What is Amazon EKS?

Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run
Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control
plane or nodes. Kubernetes is an open-source system for automating the deployment, scaling, and
management of containerized applications. Amazon EKS:

• Runs and scales the Kubernetes control plane across multiple AWS Availability Zones to ensure high
availability.
• Automatically scales control plane instances based on load, detects and replaces unhealthy control
plane instances, and it provides automated version updates and patching for them.
• Is integrated with many AWS services to provide scalability and security for your applications,
including the following capabilities:
  • Amazon ECR for container images
  • Elastic Load Balancing for load distribution
  • IAM for authentication
  • Amazon VPC for isolation
• Runs up-to-date versions of the open-source Kubernetes software, so you can use all of the existing
plugins and tooling from the Kubernetes community. Applications that are running on Amazon EKS
are fully compatible with applications running on any standard Kubernetes environment, no matter
whether they’re running in on-premises data centers or public clouds. This means that you can easily
migrate any standard Kubernetes application to Amazon EKS without any code modification.

Amazon EKS control plane architecture

Amazon EKS runs a single tenant Kubernetes control plane for each cluster. The control plane
infrastructure isn't shared across clusters or AWS accounts. The control plane consists of at least two API
server instances and three etcd instances that run across three Availability Zones within an AWS Region.
Amazon EKS:

• Actively monitors the load on control plane instances and automatically scales them to ensure high
performance.
• Automatically detects and replaces unhealthy control plane instances, restarting them across the
Availability Zones within the AWS Region as needed.
• Leverages the architecture of AWS Regions in order to maintain high availability. Because of this,
Amazon EKS is able to offer an SLA for API server endpoint availability.

Amazon EKS uses Amazon VPC network policies to restrict traffic between control plane components
to within a single cluster. Control plane components for a cluster can’t view or receive communication
from other clusters or other AWS accounts, except as authorized with Kubernetes RBAC policies. This
secure and highly available configuration makes Amazon EKS reliable and recommended for production
workloads.
How does Amazon EKS work?

Getting started with Amazon EKS is easy:

1. Create an Amazon EKS cluster in the AWS Management Console or with the AWS CLI or one of the AWS SDKs.
2. Launch managed or self-managed Amazon EC2 nodes, or deploy your workloads to AWS Fargate.
3. When your cluster is ready, you can configure your favorite Kubernetes tools, such as `kubectl`, to communicate with your cluster.
4. Deploy and manage workloads on your Amazon EKS cluster the same way that you would with any other Kubernetes environment. You can also view information about your workloads using the AWS Management Console.

To create your first cluster and its associated resources, see Getting started with Amazon EKS (p. 4). To learn about other Kubernetes deployment options, see Deployment options (p. 2).

Pricing

An Amazon EKS cluster consists of a control plane and the Amazon EC2 or AWS Fargate compute that you run pods on. For more information about pricing for the control plane, see Amazon EKS pricing. Both Amazon EC2 and Fargate provide:

- **On-Demand Instances** – Pay for the instances that you use by the second, with no long-term commitments or upfront payments. For more information, see Amazon EC2 On-Demand Pricing and AWS Fargate Pricing.
- **Savings Plans** – You can reduce your costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years. For more information, see Pricing with Savings Plans.

Deployment options

You can use Amazon EKS with any, or all, of the following deployment options:

- **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes. For more information, see What is Amazon EKS? (p. 1).
- **Amazon EKS on AWS Outposts** – Run Amazon EKS nodes on AWS Outposts. AWS Outposts enables native AWS services, infrastructure, and operating models in on-premises facilities. For more information, see Amazon EKS on AWS Outposts (p. 501).
• **Amazon EKS Anywhere** – Amazon EKS Anywhere is a deployment option for Amazon EKS that enables you to easily create and operate Kubernetes clusters on-premises. Both Amazon EKS and Amazon EKS Anywhere are built on the Amazon EKS Distro. To learn more about Amazon EKS Anywhere, and its differences with Amazon EKS, see Overview and Comparing Amazon EKS Anywhere to Amazon EKS in the Amazon EKS Anywhere documentation.

• **Amazon EKS Distro** – Amazon EKS Distro is a distribution of the same open-source Kubernetes software and dependencies deployed by Amazon EKS in the cloud. Amazon EKS Distro follows the same Kubernetes version release cycle as Amazon EKS and is provided as an open-source project. To learn more, see Amazon EKS Distro. You can also view and download the source code for the Amazon EKS Distro on GitHub.

When choosing which deployment options to use for your Kubernetes cluster, consider the following:

**Frequently asked questions**

• Q: Can I deploy Amazon EKS Anywhere in the AWS cloud?

  A: Amazon EKS Anywhere isn't designed to run in the AWS cloud. It doesn't integrate with the Kubernetes Cluster API Provider for AWS. If you plan to deploy Kubernetes clusters in the AWS cloud, we strongly recommend that you use Amazon EKS.

• Q: Can I deploy Amazon EKS Anywhere on AWS Outposts?

  A: Amazon EKS Anywhere isn't designed to run on AWS Outposts. If you're planning to deploy Kubernetes clusters on AWS Outposts, we strongly recommend that you use Amazon EKS on AWS Outposts.
Getting started with Amazon EKS

Many procedures of this user guide use the following command line tools:

- **kubectl** – A command line tool for working with Kubernetes clusters. For more information, see Installing *kubectl* (p. 4).
- **eksctl** – A command line tool for working with EKS clusters that automates many individual tasks. For more information, see Installing *eksctl* (p. 10).
- **AWS CLI** – A command line tool for working with AWS services, including Amazon EKS. For more information, see Installing, updating, and uninstalling the AWS CLI in the AWS Command Line Interface User Guide. After installing the AWS CLI, we recommend that you also configure it. For more information, see Quick configuration with *aws configure* in the AWS Command Line Interface User Guide.

There are two getting started guides available for creating a new Kubernetes cluster with nodes in Amazon EKS:

- **Getting started with Amazon EKS – eksctl** (p. 12) – This getting started guide helps you to install all of the required resources to get started with Amazon EKS using eksctl, a simple command line utility for creating and managing Kubernetes clusters on Amazon EKS. At the end of the tutorial, you will have a running Amazon EKS cluster that you can deploy applications to. This is the fastest and simplest way to get started with Amazon EKS.
- **Getting started with Amazon EKS – AWS Management Console and AWS CLI** (p. 16) – This getting started guide helps you to create all of the required resources to get started with Amazon EKS using the AWS Management Console and AWS CLI. At the end of the tutorial, you will have a running Amazon EKS cluster that you can deploy applications to. In this guide, you manually create each resource required for an Amazon EKS cluster. The procedures give you visibility into how each resource is created and how they interact with each other.

Installing *kubectl*

Kubernetes uses a command line utility called *kubectl* for communicating with the cluster API server. The *kubectl* binary is available in many operating system package managers, and this option is often much easier than a manual download and install process. You can follow the instructions for your specific operating system or package manager in the Kubernetes documentation to install.

This topic helps you to download and install the Amazon EKS vended *kubectl* binaries for macOS, Linux, and Windows operating systems. Select the tab name of your operating system. These binaries are identical to the upstream community versions, and are not unique to Amazon EKS or AWS.

**Note**
You must use a *kubectl* version that is within one minor version difference of your Amazon EKS cluster control plane. For example, a 1.21 *kubectl* client works with Kubernetes 1.20, 1.21 and 1.22 clusters.

Select the tab with the name of the operating system that you want to install *kubectl* on.

**macOS**

**To install *kubectl* on macOS**

1. Download the Amazon EKS vended *kubectl* binary for your cluster’s Kubernetes version from Amazon S3.
Installing kubectl

1. Download the kubectl binary for your Kubernetes version.

   - **Kubernetes 1.22**
     ```bash
curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/darwin/amd64/kubectl
   ```

   - **Kubernetes 1.21**
     ```bash
curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.21.2/2021-07-05/bin/darwin/amd64/kubectl
   ```

   - **Kubernetes 1.20**
     ```bash
curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.20.4/2021-04-12/bin/darwin/amd64/kubectl
   ```

   - **Kubernetes 1.19**
     ```bash
curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/darwin/amd64/kubectl
   ```

   - **Kubernetes 1.18**
     ```bash
curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.18.9/2020-11-02/bin/darwin/amd64/kubectl
   ```

   - **Kubernetes 1.17**
     ```bash
curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.17.12/2020-11-02/bin/darwin/amd64/kubectl
   ```

2. (Optional) Verify the downloaded binary with the SHA-256 sum for your binary.
   a. Download the SHA-256 sum for your cluster's Kubernetes version for macOS.

      - **Kubernetes 1.22**
        ```bash
curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/darwin/amd64/kubectl.sha256
        ```

      - **Kubernetes 1.21**
        ```bash
        ```

      - **Kubernetes 1.20**
        ```bash
curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.20.4/2021-04-12/bin/darwin/amd64/kubectl.sha256
        ```

      - **Kubernetes 1.19**
        ```bash
curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/darwin/amd64/kubectl.sha256
        ```

      - **Kubernetes 1.18**
        ```bash
curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.18.9/2020-11-02/bin/darwin/amd64/kubectl.sha256
        ```
Installing kubectl

1. Download the Amazon EKS vended kubectl binary for your cluster’s Kubernetes version from Amazon S3 using the command for your hardware platform.

   • Kubernetes 1.17

     ```
     curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.18.9/2020-11-02/bin/darwin/amd64/kubectl.sha256
     ```

     ```
     curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.17.12/2020-11-02/bin/darwin/amd64/kubectl.sha256
     ```

   b. Check the SHA-256 sum for your downloaded binary.

     ```
     openssl sha1 -sha256 kubectl
     ```

   c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match.

   3. Apply execute permissions to the binary.

     ```
     chmod +x ./kubectl
     ```

   4. Copy the binary to a folder in your PATH. If you have already installed a version of kubectl, then we recommend creating a $HOME/bin/kubectl and ensuring that $HOME/bin comes first in your $PATH.

     ```
     mkdir -p $HOME/bin && cp ./kubectl $HOME/bin/kubectl && export PATH=$HOME/bin:$PATH
     ```

   5. (Optional) Add the $HOME/bin path to your shell initialization file so that it is configured when you open a shell.

     ```
     echo 'export PATH=$PATH:$HOME/bin' >> ~/.bash_profile
     ```

   6. After you install kubectl, you can verify its version with the following command:

     ```
     kubectl version --short --client
     ```

Linux

To install kubectl on Linux

1. Download the Amazon EKS vended kubectl binary for your cluster’s Kubernetes version from Amazon S3 using the command for your hardware platform.

   • Kubernetes 1.22

     ```
     curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/linux/amd64/kubectl
     ```

     ```
     curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/linux/arm64/kubectl
     ```

   • Kubernetes 1.21

     ```
     curl -o kubectl https://s3.us-west-2.amazonaws.com/amazon-eks/1.21.2/2021-07-05/bin/linux/amd64/kubectl
     ```
2. (Optional) Verify the downloaded binary with the SHA-256 sum for your binary.
   a. Download the SHA-256 sum for your cluster's Kubernetes version for Linux using the
      command for your hardware platform.
      • Kubernetes 1.22
        curl -o kubectl.sha256 https://s3-us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/linux/amd64/kubectl.sha256
        curl -o kubectl.sha256 https://s3-us-west-2.amazonaws.com/amazon-eks/1.23.6/2022-03-09/bin/linux/arm64/kubectl.sha256
      • Kubernetes 1.21
Installing kubectl

- Kubernetes 1.20
  
  ```
  curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.21.2/2021-07-05/bin/linux/arm64/kubectl.sha256
  ```

- Kubernetes 1.20
  
  ```
  curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.20.4/2021-04-12/bin/linux/amd64/kubectl.sha256
  ```

- Kubernetes 1.20
  
  ```
  curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.20.4/2021-04-12/bin/linux/arm64/kubectl.sha256
  ```

- Kubernetes 1.19
  
  ```
  curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/linux/amd64/kubectl.sha256
  ```

- Kubernetes 1.19
  
  ```
  curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/linux/arm64/kubectl.sha256
  ```

- Kubernetes 1.18
  
  ```
  curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.18.9/2020-11-02/bin/linux/amd64/kubectl.sha256
  ```

- Kubernetes 1.18
  
  ```
  curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.18.9/2020-11-02/bin/linux/arm64/kubectl.sha256
  ```

- Kubernetes 1.17
  
  ```
  curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.17.12/2020-11-02/bin/linux/amd64/kubectl.sha256
  ```

  ```
  curl -o kubectl.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.17.12/2020-11-02/bin/linux/arm64/kubectl.sha256
  ```

b. Check the SHA-256 sum for your downloaded binary.

  ```
  openssl sha1 -sha256 kubectl
  ```

c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match.

3. Apply execute permissions to the binary.

  ```
  chmod +x ./kubectl
  ```

4. Copy the binary to a folder in your PATH. If you have already installed a version of kubectl, then we recommend creating a $HOME/bin/kubectl and ensuring that $HOME/bin comes first in your $PATH.

  ```
  mkdir -p $HOME/bin && cp ./kubectl $HOME/bin/kubectl && export PATH=$PATH:$HOME/bin
  ```

5. (Optional) Add the $HOME/bin path to your shell initialization file so that it is configured when you open a shell.
Note
This step assumes you are using the Bash shell; if you are using another shell, change
the command to use your specific shell initialization file.

```bash
echo 'export PATH=PATH:HOME/bin' >> ~/.bashrc
```

6. After you install `kubectl`, you can verify its version with the following command:

```bash
kubectl version --short --client
```

Windows

To install `kubectl` on Windows

1. Open a PowerShell terminal.
2. Download the Amazon EKS vended `kubectl` binary for your cluster's Kubernetes version from Amazon S3.
   - Kubernetes 1.22
     ```bash
curl -o kubectl.exe https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/windows/amd64/kubectl.exe
```
   - Kubernetes 1.21
     ```bash
curl -o kubectl.exe https://s3.us-west-2.amazonaws.com/amazon-eks/1.21.2/2021-07-05/bin/windows/amd64/kubectl.exe
```
   - Kubernetes 1.20
     ```bash
curl -o kubectl.exe https://s3.us-west-2.amazonaws.com/amazon-eks/1.20.4/2021-04-12/bin/windows/amd64/kubectl.exe
```
   - Kubernetes 1.19
     ```bash
curl -o kubectl.exe https://s3.us-west-2.amazonaws.com/amazon-eks/1.19.6/2021-01-05/bin/windows/amd64/kubectl.exe
```
   - Kubernetes 1.18
     ```bash
curl -o kubectl.exe https://s3.us-west-2.amazonaws.com/amazon-eks/1.18.9/2020-11-02/bin/windows/amd64/kubectl.exe
```
   - Kubernetes 1.17
     ```bash
curl -o kubectl.exe https://s3.us-west-2.amazonaws.com/amazon-eks/1.17.12/2020-11-02/bin/windows/amd64/kubectl.exe
```
3. (Optional) Verify the downloaded binary with the SHA-256 sum for your binary.
   a. Download the SHA-256 sum for your cluster's Kubernetes version for Windows.
      - Kubernetes 1.22
        ```bash
curl -o kubectl.exe.sha256 https://s3.us-west-2.amazonaws.com/amazon-eks/1.22.6/2022-03-09/bin/windows/amd64/kubectl.exe
```
Installing eksctl

This topic covers eksctl, a simple command line utility for creating and managing Kubernetes clusters on Amazon EKS. The eksctl command line utility provides the fastest and easiest way to create a new cluster with nodes for Amazon EKS. For more information and to see the official documentation, visit https://eksctl.io/.

This topic helps you to download and install eksctl binaries for macOS, Linux, and Windows operating systems. Select the tab name of your operating system.
Installing or upgrading eksctl

This section helps you to install or upgrade the latest version of the eksctl command line utility. Select the tab with the name of the operating system that you want to install eksctl on.

macOS

To install or upgrade eksctl on macOS using Homebrew

The easiest way to get started with Amazon EKS and macOS is by installing eksctl with Homebrew, an open-source tool that can be installed using these instructions. The eksctl Homebrew recipe installs eksctl and any other dependencies that are required for Amazon EKS, such as kubectl. The recipe also installs the aws-iam-authenticator (p. 408), which is required if you don’t have the AWS CLI version 1.16.156 or higher installed.

1. If you do not already have Homebrew installed on macOS, install it with the following command.

   /bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/master/install.sh)"

2. Install the Weaveworks Homebrew tap.

   brew tap weaveworks/tap

3. Install or upgrade eksctl.
   - Install eksctl with the following command:
     
     brew install weaveworks/tap/eksctl
   - If eksctl is already installed, run the following command to upgrade:
     
     brew upgrade eksctl && brew link --overwrite eksctl

4. Test that your installation was successful with the following command.

   eksctl version

   **Note**
   The GitTag version should be at least 0.92.0. If not, check your terminal output for any installation or upgrade errors, or manually download an archive of the release from https://github.com/weaveworks/eksctl/releases/download/v0.92.0/eksctl_Darwin_amd64.tar.gz, extract eksctl, and then run it.

Linux

To install or upgrade eksctl on Linux using curl

1. Download and extract the latest release of eksctl with the following command.

   curl --silent --location "https://github.com/weaveworks/eksctl/releases/latest/download/eksctl_$(uname -s)_amd64.tar.gz" | tar xz -C /tmp

2. Move the extracted binary to /usr/local/bin.
3. Test that your installation was successful with the following command.

`eksctl version`

**Note**
The GitTag version should be at least 0.92.0. If not, check your terminal output for any installation or upgrade errors, or replace the address in step 1 with https://github.com/weaveworks/eksctl/releases/download/v0.92.0/eksctl_Linux_amd64.tar.gz and complete steps 1-3 again.

**Windows**

**To install or upgrade eksctl on Windows using Chocolatey**

1. If you do not already have Chocolatey installed on your Windows system, see Installing Chocolatey.

2. Install or upgrade eksctl.
   - Install the binaries with the following command:
     ```
     choco install -y eksctl
     ```
   - If they are already installed, run the following command to upgrade:
     ```
     choco upgrade -y eksctl
     ```

3. Test that your installation was successful with the following command.

`eksctl version`

**Note**
The GitTag version should be at least 0.92.0. If not, check your terminal output for any installation or upgrade errors, or manually download an archive of the release from https://github.com/weaveworks/eksctl/releases/download/v0.92.0/eksctl_Windows_amd64.zip, extract eksctl, and then run it.

**Getting started with Amazon EKS – eksctl**

This guide helps you to create all of the required resources to get started with Amazon Elastic Kubernetes Service (Amazon EKS) using eksctl, a simple command line utility for creating and managing Kubernetes clusters on Amazon EKS. At the end of this tutorial, you will have a running Amazon EKS cluster that you can deploy applications to.

The procedures in this guide create several resources for you automatically that you have to create manually when you create your cluster using the AWS Management Console. If you'd rather manually create most of the resources to better understand how they interact with each other, then use the AWS Management Console to create your cluster and compute. For more information, see Getting started with Amazon EKS – AWS Management Console and AWS CLI (p. 16).
Prerequisites

Before starting this tutorial, you must install and configure the following tools and resources that you need to create and manage an Amazon EKS cluster.

- **kubectl** – A command line tool for working with Kubernetes clusters. This guide requires that you use version 1.22 or later. For more information, see Installing *kubectl* (p. 4).
- **eksctl** – A command line tool for working with EKS clusters that automates many individual tasks. This guide requires that you use version 0.92.0 or later. For more information, see Installing *eksctl* (p. 10).
- **Required IAM permissions** – The IAM security principal that you're using must have permissions to work with Amazon EKS IAM roles and service linked roles, AWS CloudFormation, and a VPC and related resources. For more information, see Actions, resources, and condition keys for Amazon Elastic Container Service for Kubernetes and Using service-linked roles in the IAM User Guide. You must complete all steps in this guide as the same user.

Step 1: Create your Amazon EKS cluster and nodes

**Important**

To get started as simply and quickly as possible, this topic includes steps to create a cluster and nodes with default settings. Before creating a cluster and nodes for production use, we recommend that you familiarize yourself with all settings and deploy a cluster and nodes with the settings that meet your requirements. For more information, see Creating an Amazon EKS cluster (p. 24) and Amazon EKS nodes (p. 104). Some settings can only be enabled when creating your cluster and nodes.

You can create a cluster with one of the following node types. To learn more about each type, see Amazon EKS nodes (p. 104). After your cluster is deployed, you can add other node types.

- **Fargate – Linux** – Select this type of node if you want to run Linux applications on AWS Fargate. Fargate is a serverless compute engine that lets you deploy Kubernetes pods without managing Amazon EC2 instances.
- **Managed nodes – Linux** – Select this type of node if you want to run Amazon Linux applications on Amazon EC2 instances. Though not covered in this guide, you can also add Windows self-managed (p. 139) and Bottlerocket (p. 137) nodes to your cluster.

Create your Amazon EKS cluster with the following command. You can replace `my-cluster` with your own value. The cluster name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 128 characters. Replace `region-code` with any AWS Region that is supported by Amazon EKS. For a list of AWS Regions, see Amazon EKS endpoints and quotas in the AWS General Reference guide.

**Fargate – Linux**

```
eksctl create cluster --name my-cluster --region region-code --fargate
```

**Managed nodes – Linux**

```
eksctl create cluster --name my-cluster --region region-code
```

Output

Cluster creation takes several minutes. During creation you'll see several lines of output. The last line of output is similar to the following example line.
eksctl created a kubectl config file in ~/.kube or added the new cluster's configuration within an existing config file in ~/.kube on your computer.

After cluster creation is complete, view the AWS CloudFormation stack named eksctl-my-cluster-cluster in the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation to see all of the resources that were created.

Step 2: View Kubernetes resources

1. View your cluster nodes.

```
kubectl get nodes -o wide
```

Example output:

**Fargate – Linux**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>fargate-ip-192-168-141-147</td>

<td></td>
<td></td>
<td></td>
<td></td>
<td>&lt;none&gt;</td>
</tr>
</tbody>
</table>

For more information about what you see in the output, see View workloads (p. 350).

Step 3: Delete your cluster and nodes

After you’ve finished with the cluster and nodes that you created for this tutorial, you should clean up by deleting the cluster and nodes with the following command. If you want to do more with this cluster before you clean up, see Next steps (p. 15).

```
eksctl delete cluster --name my-cluster --region region-code
```

Next steps

The following documentation topics help you to extend the functionality of your cluster.

- Deploy a sample application (p. 352) to your cluster.
- The IAM entity (user or role) that created the cluster is the only IAM user that can make calls to the Kubernetes API server using kubectl. If you want other users to have access to your cluster, see Enabling IAM user and role access to your cluster (p. 395).
- Before deploying a cluster for production use, we recommend familiarizing yourself with all of the settings for clusters (p. 24) and nodes (p. 104). Some settings (such as enabling SSH access to Amazon EC2 nodes) must be made when the cluster is created.
- To increase security for your cluster, configure the Amazon VPC Container Networking Interface plugin to use IAM roles for service accounts (p. 270).
Amazon EKS User Guide
Using the console and AWS CLI

Getting started with Amazon EKS – AWS Management Console and AWS CLI

This guide helps you to create all of the required resources to get started with Amazon Elastic Kubernetes Service (Amazon EKS) using the AWS Management Console and the AWS CLI. In this guide, you manually create each resource. At the end of this tutorial, you will have a running Amazon EKS cluster that you can deploy applications to.

The procedures in this guide give you complete visibility into how each resource is created and how the resources interact with each other. If you'd rather have most of the resources created for you automatically, use the `eksctl` CLI to create your cluster and nodes. For more information, see Getting started with Amazon EKS – `eksctl` (p. 12).

Prerequisites

Before starting this tutorial, you must install and configure the following tools and resources that you need to create and manage an Amazon EKS cluster.

- **AWS CLI** – A command line tool for working with AWS services, including Amazon EKS. This guide requires that you use version 2.5.2 or later or 1.22.86 or later. For more information, see Installing, updating, and uninstalling the AWS CLI in the AWS Command Line Interface User Guide. After installing the AWS CLI, we recommend that you also configure it. For more information, see Quick configuration with `aws configure` in the AWS Command Line Interface User Guide.

- **kubectl** – A command line tool for working with Kubernetes clusters. This guide requires that you use version 1.22 or later. For more information, see Installing `kubectl` (p. 4).

- **Required IAM permissions** – The IAM security principal that you're using must have permissions to work with Amazon EKS IAM roles and service linked roles, AWS CloudFormation, and a VPC and related resources. For more information, see Actions, resources, and condition keys for Amazon Elastic Kubernetes Service and Using service-linked roles in the IAM User Guide. You must complete all steps in this guide as the same user.

Step 1: Create your Amazon EKS cluster

Important
To get started as simply and quickly as possible, this topic includes steps to create a cluster with default settings. Before creating a cluster for production use, we recommend that you familiarize yourself with all settings and deploy a cluster with the settings that meet your requirements. For more information, see Creating an Amazon EKS cluster (p. 24). Some settings can only be enabled when creating your cluster.

To create your cluster

1. Create an Amazon VPC with public and private subnets that meets Amazon EKS requirements. Replace `region-code` with any AWS Region that is supported by Amazon EKS. For a list of AWS Regions, see Amazon EKS endpoints and quotas in the AWS General Reference guide. You can replace `my-eks-vpc-stack` with any name you choose.

```bash
```
Tip
For a list of all the resources the previous command creates, open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation. Choose the my-eks-vpc-stack stack and then choose the Resources tab.

2. Create a cluster IAM role and attach the required Amazon EKS IAM managed policy to it. Kubernetes clusters managed by Amazon EKS make calls to other AWS services on your behalf to manage the resources that you use with the service.

a. Copy the following contents to a file named cluster-role-trust-policy.json.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "eks.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

b. Create the role.

```bash
aws iam create-role \
  --role-name myAmazonEKSClusterRole \
  --assume-role-policy-document file://"cluster-role-trust-policy.json"
```

c. Attach the required Amazon EKS managed IAM policy to the role.

```bash
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::aws:policy/AmazonEKSClusterPolicy \
  --role-name myAmazonEKSClusterRole
```

3. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.

   Make sure that the AWS Region shown in the upper right of your console is the AWS Region that you want to create your cluster in. If it's not, choose the dropdown next to the AWS Region name and choose the AWS Region that you want to use.

4. Choose Add cluster, and then choose Create. If you don’t see this option, then choose Amazon EKS Clusters in the left navigation pane first.

5. On the Configure cluster page, do the following:

   a. Enter a Name for your cluster, such as my-cluster.
   b. For Cluster Service Role, choose myAmazonEKSClusterRole.
   c. Leave the remaining settings at their default values and choose Next.

6. On the Specify networking page, do the following:

   a. Choose the ID of the VPC that you created in a previous step from the VPC dropdown list. It is something like vpc-00x000x000x0x000/mys-eks-vpc-stack-VPC.
   b. Leave the remaining settings at their default values and choose Next.

7. On the Configure logging page, choose Next.

8. On the Review and create page, choose Create.

   To the right of the cluster's name, the cluster status is Creating for several minutes until the cluster provisioning process completes. Don't continue to the next step until the status is Active.
Note
You might receive an error that one of the Availability Zones in your request doesn't have sufficient capacity to create an Amazon EKS cluster. If this happens, the error output contains the Availability Zones that can support a new cluster. Retry creating your cluster with at least two subnets that are located in the supported Availability Zones for your account. For more information, see Insufficient capacity (p. 508).

Step 2: Configure your computer to communicate with your cluster

In this section, you create a kubeconfig file for your cluster. The settings in this file enable the kubectl CLI to communicate with your cluster.

To configure your computer to communicate with your cluster

1. Create or update a kubeconfig file for your cluster. Replace region-code with the AWS Region that you created your cluster in. Replace my-cluster with the name of your cluster.

   ```bash
   aws eks update-kubeconfig --region region-code --name my-cluster
   ```

   By default, the config file is created in ~/.kube or the new cluster's configuration is added to an existing config file in ~/.kube.

2. Test your configuration.

   ```bash
   kubectl get svc
   ```

   **Note**
   If you receive any authorization or resource type errors, see Unauthorized or access denied (kubectl) (p. 509) in the troubleshooting section.

   **Output**

   ```
   NAME            TYPE      CLUSTER-IP      EXTERNAL-IP   PORT(S)     AGE
   svc/kubernetes  ClusterIP  10.100.0.1     <none>        443/TCP     1m
   ```

Step 3: Create nodes

Important
To get started as simply and quickly as possible, this topic includes steps to create nodes with default settings. Before creating nodes for production use, we recommend that you familiarize yourself with all settings and deploy nodes with the settings that meet your requirements. For more information, see Amazon EKS nodes (p. 104). Some settings can only be enabled when creating your nodes.

You can create a cluster with one of the following node types. To learn more about each type, see Amazon EKS nodes (p. 104). After your cluster is deployed, you can add other node types.

- **Fargate – Linux** – Choose this type of node if you want to run Linux applications on AWS Fargate. Fargate is a serverless compute engine that lets you deploy Kubernetes pods without managing Amazon EC2 instances.
Step 3: Create nodes

- **Managed nodes – Linux** – Choose this type of node if you want to run Amazon Linux applications on Amazon EC2 instances. Though not covered in this guide, you can also add Windows self-managed (p. 139) and Bottlerocket (p. 137) nodes to your cluster.

Fargate – Linux

Create a Fargate profile. When Kubernetes pods are deployed with criteria that matches the criteria defined in the profile, the pods are deployed to Fargate.

**To create a Fargate profile**

1. Create an IAM role and attach the required Amazon EKS IAM managed policy to it. When your cluster creates pods on Fargate infrastructure, the components running on the Fargate infrastructure must make calls to AWS APIs on your behalf. This is so that they can do actions such as pull container images from Amazon ECR or route logs to other AWS services. The Amazon EKS pod execution role provides the IAM permissions to do this.

   a. Copy the following contents to a file named `pod-execution-role-trust-policy.json`. Replace `region-code` with the AWS Region that your cluster is in. If you want to use the same role in all AWS Regions in your account, replace `region-code` with `*`. Replace `111122223333` with your account ID and `my-cluster` with the name of your cluster. If you want to use the same role for all clusters in your account, replace `my-cluster` with `*`.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [{
   "Effect": "Allow",
   "Condition": {
   "ArnLike": {
   },
   "Principal": {
   "Service": "eks-fargate-pods.amazonaws.com"
   },
   "Action": "sts:AssumeRole"
   }
   }
   }
   ``

   b. Create a pod execution IAM role.

   ```bash
   aws iam create-role \
   --role-name AmazonEKSFargatePodExecutionRole \
   --assume-role-policy-document file://"pod-execution-role-trust-policy.json"
   ```

   c. Attach the required Amazon EKS managed IAM policy to the role.

   ```bash
   aws iam attach-role-policy \
   --policy-arm arn:aws:iam::123456789012:policy/AmazonEKSFargatePodExecutionRolePolicy \
   --role-name AmazonEKSFargatePodExecutionRole
   ```

2. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
3. On the Clusters page, choose the `my-cluster` cluster.
4. On the `my-cluster` page, do the following:
a. Choose the **Configuration** tab.
b. Choose the **Compute** tab.
c. Under **Fargate Profiles**, choose **Add Fargate Profile**.

5. On the **Configure Fargate Profile** page, do the following:
   a. For **Name**, enter a unique name for your Fargate profile, such as *my-profile*.
   b. For **Pod execution role**, choose the *AmazonEKSFargatePodExecutionRole* that you created in a previous step.
   c. Choose the **Subnets** dropdown and deselect any subnet with *Public* in its name. Only private subnets are supported for pods that are running on Fargate.
   d. Choose **Next**.

6. On the **Configure pod selection** page, do the following:
   a. For **Namespace**, enter *default*.
   b. Choose **Next**.

7. On the **Review and create** page, review the information for your Fargate profile and choose **Create**.

8. After a few minutes, the **Status** in the Fargate Profile configuration section will change from **Creating** to **Active**. Don't continue to the next step until the status is **Active**.

9. If you plan to deploy all pods to Fargate (none to Amazon EC2 nodes), do the following to create another Fargate profile and run the default name resolver (CoreDNS) on Fargate.
   **Note**
   If you don't do this, you won't have any nodes at this time.
   a. On the **Fargate Profile** page, choose *my-profile*.
   b. Under **Fargate profiles**, choose **Add Fargate Profile**.
   c. For **Name**, enter *CoreDNS*.
   d. For **Pod execution role**, choose the *AmazonEKSFargatePodExecutionRole* that you created in a previous step.
   e. Choose the **Subnets** dropdown and deselect any subnet with *Public* in its name. Only private subnets are supported for pods running on Fargate.
   f. Choose **Next**.
   g. For **Namespace**, enter *kube-system*.
   h. Choose **Match labels**, and then choose **Add label**.
   i. Enter *k8s-app* for **Key** and *kube-dns* for **Value**. This is necessary for the default name resolver (CoreDNS) to deploy to Fargate.
   j. Choose **Next**.
   k. On the **Review and create** page, review the information for your Fargate profile and choose **Create**.
   l. Run the following command to remove the default eks.amazonaws.com/compute-type : ec2 annotation from the CoreDNS pods.

