relevant resource page. For more information, seeWorking with tags using the console (p. 415).
- If you’re using eksctl, you can apply tags to resources when they’re created using the --tags option.
- If you’re using the AWS CLI, the Amazon EKS API, or an AWS SDK, you can apply tags to new resources using the tags parameter on the relevant API action. You can apply tags to existing resources using theTagResource API action. For more information, seeTagResource.
When you use some resource-creating actions, you can also specify tags for the resource at the same time that you create it. If tags can't be applied while the resource is being created, the resource fails to be created. This mechanism ensures that resources that you intend to tag are either created with the tags that you specify or not created at all. If you tag resources when you create them, you don't need to run custom tagging scripts after you create the resource.

Tags don't propagate to other resources that are associated with the resource that you create. For example, Fargate profile tags don't propagate to other resources that are associated with the Fargate profile, such as the pods that are scheduled with it.

## Tag restrictions

The following restrictions apply to tags:

- A maximum of 50 tags can be associated with a resource.
- Tag keys can't be repeated for one resource. Each tag key must be unique, and can only have one value.
- Keys can be up to 128 characters long in UTF-8.
- Values can be up to 256 characters long in UTF-8.
- If multiple AWS services and resources use your tagging schema, limit the types of characters you use. Some services might have restrictions on allowed characters. Generally, allowed characters are letters, numbers, spaces, and the following characters: `+ - . _ : / @`.  
- Tag keys and values are case sensitive.
- Don't use `aws:`, `AWS:`, or any upper or lowercase combination of such as a prefix for either keys or values. These are reserved only for AWS use. You can't edit or delete tag keys or values with this prefix. Tags with this prefix don't count against your tags-per-resource limit.

## Tagging your resources for billing

When you apply tags to Amazon EKS clusters, you can use them for cost allocation in your Cost & Usage Reports. The metering data in your Cost & Usage Reports shows usage across all of your Amazon EKS clusters. For more information, see AWS cost and usage report in the AWS Billing User Guide.

The AWS generated cost allocation tag, specifically `aws:eks:cluster-name`, lets you break down Amazon EC2 instance costs by individual Amazon EKS cluster in Cost Explorer. However, this tag doesn't capture the control plane expenses. The tag is automatically added to Amazon EC2 instances that participate in an Amazon EKS cluster. This behavior happens regardless of whether the instances are provisioned using Amazon EKS managed node groups, Karpenter, or directly with Amazon EC2. This specific tag doesn't count towards the 50 tags limit. To use the tag, the account owner must activate it in the AWS Billing console or by using the API. When an AWS Organizations management account owner activates the tag, it's also activated for all organization member accounts.

You can also organize your billing information based on resources that have the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information. That way, you can see the total cost of that application across several services. For more information about setting up a cost allocation report with tags, see The Monthly Cost Allocation Report in the AWS Billing User Guide.

**Note**  
If you just enabled reporting, data for the current month is available for viewing after 24 hours.

Cost Explorer is a reporting tool that's available as part of the AWS Free Tier. You can use Cost Explorer to view charts of your Amazon EKS resources from the last 13 months. You can also forecast how much you're likely to spend for the next three months. You can see patterns in how much you spend on AWS resources over time. For example, you can use it to identify areas that need further inquiry and see.
trends that you can use to understand your costs. You also can specify time ranges for the data, and view
time data by day or by month.

**Working with tags using the console**

Using the Amazon EKS console, you can manage the tags that are associated with new or existing
clusters and managed node groups.

When you select a resource-specific page in the Amazon EKS console, the page displays a list of those
resources. For example, if you select **Clusters** from the left navigation pane, the console displays a list of
Amazon EKS clusters. When you select a resource from one of these lists (for example, a specific cluster)
that supports tags, you can view and manage its tags on the **Tags** tab.

You can also use **Tag Editor** in the AWS Management Console, which provides a unified way to manage
your tags. For more information, see **Working with Tag Editor** in the **AWS Resource Groups and Tags User
Guide**.

**Adding tags on a resource on creation**

You can add tags to Amazon EKS clusters, managed node groups, and Fargate profiles when you create
them. For more information, see **Creating an Amazon EKS cluster** (p. 24).

**Adding and deleting tags on a resource**

You can add or delete the tags that are associated with your clusters directly from the resource's page.

**To add or delete a tag on an individual resource**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. On the navigation bar, select the AWS Region to use.
3. In the left navigation pane, choose **Clusters**.
4. Choose a specific cluster.
5. Choose the **Tags** tab, and then choose **Manage tags**.
6. On the **Manage tags** page, add or delete your tags as necessary.
   - To add a tag, choose **Add tag**. Then specify the key and value for each tag.
   - To delete a tag, choose **Remove tag**.
7. Repeat this process for each tag that you want to add or delete.
8. Choose **Update** to finish.

**Working with tags using the CLI, API, or eksctl**

Use the following AWS CLI commands or Amazon EKS API operations to add, update, list, and delete
the tags for your resources. You can only use **eksctl** to add tags while simultaneously creating the new
resources with one command.

**Tagging support for Amazon EKS resources**

<table>
<thead>
<tr>
<th>Task</th>
<th>AWS CLI</th>
<th>AWS Tools for Windows PowerShell</th>
<th>API action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add or overwrite one or more tags.</td>
<td>tag-resource</td>
<td>Add-EKSResourceTag</td>
<td>TagResource</td>
</tr>
</tbody>
</table>
The following examples show how to tag or untag resources using the AWS CLI.

**Example 1: Tag an existing cluster**

The following command tags an existing cluster.

```
aws eks tag-resource --resource-arn resource_ARN --tags team=devs
```

**Example 2: Untag an existing cluster**

The following command deletes a tag from an existing cluster.

```
aws eks untag-resource --resource-arn resource_ARN --tag-keys tag_key
```

**Example 3: List tags for a resource**

The following command lists the tags that are associated with an existing resource.

```
aws eks list-tags-for-resource --resource-arn resource_ARN
```

When you use some resource-creating actions, you can specify tags at the same time that you create the resource. The following actions support specifying a tag when you create a resource.

<table>
<thead>
<tr>
<th>Task</th>
<th>AWS CLI</th>
<th>AWS Tools for Windows PowerShell</th>
<th>API action</th>
<th>eksctl</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a cluster</td>
<td>create-cluster</td>
<td>New-EKSCluster</td>
<td>CreateCluster</td>
<td>create-</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>cluster</td>
</tr>
<tr>
<td>Create a managed node group*</td>
<td>create-nodegroup</td>
<td>New-EKSNodegroup</td>
<td>CreateNodegroup</td>
<td>create-</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>nodegroup</td>
</tr>
<tr>
<td>Create a Fargate profile</td>
<td>create-fargate-profile</td>
<td>New-EKSFargateProfile</td>
<td>CreateFargateProfile</td>
<td>create-fargate-profile</td>
</tr>
</tbody>
</table>

* If you want to also tag the Amazon EC2 instances when you create a managed node group, create the managed node group using a launch template. For more information, see Tagging Amazon EC2 instances (p. 115). If your instances already exist, you can manually tag the instances. For more information, see Tagging your resources in the Amazon EC2 User Guide for Linux Instances.

### Amazon EKS service quotas

Amazon EKS has integrated with Service Quotas, an AWS service that you can use to view and manage your quotas from a central location. For more information, see What Is Service Quotas? in the Service Quotas User Guide. With Service Quotas integration, you can quickly look up the value of your Amazon EKS and AWS Fargate service quotas using the AWS Management Console and AWS CLI.
AWS Management Console

To view Amazon EKS and Fargate service quotas using the AWS Management Console

2. In the left navigation pane, choose AWS Services.
3. From the AWS services list, search for and select Amazon Elastic Kubernetes Service (Amazon EKS) or AWS Fargate.

In the Service quotas list, you can see the service quota name, applied value (if it's available), AWS default quota, and whether the quota value is adjustable.
4. To view additional information about a service quota, such as the description, choose the quota name.
5. (Optional) To request a quota increase, select the quota that you want to increase, select Request quota increase, enter or select the required information, and select Request.

To work more with service quotas using the AWS Management Console, see the Service Quotas User Guide. To request a quota increase, see Requesting a Quota Increase in the Service Quotas User Guide.

AWS CLI

To view Amazon EKS and Fargate service quotas using the AWS CLI

Run the following command to view your Amazon EKS quotas.

```bash
aws service-quotas list-aws-default-service-quotas
  --query 'Quotas[*].
  {Adjustable:Adjustable,Name:QuotaName,Value:Value,Code:QuotaCode}'
  --service-code eks
  --output table
```

Run the following command to view your Fargate quotas.

```bash
aws service-quotas list-aws-default-service-quotas
  --query 'Quotas[*].
  {Adjustable:Adjustable,Name:QuotaName,Value:Value,Code:QuotaCode}'
  --service-code fargate
  --output table
```

**Note**
The quota returned is the number of Amazon ECS tasks or Amazon EKS pods that can run concurrently on Fargate in this account in the current AWS Region.

To work more with service quotas using the AWS CLI, see the Service Quotas AWS CLI Command Reference. To request a quota increase, see the request-service-quotas-increase command in the AWS CLI Command Reference.

### Service quotas

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clusters</td>
<td>Each supported Region: 100</td>
<td>Yes</td>
<td>The maximum number of EKS clusters in this account in the current Region.</td>
</tr>
<tr>
<td>Name</td>
<td>Default</td>
<td>Adjust</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>----------------------------------------------</td>
<td>--------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Control plane security groups per cluster</td>
<td>Each supported Region: 4</td>
<td>No</td>
<td>The maximum number of control plane security groups per cluster (these are specified when you create the cluster).</td>
</tr>
<tr>
<td>Fargate profiles per cluster</td>
<td>Each supported Region: 10</td>
<td>Yes</td>
<td>The maximum number of Fargate profiles per cluster.</td>
</tr>
<tr>
<td>Label pairs per Fargate profile selector</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
<td>The maximum number of label pairs per Fargate profile selector.</td>

<td>Each supported Region: 10</td>
<td>Yes</td>
<td>The maximum number of registered clusters in this account in the current Region.</td>
</tr>
<tr>
<td>Selectors per Fargate profile</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
<td>The maximum number of selectors per Fargate profile.</td>
</tr>
</tbody>
</table>

**Note**

The default values are the initial quotas set by AWS. These default values are separate from the actual applied quota values and maximum possible service quotas. For more information, see Terminology in Service Quotas in the Service Quotas User Guide.

These service quotas are listed under Amazon Elastic Kubernetes Service (Amazon EKS) in the Service Quotas console. To request a quota increase for values that are shown as adjustable, see Requesting a quota increase in the Service Quotas User Guide.

**AWS Fargate service quotas**

This section describes AWS Fargate service quotas for Amazon EKS. You can configure alarms that alert you when your usage approaches a service quota. For more information, see Creating a CloudWatch alarm to monitor Fargate resource usage metrics (p. 155).

AWS Fargate is transitioning from pod based quotas to vCPU based quotas. The following are the important dates related to the new vCPU based quotas.
• September 8, 2022 – You can now opt in to using the new vCPU based quotas ahead of automatic migration. By opting in, your account is controlled by vCPU based quotas rather than the previous pod based quotas. Pod based quotas remain the default for accounts that don't opt in.

  **Note**
  To use the vCPU based quotas with Amazon EKS before October 3, 2022, you must opt in.
  To opt in, use the AWS Support Center Console to create a Service limit increase case. Choose Fargate for Limit type and Fargate account vCPU limit opt-in for Limit. For more information, see Creating a support case in the AWS Support User Guide.

• October 3, 2022 through October 21, 2022 – All new and existing accounts are switched to the vCPU based quotas in a phased manner.

  **Note**
  To continue using the pod based quotas, you must opt out.
  To opt out, use the AWS Support Center Console to create a Service limit increase case. Choose Fargate for Limit type and Fargate account opt-out of vCPU limit for Limit. For more information, see Creating a support case in the AWS Support User Guide.

• October 31, 2022 – The last day that you can remain opted out of the vCPU based quotas.

• November 1, 2022 through November 15, 2022 – The opt-out option ends and all accounts are migrated to the vCPU based quotas. The pod based quotas are no longer available.

The following table lists the new vCPU based quota followed by the existing pod based quota. These service quotas are among those listed under the AWS Fargate service in the Service Quotas console. The following table only describes the quotas that also applicable to Amazon EKS.

You can confirm which quota type is active by looking at the Service Quotas console. If the vCPU quota is in effect, the Fargate On-Demand Pod count based quotas show 0 for the Applied quota value. Any other value indicates that the pod count quota is in effect.

New AWS accounts might have lower initial quotas that can increase over time. Fargate constantly monitors the account usage within each AWS Region, and then automatically increases the quotas based on the usage. You can also request a quota increase for values that are shown as adjustable. For more information, see Requesting a quota increase in the Service Quotas User Guide.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fargate On-Demand vCPU resource count</td>
<td>6</td>
<td>Yes</td>
<td>The number of Fargate vCPUs that can run concurrently as Fargate On-Demand in this account in the current Region.</td>
</tr>
<tr>
<td>Fargate On-Demand resource count</td>
<td>2</td>
<td>Yes</td>
<td>The number of Amazon ECS tasks and Amazon EKS pods that can run concurrently on Fargate in this account in the current Region.</td>
</tr>
</tbody>
</table>

  **Note**
  The default values are the initial quotas set by AWS. These default values are separate from the actual applied quota values and maximum possible service quotas. For more information, see Terminology in Service Quotas in the Service Quotas User Guide.
Note
Fargate additionally enforces Amazon ECS tasks and Amazon EKS pods launch rate quotas. For more information, see Fargate throttling limits in the Amazon Elastic Container Service User Guide for AWS Fargate.
Security in Amazon EKS

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. For Amazon EKS, AWS is responsible for the Kubernetes control plane, which includes the control plane nodes and etcd database. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon EKS, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility includes the following areas.
  - The security configuration of the data plane, including the configuration of the security groups that allow traffic to pass from the Amazon EKS control plane into the customer VPC
  - The configuration of the nodes and the containers themselves
  - The node's operating system (including updates and security patches)
  - Other associated application software:
    - Setting up and managing network controls, such as firewall rules
    - Managing platform-level identity and access management, either with or in addition to IAM
    - The sensitivity of your data, your company’s requirements, and applicable laws and regulations

This documentation helps you understand how to apply the shared responsibility model when using Amazon EKS. The following topics show you how to configure Amazon EKS to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Amazon EKS resources.

**Note**

Linux containers are made up of control groups (cgroups) and namespaces that help limit what a container can access, but all containers share the same Linux kernel as the host Amazon EC2 instance. Running a container as the root user (UID 0) or granting a container access to host resources or namespaces such as the host network or host PID namespace are strongly discouraged, because doing so reduces the effectiveness of the isolation that containers provide.

**Topics**

- Certificate signing (p. 422)
- Kubernetes service accounts (p. 423)
- Identity and access management for Amazon EKS (p. 439)
- Compliance validation for Amazon Elastic Kubernetes Service (p. 492)
- Resilience in Amazon EKS (p. 493)
- Infrastructure security in Amazon EKS (p. 493)
- Configuration and vulnerability analysis in Amazon EKS (p. 494)
- Security best practices for Amazon EKS (p. 495)
- Pod security policy (p. 495)
- Using AWS Secrets Manager secrets with Kubernetes (p. 498)
Certificate signing

The Kubernetes Certificates API enables automation of X.509 credential provisioning. It features a command line interface for Kubernetes API clients to request and obtain X.509 certificates from a Certificate Authority (CA). A CertificateSigningRequest (CSR) resource is used to request that a denoted signer sign the certificate. Then, the request is either approved or denied before it's signed. Kubernetes supports both build-in signers and custom signers with well-defined behaviors. This way, clients can predict what happens to their CSRs. To learn more about certificate signing, see signing requests.

One of the built-in signers is kubernetes.io/legacy-unknown. The v1beta1 API of CSR resource honored this legacy-unknown signer. However, the stable v1 API of CSR doesn't allow the signerName to be set to kubernetes.io/legacy-unknown.

Amazon EKS version 1.21 and earlier versions allowed the value legacy-unknown as the signerName in v1beta1 CSR API. This API enables the Amazon EKS Certificate Authority (CA) to generate certificates. However, in Kubernetes version 1.22, the v1beta1 CSR API is replaced by the v1 CSR API. This API doesn't support the signerName of "legacy-unknown." Given this, if you want to use Amazon EKS CA for generating certificates on version 1.22 and later, you need to use a custom signer. It was introduced in Amazon EKS version 1.22. To use the CSR v1 API version and generate a new certificate, you must migrate any existing manifests and API clients. Existing certificates that were created with the older v1beta1 API are valid and function until the certificate expires. This includes the following:

1. Trust distribution: None. There's no standard trust or distribution for this signer in a Kubernetes cluster.
2. Permitted subjects: Any
3. Permitted x509 extensions: Honors subjectAltName and key usage extensions and discards other extensions
4. Permitted key usages: Must not include usages beyond \"["key encipherment", "digital signature", "server auth"]\n5. Expiration/certificate lifetime: 1 year (default and maximum)
6. CA bit allowed/disallowed: Not allowed

Example CSR generation with signerName

These steps shows how to generate a serving certificate for DNS name myserver.default.svc using signerName: beta.eks.amazonaws.com/app-serving. Use this as a guide for your own environment.

1. Run the openssl genrsa -out myserver.key 2048 command to generate an RSA private key.

   ```bash
   openssl genrsa -out myserver.key 2048
   ```

2. Run the following command to generate a certificate request.

   ```bash
   openssl req -new -key myserver.key -out myserver.csr -subj "/CN=myserver.default.svc"
   ```

3. Generate a base64 value for the CSR request. Later, you'll use this value for the request value in your CSR.

   ```bash
   cat myserver.csr | base64 -w 0 | tr -d "\n"
   ```
4. Create a file named *mycsr.yaml* with the following contents. In the following example, `beta.eks.amazonaws.com/app-serving` is the `signerName`. Replace `base64-value` with the value returned in the previous step.

```yaml
apiVersion: certificates.k8s.io/v1
kind: CertificateSigningRequest
metadata:
  name: myserver
spec:
  request: base64-value
  signerName: beta.eks.amazonaws.com/app-serving
  usages:
    - digital signature
    - key encipherment
    - server auth
```

5. Submit the CSR.

```
kubectl apply -f mycsr.yaml
```

6. Approve the serving certificate.

```
kubectl certificate approve myserver
```

7. Verify that the certificate was issued.

```
kubectl get csr myserver
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>SIGNERNAME</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>myserver</td>
<td>3m20s</td>
<td>beta.eks.amazonaws.com/app-serving</td>
<td>kubernetes-admin</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

8. Export the issued certificate:

```
kubectl get csr myserver -o jsonpath='{.status.certificate}' | base64 -d > myserver.crt
```

---

### Kubernetes service accounts

A Kubernetes service account provides an identity for processes that run in a pod. For more information see [Managing Service Accounts](#) in the Kubernetes documentation. If your pod needs access to AWS services, you can map the service account to an AWS Identity and Access Management identity to grant that access. For more information, see [IAM roles for service accounts](#) (p. 425).

### Service account tokens

The `BoundServiceAccountTokenVolume` feature is enabled by default in Kubernetes version 1.21 and later. This feature improves the security of service account tokens by allowing workloads running on Kubernetes to request JSON web tokens that are audience, time, and key bound. Service account tokens have an expiration of one hour. In earlier Kubernetes versions, the tokens didn't have an expiration. This means that clients that rely on these tokens must refresh the tokens within an hour. The following Kubernetes client SDKs refresh tokens automatically within the required time frame:

- Go version 0.15.7 and later
• Python version 12.0.0 and later
• Java version 9.0.0 and later
• JavaScript version 0.10.3 and later
• Ruby master branch
• Haskell version 0.3.0.0
• C# version 7.0.5 and later

If your workload is using an older client version, then you must update it. To enable a smooth migration of clients to the newer time-bound service account tokens, Kubernetes version 1.21 and later adds an extended expiry period to the service account token over the default one hour. For Amazon EKS clusters, the extended expiry period is 90 days. Your Amazon EKS cluster's Kubernetes API server rejects requests with tokens older than 90 days. We recommend that you check your applications and their dependencies to make sure that the Kubernetes client SDKs are the same or later than the versions listed previously.

When the API server receives requests with tokens that are older than one hour, it annotates the API audit log event with annotations.authentication.k8s.io/stale-token. The value of the annotation looks like the following example:

```
```

If your cluster has control plane logging (p. 51) enabled, then the annotations are in the audit logs. You can use the following CloudWatch Logs Insights query to identify all the pods in your Amazon EKS cluster that are using stale tokens:

```
fields @timestamp
| filter @logStream like /kube-apiserver-audit/
| filter @message like /seconds after warning threshold/|
| parse @message "subject: *, seconds after warning threshold:*"" as subject, elapsedtime
```

The subject refers to the service account that the pod used. The elapsedtime indicates the elapsed time (in seconds) after reading the latest token. The requests to the API server are denied when the elapsedtime exceeds 90 days. You should proactively update your applications' Kubernetes client SDK to use one of the version listed previously that automatically refresh the token. If the service account token used is close to 90 days and you don't have sufficient time to update your client SDK versions before token expiration, then you can terminate existing pods and create new ones. This results in refetching of the service account token, giving you an additional 90 days to update your client version SDKs.

If the pod is part of a deployment, the suggested way to terminate pods while keeping high availability is to perform a roll out with the following command. Replace `my-deployment` with the name of your deployment.

```
kubectl rollout restart deployment/my-deployment
```

### Cluster add-ons

The following cluster add-ons have been updated to use the Kubernetes client SDKs that automatically refetch service account tokens. We recommend making sure that the listed versions, or later versions, are installed on your 1.21 or later cluster.

• Amazon VPC CNI and CNI metrics helper plugins version 1.8.0 and later. To check your current version or update it, see Managing the Amazon VPC CNI plugin for Kubernetes (p. 247) and Metrics helper (p. 303).
IAM roles for service accounts

Applications in a pod's containers can use an AWS SDK or the AWS CLI to make API requests to AWS services using AWS Identity and Access Management (IAM) permissions. Applications must sign their AWS API requests with AWS credentials. IAM roles for service accounts provide the ability to manage credentials for your applications, similar to the way that Amazon EC2 instance profiles provide credentials to Amazon EC2 instances. Instead of creating and distributing your AWS credentials to the containers or using the Amazon EC2 instance's role, you associate an IAM role with a Kubernetes service account and configure your pods to use the service account. You can't use IAM roles for service accounts with local clusters for Amazon EKS on AWS Outposts (p. 549).

IAM roles for service accounts provide the following benefits:

- **Least privilege** – You can scope IAM permissions to a service account, and only pods that use that service account have access to those permissions. This feature also eliminates the need for third-party solutions such as kiam or kube2iam.
- **Credential isolation** – A pod's containers can only retrieve credentials for the IAM role that's associated with the service account that the container uses. A container never has access to credentials that are used by other containers in other pods. When using IAM roles for service accounts, the pod's containers also have the permissions assigned to the Amazon EKS node IAM role (p. 461), unless you block pod access to the Amazon EC2 Instance Metadata Service (IMDS). For more information, see Restrict access to the instance profile assigned to the worker node.
- **Auditability** – Access and event logging is available through AWS CloudTrail to help ensure retrospective auditing.

Enable IAM roles for service accounts by completing the following procedures:

1. the section called “Creating an IAM OIDC provider” (p. 426) – You only complete this procedure once for each cluster.
2. the section called “Configuring AWS STS endpoint” (p. 434) – Complete this procedure for each unique set of permissions that you want an application to have.
3. the section called “Configuring pods” (p. 432) – Complete this procedure for each pod that needs access to AWS services.

IAM, Kubernetes, and OpenID Connect (OIDC) background information

In 2014, AWS Identity and Access Management added support for federated identities using OpenID Connect (OIDC). This feature allows you to authenticate AWS API calls with supported identity providers and receive a valid OIDC JSON web token (JWT). You can pass this token to the AWS STS AssumeRoleWithWebIdentity API operation and receive IAM temporary role credentials. You can use these credentials to interact with any AWS service, including Amazon S3 and DynamoDB.

Kubernetes has long used service accounts as its own internal identity system. Pods can authenticate with the Kubernetes API server using an auto-mounted token (which was a non-OIDC JWT) that
only the Kubernetes API server could validate. These legacy service account tokens don't expire, and
rotating the signing key is a difficult process. In Kubernetes version 1.12, support was added for a new
ProjectedServiceAccountToken feature. This feature is an OIDC JSON web token that also contains
the service account identity and supports a configurable audience.

Amazon EKS hosts a public OIDC discovery endpoint for each cluster that contains the signing keys for
the ProjectedServiceAccountToken JSON web tokens so external systems, such as IAM, can validate
and accept the OIDC tokens that are issued by Kubernetes.

Creating an IAM OIDC provider for your cluster

Your cluster has an OpenID Connect (OIDC) issuer URL associated with it. To use AWS Identity and Access
Management (IAM) roles for service accounts, an IAM OIDC provider must exist for your cluster.

Prerequisites

• An existing Amazon EKS cluster. To deploy one, see Getting started with Amazon EKS (p. 4).
• Version 2.7.32 or later or 1.25.72 or later of the AWS CLI installed and configured on your device
or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and
Quick configuration with aws configure in the AWS Command Line Interface User Guide.
• The kubectl command line tool is installed on your device or AWS CloudShell. The version can be
the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For
example, if your cluster version is 1.22, you can use kubectl version 1.21, 1.22, or 1.23 with it. To
install or upgrade kubectl, see Installing or updating kubectl (p. 4).
• An existing kubectl config file that contains your cluster configuration. To create a kubectl
config file, see Create a kubeconfig for Amazon EKS (p. 392).

You can create an OIDC provider for your cluster using eksctl or the AWS Management Console.

eksctl

Prerequisite

Version 0.112.0 or later of the eksctl command line tool installed on your device or AWS
CloudShell. To install or update eksctl, see Installing or updating eksctl (p. 10).

To create an IAM OIDC identity provider for your cluster with eksctl

1. Determine whether you have an existing IAM OIDC provider for your cluster.
   Retrieve your cluster's OIDC provider ID and store it in a variable.

   oidc_id=$(aws eks describe-cluster --name my-cluster --query
   "cluster.identity.oidc.issuer" --output text | cut -d '/' -f 5)

2. Determine whether an IAM OIDC provider with your cluster's ID is already in your account.

   aws iam list-open-id-connect-providers | grep $oidc_id

   If output is returned from the previous command, then you already have a provider for your
   cluster and you can skip the next step. If no output is returned, then you must create an IAM
   OIDC provider for your cluster.

3. Create an IAM OIDC identity provider for your cluster with the following command. Replace my-
   cluster with your own value.

   eksctl utils associate-iam-oidc-provider --cluster my-cluster --approve
AWS Management Console

To create an IAM OIDC identity provider for your cluster with the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left pane, select Clusters, and then select the name of your cluster on the Clusters page.
3. In the Details section on the Overview tab, note the value of the OpenID Connect provider URL.
5. In the left navigation pane, choose Identity Providers under Access management. If a Provider is listed that matches the URL for your cluster, then you already have a provider for your cluster. If a provider isn’t listed that matches the URL for your cluster, then you must create one.
6. To create a provider, choose Add provider.
7. For Provider type, select OpenID Connect.
8. For Provider URL, enter the OIDC provider URL for your cluster, and then choose Get thumbprint.
9. For Audience, enter sts.amazonaws.com and choose Add provider.

Next step

the section called “Configuring role and service account” (p. 427)

Configuring a Kubernetes service account to assume an IAM role

This topic covers how to configure a Kubernetes service account to assume an AWS Identity and Access Management (IAM) role. Any pods that are configured to use the service account can then access any AWS service that the role has permissions to access.

Prerequisites

• An existing cluster. If you don't have one, you can create one by following one of the Getting started with Amazon EKS (p. 4) guides.
• An existing IAM OpenID Connect (OIDC) provider for your cluster. To learn if you already have one or how to create one, see Creating an IAM OIDC provider for your cluster (p. 426).
• Version 2.7.32 or later or 1.25.72 or later of the AWS CLI installed and configured on your device or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with aws configure in the AWS Command Line Interface User Guide.
• The kubectl command line tool is installed on your device or AWS CloudShell. The version can be the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For example, if your cluster version is 1.22, you can use kubectl version 1.21.1, 1.22, or 1.23 with it. To install or upgrade kubectl, see Installing or updating kubectl (p. 4).
• An existing kubectl config file that contains your cluster configuration. To create a kubectl config file, see Create a kubeconfig for Amazon EKS (p. 392).

To associate an IAM role with a Kubernetes service account

1. If you want to associate an existing IAM policy to your IAM role, skip to the next step (p. 428).

Create an IAM policy. You can create your own policy, or copy an AWS managed policy that already grants some of the permissions that you need and customize it to your specific requirements. For more information, see Creating IAM policies in the IAM User Guide.
a. Create a file that includes the permissions for the AWS services that you want your pods to access. For a list of all actions for all AWS services, see the Service Authorization Reference.

You can run the following command to create an example policy file that allows read-only access to an Amazon S3 bucket. You can optionally store configuration information or a bootstrap script in this bucket, and the containers in your pod can read the file from the bucket and load it into your application. If you want to create this example policy, copy the following contents to your device. Replace `my-pod-secrets-bucket` with your bucket name and run the command.

```
cat > my-policy.json <<EOF
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3:GetObject",
            "Resource": "arn:aws:s3:::my-pod-secrets-bucket"
        }
    ]
}
EOF
```

b. Create the IAM policy.

```
aws iam create-policy --policy-name my-policy --policy-document file://my-policy.json
```

2. Create an IAM role and associate it with a Kubernetes service account. You can use either `eksctl` or the AWS CLI.

`eksctl`

**Prerequisite**

Version 0.112.0 or later of the `eksctl` command line tool installed on your device or AWS CloudShell. To install or update `eksctl`, see Installing or updating `eksctl` (p. 10).

Replace `my-service-account` with the name of the Kubernetes service account that you want `eksctl` to create and associate with an IAM role. Replace `default` with the namespace that you want `eksctl` to create the service account in. Replace `my-cluster` with the name of your cluster. Replace `my-role` with the name of the role that you want to associate the service account to. If it doesn't already exist, `eksctl` creates it for you. Replace `111122223333` with your account ID and `my-policy` with the name of an existing policy.

```
eksctl create iamserviceaccount --name my-service-account --namespace default --cluster my-cluster --role-name "my-role" \
   --attach-policy-arn arn:aws:iam::111122223333:policy/my-policy --approve
```

**Important**

- If the role or service account already exist, the previous command might fail. `eksctl` has different options that you can provide in those situations. For more information run `eksctl create iamserviceaccount --help`.
- Before using the service account with a pod (p. 432), the service account that you specified or that `eksctl` created must be bound to an existing Kubernetes role, or clusterrole that includes the Kubernetes permissions that you require for
IAM roles for service accounts

the service account. For more information, see Using RBAC Authorization in the Kubernetes documentation.

AWS CLI

1. If you have an existing Kubernetes service account that you want to assume an IAM role, then you can skip this step.

Create a Kubernetes service account. Copy the following contents to your device. Replace `my-service-account` with your desired name and `default` with a different namespace, if necessary. If you change `default`, the namespace must already exist.

```
cat >my-service-account.yaml <<EOF
apiVersion: v1
kind: ServiceAccount
metadata:
  name: my-service-account
  namespace: default
EOF
kubectl apply -f my-service-account.yaml
```

Important
Before using the service account with a pod (p. 432), the service account that you created must be bound to an existing Kubernetes role, or clusterrole that includes the Kubernetes permissions that you require for the service account. For more information, see Using RBAC Authorization in the Kubernetes documentation.

2. Set your AWS account ID to an environment variable with the following command.

```
account_id=$(aws sts get-caller-identity --query "Account" --output text)
```

3. Set your cluster's OIDC identity provider to an environment variable with the following command. Replace `my-cluster` with the name of your cluster.

```
oidc_provider=$(aws eks describe-cluster --name my-cluster --region $AWS_REGION --query "cluster.identity.oidc.issuer" --output text | sed -e "s/^https:////")
```

4. Set variables for the namespace and name of the service account. Replace `my-service-account` with the Kubernetes service account that you want to assume the role. Replace `default` with the namespace of the service account.

```
export namespace=default
export service_account=my-service-account
```

5. Run the following command to create a trust policy file for the IAM role. If you want to allow all service accounts within a namespace to use the role, then copy the following contents to your device. Replace `StringEquals` with `StringLike` and replace `$service_account` with `*`. You can add multiple entries in the `StringEquals` or `StringLike` conditions to allow multiple service accounts or namespaces to assume the role. To allow roles from a different AWS account than the account that your cluster is in to assume the role, see the section called “Cross-account IAM permissions” (p. 437) for more information.

```
cat >trust-relationship.json <<EOF
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

429
IAM roles for service accounts

6. Create the role. Replace `my-role` with a name for your IAM role, and `my-role-description` with a description for your role.

   ```bash
   aws iam create-role --role-name my-role --assume-role-policy-document file://trust-relationship.json --description "my-role-description"
   ```

7. Attach an IAM policy to your role. Replace `my-role` with the name of your IAM role and `my-policy` with the name of an existing policy that you created.

   ```bash
   aws iam attach-role-policy --role-name my-role --policy-arn=arn:aws:iam::$account_id:policy/my-policy
   ```

8. Annotate your service account with the Amazon Resource Name (ARN) of the IAM role that you want the service account to assume. Replace `my-role` with the name of your existing IAM role. Suppose that you allowed a role from a different AWS account than the account that your cluster is in to assume the role in a previous step. Then, make sure to specify the AWS account and role from the other account. For more information, see the section called “Cross-account IAM permissions” (p. 437).

   ```bash
   kubectl annotate serviceaccount -n $namespace $service_account eks.amazonaws.com/role-arn=arn:aws:iam::$account_id:role/my-role
   ```

3. Confirm that the role and service account are configured correctly.
   a. Confirm that the IAM role's trust policy is configured correctly.

   ```bash
   aws iam get-role --role-name my-role --query Role.AssumeRolePolicyDocument
   ```

   The example output is as follows.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "Action": "sts:AssumeRoleWithWebIdentity",
           "Condition": {
             "StringEquals": {
               "$oidc_provider:aud": "sts.amazonaws.com",
               "$oidc_provider:sub": "system:serviceaccount:$namespace:$service_account"
             }
           }
         }
       }
     ]
   }
   ```
b. Confirm that the policy that you attached to your role in a previous step is attached to the role.

```bash
aws iam list-attached-role-policies --role-name my-role --query AttachedPolicies[].PolicyArn --output text
```

The example output is as follows.

```
arn:aws:iam::111122223333:policy/my-policy
```

c. Set a variable to store the Amazon Resource Name (ARN) of the policy that you want to use. Replace `my-policy` with the name of the policy that you want to confirm permissions for.

```bash
export policy_arn=arn:aws:iam::111122223333:policy/my-policy
```

d. View the default version of the policy.

```bash
aws iam get-policy --policy-arn $policy_arn
```

The example output is as follows.