```bash
kubectl patch deployment coredns \
   -n kube-system \
   --type json \
   -p="{"op": "remove", "path": "/spec/template/metadata/annotations/eks.amazonaws.com-icompute-type"}"
```
Note
The system creates and deploys two nodes based on the Fargate profile label you added. You won't see anything listed in Node Groups because they aren't applicable for Fargate nodes, but you will see the new nodes listed in the Overview tab.

Managed nodes – Linux

Create a managed node group, specifying the subnets and node IAM role that you created in previous steps.

To create your Amazon EC2 Linux managed node group

1. Create a node IAM role and attach the required Amazon EKS IAM managed policy to it. The Amazon EKS node kubelet daemon makes calls to AWS APIs on your behalf. Nodes receive permissions for these API calls through an IAM instance profile and associated policies.
   a. Copy the following contents to a file named node-role-trust-policy.json.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Principal": {
   "Service": "ec2.amazonaws.com"
   },
   "Action": "sts:AssumeRole"
   }
   ]
   }
   ```
   b. Create the node IAM role.

   ```bash
   aws iam create-role
   --role-name myAmazonEKSNodeRole
   --assume-role-policy-document file://node-role-trust-policy.json
   ```
   c. Attach the required managed IAM policies to the role.

   ```bash
   aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy
   --role-name myAmazonEKSNodeRole
   aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly
   --role-name myAmazonEKSNodeRole
   aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy
   --role-name myAmazonEKSNodeRole
   ```

2. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#clusters.
3. Choose the name of the cluster that you created in Step 1: Create your Amazon EKS cluster (p. 16), such as my-cluster.
4. On the my-cluster page, do the following:
   a. Choose the Configuration tab.
   b. Choose the Compute tab.
   c. Choose Add Node Group.
5. On the **Configure Node Group** page, do the following:
   a. For **Name**, enter a unique name for your managed node group, such as *my-nodegroup*.
   b. For **Node IAM role name**, choose *myAmazonEKSNodeRole* role that you created in a previous step. We recommend that each node group use its own unique IAM role.
   c. Choose **Next**.

6. On the **Set compute and scaling configuration** page, accept the default values and choose **Next**.

7. On the **Specify networking** page, accept the default values and choose **Next**.

8. On the **Review and create** page, review your managed node group configuration and choose **Create**.

9. After several minutes, the **Status** in the **Node Group configuration** section will change from **Creating** to **Active**. Don't continue to the next step until the status is **Active**.

**Step 4: View resources**

You can view your nodes and Kubernetes workloads.

**To view your nodes and workloads**

1. In the left navigation pane, choose Amazon EKS **Clusters**. Then in the list of **Clusters**, choose the name of the cluster that you created, such as *my-cluster*.

2. On the **my-cluster** page, do the following:
   a. On the **Overview** tab, you see the list of **Nodes** that were deployed for the cluster. You can choose the name of a node to see more information about it. For more information about what you see here, see **View nodes** (p. 107).
   b. On the **Workloads** tab of the cluster, you see a list of the workloads that are deployed by default to an Amazon EKS cluster. You can choose the name of a workload to see more information about it. For more information about what you see here, see **View workloads** (p. 350). If you created Fargate nodes, only **coredns** has a status.

**Step 5: Delete resources**

After you've finished with the cluster and nodes that you created for this tutorial, you should delete the resources that you created. If you want to do more with this cluster before you delete the resources, see **Next steps** (p. 23).

**To delete the resources that you created in this guide**

1. Delete any node groups or Fargate profiles that you created.
   b. In the left navigation pane, choose Amazon EKS **Clusters**. In the list of clusters, choose *my-cluster*.
   c. Choose the **Configuration** tab, and then choose the **Compute** tab.
   d. If you created a node group, choose the *my-nodegroup* node group and then choose **Delete**. Enter *my-nodegroup*, and then choose **Delete**.
   e. For each Fargate profile that you created, choose it and then choose **Delete**. Enter the name of the profile, and then choose **Delete**.
Note
When deleting a second Fargate profile, you may need to wait for the first one to finish deleting.

f. Don't continue until the node group or Fargate profiles are deleted.

2. Delete the cluster.
   a. In the left navigation pane, choose Amazon EKS Clusters. In the list of clusters, choose my-cluster.
   b. Choose Delete cluster.
   c. Enter my-cluster and then choose Delete. Don't continue until the cluster is deleted.

3. Delete the VPC AWS CloudFormation stack that you created.
   b. Choose the my-eks-vpc-stack stack, and then choose Delete.
   c. In the Delete my-eks-vpc-stack confirmation dialog box, choose Delete stack.

4. Delete the IAM roles that you created.
   b. In the left navigation pane, choose Roles.
   c. Select each role you created from the list (myAmazonEKSClusterRole, as well as AmazonEKSFargatePodExecutionRole or myAmazonEKSNodeRole). Choose Delete, enter the requested confirmation text, then choose Delete.

Next steps

The following documentation topics help you to extend the functionality of your cluster.

• The IAM entity (user or role) that created the cluster is the only IAM user that can make calls to the Kubernetes API server using kubectl. If you want other users to have access to your cluster, see Enabling IAM user and role access to your cluster (p. 395).
• Deploy a sample application (p. 352) to your cluster.
• Before deploying a cluster for production use, we recommend familiarizing yourself with all of the settings for clusters (p. 24) and nodes (p. 104). Some settings (such as enabling SSH access to Amazon EC2 nodes) must be made when the cluster is created.
• To increase security for your cluster, configure the Amazon VPC Container Networking Interface plugin to use IAM roles for service accounts (p. 270).
Amazon EKS clusters

An Amazon EKS cluster consists of two primary components:

- The Amazon EKS control plane
- Amazon EKS nodes that are registered with the control plane

The Amazon EKS control plane consists of control plane nodes that run the Kubernetes software, such as etcd and the Kubernetes API server. The control plane runs in an account managed by AWS, and the Kubernetes API is exposed via the Amazon EKS endpoint associated with your cluster. Each Amazon EKS cluster control plane is single-tenant and unique, and runs on its own set of Amazon EC2 instances.

All of the data stored by the etcd nodes and associated Amazon EBS volumes is encrypted using AWS KMS. The cluster control plane is provisioned across multiple Availability Zones and fronted by an Elastic Load Balancing Network Load Balancer. Amazon EKS also provisions elastic network interfaces in your VPC subnets to provide connectivity from the control plane instances to the nodes (for example, to support kubectl exec, logs, and proxy data flows).

Amazon EKS nodes run in your AWS account and connect to your cluster's control plane via the API server endpoint and a certificate file that is created for your cluster.

**Note**

- You can find out how the different components of Amazon EKS work in Amazon EKS networking (p. 256).
- For connected clusters, see Amazon EKS Connector (p. 524).

Creating an Amazon EKS cluster

This topic walks you through creating an Amazon EKS cluster. If this is your first time creating an Amazon EKS cluster, then we recommend that you follow one of our Getting started with Amazon EKS (p. 4) guides instead. They provide complete end-to-end walkthroughs for creating an Amazon EKS cluster with nodes.

To connect an external Kubernetes cluster to view in Amazon EKS, see Amazon EKS Connector (p. 524).

**Important**

- When an Amazon EKS cluster is created, the IAM entity (user or role) that creates the cluster is added to the Kubernetes RBAC authorization table as the administrator (with system:masters permissions). Initially, only that IAM user can make calls to the Kubernetes API server using kubectl. For more information, see Enabling IAM user and role access to your cluster (p. 395). If you use the console to create the cluster, you must ensure that the same IAM user credentials are in the AWS SDK credential chain when you are running kubectl commands on your cluster.
- As a best practice, ensure that an IAM role is added to the aws-auth ConfigMap. This ensures that a cluster can be deleted after the creating user has been deleted. If you are in this situation and cannot delete a cluster, see this article to resolve the problem.

You can create a cluster with eksctl, the AWS Management Console, or the AWS CLI.
To deploy a new cluster on AWS Outposts, see Deploy an Amazon EKS cluster with worker nodes on AWS Outposts (p. 503)

```bash
eksctl
```

**Prerequisite**

Version 0.92.0 or later of the `eksctl` command line tool installed on your computer or AWS CloudShell. To install or update `eksctl`, see Installing `eksctl` (p. 10).

Create an Amazon EKS IPv4 cluster with the Amazon EKS latest Kubernetes version in your default Region. If you want to create an IPv6 cluster, you must deploy your cluster using a config file. For an example, see Deploy an IPv6 cluster and nodes (p. 289). Replace the `example-values` with your own values. You can replace `1.22` with any supported version (p. 65). The cluster name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 128 characters.

```
eksctl create cluster \
  --name my-cluster \
  --version 1.22 \
  --without-nodegroup
```

(Optional) Add the `--with-oidc` flag to the previous command to automatically create an AWS Identity and Access Management (IAM) OIDC provider (p. 466) for your cluster. Creating the OIDC provider allows some Amazon EKS add-ons or your own individual Kubernetes workloads to have specific AWS Identity and Access Management (IAM) permissions. You only need to create an IAM OIDC provider for your cluster once. To learn more about Amazon EKS add-ons, see Amazon EKS add-ons (p. 381). To learn more about assigning specific IAM permissions to your workloads, see Technical overview (p. 462).

**Tip**

To see most options that can be specified when creating a cluster with `eksctl`, use the `eksctl create cluster --help` command. To see all options, you can use a config file. For more information, see Using config files and the config file schema in the `eksctl` documentation. You can find config file examples on GitHub.

**Important**

If you plan to deploy self-managed nodes in AWS Outposts, AWS Wavelength, or AWS Local Zones after your cluster is deployed, you must have an existing VPC that meets Amazon EKS requirements and use the `--vpc-private-subnets` option with the previous command. The subnet IDs that you specify can't be the AWS Outposts, AWS Wavelength, or AWS Local Zones subnets. For more information about using an existing VPC, see Use existing VPC: other custom configuration in the `eksctl` documentation.

**Warning**

There is a `secretsEncryption` option that requires an existing AWS KMS key in AWS Key Management Service (AWS KMS). If you create a cluster using a config file with the `secretsEncryption` option and the KMS key that you use is ever deleted, then there is no path to recovery for the cluster. If you enable `secrets encryption`, the Kubernetes secrets are encrypted using the KMS key that you select. The KMS key must be symmetric, created in the same Region as the cluster, and if the KMS key was created in a different account, the user must have access to the KMS key. For more information, see Allowing users in other accounts to use a KMS key in the AWS Key Management Service Developer Guide. By default, the `create-key` command creates a symmetric key with a key policy that gives the account root admin access on AWS KMS actions and resources. For more information, see Creating keys. If you want to scope down the permissions, make sure that the `kms:DescribeKey` and `kms:CreateGrant` actions are permitted on the policy for the principal that will be calling the `create-cluster` API. Amazon EKS does not support the policy condition `kms:GrantIsForAWSResource`. Creating a cluster will not work if this action is in the KMS key policy statement.
Cluster provisioning takes several minutes. During cluster creation, you'll see several lines of output. The last line of output is similar to the following example line.

```
[✓]  EKS cluster "my-cluster" in "region-code" region is ready
```

After your cluster is created, you can migrate the Amazon VPC CNI, CoreDNS, and kube-proxy self-managed add-ons that were deployed with your cluster to Amazon EKS add-ons. For more information, see Amazon EKS add-ons (p. 381).

AWS Management Console

**Prerequisites**

- An existing VPC and a dedicated security group that meet the requirements for an Amazon EKS cluster. For more information, see Cluster VPC and subnet considerations (p. 262) and Amazon EKS security group considerations (p. 265). If you don't have a VPC, you can follow Creating a VPC for your Amazon EKS cluster (p. 258) to create one. If you want to assign IPv6 IP addresses to Pods and Services, then ensure that your VPC, subnets, and security groups meet the requirements and considerations listed in Assigning IPv6 addresses to pods and services (p. 288) or use the Amazon EKS public and private subnet AWS CloudFormation IPv6 VPC template to deploy an IPv6 VPC.
- An existing Amazon EKS cluster service IAM role. If you don't have the role, you can follow Amazon EKS IAM roles (p. 438) to create one.

**To create your cluster with the console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose **Create cluster**.
3. On the **Configure cluster** page, fill in the following fields:

   - **Name** – A unique name for your cluster.
   - **Kubernetes version** – The version of Kubernetes to use for your cluster.
   - **Cluster Service Role** – Choose the Amazon EKS cluster role to allow the Kubernetes control plane to manage AWS resources on your behalf. For more information, see the **Prerequisites** (p. 26).
   - **Secrets encryption** – (Optional) Choose to enable secrets encryption of Kubernetes secrets using a KMS key. The KMS key must be symmetric, created in the same region as the cluster, and if the KMS key was created in a different account, the user must have access to the KMS key. For more information, see Allowing users in other accounts to use a KMS key in the **AWS Key Management Service Developer Guide**.

   If no keys are listed, you must create one first. For more information, see Creating keys.

   **Note**

   By default, the create-key command creates a symmetric key with a key policy that gives the account root admin access on AWS KMS actions and resources. For more information, see Creating keys. If you want to scope down the permissions, make sure that the kms:DescribeKey and kms:CreateGrant actions are permitted on the policy for the principal that will be calling the create-cluster API.

   Amazon EKS does not support the policy condition kms:GrantIsForAWSResource. Creating a cluster will not work if this action is in the KMS key policy statement.

   **Warning**

   Deletion of the KMS key will permanently put the cluster in a degraded state. If any KMS keys used for cluster creation are scheduled for deletion, verify that this is the
intended action before deletion. Once the KMS key is deleted, there is no path to recovery for the cluster. For more information, see Deleting AWS KMS keys.

- **Tags** – (Optional) Add any tags to your cluster. For more information, see Tagging your Amazon EKS resources (p. 422).

4. Select **Next**.

5. On the **Specify networking** page, select values for the following fields:

- **VPC** – Select an existing VPC to use for your cluster. If none are listed, then you need to create one first. For more information, see the Prerequisites (p. 26).

- **Subnets** – By default, the available subnets in the VPC specified in the previous field are preselected. Unselect any subnet that you don’t want to host cluster resources, such as worker nodes or load balancers. The subnets must meet the requirements for an Amazon EKS cluster. For more information, see Cluster VPC and subnet considerations (p. 262).

  **Important**
  - If you select subnets that were created before March 26, 2020 using one of the Amazon EKS AWS CloudFormation VPC templates, be aware of a default setting change that was introduced on March 26, 2020. For more information, see Creating a VPC for your Amazon EKS cluster (p. 258).
  - Don’t select subnets in AWS Outposts, AWS Wavelength or AWS Local Zones. If you plan to deploy self-managed nodes in AWS Outposts, AWS Wavelength or AWS Local Zones subnets after you deploy your cluster, then make sure that you have, or can create, Outposts subnets in the VPC that you select.

- **Security groups** – The **SecurityGroups** value from the AWS CloudFormation output that you generated when you created your VPC (p. 258). This security group has **ControlPlaneSecurityGroup** in the dropdown name.

  **Important**
  The node AWS CloudFormation template modifies the security group that you specify here, so Amazon EKS strongly recommends that you use a dedicated security group for each cluster control plane (one per cluster). If this security group is shared with other resources, you might block or disrupt connections to those resources.

- **Choose cluster IP address family** – If the version you chose for your cluster is 1.20 or earlier, only the **IPv4** option is available. If you chose version 1.21 or later for your cluster version, then you can choose whether Kubernetes will assign **IPv4** or **IPv6** addresses to Pods and Services. You can’t change this option after cluster creation. If you choose IPv6, you can’t choose the **Configure Kubernetes Service IP address range** option. Kubernetes assigns Service addresses from the unique local address range (\(\text{fc00} : : / 7\)). You can’t specify a custom address range.

  **Important**
  You can only specify a custom CIDR block when you create a cluster and can’t change this value once the cluster is created.

- (Optional) Choose **Configure Kubernetes Service IP address range** and specify a **Service IPv4 range** if you want to specify which CIDR block Kubernetes assigns service IP addresses from. The CIDR block must meet the following requirements:

  - Within one of the following ranges: 10.0.0.0/8, 172.16.0.0/12, or 192.168.0.0/16.
  - Between /24 and /12.
  - Doesn’t overlap with any CIDR block specified in your VPC.

  We recommend specifying a CIDR block that doesn’t overlap with any other networks that are peered or connected to your VPC. If you don’t enable this, Kubernetes assigns service IP addresses from either the 10.100.0.0/16 or 172.20.0.0/16 CIDR blocks.

  **Important**
  You can only specify a custom CIDR block when you create a cluster and can’t change this value once the cluster is created.

- For **Cluster endpoint access** – Choose one of the following options:
• **Public** – Enables only public access to your cluster's Kubernetes API server endpoint. Kubernetes API requests that originate from outside of your cluster's VPC use the public endpoint. By default, access is allowed from any source IP address. You can optionally restrict access to one or more CIDR ranges such as 192.168.0.0/16, for example, by selecting **Advanced settings** and then selecting **Add source**.

• **Private** – Enables only private access to your cluster's Kubernetes API server endpoint. Kubernetes API requests that originate from within your cluster's VPC use the private VPC endpoint.

  **Important**
  If you created a VPC without outbound internet access, then you must enable private access.

• **Public and private** – Enables public and private access.

For more information about the previous options, see **Modifying cluster endpoint access** (p. 46).

6. You can accept the defaults in the **Networking add-ons** section to install the default version of the AWS VPC CNI (p. 269), CoreDNS (p. 328), and kube-proxy (p. 334) Amazon EKS add-ons, or you can select a different version. If you don't require the functionality of any of the add-ons, you can remove them once your cluster is created. If you need to manage Amazon EKS managed settings for any of these add-ons yourself, then you can remove Amazon EKS management of the add-on once your cluster is created. For more information, see **Amazon EKS add-ons** (p. 381).

  **Important**
  The AWS VPC CNI add-on is configured to use the IAM permissions assigned to the **Amazon EKS node IAM role** (p. 452). After the cluster is created, but before you deploy any Amazon EC2 nodes to your cluster, you must ensure that the AmazonEKS_CNI_Policy managed IAM policy (if using IPv4 for your cluster) or the AmazonEKS_CNI_IPV6_Policy IAM policy (that you create yourself (p. 274) if you're using IPv6 for your cluster) is attached to either the node IAM role, or to a different role associated to the Kubernetes service account that the add-on runs as. We recommend that you assign the policy to a different IAM role than the node IAM role by completing the instructions in **Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts** (p. 270). Once your cluster and IAM role are created, you can update the add-on (p. 277) to use the IAM role that you create.

7. Select **Next**.

8. On the **Configure logging** page, you can optionally choose which log types that you want to enable. By default, each log type is **Disabled**. For more information, see **Amazon EKS control plane logging** (p. 62).

9. Select **Next**.

10. On the **Review and create** page, review the information that you entered or selected on the previous pages. Select **Edit** if you need to make changes to any of your selections. Once you're satisfied with your settings, select **Create**. The **Status** field shows **CREATING** until the cluster provisioning process completes.

  **Note**
  You might receive an error that one of the Availability Zones in your request doesn't have sufficient capacity to create an Amazon EKS cluster. If this happens, the error output contains the Availability Zones that can support a new cluster. Retry creating your cluster with at least two subnets that are located in the supported Availability Zones for your account. For more information, see **Insufficient capacity** (p. 508).

Cluster provisioning takes several minutes.

11. Follow the procedures in **Create a kubeconfig for Amazon EKS** (p. 403) to enable communication with your new cluster.
12. (Optional) To use some Amazon EKS add-ons, or to enable individual Kubernetes workloads to have specific AWS Identity and Access Management (IAM) permissions, you need to create an IAM OpenID Connect (OIDC) provider for your cluster. To create an IAM OIDC provider for your cluster, see Create an IAM OIDC provider for your cluster (p. 466). You only need to create an IAM OIDC provider for your cluster once. To learn more about Amazon EKS add-ons, see Amazon EKS add-ons (p. 381). To learn more about assigning specific IAM permissions to your workloads, see Technical overview (p. 462).

13. If you're going to deploy Amazon EC2 nodes to your cluster, then you must attach one of the following policies to either your cluster IAM role, or to an IAM role that you create specifically for the Amazon VPC CNI add-on (this option requires the previous step). For more information about creating the role and configuring the add-on to use it, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).

- The AmazonEKS_CNI_Policy IAM managed policy, if you created a 1.20 or earlier cluster or a 1.21 or later cluster with the IPv4 family.
- An IAM policy that you create (p. 274), if you created a 1.21 or later cluster with the IPv6 family.

14. (Optional) Configure the VPC CNI add-on to use its own IAM role. This option requires the IAM OIDC provider created in a previous step and that you created an IAM role specifically for the add-on in the previous step. For more information, see Updating the Amazon VPC CNI Amazon EKS add-on (p. 277).

AWS CLI

**Prerequisites**

- Version 2.5.2 or later or 1.22.86 or later of the AWS CLI installed and configured on your computer or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with aws configure in the AWS Command Line Interface User Guide.

- An existing VPC and a dedicated security group that meet the requirements for an Amazon EKS cluster. For more information, see Cluster VPC and subnet considerations (p. 262) and Amazon EKS security group considerations (p. 265). If you don't have a VPC, you can follow Creating a VPC for your Amazon EKS cluster (p. 258) to create one. If you want to assign IPv6 IP addresses to Pods and Services, then ensure that your VPC, subnets, and security group meets the requirements listed in the considerations in Assigning IPv6 addresses to pods and services (p. 288).

- An existing Amazon EKS cluster IAM role. If you don't have the role, you can follow Amazon EKS IAM roles (p. 438) to create one.

**To create your cluster with the AWS CLI**

1. Create your cluster with the following command. Replace the Amazon Resource Name (ARN) of your Amazon EKS cluster IAM role that you created in Amazon EKS cluster IAM role (p. 450) and the subnet and security group IDs for the VPC that you created in Creating a VPC for your Amazon EKS cluster (p. 258). Replace my-cluster with your cluster name. Replace region-code with the AWS Region that your cluster is in. You can replace 1.22 with any supported version (p. 65).

   For subnetIds, don't specify subnets in AWS Outposts, AWS Wavelength or AWS Local Zones. If you plan to deploy self-managed nodes in AWS Outposts, AWS Wavelength or AWS Local Zones subnets after you deploy your cluster, then make sure that you have, or can create, Outposts subnets in the VPC that you specify.
If you want the cluster to assign IPv6 addresses to pods and services instead of IPv4 addresses, add `--kubernetes-network-config ipFamily=ipv6` to the following command and specify 1.21 or later for `--kubernetes-version`.

```
aws eks create-cluster \
   --region region-code \
   --name my-cluster \
   --kubernetes-version 1.21 \n   --role-arn arn:aws:iam::111122223333:role/eksClusterRole \
   --resources-vpc-config subnetIds=subnet-a9189fe2,subnet-50432629,securityGroupIds=sg-f5c54184
```

**Note**

If your IAM user doesn't have administrative privileges, you must explicitly add permissions for that user to call the Amazon EKS API operations. For more information, see Amazon EKS identity-based policy examples (p. 438).

Output:

```
{
   "cluster": {
      "name": "my-cluster",
      "createdAt": 1527785885.159,
      "version": "1.21",
      "roleArn": "arn:aws:iam::111122223333:role/eksClusterRole",
      "resourcesVpcConfig": {
         "subnetIds": [
            "subnet-a9189fe2",
            "subnet-50432629"
         ],
         "securityGroupIds": [
            "sg-f5c54184"
         ],
         "vpcId": "vpc-05401dc",
         "endpointPublicAccess": true,
         "endpointPrivateAccess": false
      },
      "status": "CREATING",
      "certificateAuthority": {}
   }
}
```

**Note**

You might receive an error that one of the Availability Zones in your request doesn't have sufficient capacity to create an Amazon EKS cluster. If this happens, the error output contains the Availability Zones that can support a new cluster. Retry creating your cluster with at least two subnets that are located in the supported Availability Zones for your account. For more information, see Insufficient capacity (p. 508).

To encrypt the Kubernetes secrets, first create a KMS key using the `create-key` operation.

```
MY_KEY_ARN=$(aws kms create-key --query KeyMetadata.Arn --output text)
```

**Note**

By default, the `create-key` command creates a symmetric key that encrypts and decrypts data. This key has a key policy that gives the account's root user admin access on AWS KMS actions and resources. For more information, see Creating keys. If you
want to scope down the permissions, make sure that the `kms:DescribeKey` and `kms:CreateGrant` actions are permitted on the policy for the principal that will be calling the `create-cluster` API. Amazon EKS does not support the policy condition `kms:GrantIsForAWSResource`. Creating a cluster will not work if this action is in the KMS key policy statement.

Add the `--encryption-config` parameter to the `aws eks create-cluster` command. Encryption of Kubernetes secrets can only be enabled when the cluster is created.

```bash
--encryption-config '[["resources":["secrets"],"provider":
{"keyArn":"$MY_KEY_ARN"}]]'
```

The `keyArn` member can contain either the alias or ARN of your KMS key. The KMS key must be

- Symmetric
- Able to encrypt and decrypt data
- Created in the same region as the cluster
- If the KMS key was created in a different account, the user must have access to the KMS key.

For more information, see Allowing users in other accounts to use a KMS key in the AWS Key Management Service Developer Guide.

**Warning**
Deletion of the KMS key permanently puts the cluster in a degraded state. If any KMS keys used for cluster creation are scheduled for deletion, verify that this is the intended action before deletion. Once the KMS key is deleted, there is no path to recovery for the cluster. For more information, see Deleting AWS KMS keys.

2. Cluster provisioning takes several minutes. You can query the status of your cluster with the following command. When your cluster status is **ACTIVE**, you can proceed.

```bash
aws eks describe-cluster \
  --region region-code \
  --name my-cluster \
  --query "cluster.status"
```

3. Follow the procedures in Create a kubeconfig for Amazon EKS (p. 403) to enable communication with your new cluster.

4. (Optional) To use some Amazon EKS add-ons, or to enable individual Kubernetes workloads to have specific AWS Identity and Access Management (IAM) permissions, you need to create an IAM OpenID Connect (OIDC) provider for your cluster. To create an IAM OIDC provider for your cluster, see Create an IAM OIDC provider for your cluster (p. 466). You only need to create an IAM OIDC provider for your cluster once. To learn more about Amazon EKS add-ons, see Amazon EKS add-ons (p. 381). To learn more about assigning specific IAM permissions to your workloads, see Technical overview (p. 462).

5. If you're going to deploy Amazon EC2 nodes to your cluster, then you must attach one of the following policies to either your cluster IAM role, or to an IAM role that you create specifically for the Amazon VPC CNI add-on (this option requires the previous step). For more information about creating the role and configuring the add-on to use it, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270):

   - The `AmazonEKS_CNI_Policy` IAM managed policy, if you created a 1.20 or earlier cluster or a 1.21 or later cluster with the IPv4 family.
   - An IAM policy that you create (p. 274), if you created a 1.21 or later cluster with the IPv6 family.
Updating a cluster

You can update an existing Amazon EKS cluster to a new Kubernetes version or secrets encryption for your cluster.

Updating an Amazon EKS cluster Kubernetes version

When a new Kubernetes version is available in Amazon EKS, you can update your Amazon EKS cluster to the latest version.

Important
We recommend that, before you update to a new Kubernetes version, you review the information in Amazon EKS Kubernetes versions (p. 65) and also review in the update steps in this topic.

New Kubernetes versions have introduced significant changes. Therefore, we recommend that you test the behavior of your applications against a new Kubernetes version before you update your production clusters. You can do this by building a continuous integration workflow to test your application behavior before moving to a new Kubernetes version.

The update process consists of Amazon EKS launching new API server nodes with the updated Kubernetes version to replace the existing ones. Amazon EKS performs standard infrastructure and readiness health checks for network traffic on these new nodes to verify that they're working as expected. If any of these checks fail, Amazon EKS reverts the infrastructure deployment, and your cluster remains on the prior Kubernetes version. Running applications aren't affected, and your cluster is never left in a non-deterministic or unrecoverable state. Amazon EKS regularly backs up all managed clusters, and mechanisms exist to recover clusters if necessary. We're constantly evaluating and improving our Kubernetes infrastructure management processes.

To update the cluster, Amazon EKS requires up to five free IP addresses from the subnets that were provided when you created the cluster. If these subnets don't have available IP addresses, then the update can fail. Additionally, if any of the subnets or security groups that were provided when the cluster was created are deleted, the cluster update process might fail.

Note
Even though Amazon EKS runs a highly available control plane, you might experience minor service interruptions during an update. For example, assume that you attempt to connect to an API server around when it's terminated and replaced by a new API server that's running the new version of Kubernetes. You might experience API call errors or connectivity issues. If this happens, retry your API operations until they succeed.

Kubernetes version 1.22 prerequisites

A number of deprecated beta APIs (v1beta1) have been removed in version 1.22 in favor of the GA (v1) version of those same APIs. As noted in the Kubernetes 1.22 API and Feature removal blog and deprecated API migration guide, API changes are required for the following deployed resources before updating a cluster to v1.22.

Before updating to 1.22, make sure to do the following:

• Change your YAML manifest files and clients to reference the new APIs.
• Update custom integrations and controllers to call the new APIs.
• Make sure that you use an updated version of any third-party tools. These tools include ingress controllers, service mesh controllers, continuous delivery systems, and other tools that call the new APIs. To check for discontinued API usage in your cluster, enable audit control plane logging and specify `v1beta` as an event filter. Replacement APIs are available in Kubernetes for several versions.
• If applicable, update load balance controller to v2.4.1 before updating to v1.22.

**Important**
If you update the clusters to version 1.22, existing persisted objects can be accessed using the new APIs. However, you must migrate manifests and update clients to use these new APIs. Updating the clusters prevents potential workload failures.

The v1.22 release removes support from the following Beta APIs. Migrate your manifests and API clients with regard to the following information.

To update the Kubernetes version for your Amazon EKS cluster

Update the Kubernetes version for your cluster.

To update the Kubernetes version for your cluster

1. Compare the Kubernetes version of your cluster control plane to the Kubernetes version of your nodes.
   
   • Get the Kubernetes version of your cluster control plane with the `kubectl version --short` command.

   ```
   kubectl version --short
   ```

   • Get the Kubernetes version of your nodes with the `kubectl get nodes` command. This command returns all self-managed and managed Amazon EC2 and Fargate nodes. Each Fargate pod is listed as its own node.

   ```
   kubectl get nodes
   ```

   Before updating your control plane to a new Kubernetes version, make sure that the Kubernetes minor version of both the managed nodes and Fargate nodes in your cluster are the same as your control plane's version. For example, if your control plane is running version 1.21 and one of your nodes is running version 1.20, you must update your nodes to version 1.21. We also recommend that you update your self-managed nodes to the same version as your control plane before updating the control plane. For more information, see Updating a managed node group (p. 119) and Self-managed node updates (p. 145). To update the version of a Fargate node, delete the pod that's represented by the node. Then, redeploy the pod after you update your control plane.

2. By default, the pod security policy admission controller is enabled on Amazon EKS clusters. Before updating your cluster, ensure that the proper pod security policies are in place. This is to avoid potential security issues. You can check for the default policy with the `kubectl get psp eks.privileged` command.

   ```
   kubectl get psp eks.privileged
   ```

   If you receive the following error, see default pod security policy (p. 492) before proceeding.

   ```
   Error from server (NotFound): podsecuritypolicies.extensions "eks.privileged" not found
   ```

3. If you originally deployed your cluster on Kubernetes 1.17 or earlier, you might need to remove a discontinued term from your CoreDNS manifest.
   
   a. Check to see if your CoreDNS manifest has a line that only has the word `upstream`.

---

<table>
<thead>
<tr>
<th>Resource</th>
<th>Beta version</th>
<th>GA version</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSIDriver CSINode StorageClass VolumeAttachment</td>
<td>storage.k8s.io/v1beta1</td>
<td>storage.k8s.io/v1</td>
<td>None</td>
</tr>
</tbody>
</table>
To update the Kubernetes version for your Amazon EKS cluster

```
kubectl get configmap coredns -n kube-system -o jsonpath='{$.data.Corefile}' | grep upstream
```

If no output is returned, this means that your manifest doesn't have the line. If this is the case, skip to the next step. If the word `upstream` is returned, remove the line.

b. Remove the line near the top of the file that only has the word `upstream` in the configmap file. Don't change anything else in the file. After the line is removed, save the changes.

```
kubectl edit configmap coredns -n kube-system -o yaml
```

4. Update your cluster using `eksctl`, the AWS Management Console, or the AWS CLI.

**Important**

- Because Amazon EKS runs a highly available control plane, you can update only one minor version at a time. For more information about this requirement, see Kubernetes Version and Version Skew Support Policy. Assume that your current version is 1.20 and you want to update to 1.22. Then, you must first update your cluster to 1.21 and then later update it from 1.21 to 1.22.
- Make sure that the `kubelet` on your managed and Fargate nodes are at the same Kubernetes version as your control plane before you update. We recommend that your self-managed nodes are at the same version as the control plane. They can be only up to one version behind the current version of the control plane.
- If your cluster is configured with a version of the Amazon VPC CNI plugin that is earlier than 1.8.0, then we recommend that you update the plugin to version 1.10.1 before updating your cluster to version 1.21 or later. For more information, see Updating the Amazon VPC CNI Amazon EKS add-on (p. 277) or Updating the Amazon VPC CNI self-managed add-on (p. 280).

**eksctl**

This procedure requires `eksctl` version 0.92.0 or later. You can check your version with the following command:

```
eksctl version
```

For instructions on how to install and update `eksctl`, see Installing or upgrading `eksctl`(p. 11).

Update the Kubernetes version of your Amazon EKS control plane to one minor version later than its current version with the following command. Replace `<my-cluster>` (including `<`) with your cluster name.

```
eksctl upgrade cluster --name <my-cluster> --approve
```

The update takes several minutes to complete.

**AWS Management Console**

a. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.

b. Choose the name of the Amazon EKS cluster to update and choose Update cluster version.

c. For Kubernetes version, select the version to update your cluster to and choose Update.

d. For Cluster name, enter the name of your cluster and choose Confirm.
The update takes several minutes to complete.