```
{
  "Policy": {
    "PolicyName": "my-policy",
    "PolicyId": "EXAMPLEBIOWGLDEXAMPLE",
    "Arn": "arn:aws:iam::111122223333:policy/my-policy",
    "Path": "/",
    "DefaultVersionId": "v1",
    ...
  }
}
```

e. View the policy contents to make sure that the policy includes all the permissions that your pod needs. If necessary, replace `v1` in the following command with the version that’s returned in the previous output.

```bash
aws iam get-policy-version --policy-arn $policy_arn --version-id v1
```

The example output is as follows.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:GetObject",
      "Resource": "arn:aws:s3:::my-pod-secrets-bucket"
    }
  ]
}
```
If you created the example policy in a previous step, then your output is the same. If you created a different policy, then the example content is different.

f. Confirm that the Kubernetes service account is annotated with the role.

```sh
table kubectl describe serviceaccount my-service-account -n default
```

The example output is as follows.

<table>
<thead>
<tr>
<th>Name</th>
<th>my-service-account</th>
</tr>
</thead>
<tbody>
<tr>
<td>Namespace</td>
<td>default</td>
</tr>
<tr>
<td>Annotations</td>
<td>eks.amazonaws.com/role-arn: arn:aws:iam::111122223333:role/my-role</td>
</tr>
<tr>
<td>Image pull secrets</td>
<td>&lt;none&gt;</td>
</tr>
<tr>
<td>Mountable secrets</td>
<td>my-service-account-token-qqjfl</td>
</tr>
<tr>
<td>Tokens</td>
<td>my-service-account-token-qqjfl</td>
</tr>
</tbody>
</table>

4. (Optional) the section called “Configuring AWS STS endpoint” (p. 434). AWS recommends using a regional AWS STS endpoint instead of the global endpoint. This reduces latency, provides built-in redundancy, and increases session token validity.

Next step

the section called “Configuring pods” (p. 432)

Configuring pods to use a Kubernetes service account

If a pod needs to access AWS services, then you must configure it to use a Kubernetes service account. The service account must be associated to an AWS Identity and Access Management (IAM) role that has permissions to access the AWS services.

Prerequisites

- An existing cluster. If you don't have one, you can create one using one of the Getting started with Amazon EKS (p. 4) guides.
- An existing IAM OpenID Connect (OIDC) provider for your cluster. To learn if you already have one or how to create one, see Creating an IAM OIDC provider for your cluster (p. 426).
- An existing Kubernetes service account that's associated with an IAM role. The service account must be annotated with the Amazon Resource Name (ARN) of the IAM role. The role must have an associated IAM policy that contains the permissions that you want your pods to have to use AWS services. For more information about how to create the service account and role, and configure them, see the section called “Configuring role and service account” (p. 427).
- Version 2.7.32 or later or 1.25.72 or later of the AWS CLI installed and configured on your device or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with aws configure in the AWS Command Line Interface User Guide.
- The `kubectl` command line tool is installed on your device or AWS CloudShell. The version can be the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For example, if your cluster version is 1.22, you can use kubectl version 1.21,1.22, or 1.23 with it. To install or upgrade kubectl, see Installing or updating kubectl (p. 4).
- An existing `kubectl` config file that contains your cluster configuration. To create a `kubectl` config file, see Create a kubeconfig for Amazon EKS (p. 392).
To configure a pod to use a service account

1. Use the following command to create a deployment manifest that you can deploy a pod to confirm configuration with. The pod uses an existing Kubernetes service account. The service account must be properly configured. For more information, see the section called “Configuring role and service account” (p. 427). Replace the example values with your own values.

```yaml
cat >my-deployment.yaml <<EOF
apiVersion: apps/v1
kind: Deployment
metadata:
  name: my-app
spec:
  selector:
    matchLabels:
      app: my-app
  template:
    metadata:
      labels:
        app: my-app
    spec:
      serviceAccountName: my-service-account
      containers:
      - name: my-app
        image: public.ecr.aws/nginx/nginx:1.21
EOF
```

2. Deploy the manifest to your cluster.

   ```bash
kubectl apply -f my-deployment.yaml
   ```

3. Confirm that the required environment variables exist for your pod.
   a. View the pods that were deployed with the deployment in the previous step.

   ```bash
   kubectl get pods | grep my-app
   ```
   The example output is as follows.

   ```
   my-app-6f4dfff6cb-76cv9 1/1 Running 0 3m28s
   ```

   b. View the ARN of the IAM role that the pod is using.

   ```bash
   kubectl describe pod my-app-6f4dfff6cb-76cv9 | grep AWS_ROLE_ARN:
   ```
   The example output is as follows.

   ```
   AWS_ROLE_ARN: arn:aws:iam::111122223333:role/my-role
   ```
   The role ARN must match the role ARN that you annotated the existing service account with. For more about annotating the service account, see the section called “Configuring role and service account” (p. 427).

   c. Confirm that the pod has a web identity token file mount.

   ```bash
   kubectl describe pod my-app-6f4dfff6cb-76cv9 | grep AWS_WEB_IDENTITY_TOKEN_FILE:
   ```
   The example output is as follows.
IAM roles for service accounts

The kubelet requests and stores the token on behalf of the pod. By default, the kubelet refreshes the token if the token is older than 80 percent of its total time to live or older than 24 hours. You can modify the expiration duration for any account other than the default service account by using the settings in your pod spec. For more information, see Service Account Token Volume Projection in the Kubernetes documentation.

The Amazon EKS Pod Identity Webhook on the cluster watches for pods that use a service account with the following annotation:

```bash
eks.amazonaws.com/role-arn: arn:aws:iam::111122223333:role/my-role
```

The webhook applies the previous environment variables to those pods. Your cluster doesn't need to use the webhook to configure the environment variables and token file mounts. You can manually configure pods to have these environment variables. The supported versions of the AWS SDK look for these environment variables first in the credential chain provider. The role credentials are used for pods that meet this criteria.

4. Confirm that your pods can interact with the AWS services using the permissions that you assigned in the IAM policy attached to your role.

   **Note**
   When a pod uses AWS credentials from an IAM role that's associated with a service account, the AWS CLI or other SDKs in the containers for that pod use the credentials that are provided by that role. If you don't restrict access to the credentials that are provided to the Amazon EKS node IAM role (p. 461), the pod still has access to these credentials. For more information, see Restrict access to the instance profile assigned to the worker node.

If your pods can't interact with the services as you expected, complete the following steps to confirm that everything is properly configured.

a. Confirm that your pods use an AWS SDK version that supports assuming an IAM role through an OpenID Connect web identity token file. For more information, see the section called “Supported SDKs” (p. 438).

b. Confirm that the deployment is using the service account.

   ```bash
ekubectl describe deployment my-app | grep "Service Account"
```

   The example output is as follows.

   ```bash
   Service Account:  my-service-account
   ```

c. If your pods still can't access services, review the steps (p. 430) that are described in the section called “Configuring role and service account” (p. 427) to confirm that your role and service account are configured properly.

### Configuring the AWS Security Token Service endpoint for a service account

If you're using a Kubernetes service account with IAM roles for service accounts (p. 425), then you can configure the type of AWS Security Token Service endpoint that's used by the service account if your cluster and platform version are the same or later than those listed in the following table. If your
Kubernetes or platform version are earlier than those listed in the table, then your service accounts can only use the global endpoint.

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Platform version</th>
<th>Default endpoint type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.23</td>
<td>eks.1</td>
<td>Regional</td>
</tr>
<tr>
<td>1.22</td>
<td>eks.1</td>
<td>Regional</td>
</tr>
<tr>
<td>1.21</td>
<td>eks.3</td>
<td>Global</td>
</tr>
<tr>
<td>1.20</td>
<td>eks.3</td>
<td>Global</td>
</tr>
<tr>
<td>1.19</td>
<td>eks.7</td>
<td>Global</td>
</tr>
</tbody>
</table>

AWS recommends using the regional AWS STS endpoints instead of the global endpoint. This reduces latency, provides built-in redundancy, and increases session token validity. The AWS Security Token Service must be active in the AWS Region where the pod is running. Moreover, your application must have built-in redundancy for a different AWS Region in the event of a failure of the service in the AWS Region. For more information, see Managing AWS STS in an AWS Region in the IAM User Guide.

**Prerequisites**

- An existing cluster. If you don't have one, you can create one using one of the Getting started with Amazon EKS (p. 4) guides.
- An existing IAM OIDC provider for your cluster. For more information, see Creating an IAM OIDC provider for your cluster (p. 426).
- An existing Kubernetes service account configured for use with the Amazon EKS IAM for service accounts (p. 425) feature.

**To configure the endpoint type used by a Kubernetes service account**

The following examples all use the `aws-node` Kubernetes service account used by the Amazon VPC CNI plugin (p. 258). You can replace the example values with your own service accounts, pods, namespaces, and other resources.

1. Select a pod that uses a service account that you want to change the endpoint for. Determine which AWS Region that the pod runs in. Replace `aws-node-6mfgv` with your pod name and `kube-system` with your pod's namespace.

   ```
   kubectl describe pod aws-node-6mfgv -n kube-system | grep Node:
   ```

   The example output is as follows.

   ```
   ip-192-168-79-166.us-west-2/192.168.79.166
   ```

   In the previous output, the pod is running on a node in the us-west-2 AWS Region.

2. Determine the endpoint type that the pod's service account is using.

   ```
   kubectl describe pod aws-node-6mfgv -n kube-system | grep AWS_STS_REGIONAL_ENDPOINTS
   ```

   The example output is as follows.
**AWS_STS_REGIONAL_ENDPOINTS**: `regional`

If the current endpoint is global, then `global` is returned in the output. If no output is returned, then the default endpoint type is in use and has not been overridden.

3. If your cluster or platform version are the same or later than those listed in the table, then you can change the endpoint type used by your service account from the default type to a different type with one of the following commands. Replace `aws-node` with the name of your service account and `kube-system` with the namespace for your service account.

   • If your default or current endpoint type is global and you want to change it to regional:

   ```
kubectl annotate serviceaccount -n kube-system aws-node eks.amazonaws.com/sts-regional-endpoints=true
   ```

   If you are using IAM roles for service accounts (p. 425) to generate pre-signed S3 URLs in your application running in pods' containers, the format of the URL for regional endpoints is similar to the following example:

   ```
https://bucket.s3.us-west-2.amazonaws.com/path?...&X-Amz-Credential=your-access-key-id/date/us-west-2/s3/aws4_request&...
   ```

   • If your default or current endpoint type is regional and you want to change it to global:

   ```
kubectl annotate serviceaccount -n kube-system aws-node eks.amazonaws.com/sts-regional-endpoints=false
   ```

   If your application is explicitly making requests to AWS STS global endpoints and you don't override the default behavior of using regional endpoints in Amazon EKS 1.22 and later clusters, then requests fail with an error. For more information, see Pod containers receive the following error: An error occurred (SignatureDoesNotMatch) when calling the GetCallerIdentity operation: Credential should be scoped to a valid region. (p. 533).

   If you're using IAM roles for service accounts (p. 425) to generate pre-signed S3 URLs in your application running in pods' containers, the format of the URL for global endpoints is similar to the following example:

   ```
https://bucket.s3.amazonaws.com/path?...&X-Amz-Credential=your-access-key-id/date/us-west-2/s3/aws4_request&...
   ```

   If you have automation that expects the pre-signed URL in a certain format or if your application or downstream dependencies that use pre-signed URLs have expectations for the AWS Region targeted, then make the necessary changes to use the appropriate AWS STS endpoint.

4. Delete and re-create any existing pods that are associated with the service account to apply the credential environment variables. The mutating web hook doesn't apply them to pods that are already running. You can replace `pods`, `kube-system`, and `-l k8s-app=aws-node` with the information for the pods that you set your annotation for.

   ```
kubectl delete pods -n kube-system -l k8s-app=aws-node
   ```

5. Confirm that the all pods restarted.
6. View the environment variables for one of the pods. Verify that the
AWS_STS_REGIONAL_ENDPOINTS value is what you set it to in a previous step.

```bash
kubectl describe pod aws-node-kzbtr -n kube-system | grep AWS_STS_REGIONAL_ENDPOINTS
```

The example output is as follows.

```text
AWS_STS_REGIONAL_ENDPOINTS=regional
```

## Cross-account IAM permissions

You can configure cross-account IAM permissions either by creating an identity provider from another account's cluster or by using chained `AssumeRole` operations. In the following examples, *Account A* owns an Amazon EKS cluster that supports IAM roles for service accounts. Pods that are running on that cluster must assume IAM permissions from *Account B*.

### Example Create an identity provider from another account's cluster

**Example**

In this example, *Account A* provides *Account B* with the OpenID Connect (OIDC) issuer URL from their cluster. *Account B* follows the instructions in [Creating an IAM OIDC provider for your cluster](p. 426) and [Configuring a Kubernetes service account to assume an IAM role](p. 427) using the OIDC issuer URL from *Account A*'s cluster. Then, a cluster administrator annotates the service account in *Account A*'s cluster to use the role from *Account B*.

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  annotations:
    eks.amazonaws.com/role-arn: arn:aws:iam::444455556666:role/account-b-role
```

### Example Use chained `AssumeRole` operations

**Example**

In this example, *Account B* creates an IAM policy with the permissions to give to pods in *Account A*'s cluster. *Account B* attaches that policy to an IAM role with a trust relationship that allows `AssumeRole` permissions to *Account A*.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111122223333:root"
      },
      "Action": "sts:AssumeRole",
      "Condition": {}
    }
  ]
}
```
Account A creates a role with a trust policy that gets credentials from the identity provider created with the cluster's OIDC issuer address.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
      },
      "Action": "sts:AssumeRoleWithWebIdentity"
    }
  ]
}
```

Account A attaches a policy to that role with the following permissions to assume the role that Account B created.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Resource": "arn:aws:iam::444455556666:role/account-b-role"
    }
  ]
}
```

The application code for pods to assume Account B's role uses two profiles: account_b_role and account_a_role. The account_b_role profile uses the account_a_role profile as its source. For the AWS CLI, the ~/.aws/config file is similar to the following.

```
[profile account_b_role]
source_profile = account_a_role
role_arn=arn:aws:iam::44455556666:role/account-b-role

[profile account_a_role]
web_identity_token_file = /var/run/secrets/eks.amazonaws.com/serviceaccount/token
role_arn=arn:aws:iam::111122223333:role/account-a-role
```

To specify chained profiles for other AWS SDKs, consult the documentation for the SDK that you're using. For more information, see Tools to Build on AWS.

**Using a supported AWS SDK**

The containers in your pods must use an AWS SDK version that supports assuming an IAM role through an OpenID Connect web identity token file. AWS SDKs that are included in Linux distribution package managers might not be new enough to support this feature. Be sure to use the following versions, or later, for your SDK:

- Java (Version 2) – 2.10.11
- Java – 1.11.704
- Go – 1.23.13
- Python (Boto3) – 1.9.220
Many popular Kubernetes add-ons, such as the Cluster Autoscaler and the Installing the AWS Load Balancer Controller add-on (p. 308), support IAM roles for service accounts. The Amazon VPC CNI plugin for Kubernetes also supports IAM roles for service accounts.

To ensure that you're using a supported SDK, follow the installation instructions for your preferred SDK at Tools to Build on AWS when you build your containers.

Identity and access management for Amazon EKS

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Amazon EKS resources. IAM is an AWS service that you can use with no additional charge.

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in Amazon EKS.

Service user – If you use the Amazon EKS service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Amazon EKS features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon EKS, see Troubleshooting Amazon EKS identity and access (p. 492).

Service administrator – If you’re in charge of Amazon EKS resources at your company, you probably have full access to Amazon EKS. It’s your job to determine which Amazon EKS features and resources your service users should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Amazon EKS, see How Amazon EKS works with IAM (p. 443).

IAM administrator – If you’re an IAM administrator, you might want to learn details about how you can write policies to manage access to Amazon EKS. To view example Amazon EKS identity-based policies that you can use in IAM, see Amazon EKS identity-based policy examples (p. 446).

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. For more information about signing in using the AWS Management Console, see Signing in to the AWS Management Console as an IAM user or root user in the IAM User Guide.

You must be authenticated (signed in to AWS) as the AWS account root user, an IAM user, or by assuming an IAM role. You can also use your company's single sign-on authentication or even sign in using Google
or Facebook. In these cases, your administrator previously set up identity federation using IAM roles. When you access AWS using credentials from another company, you are assuming a role indirectly.

To sign in directly to the AWS Management Console, use your password with your root user email address or your IAM user name. You can access AWS programmatically using your root user or IAM users access keys. AWS provides SDK and command line tools to cryptographically sign your request using your credentials. If you don't use AWS tools, you must sign the request yourself. Do this using Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 signing process in the AWS General Reference.

Regardless of the authentication method that you use, you might also be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you do not use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the AWS General Reference.

IAM users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the IAM User Guide.

An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for
Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

Every IAM entity (user or role) starts with no permissions. By default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach

To learn whether to use IAM roles or IAM users, see When to create an IAM role (instead of a user) in the IAM User Guide.

Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

Every IAM entity (user or role) starts with no permissions. By default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach
Managing access using policies

a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

**Identity-based policies**

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the *IAM User Guide*.

Identity-based policies can be further categorized as inline policies or managed policies. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the *IAM User Guide*.

**Resource-based policies**

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can’t use AWS managed policies from IAM in a resource-based policy.

**Access control lists (ACLs)**

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the *Amazon Simple Storage Service Developer Guide*.

**Other policy types**

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity’s identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the *IAM User Guide*.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for
grouping and centrally managing multiple AWS accounts that your business owns. If you enable all
features in an organization, then you can apply service control policies (SCPs) to any or all of your
accounts. The SCP limits permissions for entities in member accounts, including each AWS account
root user. For more information about Organizations and SCPs, see How SCPs work in the AWS
Organizations User Guide.

• **Session policies** – Session policies are advanced policies that you pass as a parameter when you
programmatically create a temporary session for a role or federated user. The resulting session's
permissions are the intersection of the user or role's identity-based policies and the session policies.
Permissions can also come from a resource-based policy. An explicit deny in any of these policies
overrides the allow. For more information, see Session policies in the IAM User Guide.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to
understand. To learn how AWS determines whether to allow a request when multiple policy types are
involved, see Policy evaluation logic in the IAM User Guide.

How Amazon EKS works with IAM

Before you use IAM to manage access to Amazon EKS, you should understand what IAM features are
available to use with Amazon EKS. To get a high-level view of how Amazon EKS and other AWS services
work with IAM, see AWS services that work with IAM in the IAM User Guide.

Topics

• Amazon EKS identity-based policies (p. 443)
• Amazon EKS resource-based policies (p. 445)
• Authorization based on Amazon EKS tags (p. 445)
• Amazon EKS IAM roles (p. 445)

Amazon EKS identity-based policies

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the
conditions under which actions are allowed or denied. Amazon EKS supports specific actions, resources,
and condition keys. To learn about all of the elements that you use in a JSON policy, see IAM JSON policy
elements reference in the IAM User Guide.

Actions

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can
perform actions on what resources, and under what conditions.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a
policy. Policy actions usually have the same name as the associated AWS API operation. There are some
exceptions, such as permission-only actions that don't have a matching API operation. There are also
some operations that require multiple actions in a policy. These additional actions are called dependent
actions.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Amazon EKS use the following prefix before the action: eks:. For example, to
grant someone permission to get descriptive information about an Amazon EKS cluster, you include
the DescribeCluster action in their policy. Policy statements must include either an Action or
NotAction element.
To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": ["eks:action1", "eks:action2"]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action:

```
"Action": "eks:Describe*
```

To see a list of Amazon EKS actions, see Actions Defined by Amazon Elastic Kubernetes Service in the Service Authorization Reference.

**Resources**

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as resource-level permissions.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*
```

The Amazon EKS cluster resource has the following ARN.

```
arn:aws:eks:region-code:account-id:cluster/cluster-name
```

For more information about the format of ARNs, see Amazon resource names (ARNs) and AWS service namespaces.

For example, to specify the cluster with the name my-cluster in your statement, use the following ARN:

```
```

To specify all clusters that belong to a specific account and AWS Region, use the wildcard (*):

```
```

Some Amazon EKS actions, such as those for creating resources, can't be performed on a specific resource. In those cases, you must use the wildcard (*).

```
"Resource": "*
```

To see a list of Amazon EKS resource types and their ARNs, see Resources Defined by Amazon Elastic Kubernetes Service in the Service Authorization Reference. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon Elastic Kubernetes Service.
Condition keys

Amazon EKS defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS Global Condition Context Keys in the IAM User Guide.

You can set condition keys when associating an OpenID Connect provider to your cluster. For more information, see Example IAM policy (p. 391).

All Amazon EC2 actions support the aws:RequestedRegion and ec2:Region condition keys. For more information, see Example: Restricting Access to a Specific AWS Region.

For a list of Amazon EKS condition keys, see Condition Keys for Amazon Elastic Kubernetes Service in the Service Authorization Reference. To learn which actions and resources you can use a condition key with, see Actions Defined by Amazon Elastic Kubernetes Service.

Examples

To view examples of Amazon EKS identity-based policies, see Amazon EKS identity-based policy examples (p. 446).

When you create an Amazon EKS cluster, the AWS Identity and Access Management (IAM) entity user or role, such as a federated user that creates the cluster, is automatically granted system:masters permissions in the cluster's role-based access control (RBAC) configuration in the Amazon EKS control plane. This IAM entity doesn't appear in any visible configuration, so make sure to keep track of which IAM entity originally created the cluster. To grant additional AWS users or roles the ability to interact with your cluster, you must edit the aws-auth ConfigMap within Kubernetes and create a Kubernetes rolebinding or clusterrolebinding with the name of a group that you specify in the aws-auth ConfigMap.

For more information about working with the ConfigMap, see Enabling IAM user and role access to your cluster (p. 381).

Amazon EKS resource-based policies

Amazon EKS does not support resource-based policies.

Authorization based on Amazon EKS tags

You can attach tags to Amazon EKS resources or pass tags in a request to Amazon EKS. To control access based on tags, you provide tag information in the condition element of a policy using the aws:ResourceTag/key-name, aws:RequestTag/key-name, or aws:TagKeys condition keys. For more information about tagging Amazon EKS resources, see Tagging your Amazon EKS resources (p. 412). For more information about which actions that you can use tags in condition keys with, see Actions defined by Amazon EKS in the Service Authorization Reference.

Amazon EKS IAM roles

An IAM role is an entity within your AWS account that has specific permissions.

Using temporary credentials with Amazon EKS

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling AWS STS API operations such as AssumeRole or GetFederationToken.

Amazon EKS supports using temporary credentials.
Service-linked roles

Service-linked roles allow AWS services to access resources in other services to complete an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view but not edit the permissions for service-linked roles.

Amazon EKS supports service-linked roles. For details about creating or managing Amazon EKS service-linked roles, see Using service-linked roles for Amazon EKS (p. 451).

Service roles

This feature allows a service to assume a service role on your behalf. This role allows the service to access resources in other services to complete an action on your behalf. Service roles appear in your IAM account and are owned by the account. This means that an IAM administrator can change the permissions for this role. However, doing so might break the functionality of the service.

Amazon EKS supports service roles. For more information, see Amazon EKS cluster IAM role (p. 460) and Amazon EKS node IAM role (p. 461).

Choosing an IAM role in Amazon EKS

When you create a cluster resource in Amazon EKS, you must choose a role to allow Amazon EKS to access several other AWS resources on your behalf. If you have previously created a service role, then Amazon EKS provides you with a list of roles to choose from. It's important to choose a role that has the Amazon EKS managed policies attached to it. For more information, see Check for an existing cluster role (p. 460) and Check for an existing node role (p. 462).

Amazon EKS identity-based policy examples

By default, IAM users and roles don't have permission to create or modify Amazon EKS resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating policies on the JSON tab in the IAM User Guide.

When you create an Amazon EKS cluster, the AWS Identity and Access Management (IAM) entity user or role, such as a federated user that creates the cluster, is automatically granted system:masters permissions in the cluster's role-based access control (RBAC) configuration in the Amazon EKS control plane. This IAM entity doesn't appear in any visible configuration, so make sure to keep track of which IAM entity originally created the cluster. To grant additional AWS users or roles the ability to interact with your cluster, you must edit the aws-auth ConfigMap within Kubernetes and create a Kubernetes rolebinding or clusterrolebinding with the name of a group that you specify in the aws-auth ConfigMap.

For more information about working with the ConfigMap, see Enabling IAM user and role access to your cluster (p. 381).

- Using the Amazon EKS console (p. 447)
- Allow users to view their own permissions (p. 448)
- Create a Kubernetes cluster on the AWS Cloud (p. 449)
- Create a local Kubernetes cluster on an Outpost (p. 449)
Identity-based policy examples

• Update a Kubernetes cluster (p. 450)
• List or describe all clusters (p. 450)

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon EKS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

• Get started with AWS managed policies and move toward least-privilege permissions – To get started granting permissions to your users and workloads, use the AWS managed policies that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see AWS managed policies or AWS managed policies for job functions in the IAM User Guide.

• Apply least-privilege permissions – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as least-privilege permissions. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the IAM User Guide.

• Use conditions in IAM policies to further restrict access – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

• Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see IAM Access Analyzer policy validation in the IAM User Guide.

• Require multi-factor authentication (MFA) – If you have a scenario that requires IAM users or root users in your account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Configuring MFA-protected API access in the IAM User Guide.

For more information about best practices in IAM, see Security best practices in IAM in the IAM User Guide.

Using the Amazon EKS console

To access the Amazon EKS console, an IAM entity, such as a user or role, must have a minimum set of permissions. These permissions allow the entity to list and view details about the Amazon EKS resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities with that policy attached to them.

To ensure that your IAM entities can still use the Amazon EKS console, create a policy with your own unique name, such as AmazonEKSAAdminPolicy. Attach the policy to the entities. For more information, see Adding permissions to a user in the IAM User Guide.

Important
The following example policy allows an entity to view information on the Configuration tab in the console. To view information on the Overview and Resources tabs in the AWS Management Console, the entity also needs Kubernetes permissions. For more information, see Required permissions (p. 500).
Identity-based policy examples

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

**Allow users to view their own permissions**

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.
Create a Kubernetes cluster on the AWS Cloud

This example policy includes the minimum permissions required to create an Amazon EKS cluster named `my-cluster` in the `us-west-2` AWS Region. You can replace the AWS Region with the AWS Region that you want to create a cluster in. If you see a warning that says *The actions in your policy do not support resource-level permissions and require you to choose All resources* in the AWS Management Console, it can be safely ignored. If your account already has the `AWSServiceRoleForAmazonEKS` role, you can remove the `iam:CreateServiceLinkedRole` action from the policy. If you've ever created an Amazon EKS cluster in your account then this role already exists, unless you deleted it.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "eks:CreateCluster",
    },
    {
      "Effect": "Allow",
      "Action": "iam:CreateServiceLinkedRole",
      "Resource": "arn:aws:iam::111122223333:role/aws-service-role/eks.amazonaws.com/AWSServiceRoleForAmazonEKS",
      "Condition": {
        "ForAnyValue:StringEquals": {
          "iam:AWSServiceName": "eks"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::111122223333:role/cluster-role-name"
    }
  ]
}
```

Create a local Kubernetes cluster on an Outpost

This example policy includes the minimum permissions required to create an Amazon EKS local cluster named `my-cluster` on an Outpost in the `us-west-2` AWS Region. You can replace the AWS Region with the AWS Region that you want to create a cluster in. If you see a warning that says *The actions in your policy do not support resource-level permissions and require you to choose All resources* in the AWS Management Console, it can be safely ignored. If your account already has the `AWSServiceRoleForAmazonEKSLocalOutpost` role, you can remove the `iam:CreateServiceLinkedRole` action from the policy. If you've ever created an Amazon EKS local cluster on an Outpost in your account then this role already exists, unless you deleted it.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "eks:CreateCluster",
    }
  ]
}
```
Identity-based policy examples

```
{
   "Action": [ 
      "ec2:DescribeSubnets",
      "ec2:DescribeVpcs",
      "iam:GetRole"
   ],
   "Resource": "*",
   "Effect": "Allow"
 },
{
   "Effect": "Allow",
   "Action": "iam:CreateServiceLinkedRole",
   "Resource": "arn:aws:iam::111122223333:role/aws-service-role/outposts.eks-local.amazonaws.com/AWSServiceRoleForAmazonEKSLocalOutpost"
 },
{
   "Effect": "Allow",
   "Action": [ 
      "iam:PassRole",
      "iam:ListAttachedRolePolicies"
   ],
   "Resource": "arn:aws:iam::111122223333:role/cluster-role-name"
 },
{
   "Action": [ 
      "iam:CreateInstanceProfile",
      "iam:TagInstanceProfile",
      "iam:AddRoleToInstanceProfile",
      "iam:GetInstanceProfile",
      "iam:DeleteInstanceProfile",
      "iam:RemoveRoleFromInstanceProfile"
   ],
   "Resource": "arn:aws:iam::111122223333:role/eks-local-*",
   "Effect": "Allow"
}
```

Update a Kubernetes cluster

This example policy includes the minimum permission required to update a cluster named `my-cluster` in the us-west-2 AWS Region.

```
{
   "Version": "2012-10-17",
   "Statement": [ 
      { 
         "Effect": "Allow",
         "Action": "eks:UpdateClusterVersion",
      }
   ]
}
```

List or describe all clusters

This example policy includes the minimum permissions required to list and describe all clusters in your account. An IAM user or role must be able to list and describe clusters to use the `update-kubeconfig` AWS CLI command.