AWS CLI

a. Update your Amazon EKS cluster with the following AWS CLI command. Replace the example-values with your own.

```bash
aws eks update-cluster-version \
--region <region-code> \
--name <my-cluster> \
--kubernetes-version <1.21>
```

The output is as follows.

```json
{
  "update": {
    "id": "b5f0ba18-9a87-4450-b5a0-825e6e84496f",
    "status": "InProgress",
    "type": "VersionUpdate",
    "params": [
      {
        "type": "Version",
        "value": "1.21"
      },
      {
        "type": "PlatformVersion",
        "value": "eks.1"
      }
    ],
    "errors": []
  }
}
```

b. Monitor the status of your cluster update with the following command. Use the cluster name and update ID that the previous command returned. When a Successful status is displayed, the update is complete. The update takes several minutes to complete.

```bash
aws eks describe-update \
--region <region-code> \
--name <my-cluster> \
--update-id <b5f0ba18-9a87-4450-b5a0-825e6e84496f>
```

The output is as follows.

```json
{
  "update": {
    "id": "b5f0ba18-9a87-4450-b5a0-825e6e84496f",
    "status": "Successful",
    "type": "VersionUpdate",
    "params": [
      {
        "type": "Version",
        "value": "1.21"
      },
      {
        "type": "PlatformVersion",
        "value": "eks.1"
      }
    ]
  }
}
```
Enabling secret encryption on an existing cluster

If you enable secrets encryption, the Kubernetes secrets are encrypted using the AWS KMS key that you select. The KMS key must meet the following conditions:
Enabling secret encryption on an existing cluster

- Symmetric
- Can encrypt and decrypt data
- Created in the same AWS Region as the cluster
- If the KMS key was created in a different account, the user must have access to the KMS key.

For more information, see Allowing users in other accounts to use a KMS key in the AWS Key Management Service Developer Guide.

**Warning**
You can’t disable secrets encryption after enabling it. This action is irreversible.

`eksctl`

You can enable encryption in two ways:

- Add encryption to your cluster with a single command.

  To automatically re-encrypt your secrets, run the following command.

  ```
  eksctl utils enable-secrets-encryption \\n  --cluster <my-cluster> \ 
  --key-arn arn:aws:kms:<Region-code>:<account>:key/<key>
  ```

  To opt-out of automatically re-encrypting your secrets, run the following command.

  ```
  eksctl utils enable-secrets-encryption
  --cluster my-cluster \ 
  --key-arn arn:aws:kms:<region-code>:account:key/key \ 
  --encrypt-existing-secrets=false
  ```

- Add encryption to your cluster with a `.yaml` file.

  ```
  # cluster.yaml
  apiVersion: eksctl.io/v1alpha5
  kind: ClusterConfig
  metadata:
    name: my-cluster
    region: region-code
  secretsEncryption:
    keyARN: arn:aws:kms:<Region-code>:<account>:key/<key>
  ```

  To have your secrets re-encrypt automatically, run the following command.

  ```
  eksctl utils enable-secrets-encryption -f kms-cluster.yaml
  ```

  To opt out of automatically re-encrypting your secrets, run the following command.

  ```
  eksctl utils enable-secrets-encryption -f kms-cluster.yaml --encrypt-existing-secrets=false
  ```
AWS Management Console

2. Choose the cluster that you want to add KMS encryption to.
3. Choose the **Configuration** tab.
4. Scroll down to the **Secrets encryption** section and choose **Enable**.
5. Select a key from the dropdown list and choose the **Enable** button. If no keys are listed, you must create one first. For more information, see **Creating keys**
6. Choose the **Confirm** button to use the chosen key.

AWS CLI

1. Associate the **secrets encryption** configuration with your cluster using the following AWS CLI command. Replace the **example-values** with your own.

```bash
aws eks associate-encryption-config
  --cluster-name <my-cluster> \
  --encryption-config '[["resources":["secrets"],"provider":
  {"keyArn":"arn:aws:kms:<Region-code>:<account>:key/<key>"}]]'
```

The output is as follows.

```
{
 "update": {
  "id": "3141b835-8103-423a-8e68-12c2521ff04d",
  "status": "InProgress",
  "type": "AssociateEncryptionConfig",
  "params": [
   {
    "type": "EncryptionConfig",
    "value": "[["resources":["secrets"],"provider":{"keyArn":\"arn:aws:kms:<Region-code>:<account>:key/<key>\"}]"
   }
  ],
  "createdAt": 1613754188.734,
  "errors": []
 }
}
```

2. You can monitor the status of your encryption update with the following command. Use the specific cluster name and update ID that was returned in the previous output. When a **Successful** status is displayed, the update is complete.

```bash
aws eks describe-update \
  --region <Region-code> \
  --name <my-cluster> \
  --update-id <3141b835-8103-423a-8e68-12c2521ff04d>
```

The output is as follows.

```
{
 "update": {
  "id": "3141b835-8103-423a-8e68-12c2521ff04d",
  "status": "Successful",
  "type": "AssociateEncryptionConfig",
  "params": [
   {
    "type": "EncryptionConfig",
    "value": "[["resources":["secrets"],"provider":{"keyArn":\"arn:aws:kms:<Region-code>:<account>:key/<key>\"}]"
   }
  ],
  "createdAt": 1613754188.734,
  "errors": []
 }
}
```
3. To verify that encryption is enabled in your cluster, run the `describe-cluster` command. The response contains an EncryptionConfig string.

```bash
aws eks describe-cluster --region <Region-code> --name <my-cluster>
```

After you enabled encryption on your cluster, you must encrypt all existing secrets with the new key:

**Note**
If you use `eksctl`, running the following command is necessary only if you opt out of re-encrypting your secrets automatically.

```bash
kubectl get secrets --all-namespaces -o json | kubectl annotate --overwrite -f - kms-encryption-timestamp="time value"
```

**Warning**
If you enable secrets encryption for an existing cluster and the KMS key that you use is ever deleted, then there's no way to recovery the cluster. If you delete the KMS key, you permanently put the cluster in a degraded state. For more information, see Deleting AWS KMS keys.

**Note**
By default, the `create-key` command creates a symmetric key with a key policy. This key policy gives the account root admin access on AWS KMS actions and resources. Assume that you want to scope down the permissions. Make sure that the `kms:DescribeKey` and `kms:CreateGrant` actions are permitted on the policy for the principal that calls the `create-cluster` API. Amazon EKS doesn't support the policy condition `kms:GrantIsForAWSResource`. If this action is in the KMS key policy statement, creating a cluster doesn't work.

---

**Deleting an Amazon EKS cluster**

When you're done using an Amazon EKS cluster, you should delete the resources associated with it so that you don't incur any unnecessary costs.

To remove a connected cluster, see Deregistering a cluster (p. 529)

**Important**
- If you have active services in your cluster that are associated with a load balancer, you must delete those services before deleting the cluster so that the load balancers are deleted properly. Otherwise, you can have orphaned resources in your VPC that prevent you from being able to delete the VPC.
- If you receive an error because the cluster creator has been removed, see this article to resolve.

You can delete a cluster with `eksctl`, the AWS Management Console, or the AWS CLI. Select the tab with the name of the tool that you'd like to use to delete your cluster.
To delete an Amazon EKS cluster and nodes with `eksctl`

This procedure requires `eksctl` version 0.92.0 or later. You can check your version with the following command:

```
eksctl version
```

For instructions on how to install or upgrade `eksctl`, see Installing or upgrading `eksctl` (p. 11).

1. List all services running in your cluster.

   ```
kubectl get svc --all-namespaces
```

2. Delete any services that have an associated `EXTERNAL-IP` value. These services are fronted by an Elastic Load Balancing load balancer, and you must delete them in Kubernetes to allow the load balancer and associated resources to be properly released.

   ```
kubectl delete svc <service-name>
```

3. Delete the cluster and its associated nodes with the following command, replacing `<prod>` with your cluster name.

   ```
eksctl delete cluster --name <prod>
```

Output:

```
[✓]  using region <region-code>
[✓]  deleting EKS cluster "prod"
[✓]  will delete stack "eksctl-prod-nodegroup-standard-nodes"
[✓]  waiting for stack "eksctl-prod-nodegroup-standard-nodes" to get deleted
[✓]  will delete stack "eksctl-prod-cluster"
[✓]  the following EKS cluster resource(s) for "prod" will be deleted: cluster. If in doubt, check CloudFormation console
```

AWS Management Console

To delete an Amazon EKS cluster with the AWS Management Console

1. List all services running in your cluster.

   ```
kubectl get svc --all-namespaces
```

2. Delete any services that have an associated `EXTERNAL-IP` value. These services are fronted by an Elastic Load Balancing load balancer, and you must delete them in Kubernetes to allow the load balancer and associated resources to be properly released.

   ```
kubectl delete svc <service-name>
```

3. Delete all node groups and Fargate profiles.

   a. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.

   b. In the left navigation pane, choose Amazon EKS Clusters, and then in the tabbed list of clusters, select the name of the cluster that you want to delete.
Deleting an Amazon EKS cluster

c. Select the Configuration tab. On the Compute tab, select a node group to delete, select Delete, enter the name of the node group, and then select Delete. Delete all node groups in the cluster.

   **Note**
   The node groups listed are managed node groups (p. 109) only.

d. Select a Fargate Profile to delete, select Delete, enter the name of the profile, and then select Delete. Delete all Fargate profiles in the cluster.

4. Delete all self-managed node AWS CloudFormation stacks.

   b. Select the node stack to delete, and then choose Delete.
   c. In the Delete stack confirmation dialog box, choose Delete stack. Delete all self-managed node stacks in the cluster.

5. Delete the cluster.

   a. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
   b. Select the cluster to delete and choose Delete.
   c. On the delete cluster confirmation screen, choose Delete.

6. (Optional) Delete the VPC AWS CloudFormation stack.

   b. Select the VPC stack to delete, and then choose Delete.
   c. In the Delete stack confirmation dialog box, choose Delete stack.

AWS CLI

To delete an Amazon EKS cluster with the AWS CLI

1. List all services running in your cluster.

   ```
kubectl get svc --all-namespaces
   ```

2. Delete any services that have an associated EXTERNAL-IP value. These services are fronted by an Elastic Load Balancing load balancer, and you must delete them in Kubernetes to allow the load balancer and associated resources to be properly released.

   ```
kubectl delete svc <service-name>
   ```

3. Delete all node groups and Fargate profiles.

   a. List the node groups in your cluster with the following command.

   ```
aws eks list-nodegroups --cluster-name <my-cluster>
   ```

   **Note**
   The node groups listed are managed node groups (p. 109) only.

   b. Delete each node group with the following command. Delete all node groups in the cluster.

   ```
aws eks delete-nodegroup --nodegroup-name <my-nodegroup> --cluster-name <my-cluster>
   ```
c. List the Fargate profiles in your cluster with the following command.

```
aws eks list-fargate-profiles --cluster-name <my-cluster>
```

d. Delete each Fargate profile with the following command. Delete all Fargate profiles in the cluster.

```
aws eks delete-fargate-profile --fargate-profile-name <my-fargate-profile> --cluster-name <my-cluster>
```

4. Delete all self-managed node AWS CloudFormation stacks.

   a. List your available AWS CloudFormation stacks with the following command. Find the node template name in the resulting output.

```
aws cloudformation list-stacks --query "StackSummaries[].StackName"
```

   b. Delete each node stack with the following command, replacing `<node-stack>` with your node stack name. Delete all self-managed node stacks in the cluster.

```
aws cloudformation delete-stack --stack-name <node-stack>
```

5. Delete the cluster with the following command, replacing `<my-cluster>` with your cluster name.

```
aws eks delete-cluster --name <my-cluster>
```

6. (Optional) Delete the VPC AWS CloudFormation stack.

   a. List your available AWS CloudFormation stacks with the following command. Find the VPC template name in the resulting output.

```
aws cloudformation list-stacks --query "StackSummaries[].StackName"
```

   b. Delete the VPC stack with the following command, replacing `<my-vpc-stack>` with your VPC stack name.

```
aws cloudformation delete-stack --stack-name <my-vpc-stack>
```

### Amazon EKS cluster endpoint access control

This topic helps you to enable private access for your Amazon EKS cluster's Kubernetes API server endpoint and limit, or completely disable, public access from the internet.

When you create a new cluster, Amazon EKS creates an endpoint for the managed Kubernetes API server that you use to communicate with your cluster (using Kubernetes management tools such as `kubectl`). By default, this API server endpoint is public to the internet, and access to the API server is secured using a combination of AWS Identity and Access Management (IAM) and native Kubernetes Role Based Access Control (RBAC).

You can enable private access to the Kubernetes API server so that all communication between your nodes and the API server stays within your VPC. You can limit the IP addresses that can access your API server from the internet, or completely disable internet access to the API server.
Note
Because this endpoint is for the Kubernetes API server and not a traditional AWS PrivateLink endpoint for communicating with an AWS API, it doesn't appear as an endpoint in the Amazon VPC console.

When you enable endpoint private access for your cluster, Amazon EKS creates a Route 53 private hosted zone on your behalf and associates it with your cluster's VPC. This private hosted zone is managed by Amazon EKS, and it doesn't appear in your account's Route 53 resources. In order for the private hosted zone to properly route traffic to your API server, your VPC must have enabledDnsHostnames and enableDnsSupport set to true, and the DHCP options set for your VPC must include AmazonProvidedDNS in its domain name servers list. For more information, see Updating DNS support for your VPC in the Amazon VPC User Guide.

You can define your API server endpoint access requirements when you create a new cluster, and you can update the API server endpoint access for a cluster at any time.

Modifying cluster endpoint access

Use the procedures in this section to modify the endpoint access for an existing cluster. The following table shows the supported API server endpoint access combinations and their associated behavior.

**API server endpoint access options**

<table>
<thead>
<tr>
<th>Endpoint public access</th>
<th>Endpoint private access</th>
<th>Behavior</th>
</tr>
</thead>
</table>
| Enabled                | Disabled                | • This is the default behavior for new Amazon EKS clusters.  
|                        |                         | • Kubernetes API requests that originate from within your cluster's VPC (such as node to control plane communication) leave the VPC but not Amazon's network.  
|                        |                         | • Your cluster API server is accessible from the internet. You can, optionally, limit the CIDR blocks that can access the public endpoint. If you limit access to specific CIDR blocks, then it is recommended that you also enable the private endpoint, or ensure that the CIDR blocks that you specify include the addresses that nodes and Fargate pods (if you use them) access the public endpoint from. |
| Enabled                | Enabled                 | • Kubernetes API requests within your cluster's VPC (such as node to control plane communication) use the private VPC endpoint.  
|                        |                         | • Your cluster API server is accessible from the internet. |
You can modify your cluster API server endpoint access using the AWS Management Console or AWS CLI. Select the tab with the name of the tool that you'd like to use to modify your endpoint access with.

**AWS Management Console**

**To modify your cluster API server endpoint access using the AWS Management Console**

1. Open the Amazon EKS console at [https://console.aws.amazon.com/eks/home#/clusters](https://console.aws.amazon.com/eks/home#/clusters).
2. Choose the name of the cluster to display your cluster information.
3. Choose the **Configuration** tab. On the **Networking** tab, choose **Update**.
4. For **Private access**, choose whether to enable or disable private access for your cluster’s Kubernetes API server endpoint. If you enable private access, Kubernetes API requests that originate from within your cluster’s VPC use the private VPC endpoint. You must enable private access to disable public access.

<table>
<thead>
<tr>
<th>Endpoint public access</th>
<th>Endpoint private access</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disabled</td>
<td>Enabled</td>
<td>You can, optionally, limit the CIDR blocks that can access the public endpoint.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• All traffic to your cluster API server must come from within your cluster's VPC or a connected network.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• There is no public access to your API server from the internet. Any <code>kubectl</code> commands must come from within the VPC or a connected network. For connectivity options, see <a href="#">Accessing a private only API server</a> (p. 50).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The cluster's API server endpoint is resolved by public DNS servers to a private IP address from the VPC. In the past, the endpoint could only be resolved from within the VPC.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If your endpoint does not resolve to a private IP address within the VPC for an existing cluster, you can:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Enable public access and then disable it again. You only need to do so once for a cluster and the endpoint will resolve to a private IP address from that point forward.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Update (p. 32) your cluster.</td>
</tr>
</tbody>
</table>

You can modify your cluster API server endpoint access using the AWS Management Console or AWS CLI. Select the tab with the name of the tool that you'd like to use to modify your endpoint access with.

**AWS Management Console**

**To modify your cluster API server endpoint access using the AWS Management Console**

1. Open the Amazon EKS console at [https://console.aws.amazon.com/eks/home#/clusters](https://console.aws.amazon.com/eks/home#/clusters).
2. Choose the name of the cluster to display your cluster information.
3. Choose the **Configuration** tab. On the **Networking** tab, choose **Update**.
4. For **Private access**, choose whether to enable or disable private access for your cluster’s Kubernetes API server endpoint. If you enable private access, Kubernetes API requests that originate from within your cluster’s VPC use the private VPC endpoint. You must enable private access to disable public access.
5. For **Public access**, choose whether to enable or disable public access for your cluster's Kubernetes API server endpoint. If you disable public access, your cluster's Kubernetes API server can only receive requests from within the cluster VPC.

6. (Optional) If you've enabled **Public access**, you can specify which addresses from the internet can communicate to the public endpoint. Select **Advanced Settings**. Enter a CIDR block, such as `<203.0.113.5/32>`. The block cannot include reserved addresses. You can enter additional blocks by selecting **Add Source**. There is a maximum number of CIDR blocks that you can specify. For more information, see Amazon EKS service quotas (p. 426). If you specify no blocks, then the public API server endpoint receives requests from all (0.0.0.0/0) IP addresses. If you restrict access to your public endpoint using CIDR blocks, it is recommended that you also enable private endpoint access so that nodes and Fargate pods (if you use them) can communicate with the cluster. Without the private endpoint enabled, your public access endpoint CIDR sources must include the egress sources from your VPC. For example, if you have a node in a private subnet that communicates to the internet through a NAT Gateway, you will need to add the outbound IP address of the NAT gateway as part of an allowed CIDR block on your public endpoint.

7. Choose **Update** to finish.

**AWS CLI**

**To modify your cluster API server endpoint access using the AWS CLI**

Complete the following steps using the AWS CLI version 1.22.86 or later. You can check your current version with `aws --version`. To install or upgrade the AWS CLI, see Installing the AWS CLI.

1. Update your cluster API server endpoint access with the following AWS CLI command. Substitute your cluster name and desired endpoint access values. If you set `endpointPublicAccess=true`, then you can (optionally) enter single CIDR block, or a comma-separated list of CIDR blocks for `publicAccessCidrs`. The blocks cannot include reserved addresses. If you specify CIDR blocks, then the public API server endpoint will only receive requests from the listed blocks. There is a maximum number of CIDR blocks that you can specify. For more information, see Amazon EKS service quotas (p. 426). If you restrict access to your public endpoint using CIDR blocks, it is recommended that you also enable private endpoint access so that nodes and Fargate pods (if you use them) can communicate with the cluster. Without the private endpoint enabled, your public access endpoint CIDR sources must include the egress sources from your VPC. For example, if you have a node in a private subnet that communicates to the internet through a NAT Gateway, you will need to add the outbound IP address of the NAT gateway as part of an allowed CIDR block on your public endpoint. If you specify no CIDR blocks, then the public API server endpoint receives requests from all (0.0.0.0/0) IP addresses.

**Note**
The following command enables private access and public access from a single IP address for the API server endpoint. Replace `203.0.113.5/32` with a single CIDR block, or a comma-separated list of CIDR blocks that you want to restrict network access to.

```bash
aws eks update-cluster-config \
  --region region-code \
  --name my-cluster \
  --resources-vpc-config
  endpointPublicAccess=<true>,publicAccessCidrs="203.0.113.5/32",endpointPrivateAccess=<true>
```

**Output**:

```json
{
  "update": {
```
2. Monitor the status of your endpoint access update with the following command, using the cluster name and update ID that was returned by the previous command. Your update is complete when the status is shown as Successful.

```bash
aws eks describe-update \
  --region region-code \
  --name my-cluster \
  --update-id e6f0905f-a5d4-4a2a-8c49-EXAMPLE00000
```

**Output:**

```
{
  "update": {
    "id": "e6f0905f-a5d4-4a2a-8c49-EXAMPLE00000",
    "status": "Successful",
    "type": "EndpointAccessUpdate",
    "params": [
      {
        "type": "EndpointPublicAccess",
        "value": "<true>"
      },
      {
        "type": "EndpointPrivateAccess",
        "value": "<true>"
      },
      {
        "type": "publicAccessCidrs",
        "value": "[203.0.113.5/32]"
      }
    ],
    "createdAt": "2019-01-01T12:00:00Z",
    "errors": []
  }
}
```
Accessing a private only API server

If you have disabled public access for your cluster's Kubernetes API server endpoint, you can only access the API server from within your VPC or a connected network. Here are a few possible ways to access the Kubernetes API server endpoint:

- **Connected network** – Connect your network to the VPC with an AWS transit gateway or other connectivity option and then use a computer in the connected network. You must ensure that your Amazon EKS control plane security group contains rules to allow ingress traffic on port 443 from your connected network.

- **Amazon EC2 bastion host** – You can launch an Amazon EC2 instance into a public subnet in your cluster's VPC and then log in via SSH into that instance to run `kubectl` commands. For more information, see [Linux bastion hosts on AWS](https://docs.aws.amazon.com/vpc/latest/bastion.html). You must ensure that your Amazon EKS control plane security group contains rules to allow ingress traffic on port 443 from your bastion host. For more information, see [Amazon EKS security group considerations](https://docs.aws.amazon.com/eks/latest/userguide/security-groups.html).

When you configure `kubectl` for your bastion host, be sure to use AWS credentials that are already mapped to your cluster's RBAC configuration, or add the IAM user or role that your bastion will use to the RBAC configuration before you remove endpoint public access. For more information, see [Enabling IAM user and role access to your cluster](https://docs.aws.amazon.com/eks/latest/userguide/iam-roles-for-serviceAccounts.html) (p. 395) and [Unauthorized or access denied (kubectl)](https://docs.aws.amazon.com/eks/latest/userguide/iam-roles-for-serviceAccounts.html) (p. 509).

- **AWS Cloud9 IDE** – AWS Cloud9 is a cloud-based integrated development environment (IDE) that lets you write, run, and debug your code with just a browser. You can create an AWS Cloud9 IDE in your cluster's VPC and use the IDE to communicate with your cluster. For more information, see [Creating an environment in AWS Cloud9](https://docs.aws.amazon.com/cloud9/latest/ug/get-started-guide.html). You must ensure that your Amazon EKS control plane security group contains rules to allow ingress traffic on port 443 from your IDE security group. For more information, see [Amazon EKS security group considerations](https://docs.aws.amazon.com/eks/latest/userguide/security-groups.html).

When you configure `kubectl` for your AWS Cloud9 IDE, be sure to use AWS credentials that are already mapped to your cluster's RBAC configuration, or add the IAM user or role that your IDE will use to the RBAC configuration before you remove endpoint public access. For more information, see [Enabling IAM user and role access to your cluster](https://docs.aws.amazon.com/eks/latest/userguide/iam-roles-for-serviceAccounts.html) (p. 395) and [Unauthorized or access denied (kubectl)](https://docs.aws.amazon.com/eks/latest/userguide/iam-roles-for-serviceAccounts.html) (p. 509).

Autoscaling

Autoscaling is a function that automatically scales your resources up or down to meet changing demands. This is a major Kubernetes function that would otherwise require extensive human resources to perform manually.

Amazon EKS supports two autoscaling products. The Kubernetes Cluster Autoscaler and the Karpenter open source autoscaling project. The cluster autoscaler uses AWS scaling groups, while Karpenter works directly with the Amazon EC2 fleet.

Cluster Autoscaler

The Kubernetes Cluster Autoscaler automatically adjusts the number of nodes in your cluster when pods fail or are rescheduled onto other nodes. The Cluster Autoscaler is typically installed as a Deployment in your cluster. It uses leader election to ensure high availability, but scaling is done by only one replica at a time.

Before you deploy the Cluster Autoscaler, make sure that you're familiar with how Kubernetes concepts interface with AWS features. The following terms are used throughout this topic:
• **Kubernetes Cluster Autoscaler** – A core component of the Kubernetes control plane that makes scheduling and scaling decisions. For more information, see Kubernetes Control Plane FAQ on GitHub.

• **AWS Cloud provider implementation** – An extension of the Kubernetes Cluster Autoscaler that implements the decisions of the Kubernetes Cluster Autoscaler by communicating with AWS products and services such as Amazon EC2. For more information, see Cluster Autoscaler on AWS on GitHub.

• **Node groups** – A Kubernetes abstraction for a group of nodes within a cluster. Node groups aren't a true Kubernetes resource, but they're found as an abstraction in the Cluster Autoscaler, Cluster API, and other components. Nodes that are found within a single node group might share several common properties such as labels and taints. However, they can still consist of more than one Availability Zone or instance type.

• **Amazon EC2 Auto Scaling groups** – A feature of AWS that's used by the Cluster Autoscaler. Auto Scaling groups are suitable for a large number of use cases. Amazon EC2 Auto Scaling groups are configured to launch instances that automatically join their Kubernetes cluster. They also apply labels and taints to their corresponding node resource in the Kubernetes API.

For reference, Managed node groups (p. 109) are managed using Amazon EC2 Auto Scaling groups, and are compatible with the Cluster Autoscaler.

This topic describes how you can deploy the Cluster Autoscaler to your Amazon EKS cluster and configure it to modify your Amazon EC2 Auto Scaling groups.

**Prerequisites**

Before deploying the Cluster Autoscaler, you must meet the following prerequisites:

• An existing Amazon EKS cluster – If you don’t have a cluster, see Creating an Amazon EKS cluster (p. 24).

• An existing IAM OIDC provider for your cluster. To determine whether you have one or need to create one, see Create an IAM OIDC provider for your cluster (p. 466).

• Node groups with Auto Scaling groups tags. The Cluster Autoscaler requires the following tags on your Auto Scaling groups so that they can be auto-discovered.
  • If you used eksctl to create your node groups, these tags are automatically applied.
  • If you didn’t use eksctl, you must manually tag your Auto Scaling groups with the following tags.
    For more information, see Tagging your Amazon EC2 resources in the Amazon EC2 User Guide for Linux Instances.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>k8s.io/cluster-autoscaler/&lt;my-cluster&gt;</td>
<td>owned</td>
</tr>
<tr>
<td>k8s.io/cluster-autoscaler/enabled</td>
<td>true</td>
</tr>
</tbody>
</table>

**Create an IAM policy and role**

Create an IAM policy that grants the permissions that the Cluster Autoscaler requires to use an IAM role. Replace all of the `<example-values>` (including `<>`) with your own values throughout the procedures.

1. Create an IAM policy.
   a. Save the following contents to a file that’s named cluster-autoscaler-policy.json. If your existing node groups were created with eksctl and you used the --asg-access option, then this policy already exists and you can skip to step 2.
b. Create the policy with the following command. You can change the value for `policy-name`.

```bash
aws iam create-policy
  --policy-name AmazonEKSClusterAutoscalerPolicy
  --policy-document file://cluster-autoscaler-policy.json
```

Take note of the Amazon Resource Name (ARN) that's returned in the output. You need to use it in a later step.

2. You can create an IAM role and attach an IAM policy to it using `eksctl` or the AWS Management Console. Select the desired tab for the following instructions.

**eksctl**

1. Run the following command if you created your Amazon EKS cluster with `eksctl`. If you created your node groups using the `--asg-access` option, then replace `<AmazonEKSClusterAutoscalerPolicy>` with the name of the IAM policy that `eksctl` created for you. The policy name is similar to `eksctl--<my-cluster>--nodegroup-<xxxxxxxxx>-PolicyAutoScaling`.

   ```bash
   eksctl create iamserviceaccount
     --cluster=<my-cluster> \\n     --namespace=kube-system \\n     --name=cluster-autoscaler \\n     --attach-policy-arn=arn:aws:iam::<AWS_ACCOUNT_ID>:policy/<AmazonEKSClusterAutoscalerPolicy> \\n     --override-existing-serviceaccounts \\n     --approve
   ```

2. We recommend that, if you created your node groups using the `--asg-access` option, you detach the IAM policy that `eksctl` created and attached to the Amazon EKS node IAM role (p. 452) that `eksctl` created for your node groups. You detach the policy from the node IAM role for Cluster Autoscaler to function properly. Detaching the policy doesn't give other pods on your nodes the permissions in the policy. For more information, see Removing IAM identity permissions in the Amazon EC2 User Guide for Linux Instances.

**AWS Management Console**

b. In the left navigation pane, choose Roles. Then choose Create role.
c. In the **Trusted entity type** section, choose **Web identity**.

d. In the **Web identity** section:
   i. For **Identity provider**, choose the OpenID Connect provider URL for your cluster (as shown under **Configuration Details** in Amazon EKS).
   ii. For **Audience**, choose sts.amazonaws.com.

e. Choose **Next**.

f. In the **Filter policies** box, enter **AmazonEKSClusterAutoscalerPolicy**. Then select the check box to the left of the policy name returned in the search.

g. Choose **Next**.

h. For **Role name**, enter a unique name for your role, such as **AmazonEKSClusterAutoscalerRole**.

i. For **Description**, enter descriptive text such as **Amazon EKS – Cluster autoscaler role**.

j. Choose **Create role**.

k. After the role is created, choose the role in the console to open it for editing.

l. Choose the **Trust relationships** tab, and then choose **Edit trust policy**.

m. Find the line that looks similar to the following:

```
"oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:aud":
 "sts.amazonaws.com"
```

Change the line to look like the following line. Replace **EXAMPLED539D4633E53DE1B71EXAMPLE** with your cluster's OIDC provider ID. Replace **region-code** with the AWS Region that your cluster is in.

```
"oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:sub":
 "system:serviceaccount:kube-system:cluster-autoscaler"
```

n. Choose **Update policy** to finish.

### Deploy the Cluster Autoscaler

Complete the following steps to deploy the Cluster Autoscaler. We recommend that you review **Deployment considerations (p. 55)** and optimize the Cluster Autoscaler deployment before you deploy it to a production cluster.

**To deploy the Cluster Autoscaler**

1. Download the Cluster Autoscaler YAML file.

   ```
curl -o cluster-autoscaler-autodiscover.yaml https://raw.githubusercontent.com/kubernetes/autoscaler/master/cluster-autoscaler/cloudprovider/aws/examples/cluster-autoscaler-autodiscover.yaml
```

2. Modify the YAML file and replace `<YOUR CLUSTER NAME>` with your cluster name.

3. Apply the YAML file to your cluster.

   ```
   kubectl apply -f cluster-autoscaler-autodiscover.yaml
   ```

4. Annotate the `cluster-autoscaler` service account with the ARN of the IAM role that you created previously. Replace the `<example values>` with your own values.
5. Patch the deployment to add the `cluster-autoscaler.kubernetes.io/safe-to-evict` annotation to the Cluster Autoscaler pods with the following command.

```
kubectl patch deployment cluster-autoscaler \
-n kube-system \
-p '{"spec":{"template":{"metadata":{"annotations":{"cluster-autoscaler.kubernetes.io/safe-to-evict": "false"}}}}}'
```

6. Edit the Cluster Autoscaler deployment with the following command.

```
kubectl -n kube-system edit deployment.apps/cluster-autoscaler
```

Edit the `cluster-autoscaler` container command to replace `<YOUR CLUSTER NAME>` (including <> with the name of your cluster, and add the following options. `--balance-similar-node-groups` ensures that there is enough available compute across all availability zones. `--skip-nodes-with-system-pods=false` ensures that there are no problems with scaling to zero.

- `--balance-similar-node-groups`
- `--skip-nodes-with-system-pods=false`

```
spec:
  containers:
  - command
    - ./cluster-autoscaler
    - --v=4
    - --stderrthreshold=info
    - --cloud-provider=aws
    - --skip-nodes-with-local-storage=false
    - --expander=least-waste
    - --node-group-auto-discovery=asg:tag=k8s.io/cluster-autoscaler/enabled,k8s.io/cluster-autoscaler/<YOUR CLUSTER NAME>
    - --balance-similar-node-groups
    - --skip-nodes-with-system-pods=false
```

Save and close the file to apply the changes.

7. Open the Cluster Autoscaler releases page from GitHub in a web browser and find the latest Cluster Autoscaler version that matches the Kubernetes major and minor version of your cluster. For example, if the Kubernetes version of your cluster is 1.22, find the latest Cluster Autoscaler release that begins with 1.22. Record the semantic version number (1.22.n) for that release to use in the next step.

8. Set the Cluster Autoscaler image tag to the version that you recorded in the previous step with the following command. Replace 1.22.n with your own value.

```
kubectl set image deployment cluster-autoscaler \
-n kube-system \
cluster-autoscaler=k8s.gcr.io/autoscaling/cluster-autoscaler:v<1.22.n>
```
View your Cluster Autoscaler logs

After you have deployed the Cluster Autoscaler, you can view the logs and verify that it's monitoring your cluster load.

View your Cluster Autoscaler logs with the following command.

```bash
kubectl -n kube-system logs -f deployment.apps/cluster-autoscaler
```

Example output:

```
I0926 23:15:55.165842       1 static_autoscaler.go:138] Starting main loop
I0926 23:15:55.166279       1 utils.go:595] No pod using affinity / antiaffinity found in cluster, disabling affinity predicate for this loop
I0926 23:15:55.166293       1 static_autoscaler.go:294] Filtering out schedulables
I0926 23:15:55.166330       1 static_autoscaler.go:311] No schedulable pods
I0926 23:15:55.166338       1 static_autoscaler.go:319] No unschedulable pods
I0926 23:15:55.166345       1 static_autoscaler.go:366] Calculating unneeded nodes
I0926 23:15:55.166357       1 utils.go:552] Skipping ip-192-168-3-111.<region-code>.compute.internal - node group min size reached
I0926 23:15:55.166365       1 utils.go:552] Skipping ip-192-168-71-83.<region-code>.compute.internal - node group min size reached
I0926 23:15:55.166435       1 static_autoscaler.go:393] Scale down status: unneededOnly=false lastScaleUpTime=2019-09-26 21:42:40.908059094 ...
I0926 23:15:55.166458       1 static_autoscaler.go:403] Starting scale down
I0926 23:15:55.166488       1 scale_down.go:706] No candidates for scale down
```

Deployment considerations

Review the following considerations to optimize your Cluster Autoscaler deployment.

Scaling considerations

The Cluster Autoscaler can be configured to include any additional features of your nodes. These features can include Amazon EBS volumes attached to nodes, Amazon EC2 instance types of nodes, or GPU accelerators.

Scope node groups across more than one Availability Zone

We recommend that you configure multiple node groups, scope each group to a single Availability Zone, and enable the `--balance-similar-node-groups` feature. If you only create one node group, scope that node group to span over more than one Availability Zone.

When setting `--balance-similar-node-groups` to true, make sure that the node groups you want the Cluster Autoscaler to balance have matching labels (except for automatically added zone labels). You can pass a `--balancing-ignore-label` flag to nodes with different labels to balance them regardless, but this should only be done as needed.

Optimize your node groups

The Cluster Autoscaler makes assumptions about how you’re using node groups. This includes which instance types that you use within a group. To align with these assumptions, configure your node group based on these considerations and recommendations:

- Each node in a node group must have identical scheduling properties. This includes labels, taints, and resources.
• For MixedInstancePolicies, the instance types must have compatible CPU, memory, and GPU specifications.
• The first instance type that's specified in the policy simulates scheduling.
• If your policy has additional instance types with more resources, resources might be wasted after scale out.
• If your policy has additional instance types with fewer resources than the original instance types, pods might fail to schedule on the instances.
• Configure a smaller number of node groups with a larger number of nodes because the opposite configuration can negatively affect scalability.
• Use Amazon EC2 features whenever both systems provide support them (for example, use Regions and MixedInstancePolicy.)

If possible, we recommend that you use Managed node groups (p. 109). Managed node groups come with powerful management features. These include features for Cluster Autoscaler such as automatic Amazon EC2 Auto Scaling group discovery and graceful node termination.

**Use EBS volumes as persistent storage**

Persistent storage is critical for building stateful applications, such as databases and distributed caches. With Amazon EBS volumes, you can build stateful applications on Kubernetes. However, you're limited to only building them within a single Availability Zone. For more information, see [How do I use persistent storage in Amazon EKS?](https://docs.aws.amazon.com/eks/latest/userguide/persistent-storage.html). For a better solution, consider building stateful applications that are sharded across more than one Availability Zone using a separate Amazon EBS volume for each Availability Zone. Doing so means that your application can be highly available. Moreover, the Cluster Autoscaler can balance the scaling of the Amazon EC2 Auto Scaling groups. To do this, make sure that the following conditions are met:

• Node group balancing is enabled by setting `balance-similar-node-groups=true`.
• Your node groups are configured with identical settings (outside of being in more than one Availability Zone and using different Amazon EBS volumes).

**Co-scheduling**

Machine learning distributed training jobs benefit significantly from the minimized latency of same-zone node configurations. These workloads deploy multiple pods to a specific zone. You can achieve this by setting pod affinity for all co-scheduled pods or node affinity using `topologyKey: topology.kubernetes.io/zone`. Using this configuration, the Cluster Autoscaler scales out a specific zone to match demands. Allocate multiple Amazon EC2 Auto Scaling groups, with one for each Availability Zone, to enable failover for the entire co-scheduled workload. Make sure that the following conditions are met:

• Node group balancing is enabled by setting `balance-similar-node-groups=true`.
• Node affinity, pod preemption, or both, are used when clusters include both Regional and Zonal node groups.
  • Use Node Affinity to force or encourage regional pods and avoid zonal node groups.
  • Don't schedule zonal pods onto Regional node groups. Doing so can result in imbalanced capacity for your Regional pods.
  • Configure pod preemption if your zonal workloads can tolerate disruption and relocation. Doing so enforces preemption and rescheduling on a less contested zone for your Regionally scaled pods.

**Accelerators and GPUs**

Some clusters use specialized hardware accelerators such as a dedicated GPU. When scaling out, the accelerator can take several minutes to advertise the resource to the cluster. During this time, the Cluster
Autoscaler simulates that this node has the accelerator. However, until the accelerator becomes ready and updates the available resources of the node, pending pods can't be scheduled on the node. This can result in repeated unnecessary scale out.

Nodes with accelerators and high CPU or memory utilization aren't considered for scale down even if the accelerator is unused. However, this can be result in unnecessary costs. To avoid these costs, the Cluster Autoscaler can apply special rules to consider nodes for scale down if they have unoccupied accelerators.

To ensure the correct behavior for these cases, configure the kubelet on your accelerator nodes to label the node before it joins the cluster. The Cluster Autoscaler uses this label selector to invoke the accelerator optimized behavior. Make sure that the following conditions are met:

- The kubelet for GPU nodes is configured with `--node-labels k8s.amazonaws.com/accelerator=$ACCELERATOR_TYPE`.
- Nodes with accelerators adhere to the identical scheduling properties rule.

**Scaling from zero**

Cluster Autoscaler can scale node groups to and from zero. This might result in a significant cost savings. The Cluster Autoscaler detects the CPU, memory, and GPU resources of an Auto Scaling group by inspecting the InstanceType that is specified in its LaunchConfiguration or LaunchTemplate. Some pods require additional resources such as WindowsENI or PrivateIPv4Address. Or they might require specific NodeSelectors or Taints. These latter two can't be discovered from the LaunchConfiguration. However, the Cluster Autoscaler can account for these factors by discovering them from the following tags on the Auto Scaling group.

```plaintext
Key: k8s.io/cluster-autoscaler/node-template/resources/$RESOURCE_NAME
Value: 5
Key: k8s.io/cluster-autoscaler/node-template/label/$LABEL_KEY
Value: $LABEL_VALUE
Key: k8s.io/cluster-autoscaler/node-template/taint/$TAINT_KEY
Value: NoSchedule
```

**Note**

- When scaling to zero, your capacity is returned to Amazon EC2 and might become unavailable in the future.
- You can use `describeNodegroup` to diagnose issues with managed node groups when scaling to and from zero.

**Additional configuration parameters**

There are many configuration options that can be used to tune the behavior and performance of the Cluster Autoscaler. For a complete list of parameters, see What are the parameters to CA? on GitHub.

**Performance considerations**

There are a few key items that you can change to tune the performance and scalability of the Cluster Autoscaler. The primary ones are any resources that are provided to the process, the scan interval of the algorithm, and the number of node groups in the cluster. However, there are also several other factors that are involved in the true runtime complexity of this algorithm. These include the scheduling plug-in complexity and the number of pods. These are considered to be unconfigurable parameters because they're integral to the workload of the cluster and can't easily be tuned.

**Scalability** refers to how well the Cluster Autoscaler performs as the number of pods and nodes in your Kubernetes cluster increases. If its scalability quotas are reached, the performance and functionality
of the Cluster Autoscaler degrades. Additionally, when it exceeds its scalability quotas, the Cluster Autoscaler can no longer add or remove nodes in your cluster.

*Performance* refers to how quickly the Cluster Autoscaler can make and implement scaling decisions. A perfectly performing Cluster Autoscaler instantly make decisions and invoke scaling actions in response to specific conditions, such as a pod becoming unschedulable.

Be familiar with the runtime complexity of the autoscaling algorithm. Doing so makes it easier to tune the Cluster Autoscaler to operate well in large clusters (with more than 1,000 nodes).

The Cluster Autoscaler loads the state of the entire cluster into memory. This includes the pods, nodes, and node groups. On each scan interval, the algorithm identifies unschedulable pods and simulates scheduling for each node group. Know that tuning these factors in different ways comes with different tradeoffs.

**Vertical autoscaling**

You can scale the Cluster Autoscaler to larger clusters by increasing the resource requests for its deployment. This is one of the simpler methods to do this. Increase both the memory and CPU for the large clusters. Know that how much you should increase the memory and CPU depends greatly on the specific cluster size. The autoscaling algorithm stores all pods and nodes in memory. This can result in a memory footprint larger than a gigabyte in some cases. You usually need to increase resources manually. If you find that you often need to manually increase resources, consider using the Addon Resizer or Vertical Pod Autoscaler to automate the process.

**Reducing the number of node groups**

You can lower the number of node groups to improve the performance of the Cluster Autoscaler in large clusters. If you structured your node groups on an individual team or application basis, this might be challenging. Even though this is fully supported by the Kubernetes API, this is considered to be a Cluster Autoscaler anti-pattern with repercussions for scalability. There are many advantages to using multiple node groups that, for example, use both Spot or GPU instances. In many cases, there are alternative designs that achieve the same effect while using a small number of groups. Make sure that the following conditions are met:

- Isolate pods by using namespaces rather than node groups.
- You might not be able to do this in low-trust multi-tenant clusters.
- Set pod `ResourceRequests` and `ResourceLimits` properly to avoid resource contention.
- Use larger instance types for more optimal bin packing and reduced system pod overhead.
- Avoid using `NodeTaints` or `NodeSelectors` to schedule pods. Only use them on a limited basis.
- Define Regional resources as a single Amazon EC2 Auto Scaling group with more than one Availability Zone.

**Reducing the scan interval**

Using a low scan interval, such as the default setting of ten seconds, ensures that the Cluster Autoscaler responds as quickly as possible when pods become unschedulable. However, each scan results in many API calls to the Kubernetes API and Amazon EC2 Auto Scaling group or the Amazon EKS managed node group APIs. These API calls can result in rate limiting or even service unavailability for your Kubernetes control plane.

The default scan interval is ten seconds, but on AWS, launching a node takes significantly longer to launch a new instance. This means that it's possible to increase the interval without significantly increasing overall scale up time. For example, if it takes two minutes to launch a node, don't change the interval to one minute because this might result in a trade-off of 6x reduced API calls for 38% slower scale ups.
Sharding across node groups

You can configure the Cluster Autoscaler to operate on a specific set of node groups. By using this functionality, you can deploy multiple instances of the Cluster Autoscaler. Configure each instance to operate on a different set of node groups. By doing this, you can use arbitrarily large numbers of node groups, trading cost for scalability. However, we only recommend that you do this as last resort for improving the performance of Cluster Autoscaler.

This configuration has its drawbacks. It can result in unnecessary scale out of multiple node groups. The extra nodes scale back in after the scale-down-delay.

```yaml
metadata:
  name: cluster-autoscaler
  namespace: cluster-autoscaler-1
...
--nodes=1:10:k8s-worker-asg-1
--nodes=1:10:k8s-worker-asg-2
---
metadata:
  name: cluster-autoscaler
  namespace: cluster-autoscaler-2
...
--nodes=1:10:k8s-worker-asg-3
--nodes=1:10:k8s-worker-asg-4
```

Make sure that the following conditions are true.

- Each shard is configured to point to a unique set of Amazon EC2 Auto Scaling groups.
- Each shard is deployed to a separate namespace to avoid leader election conflicts.

Cost efficiency and availability

The primary options for tuning the cost efficiency of the Cluster Autoscaler are related to provisioning Amazon EC2 instances. Additionally, cost efficiency must be balanced with availability. This section describes strategies such as using Spot instances to reduce costs and overprovisioning to reduce latency when creating new nodes.

- **Availability** – Pods can be scheduled quickly and without disruption. This is true even for when newly created pods need to be scheduled and for when a scaled down node terminates any remaining pods scheduled to it.
- **Cost** – Determined by the decision behind scale-out and scale-in events. Resources are wasted if an existing node is underutilized or if a new node is added that is too large for incoming pods. Depending on the specific use case, there can be costs that are associated with prematurely terminating pods due to an aggressive scale down decision.

Spot instances

You can use Spot Instances in your node groups to save up to 90% off the on-demand price. This has the trade-off of Spot Instances possibly being interrupted at any time when Amazon EC2 needs the capacity back. **Insufficient Capacity Errors** occur whenever your Amazon EC2 Auto Scaling group can’t scale up due to a lack of available capacity. Selecting many different instance families has two main benefits. First, it can increase your chance of achieving your desired scale by tapping into many
Spot capacity pools. Second, it can also decrease the impact of Spot Instance interruptions on cluster availability. Mixed Instance Policies with Spot Instances are a great way to increase diversity without increasing the number of node groups. However, know that, if you need guaranteed resources, use On-Demand Instances instead of Spot Instances.

Spot instances might be terminated when demand for instances rises. For more information, see the Spot Instance Interruptions section of the Amazon EC2 User Guide for Linux Instances. The AWS Node Termination Handler project automatically alerts the Kubernetes control plane when a node is going down. The project uses the Kubernetes API to cordon the node to ensure that no new work is scheduled there, then drains it and removes any existing work.

It’s critical that all instance types have similar resource capacity when configuring Mixed instance policies. The scheduling simulator of the autoscaler uses the first instance type in the Mixed Instance Policy. If subsequent instance types are larger, resources might be wasted after a scale up. If the instances are smaller, your pods may fail to schedule on the new instances due to insufficient capacity. For example, M4, M5, M5a, and M5n instances all have similar amounts of CPU and memory and are great candidates for a Mixed Instance Policy. The Amazon EC2 Instance Selector tool can help you identify similar instance types or additional critical criteria, such as size. For more information, see Amazon EC2 Instance Selector on GitHub.

We recommend that you isolate your On-Demand and Spot instances capacity into separate Amazon EC2 Auto Scaling groups. We recommend this over using a base capacity strategy because the scheduling properties of On-Demand and Spot instances are different. Spot Instances can be interrupted at any time. When Amazon EC2 needs the capacity back, preemptive nodes are often tainted, thus requiring an explicit pod toleration to the preemption behavior. This results in different scheduling properties for the nodes, so they should be separated into multiple Amazon EC2 Auto Scaling groups.

The Cluster Autoscaler involves the concept of Expanders. They collectively provide different strategies for selecting which node group to scale. The strategy --expander=least-waste is a good general purpose default, and if you’re going to use multiple node groups for Spot Instance diversification, as described previously, it could help further cost-optimize the node groups by scaling the group that would be best utilized after the scaling activity.