```
{
```

Using service-linked roles for Amazon EKS

Amazon Elastic Kubernetes Service uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.

Topics

- Using roles for Amazon EKS clusters (p. 451)
- Using roles for Amazon EKS node groups (p. 453)
- Using roles for Amazon EKS Fargate profiles (p. 455)
- Using roles to connect a Kubernetes cluster to Amazon EKS (p. 456)
- Using roles for Amazon EKS local clusters on Outpost (p. 458)

Using roles for Amazon EKS clusters

Amazon Elastic Kubernetes Service uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon EKS easier because you don't have to manually add the necessary permissions. Amazon EKS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon EKS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Amazon EKS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-linked role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon EKS

Amazon EKS uses the service-linked role named AWSServiceRoleForAmazonEKS – The role allows Amazon EKS to manage clusters in your account. The attached policies allow the role to manage the following resources: network interfaces, security groups, logs, and VPCs.

Note
The AWSServiceRoleForAmazonEKS service-linked role is distinct from the role required for cluster creation. For more information, see Amazon EKS cluster IAM role (p. 460).
The AWSServiceRoleForAmazonEKS service-linked role trusts the following services to assume the role:

- eks.amazonaws.com

The role permissions policy allows Amazon EKS to complete the following actions on the specified resources:

- AmazonEKSServiceRolePolicy

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the IAM User Guide.

Creating a service-linked role for Amazon EKS

You don’t need to manually create a service-linked role. When you create a cluster in the AWS Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a cluster, Amazon EKS creates the service-linked role for you again.

Editing a service-linked role for Amazon EKS

Amazon EKS does not allow you to edit the AWSServiceRoleForAmazonEKS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting a service-linked role for Amazon EKS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don’t have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can manually delete it.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first delete any resources used by the role.

**Note**

If the Amazon EKS service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete Amazon EKS resources used by the AWSServiceRoleForAmazonEKS role.

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Clusters.
3. If your cluster has any node groups or Fargate profiles, you must delete them before you can delete the cluster. For more information, see Deleting a managed node group (p. 120) and Deleting a Fargate profile (p. 150).
4. On the Clusters page, choose the cluster that you want to delete and choose Delete.
5. Type the name of the cluster in the deletion confirmation window, and then choose Delete.
6. Repeat this procedure for any other clusters in your account. Wait for all of the delete operations to finish.
Manually delete the service-linked role

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForAmazonEKS service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.

Supported regions for Amazon EKS service-linked roles

Amazon EKS supports using service-linked roles in all of the regions where the service is available. For more information, see Amazon EKS endpoints and quotas.

Using roles for Amazon EKS node groups

Amazon EKS uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon EKS easier because you don't have to manually add the necessary permissions. Amazon EKS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon EKS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Amazon EKS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-linked role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon EKS

Amazon EKS uses the service-linked role named AWSServiceRoleForAmazonEKSNodegroup – The role allows Amazon EKS to manage node groups in your account. The attached policies allow the role to manage the following resources: Auto Scaling groups, security groups, launch templates and IAM instance profiles.

The AWSServiceRoleForAmazonEKSNodegroup service-linked role trusts the following services to assume the role:

- eks-nodegroup.amazonaws.com

The role permissions policy allows Amazon EKS to complete the following actions on the specified resources:

- AWSServiceRoleForAmazonEKSNodegroup

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the IAM User Guide.

Creating a service-linked role for Amazon EKS

You don't need to manually create a service-linked role. When you CreateNodegroup in the AWS Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.

Important

This service-linked role can appear in your account if you completed an action in another service that uses the features supported by this role. If you were using the Amazon EKS service before
January 1, 2017, when it began supporting service-linked roles, then Amazon EKS created the AWSServiceRoleForAmazonEKSNodegroup role in your account. To learn more, see A new role appeared in my IAM account.

Creating a service-linked role in Amazon EKS (AWS API)

You don't need to manually create a service-linked role. When you create a managed node group in the AWS Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create another managed node group, Amazon EKS creates the service-linked role for you again.

Editing a service-linked role for Amazon EKS

Amazon EKS does not allow you to edit the AWSServiceRoleForAmazonEKSNodegroup service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting a service-linked role for Amazon EKS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can manually delete it.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first delete any resources used by the role.

**Note**

If the Amazon EKS service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete Amazon EKS resources used by the AWSServiceRoleForAmazonEKSNodegroup role.

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose **Clusters**.
3. Select the **Compute** tab.
4. In the **Node groups** section, choose the node group to delete.
5. Type the name of the node group in the deletion confirmation window, and then choose **Delete**.
6. Repeat this procedure for any other node groups in the cluster. Wait for all of the delete operations to finish.

Manually delete the service-linked role

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForAmazonEKSNodegroup service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.

Supported regions for Amazon EKS service-linked roles

Amazon EKS supports using service-linked roles in all of the regions where the service is available. For more information, see Amazon EKS endpoints and quotas.
Using roles for Amazon EKS Fargate profiles

Amazon EKS uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon EKS easier because you don't have to manually add the necessary permissions. Amazon EKS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon EKS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Amazon EKS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-linked role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon EKS

Amazon EKS uses the service-linked role named AWSServiceRoleForAmazonEKSForFargate – The role allows Amazon EKS Fargate to configure VPC networking required for Fargate pods. The attached policies allow the role to create and delete elastic network interfaces and describe elastic network Interfaces and resources.

The AWSServiceRoleForAmazonEKSForFargate service-linked role trusts the following services to assume the role:

- eks-fargate.amazonaws.com

The role permissions policy allows Amazon EKS to complete the following actions on the specified resources:

- AmazonEKSForFargateServiceRolePolicy

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the IAM User Guide.

Creating a service-linked role for Amazon EKS

You don't need to manually create a service-linked role. When you create a Fargate profile in the AWS Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.

Important

This service-linked role can appear in your account if you completed an action in another service that uses the features supported by this role. If you were using the Amazon EKS service before December 13, 2019, when it began supporting service-linked roles, then Amazon EKS created the AWSServiceRoleForAmazonEKSForFargate role in your account. To learn more, see A New role appeared in my IAM account.

Creating a service-linked role in Amazon EKS (AWS API)

You don't need to manually create a service-linked role. When you create a Fargate profile in the AWS Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.
If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create another managed node group, Amazon EKS creates the service-linked role for you again.

**Editing a service-linked role for Amazon EKS**

Amazon EKS does not allow you to edit the `AWSServiceRoleForAmazonEKSForFargate` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

**Deleting a service-linked role for Amazon EKS**

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can manually delete it.

**Cleaning up a service-linked role**

Before you can use IAM to delete a service-linked role, you must first delete any resources used by the role.

**Note**

If the Amazon EKS service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

**To delete Amazon EKS resources used by the `AWSServiceRoleForAmazonEKSForFargate` role.**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose **Clusters**.
3. On the **Clusters** page, select your cluster.
4. Select the **Compute** tab.
5. If there are any Fargate profiles in the **Fargate profiles** section, select each one individually, and then choose **Delete**.
6. Type the name of the profile in the deletion confirmation window, and then choose **Delete**.
7. Repeat this procedure for any other Fargate profiles in the cluster and for any other clusters in your account.

**Manually delete the service-linked role**

Use the IAM console, the AWS CLI, or the AWS API to delete the `AWSServiceRoleForAmazonEKSForFargate` service-linked role. For more information, see Deleting a service-linked role in the *IAM User Guide*.

**Supported regions for Amazon EKS service-linked roles**

Amazon EKS supports using service-linked roles in all of the regions where the service is available. For more information, see Amazon EKS endpoints and quotas.

**Using roles to connect a Kubernetes cluster to Amazon EKS**

Amazon EKS uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by
Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon EKS easier because you don't have to manually add the necessary permissions. Amazon EKS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon EKS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Amazon EKS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-linked role column. Choose a Yes with a link to view the service-linked role documentation for that service.

**Service-linked role permissions for Amazon EKS**

Amazon EKS uses the service-linked role named AWSServiceRoleForAmazonEKSConnector – The role allows Amazon EKS to connect Kubernetes clusters. The attached policies allow the role to manage necessary resources to connect to your registered Kubernetes cluster.

The AWSServiceRoleForAmazonEKSConnector service-linked role trusts the following services to assume the role:

- eks-producer.amazonaws.com

The role permissions policy allows Amazon EKS to complete the following actions on the specified resources:

- AmazonEKSConnectorServiceRolePolicy

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the IAM User Guide.

**Creating a service-linked role for Amazon EKS**

You don't need to manually create a service-linked role to connect a cluster. When you connect a cluster in the AWS Management Console, the AWS CLI, eksctl, or the AWS API, Amazon EKS creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you connect a cluster, Amazon EKS creates the service-linked role for you again.

**Editing a service-linked role for Amazon EKS**

Amazon EKS does not allow you to edit the AWSServiceRoleForAmazonEKSConnector service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

**Deleting a service-linked role for Amazon EKS**

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can manually delete it.
Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first delete any resources used by the role.

**Note**  
If the Amazon EKS service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

**To delete Amazon EKS resources used by the AWSServiceRoleForAmazonEKSConnector role.**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose **Clusters**.
3. On the **Clusters** page, select your cluster.
4. Select the **Deregister** tab and then select the **Ok** tab.

Manually delete the service-linked role

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForAmazonEKSConnector service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.

Using roles for Amazon EKS local clusters on Outpost

Amazon Elastic Kubernetes Service uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon EKS easier because you don't have to manually add the necessary permissions. Amazon EKS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon EKS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Amazon EKS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-linked role column. Choose a Yes with a link to view the service-linked role documentation for that service.

**Service-linked role permissions for Amazon EKS**

Amazon EKS uses the service-linked role named AWSServiceRoleForAmazonEKSLocalOutpost – The role allows Amazon EKS to manage local clusters in your account. The attached policies allow the role to manage the following resources: network interfaces, security groups, logs, and Amazon EC2 instances.

**Note**  
The AWSServiceRoleForAmazonEKSLocalOutpost service-linked role is distinct from the role required for cluster creation. For more information, see Amazon EKS cluster IAM role (p. 460).

The AWSServiceRoleForAmazonEKSLocalOutpost service-linked role trusts the following services to assume the role:
• `outposts.eks-local.amazonaws.com`

The role permissions policy allows Amazon EKS to complete the following actions on the specified resources:

• `AmazonEKSServiceRolePolicy`

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the IAM User Guide.

Creating a service-linked role for Amazon EKS

You don't need to manually create a service-linked role. When you create a cluster in the AWS Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a cluster, Amazon EKS creates the service-linked role for you again.

Editing a service-linked role for Amazon EKS

Amazon EKS does not allow you to edit the `AWSServiceRoleForAmazonEKSSLocalOutpost` service-linked role. After you create a service-linked role, you can't change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting a service-linked role for Amazon EKS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can manually delete it.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first delete any resources used by the role.

**Note**

If the Amazon EKS service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete Amazon EKS resources used by the AWSServiceRoleForAmazonEKSSLocalOutpost role.

1. Open the Amazon EKS console at `https://console.aws.amazon.com/eks/home#/clusters`.
2. In the left navigation pane, choose Amazon EKS Clusters.
3. If your cluster has any node groups or Fargate profiles, you must delete them before you can delete the cluster. For more information, see Deleting a managed node group (p. 120) and Deleting a Fargate profile (p. 150).
4. On the Clusters page, choose the cluster that you want to delete and choose Delete.
5. Type the name of the cluster in the deletion confirmation window, and then choose Delete.
6. Repeat this procedure for any other clusters in your account. Wait for all of the delete operations to finish.
Manually delete the service-linked role

Use the IAM console, the AWS CLI, or the AWS API to delete the AWS Service Role for Amazon EKS Local Outpost service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.

Supported regions for Amazon EKS service-linked roles

Amazon EKS supports using service-linked roles in all of the regions where the service is available. For more information, see Amazon EKS endpoints and quotas.

Amazon EKS cluster IAM role

Kubernetes clusters managed by Amazon EKS make calls to other AWS services on your behalf to manage the resources that you use with the service. Before you can create Amazon EKS clusters, you must create an IAM role with the following IAM policies:

- **AmazonEKSClusterPolicy**

  **Note**
  Prior to April 16, 2020, **AmazonEKSServicePolicy** was also required and the suggested name was eksServiceRole. With the AWS Service Role for Amazon EKS service-linked role, that policy is no longer required for clusters created on or after April 16, 2020.

Check for an existing cluster role

You can use the following procedure to check and see if your account already has the Amazon EKS cluster role.

To check for the eksClusterRole in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Roles.
3. Search the list of roles for eksClusterRole. If a role that includes eksClusterRole doesn’t exist, then see Creating the Amazon EKS cluster role (p. 461) to create the role. If a role that includes eksClusterRole does exist, then select the role to view the attached policies.
4. Choose Permissions.
5. Ensure that the AmazonEKSClusterPolicy managed policy is attached to the role. If the policy is attached, your Amazon EKS cluster role is properly configured.
6. Choose Trust relationships, and then choose Edit trust policy.
7. Verify that the trust relationship contains the following policy. If the trust relationship matches the following policy, choose Cancel. If the trust relationship doesn’t match, copy the policy into the Edit trust policy window and choose Update policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "eks.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```
Creating the Amazon EKS cluster role

You can use the AWS Management Console or the AWS CLI to create the cluster role.

AWS Management Console

To create your Amazon EKS cluster role in the IAM console
1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Roles, then Create role.
3. Under Trusted entity type, select AWS service.
4. From the Use cases for other AWS services dropdown list, choose EKS.
5. Choose EKS - Cluster for your use case, and then choose Next.
6. On the Add permissions tab, choose Next.
7. For Role name, enter a unique name for your role, such as eksClusterRole.
8. For Description, enter descriptive text such as Amazon EKS - Cluster role.
9. Choose Create role.

AWS CLI

1. Copy the following contents to a file named cluster-trust-policy.json.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "Service": "eks.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
       }
     ]
   }
   ```

2. Create the role. You can replace eksClusterRole with any name that you choose.

   ```bash
   aws iam create-role \
   --role-name eksClusterRole \
   --assume-role-policy-document file://"cluster-trust-policy.json"
   ```

3. Attach the required IAM policy to the role.

   ```bash
   aws iam attach-role-policy \
   --policy-arn arn:aws:iam::aws:policy/AmazonEKSClusterPolicy \
   --role-name eksClusterRole
   ```

Amazon EKS node IAM role

The Amazon EKS node kubelet daemon makes calls to AWS APIs on your behalf. Nodes receive permissions for these API calls through an IAM instance profile and associated policies. Before you can launch nodes and register them into a cluster, you must create an IAM role for those nodes to use when they are launched. This requirement applies to nodes launched with the Amazon EKS optimized AMI provided by Amazon, or with any other node AMIs that you intend to use.
Before you create nodes, you must create an IAM role with the following IAM policies:

- `AmazonEKSWorkerNodePolicy`
- `AmazonEC2ContainerRegistryReadOnly`
- Either the `AmazonEKS_CNI_Policy` managed policy (if you created your cluster with the IPv4 family) or an IPv6 policy that you create (p. 262) (if you created your cluster with the IPv6 family).

Rather than attaching the policy to this role however, we recommend that you attach the policy to a separate role used specifically for the Amazon VPC CNI add-on. For more information about creating a separate role for the Amazon VPC CNI add-on, see the section called “Configure plugin for IAM account” (p. 258).

Note
The Amazon EC2 node groups must have a different IAM role than the Fargate profile. For more information, see Amazon EKS pod execution IAM role (p. 465).

Check for an existing node role

You can use the following procedure to check and see if your account already has the Amazon EKS node role.

To check for the `eksNodeRole` in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Roles.
3. Search the list of roles for `eksNodeRole`, `AmazonEKSNodeRole`, or `NodeInstanceRole`. If a role with one of those names doesn't exist, then see Creating the Amazon EKS node IAM role (p. 463) to create the role. If a role that contains `eksNodeRole`, `AmazonEKSNodeRole`, or `NodeInstanceRole` does exist, then select the role to view the attached policies.
4. Choose Permissions.
5. Ensure that the `AmazonEKSWorkerNodePolicy` and `AmazonEC2ContainerRegistryReadOnly` managed policies are attached to the role. If the policies are attached, your Amazon EKS node role is properly configured.

Note
If the `AmazonEKS_CNI_Policy` policy is attached to the role, we recommend removing it and attaching it to an IAM role that is mapped to the `aws-node` Kubernetes service account instead. For more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).

6. Choose Trust relationships, and then choose Edit trust policy.
7. Verify that the trust relationship contains the following policy. If the trust relationship matches the following policy, choose Cancel. If the trust relationship doesn't match, copy the policy into the Edit trust policy window and choose Update policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "ec2.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```
Creating the Amazon EKS node IAM role

You can create the node IAM role with the AWS Management Console or the AWS CLI. Select the tab with the name of the tool that you want to create the role with.

AWS Management Console

To create your Amazon EKS node role in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Roles.
3. On the Roles page, choose Create role.
4. On the Select trusted entity page, do the following:
   a. In the Trusted entity type section, choose AWS service.
   b. Under Use case, choose EC2.
   c. Choose Next.
5. On the Add permissions page, do the following:
   a. In the Filter policies box, enter AmazonEKSWorkerNodePolicy.
   b. Select the check box to the left of AmazonEKSWorkerNodePolicy in the search results.
   c. Choose Clear filters.
   d. In the Filter policies box, enter AmazonEC2ContainerRegistryReadOnly.
   e. Select the check box to the left of AmazonEC2ContainerRegistryReadOnly in the search results.

   Either the AmazonEKS_CNI_Policy managed policy, or an IPv6 policy (p. 262) that you create must also be attached to either this role or to a different role that's mapped to the aws-node Kubernetes service account. We recommend assigning the policy to the role associated to the Kubernetes service account instead of assigning it to this role. For more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).
   f. Choose Next.
6. On the Name, review, and create page, do the following:
   a. For Role name, enter a unique name for your role, such as AmazonEKSNodeRole.
   b. For Description, replace the current text with descriptive text such as Amazon EKS - Node role.
   c. Under Add tags (Optional), add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM Entities in the IAM User Guide
   d. Choose Create role.

AWS CLI

1. Run the following command to create the node-role-trust-relationship.json file.
   ```bash
   cat >node-role-trust-relationship.json <<EOF
   {
   ```
2. Create the IAM role.

```
aws iam create-role \
  --role-name AmazonEKSNodeRole \
  --assume-role-policy-document file://"node-role-trust-relationship.json"
```

3. Attach two required IAM managed policies to the IAM role.

```
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy \
  --role-name AmazonEKSNodeRole
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly \
  --role-name AmazonEKSNodeRole
```

4. Attach one of the following IAM policies to the IAM role depending on which IP family you created your cluster with. The policy must be attached to this role or to a role associated to the Kubernetes `aws-node` service account that's used for the Amazon VPC CNI plugin for Kubernetes. We recommend assigning the policy to the role associated to the Kubernetes service account. To assign the policy to the role associated to the Kubernetes service account, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).

- **IPv4**

```
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy \
  --role-name AmazonEKSNodeRole
```

- **IPv6**

1. Copy the following text and save it to a file named `vpc-cni-ipv6-policy.json`.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:AssignIpv6Addresses",
        "ec2:DescribeInstances",
        "ec2:DescribeTags",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeInstanceTypes"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
```
Amazon EKS pod execution IAM role

The Amazon EKS pod execution role is required to run pods on AWS Fargate infrastructure.

When your cluster creates pods on AWS Fargate infrastructure, the components running on the Fargate infrastructure must make calls to AWS APIs on your behalf. This is so that they can do actions such as pull container images from Amazon ECR or route logs to other AWS services. The Amazon EKS pod execution role provides the IAM permissions to do this.

When you create a Fargate profile, you must specify a pod execution role for the Amazon EKS components that run on the Fargate infrastructure using the profile. This role is added to the cluster's Kubernetes Role based access control (RBAC) for authorization. This allows the kubelet that's running on the Fargate infrastructure to register with your Amazon EKS cluster so that it can appear in your cluster as a node.

**Note**
The Fargate profile must have a different IAM role than Amazon EC2 node groups.

**Important**
The containers running in the Fargate pod can't assume the IAM permissions associated with a pod execution role. To give the containers in your Fargate pod permissions to access other AWS services, you must use IAM roles for service accounts (p. 425).

Before you create a Fargate profile, you must create an IAM role with the AmazonEKSFargatePodExecutionRolePolicy.

**Check for a correctly configured existing pod execution role**

You can use the following procedure to check and see if your account already has a correctly configured Amazon EKS pod execution role. To avoid a confused deputy security problem, it's important that the role restricts access based on SourceArn. You can modify the execution role as needed to include support for Fargate profiles on other clusters.

To check for an Amazon EKS pod execution role in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Roles.
3. On the **Roles** page, search the list of roles for **AmazonEKSFargatePodExecutionRole**. If the role doesn't exist, see Creating the Amazon EKS pod execution role (p. 466) to create the role. If the role does exist, choose the role.

4. On the **AmazonEKSFargatePodExecutionRole** page, do the following:
   a. Choose **Permissions**.
   b. Ensure that the **AmazonEKSFargatePodExecutionRolePolicy** Amazon managed policy is attached to the role.
   c. Choose **Trust relationships**.
   d. Choose **Edit trust policy**.

5. On the **Edit trust policy** page, verify that the trust relationship contains the following policy and has a line for Fargate profiles on your cluster. If so, choose **Cancel**.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Condition": {
                "ArnLike": {
                }
            },
            "Principal": {
                "Service": "eks-fargate-pods.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

If the policy matches but doesn't have a line specifying the Fargate profiles on your cluster, you can add the following line at the top of the ArnLike object. Replace **region-code** with the AWS Region that your cluster is in, **111122223333** with your account ID, and **my-cluster** with the name of your cluster.

```json
```

If the policy doesn't match, copy the full previous policy into the form and choose **Update policy**. Replace **region-code** with the AWS Region that your cluster is in. If you want to use the same role in all AWS Regions in your account, replace **region-code** with *. Replace **111122223333** with your account ID and **my-cluster** with the name of your cluster. If you want to use the same role for all clusters in your account, replace **my-cluster** with *.

### Creating the Amazon EKS pod execution role

If you don't already have the Amazon EKS pod execution role for your cluster, you can use the AWS Management Console or the AWS CLI to create it.

**AWS Management Console**

To create an **AWS Fargate pod execution role with the AWS Management Console**

2. In the left navigation pane, choose **Roles**.
3. On the **Roles** page, choose **Create role**.

4. On the **Select trusted entity** page, do the following:
   a. In the **Trusted entity type** section, choose **AWS service**.
   b. From the **Use cases for other AWS services** dropdown list, choose **EKS**.
   c. Choose **EKS - Fargate pod**.
   d. Choose **Next**.

5. On the **Add permissions** page, choose **Next**.

6. On the **Name, review, and create** page, do the following:
   a. For **Role name**, enter a unique name for your role, such as **AmazonEKSFargatePodExecutionRole**.
   b. Under **Add tags (Optional)**, add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see **Tagging IAM Entities** in the **IAM User Guide**
   c. Choose **Create role**.

7. On the **Roles** page, search the list of roles for **AmazonEKSFargatePodExecutionRole**. Choose the role.

8. On the **AmazonEKSFargatePodExecutionRole** page, do the following:
   a. Choose **Trust relationships**.
   b. Choose **Edit trust policy**.

9. On the **Edit trust policy** page, do the following:
   a. Copy and paste the following contents into the **Edit trust policy** form. Replace **region-code** with the AWS Region that your cluster is in. If you want to use the same role in all AWS Regions in your account, replace **region-code** with *. Replace **111122223333** with your account ID and **my-cluster** with the name of your cluster. If you want to use the same role for all clusters in your account, replace **my-cluster** with *.

   ```json
   { 
   "Version": "2012-10-17",
   "Statement": [
   { 
   "Effect": "Allow",
   "Condition": {
   "ArnLike": {
   }
   },
   "Principal": {
   "Service": "eks-fargate-pods.amazonaws.com"
   },
   "Action": "sts:AssumeRole"
   }
   ]
   }
   ```
   
   b. Choose **Update policy**.
To create an AWS Fargate pod execution role with the AWS CLI

1. Copy and paste the following contents to a file named `pod-execution-role-trust-policy.json`. Replace `region-code` with the AWS Region that your cluster is in. If you want to use the same role in all AWS Regions in your account, replace `region-code` with `*`. Replace 111122223333 with your account ID and `my-cluster` with the name of your cluster. If you want to use the same role for all clusters in your account, replace `my-cluster` with `*`.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Condition": {
           "ArnLike": {
           }
         },
         "Principal": {
           "Service": "eks-fargate-pods.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
       }
     ]
   }
   ```

2. Create a pod execution IAM role.

   ```bash
   aws iam create-role
   --role-name AmazonEKSFargatePodExecutionRole
   --assume-role-policy-document file://"pod-execution-role-trust-policy.json"
   ```

3. Attach the required Amazon EKS managed IAM policy to the role.

   ```bash
   aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonEKSFargatePodExecutionRolePolicy
   --role-name AmazonEKSFargatePodExecutionRole
   ```

Amazon EKS connector IAM role

You can connect Kubernetes clusters to view them in your AWS Management Console. To connect to a Kubernetes cluster, create an IAM role.

Check for an existing connector role

You can use the following procedure to check and see if your account already has the Amazon EKS connector role.

To check for the AmazonEKSConnectorAgentRole in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Roles.
3. Search the list of roles for AmazonEKSConnectorAgentRole. If a role that includes AmazonEKSConnectorAgentRole doesn't exist, then see Creating the Amazon EKS connector.
agent role (p. 469) to create the role. If a role that includes AmazonEKSConnectorAgentRole does exist, then select the role to view the attached policies.

4. Choose Permissions.

5. Ensure that the AmazonEKSClusterPolicy managed policy is attached to the role. If the policy is attached, your Amazon EKS cluster role is properly configured.

6. Choose Trust relationships, and then choose Edit trust policy.

7. Verify that the trust relationship contains the following policy. If the trust relationship matches the following policy, choose Cancel. If the trust relationship doesn't match, copy the policy into the Edit trust policy window and choose Update policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Creating the Amazon EKS connector agent role

You can use the AWS Management Console or AWS CloudFormation to create the connector agent role. Select the tab with the name of the tool that you want to use to create the role.

AWS CLI

1. Create a file named eks-connector-agent-trust-policy.json that contains the following JSON to use for the IAM role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": ["ssm.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

2. Create a file named eks-connector-agent-policy.json that contains the following JSON to use for the IAM role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "SsmControlChannel",
      "Effect": "Allow",
      "Action": ["ssm:PutParameter"]
    }
  ]
}
```
3. Create the Amazon EKS Connector agent role using the trust policy and policy you created in the previous list items.

```bash
aws iam create-role \
  --role-name AmazonEKSConnectorAgentRole \
  --assume-role-policy-document file://eks-connector-agent-trust-policy.json
```

4. Attach the policy to your Amazon EKS Connector agent role.

```bash
aws iam put-role-policy \
  --role-name AmazonEKSConnectorAgentRole \
  --policy-name AmazonEKSConnectorAgentPolicy \
  --policy-document file://eks-connector-agent-policy.json
```

AWS CloudFormation

**To create your Amazon EKS connector agent role with AWS CloudFormation.**

1. Save the following AWS CloudFormation template to a text file on your local system.

   ```yaml
   AWSTemplateFormatVersion: '2010-09-09'
   Description: 'Provisions necessary resources needed to register clusters in EKS'
   Parameters: {}
   Resources:
     EKSConnectorSLR:
       Type: AWS::IAM::ServiceLinkedRole
       Properties:
         AWSServiceName: eks-connector.amazonaws.com
     EKSConnectorAgentRole:
       Type: AWS::IAM::Role
       Properties:
         AssumeRolePolicyDocument:
           Version: '2012-10-17'
           Statement:
             - Effect: Allow
               Action: [ 'sts:AssumeRole' ]
               Principal:
   ```

   *Note*
   This template also creates the service-linked role that would otherwise be created when the `registerCluster` API is called. See [Using roles to connect a Kubernetes cluster to Amazon EKS (p. 456)](https://docs.aws.amazon.com/eks/latest/userguide/using-iam.html) for details.
AWS managed policies for Amazon Elastic Kubernetes Service

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ReadOnlyAccess AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and
resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

AWS managed policy: AmazonEKS_CNI_Policy

You can attach the AmazonEKS_CNI_Policy to your IAM entities. Before you create an Amazon EC2 node group, this policy must be attached to either the node IAM role (p. 461), or to an IAM role that’s used specifically by the Amazon VPC CNI plugin for Kubernetes. This is so that it can perform actions on your behalf. We recommend that you attach the policy to a role that’s used only by the plugin. For more information, see Pod networking in Amazon EKS using the Amazon VPC CNI plugin for Kubernetes (p. 247) and Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).

Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks:

- **ec2** – Allows the Amazon VPC CNI plugin to perform actions such as provisioning Elastic Network Interfaces and IP addresses for pods to provide networking for applications that run in Amazon EKS.

```json
{
"Version": "2012-10-17",
"Statement": [
{
"Effect": "Allow",
"Action": [
"ec2:AssignPrivateIpAddresses",
"ec2:AttachNetworkInterface",
"ec2:CreateNetworkInterface",
"ec2:DeleteNetworkInterface",
"ec2:DescribeInstances",
"ec2:DescribeTags",
"ec2:DescribeNetworkInterfaces",
"ec2:DescribeInstanceTypes",
"ec2:DetachNetworkInterface",
"ec2:ModifyNetworkInterfaceAttribute",
"ec2:UnassignPrivateIpAddresses"
],
"Resource": "*"
},
{
"Effect": "Allow",
"Action": [
"ec2:CreateTags"
],
"Resource": ["arn:aws:ec2:*:**:network-interface/*"
]}
]}
```

AWS managed policy: AmazonEKSClusterPolicy

You can attach AmazonEKSClusterPolicy to your IAM entities. Before creating a cluster, you must have a cluster IAM role (p. 460) with this policy attached. Kubernetes clusters that are managed by Amazon EKS make calls to other AWS services on your behalf. They do this to manage the resources that you use with the service.

This policy includes the following permissions that allow Amazon EKS to complete the following tasks:
- **autoscaling** – Read and update the configuration of an Auto Scaling group. These permissions aren't used by Amazon EKS but remain in the policy for backwards compatibility.

- **ec2** – Work with volumes and network resources that are associated to Amazon EC2 nodes. This is required so that the Kubernetes control plane can join instances to a cluster and dynamically provision and manage Amazon EBS volumes that are requested by Kubernetes persistent volumes.

- **elasticloadbalancing** – Work with Elastic Load Balancers and add nodes to them as targets. This is required so that the Kubernetes control plane can dynamically provision Elastic Load Balancers requested by Kubernetes services.

- **iam** – Create a service-linked role. This is required so that the Kubernetes control plane can dynamically provision Elastic Load Balancers that are requested by Kubernetes services.

- **kms** – Read a key from AWS KMS. This is required for the Kubernetes control plane to support secrets encryption of Kubernetes secrets stored in etcd.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "autoscaling:DescribeAutoScalingGroups",
        "autoscaling:UpdateAutoScalingGroup",
        "ec2:AttachVolume",
        "ec2:AuthorizeSecurityGroupIngress",
        "ec2:CreateRoute",
        "ec2:CreateSecurityGroup",
        "ec2:CreateTags",
        "ec2:CreateVolume",
        "ec2:DeleteRoute",
        "ec2:DeleteSecurityGroup",
        "ec2:DeleteVolume",
        "ec2:DescribeInstances",
        "ec2:DescribeRouteTables",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeSubnets",
        "ec2:DescribeVolumes",
        "ec2:DescribeVolumesModifications",
        "ec2:DescribeVpcs",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DetachVolume",
        "ec2:ModifyInstanceAttribute",
        "ec2:ModifyVolume",
        "ec2:RevokeSecurityGroupIngress",
        "ec2:DescribeAccountAttributes",
        "ec2:DescribeAddresses",
        "ec2:DescribeInternetGateways",
        "elasticloadbalancing:AddTags",
        "elasticloadbalancing:ApplySecurityGroupsToLoadBalancer",
        "elasticloadbalancing:AttachLoadBalancerToSubnets",
        "elasticloadbalancing:ConfigureHealthCheck",
        "elasticloadbalancing:CreateListener",
        "elasticloadbalancing:CreateLoadBalancer",
        "elasticloadbalancing:CreateLoadBalancerListeners",
        "elasticloadbalancing:CreateLoadBalancerPolicy",
        "elasticloadbalancing:CreateTargetGroup",
        "elasticloadbalancing:DeleteListener",
        "elasticloadbalancing:DeleteLoadBalancer",
        "elasticloadbalancing:DeleteLoadBalancerListeners",
        "elasticloadbalancing:DeleteTargetGroup",
        "elasticloadbalancing:DeregisterInstancesFromLoadBalancer",
        "elasticloadbalancing:DeregisterTargets"
      ]
    }
  ]
}
```
AWS managed policies

Amazon EKS User Guide

AWS managed policy:
AmazonEKSFargatePodExecutionRolePolicy

You can attach AmazonEKSFargatePodExecutionRolePolicy to your IAM entities. Before you can create a Fargate profile, you must create a Fargate pod execution role and attach this policy to it. For more information, see Create a Fargate pod execution role (p. 145) and AWS Fargate profile (p. 147).

This policy grants the role the permissions that provide access to other AWS service resources that are required to run Amazon EKS pods on Fargate.

Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks:

- **ecr** – Allows Pods that are running on Fargate to pull container images that are stored in Amazon ECR.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecr:GetAuthorizationToken",
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage"
      ],
      "Resource": "*
    }
  ]
}
```
AWS managed policy: AmazonEKSForFargateServiceRolePolicy

You can't attach AmazonEKSForFargateServiceRolePolicy to your IAM entities. This policy is attached to a service-linked role that allows Amazon EKS to perform actions on your behalf. For more information, see AWSServiceRoleforAmazonEKSForFargate.

This policy grants necessary permissions to Amazon EKS to run Fargate tasks. The policy is only used if you have Fargate nodes.

Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks.

- **ec2** – Create and delete Elastic Network Interfaces and describe Elastic Network Interfaces and resources. This is required so that the Amazon EKS Fargate service can configure the VPC networking that's required for Fargate Pods.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateNetworkInterface",
        "ec2:CreateNetworkInterfacePermission",
        "ec2:DeleteNetworkInterface",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeSubnets",
        "ec2:DescribeVpcs",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeRouteTables"
      ],
      "Resource": "*"
    }
  ]
}
```

AWS managed policy: AmazonEKSServicePolicy

You can attach AmazonEKSServicePolicy to your IAM entities. Clusters that were created before April 16, 2020, required you to create an IAM role and attach this policy to it. Clusters that were created on or after April 16, 2020, don't require you to create a role and don't require you to assign this policy. When you create a cluster using an IAM principal that has the iam:CreateServiceLinkedRole permission, the AWSServiceRoleforAmazonEKS (p. 451) service-linked role is automatically created for you. The service-linked role has the AWS managed policy: AmazonEKSServiceRolePolicy (p. 477) attached to it.

This policy allows Amazon EKS to create and manage the necessary resources to operate Amazon EKS clusters.

Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks.

- **eks** – Update the Kubernetes version of your cluster after you initiate an update. This permission isn't used by Amazon EKS but remains in the policy for backwards compatibility.
• **ec2** – Work with Elastic Network Interfaces and other network resources and tags. This is required by Amazon EKS to configure networking that facilitates communication between nodes and the Kubernetes control plane.

• **route53** – Associate a VPC with a hosted zone. This is required by Amazon EKS to enable private endpoint networking for your Kubernetes cluster API server.

• **logs** – Log events. This is required so that Amazon EKS can ship Kubernetes control plane logs to CloudWatch.

• **iam** – Create a service-linked role. This is required so that Amazon EKS can create the `AWSServiceRoleForAmazonEKS` (p. 451) service-linked role on your behalf.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateNetworkInterface",
                "ec2:CreateNetworkInterfacePermission",
                "ec2:DeleteNetworkInterface",
                "ec2:DescribeInstances",
                "ec2:DescribeNetworkInterfaces",
                "ec2:DetachNetworkInterface",
                "ec2:DescribeSecurityGroups",
                "ec2:DescribeSubnets",
                "ec2:DescribeVpcs",
                "ec2:ModifyNetworkInterfaceAttribute",
                "iam:ListAttachedRolePolicies",
                "eks:UpdateClusterVersion"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags",
                "ec2:DeleteTags"
            ],
            "Resource": [
                "arn:aws:ec2:*:*:vpc/*",
                "arn:aws:ec2:*:*:subnet/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": "route53:AssociateVPCWithHostedZone",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "logs:CreateLogGroup",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogStream",
                "logs:DescribeLogStreams"
            ],
            "Resource": "arn:aws:logs:*:*:log-group:/aws/eks/*:*"
        },
        {
            "Effect": "Allow",
            "Action": "logs:CreateLogStream",
            "Resource": "arn:aws:logs:*:*:log-group:/aws/eks/*:*"
        }
    ]
}
```
AWS managed policy: AmazonEKSServiceRolePolicy

You can't attach AmazonEKSServiceRolePolicy to your IAM entities. This policy is attached to a service-linked role that allows Amazon EKS to perform actions on your behalf. For more information, see Service-linked role permissions for Amazon EKS (p. 451). When you create a cluster using an IAM principal that has the `iam:CreateServiceLinkedRole` permission, the AWSServiceRoleforAmazonEKS (p. 451) service-linked role is automatically created for you and this policy is attached to it.

This policy allows the service-linked role to call AWS services on your behalf.

Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks.

- **ec2** – Create and describe Elastic Network Interfaces and Amazon EC2 instances, the cluster security group (p. 245), and VPC that are required to create a cluster.
- **iam** – List all of the managed policies that attached to an IAM role. This is required so that Amazon EKS can list and validate all managed policies and permissions required to create a cluster.
- **Associate a VPC with a hosted zone** – This is required by Amazon EKS to enable private endpoint networking for your Kubernetes cluster API server.
- **Log event** – This is required so that Amazon EKS can ship Kubernetes control plane logs to CloudWatch.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ec2:CreateNetworkInterface",
            "ec2:DeleteNetworkInterface",
            "ec2:DetachNetworkInterface",
            "ec2:ModifyNetworkInterfaceAttribute",
            "ec2:DescribeInstances",
            "ec2:DescribeNetworkInterfaces",
            "ec2:DescribeSecurityGroups",
            "ec2:DescribeSubnets",
            "ec2:DescribeVpcs",
            "ec2:CreateNetworkInterfacePermission",
            "iam:ListAttachedRolePolicies",
            "ec2:CreateSecurityGroup"
         ],
         "Resource": "*"
      }
   ]
}
```
},
{

  "Resource": "arn:aws:logs::*:log-group:/aws/eks/**"
},
{
  "Effect": "Allow",
  "Action": ["logs:CreateLogStream",
              "logs:DescribeLogStreams"
AWS managed policy: AmazonEKSVPCResourceController

You can attach the AmazonEKSVPCResourceController policy to your IAM identities. If you’re using security groups for pods (p. 292), you must attach this policy to your Amazon EKS cluster IAM role (p. 460) to perform actions on your behalf.

This policy grants the cluster role permissions to manage Elastic Network Interfaces and IP addresses for nodes.

Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks:

- **ec2** – Manage Elastic Network Interfaces and IP addresses to support pod security groups and Windows nodes.

AWS managed policy: AmazonEKSWorkerNodePolicy

You can attach the AmazonEKSWorkerNodePolicy to your IAM entities. You must attach this policy to a node IAM role (p. 461) that you specify when you create Amazon EC2 nodes that allow Amazon EKS
to perform actions on your behalf. If you create a node group using `eksctl`, it creates the node IAM role and attaches this policy to the role automatically.

This policy grants Amazon EKS Amazon EC2 nodes permissions to connect to Amazon EKS clusters.

**Permissions details**

This policy includes the following permissions that allow Amazon EKS to complete the following tasks:

- **ec2** – Read instance volume and network information. This is required so that Kubernetes nodes can describe information about Amazon EC2 resources that are required for the node to join the Amazon EKS cluster.
- **eks** – Optionally describe the cluster as part of node bootstrapping.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceTypes",
                "ec2:DescribeRouteTables",
                "ec2:DescribeSecurityGroups",
                "ec2:DescribeSubnets",
                "ec2:DescribeVolumes",
                "ec2:DescribeVolumesModifications",
                "ec2:DescribeVpcs",
                "eks:DescribeCluster"
            ],
            "Resource": "*
        }
    ]
}
```

**AWS managed policy:**

**AWSServiceRoleForAmazonEKSNodegroup**

You can't attach `AWSServiceRoleForAmazonEKSNodegroup` to your IAM entities. This policy is attached to a service-linked role that allows Amazon EKS to perform actions on your behalf. For more information, see Service-linked role permissions for Amazon EKS (p. 453).

This policy grants the `AWSServiceRoleForAmazonEKSNodegroup` role permissions that allow it to create and manage Amazon EC2 node groups in your account.

**Permissions details**

This policy includes the following permissions that allow Amazon EKS to complete the following tasks:

- **ec2** – Work with security groups, tags, and launch templates. This is required for Amazon EKS managed node groups to enable remote access configuration. Additionally, Amazon EKS managed node groups create a launch template on your behalf. This is to configure the Amazon EC2 Auto Scaling group that backs each managed node group.
- **iam** – Create a service-linked role and pass a role. This is required by Amazon EKS managed node groups to manage instance profiles for the role being passed when creating a managed node group. This instance profile is used by Amazon EC2 instances launched as part of a managed node group. Amazon EKS needs to create service-linked roles for other services such as Amazon EC2 Auto Scaling groups. These permissions are used in the creation of a managed node group.
• **autoscaling** – Work with security Auto Scaling groups. This is required by Amazon EKS managed node groups to manage the Amazon EC2 Auto Scaling group that backs each managed node group. It's also used to support functionality such as evicting pods when nodes are terminated or recycled during node group updates.

"Resource": "arn:aws:ec2:*:*:*:instance-id*"
}
The AmazonEBSCSIDriverPolicy policy allows the Amazon EBS Container Storage Interface (CSI) driver to create, modify, attach, detach, and delete volumes on your behalf. It also grants the EBS CSI driver permissions to create and delete snapshots, and to list your instances, volumes, and snapshots.

The AmazonEBSCSIDriverPolicy includes the following permissions:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {"Effect": "Allow",
      "Resource": "*
    },
    {"Sid": "PermissionsToCreateAndManageInstanceProfiles",
      "Effect": "Allow",

AWS managed policy: AmazonEKSLocalOutpostClusterPolicy

You can attach this policy to IAM entities. Before creating a local cluster, you must attach this policy to your cluster role (p. 460). Kubernetes clusters that are managed by Amazon EKS make calls to other AWS services on your behalf. They do this to manage the resources that you use with the service.

The AmazonEKSLocalOutpostClusterPolicy includes the following permissions:

- **ec2** – Required permissions for Amazon EC2 instances to successfully join the cluster as control plane instances.
- **ssm** – Allows Amazon EC2 Systems Manager connection to the control plane instance, which is used by Amazon EKS to communicate and manage the local cluster in your account.
- **logs** – Allows instances to push logs to Amazon CloudWatch.
- **secretsmanager** – Allows instances to get and delete bootstrap data for the control plane instances securely from AWS Secrets Manager.
- **ecr** – Allows pods and containers that are running on the control plane instances to pull container images that are stored in Amazon Elastic Container Registry.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeInstances",
        "ec2:DescribeRouteTables",
        "ec2:DescribeTags",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeInstanceTypes",
        "ec2messages:AcknowledgeMessage",
        "ec2messages:DeleteMessage",
        "ec2messages:FailMessage",
        "ec2messages:GetEndpoint",
        "ec2messages:GetMessages",
        "ec2messages:SendMessage",
        "ssmmessages:CreateControlChannel",
        "ssmmessages:CreateDataChannel",
        "ssmmessages:OpenControlChannel",
        "ssmmessages:OpenDataChannel",
        "ssm:DescribeInstanceProperties",
        "ssm:DescribeDocumentParameters",

        "ssm:UpdateInstanceInformation",
        "ssm:UpdateInstanceAssociationStatus",
        "ssm:PutComplianceItems",
        "ssm:PutInventory",
        "ecr-public:GetAuthorizationToken",
        "ecr:GetDownloadUrlForLayer",
        "ecr:GetAuthorizationToken"
      ],
      "Resource": "*"
    }
  ]
}
```
AWS managed policy:
AmazonEKSLocalOutpostServiceRolePolicy

You can't attach this policy to your IAM entities. When you create a cluster using an IAM principal that has the iam:CreateServiceLinkedRole permission, Amazon EKS automatically creates the AWSServiceRoleforAmazonEKSLocalOutpost (p. 458) service-linked role for you and attaches this policy to it. This policy allows the service-linked role to call AWS services on your behalf for local clusters.

The AmazonEKSLocalOutpostServiceRolePolicy includes the following permissions:

- **ec2** – Allows Amazon EKS to work with security, network, and other resources to successfully launch and manage control plane instances in your account.
- **ssm** – Allows Amazon EC2 Systems Manager connection to the control plane instances, which is used by Amazon EKS to communicate and manage the local cluster in your account.
- **iam** – Allows Amazon EKS to manage the instance profile associated with the control plane instances.
- **secretsmanager** – Allows Amazon EKS to put bootstrap data for the control plane instances into AWS Secrets Manager so it can be securely referenced during instance bootstrapping.
- **outposts** – Allows Amazon EKS to get Outpost information from your account to successfully launch a local cluster in an Outpost.

**Troubleshooting Amazon EKS identity and access**

To diagnose and fix common issues that you might encounter when working with Amazon EKS and IAM see Troubleshooting IAM (p. 531).

**Compliance validation for Amazon Elastic Kubernetes Service**

Third-party auditors assess the security and compliance of AWS services as part of multiple AWS compliance programs, such as SOC, PCI, FedRAMP, and HIPAA.

To learn whether Amazon EKS or other AWS services are within the scope of specific compliance programs, see AWS Services in Scope by Compliance Program. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.
- **Architecting for HIPAA Security and Compliance on Amazon Web Services** – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.
Note
Not all AWS services are HIPAA eligible. For more information, see the HIPAA Eligible Services Reference.

- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.
- **Evaluating Resources with Rules** in the *AWS Config Developer Guide* – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.
- **AWS Audit Manager** – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

Resilience in Amazon EKS

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

Amazon EKS runs and scales the Kubernetes control plane across multiple AWS Availability Zones to ensure high availability. Amazon EKS automatically scales control plane instances based on load, detects and replaces unhealthy control plane instances, and automatically patches the control plane. After you initiate a version update, Amazon EKS updates your control plane for you, maintaining high availability of the control plane during the update.

This control plane consists of at least two API server instances and three *etcd* instances that run across three Availability Zones within an AWS Region. Amazon EKS:

- Actively monitors the load on control plane instances and automatically scales them to ensure high performance.
- Automatically detects and replaces unhealthy control plane instances, restarting them across the Availability Zones within the AWS Region as needed.
- Leverages the architecture of AWS Regions in order to maintain high availability. Because of this, Amazon EKS is able to offer an **SLA for API server endpoint availability**.

For more information about AWS Regions and Availability Zones, see **AWS global infrastructure**.

Infrastructure security in Amazon EKS

As a managed service, Amazon EKS is protected by the AWS global network security procedures that are described in the *Amazon Web Services: Overview of security processes* paper.

You use AWS published API calls to access Amazon EKS through the network. Clients must support Transport Layer Security (TLS) 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.
Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

When you create an Amazon EKS cluster, you specify the VPC subnets for your cluster to use. Amazon EKS requires subnets in at least two Availability Zones. We recommend a VPC with public and private subnets so that Kubernetes can create public load balancers in the public subnets that load balance traffic to pods running on nodes that are in private subnets.

For more information about VPC considerations, see Amazon EKS VPC and subnet requirements and considerations (p. 238).

If you create your VPC and node groups with the AWS CloudFormation templates provided in the Getting started with Amazon EKS (p. 4) walkthrough, then your control plane and node security groups are configured with our recommended settings.

For more information about security group considerations, see Amazon EKS security group requirements and considerations (p. 245).

When you create a new cluster, Amazon EKS creates an endpoint for the managed Kubernetes API server that you use to communicate with your cluster (using Kubernetes management tools such as kubectl). By default, this API server endpoint is public to the internet, and access to the API server is secured using a combination of AWS Identity and Access Management (IAM) and native Kubernetes Role Based Access Control (RBAC).

You can enable private access to the Kubernetes API server so that all communication between your nodes and the API server stays within your VPC. You can limit the IP addresses that can access your API server from the internet, or completely disable internet access to the API server.

For more information about modifying cluster endpoint access, see Modifying cluster endpoint access (p. 43).

You can implement network policies with tools such as Project Calico (p. 329). Project Calico is a third party open source project. For more information, see the Project Calico documentation.

Configuration and vulnerability analysis in Amazon EKS

Security is a critical consideration for configuring and maintaining Kubernetes clusters and applications. The Center for Internet Security (CIS) Kubernetes Benchmark provides guidance for Amazon EKS node security configurations. The benchmark:

- Is applicable to Amazon EC2 nodes (both managed and self-managed) where you are responsible for security configurations of Kubernetes components.
- Provides a standard, community-approved way to ensure that you have configured your Kubernetes cluster and nodes securely when using Amazon EKS.
- Consists of four sections; control plane logging configuration, node security configurations, policies, and managed services.
- Supports all of the Kubernetes versions currently available in Amazon EKS and can be run using kubectl, a standard open source tool for checking configuration using the CIS benchmark on Kubernetes clusters.

To learn more, see Introducing The CIS Amazon EKS Benchmark.
Amazon EKS platform versions represent the capabilities of the cluster control plane, including which Kubernetes API server flags are enabled and the current Kubernetes patch version. New clusters are deployed with the latest platform version. For details, see Amazon EKS platform versions (p. 75).

You can update an Amazon EKS cluster (p. 32) to newer Kubernetes versions. As new Kubernetes versions become available in Amazon EKS, we recommend that you proactively update your clusters to use the latest available version. For more information about Kubernetes versions in EKS, see Amazon EKS Kubernetes versions (p. 66).

Track security or privacy events for Amazon Linux 2 at the Amazon Linux Security Center or subscribe to the associated RSS feed. Security and privacy events include an overview of the issue affected, packages, and instructions for updating your instances to correct the issue.

You can use Amazon Inspector to check for unintended network accessibility of your nodes and for vulnerabilities on those Amazon EC2 instances.

Security best practices for Amazon EKS

Amazon EKS security best practices are maintained on Github: https://aws.github.io/aws-eks-best-practices/security/docs/

Pod security policy

The Kubernetes pod security policy admission controller validates pod creation and update requests against a set of rules. By default, Amazon EKS clusters ship with a fully permissive security policy with no restrictions. For more information, see Pod Security Policies in the Kubernetes documentation.

Note
This feature is deprecated in Kubernetes version 1.21 and is scheduled for removal in version 1.25. To learn more, see PodSecurityPolicy Deprecation: Past, Present, and Future on the Kubernetes blog and Using Gatekeeper as a drop-in Pod Security Policy replacement in Amazon EKS on the AWS blog. It is replaced with the Pod Security Admission feature in version 1.23.

To learn more about this feature, see Pod Security Standards (PSS) and Pod Security Admission (PSA) in the Amazon EKS best practices guide.

Amazon EKS default pod security policy

Amazon EKS clusters with Kubernetes version 1.13 and higher have a default pod security policy named eks.privileged. This policy has no restriction on what kind of pod can be accepted into the system, which is equivalent to running Kubernetes with the PodSecurityPolicy controller disabled.

Note
This policy was created to maintain backwards compatibility with clusters that did not have the PodSecurityPolicy controller enabled. You can create more restrictive policies for your cluster and for individual namespaces and service accounts and then delete the default policy to enable the more restrictive policies.

You can view the default policy with the following command.

```
kubectl get psp eks.privileged
```

The example output is as follows.
Delete default policy

For more details, you can describe the policy with the following command.

```
kubectl describe psp eks.privileged
```

The example output is as follows.

```
Name:  eks.privileged
Settings:
  Allow Privileged:                       true
  Allow Privilege Escalation:             0xc0004ce5f8
  Default Add Capabilities:               <none>
  Required Drop Capabilities:             <none>
  Allowed Capabilities:                   *
  Allowed Volume Types:                   *
  Allow Host Network:                     true
  Allow Host Ports:                       0-65535
  Allow Host FID:                         true
  Allow Host IPC:                         true
  Read Only Root Filesystem:              false
  SELinux Context Strategy: RunAsAny
    User:                                 <none>
    Role:                                 <none>
    Type:                                 <none>
    Level:                                <none>
  Run As User Strategy: RunAsAny
    Ranges:                               <none>
  FSGroup Strategy: RunAsAny
    Ranges:                               <none>
  Supplemental Groups Strategy: RunAsAny
    Ranges:                               <none>
```

You can view the full YAML file for the `eks.privileged` pod security policy, its cluster role, and cluster role binding in Install or restore the default pod security policy (p. 497).

Delete the default Amazon EKS pod security policy

If you create more restrictive policies for your pods, then after doing so, you can delete the default Amazon EKS `eks.privileged` pod security policy to enable your custom policies.

**Important**

If you are using version 1.7.0 or later of the CNI plugin and you assign a custom pod security policy to the `aws-node` Kubernetes service account used for the `aws-node` pods deployed by the Daemonset, then the policy must have `NET_ADMIN` in its `allowedCapabilities` section along with `hostNetwork: true` and `privileged: true` in the policy's `spec`.

**To delete the default pod security policy**

1. Create a file named `privileged-podsecuritypolicy.yaml` with the contents in the example file in Install or restore the default pod security policy (p. 497).
2. Delete the YAML with the following command. This deletes the default pod security policy, the ClusterRole, and the ClusterRoleBinding associated with it.
Install or restore the default pod security policy

If you are upgrading from an earlier version of Kubernetes, or have modified or deleted the default Amazon EKS eks.privileged pod security policy, you can restore it with the following steps.

To install or restore the default pod security policy

1. Create a file called privileged-podsecuritypolicy.yaml with the following contents.

```yaml
apiVersion: policy/v1beta1
kind: PodSecurityPolicy
metadata:
  name: eks.privileged
  annotations:
    kubernetes.io/description: 'privileged allows full unrestricted access to pod features, as if the PodSecurityPolicy controller was not enabled.'
    seccomp.security.alpha.kubernetes.io/allowedProfileNames: '*'
  labels:
    kubernetes.io/cluster-service: "true"
    eks.amazonaws.com/component: pod-security-policy
spec:
  privileged: true
  allowPrivilegeEscalation: true
  allowedCapabilities:
  - '*'
  volumes:
  - '*'
  hostNetwork: true
  hostPorts:
  - min: 0
  - max: 65535
  hostIPC: true
  hostPID: true
  runAsUser:
    rule: 'RunAsAny'
  seLinux:
    rule: 'RunAsAny'
  supplementalGroups:
  - rule: 'RunAsAny'
  fsGroup:
  - rule: 'RunAsAny'
  readOnlyRootFilesystem: false
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: eks:podsecuritypolicy:privileged
  labels:

2. Apply the YAML with the following command.

```bash
kubectl apply -f privileged-podsecuritypolicy.yaml
```

### Using AWS Secrets Manager secrets with Kubernetes

To show secrets from Secrets Manager and parameters from Parameter Store as files mounted in Amazon EKS pods, you can use the AWS Secrets and Configuration Provider (ASCP) for the Kubernetes Secrets Store CSI Driver.

With the ASCP, you can store and manage your secrets in Secrets Manager and then retrieve them through your workloads running on Amazon EKS. You can use IAM roles and policies to limit access to your secrets to specific Kubernetes pods in a cluster. The ASCP retrieves the pod identity and exchanges the identity for an IAM role. ASCP assumes the IAM role of the pod, and then it can retrieve secrets from Secrets Manager that are authorized for that role.

If you use Secrets Manager automatic rotation for your secrets, you can also use the Secrets Store CSI Driver rotation reconciler feature to ensure you are retrieving the latest secret from Secrets Manager.

For more information, see Using Secrets Manager secrets in Amazon EKS in the AWS Secrets Manager User Guide.

### Amazon EKS Connector considerations

The Amazon EKS Connector is an open source component that runs on your Kubernetes cluster. This cluster can be located outside of the AWS environment. This creates additional considerations for security responsibilities. This configuration can be illustrated by the following diagram. Orange represents AWS responsibilities, and blue represents customer responsibilities:
This topic describes the differences in the responsibility model if the connected cluster is outside of AWS.

**AWS responsibilities**

- Maintaining, building, and delivering Amazon EKS Connector, which is an open source component that runs on a customer’s Kubernetes cluster and communicates with AWS.
- Maintaining transport and application layer communication security between the connected Kubernetes cluster and AWS services.

**Customer responsibilities**

- Kubernetes cluster specific security, specifically along the following lines:
  - Kubernetes Secrets must be properly encrypted and protected.
  - Lock down access to the eks-connector namespace.
  - Configuring role-based access control (RBAC) permissions to manage user access from AWS. For instructions, see [Granting access to a user to view a cluster](#).
- Installing and upgrading Amazon EKS Connector.
- Maintaining the hardware, software, and infrastructure that supports the connected Kubernetes cluster.
- Securing their AWS accounts (for example, through using secure root user credentials).
View Kubernetes resources

You can view the Kubernetes resources deployed to your cluster with the AWS Management Console. You can't view Kubernetes resources with the AWS CLI or eksctl (p. 10). To view Kubernetes resources using a command-line tool, use kubectl (p. 4).

Prerequisite

To view the Resources tab and Nodes section on the Compute tab in the AWS Management Console, the user that you're signed into the AWS Management Console as, or the role that you switch to once you're signed in, must have specific IAM and Kubernetes permissions. For more information, see Required permissions (p. 500).

To view Kubernetes resources with the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the Clusters list, select the cluster that contains the Kubernetes resources that you want to view.
3. Select the Resources tab.
4. Select a Resource type group that you want to view resources for, such as Workloads. You see a list of resource types in that group.
5. Select a resource type, such as Deployments, in the Workloads group. You see a description of the resource type, a link to the Kubernetes documentation for more information about the resource type, and a list of resources of that type that are deployed on your cluster. If the list is empty, then there are no resources of that type deployed to your cluster.
6. Select a resource to view more information about it. Try the following examples:
   - Select the Workloads group, select the Deployments resource type, and then select the coredns resource. When you select a resource, you are in Structured view, by default. For some resource types, you see a Pods section in Structured view. This section lists the pods managed by the workload. You can select any pod listed to view information about the pod. Not all resource types display information in Structured View. If you select Raw view in the top right corner of the page for the resource, you see the complete JSON response from the Kubernetes API for the resource.
   - Select the Cluster group and then select the Nodes resource type. You see a list of all nodes in your cluster. The nodes can be any Amazon EKS node type (p. 94). This is the same list that you see in the Nodes section when you select the Compute tab for your cluster. Select a node resource from the list. In Structured view, you also see a Pods section. This section shows you all pods running on the node.

Required permissions

To view the Resources tab and Nodes section on the Compute tab in the AWS Management Console, the user that you're signed into the AWS Management Console as, or the role that you switch to once you're signed in, must have specific minimum IAM and Kubernetes permissions. Complete the following steps to assign the required permissions to your users and roles.

1. Make sure that the eks:AccessKubernetesApi, and other necessary IAM permissions to view Kubernetes resources, are assigned to either the user that you sign into the AWS Management
Console with, or the role that you switch to once you’ve signed in to the console. For more information about how to edit permissions for a user, see Changing permissions for a user (console) in the IAM User Guide. For more information about how to edit permissions for a role, see Modifying a role permissions policy (console) in the IAM User Guide.

The following example policy includes the necessary permissions for a user or role to view Kubernetes resources for all clusters in your account. Replace `111122223333` with your account ID.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "eks:ListFargateProfiles",
                "eks:DescribeNodegroup",
                "eks:ListNodegroups",
                "eks:ListUpdates",
                "eks:AccessKubernetesApi",
                "eks:ListAddons",
                "eks:DescribeCluster",
                "eks:DescribeAddonVersions",
                "eks:ListClusters",
                "eks:ListIdentityProviderConfigs",
                "iam:ListRoles"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "ssm:GetParameter",
            "Resource": "arn:aws:ssm:*:111122223333:parameter/*"
        }
    ]
}
```

To view nodes in connected clusters, the Amazon EKS connector IAM role (p. 468) should be able to impersonate the IAM user or role in the cluster. This allows the Amazon EKS Connector (p. 540) to map the IAM user or role to a Kubernetes user.

2. Create a Kubernetes rolebinding or clusterrolebinding that is bound to a Kubernetes role or clusterrole that has the necessary permissions to view the Kubernetes resources. To learn more about Kubernetes roles and role bindings, see Using RBAC Authorization in the Kubernetes documentation. You can apply one of the following manifests to your cluster that create a role and rolebinding or a clusterrole and clusterrolebinding with the necessary Kubernetes permissions:

- **View Kubernetes resources in all namespaces** – The group name in the file is eks-console-dashboard-full-access-group. Apply the manifest to your cluster with the following command:

  ```
  kubectl apply -f https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-full-access.yaml
  ```

- **View Kubernetes resources in a specific namespace** – The namespace in this file is default. The group name in the file is eks-console-dashboard-restricted-access-group. Apply the manifest to your cluster with the following command:

  ```
  kubectl apply -f https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-restricted-access.yaml
  ```
If you need to change the Kubernetes group name, namespace, permissions, or any other configuration in the file, then download the file and edit it before applying it to your cluster:

1. Download the file with one of the following commands:

```
curl -o eks-console-full-access.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-full-access.yaml
```

```
curl -o eks-console-restricted-access.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-restricted-access.yaml
```

2. Edit the file as necessary.

3. Apply the manifest to your cluster with one of the following commands:

```
kubectl apply -f eks-console-full-access.yaml
```

```
kubectl apply -f eks-console-restricted-access.yaml
```

3. Map the IAM user or role to the Kubernetes user or group in the `aws-auth` ConfigMap. You can use a tool such as `eksctl` to update the ConfigMap or you can update it manually by editing it.

**Important**

We recommend using `eksctl`, or another tool, to edit the ConfigMap. For information about other tools you can use, see Use tools to make changes to the `aws-authConfigMap` in the Amazon EKS best practices guides. An improperly formatted `aws-auth` ConfigMap can cause you to lose access to your cluster.

```
eksctl
```

**Prerequisite**

Version 0.112.0 or later of the `eksctl` command line tool installed on your device or AWS CloudShell. To install or update `eksctl`, see Installing or updating `eksctl` (p. 10).

1. View the current mappings in the ConfigMap. Replace `my-cluster` with the name of your cluster. Replace `region-code` with the AWS Region that your cluster is in.

```
eksctl get iamidentitymapping --cluster my-cluster --region=region-code
```

The example output is as follows.

<table>
<thead>
<tr>
<th>ARN</th>
<th>ACCOUNT</th>
<th>USERNAME</th>
<th>GROUPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>arn:aws:iam::11112223333:role/eksctl-my-cluster-my-nodegroup-NodeInstanceRole-1XLS754U3ZPA</td>
<td>system:node:{EC2PrivateDNSName}</td>
<td>system:bootstrappers,system:nodes</td>
<td></td>
</tr>
</tbody>
</table>

2. Add a mapping for a role. This example assume that you attached the IAM permissions in the first step to a role named `my-console-viewer-role`. Replace `11112223333` with your account ID.

```
eksctl create iamidentitymapping \
  --cluster my-cluster \
  --region=region-code \
```
Required permissions

```
--arn arn:aws:iam::111122223333:role/my-console-viewer-role \
--group eks-console-dashboard-full-access-group \
--no-duplicate-arns
```

Important

The role ARN can't include a path such as `role/my-team/developers/my-role`. The format of the ARN must be `arn:aws:iam::111122223333:role/my-role`. In this example, `my-team/developers/` needs to be removed.

The example output is as follows.

```
```

3. Add a mapping for a user. This example assume that you attached the IAM permissions in the first step to a user named `my-user`. Replace `111122223333` with your account ID.

```
eksctl create iamidentitymapping \
   --cluster my-cluster \
   --region=region-code \
   --arn arn:aws:iam::111122223333:user/my-user \
   --group eks-console-dashboard-restricted-access-group \
   --no-duplicate-arns
```

The example output is as follows.

```
2022-05-09 14:53:48 [✓]  adding identity "arn:aws:iam::111122223333:user/my-user" to auth ConfigMap
```

4. View the mappings in the ConfigMap again.

```
eksctl get iamidentitymapping --cluster my-cluster --region=region-code
```

The example output is as follows.

```
<table>
<thead>
<tr>
<th>ARN</th>
<th>USERNAME</th>
<th>ACCOUNT</th>
<th>GROUPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>arn:aws:iam::111122223333:role/my-console-viewer-role</td>
<td></td>
<td></td>
<td>eks-console-dashboard-full-access-group</td>
</tr>
<tr>
<td>arn:aws:iam::111122223333:user/my-user</td>
<td></td>
<td></td>
<td>eks-console-dashboard-restricted-access-group</td>
</tr>
</tbody>
</table>
```

Edit ConfigMap manually

For more information about adding users or roles to the `aws-auth` ConfigMap, see Add IAM users, roles, or AWS accounts to the ConfigMap (p. 382).

1. Open the ConfigMap for editing.
**Required permissions**

2. Add the mappings to the `aws-auth` ConfigMap, but don't replace any of the existing mappings. The following example adds mappings between IAM users and roles with permissions added in the first step and the Kubernetes groups created in the previous step:

- The `my-console-viewer-role` role and the `eks-console-dashboard-full-access-group`.
- The `my-user` user and the `eks-console-dashboard-restricted-access-group`.

These examples assume that you attached the IAM permissions in the first step to a role named `my-console-viewer-role` and a user named `my-user`. Replace `111122223333` with your account ID.

```yaml
apiVersion: v1
data:
  mapRoles: |
    - groups:
      - eks-console-dashboard-full-access-group
        rolearn: arn:aws:iam::111122223333:role/my-console-viewer-role
        username: my-console-viewer-role
  mapUsers: |
    - groups:
      - eks-console-dashboard-restricted-access-group
        userarn: arn:aws:iam::111122223333:user/my-user
        username: my-user
```

**Important**

The role ARN can't include a path such as `role/my-team/developers/my-console-viewer-role`. The format of the ARN must be `arn:aws:iam::111122223333:role/my-console-viewer-role`. In this example, `my-team/developers/` needs to be removed.

3. Save the file and exit the editor.
Observability in Amazon EKS

You can observe your data in Amazon EKS using many available monitoring or logging tools. With a Fargate log router configured, your Amazon EKS log data can be streamed to AWS services or to partner tools for data analysis. These AWS services are available in the AWS Management Console. You can monitor your Amazon EKS resources using Amazon CloudWatch. This topic describes the available functions and formats in Amazon EKS. There are many services available in the AWS Management Console that provide data for troubleshooting your Amazon EKS issues. For an overview of these services, see AWS Management Console documentation.

You can view cluster health and details by selecting your cluster’s name after selecting Clusters in the left navigation pane of the Amazon EKS console. To view details about any existing Kubernetes resources that are deployed to your cluster, see View Kubernetes resources (p. 500).

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon EKS and your AWS solutions. We recommend that you collect monitoring data from all of the parts of your AWS solution. That way, you can more easily debug a multi-point failure if one occurs. Before you start monitoring Amazon EKS, make sure that a monitoring plan that addresses the following questions.

- What are your goals? Do you need real-time notifications if your clusters scale dramatically?
- What resources need to be observed?
- How frequently do you need to observe these resources? Does your company want to respond quickly to risks?
- What tools do you intend to use? If you already run Fargate as part of your launch, then you can use the built-in log router.
- Who do you intend to perform the monitoring tasks?
- Whom do you want notifications to be sent to when something goes wrong?

Logging and monitoring in Amazon EKS

Amazon EKS provides built-in tools for logging and monitoring. You can choose your logging level which starts at the control plane. Control plane logging records all API calls to your clusters, audit information capturing what users performed what actions to your clusters, as well as role-based logs.

Amazon EKS control plane logging provides audit and diagnostic logs directly from the Amazon EKS control plane to CloudWatch Logs in your account. These logs make it easy for you to secure and run your clusters. You can select the exact log types you need, and logs are sent as log streams to a group for each Amazon EKS cluster in CloudWatch. For more information, see Amazon EKS Control Plane Logging (p. 51) and Amazon CloudWatch logging.

Note
When you check the Amazon EKS authenticator logs in Amazon CloudWatch, the entries are displayed that contain text similar to the following example text.

```
level=info msg="mapping IAM role" groups="[]"
role="arn:aws:iam::11112223333:role/YYYYYYYYYYYYYYYY-NodeManagerRole-YYYYYYYYYYYYYYYY"
username="eks:node-manager"
```

Entries that contain this text are expected. The username is an Amazon EKS internal service role that performs specific operations for managed node groups and Fargate.
For low-level, customizable logging, then Kubernetes logging is available.
Amazon EKS is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Amazon EKS. CloudTrail captures all API calls for Amazon EKS as events. The calls captured include calls from the Amazon EKS console and code calls to the Amazon EKS API operations. For more information, see Logging Amazon EKS API calls with AWS CloudTrail (p. 508).

The Kubernetes API server exposes a number of metrics that are useful for monitoring and analysis. For more information, see Control plane metrics with Prometheus (p. 408).

To configure Fluent Bit for custom Amazon CloudWatch logs, see Set up Fluent Bit as a DaemonSet to send logs to Amazon CloudWatch Logs in the Amazon CloudWatch user guide.

Amazon EKS logging and monitoring tools

Amazon Web Services provides various tools that you can use to monitor Amazon EKS. You can configure some tools to set up automatic monitoring, but some require manual calls. We recommend that you automate monitoring tasks as much as your environment and existing toolset allows.

Logging

<table>
<thead>
<tr>

Amazon EKS User Guide

Logging Amazon EKS API calls with AWS CloudTrail

Amazon EKS is integrated with AWS CloudTrail, a service that provides a record of actions that's taken by a user, role, or an AWS service in Amazon EKS. CloudTrail captures all API calls for Amazon EKS as events. This includes calls from the Amazon EKS console and from code calls to the Amazon EKS API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket. This includes events for Amazon EKS. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information that CloudTrail collects, you can determine several details about a request. For example, you can determine when the request was made to Amazon EKS, the IP address where the request was made from, and who made the request.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Amazon EKS information in CloudTrail

When you create your AWS account, CloudTrail is also enabled on your AWS account. When any activity occurs in Amazon EKS, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing events with CloudTrail event history.

For an ongoing record of events in your AWS account, including events for Amazon EKS, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data that's collected in CloudTrail logs. For more information, see the following resources.

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple regions and Receiving CloudTrail log files from multiple accounts

All Amazon EKS actions are logged by CloudTrail and are documented in the Amazon EKS API Reference. For example, calls to the CreateCluster, ListClusters and DeleteCluster sections generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. You can use the identity information to determine the following information.

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity element.

Understanding Amazon EKS log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from
any source and includes information about the requested action. This include information such as the date and time of the action and the request parameters that were used. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the CreateCluster action.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AKIAIOSFODNN7EXAMPLE",
    "arn": "arn:aws:iam::111122223333:user/username",
    "accountId": "111122223333",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "userName": "username"
  },
  "eventSource": "eks.amazonaws.com",
  "eventName": "CreateCluster",
  "awsRegion": "region-code",
  "sourceIPAddress": "205.251.233.178",
  "userAgent": "PostmanRuntime/6.4.0",
  "requestParameters": {
    "resourcesVpcConfig": {
      "subnetIds": [
        "subnet-a670c2df",
        "subnet-4f8c5004"
      ],
    },
    "roleArn": "arn:aws:iam::111122223333:role/AWSServiceRoleForAmazonEKS-CAC1G1VH3ZKZ",
    "clusterName": "test"
  },
  "responseElements": {
    "cluster": {
      "clusterName": "test",

      "createdAt": 1527535003.208,
      "roleArn": "arn:aws:iam::111122223333:role/AWSServiceRoleForAmazonEKS-CAC1G1VH3ZKZ",
      "version": "1.10",
      "resourcesVpcConfig": {
        "securityGroupIds": [],
        "vpcId": "vpc-21277358",
        "subnetIds": [
          "subnet-a670c2df",
          "subnet-4f8c5004"
        ]
      }
    },
    "requestID": "a7a0735d-62ab-11e8-9f79-81ce5b2b7d37",
    "eventID": "eab22523-174a-499c-9dd6-91e7be3ff8e3",
    "readOnly": false,
    "eventType": "AwsApiCall",
    "recipientAccountId": "111122223333"
  }
}
```

Log Entries for Amazon EKS Service Linked Roles

The Amazon EKS service linked roles make API calls to AWS resources. CloudTrail log entries with username: AWSServiceRoleForAmazonEKS and username: AWSServiceRoleForAmazonEKSNodegroup appears for calls made by the Amazon EKS service linked
Amazon EKS add-on support for ADOT Operator

Amazon EKS supports using the AWS Management Console, AWS CLI and Amazon EKS API to install and manage the AWS Distro for OpenTelemetry (ADOT) Operator. This enables a simplified experience for instrumenting your applications running on Amazon EKS to send metric and trace data to multiple monitoring service options like Amazon CloudWatch, Prometheus, and X-Ray. This topic describes how to get started using ADOT for applications running on your Amazon EKS cluster.

- Prerequisites (p. 511)
- Creating an IAM role (p. 512)
• Installing the add-on (p. 512)
• Deploying the ADOT Collector (p. 515) for your preferred monitoring option
• Deploying a sample application (p. 517) to generate OTLP data

Before installing ADOT, ensure that you have read and understand the prerequisites and considerations (p. 511).

AWS Distro for OpenTelemetry (ADOT) prerequisites and considerations

Before installing the AWS Distro for OpenTelemetry (ADOT) add-on, you must meet the following prerequisites and considerations.

• Connected clusters can't use this add-on.
• Meet the TLS certificate requirement (p. 511) to ensure end-to-end encryption.
• Grant permissions to Amazon EKS add-ons to install ADOT:

```
kubectl apply -f https://amazon-eks.s3.amazonaws.com/docs/addons-otel-permissions.yaml
```

TLS certificate requirement

The ADOT Operator uses admission webhooks to mutate and validate the Collector Custom Resource (CR) requests. In Kubernetes, the webhook requires a TLS certificate that the API server is configured to trust. There are multiple ways for you to generate the required TLS certificate. However, the default method is to install the latest version of the cert-manager manually. The cert-manager generates a self-signed certificate.

Installing cert-manager

1. Install cert-manager using the following command. This creates the necessary cert-manager objects that allow end-to-end encryption. This must be done for each cluster that will have ADOT installed.

```
kubectl apply -f https://github.com/cert-manager/cert-manager/releases/download/v1.8.2/cert-manager.yaml
```

2. Verify that cert-manager is ready using the following command.