Prioritizing a node group or Auto Scaling group

You might also configure priority-based autoscaling by using the Priority expander. --expander=priority enables your cluster to prioritize a node group or Auto Scaling group, and if it is unable to scale for any reason, it will choose the next node group in the prioritized list. This is useful in situations where, for example, you want to use P3 instance types because their GPU provides optimal performance for your workload, but as a second option you can also use P2 instance types. For example:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-autoscaler-priority-expander
  namespace: kube-system
data:
  priorities: |-
    10:
    - .*p2-node-group.*
    50:
    - .*p3-node-group.*
```

Cluster Autoscaler attempts to scale up the Amazon EC2 Auto Scaling group matching the name p3-node-group. If this operation doesn't succeed within --max-node-provision-time, it then attempts to scale an Amazon EC2 Auto Scaling group matching the name p2-node-group. This value defaults to 15 minutes and can be reduced for more responsive node group selection. However, if the value is too low, unnecessary scaleout might occur.

Overprovisioning
The Cluster Autoscaler helps to minimize costs by ensuring that nodes are only added to the cluster when they’re needed and are removed when they’re unused. This significantly impacts deployment latency because many pods must wait for a node to scale up before they can be scheduled. Nodes can take multiple minutes to become available, which can increase pod scheduling latency by an order of magnitude.

This can be mitigated using overprovisioning, which trades cost for scheduling latency. Overprovisioning is implemented using temporary pods with negative priority. These pods occupy space in the cluster. When newly created pods are unschedulable and have a higher priority, the temporary pods are preempted to make room. Then, the temporary pods become unschedulable, causing the Cluster Autoscaler to scale out new overprovisioned nodes.

There are other benefits to overprovisioning. Without overprovisioning, pods in a highly utilized cluster make less optimal scheduling decisions using the preferredDuringSchedulingIgnoredDuringExecution rule. A common use case for this is to separate pods for a highly available application across Availability Zones using AntiAffinity. Overprovisioning can significantly increase the chance that a node of the desired zone is available.

It's important to choose an appropriate amount of overprovisioned capacity. One way that you can make sure that you choose an appropriate amount is by taking your average scaleup frequency and dividing it by the duration of time it takes to scale up a new node. For example, if, on average, you require a new node every 30 seconds and Amazon EC2 takes 30 seconds to provision a new node, a single node of overprovisioning ensures that there's always an extra node available. Doing this can reduce scheduling latency by 30 seconds at the cost of a single additional Amazon EC2 instance. To make better zonal scheduling decisions, you can also overprovision the number of nodes to be the same as the number of Availability Zones in your Amazon EC2 Auto Scaling group. Doing this ensures that the scheduler can select the best zone for incoming pods.

Prevent scale down eviction

Some workloads are expensive to evict. Big data analysis, machine learning tasks, and test runners can take a long time to complete and must be restarted if they're interrupted. The Cluster Autoscaler helps to scale down any node under the scale-down-utilization-threshold. This interrupts any remaining pods on the node. However, you can prevent this from happening by ensuring that pods that are expensive to evict are protected by a label recognized by the Cluster Autoscaler. To do this, ensure that pods that are expensive to evict have the label cluster-autoscaler.kubernetes.io/safe-to-evict=false.

Karpenter

Amazon EKS supports the Karpenter open-source autoscaling project. See the Karpenter documentation to deploy it.

About Karpenter

Karpenter is a flexible, high-performance Kubernetes cluster autoscaler that helps improve application availability and cluster efficiency. Karpenter launches right-sized compute resources, (for example, Amazon EC2 instances), in response to changing application load in under a minute. Through integrating Kubernetes with AWS, Karpenter can provision just-in-time compute resources that precisely meet the requirements of your workload. Karpenter automatically provisions new compute resources based on the specific requirements of cluster workloads. These include compute, storage, acceleration, and scheduling requirements. Amazon EKS supports clusters using Karpenter, although Karpenter works with any conformant Kubernetes cluster.

How Karpenter works

Karpenter works in tandem with the Kubernetes scheduler by observing incoming pods over the lifetime of the cluster. It launches or terminates nodes to maximize application availability and cluster utilization.
When there is enough capacity in the cluster, the Kubernetes scheduler will place incoming pods as usual. When pods are launched that cannot be scheduled using the existing capacity of the cluster, Karpenter bypasses the Kubernetes scheduler and works directly with your provider’s compute service, (for example, Amazon EC2), to launch the minimal compute resources needed to fit those pods and binds the pods to the nodes provisioned. As pods are removed or rescheduled to other nodes, Karpenter looks for opportunities to terminate under-utilized nodes. Running fewer, larger nodes in your cluster reduces overhead from daemonsets and Kubernetes system components and provides more opportunities for efficient bin-packing.

Prerequisites

Before deploying Karpenter, you must meet the following prerequisites:

- An existing Amazon EKS cluster – If you don’t have a cluster, see Creating an Amazon EKS cluster (p. 24).
- An existing IAM OIDC provider for your cluster. To determine whether you have one or need to create one, see Create an IAM OIDC provider for your cluster (p. 466).
- A user or role with permission to create a cluster.
- AWS CLI
  - Installing kubectl (p. 4)
  - Using Helm with Amazon EKS (p. 421)

You can deploy Karpenter using eksctl if you prefer. See Installing eksctl (p. 10).

Amazon EKS control plane logging

Amazon EKS control plane logging provides audit and diagnostic logs directly from the Amazon EKS control plane to CloudWatch Logs in your account. These logs make it easy for you to secure and run your clusters. You can select the exact log types you need, and logs are sent as log streams to a group for each Amazon EKS cluster in CloudWatch.

You can start using Amazon EKS control plane logging by choosing which log types you want to enable for each new or existing Amazon EKS cluster. You can enable or disable each log type on a per-cluster basis using the AWS Management Console, AWS CLI (version 1.16.139 or higher), or through the Amazon EKS API. When enabled, logs are automatically sent from the Amazon EKS cluster to CloudWatch Logs in the same account.

When you use Amazon EKS control plane logging, you’re charged standard Amazon EKS pricing for each cluster that you run. You are charged the standard CloudWatch Logs data ingestion and storage costs for any logs sent to CloudWatch Logs from your clusters. You are also charged for any AWS resources, such as Amazon EC2 instances or Amazon EBS volumes, that you provision as part of your cluster.

The following cluster control plane log types are available. Each log type corresponds to a component of the Kubernetes control plane. To learn more about these components, see Kubernetes Components in the Kubernetes documentation.

- **Kubernetes API server component logs (api)** – Your cluster’s API server is the control plane component that exposes the Kubernetes API. For more information, see kube-apiserver in the Kubernetes documentation.
- **Audit (audit)** – Kubernetes audit logs provide a record of the individual users, administrators, or system components that have affected your cluster. For more information, see Auditing in the Kubernetes documentation.
Enabling and disabling control plane logs

By default, cluster control plane logs aren't sent to CloudWatch Logs. You must enable each log type individually to send logs for your cluster. CloudWatch Logs ingestion, archive storage, and data scanning rates apply to enabled control plane logs. For more information, see CloudWatch pricing.

When you enable a log type, the logs are sent with a log verbosity level of 2.

To enable or disable control plane logs with the console

1. Open the Amazon EKS console.
2. Choose the name of the cluster to display your cluster information.
3. Select the Configuration tab.
4. Under Logging, choose Manage logging.
5. For each individual log type, choose whether the log type should be Enabled or Disabled. By default, each log type is Disabled.
6. Choose Save changes to finish.

To enable or disable control plane logs with the AWS CLI

1. Check your AWS CLI version with the following command.

   ```bash
   aws --version
   ```

   If your AWS CLI version is below 1.16.139, you must first update to the latest version. To install or upgrade the AWS CLI, see Installing the AWS Command Line Interface in the AWS Command Line Interface User Guide.

2. Update your cluster's control plane log export configuration with the following AWS CLI command. Replace my-cluster with your cluster name and specify your desired endpoint access values.

   ```bash
   aws eks update-cluster-config \
   --region region-code \ 
   --name my-cluster \ 
   --logging '{"clusterLogging":{{"types": ["api","audit","authenticator","controllerManager","scheduler"],"enabled":true}}}'
   ```

   Output:

   ```json
   {
     "update": {
   ```
Viewing cluster control plane logs

After you have enabled any of the control plane log types for your Amazon EKS cluster, you can view them on the CloudWatch console.

To learn more about viewing, analyzing, and managing logs in CloudWatch, see the Amazon CloudWatch Logs User Guide.

To view your cluster control plane logs on the CloudWatch console

1. Open the CloudWatch console. The link opens the console and displays your current available log groups and filters them with the /aws/eks prefix.
2. Choose the cluster that you want to view logs for. The log group name format is /aws/eks/<cluster-name>/cluster.
3. Choose the log stream to view. The following list describes the log stream name format for each log type.
As log stream data grows, the log stream names are rotated. When multiple log streams exist for a particular log type, you can view the latest log stream by looking for the log stream name with the latest Last Event Time.

- Kubernetes API server component logs (api) – kube-apiserver-<nnn...>
- Audit (audit) – kube-apiserver-audit-<nnn...>
- Authenticator (authenticator) – authenticator-<nnn...>
- Controller manager (controllerManager) – kube-controller-manager-<nnn...>
- Scheduler (scheduler) – kube-scheduler-<nnn...>

Amazon EKS Kubernetes versions

The Kubernetes project is continually integrating new features, design updates, and bug fixes. The community releases new Kubernetes minor versions, such as 1.21. New version updates are available on average every three months. Each minor version is supported for approximately twelve months after it’s first released.

Available Amazon EKS Kubernetes versions

The following Kubernetes versions are currently available for new Amazon EKS clusters:

- 1.22.6
- 1.21.5
- 1.20.7
- 1.19.15
- 1.18.16

If your application doesn't require a specific version of Kubernetes, we recommend that you use the latest available Kubernetes version that’s supported by Amazon EKS for your clusters. As new Kubernetes versions become available in Amazon EKS, we recommend that you proactively update your clusters to use the latest available version. For instructions on how to update your cluster, see Updating a cluster (p. 52). For more information about Kubernetes releases, see Amazon EKS Kubernetes release calendar (p. 72) and Amazon EKS version support and FAQ (p. 73).

Note

Starting with the Kubernetes version 1.23 launch, officially published Amazon EKS AMIs will include containerd as the only runtime. Kubernetes version 1.18–1.21 use Docker as the default runtime. However, these versions have a bootstrap flag option that you can use test out your workloads on any supported cluster with containerd. For more information, see Amazon EKS is ending support for Dockershim (p. 173).

Kubernetes 1.22

Kubernetes 1.22 is now available in Amazon EKS. For more information about Kubernetes 1.22, see the official release announcement.

Important

- Amazon EKS doesn't currently support Windows for Kubernetes 1.22, but support will be added soon.
- Kubernetes 1.22 removes a number of APIs that are no longer available. You might need to make changes to your application before you upgrade to Amazon EKS v1.22. Follow the Kubernetes version 1.22 prerequisites (p. 32) carefully before updating your cluster.
The Ingress API versions extensions/v1beta1 and networking.k8s.io/v1beta1 have been removed in Kubernetes 1.22. If you're using the AWS Load Balancer controller, you must upgrade to at least version 2.4.1 before you upgrade your Amazon EKS clusters to version 1.22. Additionally, you must modify Ingress manifests to use apiVersion networking.k8s.io/v1. This has been available since Kubernetes v1.19. For more information about changes between Ingress v1beta1 and v1, see the Kubernetes documentation. The AWS Load Balancer controller sample manifest uses the v1 spec.

The Amazon EKS legacy Windows support controllers use the admissionregistration.k8s.io/v1beta1 API that was removed in Kubernetes 1.22. If you're running Windows workloads, you must remove legacy Windows support before upgrading to Amazon EKS v1.22.

The CertificateSigningRequest (CSR) API version certificates.k8s.io/v1beta1 was removed in Kubernetes 1.22. You must migrate manifests and API clients to use the certificates.k8s.io/v1 CSR API. This API has been available since v1.19. For instructions on how to use CSR in Amazon EKS, see Certificate signing (p. 430).

The CustomResourceDefinition API version apiextensions.k8s.io/v1beta1 was removed in Kubernetes 1.22. Make sure that all custom resource definitions in your cluster are updated to v1. API version v1 custom resource definitions are required to have Open API v3 schema validation defined. For more information, see the Kubernetes documentation.

If you're using App Mesh, you must upgrade to at least App Mesh controller v1.4.3 or later before you upgrade to Amazon EKS 1.22. Older versions of the App Mesh controller use v1beta1 CustomResourceDefinition API version and aren't compatible with Kubernetes version 1.22 and later.

Amazon EKS v1.22 enables the EndpointSliceTerminatingCondition feature by default, which will include pods in terminating state within EndpointSlices. If you set enableEndpointSlices to True (the default is disabled) in the AWS Load Balancer controller, you must upgraded to at least AWS Load Balancer controller version 2.4.1+ before upgrading to Amazon EKS v1.22.

Starting with Amazon EKS version 1.22, kube-proxy is configured by default to expose Prometheus metrics outside the pod. This behavior change addresses the request made in containers roadmap issue #657.

The initial launch of Amazon EKS v1.22 uses etcd v3.4 as a backend, and is not affected by the possibility of data corruption present in etcd v3.5.

Starting with Amazon EKS 1.22, Amazon EKS is decoupling AWS cloud-specific control logic from core control plane code to the out-of-tree AWS Kubernetes Cloud Controller Manager. This is in line with the upstream Kubernetes recommendation. By decoupling the interoperability logic between Kubernetes and the underlying cloud infrastructure, the cloud-controller-manager component enables cloud providers to release features at a different pace compared to the main Kubernetes project. This change is transparent and requires no action. However, a new log stream named "cloud-controller-manager" now appears under the "ControllerManager" log type when enabled. For more information, see Amazon EKS control plane logging.

Starting with Amazon EKS 1.22, Amazon EKS is changing the default AWS STS endpoint used by IAM Role for Service Account (IRSA) to be the regional endpoint instead of the global endpoint to reduce latency and improve reliability. You can optionally configure IRSA to use the global endpoint in Associate an IAM role to a service account (p. 470).

The following Kubernetes features are now supported in Kubernetes 1.22 Amazon EKS clusters:

- **Server-side Apply graduates to GA** - Server-side Apply helps users and controllers manage their resources through declarative configurations. It allows them to create or modify objects declaratively by sending their fully specified intent. After being in beta for a couple releases, Server-side Apply is now generally available.
- **BoundServiceAccountTokenVolume** graduated to stable and is enabled by default in Kubernetes version 1.22. This feature improves security of service account tokens. It allows workloads that are running on Kubernetes to request JSON Web Tokens that are audience, time, and key bound. Service account tokens now have an expiration of one hour. In previous Kubernetes versions, they didn't have an expiration. This means that clients that rely on these tokens must refresh the tokens within an hour.
These newer Kubernetes client SDKs have been updated to refresh tokens automatically in this time frame:

- Go v0.15.7 and later
- Python v12.0.0 and later
- Java v9.0.0 and later
- Javascript v0.10.3 and later
- Ruby master branch
- Haskell v0.3.0.0

If your workload is using an older client version then you must update it. To enable a smooth migration of clients to the newer time-bound service account tokens, version 1.22 adds an extended lifetime of one year to the service account token over the default one hour so that clients can continue to use already generated token for one year even after the token has been refreshed. You can use this additional time to update clients in your workloads to periodically read refreshed tokens. If you don't update your client libraries to read refreshed tokens, any requests are rejected after the token expiration. If you're using VPC CNI version 1.7.X or earlier, we recommend you update to the latest version because the newer versions use Kubernetes client SDK that automatically refreshes the token. To check if you have clients in your Amazon EKS cluster that aren't refreshing tokens, enable Amazon EKS control plane audit log, and search for the occurrence of annotation authentication.k8s.io/stale token. You can also check for the Kubernetes API server metric serviceaccount_stale_tokens_total to detect clients that aren't refreshing the token.

- Warning mechanism for deprecated API user - Use of deprecated APIs produces warnings visible to API consumers, and metrics visible to cluster administrators.

For the complete Kubernetes 1.22 changelog, see https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.22.md#changelog-since-v1210

**Kubernetes 1.21**

Kubernetes 1.21 is now available in Amazon EKS. For more information about Kubernetes 1.21, see the official release announcement.

**Important**

- **BoundServiceAccountTokenVolume** graduated to beta and is enabled by default in Kubernetes version 1.21. This feature improves security of service account tokens by allowing workloads running on Kubernetes to request JSON Web Tokens that are audience, time, and key bound. Service account tokens now have an expiration of one hour. In previous Kubernetes versions, they didn't have an expiration. This means that clients that rely on these tokens must refresh the tokens within an hour. These newer Kubernetes client SDKs have been updated to refresh tokens automatically in this time frame:
  - Go v0.15.7 and later
  - Python v12.0.0 and later
  - Java v9.0.0 and later
  - Javascript v0.10.3 and later
  - Ruby master branch
  - Haskell v0.3.0.0

If your workload is using an older client version then you must update it. To enable a smooth migration of clients to the newer time-bound service account tokens, version 1.21 adds an extended lifetime of one year to the service account token over the default one hour so that clients can continue to use already generated token for one year even after the token has been refreshed. You can use this additional time to update clients in your workloads to periodically read refreshed tokens. If you do not
update your client libraries to read refreshed tokens, then any requests would be rejected after the
token expiration.

If you’re using a version of the Amazon VPC CNI plugin that is earlier than 1.8.0, then we
recommend that you update to version 1.10.1, which leverages the Kubernetes client SDK that
automatically refreshes the token. To check if you have clients in your Amazon EKS cluster that
are not refreshing tokens, enable the Amazon EKS control plane audit log and search for the
authentication.k8s.io/stale-token annotation. You can also check for the Kubernetes API
server metric serviceaccount_stale_tokens_total to detect clients that are not refreshing the
token.

- **Dual-stack networking** support (IPv4 and IPv6 addresses) on pods, services, and nodes reached beta
  status. However, Amazon EKS and the Amazon VPC CNI don’t currently support dual stack networking.
- The Amazon EKS Optimized Amazon Linux 2 AMI now contains a bootstrap flag to enable the
  containerd runtime as a Docker alternative. This flag allows preparation for the removal of
  Docker as a supported runtime in the next Kubernetes release. For more information, see Enable the
  containerd runtime bootstrap flag (p. 182). This can be tracked through the container roadmap on
  Github.
- Managed node groups support for Cluster Autoscaler priority expander.

Newly created managed node groups on Amazon EKS v1.21 clusters use the following format for the
underlying Auto Scaling group name:

`eks-<managed-node-group-name>-<uuid>`

This enables using the priority expander feature of Cluster Autoscaler to scale node groups based
on user defined priorities. A common use case is to prefer scaling spot node groups over on-demand
groups. This behavior change solves the containers roadmap issue #1304.

The following Kubernetes features are now supported in Kubernetes 1.21 Amazon EKS clusters:

- **CronJobs** (previously ScheduledJobs) have now graduated to stable status. With this change, users
  perform regularly scheduled actions such as backups and report generation.
- **Immutable Secrets and ConfigMaps** have now graduated to stable status. A new, immutable field
  was added to these objects to reject changes. This rejection protects the cluster from updates
  that can unintentionally break the applications. Because these resources are immutable, kubelet
doesn’t watch or poll for changes. This reduces kube-apiserver load and improving scalability and
  performance.
- **Graceful Node Shutdown** has now graduated to beta status. With this update, the kubelet is aware
  of node shutdown and can gracefully terminate that node’s pods. Before this update, when a node
  shutdown, its pods didn’t follow the expected termination lifecycle. This caused workload problems.
  Now, the kubelet can detect imminent system shutdown through systemd, and inform running pods
  so they terminate gracefully.
- Pods with multiple containers can now use the kubectl.kubernetes.io/default-container
  annotation to have a container preselected for kubectl commands.
- PodSecurityPolicy is being phased out. PodSecurityPolicy will still be functional for several more
  releases according to Kubernetes deprecation guidelines. For more information, see PodSecurityPolicy
  Deprecation: Past, Present, and Future and the AWS blog.

For the complete Kubernetes 1.21 changelog, see https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.21.md.

**Kubernetes 1.20**

For more information about Kubernetes 1.20, see the official release announcement.
Important

- 1.20 brings new default roles and users. You can find more information in Default EKS Kubernetes roles and users. Ensure that you are using a supported cert-manager version.

The following Kubernetes features are now supported in Kubernetes 1.20 Amazon EKS clusters:

- **API Priority and Fairness** has reached beta status and is enabled by default. This allows kube-apiserver to categorize incoming requests by priority levels.
- **RuntimeClass** has reached stable status. The RuntimeClass resource provides a mechanism for supporting multiple runtimes in a cluster and surfaces information about that container runtime to the control plane.
- **Process ID Limits** has now graduated to general availability.
- **kubectl debug** has reached beta status. kubectl debug provides support for common debugging workflows directly from kubectl.
- The Docker container runtime has been phased out. The Kubernetes community has written a blog post about this in detail with a dedicated FAQ page. Docker-produced images can continue to be used and will work as they always have. You can safely ignore the Dockershim deprecation warning message printed in kubelet startup logs. EKS will eventually move to containerd as the runtime for the EKS optimized Amazon Linux 2 AMI. You can follow the containers roadmap issue for more details.
- Pod Hostname as FQDN has graduated to beta status. This feature allows setting a pod’s hostname to its Fully Qualified Domain Name (FQDN), giving the ability to set the hostname field of the kernel to the FQDN of a Pod.
- The client-go credential plugins can now be passed in the current cluster information via the KUBERNETES_EXEC_INFO environment variable. This enhancement allows Go clients to authenticate using external credential providers, such as a key management system (KMS).

For the complete Kubernetes 1.20 changelog, see https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.20.md.

Kubernetes 1.19

For more information about Kubernetes 1.19, see the official release announcement.

Important

- Starting with 1.19, Amazon EKS no longer adds the kubernetes.io/cluster/<cluster-name> tag to subnets passed in when clusters are created. This subnet tag is only required if you want to influence where the Kubernetes service controller or AWS Load Balancer Controller places Elastic Load Balancers. For more information about the requirements of subnets passed to Amazon EKS during cluster creation, see updates to the section called “VPC considerations” (p. 262).
- Subnet tags aren't modified on existing clusters updated to 1.19.
- The AWS Load Balancer Controller version v2.1.1 and earlier required the <cluster-name> subnet tag. In version v2.1.2 and later, you can specify the tag to refine subnet discovery, but it's not required. For more information about the AWS Load Balancer Controller, see Installing the AWS Load Balancer Controller add-on (p. 320). For more information about subnet tagging when using a load balancer, see Application load balancing on Amazon EKS (p. 371) and Network load balancing on Amazon EKS (p. 365).

- You're no longer required to provide a security context for non-root containers that must access the web identity token file for use with IAM roles for service accounts. For more information, see IAM roles for service accounts (p. 461) and proposal for file permission handling in projected service account volume on GitHub.
• The pod identity webhook has been updated to address the missing startup probes GitHub issue. The webhook also now supports an annotation to control token expiration. For more information, see the GitHub pull request.

• CoreDNS version 1.8.0 is the recommended version for Amazon EKS 1.19 clusters. This version is installed by default in new Amazon EKS 1.19 clusters. For more information, see Managing the CoreDNS add-on (p. 328).

• Amazon EKS optimized Amazon Linux 2 AMIs include the Linux kernel version 5.4 for Kubernetes version 1.19. For more information, see Amazon EKS optimized Amazon Linux AMI (p. 185).

• The CertificateSigningRequest API has been promoted to stable certificates.k8s.io/v1 with the following changes:
  • `spec.signerName` is now required. You can't create requests for kubernetes.io/legacy-unknown with the certificates.k8s.io/v1 API.
  • You can continue to create CSRs with the kubernetes.io/legacy-unknown signer name with the certificates.k8s.io/v1beta1 API.
  • You can continue to request that a CSR to is signed for a non-node server cert, webhooks (for example, with the certificates.k8s.io/v1beta1 API). These CSRs aren't auto-approved.
  • To approve certificates, a privileged user requires kubectl 1.18.8 or later.

  For more information about the certificate v1 API, see Certificate Signing Requests in the Kubernetes documentation.

The following Amazon EKS Kubernetes resources are critical for the Kubernetes control plane to work. We recommend that you don't delete or edit them.

<table>
<thead>
<tr>
<th>Permission</th>
<th>Kind</th>
<th>Namespace</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>controller</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following Kubernetes features are now supported in Kubernetes 1.19 Amazon EKS clusters:

• The ExtendedResourceToleration admission controller is enabled. This admission controller automatically adds tolerations for taints to pods requesting extended resources, such as GPUs. This way, you don't have to manually add the tolerations. For more information, see ExtendedResourceToleration in the Kubernetes documentation.

• Elastic Load Balancers (CLB and NLB) provisioned by the in-tree Kubernetes service controller support filtering the nodes included as instance targets. This can help prevent reaching target group limits in large clusters. For more information, see the related GitHub issue and the service.beta.kubernetes.io/aws-load-balancer-target-node-labels annotation under Other ELB annotations in the Kubernetes documentation.

• Pod Topology Spread has reached stable status. You can use topology spread constraints to control how pods are spread across your cluster among failure-domains such as regions, zones, nodes, and
other user-defined topology domains. This can help to achieve high availability, as well as efficient resource utilization. For more information, see Pod Topology Spread Constraints in the Kubernetes documentation.

- The Ingress API has reached general availability. For more information, see Ingress in the Kubernetes documentation.

- EndpointSlices are enabled by default. EndpointSlices are a new API that provides a more scalable and extensible alternative to the Endpoints API for tracking IP addresses, ports, readiness, and topology information for Pods backing a Service. For more information, see Scaling Kubernetes Networking With EndpointSlices in the Kubernetes blog.

- Secret and ConfigMap volumes can now be marked as immutable. This significantly reduces load on the API server if there are many Secret and ConfigMap volumes in the cluster. For more information, see ConfigMap and Secret in the Kubernetes documentation.

For the complete Kubernetes 1.19 changelog, see https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.19.md.

Kubernetes 1.18

For more information about Kubernetes 1.18, see the official release announcement.

The following Kubernetes features are now supported in Kubernetes 1.18 Amazon EKS clusters:

- Topology Manager has reached beta status. This feature allows the CPU and Device Manager to coordinate resource allocation decisions, optimizing for low latency with machine learning and analytics workloads. For more information, see Control Topology Management Policies on a node in the Kubernetes documentation.

- Server-side Apply is updated with a new beta version. This feature tracks and manages changes to fields of all new Kubernetes objects. This helps you to know what changed your resources and when. For more information, see What is Server-side Apply? in the Kubernetes documentation.

- A new pathType field and a new IngressClass resource has been added to the Ingress specification. These features make it simpler to customize Ingress configuration, and are supported by the AWS Load Balancer Controller (p. 371) (formerly called the ALB Ingress Controller). For more information, see Improvements to the Ingress API in Kubernetes 1.18 in the Kubernetes documentation.

- Configurable horizontal pod autoscaling behavior. For more information, see Support for configurable scaling behavior in the Kubernetes documentation.

- In 1.18 clusters, you no longer need to include the AWS_DEFAULT_REGION=<region-code> environment variable to pods when using IAM roles for service accounts in China Regions, whether you use the mutating web hook or configure the environment variables manually. You still need to include the variable for all pods in earlier versions.

- New clusters contain updated default values in externalTrafficPolicy. HealthyThresholdCount and UnhealthyThresholdCount are 2 each, and HealthCheckIntervalSeconds is reduced to 10 seconds. Clusters created in older versions and upgraded retain the old values.

For the complete Kubernetes 1.18 changelog, see https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.18.md.

Kubernetes 1.17

For more information about Kubernetes 1.17, see the official release announcement.
Important

- The **CSIMigrationAWS** feature flag isn't enabled on EKS. It will be enabled in a future release. Detailed migration instructions will also be provided at that time. For more information about CSI migration, see the Kubernetes blog.

The following Kubernetes features are now supported in Kubernetes 1.17 Amazon EKS clusters:

- **Cloud Provider Labels** have reached general availability. If you're using the beta labels in your pod specs for features such as node affinity, or in any custom controllers, then we recommend that you start migrating them to the new GA labels. For information about the new labels, see the following Kubernetes documentation:
  - `node.kubernetes.io/instance-type`
  - `topology.kubernetes.io/region`
  - `topology.kubernetes.io/zone`
- The **ResourceQuotaScopeSelectors** feature has graduated to generally available. You can use this feature to limit the number of resources a quota supports to only those that pertain to the scope.
- The **TaintNodesByCondition** feature has graduated to generally available. This feature allows you to taint nodes that have conditions such as high disk or memory pressure.
- The **CSI Topology** feature has graduated to generally available, and is fully supported by the **EBS CSI driver**. You can use topology to restrict the Availability Zone where a volume is provisioned.
- **Finalizer protection** for services of type **LoadBalancer** has graduated to generally available. This feature ensures that a service resource isn't fully deleted until the correlating load balancer is also deleted.
- Custom resources now support **default values**. You specify values in an OpenAPI v3 validation schema.
- The **Windows containers RunAsUsername** feature is now in beta. You can use it to run Windows applications in a container as a different user name than the default.

For the complete Kubernetes 1.17 changelog, see [https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.17.md](https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.17.md).

### Amazon EKS Kubernetes release calendar

**Note**

Dates with only a month and a year are approximate and are updated with an exact date when it's known.

<table>

Amazon EKS version support and FAQ

In line with the Kubernetes community support for Kubernetes versions, Amazon EKS is committed to supporting at least four production-ready versions of Kubernetes at any given time. We will announce the end of support date of a given Kubernetes minor version at least 60 days before the end of support date. Because of the Amazon EKS qualification and release process for new Kubernetes versions, the end of support date of a Kubernetes version on Amazon EKS will be on or after the date that the Kubernetes project stops supporting the version upstream.

Frequently asked questions

Q: How long is a Kubernetes version supported by Amazon EKS?
A: A Kubernetes version is supported for 14 months after first being available on Amazon EKS. This is true even if upstream Kubernetes no longer support a version that's available on Amazon EKS. We backport security patches that are applicable to the Kubernetes versions that are supported on Amazon EKS.

Q: Am I notified when support is ending for a Kubernetes version on Amazon EKS?
A: Yes, if any clusters in your account are running the version nearing the end of support, Amazon EKS sends out a notice through the AWS Health Dashboard approximately 12 months after the Kubernetes version was released on Amazon EKS. The notice includes the end of support date. This is at least 60 days from the date of the notice.

Q: What happens on the end of support date?
A: On the end of support date, you can no longer create new Amazon EKS clusters with the unsupported version. Existing control planes are automatically updated by Amazon EKS to the earliest supported version through a gradual deployment process after the end of support date. After the automatic control plane update, make sure to manually update cluster add-ons and Amazon EC2 nodes. For more information, see the section called “To update the Kubernetes version for your Amazon EKS cluster” (p. 36).

Q: When exactly is my control plane automatically updated after the end of support date?
A: Amazon EKS can't provide specific timeframes. Automatic updates can happen at any time after the end of support date. We recommend that you proactively update your control plane without relying on the Amazon EKS automatic update process. For more information, see the section called “Updating a cluster” (p. 32).

Q: Can I leave my control plane on a Kubernetes version indefinitely?
A: No, cloud security at AWS is the highest priority. Past a certain point (usually one year), the Kubernetes community stops releasing CVE patches and discourages CVE submission for deprecated versions. This means that vulnerabilities specific to an older version of Kubernetes might not even be reported. This leaves clusters exposed with no notice and no remediation options in the event of a vulnerability. Given this, Amazon EKS doesn't allow control planes to stay on a version that reached end of support.

Q: Which Kubernetes features are supported by Amazon EKS?
A: Amazon EKS supports all general availability features of the Kubernetes API. It also supports all beta features, which are enabled by default. Alpha features aren't supported.

Q: Are Amazon EKS managed node groups automatically updated along with the cluster control plane version?
A: No, a managed node group creates Amazon EC2 instances in your account. These instances aren't automatically upgraded when you or Amazon EKS update your control plane. Assume that Amazon EKS automatically updates your control plane. The Kubernetes version that's on your managed node group might be more than one version earlier than your control plane. Then, assume that a managed node
group contains instances that are running a version of Kubernetes that's more than one version earlier than the control plane. The node group has a health issue in the Node Groups section of the Compute tab on the Configuration tab of your cluster in the console. Last, if a node group has an available version update, Update now appears next to the node group in the console. For more information, see the section called “Updating a managed node group” (p. 119). We recommend maintaining the same Kubernetes version on your control plane and nodes.

**Q: Are self-managed node groups automatically updated along with the cluster control plane version?**

**A: No,** a self-managed node group includes Amazon EC2 instances in your account. These instances aren't automatically upgraded when you or Amazon EKS update the control plane version on your behalf. A self-managed node group doesn't have any indication in the console that it needs updating. You can view the kubelet version installed on a node by selecting the node in the Nodes list on the Overview tab of your cluster to determine which nodes need updating. You must manually update the nodes. For more information, see the section called “Updates” (p. 145).

The Kubernetes project tests compatibility between the control plane and nodes for up to two minor versions. For example, 1.20 nodes continue to operate when orchestrated by a 1.22 control plane. However, running a cluster with nodes that are persistently two minor versions behind the control plane isn't recommended. For more information, see Kubernetes version and version skew support policy in the Kubernetes documentation. We recommend maintaining the same Kubernetes version on your control plane and nodes.

**Q: Are pods running on Fargate automatically upgraded with an automatic cluster control plane version upgrade?**

Yes, Fargate pods run on infrastructure in AWS owned accounts on the Amazon EKS side of the shared responsibility model (p. 429). Amazon EKS uses the Kubernetes eviction API to attempt to gracefully drain pods that are running on Fargate. For more information, see The Eviction API in the Kubernetes documentation. If a pod can't be evicted, Amazon EKS issues a Kubernetes delete pod command. We strongly recommend running Fargate pods as part of a replication controller such as a Kubernetes deployment. This is so a pod is automatically rescheduled after deletion. For more information, see Deployments in the Kubernetes documentation. The new version of the Fargate pod is deployed with a kubelet version that's the same version as your updated cluster control plane version.

**Important**

If you update the control plane, you still need to update the Fargate nodes yourself. To update Fargate nodes, delete the Fargate pod represented by the node and redeploy the pod. The new pod is deployed with a kubelet version that's the same version as your cluster.

### Amazon EKS platform versions

Amazon EKS platform versions represent the capabilities of the Amazon EKS cluster control plane, such as which Kubernetes API server flags are enabled, as well as the current Kubernetes patch version. Each Kubernetes minor version has one or more associated Amazon EKS platform versions. The platform versions for different Kubernetes minor versions are independent.

When a new Kubernetes minor version is available in Amazon EKS, such as 1.21, the initial Amazon EKS platform version for that Kubernetes minor version starts at eks.1. However, Amazon EKS releases new platform versions periodically to enable new Kubernetes control plane settings and to provide security fixes.

When new Amazon EKS platform versions become available for a minor version:

- The Amazon EKS platform version number is incremented (eks.<n+1>).
- Amazon EKS automatically upgrades all existing clusters to the latest Amazon EKS platform version for their corresponding Kubernetes minor version.
- Amazon EKS might publish a new node AMI with a corresponding patch version. However, all patch versions are compatible between the EKS control plane and node AMIs for a given Kubernetes minor version.

New Amazon EKS platform versions don’t introduce breaking changes or cause service interruptions.

**Note**
Automatic upgrades of existing Amazon EKS platform versions are rolled out incrementally. The roll-out process might take some time. If you need the latest Amazon EKS platform version features immediately, you should create a new Amazon EKS cluster.

Clusters are always created with the latest available Amazon EKS platform version (eks.<n>) for the specified Kubernetes version. If you update your cluster to a new Kubernetes minor version, your cluster receives the current Amazon EKS platform version for the Kubernetes minor version that you updated to.

The current and recent Amazon EKS platform versions are described in the following tables.

### Kubernetes version 1.22

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Amazon EKS platform version</th>
<th>Enabled admission controllers</th>
<th>Release notes</th>
<th>Release date</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.22.6</td>
<td>eks.1</td>
<td>NamespaceLifecycle, LimitRanger, ServiceAccount, DefaultStorageClass, ResourceQuota, DefaultTolerationSeconds, NodeRestriction, MutatingAdmissionWebhook, ValidatingAdmissionWebhook, PodSecurityPolicy, TaintNodesByCondition, StorageObjectInUseProtection, PersistentVolumeClaimResize, ExtendedResourceToleration, CertificateApproval, PodPriority, CertificateSigning, CertificateSubjectRestriction, RuntimeClass, DefaultIngressClass</td>
<td>Initial release of Kubernetes 1.22 for Amazon EKS. For more information, see Kubernetes 1.22 (p. 65).</td>
<td>April 4, 2022</td>
</tr>
</tbody>
</table>

### Kubernetes version 1.21

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Amazon EKS platform version</th>
<th>Enabled admission controllers</th>
<th>Release notes</th>

</tbody>
</table>

### Release notes

- New platform version with security fixes and enhancements.
- Initial release of Kubernetes 1.19 for Amazon EKS. For more information, see Kubernetes 1.19 (p. 69).

</tbody>
</table>
## Windows support

Before deploying Windows nodes, be aware of the following considerations.

### Considerations

- Amazon EKS doesn't currently support Windows for Kubernetes 1.22, but support will be added soon.
• Amazon EC2 instance types C3, C4, D2, I2, M4 (excluding m4.16xlarge), M6a.x, and R3 instances are not supported for Windows workloads.
• Host networking mode is not supported for Windows workloads.
• Amazon EKS clusters must contain one or more Linux or Fargate nodes to run core system pods that only run on Linux, such as CoreDNS.
• The kubelet and kube-proxy event logs are redirected to the EKS Windows Event Log and are set to a 200 MB limit.
• You can't use Security groups for pods (p. 307) with pods running on Windows nodes.
• You can't use custom networking (p. 300) with Windows nodes.
• You can't use IP prefixes (p. 303) with Windows nodes. This is a requirement for using IPv6 (p. 288), so you can't use IPv6 with Windows nodes either.
• Windows nodes support one elastic network interface per node. The number of pods that you can run per Windows node is equal to the number of IP addresses available per elastic network interface for the node's instance type, minus one. For more information, see IP addresses per network interface per instance type in the Amazon EC2 User Guide for Windows Instances.
• In an Amazon EKS cluster, a single service with a load balancer can support up to 64 back-end pods. Each pod has its own unique IP address. This is a limitation of the Windows operating system on the Amazon EC2 nodes.
• You can't deploy Windows managed or Fargate nodes. You can only create self-managed Windows nodes. For more information, see Launching self-managed Windows nodes (p. 139).
• You can't retrieve logs from the vpc-resource-controller Pod. You previously could when you deployed the controller to the data plane.
• There is a cool down period before an IPv4 address is assigned to a new Pod. This prevents traffic from flowing to an older Pod with the same IPv4 address due to stale kube-proxy rules.
• The source for the controller is managed on GitHub. To contribute to, or file issues against the controller, visit the project on GitHub.

Prerequisites

• An existing cluster. The cluster must be running one of the Kubernetes versions and platform versions listed in the following table. Any Kubernetes and platform versions later than those listed are also supported. If your cluster or platform version is earlier than one of the following versions, you need to enable legacy Windows support (p. 94) on your cluster's data plane. Once your cluster is at one of the following Kubernetes and platform versions, or later, you can remove legacy Windows support (p. 93) and enable Windows support (p. 92) on your control plane.

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Platform version</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.21</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.20</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.19</td>
<td>eks.7</td>
</tr>
<tr>
<td>1.18</td>
<td>eks.9</td>
</tr>
<tr>
<td>1.17</td>
<td>eks.10</td>
</tr>
</tbody>
</table>

Your cluster must have at least one (we recommend at least two) Linux node or Fargate pod to run CoreDNS. If you enable legacy Windows support, you must use a Linux node (you can't use a Fargate pod) to run CoreDNS.
• An existing Amazon EKS cluster IAM role (p. 450).
Enabling Windows support

If your cluster is not at, or later, than one of the Kubernetes and platform versions listed in the Prerequisites (p. 91), you must enable legacy Windows support instead. For more information, see Enabling legacy Windows support (p. 94).

If you've never enabled Windows support on your cluster, skip to the next step.

If you enabled Windows support on a cluster that is earlier than a Kubernetes or platform version listed in the Prerequisites (p. 91), then you must first remove the vpc-resource-controller and vpc-admission-webhook from your data plane (p. 93). They're deprecated and no longer needed.

To enable Windows support for your cluster

1. If you don't have Amazon Linux nodes in your cluster and use security groups for pods, skip to the next step. Otherwise, confirm that the AmazonEKSVPCResourceController managed policy is attached to your cluster role (p. 450). Replace eksClusterRole with your cluster role name.

   ```bash
   aws iam list-attached-role-policies --role-name eksClusterRole
   ```

   Example output:

   ```json
   {
   "AttachedPolicies": [
   { "PolicyName": "AmazonEKSClusterPolicy", "PolicyArn": "arn:aws:iam::aws:policy/AmazonEKSClusterPolicy"
   },
   { "PolicyName": "AmazonEKSVPCResourceController", "PolicyArn": "arn:aws:iam::aws:policy/AmazonEKSVPCResourceController"
   }
   ]
   }
   ```

   If the policy is attached, as it is in the previous output, skip the next step.

2. Attach the AmazonEKSVPCResourceController managed policy to your Amazon EKS cluster IAM role (p. 450). Replace eksClusterRole with your cluster role name.

   ```bash
   aws iam attach-role-policy
   --role-name eksClusterRole
   --policy-arn arn:aws:iam::aws:policy/AmazonEKSVPCResourceController
   ```

3. Create a file named `vpc-resource-controller-configmap.yaml` with the following contents.

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: amazon-vpc-cni
     namespace: kube-system
   data:
     enable-windows-ipam: "true"
   ```

4. Apply the ConfigMap to your cluster.

   ```bash
   kubectl apply -f vpc-resource-controller-configmap.yaml
   ```
Removing legacy Windows support from your data plane

If you enabled Windows support on a cluster that is earlier than a Kubernetes or platform version listed in the Prerequisites (p. 91), then you must first remove the vpc-resource-controller and vpc-admission-webhook from your data plane. They're deprecated and no longer needed because the functionality that they provided is now enabled on the control plane.

1. Uninstall the vpc-resource-controller with the following command. Use this command regardless of which tool you originally installed it with. Replace region-code (only the instance of that text after /manifests/) with the AWS Region that your cluster is in.

   ```bash
   ```

2. Uninstall the vpc-admission-webhook using the instructions for the tool that you installed it with.

   eksctl

   Run the following commands.

   ```bash
   kubectl delete deployment -n kube-system vpc-admission-webhook
   kubectl delete service -n kube-system vpc-admission-webhook
   kubectl delete mutatingwebhookconfigurations.admissionregistration.k8s.io vpc-admission-webhook-cfg
   ```

   kubectl on macOS or Windows

   Run the following command. Replace region-code (only the instance of that text after /manifests/) with the AWS Region that your cluster is in.

   ```bash
   ```

3. Enable Windows support (p. 92) for your cluster on the control plane.

Disabling Windows support

To disable Windows support on your cluster

1. If your cluster contains Amazon Linux nodes and you use security groups for pods (p. 307) with them, then skip this step.

   Remove the AmazonVPCResourceController managed IAM policy from your cluster role (p. 450). Replace eksClusterRole with the name of your cluster role and 111122223333 with your account ID.

   ```bash
   aws iam detach-role-policy \  
    --role-name eksClusterRole \  
    --policy-arn arn:aws:iam::aws:policy/AmazonEKSVPCResourceController
   ```

2. Disable Windows IPAM in the amazon-vpc-cni ConfigMap.
Deploying Pods

When you deploy Pods to your cluster, you need to specify the operating system that they use if you’re running a mixture of node types.

For Linux pods, use the following node selector text in your manifests.

```
nodeSelector:
    kubernetes.io/os: linux
    kubernetes.io/arch: amd64
```

For Windows pods, use the following node selector text in your manifests.

```
nodeSelector:
    kubernetes.io/os: windows
    kubernetes.io/arch: amd64
```

You can deploy a sample application (p. 352) to see the node selectors in use.

### Enabling legacy Windows support

If your cluster is at, or later, than one of the Kubernetes and platform versions listed in the Prerequisites (p. 91), then we recommend that you enable Windows support on your control plane instead. For more information, see Enabling Windows support (p. 92).

The following steps help you to enable legacy Windows support for your Amazon EKS cluster's data plane if your cluster or platform version are earlier than the versions listed in the Prerequisites (p. 91). Once your cluster and platform version are at, or later than a version listed in the Prerequisites (p. 91), we recommend that you remove legacy Windows support (p. 93) and enable it for your control plane (p. 92).

You can use eksctl, a Windows client, or a macOS or Linux client to enable legacy Windows support for your cluster.

```bash
eksctl
```

**To enable legacy Windows support for your cluster with eksctl**

**Prerequisite**

This procedure requires eksctl version 0.92.0 or later. You can check your version with the following command.

```
eksctl version
```

For more information about installing or upgrading eksctl, see Installing or upgrading eksctl (p. 11).

1. Enable Windows support for your Amazon EKS cluster with the following eksctl command. Replace `my-cluster` with the name of your cluster. This command deploys the VPC resource controller and VPC admission controller webhook that are required on Amazon EKS clusters to run Windows workloads.
**Amazon EKS User Guide**

**Enabling legacy Windows support**

```
eksctl utils install-vpc-controllers --cluster my-cluster --approve
```

**Important**

The VPC admission controller webhook is signed with a certificate that expires one year after the date of issue. To avoid down time, make sure to renew the certificate before it expires. For more information, see Renewing the VPC admission webhook certificate (p. 98).

2. After you have enabled Windows support, you can launch a Windows node group into your cluster. For more information, see Launching self-managed Windows nodes (p. 139).

**Windows**

To enable legacy Windows support for your cluster with a Windows client

In the following steps, replace `region-code` with the AWS Region that your cluster resides in.

1. Deploy the VPC resource controller to your cluster.

```bash
```

2. Deploy the VPC admission controller webhook to your cluster.
   a. Download the required scripts and deployment files.
      ```bash
      ```
   
   b. Install OpenSSL and jq.
   
   c. Set up and deploy the VPC admission webhook.
      ```bash
      ./Setup-VPCAdmissionWebhook.ps1 -DeploymentTemplate ".\vpc-admission-webhook-deployment.yaml"
      ```

**Important**

The VPC admission controller webhook is signed with a certificate that expires one year after the date of issue. To avoid down time, make sure to renew the certificate before it expires. For more information, see Renewing the VPC admission webhook certificate (p. 98).

3. Determine if your cluster has the required cluster role binding.

```bash
kubectl get clusterrolebinding eks:kube-proxy-windows
```

If output similar to the following example output is returned, then the cluster has the necessary role binding.
Enabling legacy Windows support

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>eks:kube-proxy-windows</td>
<td>10d</td>
</tr>
</tbody>
</table>

If the output includes `Error from server (NotFound)`, then the cluster does not have the necessary cluster role binding. Add the binding by creating a file named `eks-kube-proxy-windows-crb.yaml` with the following content.

```yaml
kind: ClusterRoleBinding
apiVersion: rbac.authorization.k8s.io/v1beta1
metadata:
  name: eks:kube-proxy-windows
  labels:
    k8s-app: kube-proxy
    eks.amazonaws.com/component: kube-proxy
subjects:
  - kind: Group
    name: "eks:kube-proxy-windows"
roleRef:
  kind: ClusterRole
  name: system:node-proxier
  apiGroup: rbac.authorization.k8s.io
```

Apply the configuration to the cluster.

```bash
kubectl apply -f eks-kube-proxy-windows-crb.yaml
```

4. After you have enabled Windows support, you can launch a Windows node group into your cluster. For more information, see Launching self-managed Windows nodes (p. 139).

macOS and Linux

To enable legacy Windows support for your cluster with a macOS or Linux client

This procedure requires that the `openssl` library and `jq` JSON processor are installed on your client system.

In the following steps, replace `region-code` with the AWS Region that your cluster resides in.

1. Deploy the VPC resource controller to your cluster.

```bash
```

2. Create the VPC admission controller webhook manifest for your cluster.
   a. Download the required scripts and deployment files.

```bash
```
   b. Add permissions to the shell scripts so that they can be run.
Enabling legacy Windows support

```bash
chmod +x webhook-create-signed-cert.sh webhook-patch-ca-bundle.sh
```
c. Create a secret for secure communication.

```bash
./webhook-create-signed-cert.sh
```
d. Verify the secret.

```bash
kubectl get secret -n kube-system vpc-admission-webhook-certs
```
e. Configure the webhook and create a deployment file.

```bash
cat ./vpc-admission-webhook-deployment.yaml | ./webhook-patch-ca-bundle.sh > vpc-admission-webhook.yaml
```

3. Deploy the VPC admission webhook.

```bash
kubectl apply -f vpc-admission-webhook.yaml
```

**Important**
The VPC admission controller webhook is signed with a certificate that expires one year after the date of issue. To avoid down time, make sure to renew the certificate before it expires. For more information, see Renewing the VPC admission webhook certificate (p. 98).

4. Determine if your cluster has the required cluster role binding.

```bash
kubectl get clusterrolebinding eks:kube-proxy-windows
```

If output similar to the following example output is returned, then the cluster has the necessary role binding.

<table>
<thead>
<tr>
<th>NAME</th>
<th>ROLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>eks:kube-proxy-windows</td>
<td>ClusterRole/system:node-proxier</td>
<td>19h</td>
</tr>
</tbody>
</table>

If the output includes Error from server (NotFound), then the cluster does not have the necessary cluster role binding. Add the binding by creating a file named `eks-kube-proxy-windows-crb.yaml` with the following content.

```yaml
kind: ClusterRoleBinding
apiVersion: rbac.authorization.k8s.io/v1beta1
metadata:
  name: eks:kube-proxy-windows
labels:
  k8s-app: kube-proxy
  eks.amazonaws.com/component: kube-proxy
subjects:
- kind: Group
  name: "eks:kube-proxy-windows"
roleRef:
  kind: ClusterRole
  name: system:node-proxier
  apiGroup: rbac.authorization.k8s.io
```

Apply the configuration to the cluster.
5. After you have enabled Windows support, you can launch a Windows node group into your cluster. For more information, see Launching self-managed Windows nodes (p. 139).

Renewing the VPC admission webhook certificate

The certificate used by the VPC admission webhook expires one year after issue. To avoid down time, it’s important that you renew the certificate before it expires. You can check the expiration date of your current certificate with the following command.

```
kubectl get secret \
  -n kube-system \
  vpc-admission-webhook-certs -o json | \ 
  jq -r '.data."cert.pem"' | \ 
  base64 -decode | \ 
  openssl x509 \ 
  -noout \ 
  -enddate | \ 
  cut -d= -f2
```

Example output:

```
May 28 14:23:00 2022 GMT
```

You can renew the certificate using `eksctl` or a Windows or Linux/macOS computer. Follow the instructions for the tool you originally used to install the VPC admission webhook. For example, if you originally installed the VPC admission webhook using `eksctl`, then you should renew the certificate using the instructions on the `eksctl` tab.

`eksctl`

1. Reinstall the certificate. Replace `<cluster-name>` (including <> ) with the name of your cluster.

```
eksctl utils install-vpc-controllers -cluster <cluster-name> -approve
```

2. Verify that you receive the following output.

```
2021/05/28 05:24:59 [INFO] generate received request
2021/05/28 05:24:59 [INFO] received CSR
2021/05/28 05:24:59 [INFO] generating key: rsa-2048
2021/05/28 05:24:59 [INFO] encoded CSR
```

3. Restart the webhook deployment.

```
kubectl rollout restart deployment -n kube-system vpc-admission-webhook
```

4. If the certificate that you renewed was expired, and you have Windows pods stuck in the `Container creating state`, then you must delete and redeploy those pods.

`Windows`

1. Get the script to generate new certificate.
Viewing API server flags

You can use the control plane logging feature for Amazon EKS clusters to view the API server flags that were enabled when a cluster was created. For more information, see Amazon EKS control plane logging (p. 62). This topic shows you how to view the API server flags for an Amazon EKS cluster in the Amazon CloudWatch console.

When a cluster is first created, the initial API server logs include the flags that were used to start the API server. If you enable API server logs when you launch the cluster, or shortly thereafter, these logs are sent to CloudWatch Logs and you can view them there.

```bash
```

2. Prepare parameter for the script.

```bash
./webhook-create-signed-cert.ps1 -ServiceName vpc-admission-webhook-svc -SecretName vpc-admission-webhook-certs -Namespace kube-system
```

3. Restart the webhook deployment.

```bash
kubectl rollout restart deployment -n kube-system vpc-admission-webhook-deployment
```

4. If the certificate that you renewed was expired, and you have Windows pods stuck in the Container creating state, then you must delete and redeploy those pods.

### Linux and macOS

**Prerequisite**

You must have OpenSSL and jq installed on your computer.

1. Get the script to generate new certificate.

```bash
```

2. Change the permissions.

```bash
chmod +x webhook-create-signed-cert.sh
```

3. Run the script.

```bash
./webhook-create-signed-cert.sh
```

4. Restart the webhook.

```bash
kubectl rollout restart deployment -n kube-system vpc-admission-webhook-deployment
```

5. If the certificate that you renewed was expired, and you have Windows pods stuck in the Container creating state, then you must delete and redeploy those pods.

---

**Viewing API server flags**

You can use the control plane logging feature for Amazon EKS clusters to view the API server flags that were enabled when a cluster was created. For more information, see Amazon EKS control plane logging (p. 62). This topic shows you how to view the API server flags for an Amazon EKS cluster in the Amazon CloudWatch console.

When a cluster is first created, the initial API server logs include the flags that were used to start the API server. If you enable API server logs when you launch the cluster, or shortly thereafter, these logs are sent to CloudWatch Logs and you can view them there.
To view API server flags for a cluster

1. If you have not already done so, enable API server logs for your Amazon EKS cluster.
   a. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
   b. Choose the name of the cluster to display your cluster information.
   c. Select the Configuration tab. On the Logging tab, choose Manage logging.
   d. For API server, make sure that the log type is Enabled.
   e. Choose Save changes to finish.
2. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/
3. Choose Logs, then Log groups in the side menu. Choose the cluster of which you want to see the logs, then choose the Log streams tab.
4. In the list of log streams, find the earliest version of the kube-apiserver-<example-ID-288ec988b77a59d70ec77> log stream. Use the Last Event Time column to determine the log stream ages.
5. Scroll up to the earliest events (the beginning of the log stream). You should see the initial API server flags for the cluster.

Note
If you don’t see the API server logs at the beginning of the log stream, then it is likely that the API server log file was rotated on the server before you enabled API server logging on the server. Any log files that are rotated before API server logging is enabled cannot be exported to CloudWatch. However, you can create a new cluster with the same Kubernetes version and enable the API server logging when you create the cluster. Clusters with the same platform version have the same flags enabled, so your flags should match the new cluster’s flags. When you finish viewing the flags for the new cluster in CloudWatch, you can delete the new cluster.

Private clusters

This topic describes how to deploy an Amazon EKS private cluster without outbound internet access. If you’re not familiar with Amazon EKS networking, see De-mystifying cluster networking for Amazon EKS worker nodes.

Requirements

The following requirements must be met to run Amazon EKS in a private cluster without outbound internet access.

- A container image must be in or copied to Amazon Elastic Container Registry (Amazon ECR) or to a registry inside the VPC to be pulled. For more information, see Creating local copies of container images (p. 102).
- Endpoint private access is required for nodes to register with the cluster endpoint. Endpoint public access is optional. For more information, see Amazon EKS cluster endpoint access control (p. 45).
- For Linux and Windows nodes, you must include bootstrap arguments when launching self-managed nodes. This text bypasses the Amazon EKS introspection and doesn’t require access to the Amazon EKS API from within the VPC. Replace api-server-endpoint and certificate-authority with the values from your Amazon EKS cluster.
- For Linux nodes:

```
--apiserver-endpoint api-server-endpoint --b64-cluster-ca certificate-authority
```
For additional arguments, see the bootstrap script on GitHub.

**For Windows nodes:**

```
-APIServerEndpoint api-server-endpoint -Base64ClusterCA certificate-authority
```

For additional arguments, see Amazon EKS optimized Windows AMI (p. 222).

**The aws-auth ConfigMap must be created from within the VPC. For more information about create the aws-auth ConfigMap, see Enabling IAM user and role access to your cluster (p. 395).**

## Considerations

Here are some things to consider when running Amazon EKS in a private cluster without outbound internet access.

- Many AWS services support private clusters, but you must use a VPC endpoint. For more information, see VPC endpoints. Some commonly-used services and endpoints include:

<table>
<thead>
<tr>
<th>Service</th>
<th>Endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Elastic Container Registry</td>
<td>com.amazonaws.region-code.ecr.api and</td>
</tr>
<tr>
<td></td>
<td>com.amazonaws.region-code.ecr.dkr</td>
</tr>
<tr>
<td>Application Load Balancers and Network Load</td>
<td>com.amazonaws.region-code.elasticloadbalancing</td>
</tr>
<tr>
<td>Balancers</td>
<td></td>
</tr>
<tr>
<td>AWS X-Ray</td>
<td>com.amazonaws.region-code.xray</td>
</tr>
<tr>
<td>Amazon CloudWatch Logs</td>
<td>com.amazonaws.region-code.logs</td>
</tr>
<tr>
<td>IAM roles for service accounts (p. 461)</td>
<td>com.amazonaws.region-code.sts</td>
</tr>
<tr>
<td>App Mesh</td>
<td>com.amazonaws.region-code.appmesh-envoy-management</td>
</tr>
<tr>
<td>• The App Mesh sidecar injector for Kubernetes is supported. For more information, see App Mesh sidecar injector on GitHub.</td>
<td></td>
</tr>
<tr>
<td>• The App Mesh controller for Kubernetes isn't supported. For more information, see App Mesh controller on GitHub.</td>
<td></td>
</tr>
<tr>
<td>• Cluster Autoscaler (p. 50) is supported.</td>
<td></td>
</tr>
<tr>
<td>When deploying Cluster Autoscaler pods, make</td>
<td></td>
</tr>
<tr>
<td>sure that the command line includes --aws-use-static-instance-list=true. For more information, see Use Static Instance List on GitHub. The worker node VPC must also include the STS VPC endpoint and autoscaling VPC endpoint.</td>
<td></td>
</tr>
</tbody>
</table>

- Before deploying the Amazon EFS CSI driver (p. 238), the kustomization.yaml file must be changed to set the container images to use the same AWS Region as the Amazon EKS cluster.

- Self-managed and managed nodes (p. 131) are supported. The instances for nodes must have access to the VPC endpoints. If you create a managed node group, the VPC endpoint security group must allow the CIDR for the subnets, or you must add the created node security group to the VPC endpoint security group.
• The Amazon FSx for Lustre CSI driver (p. 250) isn't supported.

• AWS Fargate (p. 152) is supported with private clusters. You can use the AWS Load Balancer Controller (p. 320) to deploy AWS Application Load Balancers (ALBs) and Network Load Balancers with. The controller supports network load balancers with IP targets, which are required for use with Fargate. For more information, see Application load balancing on Amazon EKS (p. 371) and Create a network load balancer (p. 367).

• Installing the AWS Load Balancer Controller add-on (p. 320) is supported. However, while installing, you should use command line flags to set enable-shield, enable-waf, and enable-wafv2 to false. In addition, certificate discovery with hostnames from the Ingress objects isn't supported. This is because the controller needs to reach ACM, which doesn't have a VPC endpoint.

Creating local copies of container images

Because a private cluster has no outbound internet access, container images can't be pulled from external sources such as Docker Hub. Instead, container images must be copied locally to Amazon ECR or to an alternative registry accessible in the VPC. A container image can be copied to Amazon ECR from outside the private VPC. The private cluster accesses the Amazon ECR repository using the Amazon ECR VPC endpoints. You must have Docker and the AWS CLI installed on the workstation that you use to create the local copy.

To create a local copy of a container image

1. Create an Amazon ECR repository. For more information, see Creating a repository.
2. Pull the container image from the external registry using `docker pull`.
3. Tag your image with the Amazon ECR registry, repository, and the optional image tag name combination using `docker tag`.
4. Authenticate to the registry. For more information, see Registry authentication.
5. Push the image to Amazon ECR using `docker push`.

Note
Make sure to update your resource configuration to use the new image location.

The following example pulls the `amazon/aws-node-termination-handler` image, using tag `v1.3.1-linux-amd64`, from Docker Hub and creates a local copy in Amazon ECR.

```
aws ecr create-repository --repository-name amazon/aws-node-termination-handler
docker pull amazon/aws-node-termination-handler:v1.3.1-linux-amd64
docker tag amazon/aws-node-termination-handler 111122223333.dkr.ecr.region-code.amazonaws.com/amazon/aws-node-termination-handler:v1.3.1-linux-amd64
avs ecr get-login-password --region region-code | docker login --username AWS --password-stdin 111122223333.dkr.ecr.region-code.amazonaws.com
docker push 111122223333.dkr.ecr.region-code.amazonaws.com/amazon/aws-node-termination-handler:v1.3.1-linux-amd64
```

AWS STS endpoints for IAM roles for service accounts

Pods configured with IAM roles for service accounts (p. 461) acquire credentials from an AWS Security Token Service (AWS STS) API call. If there is no outbound internet access, you must create and use an AWS STS VPC endpoint in your VPC. Most AWS v1 SDKs use the global AWS STS endpoint by default (`sts.amazonaws.com`), which doesn't use the AWS STS VPC endpoint. To use the AWS STS VPC endpoint, you may need to configure the SDK to use the regional AWS STS endpoint (`sts.region-code.amazonaws.com`). You can do this by setting the `AWS_STS_REGIONAL_ENDPOINTS` environment variable with a value of `regional`, along with the AWS Region.
For example, in a pod spec:

```yaml
...
containers:
  - env:
    - name: region-code
      value: region-code
    - name: AWS_STS_REGIONAL_ENDPOINTS
      value: regional
```

Replace `region-code` with the AWS Region that your cluster is in.
Amazon EKS nodes

Your Amazon EKS cluster can schedule pods on any combination of Self-managed nodes (p. 131), Amazon EKS Managed node groups (p. 109), and AWS Fargate (p. 152). To learn more about nodes deployed in your cluster, see View nodes (p. 107).

Note
Nodes must be in the same VPC as the subnets you selected when you created the cluster. However, the nodes don’t have to be in the same subnets.

The following table provides several criteria to evaluate when deciding which options best meet your requirements.

Note
Bottlerocket has some specific differences from the general information in this table. For more information, see the Bottlerocket documentation on GitHub.

<table>
<thead>
<tr>
<th>Criteria</th>
<th>EKS managed node groups</th>
<th>Self managed nodes</th>
<th>AWS Fargate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Can be deployed to AWS Outposts</td>
<td>No</td>
<td>Yes – For more information, see Amazon EKS on AWS Outposts (p. 501).</td>
<td>No</td>
</tr>
<tr>
<td>Can be deployed to AWS Local Zones</td>
<td>No</td>
<td>Yes – For more information, see Amazon EKS on AWS Local Zones (p. 507).</td>
<td>No</td>
</tr>
<tr>
<td>Can run containers that require Windows</td>
<td>No</td>
<td>Yes (p. 90) – Your cluster still requires at least one (two recommended for availability) Linux node though.</td>
<td>No</td>
</tr>
<tr>
<td>Can run containers that require Linux</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Can run workloads that require the Inferentia chip</td>
<td>Yes (p. 390) – Amazon Linux nodes only</td>
<td>Yes (p. 390) – Amazon Linux only</td>
<td>No</td>
</tr>
<tr>
<td>Can run workloads that require a GPU</td>
<td>Yes (p. 183) – Amazon Linux nodes only</td>
<td>Yes (p. 183) – Amazon Linux only</td>
<td>No</td>
</tr>
<tr>
<td>Can run workloads that require Arm processors</td>
<td>Yes (p. 184)</td>
<td>Yes (p. 184)</td>
<td>No</td>
</tr>
<tr>
<td>Can run AWS Bottlerocket</td>
<td>Yes</td>
<td>Yes (p. 137)</td>
<td>No</td>
</tr>
<tr>
<td>Pods share a kernel runtime environment with other pods</td>
<td>Yes – All of your pods on each of your nodes</td>
<td>Yes – All of your pods on each of your nodes</td>
<td>No – Each pod has a dedicated kernel</td>
</tr>
</tbody>
</table>
## Criteria

<table>
<thead>
<tr>
<th>Criteria</th>
<th>EKS managed node groups</th>
<th>Self managed nodes</th>
<th>AWS Fargate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pods share CPU, memory, storage, and network resources with other pods.</td>
<td>Yes – Can result in unused resources on each node</td>
<td>Yes – Can result in unused resources on each node</td>
<td>No – Each pod has dedicated resources and can be sized independently to maximize resource utilization.</td>
</tr>
<tr>
<td>Pods can use more hardware and memory than requested in pod specs</td>
<td>Yes – If the pod requires more resources than requested, and resources are available on the node, the pod can use additional resources.</td>
<td>Yes – If the pod requires more resources than requested, and resources are available on the node, the pod can use additional resources.</td>
<td>No – The pod can be re-deployed using a larger vCPU and memory configuration though.</td>
</tr>
<tr>
<td>Must deploy and manage Amazon EC2 instances</td>
<td>Yes (p. 113) – automated through Amazon EKS if you deployed an Amazon EKS optimized AMI. If you deployed a custom AMI, then you must update the instance manually.</td>
<td>Yes – Manual configuration or using Amazon EKS provided AWS CloudFormation templates to deploy Linux (x86) (p. 132), Linux (Arm) (p. 184), or Windows (p. 90) nodes.</td>
<td>No</td>
</tr>
<tr>
<td>Must secure, maintain, and patch the operating system of Amazon EC2 instances</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Can provide bootstrap arguments at deployment of a node, such as extra kubelet arguments.</td>
<td>Yes – Using a launch template (p. 124) with a custom AMI</td>
<td>Yes – For more information, view the bootstrap script usage information on GitHub.</td>
<td>No</td>
</tr>
<tr>
<td>Can assign IP addresses to pods from a different CIDR block than the IP address assigned to the node.</td>
<td>Yes – Using a launch template (p. 124) with a custom AMI</td>
<td>Yes, using CNI custom networking (p. 300).</td>
<td>No</td>
</tr>
<tr>
<td>Can SSH into node</td>
<td>Yes</td>
<td>Yes</td>
<td>No – There's no node host operating system to SSH to.</td>
</tr>
<tr>
<td>Can deploy your own custom AMI to nodes</td>
<td>Yes – Using a launch template (p. 124)</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Criteria</td>
<td>EKS managed node groups</td>
<td>Self managed nodes</td>
<td>AWS Fargate</td>
</tr>
<tr>
<td>----------</td>
<td>-------------------------</td>
<td>--------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Can deploy your own custom CNI to nodes</td>
<td>Yes – Using a launch template (p. 124) with a custom AMI</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Must update node AMI on your own</td>
<td>Yes (p. 119) – If you deployed an Amazon EKS optimized AMI, you’re notified in the Amazon EKS console when updates are available. You can perform the update with one-click in the console. If you deployed a custom AMI, you’re not notified in the Amazon EKS console when updates are available. You must perform the update on your own.</td>
<td>Yes (p. 150) – Using tools other than the Amazon EKS console. This is because self managed nodes can’t be managed with the Amazon EKS console.</td>
<td>No</td>
</tr>
<tr>

### View nodes

The Amazon EKS console shows information about all of your cluster’s nodes. This includes Amazon EKS managed nodes, self managed nodes, connected nodes, and Fargate. Nodes represent the compute resources provisioned for your cluster from the perspective of the Kubernetes API. For more information, see Nodes in the Kubernetes documentation. To learn more about the different types of Amazon EKS nodes that you can deploy your workloads (p. 350) to, see Amazon EKS nodes (p. 104).

### Prerequisites

The IAM user or IAM role that you sign into the AWS Management Console with must meet the following requirements.

- Have the `eks:AccessKubernetesApi` and other necessary IAM permissions to view nodes attached to it. For an example IAM policy, see View nodes and workloads for all clusters in the AWS Management Console (p. 440).
For nodes in connected clusters, the Amazon EKS Connector Service account can impersonate the IAM or role in the cluster. This allows the eks-connector to map the IAM user or role to a Kubernetes user.

- Is mapped to Kubernetes user or group in the aws-auth configmap. For more information, see Enabling IAM user and role access to your cluster (p. 395).
- The Kubernetes user or group that the IAM user or role is mapped to in the configmap must be bound to a Kubernetes role or clusterrole. Additionally, this role or clusterrole must have the permissions to view the resources in the namespaces that you want to view. For more information, see Using RBAC Authorization in the Kubernetes documentation. You can download the following example manifests that create a clusterrole and clusterrolebinding or a role and rolebinding:

  ```
  curl -o eks-console-full-access.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-full-access.yaml
  ```

- View Kubernetes resources in all namespaces – The group name in the file is eks-console-dashboard-full-access-group. It is the group that your IAM user or role must be mapped to in the aws-auth configmap. You can change the name of the group before applying it to your cluster, if you want. Then, you can map your IAM user or role to that group in the ConfigMap. To download the file, run the following command.

  ```
  curl -o eks-console-restricted-access.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-restricted-access.yaml
  ```

To view nodes using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Amazon EKS Clusters, and then in the Clusters list, choose the cluster that you want to view compute resources for.
3. On the Overview tab, you see a list of all compute Nodes for your cluster and the nodes' status.
   
   **Important**
   
   If you can't see any Nodes on the Overview tab, or you see a Your current user or role does not have access to Kubernetes objects on this EKS cluster error, see the prerequisites for this topic. If you don't resolve the issue, you can still view and manage your Amazon EKS cluster on the Configuration tab.

   **Note**

   Each pod that runs on Fargate is registered as a separate Kubernetes node within the cluster. This is because Fargate runs each pod in an isolated compute environment and independently connects to the cluster control plane. For more information, see AWS Fargate (p. 152).
4. In the Nodes list, you see a list of all of the managed, self-managed, connected, and Fargate nodes for your cluster. Selecting the link for one of the nodes provides the following information about the node:

   - The Amazon EC2 Instance type, Kernel version, Kubelet version, Container runtime, OS and OS image for managed and self-managed nodes. Connected clusters don't display the Instance type.
   - Deep links to the Amazon EC2 console and the Amazon EKS managed node group (if applicable) for the node.
   - The Resource allocation, which shows baseline and allocatable capacity for the node.
• **Conditions** describe the current operational status of the node. This is useful information for troubleshooting issues on the node.

Conditions are reported back to the Kubernetes control plane by the Kubernetes agent `kubelet` that runs locally on each node. For more information, see `kubelet` in the Kubernetes documentation. Conditions on the node are always reported as part of the node detail and the **Status** of each condition along with its **Message** indicates the health of the node for that condition. The following common conditions are reported for a node:

- **Ready** – This condition is **TRUE** if the node is healthy and can accept pods. The condition is **FALSE** if the node isn't ready and can't accept pods. **UNKNOWN** indicates that the Kubernetes control plane has not recently received a heartbeat signal from the node. The heartbeat timeout period is set to the Kubernetes default of 40 seconds for Amazon EKS clusters.
- **Memory pressure** – This condition is **FALSE** under normal operation and **TRUE** if node memory is low.
- **Disk pressure** – This condition is **FALSE** under normal operation and **TRUE** if disk capacity for the node is low.
- **PID pressure** – This condition is **FALSE** under normal operation and **TRUE** if there are too many processes running on the node. On the node, each container runs as a process with a unique Process ID, or PID.
- **NetworkUnavailable** – This condition is **FALSE**, or not present, under normal operation. If **TRUE**, the network for the node isn't properly configured.
- The Kubernetes **Labels** and **Annotations** assigned to the node. These could have been assigned by you, by Kubernetes, or by the Amazon EKS API when the node was created. These values can be used by your workloads for scheduling pods.

### Managed node groups

Amazon EKS managed node groups automate the provisioning and lifecycle management of nodes (Amazon EC2 instances) for Amazon EKS Kubernetes clusters.

With Amazon EKS managed node groups, you don’t need to separately provision or register the Amazon EC2 instances that provide compute capacity to run your Kubernetes applications. You can create, automatically update, or terminate nodes for your cluster with a single operation. Node updates and terminations automatically drain nodes to ensure that your applications stay available.

Every managed node is provisioned as part of an Amazon EC2 Auto Scaling group that's managed for you by Amazon EKS. Every resource including the instances and Auto Scaling groups runs within your AWS account. Each node group runs across multiple Availability Zones that you define.

You can add a managed node group to new or existing clusters using the Amazon EKS console, `eksctl`, AWS CLI; AWS API, or infrastructure as code tools including AWS CloudFormation. Nodes launched as part of a managed node group are automatically tagged for auto-discovery by the Kubernetes cluster autoscaler. You can use the node group to apply Kubernetes labels to nodes and update them at any time.

There are no additional costs to use Amazon EKS managed node groups, you only pay for the AWS resources you provision. These include Amazon EC2 instances, Amazon EBS volumes, Amazon EKS cluster hours, and any other AWS infrastructure. There are no minimum fees and no upfront commitments.

To get started with a new Amazon EKS cluster and managed node group, see [Getting started with Amazon EKS – AWS Management Console and AWS CLI (p. 16)](#).

To add a managed node group to an existing cluster, see [Creating a managed node group (p. 113)](#).
Managed node groups concepts

- Amazon EKS managed node groups create and manage Amazon EC2 instances for you.
- Every managed node is provisioned as part of an Amazon EC2 Auto Scaling group that's managed for you by Amazon EKS. Moreover, every resource including Amazon EC2 instances and Auto Scaling groups run within your AWS account.
- The Auto Scaling group of a managed node group spans every subnet that you specify when you create the group.
- Amazon EKS tags managed node group resources so that they are configured to use the Kubernetes Cluster Autoscaler (p. 50).

**Important**
If you are running a stateful application across multiple Availability Zones that is backed by Amazon EBS volumes and using the Kubernetes Cluster Autoscaler (p. 50), you should configure multiple node groups, each scoped to a single Availability Zone. In addition, you should enable the `--balance-similar-node-groups` feature.

- You can use a custom launch template for a greater level of flexibility and customization when deploying managed nodes. If you deploy using a launch template, you can also use a custom AMI. For more information, see Launch template support (p. 124). If you don't use a custom launch template when first creating a managed node group, there is an auto-generated launch template. Don't manually modify this auto-generated template or errors occur.
- Amazon EKS follows the shared responsibility model for CVEs and security patches on managed node groups. When managed nodes run an Amazon EKS optimized AMI, Amazon EKS is responsible for building patched versions of the AMI when bugs or issues are reported. We can publish a fix. However, you're responsible for deploying these patched AMI versions to your managed node groups. When managed nodes run a custom AMI, you're responsible for building patched versions of the AMI when bugs or issues are reported and then deploying the AMI. For more information, see Updating a managed node group (p. 119).
- Amazon EKS managed node groups can be launched in both public and private subnets. If you launch a managed node group in a public subnet on or after April 22, 2020, the subnet must have `MapPublicIpOnLaunch` set to true for the instances to successfully join a cluster. If the public subnet was created using `eksctl` or the Amazon EKS vended AWS CloudFormation templates (p. 258) on or after March 26, 2020, then this setting is already set to true. If the public subnets were created before March 26, 2020, you must change the setting manually. For more information, see Modifying the public IPv4 addressing attribute for your subnet.
- When using VPC endpoints in private subnets, you must create endpoints for `com.amazonaws.region.ecr.api`, `com.amazonaws.region.ecr.dkr`, and a gateway endpoint for Amazon S3. For more information, see Amazon ECR interface VPC endpoints (AWS PrivateLink).
- Managed node groups can't be deployed on AWS Outposts (p. 501) or in AWS Wavelength or AWS Local Zones.
- You can create multiple managed node groups within a single cluster. For example, you can create one node group with the standard Amazon EKS optimized Amazon Linux 2 AMI for some workloads and another with the GPU variant for workloads that require GPU support.
- If your managed node group encounters an Amazon EC2 instance status check failure, Amazon EKS returns an error message to help you to diagnose the issue. For more information, see Managed node group errors (p. 510).
- Amazon EKS adds Kubernetes labels to managed node group instances. These Amazon EKS provided labels are prefixed with `eks.amazonaws.com`.
- Amazon EKS automatically drains nodes using the Kubernetes API during terminations or updates. Updates respect the pod disruption budgets that you set for your pods.
- There are no additional costs to use Amazon EKS managed node groups. You only pay for the AWS resources that you provision.
• If you want to encrypt Amazon EBS volumes for your nodes, you can deploy the nodes using a launch template. To deploy managed nodes with encrypted Amazon EBS volumes without using a launch template, encrypt all new Amazon EBS volumes created in your account. For more information, see Encryption by default in the Amazon EC2 User Guide for Linux Instances.

Managed node group capacity types

When creating a managed node group, you can choose either the On-Demand or Spot capacity type. Amazon EKS deploys a managed node group with an Amazon EC2 Auto Scaling Group that either contains only On-Demand or only Amazon EC2 Spot Instances. You can schedule pods for fault tolerant applications to Spot managed node groups, and fault intolerant applications to On-Demand node groups within a single Kubernetes cluster. By default, a managed node group deploys On-Demand Amazon EC2 instances.

On-Demand

With On-Demand Instances, you pay for compute capacity by the second, with no long-term commitments.

How it works

By default, if you don't specify a Capacity Type, the managed node group is provisioned with On-Demand Instances. A managed node group configures an Amazon EC2 Auto Scaling group on your behalf with the following settings applied:

• The allocation strategy to provision On-Demand capacity is set to prioritized. Managed node groups use the order of instance types passed in the API to determine which instance type to use first when fulfilling On-Demand capacity. For example, you might specify three instance types in the following order: c5.large, c4.large, and c3.large. When your On-Demand Instances are launched, the managed node group fulfills On-Demand capacity by starting with c5.large, then c4.large, and then c3.large. For more information, see Amazon EC2 Auto Scaling group in the Amazon EC2 Auto Scaling User Guide.

• Amazon EKS adds the following Kubernetes label to all nodes in your managed node group that specifies the capacity type: eks.amazonaws.com/capacityType: ON_DEMAND. You can use this label to schedule stateful or fault intolerant applications on On-Demand nodes.

Spot

Amazon EC2 Spot Instances are spare Amazon EC2 capacity that offers steep discounts off of On-Demand prices. Amazon EC2 Spot Instances can be interrupted with a two-minute interruption notice when EC2 needs the capacity back. For more information, see Spot Instances in the Amazon EC2 User Guide for Linux Instances. You can configure a managed node group with Amazon EC2 Spot Instances to optimize costs for the compute nodes running in your Amazon EKS cluster.

How it works

To use Spot Instances inside a managed node group, create a managed node group by setting the capacity type as spot. A managed node group configures an Amazon EC2 Auto Scaling group on your behalf with the following Spot best practices applied:

• The allocation strategy to provision Spot capacity is set to capacity-optimized to ensure that your Spot nodes are provisioned in the optimal Spot capacity pools. To increase the number of Spot capacity pools available for allocating capacity from, configure a managed node group to use multiple instance types.
Amazon EC2 Spot Capacity Rebalancing is enabled so that Amazon EKS can gracefully drain and rebalance your Spot nodes to minimize application disruption when a Spot node is at elevated risk of interruption. For more information, see Amazon EC2 Auto Scaling Capacity Rebalancing in the Amazon EC2 Auto Scaling User Guide.

- When a Spot node receives a rebalance recommendation, Amazon EKS automatically attempts to launch a new replacement Spot node and waits until it successfully joins the cluster.
- When a replacement Spot node is bootstrapped and in the Ready state on Kubernetes, Amazon EKS cordons and drains the Spot node that received the rebalance recommendation. Cordonning the Spot node ensures that the service controller doesn’t send any new requests to this Spot node. It also removes it from its list of healthy, active Spot nodes. Draining the Spot node ensures that running pods are evicted gracefully.
- If a Spot two-minute interruption notice arrives before the replacement Spot node is in a Ready state, Amazon EKS starts draining the Spot node that received the rebalance recommendation.
- Amazon EKS adds the following Kubernetes label to all nodes in your managed node group that specifies the capacity type: eks.amazonaws.com/capacityType: SPOT. You can use this label to schedule fault tolerant applications on Spot nodes.

**Considerations for selecting a capacity type**

When deciding whether to deploy a node group with On-Demand or Spot capacity, you should consider the following conditions:

- Spot Instances are a good fit for stateless, fault-tolerant, flexible applications. These include batch and machine learning training workloads, big data ETLs such as Apache Spark, queue processing applications, and stateless API endpoints. Because Spot is spare Amazon EC2 capacity, which can change over time, we recommend that you use Spot capacity for interruption-tolerant workloads. More specifically, Spot capacity is suitable for workloads that can tolerate periods where the required capacity isn't available.
- We recommend that you use On-Demand for applications that are fault intolerant. This includes cluster management tools such as monitoring and operational tools, deployments that require StatefulSets, and stateful applications, such as databases.
- To maximize the availability of your applications while using Spot Instances, we recommend that you configure a Spot managed node group to use multiple instance types. We recommend applying the following rules when using multiple instance types:
  - Within a managed node group, if you're using the Cluster Autoscaler (p. 50), we recommend using a flexible set of instance types with the same amount of vCPU and memory resources. This is to ensure that the nodes in your cluster scale as expected. For example, if you need four vCPUs and eight GiB memory, use c3.xlarge, c4.xlarge, c5.xlarge, c5d.xlarge, c5a.xlarge, c5n.xlarge, or other similar instance types.
  - To enhance application availability, we recommend deploying multiple Spot managed node groups. For this, each group should use a flexible set of instance types that have the same vCPU and memory resources. For example, if you need 4 vCPUs and 8 GiB memory, we recommend that you create one managed node group with c3.xlarge, c4.xlarge, c5.xlarge, c5d.xlarge, c5a.xlarge, c5n.xlarge, or other similar instance types, and a second managed node group with m3.xlarge, m4.xlarge, m5.xlarge, m5d.xlarge, m5a.xlarge, m5n.xlarge or other similar instance types.
  - When deploying your node group with the Spot capacity type that's using a custom launch template, use the API to pass multiple instance types. Don't pass a single instance type through the launch template. For more information about deploying a node group using a launch template, see Launch template support (p. 124).
Creating a managed node group

This topic describes how you can launch an Amazon EKS managed node group of nodes that register with your Amazon EKS cluster. After the nodes join the cluster, you can deploy Kubernetes applications to them.

If this is your first time launching an Amazon EKS managed node group, we recommend that you follow one of our Getting started with Amazon EKS (p. 4) guides instead. The guides provide walkthroughs for creating an Amazon EKS cluster with nodes.

Important

- Amazon EKS nodes are standard Amazon EC2 instances. You're billed based on the normal Amazon EC2 prices. For more information, see Amazon EC2 Pricing.
- You can't create managed nodes in an AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled. You can create self-managed nodes in an AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled. For more information, see Launching self-managed Amazon Linux nodes (p. 132), Launching self-managed Windows nodes (p. 139), and Launching self-managed Bottlerocket nodes (p. 137).

Prerequisites

- An existing Amazon EKS cluster. To deploy one, see Creating an Amazon EKS cluster (p. 24).
- (Optional, but recommended) The Amazon VPC CNI add-on configured with its own IAM role that has the necessary IAM policy attached to it. For more information, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).
- Familiarity with the considerations listed in Choosing an Amazon EC2 instance type (p. 171). Depending on the instance type you choose, there may be additional prerequisites for your cluster and VPC.

You can create a managed node group with eksctl or the AWS Management Console.

eksctl

To create a managed node group with eksctl

This procedure requires eksctl version 0.92.0 or later. You can check your version with the following command:

```
eksctl version
```

For instructions on how to install or upgrade eksctl, see Installing or upgrading eksctl (p. 11).

1. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy is attached to your the section called “Node IAM role” (p. 452), we recommend assigning it to an IAM role that you associate to the Kubernetes aws-node service account instead. For more information, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).

2. Create a managed node group with or without using a custom launch template. Manually specifying a launch template allows for greater customization of a node group. For example, it can allow deploying a custom AMI or providing arguments to the bootstrap.sh script in an Amazon EKS optimized AMI. For a complete list of every available option and default, enter the following command.

```
eksctl create nodegroup --help
```
Replace every *example-value* with your own values.

**Important**

If you don’t use a custom launch template when first creating a managed node group, don’t use one at a later time for the node group. If you didn’t specify a custom launch template, the system auto-generates a launch template that we don’t recommend that you modify manually. Manually modifying this auto-generated launch template might cause errors.

- **Without a launch template** – *eksctl* creates a default Amazon EC2 launch template in your account and deploys the node group using a launch template that it creates based on options that you specify. Before specifying a value for --node-type, see Choosing an Amazon EC2 instance type (p. 171).

Replace *my-key* with the name of your Amazon EC2 key pair or public key. This key is used to SSH into your nodes after they launch. If you don’t already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 key pairs in the *Amazon EC2 User Guide for Linux Instances*.

If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region, then we recommend blocking pod access to IMDS. For more information, see Restrict access to the instance profile assigned to the worker node. If you want to block pod access to IMDS, then add the **--disable-pod-imds** option to the following command.

```
eksctl create nodegroup \
--cluster my-cluster \
--region region-code \
--name my-mng \
--node-type m5.large \
--nodes 3 \
--nodes-min 2 \
--nodes-max 4 \
--ssh-access \
--ssh-public-key my-key
```

Your instances can optionally assign a significantly higher number of IP addresses to pods, assign IP addresses to pods from a different CIDR block than the instance’s, and be deployed to a cluster without internet access. For more information, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 303), CNI custom networking (p. 300), and Private clusters (p. 100) for additional options to add to the previous command.

Managed node groups calculates and applies a single value for the maximum number of pods that can run on each node of your node group, based on instance type. If you create a node group with different instance types, the smallest value calculated across all instance types is applied as the maximum number of pods that can run on every instance type in the node group. Managed node groups calculates the value using the script referenced in Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 172).