```
kubectl get pod -w -n cert-manager
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>cert-manager-5597cff495-mnb2p</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>12d</td>
</tr>
<tr>
<td>cert-manager-cainjector-bd5f9c764-8jp5g</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>12d</td>
</tr>
<tr>
<td>cert-manager-webhook-5f57f59fbc-h9st8</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>12d</td>
</tr>
</tbody>
</table>
Create an IAM role

Each cluster where you install AWS Distro for OpenTelemetry (ADOT) (p. 512) must have this role to grant your AWS service account permissions. Follow these steps to create and associate your IAM role to your Amazon EKS service account using IRSA (p. 425):

1. Creating an IAM OIDC provider for your cluster (p. 426).
2. Create your service account and IAM role. Note the following flags included in this command:
   - For the `--name` flag, specify the name of the service account you want to create. In this example, it is `adot-collector`.
   - For the `--namespace` flag, specify the namespace your service account will reside in; for this example you will use the `default` namespace.
   - For the `--cluster` flag, specify the name of your cluster.
   - Use the `--attach-policy-arn` parameter to specify the managed IAM policy for the integration you are using to the role. For example, if you are using ADOT Collector to send metric data to CloudWatch, you specify the CloudWatchAgentServerPolicy managed policy.
   - The `--override-existing-serviceaccounts` flag is for a service account already created in the cluster without an IAM role. You can exclude this if the service account does not have an IAM role.

   Enter the following command considering the previous notes:

   ```bash
   eksctl create iamserviceaccount
   --name adot-collector
   --namespace default
   --cluster my-cluster
   --attach-policy-arn arn:aws:iam::aws:policy/AmazonPrometheusRemoteWriteAccess
   --attach-policy-arn arn:aws:iam::aws:policy/AWSXrayWriteOnlyAccess
   --attach-policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
   --approve
   --override-existing-serviceaccounts
   ```

   In the following collector configurations, the `serviceAccount: adot-collector` field to the configuration has been added to use IRSA.

Manage the AWS Distro for OpenTelemetry Operator

The AWS Distro for OpenTelemetry (ADOT) Operator is available as an Amazon EKS add-on. After installing the ADOT Operator, you can configure the ADOT Collector to specify the deployment type and the service that will receive your application metric or trace data. This topic describes how to manage the ADOT add-on.

- Install the AWS Distro for OpenTelemetry (ADOT) Operator (p. 512)
- Update the AWS Distro for OpenTelemetry (ADOT) Operator (p. 513)
- Remove the AWS Distro for OpenTelemetry (ADOT) Operator (p. 514)

To install the ADOT Collector, see Deploy the AWS Distro for OpenTelemetry Collector (p. 515).

Install the AWS Distro for OpenTelemetry (ADOT) Operator

Installing the ADOT add-on includes the ADOT Operator, which in turn deploys the ADOT Collector. The ADOT Operator is a custom controller which introduces a new object type called the
OpenTelemetryCollector through CustomResourceDefinition (CRD). When the ADOT Operator detects the presence of the OpenTelemetryCollector resource, then it installs the ADOT Collector.

Prerequisites

- You have met the ADOT prerequisites (p. 511).
- kubectl is installed.
- Update your kubeconfig if necessary using the following command.

```
aws eks update-kubeconfig --name my-cluster --region region-code
```
- eksctl is installed.
- AWS CLI version 2 is installed.
- An existing Amazon EKS cluster.
- An existing Amazon EKS service IAM role. If you don't have the role, you can follow Create an IAM role (p. 512) to create one.

AWS Management Console

Install the ADOT Amazon EKS add-on to your Amazon EKS cluster using the following steps:

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left pane, select Clusters, and then select the name of your cluster on the Clusters page.
3. Choose the Add-ons tab.
4. Click Add new and select AWS Distro for OpenTelemetry from the drop-down list.
5. The default version will be selected in the Version drop-down. Click Override existing configuration for this add-on on the cluster if a service account is already created in the cluster without an IAM Role.
6. Click Add.

AWS CLI

1. Install the ADOT Amazon EKS add-on to your Amazon EKS cluster using the command:

```
aws eks create-addon --addon-name adot --cluster-name my-cluster
```

The status field value will be CREATING until complete.

2. Verify that ADOT is installed and running using the command:

```
aws eks describe-addon --addon-name adot --cluster-name my-cluster
```

You'll see "status": "ACTIVE" when creation is complete.

Update the AWS Distro for OpenTelemetry (ADOT) Operator

Amazon EKS does not automatically update ADOT on your cluster. You must initiate the update and then Amazon EKS updates the Amazon EKS add-on for you.

To update the ADOT Amazon EKS add-on using the AWS CLI

1. Check the current version of your ADOT add-on. Replace my-cluster with your cluster name.
aws eks describe-addon \
  --cluster-name my-cluster \
  --addon-name adot \
  --query "addon.addonVersion" \
  --output text

2. Determine the ADOT versions are available that are supported by your cluster's version.

aws eks describe-addon-versions \
  --addon-name adot \
  --kubernetes-version 1.19 \
  --query "addons[].addonVersions[].[addonVersion, compatibilities[]].defaultVersion" \
  --output text

The example output is as follows.

```
1.8.0
True
1.7.0
False
```

The version with True underneath is the default version deployed with new clusters. Later versions can be returned and updated, if necessary.

3. To update the ADOT version, use the following command and replace the addon-version value with the desired version.

aws eks update-addon \
  --cluster-name my-cluster \
  --addon-name adot \
  --addon-version 1.8.0 \
  --resolve-conflicts OVERWRITE

**Note**
The --resolve-conflicts OVERWRITE option will resolve any conflicts with Amazon EKS add-on settings by overwriting your settings. Ensure that your settings don't require management. Without this option, conflicts must be resolved manually. For more information, see Amazon EKS add-on configuration (p. 368).

**Remove the AWS Distro for OpenTelemetry (ADOT) Operator**

- You must delete the ADOT Collector resource separately from the ADOT Collector. In this command, specify the YAML file that you used to deploy the ADOT Collector:

  ```
kubectl delete -f collector-config.yaml
  ```

- You can remove the ADOT Operator through either the AWS CLI or eksctl. If you remove the ADOT Operator, you must follow the installation instructions (p. 512) again to reinstall:

  **CLI**

  ```
aws eks delete-addon --addon-name adot --cluster-name my-cluster
  ```

  ```
eksctl
  ```
Deploy the AWS Distro for OpenTelemetry Collector

Once the AWS Distro for OpenTelemetry (ADOT) Operator is installed (p. 512) and running, you can deploy the ADOT Collector into your Amazon EKS cluster. The ADOT Collector can be deployed in one of four modes: Deployment, Daemonset, StatefulSet, and Sidecar and can be deployed for visibility by an individual service. For more information on these deployment modes, see the ADOT Collector installation instructions on Github.

You can deploy the ADOT Collector by applying a YAML file to your cluster. You should have already installed the ADOT Operator (p. 512). You can Create an IAM role (p. 512) with your Amazon EKS service account using IRSA (p. 425). By doing this, your service account can provide AWS permissions to the containers you run in any pod that uses that service account.

We provide ADOT Collector examples for the following services (in deployment modes):
- Prometheus (p. 515)
- Amazon CloudWatch (p. 516)
- X-Ray (p. 516)

Deploy the AWS Distro for OpenTelemetry Collector for Amazon Managed Service for Prometheus in deployment mode

The following procedure uses an example YAML file with deployment as the mode value. This is the default mode and deploys the ADOT Collector similarly to a standalone application. This configuration receives OTLP metrics from the sample application and Amazon Managed Service for Prometheus metrics scraped from pods on the cluster. You can change the mode to Daemonset, StatefulSet, and Sidecar depending on your deployment strategy. For a Daemonset deployment, see Advanced Collector Configuration for Amazon Managed Prometheus in the ADOT documentation or click here to download the DaemonSet example.

1. Download the collector-config-amp.yaml file to your computer. You can also view the file on GitHub.

   ```
   ```

2. In collector-config-amp.yaml, replace the following with your own values:

   ```
   mode: deployment
   serviceAccount: adot-collector
   endpoint: "<YOUR_REMOTE_WRITE_ENDPOINT>"
   region: "<YOUR_AWS_REGION>"
   name: adot-collector
   ```

3. Apply the YAML file to your cluster to deploy the ADOT Collector:

   ```
   kubectl apply -f collector-config-amp.yaml
   ```
Deploy the AWS Distro for OpenTelemetry Collector for CloudWatch

The AWS Distro for OpenTelemetry (ADOT) Collector can be deployed to receive OTLP metrics for export to Amazon CloudWatch. This procedure downloads an example YAML file that you can apply to your cluster.

1. Download the `collector-config-cloudwatch.yaml` file to your computer. You can also view the file on GitHub.

   ```
   ```

2. In `collector-config-cloudwatch.yaml`, replace the following with your own values:
   - mode: `deployment`
   - serviceAccount: `adot-collector`
   - value: `<YOUR_EKS_CLUSTER_NAME>`
   - region: `"<YOUR_AWS_REGION>"
   - name: `adot-collector`

3. Apply the YAML file to your cluster to deploy the ADOT Collector:

   ```
kubectl apply -f collector-config-cloudwatch.yaml
   ```

4. (Optional) Verify the metrics data is being sent to Amazon CloudWatch by opening the Amazon CloudWatch console and open the Metrics menu on the left. Select All metrics and click the `AOCDockerDemo/AOCDockerDemoService` box under custom namespaces. You can view any metrics data by selecting any grouping.

Deploy the AWS Distro for OpenTelemetry (ADOT) Collector for X-Ray

You can deploy the AWS Distro for OpenTelemetry (ADOT) Collector to send traces to X-Ray by applying a YAML configuration file. This procedure downloads an example YAML file that you can apply to your cluster.

1. Download the `collector-config-xray.yaml` file to your computer. You can also view the file on GitHub.

   ```
   ```

2. In `collector-config-xray.yaml`, replace the following with your own values:
   - mode: `deployment`
   - serviceAccount: `adot-collector`
   - region: `"<YOUR_AWS_REGION>"

3. Apply the YAML file to your cluster to deploy the ADOT Collector:

   ```
kubectl apply -f collector-config-xray.yaml
   ```
4. (Optional) Verify trace data is being sent to X-Ray by opening the X-Ray console and select Traces from the left menu. Your trace data should be present.

**Deploy a sample application to test the AWS Distro for OpenTelemetry Collector**

The sample application will generate and send OTLP data to any of the services that you have configured through the AWS Distro for OpenTelemetry (ADOT) Collector deployment (p. 515). This step is optional if you already have an application running inside your cluster that can produce data. Consult your application’s documentation to ensure that data is sent to the correct endpoints.

The sample application and traffic generator were largely taken from an example in the ADOT Collector repository. A docker-compose.yaml file was translated to Kubernetes resources using the Kompose tool.

To apply the traffic generator and sample application, do the following steps.

1. Download the traffic-generator.yaml file to your computer. You can also view the file on GitHub.

   ```bash
   ```

2. In traffic-generator.yaml, make sure that the kind value reflects your deployment mode:

   ```yaml
   kind: Deployment
   ```

   traffic-generator.yaml makes http calls to the Kubernetes service sample-app:4567. This allows the traffic generator to interact with the sample application on port 4567. sample-app resolves to the IP address of the sample-app pod.

3. Apply traffic-generator.yaml to your cluster.

   ```bash
   kubectl apply -f traffic-generator.yaml
   ```

4. Download the sample-app.yaml file to your computer. You can also view the file on GitHub.

   ```bash
   ```

5. In sample-app.yaml, replace the following with your own AWS Region:

   ```yaml
   value: "<YOUR_AWS_REGION>"
   ```

The following actions are defined by sample-app.yaml:

- The Service resource configures port: 4567 to allow HTTP requests for the traffic generator.
- The Deployment resource configures some environment variables:
  - The LISTEN_ADDRESS is configured to 0.0.0.0:4567 for HTTP requests from the traffic generator.
  - The OTEL_EXPORTER_OTLP_ENDPOINT has a value of http://my-collector-collector:4317. my-collector-collector is the name of the Kubernetes service that allows the sample application to interact with the ADOT Collector on port 4317. In the ADOT Collector configuration, the ADOT Collector receives metrics and traces from an endpoint: 0.0.0.0:4317.
6. Apply `sample-app.yaml` to your cluster.

```
kubectl apply -f sample-app.yaml
```
Creating Amazon EKS resources with AWS CloudFormation

Amazon EKS is integrated with AWS CloudFormation, a service that helps you model and set up your AWS resources so that you can spend less time creating and managing your resources and infrastructure. You create a template that describes all the AWS resources that you want, for example an Amazon EKS cluster, and AWS CloudFormation takes care of provisioning and configuring those resources for you.

When you use AWS CloudFormation, you can reuse your template to set up your Amazon EKS resources consistently and repeatedly. Just describe your resources once, and then provision the same resources over and over in multiple AWS accounts and Regions.

Amazon EKS supports creating clusters and node groups in AWS CloudFormation. For more information, including examples of JSON and YAML templates for your Amazon EKS resources, see Amazon EKS resource type reference in the AWS CloudFormation User Guide.

Learn more about AWS CloudFormation

To learn more about AWS CloudFormation, see the following resources:

- AWS CloudFormation
- AWS CloudFormation User Guide
- AWS CloudFormation Command Line Interface User Guide
Use AWS App Mesh with Kubernetes

AWS App Mesh (App Mesh) is a service mesh that makes it easy to monitor and control services. App Mesh standardizes how your services communicate, giving you end-to-end visibility and helping to ensure high availability for your applications. App Mesh gives you consistent visibility and network traffic controls for every service in an application. You can get started using App Mesh with Kubernetes by completing the Getting started with AWS App Mesh and Kubernetes tutorial in the AWS App Mesh User Guide. The tutorial recommends that you have existing services deployed to Kubernetes that you want to use App Mesh with.

Amazon EKS and AWS Local Zones

An AWS Local Zone is an extension of an AWS Region in geographic proximity to your users. Local Zones have their own connections to the internet and support AWS Direct Connect. Resources created in a Local Zone can serve local users with low-latency communications. For more information, see Local Zones.

Amazon EKS supports certain resources in Local Zones. This includes self-managed Amazon EC2 nodes (p. 121), Amazon EBS volumes, and Application Load Balancers (ALBs). We recommend that you consider the following when using Local Zones as part of your Amazon EKS cluster.

Nodes

You can't create managed node groups or Fargate nodes in Local Zones with Amazon EKS. However, you can create self-managed Amazon EC2 nodes in Local Zones using the Amazon EC2 API, AWS CloudFormation, or eksctl. For more information, see Self-managed nodes (p. 121).

Network architecture

- The Amazon EKS managed Kubernetes control plane always runs in the AWS Region. The Amazon EKS managed Kubernetes control plane can't run in the Local Zone. Because Local Zones appear as a subnet within your VPC, Kubernetes sees your Local Zone resources as part of that subnet.
- The Amazon EKS Kubernetes cluster communicates with the Amazon EC2 instances you run in the AWS Region or Local Zone using Amazon EKS managed elastic network interfaces. To learn more about Amazon EKS networking architecture, see Amazon EKS networking (p. 238).
- Unlike regional subnets, Amazon EKS can't place network interfaces into your Local Zone subnets. This means that you must not specify Local Zone subnets when you create your cluster.

Deep Learning Containers

AWS Deep Learning Containers are a set of Docker images for training and serving models in TensorFlow on Amazon EKS and Amazon Elastic Container Service (Amazon ECS). Deep Learning Containers provide optimized environments with TensorFlow, Nvidia CUDA (for GPU instances), and Intel MKL (for CPU instances) libraries and are available in Amazon ECR.

To get started using AWS Deep Learning Containers on Amazon EKS, see AWS Deep Learning Containers on Amazon EKS in the AWS Deep Learning AMI Developer Guide.
Amazon EKS troubleshooting

This chapter covers some common errors that you may see while using Amazon EKS and how to work around them.

Insufficient capacity

If you receive the following error while attempting to create an Amazon EKS cluster, then one of the Availability Zones you specified does not have sufficient capacity to support a cluster.

```
Cannot create cluster 'example-cluster' because region-1d, the targeted Availability Zone, does not currently have sufficient capacity to support the cluster. Retry and choose from these Availability Zones: region-1a, region-1b, region-1c
```

Retry creating your cluster with subnets in your cluster VPC that are hosted in the Availability Zones returned by this error message.

Nodes fail to join cluster

There are a few common reasons that prevent nodes from joining the cluster:

- The `aws-auth-cm.yaml` file doesn't have the correct IAM role ARN for your nodes. Ensure that the node IAM role ARN (not the instance profile ARN) is specified in your `aws-auth-cm.yaml` file. For more information, see Launching self-managed Amazon Linux nodes (p. 122).
- The `ClusterName` in your node AWS CloudFormation template doesn't exactly match the name of the cluster you want your nodes to join. Passing an incorrect value to this field results in an incorrect configuration of the node's `/var/lib/kubelet/kubeconfig` file, and the nodes will not join the cluster.
- The node is not tagged as being owned by the cluster. Your nodes must have the following tag applied to them, where `my-cluster` is replaced with the name of your cluster.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/cluster/my-cluster</td>
<td>owned</td>
</tr>
</tbody>
</table>

- The nodes may not be able to access the cluster using a public IP address. Ensure that nodes deployed in public subnets are assigned a public IP address. If not, you can associate an Elastic IP address to a node after it's launched. For more information, see Associating an Elastic IP address with a running instance or network interface. If the public subnet is not set to automatically assign public IP addresses to instances deployed to it, then we recommend enabling that setting. For more information, see Modifying the public IPv4 addressing attribute for your subnet. If the node is deployed to a private subnet, then the subnet must have a route to a NAT gateway that has a public IP address assigned to it.
- The STS endpoint for the AWS Region that you're deploying the nodes to is not enabled for your account. To enable the region, see Activating and deactivating AWS STS in an AWS Region.
- The worker node doesn't have a private DNS entry, resulting in the `kubelet` log containing a node "" not found error. Ensure that the VPC where the worker node is created has values set for `domain-name` and `domain-name-servers` as Options in a DHCP options set. The default values are `domain-name:<region>.compute.internal` and `domain-name-servers:AmazonProvidedDNS`. For more information, see DHCP options sets in the Amazon VPC User Guide.
To identify and troubleshoot common causes that prevent worker nodes from joining a cluster, you can use the AWS Support - Troubleshoot EKS Worker Node runbook. For more information, see AWS Support - Troubleshoot EKS Worker Node in the AWS Systems Manager Automation runbook reference.

Unauthorized or access denied (kubectl)

If you receive one of the following errors while running kubectl commands, then your kubectl is not configured properly for Amazon EKS or the IAM user or role credentials that you are using do not map to a Kubernetes RBAC user with sufficient permissions in your Amazon EKS cluster.

- could not get token: AccessDenied: Access denied
- error: You must be logged in to the server (Unauthorized)
- error: the server doesn't have a resource type "svc"

This could be because the cluster was created with one set of AWS credentials (from an IAM user or role), and kubectl is using a different set of credentials.

When an Amazon EKS cluster is created, the IAM entity (user or role) that creates the cluster is added to the Kubernetes RBAC authorization table as the administrator (with `system:masters` permissions). Initially, only that IAM user can make calls to the Kubernetes API server using kubectl. For more information, see Enabling IAM user and role access to your cluster (p. 381). If you use the console to create the cluster, you must ensure that the same IAM user credentials are in the AWS SDK credential chain when you are running kubectl commands on your cluster.

If you install and configure the AWS CLI, you can configure the IAM credentials for your user. For more information, see Configuring the AWS CLI in the AWS Command Line Interface User Guide.

If you assumed a role to create the Amazon EKS cluster, you must ensure that kubectl is configured to assume the same role. Use the following command to update your kubeconfig file to use an IAM role.

```
aws eks update-kubeconfig \
  --region region-code \
  --name my-cluster \
  --role-arn arn:aws:iam::111122223333:role/role_name
```

To map an IAM user to a Kubernetes RBAC user, see Enabling IAM user and role access to your cluster (p. 381).

aws-iam-authenticator Not found

If you receive the error "aws-iam-authenticator": executable file not found in $PATH, then your kubectl is not configured for Amazon EKS. For more information, see Installing aws-iam-authenticator (p. 396).

Note
The aws-iam-authenticator isn't required if you have the AWS CLI version 1.16.156 or higher installed.

hostname doesn't match

Your system's Python version must be 2.7.9 or later. Otherwise, you receive hostname doesn't match errors with AWS CLI calls to Amazon EKS. For more information, see What are "hostname doesn't match" errors? in the Python Requests FAQ.
getsockopt: no route to host

Docker runs in the 172.17.0.0/16 CIDR range in Amazon EKS clusters. We recommend that your cluster’s VPC subnets do not overlap this range. Otherwise, you will receive the following error:

```
```

Managed node group errors

If you receive the error “Instances failed to join the kubernetes cluster” in the AWS Management Console, ensure that either the cluster’s private endpoint access is enabled, or that you have correctly configured CIDR blocks for public endpoint access. For more information, see Amazon EKS cluster endpoint access control (p. 43).

If your managed node group encounters a hardware health issue, Amazon EKS returns an error message to help you to diagnose the issue. These health checks don’t detect software issues because they are based on Amazon EC2 health checks. The following list shows the error messages and their associated descriptions.

- **AccessDenied**: Amazon EKS or one or more of your managed nodes is failing to authenticate or authorize with your Kubernetes cluster API server. For more information about resolving this error, see Fixing AccessDenied errors for managed node groups (p. 524).

- **AmiIdNotFound**: We couldn’t find the AMI Id associated with your Launch Template. Make sure that the AMI exists and is shared with your account.

- **AutoScalingGroupNotFound**: We couldn’t find the Auto Scaling group associated with the managed node group. You may be able to recreate an Auto Scaling group with the same settings to recover.

- **ClusterUnreachable**: Amazon EKS or one or more of your managed nodes is unable to communicate with your Kubernetes cluster API server. This can happen if there are network disruptions or if API servers are timing out processing requests.

- **Ec2SecurityGroupNotFound**: We couldn’t find the cluster security group for the cluster. You must recreate your cluster.

- **Ec2SecurityGroupDeletionFailure**: We could not delete the remote access security group for your managed node group. Remove any dependencies from the security group.

- **Ec2LaunchTemplateNotFound**: We couldn’t find the Amazon EC2 launch template for your managed node group. You must recreate your node group to recover.

- **Ec2LaunchTemplateVersionMismatch**: The Amazon EC2 launch template version for your managed node group doesn’t match the version that Amazon EKS created. You may be able to revert to the version that Amazon EKS created to recover.

- **IamInstanceProfileNotFound**: We couldn’t find the IAM instance profile for your managed node group. You may be able to recreate an instance profile with the same settings to recover.

- **IamNodeRoleNotFound**: We couldn’t find the IAM role for your managed node group. You may be able to recreate an IAM role with the same settings to recover.

- **AsgInstanceLaunchFailures**: Your Auto Scaling group is experiencing failures while attempting to launch instances.

- **NodeCreationFailure**: Your launched instances are unable to register with your Amazon EKS cluster. Common causes of this failure are insufficient node IAM role (p. 461) permissions or lack of outbound internet access for the nodes. Your nodes must meet either of the following requirements:
  - Able to access the internet using a public IP address. The security group associated to the subnet the node is in must allow the communication. For more information, see the section called “Subnet requirements and considerations” (p. 239) and the section called “Security group requirements” (p. 245).
• Your nodes and VPC must meet the requirements in the section called “Private cluster requirements” (p. 63).

• **InstanceLimitExceeded**: Your AWS account is unable to launch any more instances of the specified instance type. You may be able to request an Amazon EC2 instance limit increase to recover.

• **InsufficientFreeAddresses**: One or more of the subnets associated with your managed node group doesn’t have enough available IP addresses for new nodes.

• **InternalFailure**: These errors are usually caused by an Amazon EKS server-side issue.

**Fixing AccessDenied errors for managed node groups**

The most common cause of AccessDenied errors when performing operations on managed node groups is missing the eks:node-manager ClusterRole or ClusterRoleBinding. Amazon EKS sets up these resources in your cluster as part of onboarding with managed node groups, and these are required for managing the node groups.

The ClusterRole may change over time, but it should look similar to the following example:

```yaml
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: eks:node-manager
rules:
- apiGroups:
  - ''
  resources:
  - pods
  verbs:
  - get
  - list
  - watch
  - delete
  - apiGroups:
    - ''
    resources:
    - nodes
    verbs:
    - get
    - list
    - watch
    - patch
- apiGroups:
  - ''
  resources:
  - pods/eviction
  verbs:
  - create
```

The ClusterRoleBinding may change over time, but it should look similar to the following example:

```yaml
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: eks:node-manager
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: eks:node-manager
subjects:
- apiGroup: rbac.authorization.k8s.io
```

524
Verify that the eks:node-manager ClusterRole exists.

```
kubectl describe clusterrole eks:node-manager
```

If present, compare the output to the previous ClusterRole example.

Verify that the eks:node-manager ClusterRoleBinding exists.

```
kubectl describe clusterrolebinding eks:node-manager
```

If present, compare the output to the previous ClusterRoleBinding example.

If you’ve identified a missing or broken ClusterRole or ClusterRoleBinding as the cause of an AccessDenied error while requesting managed node group operations, you can restore them. Save the following contents to a file named `eks-node-manager-role.yaml`.

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: eks:node-manager
rules:
- apiGroups:
  - ''
  resources:
  - pods
  verbs:
  - get
  - list
  - watch
  - delete
  - apiGroups:
  - ''
  resources:
  - nodes
  verbs:
  - get
  - list
  - watch
  - patch
  - apiGroups:
  - ''
  resources:
  - pods/eviction
  verbs:
  - create
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: eks:node-manager
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: eks:node-manager
subjects:
- apiGroup: rbac.authorization.k8s.io
  kind: User
  name: eks:node-manager
```
Apply the file.

```bash
ekubectl apply -f eks-node-manager-role.yaml
```

Retry the node group operation to see if that resolved your issue.

**CNI log collection tool**

The Amazon VPC CNI plugin for Kubernetes has its own troubleshooting script that is available on nodes at `/opt/cni/bin/aws-cni-support.sh`. You can use the script to collect diagnostic logs for support cases and general troubleshooting.

Use the following command to run the script on your node:

```bash
sudo bash /opt/cni/bin/aws-cni-support.sh
```

**Note**

If the script is not present at that location, then the CNI container failed to run. You can manually download and run the script with the following command:

```bash
sudo bash eks-log-collector.sh
```

The script collects the following diagnostic information. The CNI version that you have deployed can be earlier than the script version.

```
This is version 0.6.1. New versions can be found at https://github.com/awslabs/amazon-eks-ami

Trying to collect common operating system logs...

```

The diagnostic information is collected and stored at:

```
/var/log/eks_i-0717c9d54b6cf0019_2020-03-24_0103-UTC_0.6.1.tar.gz
```

**Container runtime network not ready**

You may receive a `Container runtime network not ready` error and authorization errors similar to the following:
The errors are most likely because the AWS IAM Authenticator (aws-auth) configuration map isn't applied to the cluster. The configuration map provides the system:bootstrappers and system:nodes Kubernetes RBAC permissions for nodes to register to the cluster. To apply the configuration map to your cluster, see Apply the aws-authConfigMap to your cluster (p. 387).

The authenticator doesn't recognize a **Role ARN** if it includes a path other than /, such as the following example:

```
arn:aws:iam::111122223333:role/development/apps/prod-iam-role-NodeInstanceRole-621LVEXAMPLE
```

When specifying a **Role ARN** in the configuration map that includes a path other than /, you must drop the path. The previous ARN should be specified as the following:

```
arn:aws:iam::111122223333:role/prod-iam-role-NodeInstanceRole-621LVEXAMPLE
```

**TLS handshake timeout**

When a node is unable to establish a connection to the public API server endpoint, you may see an error similar to the following error.

```
server.go:233] failed to run Kubelet: could not init cloud provider "aws": error finding instance i-1111f2222f333e44c: "error listing AWS instances: "RequestError: send request failed\ncaused by: Post  net/http: TLS handshake timeout"
```

The kubelet process will continually respawn and test the API server endpoint. The error can also occur temporarily during any procedure that performs a rolling update of the cluster in the control plane, such as a configuration change or version update.

To resolve the issue, check the route table and security groups to ensure that traffic from the nodes can reach the public endpoint.

**InvalidClientTokenId**

If you're using IAM roles for service accounts for a pod or DaemonSet deployed to a cluster in a China AWS Region, and haven't set the `AWS_DEFAULT_REGION` environment variable in the spec, the pod or DaemonSet may receive the following error:

```
An error occurred (InvalidClientTokenId) when calling the GetCallerIdentity operation: The security token included in the request is invalid
```

To resolve the issue, you need to add the `AWS_DEFAULT_REGION` environment variable to your pod or DaemonSet spec, as shown in the following example pod spec.

```
apiVersion: v1
class: Pod
```
VPC admission webhook certificate expiration

If the certificate used to sign the VPC admission webhook expires, the status for new Windows pod deployments stays at ContainerCreating.

To resolve the issue if you have legacy Windows support on your data plane, see the section called "Renew VPC admission webhook certificate" (p. 62). If your cluster and platform version are later than a version listed in the Windows support prerequisites (p. 55), then we recommend that you remove legacy Windows support on your data plane and enable it for your control plane. Once you do, you don't need to manage the webhook certificate. For more information, see Enabling Windows support for your Amazon EKS cluster (p. 54).

Node groups must match Kubernetes version before updating control plane

Before you update a control plane to a new Kubernetes version, the minor version of the managed and Fargate nodes in your cluster must be the same as the version of your control plane's current version. The EKS update-cluster-version API rejects requests until you update all EKS managed nodes to the current cluster version. EKS provides APIs to update managed nodes. For information on updating managed node group Kubernetes versions, see Updating a managed node group (p. 107). To update the version of a Fargate node, delete the pod that's represented by the node and redeploy the pod after you update your control plane. For more information, see Updating an Amazon EKS cluster Kubernetes version (p. 32).

When launching many nodes, there are Too Many Requests errors

If you launch many nodes simultaneously, you may see an error message in the Amazon EC2 user data execution logs that says Too Many Requests. This can occur because the control plane is being overloaded with describeCluster calls. The overloading results in throttling, nodes failing to run the bootstrap script, and nodes failing to join the cluster altogether.

Make sure that --apiserver-endpoint, --b64-cluster-ca, and --dns-cluster-ip arguments are being passed to the worker node bootstrap script. When including these arguments, there's no need for the bootstrap script to make a describeCluster call, which helps prevent the control plane from being overloaded. For more information, see Provide user data to pass arguments to the bootstrap.sh file included with an Amazon EKS optimized AMI (p. 117).

HTTP 401 unauthorized error response on Kubernetes API server requests

You see these errors if a pod's service account token has expired on a 1.21 or later cluster.
Your Amazon EKS version 1.21 or later cluster's Kubernetes API server rejects requests with tokens older than 90 days. In previous Kubernetes versions, tokens did not have an expiration. This means that clients that rely on these tokens must refresh them within an hour. To prevent the Kubernetes API server from rejecting your request due to an invalid token, the Kubernetes client SDK version used by your workload must be the same, or later than the following versions:

- Go version 0.15.7 and later
- Python version 12.0.0 and later
- Java version 9.0.0 and later
- JavaScript version 0.10.3 and later
- Ruby master branch
- Haskell version 0.3.0.0
- C# version 7.0.5 and later

You can identify all existing pods in your cluster that are using stale tokens. For more information, see Kubernetes service accounts (p. 424).

**Amazon EKS platform version is more than two versions behind the current platform version**

This can happen when Amazon EKS isn't able to automatically update your cluster's platform version (p. 75). Though there are many causes for this, some of the common causes follow. If any of these problems apply to your cluster, it may still function, it's platform version just won't be updated by Amazon EKS.

**Problem**

The cluster IAM role (p. 460) was deleted – This role was specified when the cluster was created. You can see which role was specified with the following command. Replace `my-cluster` with the name of your cluster.

```bash
aws eks describe-cluster --name my-cluster --query cluster.roleArn --output text | cut -d / -f 2
```

The example output is as follows.

```text
eksClusterRole
```

**Solution**

Create a new cluster IAM role (p. 460) with the same name.

**Problem**

A subnet specified during cluster creation was deleted – The subnets to use with the cluster were specified during cluster creation. You can see which subnets were specified with the following command. Replace `my-cluster` with the name of your cluster.

```bash
aws eks describe-cluster --name my-cluster --query cluster.resourcesVpcConfig.subnetIds
```

The example output is as follows.

```json
[
]
```
**Solution**

Confirm whether the subnet IDs exist in your account.

```bash
vpc_id=$(aws eks describe-cluster --name my-cluster --query cluster.resourcesVpcConfig.vpcId --output text)
aws ec2 describe-subnets --filters "Name=vpc-id,Values=$vpc_id" --query "Subnets[*].SubnetId"
```

The example output is as follows.

```
[  
  "subnet-EXAMPLE3",
  "subnet-EXAMPLE4"
]
```

If the subnet IDs returned in the output don't match the subnet IDs that were specified when the cluster was created, then if you want Amazon EKS to update the cluster, you might need to create a new cluster. This is because if you specified more than two subnets when you created your cluster, Amazon EKS randomly selects subnets that you specified to create new elastic network interfaces in. These network interfaces enable the control plane to communicate with your nodes. Amazon EKS won't update the cluster if the subnet it selects doesn't exist. You have no control over which of the subnets that you specified at cluster creation that Amazon EKS chooses to create a new network interface in. You can't create new subnets for your cluster to use after cluster creation.

When you initiate a Kubernetes version update for your cluster, the update can fail for the same reason.

**Problem**

A security group specified during cluster creation was deleted – If you specified security groups during cluster creation, you can see their IDs with the following command. Replace `my-cluster` with the name of your cluster.

```bash
aws eks describe-cluster --name my-cluster --query cluster.resourcesVpcConfig.securityGroupIds
```

The example output is as follows.

```
[  
  "$g-EXAMPLE1"
]
```

If `[]` is returned, then no security groups were specified when the cluster was created and a missing security group isn't the problem. If security groups are returned, then confirm that the security groups exist in your account.

**Solution**

Confirm whether these security groups exist in your account.

```bash
vpc_id=$(aws eks describe-cluster --name my-cluster --query cluster.resourcesVpcConfig.vpcId --output text)
```
aws ec2 describe-security-groups --filters "Name=vpc-id,Values=$vpc_id" --query "SecurityGroups[*].GroupId"

The example output is as follows.

```
[
  "sg-EXAMPLE2"
]
```

If the security group IDs returned in the output don't match the security group IDs that were specified when the cluster was created, then if you want Amazon EKS to update the cluster, you need to create a new cluster. Amazon EKS won’t update a cluster if the security group IDs specified at cluster creation don’t exist. You can’t specify different security groups after cluster creation.

When you initiate a Kubernetes version update for your cluster, the update can fail for the same reason.

**Other reasons that Amazon EKS doesn’t update the platform version of your cluster**

- You don’t have at least six (though we recommend 16) available IP addresses in each of the subnets that you specified when you created your cluster. If you don’t have enough available IP addresses in the subnet, you either need to free up IP addresses in the subnet or you need to create a new cluster that uses subnets with enough available IP addresses.
- You enabled secrets encryption (p. 48) when you created your cluster and the AWS KMS key that you specified has been deleted. If you want Amazon EKS to update the cluster, you need to create a new cluster.

**Troubleshooting IAM**

This topic covers some common errors that you may see while using Amazon EKS with IAM and how to work around them.

**AccessDeniedException**

If you receive an AccessDeniedException when calling an AWS API operation, then the AWS Identity and Access Management (IAM) user or role credentials that you are using do not have the required permissions to make that call.

```
```

In the previous example message, the user does not have permissions to call the Amazon EKS DescribeCluster API operation. To provide Amazon EKS admin permissions to a user, see Amazon EKS identity-based policy examples (p. 446).

For more general information about IAM, see Controlling access using policies in the IAM User Guide.

**Can’t see Nodes on the Compute tab or anything on the Resources tab and you receive an error in the AWS Management Console**

You may see a console error message that says Your current user or role does not have access to Kubernetes objects on this EKS cluster. Make sure that the IAM user that you're
signed into the AWS Management Console with (or role that you switched to after signing in) has the necessary permissions. For more information, see Required permissions (p. 500).

**aws-auth ConfigMap does not grant access to the cluster**

AWS IAM Authenticator does not permit a path in the role ARN used in the ConfigMap. Therefore, before you specify rolearn, remove the path. For example, change

```text
arn:aws:iam::111122223333:role/team/developers/eks-admin
```

```text
to
```

```text
arn:aws:iam::111122223333:role/eks-admin.
```

**I Am not authorized to perform iam:PassRole**

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to Amazon EKS.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in Amazon EKS. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```text
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

**I want to view my access keys**

After you create your IAM user access keys, you can view your access key ID at any time. However, you can't view your secret access key again. If you lose your secret key, you must create a new access key pair.

Access keys consist of two parts: an access key ID (for example, `AKIAIOSFODNN7EXAMPLE`) and a secret access key (for example, `wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY`). Like a user name and password, you must use both the access key ID and secret access key together to authenticate your requests. Manage your access keys as securely as you do your user name and password.

**Important**

Do not provide your access keys to a third party, even to help find your canonical user ID. By doing this, you might give someone permanent access to your account.

When you create an access key pair, you are prompted to save the access key ID and secret access key in a secure location. The secret access key is available only at the time you create it. If you lose your secret access key, you must add new access keys to your IAM user. You can have a maximum of two access keys. If you already have two, you must delete one key pair before creating a new one. To view instructions, see Managing access keys in the IAM User Guide.

**I'm an administrator and want to allow others to access Amazon EKS**

To allow others to access Amazon EKS, you must create an IAM entity (user or role) for the person or application that needs access. They will use the credentials for that entity to access AWS. You must then attach a policy to the entity that grants them the correct permissions in Amazon EKS.

To get started right away, see Creating your first IAM delegated user and group in the IAM User Guide.
I want to allow people outside of my AWS account to access my Amazon EKS resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon EKS supports these features, see How Amazon EKS works with IAM (p. 443).
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the IAM User Guide.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the IAM User Guide.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the IAM User Guide.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

Pod containers receive the following error: An error occurred (SignatureDoesNotMatch) when calling the GetCallerIdentity operation: Credential should be scoped to a valid region.

Your containers receive this error if your application is explicitly making requests to the AWS STS global endpoint (https://sts.amazonaws) and your Kubernetes service account is configured to use a regional endpoint. You can resolve the issue with one of the following options:

- Update your application code to remove explicit calls to the AWS STS global endpoint.
- Update your application code to make explicit calls to regional endpoints such as https://sts.us-west-2.amazonaws.com. Your application should have redundancy built in to pick a different AWS Region in the event of a failure of the service in the AWS Region. For more information, see Managing AWS STS in an AWS Region in the IAM User Guide.
- Configure your service accounts to use the global endpoint. All versions earlier than 1.22 use the global endpoint by default, but version 1.22 and later clusters use the regional endpoint by default. If your code makes explicit calls to the global endpoint on a 1.22 or later cluster, you'll receive the error if you're using the default endpoint type. For more information, see Configuring the AWS Security Token Service endpoint for a service account (p. 434).

Troubleshooting issues in Amazon EKS Connector

This topic covers some of the common errors that you might encounter while using the Amazon EKS Connector, including instructions on how to resolve them, workarounds, and frequently asked questions.

Common issues

This section describes how you can troubleshoot some functional issues that you might encounter while using Amazon EKS Connector. It provides solutions and workarounds for these issues.
Console error: the cluster is stuck in the Pending state

If, after you registered the cluster, the cluster gets stuck in the Pending state on the Amazon EKS console, it might be because Amazon EKS Connector didn't successfully connect the cluster to AWS yet. For a registered cluster, the Pending state means that the connection wasn't already successfully established. To resolve this issue, make sure that you have applied the manifest to the target Kubernetes cluster. If you did apply it to the cluster but the cluster is still in the Pending state, then most likely Amazon EKS Connector might be unhealthy in your cluster. To troubleshoot this issue, see the section that's named Amazon EKS connector pods are crash looping (p. 535) in this topic.

Console error: User “system:serviceaccount:eks-connector:eks-connector” can't impersonate resource “users” in API group “” at cluster scope

Amazon EKS Connector uses Kubernetes user impersonation to act on behalf of users from the AWS Management Console. For each IAM identity that accesses the Kubernetes API from the AWS eks-connector service account, they must be granted permission to impersonate the corresponding Kubernetes user with an IAM ARN as their user name. In the following examples, the IAM ARN is mapped to a Kubernetes user.

- IAM user john from AWS account 111122223333 is mapped to a Kubernetes user.

```
arn:aws:iam::111122223333:user/john
```

- IAM role admin from AWS account 111122223333 is mapped to a Kubernetes user:

```
arn:aws:iam::111122223333:role/admin
```

The result is an IAM role ARN, instead of the STS session ARN.

For instructions on how to configure the ClusterRole and ClusterRoleBinding to grant eks-connector service account privilege to impersonate the mapped user, see Granting access to a user to view Kubernetes resources on a cluster (p. 544). Make sure that, in the template, %IAM_ARN% is replaced with IAM ARN of the AWS Management Console user.

Console error: ... is forbidden: User ... cannot list resource “… in API group” at the cluster scope

Consider the following problem. The Amazon EKS Connector has successfully impersonated the requesting AWS Management Console user in the target Kubernetes cluster. However, the impersonated user doesn't have RBAC permission on Kubernetes API operations.

To resolve this issues, as the cluster administrator, you must grant the appropriate level of RBAC privileges to individual Kubernetes users. For more information and examples, see Granting access to a user to view Kubernetes resources on a cluster (p. 544).

Console error: Amazon EKS can't communicate with your Kubernetes cluster API server. The cluster must be in an ACTIVE state for successful connection. Try again in few minutes.

If the Amazon EKS service can't communicate with Amazon EKS connector in the target cluster, it might be because of one of the following reasons:

- Amazon EKS Connector in the target cluster is unhealthy.
- Poor connectivity or an interrupted connection between the target cluster and the AWS Region.
To resolve this, check the Inspect logs of Amazon EKS Connector (p. 537). If you don't see an error for the Amazon EKS connector, retry the connection after a few minutes. If you regularly experience high latency or intermittent connectivity for the target cluster, consider re-registering the cluster to an AWS Region that's located closer to you.

**Amazon EKS connector pods are crash looping**

There are many reasons that can cause an EKS connector pod to enter the CrashLoopBackOff status. This issue likely involves the connector-init container. In the following example, it was the connector-init container that entered the CrashLoopBackOff status.

```
kubectl get pods -n eks-connector
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>eks-connector-0</td>
<td>0/2</td>
<td>Init:CrashLoopBackOff</td>
<td>1</td>
<td>7s</td>
</tr>
</tbody>
</table>

To troubleshoot this issue, Inspect logs of Amazon EKS Connector (p. 537).

**failed to initiate eks-connector: InvalidActivation**

When you start Amazon EKS Connector for the first time, it registers an activationId and activationCode with Amazon Web Services. The registration might fail, which can cause the connector-init container to crash.

```
F1116 20:30:47.261469       1 init.go:43] failed to initiate eks-connector: 
InvalidActivation:
```

To troubleshoot this issue, consider the following causes and recommended fixes:

- Registration might have failed because the activationId and activationCode aren't in your manifest file. If this is the case, make sure that they are the correct values that were returned from the RegisterCluster API operation, and that the activationCode is in the manifest file. The activationCode is added to Kubernetes secrets, so it must be base64 encoded. For more information, see Step 1: Registering the cluster (p. 541).
- Registration might have failed because your activation expired. This is because, for security reasons, you must activate the EKS connector within 3 days after registering the cluster. To resolve this issue, make sure that the EKS connector manifest is applied to the target Kubernetes cluster before the expiry date and time. To confirm your activation expiry date, call the DescribeCluster API operation. In the following example response, the expiry date and time is recorded as 2021-11-12T22:28:51.101000-08:00.

```
aws eks describe-cluster --name my-cluster
```

```json
{  
  "cluster": {  
    "name": "my-cluster",  
    "arn": "arn:aws:eks:us-east-1:123456789012:cluster/my-cluster",  
    "createdAt": "2021-11-09T22:28:51.449000-08:00",  
    "status": "FAILED",  
    "tags": {  
      },  
    "connectorConfig": {  
      "activationId": "00000000-0000-0000-0000-000000000000",  
      "activationExpiry": "2021-11-12T22:28:51.101000-08:00",  
      "provider": "OTHER",  
      "roleArn": "arn:aws:iam::123456789012:role/my-connector-role"  
    }  
  }  
}  
```
If the 
activationExpiry passed, deregister the cluster and register it again. Do this generates a new activation.

**Cluster worker node is missing outbound connectivity**

To work properly, EKS connector requires outbound connectivity to several AWS endpoints. You can't connect a private cluster without outbound connectivity to a target AWS Region. To resolve this issue, you must add the necessary outbound connectivity. For information about connector requirements, see Amazon EKS Connector considerations (p. 540).

**Amazon EKS connector pods are in ImagePullBackOff state**

If you run the getpods command and pods are in the ImagePullBackOff state, they can't work properly. If EKS Connector pod is in ImagePullBackOff state, they can't work properly. See the following example:

```
kubectl get pods -n eks-connector
NAME              READY   STATUS                  RESTARTS   AGE
eks-connector-0   0/2     Init:ImagePullBackOff   0          4s
```

The default Amazon EKS Connector manifest file references images from Amazon ECR Public Registry. It is possible that the target Kubernetes cluster cannot pull images from Amazon ECR Public. Either resolve the Amazon ECR Public image pull issue, or consider mirroring the images in the private container registry of your choice.

**Frequently asked questions**

**Q: How does the underlying technology behind Amazon EKS Connector work?**

**A:** The Amazon EKS Connector is based on the System Manager (SSM) Agent. The EKS Connector runs as a StatefulSet on your Kubernetes cluster. It establishes a connection and proxies the communication between the API server of your cluster and Amazon Web Services. It does this to display cluster data in the Amazon EKS console until you disconnect the cluster from AWS. SSM agent is an open source project. For more information about this project, see the GitHub project page.

**Q: I have an on-premises Kubernetes cluster that I want to connect. Do I need to open firewall ports to connect it?**

**A:** No, you don't need to open any firewall ports. The Kubernetes cluster only requires outbound connection to AWS Regions. AWS services never access resources in your on-premises network. The Amazon EKS Connector runs on your cluster and initiates the connection to AWS. When the cluster registration completes, AWS only issues commands to the Amazon EKS Connector after you start an action from the Amazon EKS console that requires information from the Kubernetes API server on your cluster.

**Q: What data is sent from my cluster to AWS by the Amazon EKS Connector?**

**A:** The Amazon EKS Connector sends technical information that's necessary for your cluster to be registered on AWS. It also sends cluster and workload metadata for the Amazon EKS console features that customers request. Amazon EKS Connector only gathers or sends this data if you start an action from the Amazon EKS console or the Amazon EKS API that necessitates the data to be sent to AWS. Other than the Kubernetes version number, AWS doesn't store any data by default. It stores them only if you authorize it.

**Q: Can I connect a cluster outside of an AWS Region?**
A: Yes, you can connect a cluster from any location to Amazon EKS. Moreover, your EKS service can be located in any AWS public commercial AWS Region. This works with a valid network connection from your cluster to the target AWS Region. We recommend that you pick an AWS Region, which is the closest to your cluster location for UI performance optimization. For example, if you have a cluster running in Tokyo, connect your cluster to the AWS Region in Tokyo (that is, the `ap-northeast-1` AWS Region) for low latency. You can connect a cluster from any location to the Amazon EKS in any of the public commercial AWS Regions, except the China or GovCloud AWS Regions.

**Basic troubleshooting**

This section describes steps to diagnose the issue if it’s unclear.

**Check Amazon EKS Connector status**

Check the Amazon EKS Connector status by using the following commands.

```bash
kubectl get pods -n eks-connector
```

**Inspect logs of Amazon EKS Connector**

The Amazon EKS Connector Pod consists of three containers. To retrieve full logs for all of these containers so that you can inspect them, run the following commands:

- **connector-init**
  ```bash
  kubectl logs eks-connector-0 --container connector-init -n eks-connector
  kubectl logs eks-connector-1 --container connector-init -n eks-connector
  ```

- **connector-proxy**
  ```bash
  kubectl logs eks-connector-0 --container connector-proxy -n eks-connector
  kubectl logs eks-connector-1 --container connector-proxy -n eks-connector
  ```

- **connector-agent**
  ```bash
  kubectl exec eks-connector-0 --container connector-agent -n eks-connector -- cat /var/log/amazon/ssm/amazon-ssm-agent.log
  kubectl exec eks-connector-1 --container connector-agent -n eks-connector -- cat /var/log/amazon/ssm/amazon-ssm-agent.log
  ```

**Get the effective cluster name**

Amazon EKS clusters are uniquely identified by `clusterName` within a single AWS account and AWS Region. If you have multiple connected clusters in Amazon EKS, you can confirm which Amazon EKS cluster that the current Kubernetes cluster is registered. To do this, enter the following to find out the `clusterName` of the current cluster.

```bash
kubectl exec eks-connector-0 --container connector-agent -n eks-connector -- cat /var/log/amazon/ssm/amazon-ssm-agent.log
  | grep -ml -oE "eks_c:[a-zA-Z0-9-_.]+" 
  | sed -E "s/^[a-zA-Z0-9-_.]+_\[/\1/" 
kubectl exec eks-connector-1 --container connector-agent -n eks-connector -- cat /var/log/amazon/ssm/amazon-ssm-agent.log
  | grep -ml -oE "eks_c:[a-zA-Z0-9-_.]+" 
  | sed -E "s/^[a-zA-Z0-9-_.]+_\[/\1/"
```
Miscellaneous commands

The following commands are useful to retrieve information that you need to troubleshoot issues.

- Use the following command to gather images that's used by pods in Amazon EKS Connector.

```bash
kubectl get pods -n eks-connector -o jsonpath="{.items[*].spec.containers[*].image}" | tr -s '[:space:]' '
'
```

- Use the following command to gather worker node names that Amazon EKS Connector is running on.

```bash
kubectl get pods -n eks-connector -o jsonpath="{.items[*].spec.nodeName}" | tr -s '[:space:]' '
'
```

- Run the following command to get your Kubernetes client and server versions.

```bash
kubectl version
```

- Run the following command to get information about your worker nodes.

```bash
kubectl get nodes -o wide --show-labels
```

Troubleshooting issues in ADOT Amazon EKS add-on

This topic covers some of the common errors that you might encounter while using the ADOT Amazon EKS add-on, including instructions on how to resolve them, workarounds, and frequently asked questions.

Common issues

This section describes functional issues that you might encounter while using ADOT Amazon EKS add-on and troubleshooting steps.

**error**: "code": "AccessDenied", "message": "roles.rbac.authorization.k8s.io \"opentelemetry-operator-leader-election-role\" is forbidden: User \"eks:addon-manager\" cannot patch resource \"roles\" in API group \"rbac.authorization.k8s.io\" in the namespace \"opentelemetry-operator-system\"

You do not have permission to install the ADOT for Amazon EKS add-on. See Install the AWS Distro for OpenTelemetry (ADOT) Operator (p. 512). If you have deleted the add-on and are now reinstalling, ensure that you have applied permissions (p. 511).

**Create add-on error**: "status": "CREATE_FAILED"

- Possibly a conflict. You can overwrite conflicts by adding the flag: `--resolve-conflicts=OVERWRITE` and run the create command again.
- An unsupported architecture, such as ARM64. Consult your logs to determine if this is the case.
Delete add-on error: "status": "DELETE_FAILED"

You can remove the ADOT Operator from being managed by Amazon EKS add-ons by adding the --preserve flag to your delete command.
Amazon EKS Connector

You can use Amazon EKS Connector to register and connect any conformant Kubernetes cluster to AWS and visualize it in the Amazon EKS console. After a cluster is connected, you can see the status, configuration, and workloads for that cluster in the Amazon EKS console. You can use this feature to view connected clusters in Amazon EKS console, but you can't manage them. The Amazon EKS Connector can connect the following types of Kubernetes clusters to Amazon EKS. The Amazon EKS Connector is also an open source project on Github. For additional technical content, including frequently asked questions and troubleshooting, see Troubleshooting issues in Amazon EKS Connector (p. 533)

- On-premises Kubernetes clusters
- Self-managed clusters that are running on Amazon EC2
- Managed clusters from other cloud providers

Amazon EKS Connector considerations

Before you use Amazon EKS Connector, understand the following:

- You must have administrative privileges to the Kubernetes cluster to connect the cluster to Amazon EKS.
- The Kubernetes cluster must have Linux 64-bit (x86) worker nodes present before connecting. ARM worker nodes aren't supported.
- You must have worker nodes in your Kubernetes cluster that have outbound access to the $ssm$. and $ssmmessages$. Systems Manager endpoints. For more information, see Systems Manager endpoints in the AWS General Reference.
- By default, you can connect up to 10 clusters in a Region. You can request an increase through the service quota console. See Requesting a quota increase for more information.
- Only the Amazon EKS RegisterCluster, ListClusters, DescribeCluster, and DeregisterCluster APIs are supported for external Kubernetes clusters.
- You must have the following permissions to register a cluster:
  - eks:RegisterCluster
  - ssm:CreateActivation
  - ssm:DeleteActivation
  - iam:PassRole
- You must have the following permissions to deregister a cluster:
  - eks:DeregisterCluster
  - ssm:DeleteActivation
  - ssm:DeregisterManagedInstance

Required IAM roles for Amazon EKS Connector

Using the Amazon EKS Connector requires the following two IAM roles:

- The Amazon EKS Connector service-linked role is created when you register the cluster.
- The Amazon EKS Connector agent IAM role must be created manually. See Amazon EKS connector IAM role (p. 468) for details.
To enable cluster and workload view permission for another user, you must apply the eks-connector and Amazon EKS Connector cluster roles to your cluster. Follow the steps in Granting access to a user to view Kubernetes resources on a cluster (p. 544).

Connecting a cluster

Step 1: Registering the cluster

You can connect an external Kubernetes cluster to Amazon EKS with AWS CLI and the AWS Management Console. This process involves two steps: registering the cluster with Amazon EKS and applying a YAML manifest file to enable connectivity. To allow another user to view the cluster, follow the instructions in Granting access to a user to view Kubernetes resources on a cluster (p. 544).

You must have the following permissions to register a cluster:

- eks:RegisterCluster
- ssm:CreateActivation
- ssm:DeleteActivation
- iam:PassRole

**Prerequisites**

- eksctl version 0.68 or later must be installed. To install or upgrade it, see Getting started with eksctl.
- The Amazon EKS Connector agent IAM role was created. For more information, see Connector IAM role.

To register your cluster with eksctl

1. Register the cluster by providing a name, provider, and region.

```bash
eksctl register cluster --name my-cluster --provider my-provider --region region-code
```

This creates two files on your local drive: `my-first-registered-cluster.yaml` and `eks-connector-binding.yaml` files. These two files must be applied to the external cluster within three days, or the registration expires.

2. In the cluster's native environment, apply the `eks-connector-binding.yaml` file:

```bash
kubectl apply -f eks-connector-binding.yaml
```

**AWS CLI**

**Prerequisites**

- AWS CLI must be installed. To install or upgrade it, see Installing the AWS CLI.
- Ensure the Amazon EKS Connector agent role was created.
To register your cluster with the AWS CLI

1. For the Connector configuration, specify your Amazon EKS Connector agent IAM role. For more information, see Required IAM roles for Amazon EKS Connector (p. 540).

   ```
   aws eks register-cluster \
   --name my-first-registered-cluster \ 
   --connector-config roleArn=arn:aws:iam::111122223333:role/AmazonEKSConnectorAgentRole,provider="OTHER" \ 
   --region AWS_REGION
   ```

   The example output is as follows.

   ```
   {
   "cluster": {
   "name": "my-first-registered-cluster",
   "createdAt": 1627669203.531,
   "ConnectorConfig": {
   "activationId": "xxxxxxxxACTIVATION_IDxxxxxxxx",
   "activationCode": "xxxxxxxxACTIVATION_CODExxxxxxxx",
   "activationExpiry": 1627672543.0,
   "provider": "OTHER",
   "roleArn": "arn:aws:iam::111122223333:role/AmazonEKSConnectorAgentRole"
   },
   "status": "CREATING"
   }
   }
   ```

   You use the region, activationId, and activationCode values in a later step.

2. Download the Amazon EKS Connector YAML file.

   ```
   ```

3. Edit the Amazon EKS Connector YAML file to replace all references of `%AWS_REGION%`%, `%EKS_ACTIVATION_ID%`, and `%EKS_ACTIVATION_CODE%` with the region, activationId, and activationCode from the output of your registration command.

   The following example command can replace these values.

   ```
   sed -i "s~%AWS_REGION%~$AWS_REGION~g; s~%EKS_ACTIVATION_ID%~$EKS_ACTIVATION_ID~g; s~%EKS_ACTIVATION_CODE%~$(echo -n $EKS_ACTIVATION_CODE | base64)~g" eks-connector.yaml
   ```

   **Important**

   Ensure that your activation code is in the base64 format.

AWS Management Console

**Prerequisites**

- Ensure the Amazon EKS Connector agent role was created.

**To register your Kubernetes cluster with the console.**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#clusters.

542
2. Choose **Add cluster** and select **Register** to bring up the configuration page.

3. On the **Configure cluster** section, fill in the following fields:
   - **Name** – A unique name for your cluster.
   - **Provider** – Choose to display the dropdown list of Kubernetes cluster providers. If you don't know the specific provider, select Other.
   - **EKS Connector role** – Select the role to use for connecting the cluster.

4. Select **Register cluster**.

5. The Cluster overview page displays. Choose **Download YAML file** to download the manifest file to your local drive.

   **Important**
   - This is your only opportunity to download this file. Don't navigate away from this page, as the link will not be accessible and you must deregister the cluster and start the steps from the beginning.
   - The manifest file can be used only once for the registered cluster. If you delete resources from the Kubernetes cluster, you must re-register the cluster and obtain a new manifest file.

Continue to the next step to apply the manifest file to your Kubernetes cluster.

### Step 2: Applying the manifest file

Complete the connection by applying the Amazon EKS Connector manifest file to your Kubernetes cluster. To do this, you must use the AWS CLI or `eksctl` for the registration methods described previously. If the manifest is applied within three days, the Amazon EKS Connector registration expires. If the cluster connection expires, the cluster must be deregistered before connecting the cluster again.

1. In the native environment of the cluster, you can apply the updated manifest file by running the following command:

   ```bash
   kubectl apply -f eks-connector.yaml
   ```

2. After the Amazon EKS Connector manifest and role binding YAML files are applied to your Kubernetes cluster, confirm that the cluster is now connected.

   ```bash
   aws eks describe-cluster \
   --name "my-first-registered-cluster" \
   --region AWS_REGION
   ```

   The output should include `status=ACTIVE`.

3. You can now add Tags to your cluster (optional). See [Tagging your Amazon EKS resources](#) for more information.

To grant additional IAM users access to the Amazon EKS console to view Kubernetes resources in a connected cluster, see [Granting access to a user to view Kubernetes resources on a cluster](#) (p. 544).
Granting access to a user to view Kubernetes resources on a cluster

Grant additional IAM users access to the Amazon EKS console to view information about Kubernetes resources running on your connected cluster.

Prerequisites

The IAM user or role that you use to access the AWS Management Console must meet the following requirements.

- It has the `eks:AccessKubernetesApi` permission.
- The Amazon EKS Connector Service account can impersonate the IAM or role in the cluster. This allows the eks-connector to map the IAM user or role to a Kubernetes user.

To create and apply the Amazon EKS Connector cluster role

1. Download the `eks-connector` cluster role template.

   ```bash
   ```

2. Edit the cluster role template YAML file. Replace references of `%IAM_ARN%` with the Amazon Resource Name (ARN) of your IAM user or role.

3. Apply the Amazon EKS Connector cluster role YAML to your Kubernetes cluster.

   ```bash
cubectl apply -f eks-connector-clusterrole.yaml
   ```

For an IAM user or role to view Kubernetes resources in Amazon EKS console, the user or role must be associated with a Kubernetes role or clusterrole with necessary permissions to read the resources. For more information, see Using RBAC Authorization in the Kubernetes documentation.

To configure an IAM user to access the connected cluster

1. You can download the example manifest file to create a `clusterrole` and `clusterrolebinding` or a `role` and `rolebinding`:

   - **View Kubernetes resources in all namespaces** – The `eks-connector-console-dashboard-full-access-clusterrole` cluster role gives access to all namespaces and resources that can be visualized in the console. You can change the name of the `role`, `clusterrole` and their corresponding binding before applying it to your cluster. Use the following command to download a sample file.

     ```bash
     ```

   - **View Kubernetes resources in a specific namespace** – The namespace in this file is `default`, so if you want to specify a different namespace, edit the file before applying it to your cluster. Use the following command to download a sample file.

     ```bash
     ```

Deregistering a cluster

If you are finished using a connected cluster, you can deregister it. After it’s deregistered, the cluster is no longer visible in the Amazon EKS console.

You must have the following permissions to call the deregisterCluster API:

- eks:DeregisterCluster
- ssm:DeleteActivation
- ssm:DeregisterManagedInstance

**Prerequisites**

- `eksctl` version 0.68 or later must be installed. To install or upgrade it, see [Getting started with eksctl](#).
- Ensure the Amazon EKS Connector agent role was created.

**To deregister your cluster with eksctl**

- For the Connector configuration, specify your Amazon EKS Connector agent IAM role. For more information, see [Required IAM roles for Amazon EKS Connector](#).

```bash
eksctl deregister cluster --name my-cluster
```

**AWS CLI**

**Prerequisites**

- AWS CLI must be installed. To install or upgrade it, see [Installing the AWS CLI](#).
- Ensure the Amazon EKS Connector agent role was created.

Deregister the connected cluster.
Deregister a cluster

```
aws eks deregister-cluster \
  --name my-cluster \
  --region region-code
```

AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose Clusters.
3. On the Clusters page, select the connected cluster and select Deregister.
4. Confirm that you want to deregister the cluster.

To clean up the resources on your Kubernetes cluster.

1. Delete the Amazon EKS Connector YAML file from your Kubernetes cluster.

   ```
kubectl delete -f eks-connector.yaml
   ```

2. If you created clusterrole or clusterrolebinding for an additional IAM user to access the cluster, ensure that you delete them from your Kubernetes cluster.
Amazon EKS on AWS Outposts

You can use Amazon EKS to run on-premises Kubernetes applications on AWS Outposts. You can deploy Amazon EKS on Outposts in the following ways:

- **Extended clusters** – Run the Kubernetes control plane in an AWS Region and nodes on your Outpost.
- **Local clusters** – Run the Kubernetes control plane and nodes on your Outpost.

For both deployment options, the Kubernetes control plane is fully managed by AWS. You can use the same Amazon EKS APIs, tools, and console that you use in the cloud to create and run Amazon EKS on Outposts.

The following diagram shows these deployment options.

---

**When to use each deployment option**

Both local and extended clusters are general-purpose deployment options and can be used for a range of applications.

Local clusters enable you to run the entire Amazon EKS cluster locally on Outposts. This option can mitigate the risk of application downtime that can result from temporary network disconnects to the cloud, such as those caused by fiber cuts or weather events. Because the entire Amazon EKS cluster runs locally on Outposts, applications remain available, and you can perform cluster operations during network disconnects to the cloud. For more information, see the section called “Network disconnects” (p. 558). If you're concerned about the quality of the network connection from your Outposts to the parent AWS Region, and require high availability through network disconnects, you should use the local cluster deployment option.

Extended clusters enable you to conserve capacity on your Outpost because the Kubernetes control plane runs in the parent AWS Region. This option may be a better fit if you are able to invest in reliable, redundant network connectivity from your Outpost to the AWS Region. The quality of the network connection is critical for this option. This is because the way that Kubernetes handles network disconnects between the Kubernetes control plane and nodes may lead to application downtime depending on your cluster and workload configuration. For more information on the behavior of Kubernetes, see Scheduling, Preemption, and Eviction in the Kubernetes documentation.
Comparing the deployment options

The following tables compares the differences between the two options.

<table>
<thead>
<tr>
<th>Feature</th>

Local clusters for Amazon EKS on AWS Outposts

Local clusters enable you to run your entire Amazon EKS cluster locally on AWS Outposts. This helps you mitigate the risk of application downtime that can result from temporary network disconnects to the cloud, such as downtime caused by fiber cuts or weather events. Because the entire Kubernetes cluster runs locally on Outposts, applications remain available. You can perform cluster operations during network disconnects to the cloud. For more information, see the section called “Network disconnects” (p. 558). The following diagram shows a local cluster deployment.

Local clusters are generally available for use with Outposts racks.

Supported regions

You can create local clusters in the following AWS Regions: US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon), Asia Pacific (Tokyo), Asia Pacific (Seoul), Europe (Frankfurt), Europe (London), Middle East (Bahrain), and South America (São Paulo). For detailed information about supported features, see the section called “Comparing the deployment options” (p. 548).

Topics

- Creating a local cluster on an Outpost (p. 550)
- Amazon EKS local cluster platform versions (p. 556)
- Amazon EKS local cluster VPC and subnet requirements and considerations (p. 557)
- Preparing for network disconnects (p. 558)
- Capacity considerations (p. 561)
- Troubleshooting local clusters for Amazon EKS on AWS Outposts (p. 562)
Creating a local cluster on an Outpost

This topic provides an overview of the things to consider when running a local cluster on an Outpost. The topic also provides instructions for how to deploy a local cluster on an Outpost.

Considerations

Important

• These considerations aren't replicated in related Amazon EKS documentation. Due to this, if other Amazon EKS documentation topics conflict with considerations listed here, then these considerations override information found in related topics.

• These considerations might change frequently. We recommend that you regularly review this topic for current considerations.

• Many of the considerations are different than the considerations for creating a cluster on the AWS Cloud.

• Local clusters support Outpost racks only. A single local cluster can run across multiple physical Outpost racks that comprise a single logical Outpost. A single local cluster can't run across multiple logical Outposts. Each logical Outpost has a single Outpost ARN.

• Local clusters run and manage the Kubernetes control plane in your account on the Outpost. Running workloads on the Kubernetes control plane instances, and modifications to the Kubernetes control plane components, are not supported. These nodes are managed by the Amazon EKS service. Changes to the Kubernetes control plane don't persist through automatic Amazon EKS management actions, such as patching.

• Local clusters support Kubernetes version 1.21 only.

• Local clusters support self-managed add-ons and self-managed Amazon Linux 2 node groups. The Amazon VPC CNI plugin for Kubernetes (p. 253), kube-proxy (p. 328), and CoreDNS (p. 316) add-ons are automatically install on local clusters.

• Local clusters require the use of Amazon EBS on Outposts. Your Outpost must have Amazon EBS available for the Kubernetes control plane storage.

• Local clusters use Amazon EBS on Outposts. Your Outpost must have Amazon EBS available for the Kubernetes control plane storage. Outposts support Amazon EBS gp2 volumes only.

• Amazon EBS backed Kubernetes PersistentVolumes are supported using the Amazon EBS CSI driver.

Prerequisites

• Familiarity with the Outposts deployment options (p. 548), the section called "Capacity considerations" (p. 561), and the section called "VPC and subnet requirements" (p. 557).

• An existing Outpost. For more information, see What is AWS Outposts.

• The kubectl command line tool is installed on your computer or AWS CloudShell. The version can be the same as or up to one minor version earlier or later than the Kubernetes version of your cluster. For example, if your cluster version is 1.21, you can use kubectl version 1.20,1.21, or 1.22 with it. To install or upgrade kubectl, see the section called “Installing kubectl” (p. 4).

• Version 2.7.32 or later or 1.25.72 or later of the AWS CLI installed and configured on your device or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with aws configure in the AWS Command Line Interface User Guide.

• An IAM user or role with permissions to create and describe an Amazon EKS cluster. For more information, see the section called “Create a local Kubernetes cluster on an Outpost” (p. 449) and the section called “List or describe all clusters” (p. 450).
When a local Amazon EKS cluster is created, the IAM entity (user or role) that creates the cluster is permanently added to the Kubernetes RBAC authorization table as the administrator. This entity has `system:masters` permissions. The identity of this entity isn't visible in your cluster configuration. So, it's important to note the entity that created the cluster and make sure that you never delete it. Initially, only the IAM entity that created the server can make calls to the Kubernetes API server using `kubectl`. If you use the console to create the cluster, you must ensure that the same IAM credentials are in the AWS SDK credential chain when you run `kubectl` commands on your cluster. After your cluster is created, you can grant other IAM entities access to your cluster.

To create a local Amazon EKS local cluster

You can create a local cluster with `eksctl`, the AWS Management Console, the AWS CLI, the Amazon EKS API, the AWS SDKs, AWS CloudFormation or Terraform.

1. Create a local cluster.

    `eksctl`

    **Prerequisite**

    Version 0.112.0 or later of the `eksctl` command line tool installed on your device or AWS CloudShell. To install or update `eksctl`, see Installing or updating `eksctl` (p. 10).

    **To create your cluster with eksctl**

    1. Copy the contents that follow to your device. Replace the following values and then run the modified command to create the `outpost-control-plane.yaml` file:
       - Replace `region-code` with the supported AWS Region (p. 549) that you want to create your cluster in.
       - Replace `my-cluster` with a name for your cluster. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. The name must be unique within the AWS Region and AWS account that you're creating the cluster in.
       - Replace `vpc-ExampleID1` and `subnet-ExampleID1` with the IDs of your existing VPC and subnet. The VPC and subnet must meet the requirements in the section called “VPC and subnet requirements” (p. 557).
       - Replace `uniqueid` with the ID of your Outpost.
       - Replace `m5.large` with an instance type available on your Outpost. Before choosing an instance type, see the section called “Capacity considerations” (p. 561). Three control plane instances are deployed. You can't change this number.