- **With a launch template** – The launch template must already exist and must meet the requirements specified in Launch template configuration basics (p. 124). If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region, then we recommend blocking pod access to IMDS. For more information, see Restrict access to the instance profile assigned to the worker node. If you want to block pod access to IMDS, then specify the necessary settings in the launch template.
Creating a managed node group

a. Create a file named `eks-nodegroup.yaml` with the following contents. Several settings that you specify when deploying without a launch template are moved into the launch template. If you don't specify a version, the template's default version is used.

```yaml
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: my-cluster
  region: region-code
managedNodeGroups:
  - name: node-group-lt
    launchTemplate:
      id: lt-id
      version: "1"
```

For a complete list of `eksctl` config file settings, see Config file schema in the `eksctl` documentation. Your instances can optionally assign a significantly higher number of IP addresses to pods, assign IP addresses to pods from a different CIDR block than the instance's, use the `containerd` runtime, and be deployed to a cluster without outbound internet access. For more information, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 303), CNI custom networking (p. 300), Enable the `containerd` runtime bootstrap flag (p. 182), and Private clusters (p. 100) for additional options to add to the config file.

If you didn't specify an AMI ID in your launch template, managed node groups calculates and applies a single value for the maximum number of pods that can run on each node of your node group, based on instance type. If you create a node group with different instance types, the smallest value calculated across all instance types is applied as the maximum number of pods that can run on every instance type in the node group. Managed node groups calculates the value using the script referenced in Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 172).

If you specified an AMI ID in your launch template, specify the maximum number of pods that can run on each node of your node group if you're using custom networking (p. 300) or want to increase the number of IP addresses assigned to your instance (p. 303). For more information, see Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 172).

b. Deploy the nodegroup with the following command.

```
eksctl create nodegroup --config-file eks-nodegroup.yaml
```

AWS Management Console

To create a managed node group using the AWS Management Console

1. Wait for your cluster status to show as ACTIVE. You can't create a managed node group for a cluster that isn't already ACTIVE.
2. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
3. Choose the name of the cluster that you want to create a managed node group in.
4. Select the Configuration tab.
5. On the Configuration tab, select the Compute tab, and then choose Add Node Group.
6. On the Configure Node Group page, fill out the parameters accordingly, and then choose Next.
   - Name – Enter a unique name for your managed node group.
• **Node IAM Role** – Choose the node instance role to use with your node group. For more information, see Amazon EKS node IAM role (p. 452).

  **Important**
  
  We recommend using a role that’s not currently in use by any self-managed node group. Otherwise, you plan to use with a new self-managed node group. For more information, see Deleting a managed node group (p. 130).

• **Use launch template** – (Optional) Choose if you want to use an existing launch template. Select a Launch Template Name. Then, select a Launch template version. If you don’t select a version, then Amazon EKS uses the template’s default version. Launch templates allow for more customization of your node group, such as allowing you to deploy a custom AMI, assign a significantly higher number of IP addresses to pods, assign IP addresses to pods from a different CIDR block than the instance’s, enable the containerd runtime for your instances, and deploying nodes to a cluster without outbound internet access. For more information, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 303), CNI custom networking (p. 300), Enable the containerd runtime bootstrap flag (p. 182), and Private clusters (p. 100).

  The launch template must meet the requirements in Launch template support (p. 124). If you don’t use your own launch template, the Amazon EKS API creates a default Amazon EC2 launch template in your account and deploys the node group using the default launch template.

  If you implement IAM roles for service accounts (p. 461), assign necessary permissions directly to every pod that requires access to AWS services, and no pods in your cluster require access to IMDS for other reasons, such as retrieving the current AWS Region, then you can also disable access to IMDS for pods that don’t use host networking in a launch template. For more information, see Restrict access to the instance profile assigned to the worker node.

• **Kubernetes labels** – (Optional) You can choose to apply Kubernetes labels to the nodes in your managed node group.

• **Kubernetes taints** – (Optional) You can choose to apply Kubernetes taints to the nodes in your managed node group. The available options in the Effect menu are NoSchedule, NoExecute, and PreferNoSchedule.

• **Tags** – (Optional) You can choose to tag your Amazon EKS managed node group. These tags don’t propagate to other resources in the node group, such as Auto Scaling groups or instances. For more information, see Tagging your Amazon EKS resources (p. 422).

• **Node group update configuration** – (Optional) You can select the number or percentage of nodes to be updated in parallel. Select either Number or Percentage to enter a value. These nodes won’t be available during the update.

7. On the Set compute and scaling configuration page, fill out the parameters accordingly, and then choose Next.

• **AMI type** – Choose Amazon Linux 2 (AL2_x86_64) for Linux non-GPU instances, Amazon Linux 2 GPU Enabled (AL2_x86_64_GPU) for Linux GPU instances, Amazon Linux 2 Arm (AL2_ARM_64) for Linux Arm instances, Bottlerocket (BOTTLEROCKET_x86_64) for Bottlerocket x86_64 instances, or Bottlerocket Arm (BOTTLEROCKET_ARM_64) for Bottlerocket Arm instances.

  If you are deploying Arm instances, be sure to review the considerations in Amazon EKS optimized Arm Amazon Linux AMIs (p. 184) before deploying.

  If you specified a launch template on the previous page, and specified an AMI in the launch template, then you can’t select a value. The value from the template is displayed. The AMI specified in the template must meet the requirements in Specifying an AMI (p. 128).

• **Capacity type** – Select a capacity type. For more information about choosing a capacity type, see Managed node group capacity types (p. 111). You can’t mix different capacity types.
within the same node group. If you want to use both capacity types, create separate node groups, each with their own capacity and instance types.

- **Instance types** – By default, one or more instance type is specified. To remove a default instance type, select the X on the right side of the instance type. Choose the instance types to use in your managed node group.

The console displays a set of commonly used instance types. For the complete set of supported instance types, see the list in eni-max-pods.txt on GitHub. If you need to create a managed node group with an instance type that's not displayed, then use eksctl, the AWS CLI, AWS CloudFormation, or an SDK to create the node group. If you specified a launch template on the previous page, then you can't select a value because the instance type must be specified in the launch template. The value from the launch template is displayed. If you selected Spot for Capacity type, then we recommend specifying multiple instance types to enhance availability.

- **Disk size** – Enter the disk size (in GiB) to use for your node's root volume.

If you specified a launch template on the previous page, then you can't select a value because it must be specified in the launch template.

- **Minimum size** – Specify the minimum number of nodes that the managed node group can scale in to.

- **Maximum size** – Specify the maximum number of nodes that the managed node group can scale out to.

- **Desired size** – Specify the current number of nodes that the managed node group should maintain at launch.

  **Note**
  Amazon EKS doesn't automatically scale your node group in or out. However, you can configure the Kubernetes Cluster Autoscaler (p. 50) to do this for you.

- For **Maximum unavailable**, select one of the following options and specify a **Value**:
  - **Number** – Select and specify the number of nodes in your node group that can be updated in parallel. These nodes will be unavailable during update.
  - **Percentage** – Select and specify the percentage of nodes in your node group that can be updated in parallel. These nodes will be unavailable during update. This is useful if you have a large number of nodes in your node group.

8. On the **Specify networking** page, fill out the parameters accordingly, and then choose **Next**.

- **Subnets** – Choose the subnets to launch your managed nodes into.

  **Important**
  If you are running a stateful application across multiple Availability Zones that is backed by Amazon EBS volumes and using the Kubernetes Cluster Autoscaler (p. 50), you should configure multiple node groups, each scoped to a single Availability Zone. In addition, you should enable the --balance-similar-node-groups feature.

  **Important**
  - If you choose a public subnet, and your cluster has only the public API server endpoint enabled, then the subnet must have MapPublicIPOnLaunch set to true for the instances to successfully join a cluster. If the subnet was created using eksctl or the Amazon EKS vended AWS CloudFormation templates (p. 258) on or after March 26, 2020, then this setting is already set to true. If the subnets were created with eksctl or the AWS CloudFormation templates before March 26, 2020, then you need to change the setting manually. For more information, see Modifying the public IPv4 addressing attribute for your subnet.
  - If you use a launch template and specify multiple network interfaces, Amazon EC2 won't auto-assign a public IPv4 address, even if MapPublicIpOnLaunch is set to true. For nodes to join the cluster in this scenario, you must either enable
the cluster's private API server endpoint, or launch nodes in a private subnet with outbound internet access provided through an alternative method, such as a NAT Gateway. For more information, see Amazon EC2 instance IP addressing in the Amazon EC2 User Guide for Linux Instances.

- **Configure SSH access to nodes** (Optional). Enabling SSH allows you to connect to your instances and gather diagnostic information if there are issues. Complete the following steps to enable remote access. We highly recommend enabling remote access when you create a node group. You can't enable remote access after the node group is created.

  If you chose to use a launch template, then this option isn't shown. To enable remote access to your nodes, specify a key pair in the launch template and ensure that the proper port is open to the nodes in the security groups that you specify in the launch template. For more information, see Using custom security groups (p. 126).

- **For SSH key pair** (Optional), choose an Amazon EC2 SSH key to use. For more information, see Amazon EC2 key pairs in the Amazon EC2 User Guide for Linux Instances. If you chose to use a launch template, then you can't select one. When an Amazon EC2 SSH key is provided for node groups using Bottlerocket AMIs, the administrative container is also enabled. For more information, see Admin container on GitHub.

- For **Allow SSH remote access from**, if you want to limit access to specific instances, then select the security groups that are associated to those instances. If you don't select specific security groups, then SSH access is allowed from anywhere on the internet (0.0.0.0/0).

9. On the **Review and create** page, review your managed node group configuration and choose **Create**.

   If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 508) in the Troubleshooting guide.

10. Watch the status of your nodes and wait for them to reach the **Ready** status.

   kubectl get nodes --watch

11. (GPU nodes only) If you chose a GPU instance type and the Amazon EKS optimized accelerated AMI, then you must apply the NVIDIA device plugin for Kubernetes as a DaemonSet on your cluster with the following command.

   kubectl apply -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.9.0/nvidia-device-plugin.yml

12. (Optional) After you add Linux worker nodes to your cluster, follow the procedures in Windows support (p. 90) to add Windows support to your cluster and to add Windows worker nodes. Every Amazon EKS cluster must contain at least one Linux worker node, even if you only want to run Windows workloads in your cluster.

Now that you have a working Amazon EKS cluster with nodes, you're ready to start installing Kubernetes add-ons and deploying applications to your cluster. The following documentation topics help you to extend the functionality of your cluster.

- The IAM entity (user or role) that created the cluster is the only IAM user that can make calls to the Kubernetes API server using `kubectl`. If you want other users to have access to your cluster, see Enabling IAM user and role access to your cluster (p. 395).

- Restrict access to the instance metadata service – If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region, then we recommend blocking pod access to IMDS. For more information, see Restrict access to the instance profile assigned to the worker node.
• **Cluster Autoscaler (p. 50)** – Configure the Kubernetes Cluster Autoscaler to automatically adjust the number of nodes in your node groups.
• Deploy a sample application (p. 352) to your cluster.
• **Cluster management (p. 413)** – Learn how to use important tools for managing your cluster.

## Updating a managed node group

When you initiate a managed node group update, Amazon EKS automatically updates your nodes for you, completing the steps listed in Managed node update behavior (p. 121). If you’re using an Amazon EKS optimized AMI, Amazon EKS automatically applies the latest security patches and operating system updates to your nodes as part of the latest AMI release version.

There are several scenarios where it’s useful to update your Amazon EKS managed node group’s version or configuration:

• You have updated the Kubernetes version for your Amazon EKS cluster and want to update your nodes to use the same Kubernetes version.
• A new AMI release version is available for your managed node group. For more information about AMI versions, see these sections:
  • Amazon EKS optimized Amazon Linux AMI versions (p. 185)
  • Amazon EKS optimized Bottlerocket AMIs (p. 203)
  • Amazon EKS optimized Windows AMI versions (p. 216)
• You want to adjust the minimum, maximum, or desired count of the instances in your managed node group.
• You want to add or remove Kubernetes labels from the instances in your managed node group.
• You want to add or remove AWS tags from your managed node group.
• You need to deploy a new version of a launch template with configuration changes, such as an updated custom AMI.
• You have deployed version 1.9.0 or later of the Amazon VPC CNI add-on, enabled the add-on for prefix delegation, and want new AWS Nitro System instances in a node group to support a significantly increased number of pods. For more information, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 303).

If there's a newer AMI release version for your managed node group's Kubernetes version, you can update your node group's version to use the newer AMI version. Similarly, if your cluster is running a Kubernetes version that's newer than your node group, you can update the node group to use the latest AMI release version to match your cluster's Kubernetes version.

When a node in a managed node group is terminated due to a scaling operation or update, the pods in that node are drained first. For more information, see Managed node update behavior (p. 121).

### Update a node group version

You can update a node group version with `eksctl` or the AWS Management Console. Select the tab with the name of the tool that you want to use to update your node group. The version that you update to can’t be later than the control plane’s version.

```
eksctl
```

**To update a node group version with `eksctl`**

• Update a managed node group to the latest AMI release of the same Kubernetes version that's currently deployed on the nodes with the following command. Replace every `example-value` with your own values.

```
```
Amazon EKS User Guide
Updating a managed node group

```
eksctl upgrade nodegroup --name=node-group-name --cluster=cluster-name
```

**Note**

If you're upgrading a node group that's deployed with a launch template to a new launch template version, add `--launch-template-version version-number` to the preceding command. The launch template must meet the requirements described in Launch template support (p. 124). If the launch template includes a custom AMI, the AMI must meet the requirements in Specifying an AMI (p. 128). When you upgrade your node group to a newer version of your launch template, every node is recycled to match the new configuration of the launch template version that's specified.

You can't directly upgrade a node group that's deployed without a launch template to a new launch template version. Instead, you must deploy a new node group using the launch template to update the node group to a new launch template version.

You can upgrade a node group to the same version as the control plane's Kubernetes version. For example, if you have a cluster running Kubernetes 1.22, you can upgrade nodes currently running Kubernetes 1.21 to version 1.22 with the following command.

```
eksctl upgrade nodegroup \
--name=node-group-name \
--cluster=cluster-name \
--kubernetes-version=1.22
```

### AWS Management Console

**To update a node group version with the AWS Management Console**

1. Open the Amazon EKS console at [https://console.aws.amazon.com/eks/home#/clusters](https://console.aws.amazon.com/eks/home#/clusters).
2. Choose the cluster that contains the node group to update.
3. If at least one node group has an available update, a box appears at the top of the page notifying you of the available update. If you select the **Configuration** tab and then the **Compute** tab, you'll see **Update now** in the **AMI release version** column in the **Node Groups** table for the node group that has an available update. To update the node group, select **Update now**. You won't see a notification for node groups that were deployed with a custom AMI. If your nodes are deployed with a custom AMI, complete the following steps to deploy a new updated custom AMI.
   - a. Create a new version of your AMI.
   - b. Create a new launch template version with the new AMI ID.
   - c. Upgrade the nodes to the new version of the launch template.
4. On the **Update Node Group version** page, select:
   - **Update Node Group version** – This option is unavailable if you deployed a custom AMI or your Amazon EKS optimized AMI is currently on the latest version for your cluster.
   - **Launch template version** – This option is unavailable if the node group is deployed without a custom launch template. You can only update the launch template version for a node group that has been deployed with a custom launch template. Select the version that you want to update the node group to. If your node group is configured with a custom AMI, then the version that you select must also specify an AMI. When you upgrade to a newer version of your launch template, every node is recycled to match the new configuration of the launch template version specified.
5. For **Update strategy**, select one of the following options and then choose **Update**.
• **Rolling update** – This option respects the pod disruption budgets for your cluster. Updates fail if there's a pod disruption budget issue that causes Amazon EKS to be unable to gracefully drain the pods that are running on this node group.

• **Force update** – This option doesn't respect pod disruption budgets. Updates occur regardless of pod disruption budget issues by forcing node restarts to occur.

### Edit a node group configuration

You can modify some of the configurations of a managed node group.

**To edit a node group configuration**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster that contains the node group to edit.
3. Select the **Configuration** tab. On the **Compute** tab, select the node group to edit, and choose **Edit**.
4. (Optional) On the **Edit node group** page, edit the **Group configuration**.
   - **Tags** – Add tags to or remove tags from your node group resource. These tags are only applied to the Amazon EKS node group. They don't propagate to other resources, such as subnets or Amazon EC2 instances in the node group.
   - **Kubernetes labels** – Add or remove Kubernetes labels to the nodes in your node group. The labels shown here are only the labels that you have applied with Amazon EKS. Other labels may exist on your nodes that aren't shown here.
   - **Kubernetes taints** – Add or remove Kubernetes taints to the nodes in your node group. Added taints can have the effect of either **No_Schedule**, **Prefer_No_Schedule**, or **No_Execute**.
5. (Optional) On the **Edit node group** page, edit the **Group size**.
   - **Minimum size** – Specify the minimum number of nodes that the managed node group can scale in to.
   - **Maximum size** – Specify the maximum number of nodes that the managed node group can scale out to. For the maximum number of nodes supported in a node group, see Amazon EKS service quotas (p. 426).
   - **Desired size** – Specify the current number of nodes that the managed node group should maintain.
6. (Optional) Edit the **Node Group update configuration**. Select either **Number** or **Percentage**.
   - **Number** – Select and specify the number of nodes in your node group that can be updated in parallel. These nodes will be unavailable during update.
   - **Percentage** – Select and specify the percentage of nodes in your node group that can be updated in parallel. These nodes will be unavailable during update. This is useful if you have many nodes in your node group.
7. When you're finished editing, choose **Save changes**.

### Managed node update behavior

The Amazon EKS managed worker node upgrade strategy has four different phases described in the following sections.

**Setup phase**

The setup phase has these steps:
1. Creates a new Amazon EC2 launch template version for the Auto Scaling group that’s associated with your node group. The new launch template version uses the target AMI or customer-provided launch template version for the update.

2. Updates the Auto Scaling group to use the latest launch template version.

3. Determines the maximum quantity of nodes to upgrade in parallel using the `updateConfig` property for the node group. The maximum unavailable has a quota of 100 nodes. The default value is one node. For more information, see the `updateConfig` property in the Amazon EKS API Reference.

**Scale up phase**

When upgrading the nodes in a managed node group, the upgraded nodes are launched in the same Availability Zone as those that are being upgraded. To guarantee this placement, we use Amazon EC2's Availability Zone Rebalancing. For more information, see Availability Zone Rebalancing in the Amazon EC2 Auto Scaling User Guide. To meet this requirement, it's possible that we'd launch up to two instances per Availability Zone in your Managed Node Group.

The scale up phase has these steps:

1. Increments the Auto Scaling Group’s maximum size and desired size by the larger of either:
   - Up to twice the number of Availability Zones that the Auto Scaling group is deployed in.
   - The maximum unavailable of upgrade.

   For example, if your node group has five Availability Zones and `maxUnavailable` as one, the upgrade process can launch a maximum of 10 nodes. However when `maxUnavailable` is 20 (or anything greater than 10, the process would launch 20 new nodes).

2. After scaling the Auto Scaling Group, it checks if the nodes using the latest configuration are present in the node group. This step succeeds only when it meets these criteria:
   - At least one new node is launched in every Availability Zone where the node exists.
   - Every new node should be in Ready state.
   - New nodes should have Amazon EKS applied labels.

   These are the Amazon EKS applied labels on the worker nodes in a regular node group:
   - `eks.amazonaws.com/nodegroup-image=<$amiName>`
   - `eks.amazonaws.com/nodegroup=<$nodeGroupName>`

   These are the Amazon EKS applied labels on the worker nodes in a custom launch template or AMI node group:
   - `eks.amazonaws.com/nodegroup-image=<$amiName>`
   - `eks.amazonaws.com/nodegroup=<$nodeGroupName>`
   - `eks.amazonaws.com/sourceLaunchTemplateId=<$launchTemplateId>`
   - `eks.amazonaws.com/sourceLaunchTemplateVersion=<$launchTemplateVersion>`

3. Applies an `eks.amazonaws.com/nodegroup=unschedulable:NoSchedule` taint on every node in the node group without the latest labels. This prevents nodes that have already been updated from a previous failed update from being tainted.

The following are known reasons which lead to a `NodeCreationFailure` error in this phase:

- **Insufficient capacity in the Availability Zone** – There is a possibility that the Availability Zone might not have capacity of requested instance types. It's recommended to configure multiple instance types while creating a managed node group.

- **Customers hitting EC2 instance limits in their account** – You may need to increase the number of Amazon EC2 instances your account can run simultaneously using Service Quotas. For more
information, see EC2 Service Quotas in the Amazon Elastic Compute Cloud User Guide for Linux Instances.

- **Custom user data** – Custom user data can sometimes break the bootstrap process. This scenario can lead to the **kubelet** not starting on the node or nodes not getting expected Amazon EKS labels on them. For more information on handling custom LT/AMI, see Specifying an AMI (p. 128).

- **Any changes which make a node unhealthy or not ready** – Node disk pressure, memory pressure, and similar conditions can lead to a node not going to **Ready** state.

### Upgrade phase

The upgrade phase has these steps:

1. Randomly selects a node, up to the maximum unavailable configured for the node group.
2. Drains the pods from the node. If the pods don’t leave the node within 15 minutes and there’s no force flag, the upgrade phase fails with a **PodEvictionFailure** error. For this scenario, you can apply the force flag with the **update-nodegroup-version** request to delete the pods.
3. Cordons the node after every pod is evicted and waits for 60 seconds. This is done so that the service controller doesn’t send any new requests to this node and removes this node from its list of active nodes.
4. Sends a termination request to the Auto Scaling Group for the cordoned node.
5. Repeats the previous upgrade steps until there are no nodes in the node group that are deployed with the earlier version of the launch template.

The following are known reasons which lead to a **PodEvictionFailure** error in this phase:

- **Aggressive PDB** – Aggressive PDB is defined on the pod or there are multiple PDBs pointing to the same pod.
- **Deployment tolerating all the taints** – Once every pod is evicted, it’s expected for the node to be empty because the node is tainted in the earlier steps. However, if the deployment tolerates every taint, then the node is more likely to be non-empty, leading to pod eviction failure.

### Scale down phase

The scale down phase decrements the Auto Scaling group maximum size and desired size by one to return to values before the update started.

If the Upgrade workflow determines that the Cluster Autoscaler is scaling up the node group during the scale down phase of the workflow, it exits immediately without bringing the node group back to its original size.

### Node taints on managed node groups

Amazon EKS supports configuring Kubernetes taints through managed node groups. Taints and tolerations work together to ensure that pods aren't scheduled onto inappropriate nodes.

One or more taints can be applied to a node. This marks that the node shouldn't accept any pods that don't tolerate the taints. Tolerations are applied to pods and allow, but don't require, the pods to schedule onto nodes with matching taints.

Kubernetes node taints can be applied to new and existing managed node groups using the AWS Management Console or through the Amazon EKS API.

The following is an example of creating a node group with a taint using the AWS CLI:

```
aws eks create-nodegroup \
```
Launch template support

Managed node groups are always deployed with a launch template to be used with the Amazon EC2 Auto Scaling Group. The Amazon EKS API creates this launch template either by copying one you provide or by creating one automatically with default values in your account. For the highest level of customization, you can deploy managed nodes using your own launch template and a custom AMI. We don’t recommend that you modify auto-generated launch templates. So, make sure to specify a custom one when first creating a managed node group if you want greater flexibility.

After you deployed a managed node group with your own launch template, update it with a different version of the same launch template. When you update your node group to a different version of your launch template, all nodes in the group are recycled to match the new configuration of the specified launch template version. Existing node groups that don’t use a custom launch template can’t be updated directly. Rather, you must create a new node group with a custom launch template to do so.

Launch template configuration basics

You can create an Amazon EC2 Auto Scaling launch template with the AWS Management Console, AWS CLI, or an AWS SDK. For more information, see Creating a Launch Template for an Auto Scaling Group in the Amazon EC2 Auto Scaling User Guide. Some of the settings in a launch template are similar to the settings used for managed node configuration. When deploying or updating a node group with a launch template, some settings must be specified in either the node group configuration or the launch template. Don’t specify both places. If a setting exists where it shouldn’t, then operations such as creating or updating a node group fail.

The following table lists the settings that are prohibited in a launch template. It also lists similar settings, if any are available, are required in the managed node group configuration. The listed settings are the settings that appear in the console. They might have similar but different names in the AWS CLI and SDK.

```json
--cli-input-json '
{
"clusterName": "my-cluster",
...
"taints": [
  {
    "key": "dedicated",
    "value": "gpuGroup",
    "effect": "NO_SCHEDULE"
  }
],
}
',
```

For more information on taints and tolerations, see the Kubernetes documentation. For more information and examples of usage, see the Kubernetes reference documentation.

**Note**

- Maximum of 50 taints are allowed for one node group.
- Taints can be updated after you create the node group using the UpdateNodegroupConfig API.
- The taint key must begin with a letter or number. It can contain letters, numbers, hyphens (-), periods (.), and underscores (_). It can be up to 63 characters long.
- Optionally, the taint key can begin with a DNS subdomain prefix and a single /. If it begins with a DNS subdomain prefix, it can be 253 characters long.
- The value is optional and must begin with a letter or number. It can contain letters, numbers, hyphens (-), periods (.), and underscores (_). It can be up to 63 characters long.
- The effect must be one of No_Schedule, Prefer_No_Schedule, or No_Execute.
### Launch template – Prohibited vs. Amazon EKS node group configuration

<table>
<thead>
<tr>
<th>Launch template – Prohibited</th>
<th>Amazon EKS node group configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>IAM instance profile</strong> under Advanced details</td>
<td><strong>Node IAM Role</strong> under Node Group configuration on the Configure Node Group page</td>
</tr>
<tr>
<td><strong>Subnet</strong> under Network interfaces (Add network interface)</td>
<td><strong>Subnets</strong> under Node Group network configuration on the Specify networking page</td>
</tr>
<tr>
<td><strong>Shutdown behavior</strong> and <strong>Stop - Hibernate behavior</strong> under Advanced details. Retain default Don't include in launch template setting in launch template for both settings.</td>
<td>No equivalent. Amazon EKS must control the instance lifecycle, not the Auto Scaling group.</td>
</tr>
</tbody>
</table>

The following table lists the prohibited settings in a managed node group configuration. It also lists similar settings, if any are available, which are required in a launch template. The listed settings are the settings that appear in the console. They might have similar names in the AWS CLI and SDK.

<table>
<thead>
<tr>
<th>Amazon EKS node group configuration – Prohibited</th>
<th>Launch template</th>
</tr>
</thead>
</table>
| (Only if you specified a custom AMI in a launch template) **AMI type** under Node Group compute configuration on Set compute and scaling configuration page – Console displays Specified in launch template and the AMI ID that was specified. If an AMI type wasn't specified in the launch template, you can select an AMI in the node group configuration. | **AMI** under Launch template contents – You must specify an ID if you have either of the following requirements:  
- Using a custom AMI. If you specify an AMI that doesn't meet the requirements listed in Specifying an AMI (p. 128), the node group deployment will fail.  
- Want to provide user data to provide arguments to the bootstrap.sh file included with an Amazon EKS optimized AMI. You can enable your instances to assign a significantly higher number of IP addresses to pods, assign IP addresses to pods from a different CIDR block than the instance's, enable the containerd runtime, or deploy a private cluster without outbound internet access. For more information, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 303), CNI custom networking (p. 300), Enable the containerd runtime bootstrap flag (p. 182), Private clusters (p. 100), and Specifying an AMI (p. 128). |
| **Disk size** under Node Group compute configuration on Set compute and scaling configuration page – Console displays Specified in launch template. | **Size** under Storage (Volumes) (Add new volume). You must specify this in the launch template. |
| **SSH key pair** under Node Group configuration on the Specify Networking page – The console displays the key that was specified in the launch template or displays Not specified in launch template. | **Key pair name** under Key pair (login). |
Amazon EKS User Guide
Launch template support

<table>
<thead>
<tr>
<th>Amazon EKS node group configuration – Prohibited</th>
<th>Launch template</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can't specify source security groups that are allowed remote access when using a launch template.</td>
<td><strong>Security groups</strong> under <strong>Network settings</strong> for the instance or <strong>Security groups</strong> under <strong>Network interfaces</strong> (<strong>Add network interface</strong>), but not both. For more information, see <strong>Using custom security groups</strong> (p. 126).</td>
</tr>
</tbody>
</table>

**Note**

- If you deploy a node group using a launch template, specify zero or one **Instance type** under **Launch template contents** in a launch template. Alternatively, you can specify 0–20 instance types for **Instance types** on the **Set compute and scaling configuration** page in the console. Or, you can do so using other tools that use the Amazon EKS API. If you specify an instance type in a launch template, and use that launch template to deploy your node group, then you can't specify any instance types in the console or using other tools that use the Amazon EKS API. If you don't specify an instance type in a launch template, in the console, or using other tools that use the Amazon EKS API, the **t3.medium** instance type is used. If your node group is using the Spot capacity type, then we recommend specifying multiple instance types using the console. For more information, see **Managed node group capacity types** (p. 111).

- If any containers that you deploy to the node group use the Instance Metadata Service Version 2, make sure to set the **Metadata response hop limit** to 2 in your launch template. For more information, see **Instance metadata and user data** in the **Amazon EC2 User Guide for LinuxInstances**. If you deploy a managed node group without using a custom launch template, this value is automatically set for the node group in the default launch template.

**Tagging Amazon EC2 instances**

You can use the **TagSpecification** parameter of a launch template to specify which tags to apply to Amazon EC2 instances in your node group. The IAM entity calling the **CreateNodegroup** or **UpdateNodegroupVersion** APIs must have permissions for **ec2:RunInstances** and **ec2:CreateTags**, and the tags must be added to the launch template.

**Using custom security groups**

You can use a launch template to specify custom Amazon EC2 **security groups** to apply to instances in your node group. This can be either in the instance level security groups parameter or as part of the network interface configuration parameters. However, you can't create a launch template that specifies both instance level and network interface security groups. Consider the following conditions that apply to using custom security groups with managed node groups:

- **Amazon EKS only allows launch templates with a single network interface specification.**
- **By default, Amazon EKS applies the cluster security group (p. 265) to the instances in your node group to facilitate communication between nodes and the control plane.** If you specify custom security groups in the launch template using either option mentioned earlier, Amazon EKS doesn't add the cluster security group. So, you must ensure that the inbound and outbound rules of your security groups enable communication with the endpoint of your cluster. If your security group rules are incorrect, the worker nodes can't join the cluster. For more information about security group rules, see **Amazon EKS security group considerations** (p. 265).
- **If you need SSH access to the instances in your node group, include a security group that allows that access.**
Amazon EC2 user data

The launch template includes a section for custom user data. You can specify configuration settings for your node group in this section without manually creating individual custom AMIs. For more information about the settings available for Bottlerocket, see Using user data on GitHub.

You can supply Amazon EC2 user data in your launch template using cloud-init when launching your instances. For more information, see the cloud-init documentation. Your user data can be used to perform common configuration operations. This includes the following operations:

- Including users or groups
- Installing packages

Amazon EC2 user data in launch templates that are used with managed node groups must be in the MIME multi-part archive format for Amazon Linux AMIs and TOML format for Bottlerocket AMIs. This is because your user data is merged with Amazon EKS user data required for nodes to join the cluster. Don't specify any commands in your user data that starts or modifies kubelet. This is performed as part of the user data merged by Amazon EKS. Certain kubelet parameters, such as setting labels on nodes, can be configured directly through the managed node groups API.

**Note**
For more information about advanced kubelet customization, including manually starting it or passing in custom configuration parameters, see Specifying an AMI (p. 128). If a custom AMI ID is specified in a launch template, Amazon EKS doesn't merge user data.

The following details provide more information about the user data section for Amazon Linux or Bottlerocket.

Amazon Linux user data

You can combine multiple user data blocks together into a single MIME multi-part file. For example, you can combine a cloud boothook that configures the Docker daemon with a user data shell script that installs a custom package. A MIME multi-part file consists of the following components:

- The content type and part boundary declaration – Content-Type: multipart/mixed; boundary="==MYBOUNDARY=="
- The MIME version declaration – MIME-Version: 1.0
- One or more user data blocks, which contain the following components:
  - The opening boundary, which signals the beginning of a user data block ––==MYBOUNDARY==–
  - The content type declaration for the block: Content-Type: text/cloud-config; charset="us-ascii". For more information about content types, see the cloud-init documentation.
  - The content of the user data (for example, a list of shell commands or cloud-init directives).
  - The closing boundary, which signals the end of the MIME multi-part file: ––==MYBOUNDARY==–

The following is an example of a MIME multi-part file that you can use to create your own.

```plaintext
MIME-Version: 1.0
Content-Type: multipart/mixed; boundary="==MYBOUNDARY=="

--==MYBOUNDARY==
Content-Type: text/x-shellscript; charset="us-ascii"

#!/bin/bash
echo "Running custom user data script"

```

127
Bottlerocket user data

Bottlerocket structures user data in the TOML format. You can provide user data to be merged with the user data provided by Amazon EKS. For example, you can provide additional kubelet settings.

```toml
[settings.kubernetes.system-reserved]
cpu = "10m"
memory = "100Mi"
ephemeral-storage= "1Gi"
```

For more information about the supported settings, see Bottlerocket documentation. You can configure node labels and taints in your user data. However, we recommend that you configure these within your node group instead. Amazon EKS applies these configurations when you do so.

When user data is merged, formatting isn’t preserved, but the content remains the same. The configuration that you provide in your user data overrides any settings that are configured by Amazon EKS. So, if you set settings.kubernetes.max-pods or settings.kubernetes.cluster-dns-ip, values in your user data are applied to the nodes.