    ```
    cat >outpost-control-plane.yaml <<EOF
    apiVersion: eksctl.io/v1alpha5
    kind: ClusterConfig
    metadata:
      name: my-cluster
      region: region-code
      version: 1.21
    vpc:
      clusterEndpoints:
        privateAccess: true
        id: "vpc-vpc-ExampleID1"
      subnets:
        private:
          outpost-subnet-1:
            id: "subnet-subnet-ExampleID1"
    EOF
    ```
Creating a local cluster

outposts:
  controlPlaneInstanceType: m5.large

For a complete list of all available options and defaults, see AWS Outposts Support and Config file schema in the eksctl documentation.

2. Create the cluster using the configuration file that you created in the previous step. Eksctl creates a VPC and one subnet on your Outpost to deploy the cluster in.

    eksctl create cluster -f outpost-control-plane.yaml

Cluster provisioning takes several minutes. While the cluster is being created, several lines of output appear. The last line of output is similar to the following example line.

    [✓]  EKS cluster "my-cluster" in "region-code" region is ready

Tip
To see the most options that you can specify when creating a cluster with eksctl, use the eksctl create cluster --help command. To see all the available options, you can use a config file. For more information, see Using config files and the config file schema in the eksctl documentation. You can find config file examples on GitHub.

AWS Management Console

Prerequisite
An existing VPC and subnet that meet Amazon EKS requirements. For more information, see the section called "VPC and subnet requirements" (p. 557).

To create your cluster with the AWS Management Console

1. If you already have a local cluster IAM role, or you're going to create your cluster with eksctl, then you can skip this step. By default, eksctl creates a role for you.
   a. Run the following command to create an IAM trust policy JSON file.

      cat >eks-local-cluster-role-trust-policy.json <<EOF
      {
        "Version": "2012-10-17",
        "Statement": [
          {
            "Effect": "Allow",
            "Principal": {
              "Service": "ec2.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
          }
        ]
      }
      EOF

   b. Create the Amazon EKS cluster IAM role. To create an IAM role, the IAM entity (user or role) that is creating the role must be assigned the following IAM action (permission):
      iam:CreateRole.

      aws iam create-role --role-name myAmazonEKSLocalClusterRole --assume-role-policy-document file://"eks-local-cluster-role-trust-policy.json"
c. Attach the Amazon EKS managed policy named
AmazonEKSSLocalOutpostClusterPolicy to the role. To attach an IAM policy
to an IAM entity (user or role), the IAM entity that is attaching the policy must be
assigned one of the following IAM actions (permissions): iam:AttachUserPolicy or
iam:AttachRolePolicy.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/
AmazonEKSSLocalOutpostClusterPolicy --role-name myAmazonEKSSLocalClusterRole
```

2. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
3. At the top of the console screen, make sure that you have selected a supported AWS
Region (p. 549).
4. Choose Add cluster and then choose Create.
5. On the Configure cluster page, enter or select values for the following fields:
   - Kubernetes control plane location – Choose AWS Outposts.
   - Outpost ID – Choose the ID of the Outpost that you want to create your control plane on.
   - Instance type – Select an instance type. Only the instance types available in your Outpost
     are displayed. In the drop-down list, each instance type describes how many nodes the
     instance type is recommended for. Before choosing an instance type, see the section called
     “Capacity considerations” (p. 561). All replicas are deployed using the same instance
type. You can't change the instance type after your cluster is created. Three control plane
instances are deployed. You can't change this number.
   - Name – A name for your cluster. It must be unique in your AWS account. The name can
     contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an
     alphabetic character and can't be longer than 100 characters. The name must be unique
     within the AWS Region and AWS account that you're creating the cluster in.
   - Kubernetes version – Only version 1.21 is available.
   - Cluster service role – Choose the Amazon EKS cluster IAM role that you created in a
     previous step to allow the Kubernetes control plane to manage AWS resources on your
     behalf.
   - Tags – (Optional) Add any tags to your cluster. For more information, see Tagging your
     Amazon EKS resources (p. 412).
6. Select Next.
7. On the Specify networking page, select values for the following fields:
   - VPC – Choose an existing VPC. The VPC must have a sufficient number of IP addresses
     available for the cluster, any nodes, and other Kubernetes resources that you want to
     create. You VPC must meet the requirements in the section called “VPC requirements and
     considerations” (p. 557).
   - Subnets – By default, all available subnets in the VPC specified in the previous field are
     preselected. The subnets that you choose must meet the requirements in the section called
     “Subnet requirements and considerations” (p. 557). You can't change which subnets you
     want to use after cluster creation.

**Security groups** – (Optional) Specify one or more security groups that you want Amazon
EKS to associate to the network interfaces that it creates. Whether you choose any security
groups or not, Amazon EKS creates a security group that enables communication between
your cluster and your VPC. Amazon EKS associates this security group, and any that
you choose, to the network interfaces that it creates. For more information about the
cluster security group that Amazon EKS creates, see the section called “Security group
requirements” (p. 245). You can modify the rules in the cluster security group that Amazon
EKS creates. If you choose to add your own security groups, you can't change the ones that
you choose after cluster creation. For on-premises hosts to communicate with the cluster
endpoint, you must allow inbound traffic from the cluster security group.
8. Select Next.

9. On the Configure logging page, you can optionally choose which log types that you want to enable. By default, each log type is Disabled. Before selecting a different option, familiarize yourself with the information in Amazon EKS control plane logging (p. 51). After you create the cluster, you can change this option.

10. Select Next.

11. On the Review and create page, review the information that you entered or selected on the previous pages. If you need to make changes, choose Edit. When you're satisfied, choose Create. The Status field shows CREATING while the cluster is provisioned.

Cluster provisioning takes several minutes.

2. After your cluster is created you can view the Amazon EC2 control plane instances that were created.

```bash
aws ec2 describe-instances --query 'Reservations[*].Instances[*].{Name:Tags[?Key==`Name`][0].Value}' | grep my-cluster-control-plane
```

The example output is as follows.

```
"Name": "my-cluster-control-plane-id1"
"Name": "my-cluster-control-plane-id2"
"Name": "my-cluster-control-plane-id3"
```

Each instance is tainted with node-role.eks-local.amazonaws.com/control-plane so that no workloads are ever scheduled on the control plane instances. For more information about taints, see Taints and Tolerations in the Kubernetes documentation. Amazon EKS continuously monitors the state of local clusters. We perform automatic management actions, such as security patches and repairing unhealthy instances. When local clusters are disconnected from the cloud, we complete actions to ensure that the cluster is repaired to a healthy state upon reconnect.

3. If you created your cluster using eksctl, then you can skip this step. This is because eksctl already completed this step for you. Enable kubectl to communicate with your cluster by adding a new context to the kubectl config file. For more information about how to create and update the file, see the section called “Create a kubeconfig for Amazon EKS” (p. 392).

```bash
aws eks update-kubeconfig --region region-code --name my-cluster
```

The example output is as follows.

```
```

4. To connect to your local cluster’s Kubernetes API server, you must have access to the local gateway for the subnet, or connect from within the VPC. For more information about connecting an Outpost rack to your on-premises network, see How local gateways for racks work in the AWS Outposts User Guide. If using Direct VPC Routing, the private IP addresses of the Kubernetes control plane instances are automatically broadcasted over your local network if the Outpost subnet has a route to your local gateway. The local cluster’s Kubernetes API server endpoint is hosted in Amazon Route 53 (Route 53), and can be resolved by public DNS servers to the Kubernetes API servers' private IP addresses.

Local clusters' Kubernetes control plane instances are configured with static elastic network interfaces with fixed private IP addresses that don't change throughout the cluster lifecycle. If machines that interact with the Kubernetes API server may not have connectivity to Route 53 during network disconnects, we recommend configuring /etc/hosts with the static private IP addresses for continued operations. We also recommend setting up local DNS servers and connecting them to
creating a local cluster

your Outpost as defined in the AWS Outposts documentation. Confirm communication with your cluster by running the following command.

```
kubectl get svc
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes</td>
<td>ClusterIP</td>
<td>10.100.0.1</td>
<td>&lt;none&gt;</td>
<td>443/TCP</td>
<td>28h</td>
</tr>
</tbody>
</table>

5. (Optional) If your Outpost doesn't have any production services running on it and you want to test authentication to your local cluster when it's in a disconnected state from the AWS Cloud, see the section called “Network disconnects” (p. 558).

**Internal resources**

Amazon EKS creates the following resources on your cluster. The resources are for Amazon EKS internal use. For proper functioning of your cluster, don't edit or modify these resources.

- The following **mirror pods**:
  - aws-iam-authenticator-
    node-hostname
  - eks-certificates-controller-
    node-hostname
  - etcd-
    node-hostname
  - kube-apiserver-
    node-hostname
  - kube-controller-manager-
    node-hostname
  - kube-scheduler-
    node-hostname
- The following self-managed add-ons:
  - kube-system/coredns
  - kube-system/kube-proxy (not created until you add your first node)
  - kube-system/aws-node (not created until you add your first node). Local clusters use the Amazon VPC CNI plugin for Kubernetes plugin for cluster networking. Do not change the configuration for control plane instances (Pods named aws-node-controlplane-*). There are configuration variables that allow you to change the default value for when the plugin creates new network interfaces. For more information, see the documentation on GitHub.
  - The following services:
    - default/kubernetes
    - kube-system/kube-dns
  - A PodSecurityPolicy named eks.system
  - A ClusterRole named eks:system:podsecuritypolicy
  - A ClusterRoleBinding named eks:system
  - A default PodSecurityPolicy (p. 495)
  - In addition to the **cluster security group** (p. 245), Amazon EKS creates a security group in your AWS account named eks-local-internal-do-not-use-or-edit-cluster-name-uniqueid. This security group allows traffic to flow freely between Kubernetes components running on the control plane instances.

Recommended next steps:

- Grant the IAM entity that created the cluster the required permissions to view Kubernetes resources in the AWS Management Console (p. 500)
• Grant IAM entities access to your cluster (p. 381). If you want the entities to view Kubernetes resources in the Amazon EKS console, grant the section called “Required permissions” (p. 500) to the entities.

• Configure logging for your cluster (p. 51)

• Familiarize yourself with what happens during network disconnects (p. 558).

• Add nodes to your cluster (p. 567)

• Consider setting up a backup plan for your etcd. Amazon EKS doesn't support automated backup and restore of etcd for local clusters. For more information, see Backing up an etcd cluster in the Kubernetes documentation. The two main options are using etcdctl to automate taking snapshots or using Amazon EBS storage volume backup.

Amazon EKS local cluster platform versions

Local cluster platform versions represent the capabilities of the Amazon EKS cluster on Outposts, including the components that run on the Kubernetes control plane, which Kubernetes API server flags are enabled, as well as the current Kubernetes patch version. Each Kubernetes minor version has one or more associated platform versions. The platform versions for different Kubernetes minor versions are independent. The platform versions for local clusters and Amazon EKS clusters in the cloud are independent.

When a new Kubernetes minor version is available for local clusters, such as 1.21, the initial platform version for that Kubernetes minor version starts at eks-local-outposts.1. However, Amazon EKS releases new platform versions periodically to enable new Kubernetes control plane settings and to provide security fixes.

When new local cluster platform versions become available for a minor version:

• The platform version number is incremented (eks-local-outposts.n+1).

• Amazon EKS automatically upgrades all existing local clusters to the latest platform version for their corresponding Kubernetes minor version. Automatic updates of existing platform versions are rolled out incrementally. The roll-out process might take some time. If you need the latest platform version features immediately, then you should create a new local cluster.

• Amazon EKS might publish a new node AMI with a corresponding patch version. All patch versions are compatible between the Kubernetes control plane and node AMIs for a given Kubernetes minor version.

New platform versions don't introduce breaking changes or cause service interruptions.

Local clusters are always created with the latest available platform version (eks-local-outposts.n) for the specified Kubernetes version.

The current and recent platform versions are described in the following tables.

Kubernetes version 1.21

The following admission controllers are enabled for all 1.21 platform versions:

Amazon EKS local cluster VPC and subnet requirements and considerations

When you create a local cluster, you specify a VPC and at least one private subnet that runs on Outposts. This topic provides an overview of the VPC and subnets requirements and considerations that you use with your local cluster.

VPC requirements and considerations

When you create a local cluster, the VPC that you specify must meet the following requirements and considerations:

- Have a sufficient number of IP addresses available for the local cluster, any nodes, and other Kubernetes resources that you want to create. If the VPC that you want to use doesn't have a sufficient number of IP addresses, try to increase the number of available IP addresses. You can do this by associating additional Classless Inter-Domain Routing (CIDR) blocks with your VPC. You can associate private (RFC 1918) and public (non-RFC 1918) CIDR blocks to your VPC either before or after you create your cluster. It can take a cluster up to five hours for a CIDR block that you associated with a VPC to be recognized.

- Can't have IP prefixes assigned or IPv6 CIDR blocks. Due to these constraints, the information in the section called “Increase available IP addresses” (p. 289) and the section called “IPv6” (p. 264) isn’t applicable.

- Have DNS hostname and DNS resolution enabled. Without these features, local cluster creation fails and you'll need to enable the features and recreate your cluster. For more information, see DNS attributes for your VPC in the Amazon VPC User Guide.

- To access your local cluster over your local network, your VPC must be associated with your Outpost's local gateway route table. For more information, see VPC associations in the AWS Outposts User Guide.

Subnet requirements and considerations

You must specify at least one private subnet during cluster creation. If you specify more than one subnet, the Kubernetes control plane instances are evenly distributed across the subnets. If more than one subnet is specified, the subnets must exist on the same Outpost and have proper routes and security group permissions to communicate with each other. The subnets that you specify when you create a local cluster must meet the following requirements:

- Exist on the same logical Outpost.

- Collectively have at least three available IP addresses for the Kubernetes control plane instances. If three subnets are specified, then each subnet must have at least one available IP address. If two subnets are specified, then each subnet must have at least two available IP addresses. If one subnet is specified, then the subnet must have at least three available IP addresses.

- An associated route table that has a route to a NAT gateway running in a public subnet in the Outpost's parent Availability Zone. The public subnet must have a route to an internet gateway. This

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Amazon EKS platform version</th>
<th>Release notes</th>
<th>Release date</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.21.13</td>
<td>eks-local-outposts.1</td>
<td>Initial release of local Amazon EKS clusters on Outposts.</td>
<td>September 19, 2022</td>
</tr>
</tbody>
</table>
route enables outbound internet access, and prevents unsolicited inbound connections from the internet to instances on the Outpost.

- A route to the Outpost rack’s local gateway to access the Kubernetes API server over your local network. If the subnets don’t have a route to the Outpost rack’s local gateway, then you must communicate with your Kubernetes API server from within the VPC.
- Use IP address-based naming. Amazon EC2 resource-based naming isn’t supported by Amazon EKS.

**Preparing for network disconnects**

You can continue to use your local Amazon EKS cluster on an Outpost if your local network has lost connectivity with the AWS Cloud. This topic covers some of the important considerations to prepare for your local cluster to be in a disconnected state

**Considerations**

- Local clusters enable stability and continued operations during temporary, unplanned network disconnects. AWS Outposts remains a fully connected offering that acts as an extension of the AWS Cloud in your data center. In the event of network disconnects between your Outpost and AWS Cloud, you should attempt to restore your connection following the AWS Outposts rack network troubleshooting checklist in the AWS Outposts User Guide. For information on how to troubleshoot issues with local clusters, see the section called “Troubleshooting” (p. 562).
- Outposts emit a ConnectedStatus metric that you can use to monitor the connectivity state of your Outpost. For more information, see Outposts Metrics in the AWS Outposts User Guide.
- Local clusters use IAM as the default authentication mechanism using the AWS Identity and Access Management authenticator for Kubernetes. Because IAM isn’t available during network disconnects, local clusters support an alternative authentication mechanism using x.509 certificates that you can use to connect to your cluster during network disconnects. For information on how to obtain and use an x.509 certificate for your cluster, see the section called “Authenticating to your cluster” (p. 559).
- If you are unable to access Route 53 during network disconnects, consider using local DNS servers in your on-premises environment. The Kubernetes control plane instances use static IP addresses. You can configure the hosts that you use to connect to your cluster with the endpoint hostname and IP addresses as an alternative to using local DNS servers. For more information, see DNS in the AWS Outposts User Guide.
- If you anticipate increases in application traffic during network disconnects, you can provision spare compute capacity in your cluster when connected to the cloud. Amazon EC2 instances are included in the price of AWS Outposts, so running spare instances doesn’t impact your AWS usage cost.
- During network disconnects, to enable create, update, and scale operations for workloads, your application’s container images must be accessible over the local network and your cluster must have enough capacity. Local clusters don’t host a container registry for you. Container images are cached on the nodes if the pods have previously run on those nodes. If you typically pull your application’s container images from Amazon ECR in the cloud, consider running a local cache or registry if you require create, update, and scale operations for workload resources during network disconnects.
- Local clusters use Amazon EBS as the default storage class for persistent volumes and the Amazon EBS CSI driver to manage the lifecycle of Amazon EBS persistent volumes. During network disconnects, pods backed by Amazon EBS can’t be created, updated, or scaled because these operations require calls to the Amazon EBS API in the cloud. If you’re deploying stateful workloads on local clusters and require create, update, or scale operations during network disconnects, consider using an alternative storage mechanism.
- The Amazon EKS control plane logs are cached locally on the Kubernetes control plane instances during network disconnects. Upon reconnect, the logs are sent to CloudWatch Logs in the parent AWS Region. You can use your choice of tools such as Prometheus, Grafana, and Amazon EKS partner solutions to monitor the cluster locally using the Kubernetes API server’s metrics endpoint or using Fluent Bit for logs.
• If you are using the AWS Load Balancer Controller on Outposts for application traffic, existing pods fronted by the AWS Load Balancer Controller continue to receive traffic during network disconnects. New pods created during network disconnects don’t receive traffic until the Outpost is reconnected to the AWS Cloud. Consider setting the replica count for your applications while connected to the AWS Cloud to accommodate your scaling needs during network disconnects.

• The Amazon VPC CNI plugin for Kubernetes default to secondary IP mode. It is configured with \texttt{WARM}_{\texttt{ENI}}_{\texttt{TARGET}}=1\), which allows the plugin to keep “a full elastic network interface” of available IP addresses available. Consider changing \texttt{WARM}_{\texttt{ENI}}_{\texttt{TARGET}}, \texttt{WARM}_{\texttt{IP}}_{\texttt{TARGET}}, and \texttt{MINIMUM}_{\texttt{IP}}_{\texttt{TARGET}} values according to your scaling needs during a disconnected state. For more information, see the \texttt{readme} file for the plugin on GitHub. For a list of the maximum number of pods supported by each instance type, see the \texttt{eni-max-pods.txt} file on GitHub.

### Authenticating to your local cluster during a network disconnect

AWS Identity and Access Management isn’t available during network disconnects. You aren’t able to authenticate to your local cluster using IAM credentials while disconnected. You can connect to your cluster over your local network using x509 certificates when disconnected. You need to download and store a client X509 certificate to use during disconnects. In this topic you learn how to create and use the certificate to authenticate to your cluster when it’s in a disconnected state.

1. Create a certificate signing request.
   a. Generate a certificate signing request.

   ```bash
   openssl req -new -newkey rsa:4096 -nodes -days 365
   -keyout admin.key -out admin.csr -subj "/CN=admin"
   ```

   b. Create a certificate signing request in Kubernetes.

   ```bash
   BASE64_CSR=$(cat admin.csr | base64 -w 0)
   cat << EOF > admin-csr.yaml
   apiVersion: certificates.k8s.io/v1
   kind: CertificateSigningRequest
   metadata:
     name: admin-csr
   spec:
     signerName: kubernetes.io/kube-apiserver-client
     request: ${BASE64_CSR}
     usages:
       - client auth
   EOF
   ```

2. Create a certificate signing request using `kubectl`.

   ```bash
   kubectl create -f admin-csr.yaml
   ```

3. Check the status of the certificate signing request.

   ```bash
   kubectl get csr admin-csr
   ```

   The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>admin-csr</td>
<td>11m</td>
<td>kubernetes-admin</td>
<td>Pending</td>
</tr>
</tbody>
</table>

   Kubernetes has created the certificate signing request.
4. Approve the certificate signing request.

```bash
kubectl certificate approve admin-csr
```

5. Recheck the certificate signing request status for approved.

```bash
kubectl get csr admin-csr
```

The example output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>admin-csr</td>
<td>11m</td>
<td>kubernetes-admin</td>
<td>Approved</td>
</tr>
</tbody>
</table>

6. Retrieve and verify the certificate.

   a. Retrieve the certificate.

```bash
kubectl get csr admin-csr -o jsonpath='{.status.certificate}' | base64 --decode > admin.crt
```

   b. Verify the certificate.

```bash
cat admin.crt
```

7. Create a cluster role binding for an admin user.

```bash
kubectl create clusterrolebinding admin --clusterrole=cluster-admin --user=admin --group=system:masters
```

8. Generate a user-scoped kubeconfig for a disconnected state.

You can generate a `kubeconfig` file using the downloaded `admin` certificates. Replace `my-cluster` and `apiserver-endpoint` in the following commands.

```bash
aws eks describe-cluster --name my-cluster
  --query "cluster.certificateAuthority"  
  --output text | base64 --decode > ca.crt

kubectl config --kubeconfig admin.kubeconfig set-cluster my-cluster 
  --certificate-authority=ca.crt --server apiserver-endpoint --embed-certs

kubectl config --kubeconfig admin.kubeconfig set-credentials admin 
  --client-certificate=admin.crt --client-key=admin.key --embed-certs

kubectl config --kubeconfig admin.kubeconfig set-context admin@my-cluster 
  --cluster my-cluster --user admin

kubectl config --kubeconfig admin.kubeconfig use-context admin@my-cluster
```

```bash
kubectl get nodes --kubeconfig admin.kubeconfig
```
10. If you have services already in production on your Outpost, then skip this step. If Amazon EKS is
the only service running on your Outpost and the Outpost isn't currently in production, then you
can simulate a network disconnect. Before you go into production with your local cluster, you can
simulate a disconnect to make sure that you can still access your cluster when it's in a disconnected
state.

   a. Apply firewall rules on the networking devices that connect your Outpost to the AWS Region.
   This disconnects the service link of the Outpost. You aren't able to create any new instances.
   Currently running instances lose connectivity to the AWS Region and the internet.

   b. You can test the connection to your local cluster while disconnected using the x509 certificate.
   Make sure to change your kubeconfig to the admin.kubeconfig you created in a previous
   step. Replace my-cluster with the name of your local cluster.

   ```bash
   kubectl config use-context admin@my-cluster --kubeconfig admin.kubeconfig
   ```

   If you notice any issues with your local clusters while they're in a disconnected state, then we
recommend opening a support ticket.

### Capacity considerations

This topic provides guidance for selecting the Kubernetes control plane instance type for your local
Amazon EKS cluster on an Outpost.

When selecting an instance type (m5, c5, r5, or other) to use for your local cluster's Kubernetes control
plane on Outposts, you must first confirm the instance types that are available on your Outpost
configuration. Once you have identified the available instance types, you must then select the instance
size (large, xlarge, 2xlarge, or other) based on the number of nodes that your workloads require. The following table provides recommendations for choosing an instance size.

**Note**

The instance sizes must have been slotted on your Outposts, and you must have spare capacity
for three instances of the size available on your Outposts for the lifetime of your local cluster.
For a list of the available Amazon EC2 instance types, see Compute and storage in AWS Outposts rack features.

<table>
<thead>
<tr>
<th>Number of nodes</th>
<th>Kubernetes control plane instance size</th>
</tr>
</thead>
<tbody>
<tr>
<td>1–20</td>
<td>large</td>
</tr>
<tr>
<td>21–100</td>
<td>xlarge</td>
</tr>
<tr>
<td>101–250</td>
<td>2xlarge</td>
</tr>
<tr>
<td>251–500</td>
<td>4xlarge</td>
</tr>
</tbody>
</table>

The storage for the Kubernetes control plane requires 246 GB of Amazon EBS storage per local cluster to
meet etcd's required IOPS. The Amazon EBS volumes are provisioned automatically for you during local
cluster creation.
Troubleshooting local clusters for Amazon EKS on AWS Outposts

This topic covers some common errors that you may see while using local clusters and how to work around them. While local clusters are similar to Amazon EKS clusters in the cloud, there are some differences in how a local cluster is managed by the Amazon EKS service.

API behavior

Local clusters are created through the Amazon EKS API, but are executed in an asynchronous manner. This means that requests to the Amazon EKS API return immediately for local clusters, and may succeed, fail fast (input validation errors), or fail with descriptive validation errors at a later point during the execution of the request. This behavior is similar to that of the Kubernetes API.

Local clusters do not transition to a FAILED status. The Amazon EKS service attempts to reconcile the cluster state with the user-requested desired state in a continuous manner. As a result, a local cluster may remain in the CREATING state for an extended period of time until the underlying issue is resolved.

Describe cluster health field

Local cluster issues can be discovered with the describe-cluster Amazon EKS AWS CLI command. Local cluster issues are surfaced by the cluster.health field of the describe-cluster command's response. The message contained in this field includes an error code, descriptive message, and related resource IDs. This information is available through the Amazon EKS API and AWS CLI only. In the following example, replace my-cluster with the name of your local cluster.

```
aws eks describe-cluster --name my-cluster --query 'cluster.health'
```

An example of the output that might be returned follows.

```
{
    "issues": [
        {
            "code": "ConfigurationConflict",
            "message": "The instance type 'm5.large' is not supported in Outpost 'my-outpost-arn'.",
            "resourceIds": [
                "my-cluster-arn"
            ]
        }
    ]
}
```

If the problem is beyond repair, you might need to delete the local cluster and create a new one. For example, trying to provision a cluster with an instance type that is not available on your Outpost. The following table includes common health related errors:

<table>
<thead>
<tr>
<th>Error scenario</th>
<th>Code</th>
<th>Message</th>
<th>ResourceIds</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provided subnets don't exist</td>
<td>ResourceNotFnd</td>
<td>The subnet ID subnet-id does not exist</td>
<td>All provided subnet IDs</td>
</tr>
<tr>
<td>Provided subnets don't belong to the same VPC</td>
<td>ConfigurationConflict</td>
<td>Subnets specified must belong to the same VPC</td>
<td>All provided subnet IDs</td>
</tr>
<tr>
<td>Error scenario</td>
<td>Code</td>

<tr>
<td>Your account exceeds your elastic network interface limit</td>
<td>ResourceLimitExceeded</td>
<td>Error message returned by Amazon EC2 API</td>
<td>Target subnet ID</td>
</tr>
</tbody>
</table>
### Error scenario

Control plane instances aren't reachable through AWS Systems Manager. For resolution, see the section called "Control plane instances aren't reachable through AWS Systems Manager" (p. 567).

<table>
<thead>
<tr>
<th>Code</th>
<th>Message</th>
<th>Resource IDs</th>
</tr>
</thead>
<tbody>
<tr>
<td>ClusterUnreachable</td>
<td>Amazon EKS control plane instances are not reachable through SSM. Please verify your SSM and network configuration, and reference the EKS on Outposts troubleshooting documentation.</td>
<td>Amazon EC2 instance IDs</td>
</tr>
</tbody>
</table>

There's an error describing a managed security group or elastic network interface

<table>
<thead>
<tr>
<th>Based on Amazon EC2 client error code.</th>
<th>Error message returned by Amazon EC2 API</th>
<th>All managed security group IDs</th>
</tr>
</thead>
</table>

There's an error in authorizing or revoking security group ingress rules. This applies to both the cluster and control plane security groups.

<table>
<thead>
<tr>
<th>Based on Amazon EC2 client error code.</th>
<th>Error message returned by Amazon EC2 API</th>
<th>Problematic security group ID</th>
</tr>
</thead>
</table>

There's an error deleting an elastic network interface for a control plane instance

<table>
<thead>
<tr>
<th>Based on Amazon EC2 client error code.</th>
<th>Error message returned by Amazon EC2 API</th>
<th>Problematic elastic network interface ID</th>
</tr>
</thead>
</table>

The following table lists errors from other AWS services that are presented in the health field of the describe-cluster response:

<table>
<thead>
<tr>
<th>Amazon EC2 error code</th>
<th>Cluster health issue code</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>AuthFailure</td>

### Amazon EC2 error code | Cluster health issue code | Additional information
---|---|---
InvalidSubnetID.NotFound | ResourceNotFound | to continue to manage and monitor these AWS resources
InvalidPermission.NotFound | ResourceNotFound | Refers to the ingress rules of a security group
InvalidGroup.NotFound | ResourceNotFound | Refers to the ingress rules of a security group
InvalidNetworkInterfaceID.NotFound | ResourceNotFound | Refers to the ingress rules of a security group
InsufficientFreeAddresses.InInsufficientCapacityOnOutpost | ResourceLimitExceeded | Subnet resource limit
InsufficientCapacityOnOutpost | ResourceLimitExceeded | Outpost capacity limit
NetworkInterfaceLimitExceeded | ResourceLimitExceeded | Elastic network interface limit
SecurityGroupLimitExceeded | ResourceLimitExceeded | Security group limit
VcpuLimitExceeded | ResourceLimitExceeded | This is observed when creating an Amazon EC2 instance in a new account. The error might be similar to "You have requested more vCPU capacity than your current vCPU limit of 32 allows for the instance bucket that the specified instance type belongs to. Please visit http://aws.amazon.com/contact-us/ec2-request to request an adjustment to this limit."
InvalidParameterValue | ConfigurationConflict | Amazon EC2 returns this error code if the specified instance type isn't supported on the Outpost.

**Unable to create or modify clusters**

Local clusters require different permissions and policies than Amazon EKS clusters in the cloud. When cluster creation fails with an `InvalidPermissions` result, check to see that the cluster role you are using has the `AmazonEKSLocalOutpostClusterPolicy` (p. 486) managed policy attached to it. All other API calls require the same set of permissions as Amazon EKS clusters in the cloud.

**Cluster is stuck in CREATING state**

Local cluster creation time might vary depending on the characteristics of your network configuration, Outpost configuration, and the cluster you are trying to create. A local cluster should be created and be
ACTIVE within 15–20 minutes. If a local cluster remains in the CREATING state, a call to describe-cluster might provide hints of the cause in the cluster.health field.

The most common issues follow.

**AWS Systems Manager (Systems Manager)**

- Unable to connect to the control plane instance from the AWS Region using Systems Manager. You can verify this by calling `aws ssm start-session --target instance-id` from an in-region bastion host. If that fails, determine whether Systems Manager is running on the control plane instance and refer to the AWS Systems Manager User Guide for further help. Alternatively, you can simply delete this cluster and try to recreate the cluster.
- Control plane instances might not have internet access. Check to see whether the subnet you provided when creating the cluster has a NAT gateway configured and that its VPC has an internet gateway configured. Use VPC reachability analyzer to verify that the control plane instance can reach the internet gateway. For more information, see Getting started with VPC Reachability Analyzer.
- The provided role ARN is missing policies. Check to see if the section called “AmazonEKSLocalOutpostClusterPolicy” (p. 486) was removed from the role. This can also happen due to a misconfigured AWS CloudFormation stack.

**Multiple subnets misconfigured and specified when creating a cluster**

- All provided subnets must be associated with the same Outpost and be able to reach each another. When multiple subnets are specified during cluster creation, Amazon EKS tries to spread the control plane instances across multiple subnets.
- The Amazon EKS managed security groups are applied at the elastic network interface. There could be other configuration elements that are conflicting with it, such as NACL firewall rules.

**VPC and subnet DNS configuration is misconfigured or missing**

Review the section called "VPC and subnet requirements" (p. 557).

Unable to join nodes to a cluster

**Common causes:**

- AMI issues
  - You're using an unsupported AMI. You must be using v20220620 or later of an the section called “Amazon Linux” (p. 165) Amazon EKS optimized Amazon Linux.
  - If you used an AWS CloudFormation template to create your nodes, make sure it wasn't using an unsupported AMI.
- Missing AWS IAM Authenticator ConfigMap – If it's missing, you need to create it. For more information, see the section called “Apply the aws-authConfigMap to your cluster” (p. 387).
- Wrong security group is used – Make sure to use eks-cluster-sg-cluster-name-uniqueid for your worker nodes' security group. The selected security group is changed by AWS CloudFormation to allow a new security group each time the stack is used.
- Following unexpected private link VPC steps – Wrong CA data (--b64-cluster-ca) or API Endpoint (--apiserver-endpoint) are passed.
- Misconfigured pod security policy
  - The CoreDNS and Amazon VPC CNI plugin for Kubernetes Daemonsets must run on nodes for nodes to be able to properly join and communicate with the cluster.
  - The Amazon VPC CNI plugin for Kubernetes requires some privileged networking features in order to work properly. You can view the privileged networking features with the following command: `kubectl describe psp eks.privileged`.
We recommend that you don't modify the default pod security policy. For more information, see the section called “Pod security policy” (p. 495).

Collecting logs

When an Outpost gets disconnected from its AWS Region, the Kubernetes cluster should continue working normally, but you should be familiar with the section called “Network disconnects” (p. 558). If you encounter other issues, you should contact AWS support. It can guide you on how to download and run a log collection tool so that you can collect logs from your Kubernetes cluster control plane instances and send them to AWS support for further investigation.

Control plane instances aren't reachable through AWS Systems Manager

When the Amazon EKS control plane instances aren't reachable through AWS Systems Manager (Systems Manager), Amazon EKS displays the following error for your cluster.

Amazon EKS control plane instances are not reachable through SSM. Please verify your SSM and network configuration, and reference the EKS on Outposts troubleshooting documentation.

To resolve this issue, make sure that your VPC and subnets meet the requirements in the section called “VPC and subnet requirements” (p. 557) and that you have completed the steps in Setting up Session Manager in the AWS Systems Manager User Guide.

Launching self-managed Amazon Linux nodes on an Outpost

This topic describes how you can launch Auto Scaling groups of Amazon Linux nodes on an Outpost that register with your Amazon EKS cluster. The cluster can be on the AWS Cloud or on an Outpost.

Prerequisites

- An existing Outpost. For more information, see What is AWS Outposts.
- An existing Amazon EKS cluster. To deploy a cluster on the AWS Cloud, see the section called “Creating a cluster” (p. 24). To deploy a cluster on an Outpost, see the section called “Local clusters” (p. 549).
- If you're creating your nodes in a cluster on the AWS Cloud and you have subnets in the AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled, those subnets must not have been passed in when you created your cluster. If you're creating your noes in a cluster on an Outpost, you must have passed in an Outpost subnet when creating your cluster.
- Optional, but recommended for clusters on the AWS Cloud – The Amazon VPC CNI plugin for Kubernetes add-on configured with its own IAM role that has the necessary IAM policy attached to it. For more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258). Local clusters do not support IAM roles for service accounts.

You can create a self-managed Amazon Linux node group with eksctl or the AWS Management Console (with an AWS CloudFormation template). You can also use Terraform.

eksctl

**Prerequisite**
Version 0.112.0 or later of the `eksctl` command line tool installed on your device or AWS CloudShell. To install or update `eksctl`, see Installing or updating `eksctl` (p. 10).

**To launch self-managed Linux nodes using `eksctl`**

1. If your cluster is on the AWS Cloud and the `AmazonEKS_CNI_Policy` managed IAM policy is attached to your the section called “Node IAM role” (p. 461), we recommend assigning it to an IAM role that you associate to the Kubernetes `aws-node` service account instead. For more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258). If your cluster is on your Outpost, the policy must be attached to your node role.

2. The following command creates a node group in an existing cluster. The cluster must have been created using `eksctl`. Replace `al-nodes` with a name for your node group. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. Replace `my-cluster` with the name of your cluster. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters. If your cluster exists on an Outpost, replace `id` with the ID of an Outpost subnet. If your cluster exists on the AWS Cloud, replace `id` with the ID of a subnet that you didn't specify when you created your cluster. Replace `instance-type` with an instance type supported by your Outpost. Replace the remaining `example values` with your own values. The nodes are created with the same Kubernetes version as the control plane, by default.

Replace `instance-type` with an instance type available on your Outpost.

Replace `my-key` with the name of your Amazon EC2 key pair or public key. This key is used to SSH into your nodes after they launch. If you don't already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 key pairs in the Amazon EC2 User Guide for Linux Instances.

Create your node group with the following command.

```
    eksctl create nodegroup --cluster my-cluster --name al-nodes --node-type instance-type \
    --nodes 3 --nodes-min 1 --nodes-max 4 --managed=false --node-volume-type gp2 
    subnet-ids subnet-id
```

If your cluster is deployed on the AWS Cloud and you want to deploy a node group that:

- can assign IPv4 addresses to pods from a different CIDR block than that of the instance, see Tutorial: Custom networking (p. 276).
- doesn't have outbound internet access, see Private cluster requirements (p. 63).

For a complete list of all available options and defaults, see AWS Outposts Support in the `eksctl` documentation.

If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 521) in Troubleshooting (p. 521) and the section called “Unable to join nodes to a cluster” (p. 566) in the section called “Troubleshooting” (p. 562).

The example output is as follows. Several lines are output while the nodes are created. One of the last lines of output is the following example line.

```
    [✓]  created 1 nodegroup(s) in cluster "my-cluster"
```
AWS Management Console

**Step 1: To launch self-managed Amazon Linux nodes using the AWS Management Console**

1. Download the latest version of the AWS CloudFormation template.

   ```shell
   ``

3. Choose **Create stack** and then select **With new resources (standard)**.

4. For **Specify template**, select **Upload a template file** and then select **Choose file**. Select the `amazon-eks-nodegroup.yaml` file that you downloaded in a previous step and then select **Next**.

5. On the **Specify stack details** page, enter the following parameters accordingly, and then choose **Next**:
   - **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it `al-nodes`. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 100 characters.
   - **ClusterName**: Enter the name of your cluster. If this name doesn't match your cluster name, your nodes can't join the cluster.
   - **ClusterControlPlaneSecurityGroup**: Choose the **SecurityGroups** value from the AWS CloudFormation output that you generated when you created your VPC (p. 241). The following steps show one operation to retrieve the applicable group.
     1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
     2. Choose the name of the cluster.
     3. Choose the **Networking** tab.
     4. Use the **Additional security groups** value as a reference when selecting from the **ClusterControlPlaneSecurityGroup** dropdown list.
   - **NodeGroupName**: Enter a name for your node group. This name can be used later to identify the Auto Scaling node group that's created for your nodes.
   - **NodeAutoScalingGroupMinSize**: Enter the minimum number of nodes that your node Auto Scaling group can scale in to.
   - **NodeAutoScalingGroupDesiredCapacity**: Enter the desired number of nodes to scale to when your stack is created.
   - **NodeAutoScalingGroupMaxSize**: Enter the maximum number of nodes that your node Auto Scaling group can scale out to.
   - **NodeInstanceType**: Choose an instance type for your nodes. If your cluster is running on the AWS Cloud, then for more information, see *Choosing an Amazon EC2 instance type* (p. 162). If your cluster is running on an Outpost, then you can only select an instance type that is available on your Outpost.
   - **NodeImageIdSSMParam**: Pre-populated with the Amazon EC2 Systems Manager parameter of a recent Amazon EKS optimized Amazon Linux AMI ID for a Kubernetes version. To use a different Kubernetes minor version supported with Amazon EKS, replace `1.x` with a different supported version (p. 66). We recommend specifying the same Kubernetes version as your cluster.

To use the Amazon EKS optimized accelerated AMI, replace `amazon-linux-2` with `amazon-linux-2-gpu`. To use the Amazon EKS optimized Arm AMI, replace `amazon-linux-2` with `amazon-linux-2-arm64`.
Launching nodes

Note
The Amazon EKS node AMI is based on Amazon Linux 2. You can track security or privacy events for Amazon Linux 2 at the Amazon Linux Security Center or subscribe to the associated RSS feed. Security and privacy events include an overview of the issue, what packages are affected, and how to update your instances to correct the issue.

- **NodeImageId**: (Optional) If you’re using your own custom AMI (instead of the Amazon EKS optimized AMI), enter a node AMI ID for your AWS Region. If you specify a value here, it overrides any values in the `NodeImageIdSSMParam` field.
- **NodeVolumeSize**: Specify a root volume size for your nodes, in GiB.
- **KeyName**: Enter the name of an Amazon EC2 SSH key pair that you can use to connect using SSH into your nodes with after they launch. If you don’t already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 key pairs in the Amazon EC2 User Guide for Linux Instances.

Note
If you don’t provide a key pair here, the AWS CloudFormation stack creation fails.

- **BootstrapArguments**: There are several optional arguments that you can pass to your nodes. For more information, view the bootstrap script usage information on GitHub.
- **DisableIMDSv1**: By default, each node supports the Instance Metadata Service Version 1 (IMDSv1) and IMDSv2. You can disable IMDSv1. To prevent future nodes and pods in the node group from using IMDSv1, set `DisableIMDSv1` to `true`. For more information about IMDS, see Configuring the instance metadata service. For more information about restricting access to it on your nodes, see Restrict access to the instance profile assigned to the worker node.
- **VpcId**: Enter the ID for the VPC (p. 241) that you created. Before choosing a VPC, review the section called “VPC requirements and considerations” (p. 557).
- **Subnets**: If your cluster is on an Outpost, then choose at least one private subnet in your VPC. Before choosing subnets, review the section called “Subnet requirements and considerations” (p. 557). You can see which subnets are private by opening each subnet link from the Networking tab of your cluster.

Important
- Make sure that you’re aware of the considerations and extra steps in Private cluster requirements (p. 63).
- If your cluster in on the AWS Cloud, and you select AWS Outposts, Wavelength, or Local Zone subnets, the subnets must not have been passed in when you created the cluster.

6. Select your desired choices on the Configure stack options page, and then choose Next.
7. Select the check box to the left of I acknowledge that AWS CloudFormation might create IAM resources., and then choose Create stack.
8. When your stack has finished creating, select it in the console and choose Outputs.
9. Record the **NodeInstanceRole** for the node group that was created. You need this when you configure your Amazon EKS nodes.

Step 2: To enable nodes to join your cluster

Note
If you launched nodes inside a private VPC without outbound internet access, make sure to enable nodes to join your cluster from within the VPC.

1. Download, edit, and apply the AWS IAM Authenticator configuration map.
   a. Download the configuration map using the following command.
b. In the `aws-auth-cm.yaml` file, set the `rolearn` to the value that you recorded in the previous procedure. You can do this with a text editor, or by replacing `my-node-instance-role` and running the following command:

```
sed -i.bak -e 's|<ARN of instance role (not instance profile)>|my-node-instance-role|' aws-auth-cm.yaml
```

c. Apply the configuration. This command may take a few minutes to finish.

```
kubectl apply -f aws-auth-cm.yaml
```

**Note**

If you receive any authorization or resource type errors, see Unauthorized or access denied (`kubectl`) (p. 522) in the troubleshooting section.

If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 521) in Troubleshooting (p. 521) and the section called “Unable to join nodes to a cluster” (p. 566) in the section called “Troubleshooting” (p. 562).

2. Watch the status of your nodes and wait for them to reach the **Ready** status.

```
kubectl get nodes --watch
```

Enter Ctrl+C to return to a shell prompt.

3. Install the Amazon EBS CSI driver. For more information, see Installation on GitHub. In the **Set up driver permission** section, make sure to follow the instruction for the Using IAM instance profile option. You must use the `gp2` storage class. The `gp3` storage class isn’t supported.

To create a `gp2` storage class on your cluster, complete the following steps.

1. Run the following command to create the `gp2-storage-class.yaml` file.

```
cat >gp2-storage-class.yaml <<EOF
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  annotations:
    storageclass.kubernetes.io/is-default-class: "true"
  name: ebs-sc
provisioner: ebs.csi.aws.com
volumeBindingMode: WaitForFirstConsumer
parameters:
  type: gp2
  encrypted: "true"
allowVolumeExpansion: true
EOF
```

2. Apply the manifest to your cluster.

```
kubectl apply -f gp2-storage-class.yaml
```

4. (GPU nodes only) If you chose a GPU instance type and the Amazon EKS optimized accelerated AMI, you must apply the NVIDIA device plugin for Kubernetes as a DaemonSet on your cluster with the following command.
5. (Optional) Deploy a sample application (p. 338) to test your cluster and Linux nodes.

6. If your cluster is deployed on an Outpost, then skip this step. If your cluster is deployed on the AWS Cloud, the following information is optional. If the `AmazonEKS_CNI_Policy` managed IAM policy is attached to your section called “Node IAM role” (p. 461), we recommend assigning it to an IAM role that you associate to the Kubernetes `aws-node` service account instead. For more information, see Configuring the Amazon VPC CNI plugin for Kubernetes to use IAM roles for service accounts (p. 258).
Related projects

These open-source projects extend the functionality of Kubernetes clusters running on or outside of AWS, including clusters managed by Amazon EKS.

Management tools

Related management tools for Amazon EKS and Kubernetes clusters.

**eksctl**

`eksctl` is a simple CLI tool for creating clusters on Amazon EKS.

Amazon EKS new features and roadmap

You can learn about new Amazon EKS features by scrolling to the What's New feed on the What's New with AWS page. You can also review the roadmap on GitHub, which lets you know about upcoming features and priorities so that you can plan how you want to use Amazon EKS in the future. You can provide direct feedback to us about the roadmap priorities.
# Document history for Amazon EKS

The following table describes the major updates and new features for the Amazon EKS User Guide. We also update the documentation frequently to address the feedback that you send us.

<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local clusters on AWS Outposts are now available</td>
<td>You can now create an Amazon EKS local cluster on an Outpost.</td>
<td>September 19, 2022</td>
</tr>
<tr>
<td>Fargate vCPU based quotas</td>
<td>Fargate is transitioning from pod based quotas to vCPU based quotas.</td>
<td>September 8, 2022</td>
</tr>
<tr>
<td>Cost monitoring</td>
<td>Amazon EKS now supports Kubecost, which enables you to monitor costs broken down by Kubernetes resources including pods, nodes, namespaces, and labels.</td>
<td>August 24, 2022</td>
</tr>
<tr>
<td>Tag resources for billing</td>
<td>Added <code>aws:eks:cluster-name</code> generated cost allocation tag support for all clusters.</td>
<td>August 16, 2022</td>

</tr>
<tr>
<td>Create multi-homed pods using Multus</td>
<td>You can now add multiple network interfaces to a pod using Multus.</td>
<td>August 2, 2021</td>
</tr>
<tr>
<td>Add more IP addresses to your Linux Amazon EC2 nodes</td>
<td>You can now add significantly more IP addresses to your Linux Amazon EC2 nodes. This means that you can run a higher density of pods on each node.</td>
<td>July 27, 2021</td>
</tr>
<tr>
<td>Kubernetes version 1.21</td>
<td>Added Kubernetes version 1.21 support.</td>
<td>July 19, 2021</td>
</tr>
<tr>
<td>Containerd runtime bootstrap</td>
<td>The Amazon EKS optimized accelerated Amazon Linux Amazon Machine Image (AMI) now contains a bootstrap flag that you can use to enable the containerd runtime in Amazon EKS optimized and Bottlerocket AMIs. This flag is available in all supported Kubernetes versions of the AMI.</td>
<td>July 19, 2021</td>
</tr>
<tr>
<td>Added managed policies topic</td>
<td>A list of all Amazon EKS IAM managed policies and changes that were made to them since June 17, 2021.</td>
<td>June 17, 2021</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>Use security groups for pods with Fargate</td>
<td>You can now use security groups for pods with Fargate, in addition to using them with Amazon EC2 nodes.</td>
<td>June 1, 2021</td>
</tr>
<tr>
<td>Added CoreDNS and kube-proxy Amazon EKS add-ons</td>
<td>Amazon EKS can now help you manage the CoreDNS and kube-proxy Amazon EKS add-ons for your cluster.</td>
<td>May 19, 2021</td>
</tr>
<tr>
<td>Kubernetes version 1.20</td>
<td>Added Kubernetes version 1.20 support for new clusters and version upgrades.</td>
<td>May 18, 2021</td>
</tr>
<tr>
<td>AWS Load Balancer Controller 2.2.0 released</td>
<td>You can now use the AWS Load Balancer Controller to create Elastic Load Balancers using instance or IP targets.</td>
<td>May 14, 2021</td>
</tr>
<tr>
<td>Node taints for managed node groups</td>
<td>Amazon EKS now supports adding node taints to managed node groups.</td>
<td>May 11, 2021</td>
</tr>
<tr>
<td>Secrets encryption for existing clusters</td>
<td>Amazon EKS now supports adding secrets encryption to existing clusters.</td>
<td>February 26, 2021</td>
</tr>
<tr>
<td>Kubernetes version 1.19</td>
<td>Added Kubernetes version 1.19 support for new clusters and version upgrades.</td>
<td>February 16, 2021</td>
</tr>
<tr>
<td>Amazon EKS now supports OpenID Connect (OIDC) identity providers as a method to authenticate users to a version 1.16 or later cluster.</td>
<td>OIDC identity providers can be used with, or as an alternative to AWS Identity and Access Management (IAM).</td>
<td>February 12, 2021</td>
</tr>
<tr>
<td>View node and workload resources in the AWS Management Console</td>
<td>You can now view details about your managed, self-managed, and Fargate nodes and your deployed Kubernetes workloads in the AWS Management Console.</td>
<td>December 1, 2020</td>
</tr>
<tr>
<td>Deploy Spot Instance types in a managed node group</td>
<td>You can now deploy multiple Spot or On-Demand Instance types to a managed node group.</td>
<td>December 1, 2020</td>
</tr>
<tr>
<td>Amazon EKS can now manage specific add-ons for your cluster</td>
<td>You can manage add-ons yourself, or allow Amazon EKS to control the launch and version of an add-on through the Amazon EKS API.</td>
<td>December 1, 2020</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>Share an ALB across multiple Ingresses</td>
<td>You can now share an AWS Application Load Balancer (ALB) across multiple Kubernetes Ingresses. In the past, you had to deploy a separate ALB for each Ingress.</td>
<td>October 23, 2020</td>
</tr>
<tr>
<td>NLB IP target support</td>
<td>You can now deploy a Network Load Balancer with IP targets. This means that you can use an NLB to load balance network traffic to Fargate pods and directly to pods that are running on Amazon EC2 nodes.</td>
<td>October 23, 2020</td>
</tr>
<tr>
<td>Kubernetes version 1.18 (p. 578)</td>
<td>Added Kubernetes version 1.18 support for new clusters and version upgrades.</td>
<td>October 13, 2020</td>
</tr>
<tr>
<td>Specify a custom CIDR block for Kubernetes service IP address assignment.</td>
<td>You can now specify a custom CIDR block that Kubernetes assigns service IP addresses from.</td>
<td>September 29, 2020</td>
</tr>
<tr>
<td>Assign security groups to individual pods</td>
<td>You can now associate different security groups to some of the individual pods that are running on many Amazon EC2 instance types.</td>
<td>September 9, 2020</td>
</tr>
<tr>
<td>Deploy Bottlerocket on your nodes</td>
<td>You can now deploy nodes that are running Bottlerocket.</td>
<td>August 31, 2020</td>
</tr>
<tr>
<td>The ability to launch Arm nodes is generally available</td>
<td>You can now launch Arm nodes in managed and self-managed node groups.</td>
<td>August 17, 2020</td>
</tr>
<tr>
<td>Managed node group launch templates and custom AMI</td>
<td>You can now deploy a managed node group that uses an Amazon EC2 launch template. The launch template can specify a custom AMI, if you choose.</td>
<td>August 17, 2020</td>
</tr>
<tr>
<td>EFS support for AWS Fargate</td>
<td>You can now use Amazon EFS with AWS Fargate.</td>
<td>August 17, 2020</td>
</tr>
<tr>
<td>Amazon EKS platform version update</td>
<td>This is a new platform version with security fixes and enhancements. This includes UDP support for services of type LoadBalancer when using Network Load Balancers with Kubernetes version 1.15 or later. For more information, see the Allow UDP for AWS Network Load Balancer issue on GitHub.</td>
<td>August 12, 2020</td>
</tr>

<tr>
<td>Amazon EKS AWS Region expansion (p. 578)</td>
<td>Amazon EKS is now available in the Africa (Cape Town) (af-south-1) and Europe (Milan) (eu-south-1) AWS Regions.</td>
<td>August 6, 2020</td>
</tr>
<tr>
<td>Fargate usage metrics</td>
<td>AWS Fargate provides CloudWatch usage metrics that provide visibility into your account’s usage of Fargate On-Demand resources.</td>
<td>August 3, 2020</td>
</tr>
<tr>
<td>Kubernetes version 1.17 (p. 578)</td>
<td>Added Kubernetes version 1.17 support for new clusters and version upgrades.</td>
<td>July 10, 2020</td>
</tr>
<tr>
<td>Create and manage App Mesh resources from within Kubernetes with the App Mesh controller for Kubernetes</td>
<td>You can create and manage App Mesh resources from within Kubernetes. The controller also automatically injects the Envoy proxy and init containers into pods that you deploy.</td>
<td>June 18, 2020</td>
</tr>
<tr>
<td>Amazon EKS now supports Amazon EC2 Inf1 nodes</td>
<td>You can add Amazon EC2 Inf1 nodes to your cluster.</td>
<td>June 4, 2020</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 578)</td>
<td>Amazon EKS is now available in the AWS GovCloud (US-East) (us-gov-east-1) and AWS GovCloud (US-West) (us-gov-west-1) AWS Regions.</td>
<td>May 13, 2020</td>
</tr>
<tr>
<td>Kubernetes 1.12 is no longer supported on Amazon EKS</td>
<td>Kubernetes version 1.12 is no longer supported on Amazon EKS. Update any 1.12 clusters to version 1.13 or later to avoid service interruption.</td>
<td>May 12, 2020</td>
</tr>
<tr>
<td>Kubernetes version 1.16 (p. 578)</td>
<td>Added Kubernetes version 1.16 support for new clusters and version upgrades.</td>
<td>April 30, 2020</td>
</tr>
<tr>
<td>Added the AWSServiceRoleForAmazonEKS service-linked role</td>
<td>Added the AWSServiceRoleForAmazonEKS service-linked role.</td>
<td>April 16, 2020</td>
</tr>
<tr>
<td>Kubernetes version 1.15 (p. 578)</td>
<td>Added Kubernetes version 1.15 support for new clusters and version upgrades.</td>
<td>March 10, 2020</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 578)</td>
<td>Amazon EKS is now available in the Beijing (cn-north-1) and Ningxia (cn-northwest-1) AWS Regions.</td>
<td>February 26, 2020</td>
</tr>
<tr>
<td>FSx for Lustre CSI driver</td>
<td>Added topic for installing the FSx for Lustre CSI Driver on Kubernetes 1.14 Amazon EKS clusters.</td>
<td>December 23, 2019</td>
</tr>
<tr>
<td>Feature Description</td>
<td>Description</td>
<td>Date</td>

<tr>
<td>Restrict network access to the public access endpoint of a cluster</td>
<td>With this update, you can use Amazon EKS to restrict the CIDR ranges that can communicate to the public access endpoint of the Kubernetes API server.</td>
<td>December 20, 2019</td>
</tr>
<tr>
<td>Resolve the private access endpoint address for a cluster from outside of a VPC</td>
<td>With this update, you can use Amazon EKS to resolve the private access endpoint address for the Kubernetes API server from outside of a VPC.</td>
<td>December 13, 2019</td>
</tr>
<tr>
<td>(Beta) Amazon EC2 A1 Amazon EC2 instance nodes</td>
<td>Launch Amazon EC2 A1 Amazon EC2 instance nodes that register with your Amazon EKS cluster.</td>
<td>December 4, 2019</td>
</tr>
<tr>
<td>Creating a cluster on AWS Outposts</td>
<td>Amazon EKS now supports creating clusters on AWS Outposts.</td>
<td>December 3, 2019</td>
</tr>
<tr>
<td>AWS Fargate on Amazon EKS</td>
<td>Amazon EKS Kubernetes clusters now support running pods on Fargate.</td>
<td>December 3, 2019</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 578)</td>
<td>Amazon EKS is now available in the Canada (Central) (ca-central-1) AWS Region.</td>
<td>November 21, 2019</td>
</tr>
<tr>
<td>Managed node groups</td>
<td>Amazon EKS managed node groups automate the provisioning and lifecycle management of nodes (Amazon EC2 instances) for Amazon EKS Kubernetes clusters.</td>
<td>November 18, 2019</td>
</tr>
<tr>
<td>Amazon EKS platform version update</td>
<td>New platform versions to address CVE-2019-11253.</td>
<td>November 6, 2019</td>
</tr>
<tr>
<td>Kubernetes 1.11 is no longer supported on Amazon EKS</td>
<td>Kubernetes version 1.11 is no longer supported on Amazon EKS. Please update any 1.11 clusters to version 1.12 or higher to avoid service interruption.</td>
<td>November 4, 2019</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 578)</td>
<td>Amazon EKS is now available in the South America (São Paulo) (sa-east-1) AWS Region.</td>
<td>October 16, 2019</td>
</tr>
<tr>
<td>Windows support</td>
<td>Amazon EKS clusters running Kubernetes version 1.14 now support Windows workloads.</td>
<td>October 7, 2019</td>
</tr>
<tr>
<td>Autoscaling</td>
<td>Added a chapter to cover some of the different types of Kubernetes autoscaling that are supported on Amazon EKS clusters.</td>
<td>September 30, 2019</td>
</tr>
<tr>
<td><strong>Kubernetes Dashboard update</strong></td>
<td>Updated topic for installing the Kubernetes Dashboard on Amazon EKS clusters to use the beta 2.0 version.</td>
<td>September 28, 2019</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td><strong>Amazon EFS CSI driver</strong></td>
<td>Added topic for installing the Amazon EFS CSI Driver on Kubernetes 1.14 Amazon EKS clusters.</td>
<td>September 19, 2019</td>
</tr>
<tr>
<td><strong>Amazon EC2 Systems Manager parameter for Amazon EKS optimized AMI ID</strong></td>
<td>Added topic for retrieving the Amazon EKS optimized AMI ID using an Amazon EC2 Systems Manager parameter. The parameter eliminates the need for you to look up AMI IDs.</td>
<td>September 18, 2019</td>
</tr>
<tr>
<td><strong>Amazon EKS resource tagging</strong></td>
<td>You can manage the tagging of your Amazon EKS clusters.</td>
<td>September 16, 2019</td>
</tr>
<tr>
<td><strong>Amazon EBS CSI driver</strong></td>
<td>Added topic for installing the Amazon EBS CSI driver on Kubernetes 1.14 Amazon EKS clusters.</td>
<td>September 9, 2019</td>
</tr>
<tr>
<td><strong>New Amazon EKS optimized AMI patched for CVE-2019-9512 and CVE-2019-9514</strong></td>
<td>Amazon EKS has updated the Amazon EKS optimized AMI to address CVE-2019-9512 and CVE-2019-9514.</td>
<td>September 6, 2019</td>
</tr>
<tr>
<td><strong>Announcing deprecation of Kubernetes 1.11 in Amazon EKS</strong></td>
<td>Amazon EKS discontinued support for Kubernetes version 1.11 on November 4, 2019.</td>
<td>September 4, 2019</td>
</tr>
<tr>
<td><strong>Kubernetes version 1.14 (p. 578)</strong></td>
<td>Added Kubernetes version 1.14 support for new clusters and version upgrades.</td>
<td>September 3, 2019</td>
</tr>
<tr>
<td><strong>IAM roles for service accounts</strong></td>
<td>With IAM roles for service accounts on Amazon EKS clusters, you can associate an IAM role with a Kubernetes service account. With this feature, you no longer need to provide extended permissions to the node IAM role. This way, pods on that node can call AWS APIs.</td>
<td>September 3, 2019</td>
</tr>
<tr>
<td><strong>Amazon EKS AWS Region expansion (p. 578)</strong></td>
<td>Amazon EKS is now available in the Middle East (Bahrain) (me-south-1) AWS Region.</td>
<td>August 29, 2019</td>
</tr>
<tr>
<td><strong>Amazon EKS platform version update</strong></td>
<td>New platform versions to address CVE-2019-9512 and CVE-2019-9514.</td>
<td>August 28, 2019</td>
</tr>
<tr>
<td><strong>Amazon EKS platform version update</strong></td>
<td>New platform versions to address <strong>CVE-2019-11247</strong> and <strong>CVE-2019-11249</strong>.</td>
<td>August 5, 2019</td>
</tr>
<tr>
<td><strong>Amazon EKS Region expansion (p. 578)</strong></td>
<td>Amazon EKS is now available in the Asia Pacific (Hong Kong) (ap-east-1) AWS Region.</td>
<td>July 31, 2019</td>
</tr>
<tr>
<td><strong>Kubernetes 1.10 no longer supported on Amazon EKS</strong></td>
<td>Kubernetes version 1.10 is no longer supported on Amazon EKS. Update any 1.10 clusters to version 1.11 or higher to avoid service interruption.</td>
<td>July 30, 2019</td>
</tr>
<tr>
<td><strong>Added topic on ALB ingress controller</strong></td>
<td>The AWS ALB Ingress Controller for Kubernetes is a controller that causes an ALB to be created when ingress resources are created.</td>
<td>July 11, 2019</td>
</tr>
<tr>
<td><strong>New Amazon EKS optimized AMI</strong></td>
<td>Removing unnecessary kubectl binary from AMIs.</td>
<td>July 3, 2019</td>
</tr>
<tr>
<td><strong>Kubernetes version 1.13 (p. 578)</strong></td>
<td>Added Kubernetes version 1.13 support for new clusters and version upgrades.</td>
<td>June 18, 2019</td>
</tr>
<tr>
<td><strong>New Amazon EKS optimized AMI patched for <strong>AWS-2019-005</strong></strong></td>
<td>Amazon EKS has updated the Amazon EKS optimized AMI to address the vulnerabilities that are described in <strong>AWS-2019-005</strong>.</td>
<td>June 17, 2019</td>
</tr>
<tr>
<td><strong>Announcing discontinuation of support of Kubernetes 1.10 in Amazon EKS</strong></td>
<td>Amazon EKS stopped supporting Kubernetes version 1.10 on July 22, 2019.</td>
<td>May 21, 2019</td>
</tr>
<tr>
<td><strong>Amazon EKS platform version update</strong></td>
<td>New platform version for Kubernetes 1.11 and 1.10 clusters to support custom DNS names in the kubectl certificate and improve etcd performance.</td>
<td>May 21, 2019</td>
</tr>
<tr>
<td><strong>AWS CLI get-token command (p. 578)</strong></td>
<td>The aws eks get-token command was added to the AWS CLI. You no longer need to install the AWS IAM Authenticator for Kubernetes to create client security tokens for cluster API server communication. Upgrade your AWS CLI installation to the latest version to use this new functionality. For more information, see <strong>Installing the AWS Command Line Interface</strong> in the <strong>AWS Command Line Interface User Guide</strong>.</td>
<td>May 10, 2019</td>
</tr>
<tr>
<td>Getting started with eksctl</td>
<td>This getting started guide describes how you can install all of the required resources to get started with Amazon EKS using eksctl. This is a simple command line utility for creating and managing Kubernetes clusters on Amazon EKS.</td>
<td>May 10, 2019</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>Amazon EKS platform version update</td>
<td>New platform version for Kubernetes 1.12 clusters to support custom DNS names in the kubelet certificate and improve etcd performance. This fixes a bug that caused node kubelet daemons to request a new certificate every few seconds.</td>
<td>May 8, 2019</td>
</tr>
<tr>
<td>Prometheus tutorial</td>
<td>Added topic for deploying Prometheus to your Amazon EKS cluster.</td>
<td>April 5, 2019</td>
</tr>
<tr>
<td>Amazon EKS control plane logging</td>
<td>With this update, you can get audit and diagnostic logs directly from the Amazon EKS control pane. You can use these CloudWatch logs in your account as reference for securing and running clusters.</td>
<td>April 4, 2019</td>
</tr>
<tr>
<td>Kubernetes version 1.12 (p. 578)</td>
<td>Added Kubernetes version 1.12 support for new clusters and version upgrades.</td>
<td>March 28, 2019</td>
</tr>
<tr>
<td>Added App Mesh getting started guide</td>
<td>Added documentation for getting started with App Mesh and Kubernetes.</td>
<td>March 27, 2019</td>
</tr>
<tr>
<td>Amazon EKS API server endpoint private access</td>
<td>Added documentation for disabling public access for your Amazon EKS cluster's Kubernetes API server endpoint.</td>
<td>March 19, 2019</td>
</tr>
<tr>
<td>Added topic for installing the Kubernetes Metrics Server</td>
<td>The Kubernetes Metrics Server is an aggregator of resource usage data in your cluster.</td>
<td>March 18, 2019</td>
</tr>
<tr>
<td>Added list of related open source projects</td>
<td>These open source projects extend the functionality of Kubernetes clusters running on AWS, including clusters that are managed by Amazon EKS.</td>
<td>March 15, 2019</td>
</tr>
<tr>
<td>Added topic for installing Helm locally</td>
<td>The <code>helm</code> package manager for Kubernetes helps you install and manage applications on your Kubernetes cluster. This topic shows how to install and run the <code>helm</code> and <code>tiller</code> binaries locally. That way, you can install and manage charts using the Helm CLI on your local system.</td>
<td>March 11, 2019</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>Amazon EKS platform version update</td>
<td>New platform version that updates Amazon EKS Kubernetes 1.11 clusters to patch level 1.11.8 to address CVE-2019-1002100.</td>
<td>March 8, 2019</td>
</tr>
<tr>
<td>Increased cluster limit</td>
<td>Amazon EKS has increased the number of clusters that you can create in an AWS Region from 3 to 50.</td>
<td>February 13, 2019</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 578)</td>
<td>Amazon EKS is now available in the Europe (London) (eu-west-2), Europe (Paris) (eu-west-3), and Asia Pacific (Mumbai) (ap-south-1) AWS Regions.</td>
<td>February 13, 2019</td>
</tr>
<tr>
<td>New Amazon EKS optimized AMI patched for ALAS-2019-1156</td>
<td>Amazon EKS has updated the Amazon EKS optimized AMI to address the vulnerability that’s described in ALAS-2019-1156.</td>
<td>February 11, 2019</td>
</tr>
<tr>
<td>New Amazon EKS optimized AMI patched for ALAS2-2019-1141</td>
<td>Amazon EKS has updated the Amazon EKS optimized AMI to address the CVEs that are referenced in ALAS2-2019-1141.</td>
<td>January 9, 2019</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 578)</td>
<td>Amazon EKS is now available in the Asia Pacific (Seoul) (ap-northeast-2) AWS Region.</td>
<td>January 9, 2019</td>
</tr>
<tr>
<td>Amazon EKS region expansion (p. 578)</td>
<td>Amazon EKS is now available in the following additional AWS Regions: Europe (Frankfurt) (eu-central-1), Asia Pacific (Tokyo) (ap-northeast-1), Asia Pacific (Singapore) (ap-southeast-1), and Asia Pacific (Sydney) (ap-southeast-2).</td>
<td>December 19, 2018</td>
</tr>
<tr>
<td>Amazon EKS cluster updates</td>
<td>Added documentation for Amazon EKS cluster Kubernetes version updates and node replacement.</td>
<td>December 12, 2018</td>
</tr>
<tr>
<td><strong>Amazon EKS AWS Region expansion (p. 578)</strong></td>
<td>Amazon EKS is now available in the Europe (Stockholm) (eu-north-1) AWS Region.</td>
<td>December 11, 2018</td>
</tr>
<tr>
<td><strong>Amazon EKS platform version update</strong></td>
<td>New platform version updating Kubernetes to patch level 1.10.11 to address CVE-2018-1002105.</td>
<td>December 4, 2018</td>
</tr>
<tr>
<td><strong>Added version 1.0.0 support for the ALB ingress controller</strong></td>
<td>The ALB ingress controller releases version 1.0.0 with formal support from AWS.</td>
<td>November 20, 2018</td>
</tr>
<tr>
<td><strong>Added support for CNI network configuration</strong></td>
<td>The Amazon VPC CNI plugin for Kubernetes version 1.2.1 now supports custom network configuration for secondary pod network interfaces.</td>
<td>October 16, 2018</td>
</tr>
<tr>
<td><strong>Added support for MutatingAdmissionWebhook and ValidatingAdmissionWebhook</strong></td>
<td>Amazon EKS platform version 1.10-eks.2 now supports MutatingAdmissionWebhook and ValidatingAdmissionWebhook admission controllers.</td>
<td>October 10, 2018</td>
</tr>
<tr>
<td><strong>Added partner AMI information</strong></td>
<td>Canonical has partnered with Amazon EKS to create node AMIs that you can use in your clusters.</td>
<td>October 3, 2018</td>
</tr>
<tr>
<td><strong>Added instructions for AWS CLI update-kubeconfig command</strong></td>
<td>Amazon EKS has added the update-kubeconfig to the AWS CLI to simplify the process of creating a kubeconfig file for accessing your cluster.</td>
<td>September 21, 2018</td>
</tr>
<tr>
<td><strong>New Amazon EKS optimized AMIs</strong></td>
<td>Amazon EKS has updated the Amazon EKS optimized AMIs (with and without GPU support) to provide various security fixes and AMI optimizations.</td>
<td>September 13, 2018</td>
</tr>
<tr>
<td><strong>Amazon EKS AWS Region expansion (p. 578)</strong></td>
<td>Amazon EKS is now available in the Europe (Ireland) (eu-west-1) Region.</td>
<td>September 5, 2018</td>
</tr>
<tr>
<td><strong>Amazon EKS platform version update</strong></td>
<td>New platform version with support for Kubernetes aggregation layer and the Horizontal Pod Autoscaler (HPA).</td>
<td>August 31, 2018</td>
</tr>
<tr>
<td><strong>New Amazon EKS optimized AMIs and GPU support</strong></td>
<td>Amazon EKS has updated the Amazon EKS optimized AMI to use a new AWS CloudFormation node template and bootstrap script. In addition, a new Amazon EKS optimized AMI with GPU support is available.</td>
<td>August 22, 2018</td>