Amazon EKS doesn’t support all valid TOML. The following is a list of known unsupported formats:

- Quotes within quoted keys: 'quoted "value"' = "value"
- Escaped quotes in values: str = "I'm a string. \"You can quote me\"
- Mixed floats and integers: numbers = [ 0.1, 0.2, 0.5, 1, 2, 5 ]
- Mixed types in arrays: contributors = ["foo@example.com", { name = "Baz", email = "baz@example.com" }]
- Bracketed headers with quoted keys: [foo."bar.baz"]

Specifying an AMI

If you have either of the following requirements, then specify an AMI ID in the `imageId` field of your launch template. Select the requirement you have for additional information.

Provide user data to pass arguments to the `bootstrap.sh` file included with an Amazon EKS optimized AMI

Bootstrapping is a term used to describe adding commands that can be run when an instance starts. You can pass arguments to the `bootstrap.sh` script by using `eksctl` without specifying a launch template. Or you can do so by specifying the information in the user data section of a launch template.

Eksctl without specifying a launch template

Create a file named `my-nodegroup.yaml` with the following contents. This example creates a node group using `containerd` as the runtime. It also provides an additional kubelet argument to set a custom max-pods value using the `bootstrap.sh` script included with the Amazon EKS optimized AMI. For more information, see the `bootstrap.sh` file on GitHub.

Replace every `example-value` with your own values. For help with selecting `my-max-pods-value`, see Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 172).
name: my-cluster
region: region-code

managedNodeGroups:
- name: my-nodegroup
  ami: ami-0e6af48ea232fbdb1
  instanceType: m5.large
  privateNetworking: true
disableIMDSv1: true
labels: { x86-al2-specified-mng }
overrideBootstrapCommand: |
  #!/bin/bash
  /etc/eks/bootstrap.sh my-cluster
  --kubelet-extra-args '--max-pods=my-max-pods-value'
  --b64-cluster-ca certificateAuthority
  --apiserver-endpoint endpoint
  --dns-cluster-ip serivceIpv4Cidr.10
  --use-max-pods false
  --container-runtime containerd

The only required argument in the previous example is the cluster name (my-cluster). However, by setting the values for --apiserver-endpoint, --b64-cluster-ca, and --dns-cluster-ip, there's no need for the bootstrap script to make a describeCluster call. This is useful in private cluster setups or clusters where you're scaling in and out nodes frequently.

You can find the values for your cluster to specify the values for the optional arguments with the following command.

```
aws eks describe-cluster --name my-cluster
```

The example values for the optional arguments are the name of the properties returned in the output from the command. The value for --dns-cluster-ip is your service CIDR with .10 at the end. For example, if the returned value for serviceIpv4Cidr is 10.100.0.0/16, then your value is 10.100.0.10.

For every available eksctl config file option, see Config file schema in the eksctl documentation. The eksctl utility still creates a launch template for you and populates its user data with the data that you provide in the config file.

Create a node group with the following command.

```
eksctl create nodegroup --config-file=my-nodegroup.yaml
```

User data in a launch template

Specify the following information in the user data section of your launch template. This example creates a node group that containerd as the runtime. It also provides an additional kubelet argument to set a custom max-pods value using the bootstrap.sh script included with the Amazon EKS optimized AMI. For more information, see the bootstrap.sh file on GitHub.

Replace every example-value with your own values. For help with selecting my-max-pods-value, see Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 172).
Deleting a managed node group

This topic describes how you can delete an Amazon EKS managed node group.

The only required argument in the previous example is the cluster name (`my-cluster`). However, by setting the values for `--apiserver-endpoint`, `--b64-cluster-ca` and `--dns-cluster-ip`, there's no need for the bootstrap script to make a describeCluster call. This is useful in private cluster setups or clusters where you're scaling in and out nodes frequently.

You can find the values for your cluster to specify the values for the optional arguments with the following command.

```
aws eks describe-cluster --name my-cluster
```

The example values for the optional arguments are the name of the properties returned in the output from the command. The value for `--dns-cluster-ip` is your service CIDR with .10 at the end. For example, if the returned value for `serviceIpv4Cidr` is `10.100.0.0/16`, then your value is `10.100.0.10`.

Run a custom AMI due to specific security, compliance, or internal policy requirements

For more information, see Amazon Machine Images (AMI) in the Amazon EC2 User Guide for Linux Instances. The Amazon EKS AMI build specification contains resources and configuration scripts for building a custom Amazon EKS AMI based on Amazon Linux 2. For more information, see Amazon EKS AMI Build Specification on GitHub. To build custom AMIs installed with other operating systems, see Amazon EKS Sample Custom AMIs on GitHub.

**Important**

When specifying an AMI, Amazon EKS doesn't merge any user data. Rather, you're responsible for supplying the required bootstrap commands for nodes to join the cluster. If your nodes fail to join the cluster, the Amazon EKS CreateNodegroup and UpdateNodegroupVersion actions also fail.

The following are the limits and conditions involved with specifying an AMI ID with managed node groups:

- You must create a new node group to switch between specifying an AMI ID in a launch template and not specifying an AMI ID.
- You aren't notified in the console when a newer AMI version is available. To update your node group to a newer AMI version, you need to create a new version of your launch template with an updated AMI ID. Then, you need to update the node group with the new launch template version.
- The following fields can't be set in the API if you specify an AMI ID:
  - `amiType`
  - `releaseVersion`
  - `version`
- You can't specify a Windows AMI ID because Windows can't be used in managed node groups.

Deleting a managed node group

This topic describes how you can delete an Amazon EKS managed node group.
When you delete a managed node group, Amazon EKS first sets the minimum, maximum, and desired size of your Auto Scaling group to zero. This then causes your node group to scale down. Before each instance is terminated, Amazon EKS sends a signal to drain the pods from that node and then waits a few minutes. If the pods haven't drained after a few minutes, Amazon EKS lets Auto Scaling continue the termination of the instance. After every instance is terminated, the Auto Scaling group is deleted.

**Important**

If you delete a managed node group that uses a node IAM role that isn't used by any other managed node group in the cluster, the role is removed from the `aws-auth` ConfigMap (p. 395). If any of the self-managed node groups in the cluster are using the same node IAM role, the self-managed nodes move to the NotReady status. Additionally, the cluster operation are also disrupted. You can add the mapping back to the ConfigMap to minimize disruption.

You can delete a managed node group with `eksctl` or the AWS Management Console.

**eksctl**

**To delete a managed node group with eksctl**

- Enter the following command. Replace every `example-value` with your own values.

```
eksctl delete nodegroup \
  --cluster my-cluster \
  --region region-code \
  --name my-mng
```

**AWS Management Console**

**To delete your managed node group using the AWS Management Console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster that contains the node group to delete.
3. Select the **Configuration** tab. On the **Compute** tab, select the node group to delete, and choose **Delete**.
4. On the **Delete Node group: <node group name>** page, enter the name of the node group in the text field and choose **Delete**.

**Self-managed nodes**

A cluster contains one or more Amazon EC2 nodes that pods are scheduled on. Amazon EKS nodes run in your AWS account and connect to the control plane of your cluster through the cluster API server endpoint. You deploy one or more nodes into a node group. A node group is one or more Amazon EC2 instances that are deployed in an Amazon EC2 Auto Scaling group. All instances in a node group must have the following characteristics:

- Be the same instance type
- Be running the same Amazon Machine Image (AMI)
- Use the same Amazon EKS node IAM role (p. 452)

A cluster can contain several node groups. If each node group meets the previous requirements, the cluster can contain node groups that contain different instance types and host operating systems. Each node group can contain several nodes.
Amazon EKS nodes are standard Amazon EC2 instances. You're billed for them based on EC2 prices. For more information, see Amazon EC2 pricing.

Amazon EKS provides specialized Amazon Machine Images (AMI) that are called Amazon EKS optimized AMIs. The AMIs are configured to work with Amazon EKS and include Docker, kubelet, and the AWS IAM Authenticator. The AMIs also contain a specialized bootstrap script that allows it to discover and connect to your cluster's control plane automatically.

If you restrict access to the public endpoint of your cluster using CIDR blocks, we recommend that you also enable private endpoint access. This is so that nodes can communicate with the cluster. Without the private endpoint enabled, the CIDR blocks that you specify for public access must include the egress sources from your VPC. For more information, see Amazon EKS cluster endpoint access control (p. 45).

To add self-managed nodes to your Amazon EKS cluster, see the topics that follow. If you launch self-managed nodes manually, add the following tag to each node. For more information, see Adding and deleting tags on an individual resource. If you follow the steps in the guides that follow, the required tag is automatically added to nodes for you.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/cluster/cluster-name</td>
<td>owned</td>
</tr>
</tbody>
</table>

For more information about nodes from a general Kubernetes perspective, see Nodes in the Kubernetes documentation.

Topics

- Launching self-managed Amazon Linux nodes (p. 132)
- Launching self-managed Bottlerocket nodes (p. 137)
- Launching self-managed Windows nodes (p. 139)
- Self-managed node updates (p. 145)

# Launching self-managed Amazon Linux nodes

This topic describes how you can launch an Auto Scaling group of Linux nodes that register with your Amazon EKS cluster. After the nodes join the cluster, you can deploy Kubernetes applications to them. You can also launch self-managed Amazon Linux 2 nodes with eksctl or the AWS Management Console.

## Prerequisites

- An existing Amazon EKS cluster. To deploy one, see Creating an Amazon EKS cluster (p. 24). If you have subnets in the AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled, those subnets must not have been passed in when you created your cluster.
- (Optional, but recommended) The Amazon VPC CNI add-on configured with its own IAM role that has the necessary IAM policy attached to it. For more information, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).
- Familiarity with the considerations listed in Choosing an Amazon EC2 instance type (p. 171). Depending on the instance type you choose, there may be additional prerequisites for your cluster and VPC.

```
eksctl
```

### Prerequisite
Version 0.92.0 or later of the `eksctl` command line tool installed on your computer or AWS CloudShell. To install or update `eksctl`, see Installing `eksctl` (p. 10).

**To launch self-managed Linux nodes using `eksctl`**

1. (Optional) If the `AmazonEKS_CNI_Policy` managed IAM policy is attached to your section called "Node IAM role" (p. 452), we recommend assigning it to an IAM role that you associate to the Kubernetes `aws-node` service account instead. For more information, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).

2. The following command creates a node group in an existing cluster. Replace every `example-value` with your own values. The nodes are created with the same Kubernetes version as the control plane, by default.

   ```bash
   eksctl create nodegroup
   --cluster my-cluster
   --name al-nodes
   --node-type t3.medium
   --nodes 3
   --nodes-min 1
   --nodes-max 4
   --ssh-access
   --managed=false
   --ssh-public-key my-key
   ```

   For a complete list of supported values for `--node-type`, see `amazon-eks-nodegroup.yaml` on GitHub. Before choosing a value for `--node-type`, review Choosing an Amazon EC2 instance type (p. 171).

   Replace `my-key` with the name of your Amazon EC2 key pair or public key. This key is used to SSH into your nodes after they launch. If you don’t already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 key pairs in the Amazon EC2 User Guide for Linux Instances.

   Create your node group with the following command.

   **Important**

   If you want to deploy a node group to AWS Outposts, AWS Wavelength, or AWS Local Zones subnets, there are additional considerations:

   - The subnets must not have been passed in when you created the cluster.
   - You must create the node group with a config file that specifies the subnets and `volumeType: gp2`. For more information, see Create a nodegroup from a config file and Config file schema in the `eksctl` documentation.

   To deploy a node group that allows your instance to assign a significantly higher number of IP addresses to pods, assign IP addresses to pods from a different CIDR block than that of the instance. Then, enable the `containerd` runtime you must deploy the node group using a config file. For more information, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 303), CNI custom networking (p. 300), and Enable the `containerd` runtime bootstrap flag (p. 182). For instructions on how to deploy a private node group without outbound internet access, see Private clusters (p. 100). For a complete list of all available options and defaults, enter the following command.

   ```bash
   eksctl create nodegroup --help
   ```

   If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 508) in the Troubleshooting guide.
The output is as follows. Several lines are output while the nodes are created. One of the last lines of output is the following example line.

```
[✓] created 1 nodegroup(s) in cluster "my-cluster"
```

3. (Optional) If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region, then we recommend blocking pod access to IMDS. For more information, see Restrict access to the instance profile assigned to the worker node.

AWS Management Console

**Step 1: To launch self-managed Linux nodes using the AWS Management Console**

1. Wait for your cluster status to show as **ACTIVE**. If you launch your nodes before the cluster is active, the nodes fail to register with the cluster and you will have to relaunch them.
2. Download the latest version of the AWS CloudFormation template.
   
   ```
   ```
4. Choose **Create stack** and then select **With new resources (standard)**.
5. For **Specify template**, select **Upload a template file** and then select **Choose file**. Select the `amazon-eks-nodegroup.yaml` file that you downloaded in step 2 and then select **Next**.
6. On the **Specify stack details** page, enter the following parameters accordingly:
   - **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it `cluster-name-nodes`. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 128 characters.
   - **ClusterName**: Enter the name that you used when you created your Amazon EKS cluster. This name must equal the cluster name or your nodes can't join the cluster.
   - **ClusterControlPlaneSecurityGroup**: Choose the **SecurityGroups** value from the AWS CloudFormation output that you generated when you created your VPC (p. 258).

   The following steps show one operation to retrieve the applicable group.
   1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
   2. Choose the name of the cluster.
   3. Choose the **Configuration** tab.
   4. Choose the **Networking** tab.
   5. Use the **Additional Security Group** value as a reference when selecting from the **ClusterControlPlaneSecurityGroup** dropdown list.
   - **NodeGroupName**: Enter a name for your node group. This name can be used later to identify the Auto Scaling node group that's created for your nodes.
   - **NodeAutoScalingGroupMinSize**: Enter the minimum number of nodes that your node Auto Scaling group can scale in to.
   - **NodeAutoScalingGroupDesiredCapacity**: Enter the desired number of nodes to scale to when your stack is created.
   - **NodeAutoScalingGroupMaxSize**: Enter the maximum number of nodes that your node Auto Scaling group can scale out to.
• **NodeInstanceType**: Choose an instance type for your nodes.

• **NodeImageIdSSMParam**: Pre-populated with the Amazon EC2 Systems Manager parameter of a recent Amazon EKS optimized Amazon Linux AMI ID for a Kubernetes version. To use a different Kubernetes minor version supported with Amazon EKS, replace 1.x with a different supported version (p. 65). We recommend specifying the same Kubernetes version as your cluster.

To use the Amazon EKS optimized accelerated AMI, replace `amazon-linux-2` with `amazon-linux-2-gpu`. To use the Amazon EKS optimized Arm AMI, replace `amazon-linux-2` with `amazon-linux-2-arm64`.

**Note**
The Amazon EKS node AMI is based on Amazon Linux 2. You can track security or privacy events for Amazon Linux 2 at the Amazon Linux Security Center or subscribe to the associated RSS feed. Security and privacy events include an overview of the issue, what packages are affected, and how to update your instances to correct the issue.

• **NodeImageId**: (Optional) If you're using your own custom AMI (instead of the Amazon EKS optimized AMI), enter a node AMI ID for your AWS Region. If you specify a value here, it overrides any values in the **NodeImageIdSSMParam** field.

• **NodeVolumeSize**: Specify a root volume size for your nodes, in GiB.

• **KeyName**: Enter the name of an Amazon EC2 SSH key pair that you can use to connect using SSH into your nodes with after they launch. If you don't already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 key pairs in the Amazon EC2 User Guide for Linux Instances.

  **Note**
  If you don't provide a key pair here, the AWS CloudFormation stack creation fails.

• **BootstrapArguments**: Specify any optional arguments to pass to the node bootstrap script, such as extra `kubelet` arguments. For more information, view the bootstrap script usage information on GitHub. To deploy a node group that allows your instance to assign a significantly higher number of IP addresses to pods, assign IP addresses to pods from a different CIDR block than that of the instance. Then, enable the `containerd` runtime or deploy a private cluster without outbound internet access. For information about arguments to add, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 303), CNI custom networking (p. 300), Enable the `containerd` runtime bootstrap flag (p. 182), and Private clusters (p. 100).

• **DisableIMDSv1**: By default, each node supports the Instance Metadata Service Version 1 (IMDSv1) and IMDSv2. You can disable IMDSv1. To prevent future nodes and pods in the node group from using MDSv1, set `DisableIMDSv1` to `true`. For more information about IMDS, see Configuring the instance metadata service. For more information about restricting access to it on your nodes, see Restrict access to the instance profile assigned to the worker node.

• **VpcId**: Enter the ID for the VPC (p. 258) that you created.

• **Subnets**: Choose the subnets that you created for your VPC. If you created your VPC using the steps that are described in Creating a VPC for your Amazon EKS cluster (p. 258), specify only the private subnets within the VPC for your nodes to launch into.

  **Important**
  - If any of the subnets are public subnets, then they must have the automatic public IP address assignment setting enabled. If the setting isn't enabled for the public subnet, then any nodes that you deploy to that public subnet won't be assigned a public IP address and won't be able to communicate with the cluster or other AWS services. If the subnet was deployed before March 26, 2020 using either of the Amazon EKS AWS CloudFormation VPC templates (p. 258), or by using `eksctl`, then automatic public IP address assignment is disabled for public subnets. For information about how to enable public IP address assignment for a subnet, see
Modifying the Public IPv4 Addressing Attribute for Your Subnet. If the node is deployed to a private subnet, then it's able to communicate with the cluster and other AWS services through a NAT gateway.

- If the subnets don't have internet access, make sure that you're aware of the considerations and extra steps in Private clusters (p. 100).
- If you're deploying the nodes in a 1.18 or earlier cluster, make sure that the subnets you select are tagged with the cluster name. Replace `my-cluster` with the name of your cluster. Then, run the following command to see a list of the subnets currently tagged with your cluster name.

```bash
aws ec2 describe-subnets --filters Name=tag:kubernetes.io/cluster/my-cluster,Values=shared | grep SubnetId
```

If the subnet you want to select isn't returned in the output from the previous command, manually add the tag to the subnet. For more information, see Subnet tagging (p. 265).

- If you select AWS Outposts, AWS Wavelength, or AWS Local Zones subnets, the subnets must not have been passed in when you created the cluster.

7. Acknowledge that the stack might create IAM resources, and then choose Create stack.
8. When your stack has finished creating, select it in the console and choose Outputs.
9. Record the `NodeInstanceRole` for the node group that was created. You need this when you configure your Amazon EKS nodes.

Step 2: To enable nodes to join your cluster

**Note**
If you launched nodes inside a private VPC without outbound internet access, make sure to enable nodes to join your cluster from within the VPC.

1. Download, edit, and apply the AWS IAM Authenticator configuration map.
   a. Download the configuration map using the following command.

   ```bash
   curl -o aws-auth-cm.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/cloudformation/2020-10-29/aws-auth-cm.yaml
   ```
   b. Open the file with your text editor. Replace the ARN of instance role (not instance profile) snippet with the `NodeInstanceRole` value that you recorded in the previous procedure, and save the file.

   **Important**
   Don't modify any other lines in this file.

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: aws-auth
     namespace: kube-system
   data:
     mapRoles: |
       - rolearn: ARN of instance role (not instance profile)
         username: system:node:{{EC2PrivateDNSName}}
       groups:
         - system:bootstrappers
         - system:nodes
   ```
   c. Apply the configuration. This command may take a few minutes to finish.
**Launching self-managed Bottlerocket nodes**

**Note**
Managed node groups might offer some advantages for your use case. For more information, see Managed node groups (p. 109).

This topic describes how to launch an Auto Scaling group of Bottlerocket nodes that register with your Amazon EKS cluster. Bottlerocket is a Linux-based open-source operating system from AWS that you can use for running containers on virtual machines or bare metal hosts. After the nodes join the cluster, you can deploy Kubernetes applications to them. For more information about Bottlerocket, see Using a Bottlerocket AMI with Amazon EKS on GitHub and Custom AMI support in the eksctl documentation.

For information about in-place upgrades, see Bottlerocket Update Operator on GitHub.

**Important**
Amazon EKS nodes are standard Amazon EC2 instances, and you are billed for them based on normal Amazon EC2 instance prices. For more information, see Amazon EC2 pricing.

**Important**
- You can deploy to Amazon EC2 instances with x86 or Arm processors. However, you can't deploy to instances that have Inferentia chips.
- You can't deploy to the following regions: China (Beijing) (cn-north-1) or China (Ningxia) (cn-northwest-1).
• There is no AWS CloudFormation template to deploy nodes with.
• Bottlerocket images don't come with an SSH server or a shell. You can use out-of-band access methods to allow SSH enabling the admin container and to pass some bootstrapping configuration steps with user data. For more information, see these sections in the bottlerocket README.md on GitHub:
  • Exploration
  • Admin container
  • Kubernetes settings

**To launch Bottlerocket nodes using eksctl**

This procedure requires eksctl version 0.92.0 or later. You can check your version with the following command:

```
eksctl version
```

For instructions on how to install or upgrade eksctl, see Installing or upgrading eksctl (p. 11).

**Note**

This procedure only works for clusters that were created with eksctl.

1. Create a file named `bottlerocket.yaml` with the following contents. Replace every example-value with your own values. To deploy on Arm instances, replace `m5.large` with an Arm instance type. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

   If specifying an Arm Amazon EC2 instance type, then review the considerations in Amazon EKS optimized Arm Amazon Linux AMIs (p. 184) before deploying. For instructions on how to deploy using a custom AMI, see Building Bottlerocket on GitHub and Custom AMI support in the eksctl documentation. To deploy a managed node group, deploy a custom AMI using a launch template. For more information, see Launch template support (p. 124).

   **Important**

   To deploy a node group to AWS Outposts, AWS Wavelength, or AWS Local Zones subnets, don't pass AWS Outposts, AWS Wavelength, or AWS Local Zones subnets when you create the cluster. You must specify the subnets in the following example. For more information see Create a nodegroup from a config file and Config file schema in the eksctl documentation. Replace `region-code` with the AWS Region that your cluster is in.

```
---
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: my-cluster
  region: region-code
  version: '1.22'
iam:
  withOIDC: true
nodeGroups:
- name: ng-bottlerocket
  instanceType: m5.large
  desiredCapacity: 3
  amiFamily: Bottlerocket
  ami: auto-ssm
  iam:
    attachPolicyARNs:
```
2. Deploy your nodes with the following command.

   ```bash
eksctl create cluster --config-file=bottlerocket.yaml
   ```

   The output is as follows. Several lines are output while the nodes are created. One of the last lines of output is the following example line.

   ```text
   [✓]  created 1 nodegroup(s) in cluster "my-cluster"
   ```

3. (Optional) Create a Kubernetes persistent volume on a Bottlerocket node using the Amazon EBS CSI Plugin. The default Amazon EBS driver relies on file system tools that aren't included with Bottlerocket. For more information about creating a storage class using the driver, see Amazon EBS CSI driver (p. 225).

4. (Optional) By default, kube-proxy sets the `nf_conntrack_max` kernel parameter to a default value that may differ from what Bottlerocket originally sets at boot. To keep Bottlerocket's default setting, edit the kube-proxy configuration with the following command.

   ```bash
   kubectl edit -n kube-system daemonset kube-proxy
   ```

   Add `--conntrack-max-per-core` and `--conntrack-min` to the `kube-proxy` arguments that are in the following example. A setting of 0 implies no change.

   ```yaml
   containers:
   - command:
     - kube-proxy
     - --v=2
     - --config=/var/lib/kube-proxy-config/config
     - --conntrack-max-per-core=0
     - --conntrack-min=0
   ```

5. (Optional) Deploy a sample application (p. 352) to test your Bottlerocket nodes.

6. (Optional) If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region, then we recommend blocking pod access to IMDS. For more information, see Restrict access to the instance profile assigned to the worker node.

### Launching self-managed Windows nodes

This topic describes how to launch an Auto Scaling group of Windows nodes that register with your Amazon EKS cluster. After the nodes join the cluster, you can deploy Kubernetes applications to them.

**Important**

Amazon EKS nodes are standard Amazon EC2 instances, and you are billed for them based on normal Amazon EC2 instance prices. For more information, see Amazon EC2 pricing.

Enable Windows support for your cluster. We recommend that you review important considerations before you launch a Windows node group. For more information, see Enabling Windows support (p. 92).

You can launch self-managed Windows nodes with `eksctl` or the AWS Management Console.
**To launch self-managed Windows nodes using eksctl**

This procedure requires that you have installed eksctl, and that your eksctl version is at least 0.92.0. You can check your version with the following command.

```
eksctl version
```

For instructions on how to install or upgrade eksctl, see Installing or upgrading eksctl (p. 11).

**Note**

This procedure only works for clusters that were created with eksctl.

1. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy (if you have an IPv4 cluster) or the AmazonEKS_CNI_IPV6_Policy (that you created yourself (p. 274) if you have an IPv6 cluster) is attached to your the section called “Node IAM role” (p. 452), we recommend assigning it to an IAM role that you associate to the Kubernetes aws-node service account instead. For more information, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).

2. This procedure assumes that you have an existing cluster. If you don't already have an Amazon EKS cluster and an Amazon Linux 2 node group to add a Windows node group to, we recommend that you follow the Getting started with Amazon EKS – eksctl (p. 12) guide. The guide provides a complete walkthrough for how to create an Amazon EKS cluster with Amazon Linux nodes.

Create your node group with the following command. Replace every `example-value` with your own values.

```
Important
To deploy a node group to AWS Outposts, AWS Wavelength, or AWS Local Zones subnets, don't pass the AWS Outposts, AWS Wavelength, or AWS Local Zones subnets when you create the cluster. Create the node group with a config file, specifying the AWS Outposts, AWS Wavelength, or AWS Local Zones subnets. For more information, see Create a nodegroup from a config file and Config file schema in the eksctl documentation.

Note
Amazon EKS optimized Windows AMIs can be configured to use containerd as a runtime. When using eksctl for launching Windows nodes, specify containerRuntime as containerd in the node group configuration. For more information, see Enable the containerd runtime bootstrap flag (p. 214) in this user guide or Define container runtime in the eksctl documentation. Replace `region-code` with the AWS Region that your cluster is in.

```bash
eksctl create nodegroup
--region region-code
--cluster my-cluster
--name ng-windows
--node-type t2.large
--nodes 3
--nodes-min 1
--nodes-max 4
--node-ami-family WindowsServer2019FullContainer
```

**Note**

- If nodes fail to join the cluster, see Nodes fail to join cluster (p. 508) in the Troubleshooting guide.
To see the available options for eksctl commands, enter the following command.

```
eksctl command -help
```

The output is as follows. Several lines are output while the nodes are created. One of the last lines of output is the following example line.

```
[#] created 1 nodegroup(s) in cluster "my-cluster"
```

3. (Optional) Deploy a sample application (p. 352) to test your cluster and Windows nodes.
4. (Optional) If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region, then we recommend blocking pod access to IMDS. For more information, see Restrict access to the instance profile assigned to the worker node.

### AWS Management Console

**Prerequisites**

- An existing Amazon EKS cluster and a Linux node group. If you don’t have these resources, we recommend that you follow one of our Getting started with Amazon EKS (p. 4) guides to create them. The guides describe how to create an Amazon EKS cluster with Linux nodes.
- An existing VPC and security group that meet the requirements for an Amazon EKS cluster. For more information, see Cluster VPC and subnet considerations (p. 262) and Amazon EKS security group considerations (p. 265). The Getting started with Amazon EKS (p. 4) guide creates a VPC that meets the requirements. Alternatively, you can also follow Creating a VPC for your Amazon EKS cluster (p. 258) to create one manually.
- An existing Amazon EKS cluster that uses a VPC and security group that meets the requirements of an Amazon EKS cluster. For more information, see Creating an Amazon EKS cluster (p. 24). If you have subnets in the AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled, those subnets must not have been passed in when you created the cluster.

**Step 1: To launch self-managed Windows nodes using the AWS Management Console**

1. Wait for your cluster status to show as ACTIVE. If you launch your nodes before the cluster is active, the nodes fail to register with the cluster and you need to relaunch them.
2. Open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation
3. Choose Create stack.
4. For Specify template, select Amazon S3 URL, copy the following URL, paste it into Amazon S3 URL, and select Next twice.

   ```
   ```

5. On the Quick create stack page, enter the following parameters accordingly:

   - **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it `cluster-name-nodes`.
   - **ClusterName**: Enter the name that you used when you created your Amazon EKS cluster.
Important
This name must exactly match the name that you used in Step 1: Create your Amazon EKS cluster (p. 16). Otherwise, your nodes can't join the cluster.

• **ClusterControlPlaneSecurityGroup**: Choose the security group from the AWS CloudFormation output that you generated when you created your VPC (p. 258).

The following steps show one method to retrieve the applicable group.

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the name of the cluster.
3. Choose the **Configuration** tab.
4. Choose the **Networking** tab.
5. Use the **Additional Security Group** value as a reference when selecting from the **ClusterControlPlaneSecurityGroup** dropdown list.

• **NodeGroupName**: Enter a name for your node group. This name can be used later to identify the Auto Scaling node group that's created for your nodes.

• **NodeAutoScalingGroupMinSize**: Enter the minimum number of nodes that your node Auto Scaling group can scale in to.

• **NodeAutoScalingGroupDesiredCapacity**: Enter the desired number of nodes to scale to when your stack is created.

• **NodeAutoScalingGroupMaxSize**: Enter the maximum number of nodes that your node Auto Scaling group can scale out to.

• **NodeInstanceType**: Choose an instance type for your nodes.

  **Note**
  The supported instance types for the latest version of the Amazon VPC CNI plugin for Kubernetes are listed in `vpc_ip_resource_limit.go` on GitHub. You might need to update your CNI version to use the latest supported instance types. For more information, see Updating the Amazon VPC CNI self-managed add-on (p. 280).

• **NodeImageIdSSMParam**: Pre-populated with the Amazon EC2 Systems Manager parameter of the current recommended Amazon EKS optimized Windows Core AMI ID. To use the full version of Windows, replace Core with Full.

• **NodeImageId**: (Optional) If you’re using your own custom AMI (instead of the Amazon EKS optimized AMI), enter a node AMI ID for your AWS Region. If you specify a value for this field, it overrides any values in the **NodeImageIdSSMParam** field.

• **NodeVolumeSize**: Specify a root volume size for your nodes, in GiB.

• **KeyName**: Enter the name of an Amazon EC2 SSH key pair that you can use to connect using SSH into your nodes with after they launch. If you don’t already have an Amazon EC2 key pair, you can create one in the AWS Management Console. For more information, see Amazon EC2 key pairs in the Amazon EC2 User Guide for Windows Instances.

  **Note**
  If you don’t provide a key pair here, the AWS CloudFormation stack fails to be created.

• **BootstrapArguments**: Specify any optional arguments to pass to the node bootstrap script, such as extra kubectl arguments using `--KubeletExtraArgs`.

  **Note**
  You can configure Amazon EKS optimized Windows AMIs to use containerd as a runtime. When using an AWS CloudFormation template to create Windows nodes, specify `-ContainerRuntime containerd` in a bootstrap argument to enable the containerd runtime. For more information, see Enable the containerd runtime bootstrap flag (p. 214).

• **DisableIMDSv1**: By default, each node supports the Instance Metadata Service Version 1 (IMDSv1) and IMDSv2. You can disable IMDSv1. To prevent future nodes and pods in the node.
group from using MDSv1, set DisableIMDSv1 to true. For more information about IMDS, see Configuring the instance metadata service.

- **VpcId**: Select the ID for the VPC (p. 258) that you created.
- **NodeSecurityGroups**: Select the security group that was created for your Linux node group when you created your VPC (p. 258). If your Linux nodes have more than one security group attached to them, specify all of them. This for, for example, if the Linux node group was created with eksctl.
- **Subnets**: Choose the subnets that you created. If you created your VPC using the steps in Creating a VPC for your Amazon EKS cluster (p. 258), then specify only the private subnets within the VPC for your nodes to launch into.

**Important**

- If any of the subnets are public subnets, then they must have the automatic public IP address assignment setting enabled. If the setting isn’t enabled for the public subnet, then any nodes that you deploy to that public subnet won’t be assigned a public IP address and won’t be able to communicate with the cluster or other AWS services. If the subnet was deployed before March 26, 2020 using either of the Amazon EKS AWS CloudFormation VPC templates (p. 258), or by using eksctl, then automatic public IP address assignment is disabled for public subnets. For information about how to enable public IP address assignment for a subnet, see Modifying the Public IPv4 Addressing Attribute for Your Subnet. If the node is deployed to a private subnet, then it’s able to communicate with the cluster and other AWS services through a NAT gateway.

- If the subnets don’t have internet access, then make sure that you’re aware of the considerations and extra steps in Private clusters (p. 100).

- If you’re deploying the nodes in a 1.18 or earlier cluster, make sure that the subnets you select are tagged with the cluster name. Replace my-cluster with the name of your cluster. Then, run the following command to see a list of the subnets currently tagged with your cluster name.

```bash
aws ec2 describe-subnets --filters Name=tag:kubernetes.io/cluster/my-cluster,Values=shared | grep SubnetId
```

If the subnet you want to select isn’t returned in the output from the previous command, manually add the tag to the subnet. For more information, see Subnet tagging (p. 265).

- If you select AWS Outposts, AWS Wavelength, or AWS Local Zones subnets, then the subnets must not have been passed in when you created the cluster.

6. Acknowledge that the stack might create IAM resources, and then choose **Create stack**.

7. When your stack has finished creating, select it in the console and choose **Outputs**.

8. Record the **NodeInstanceRole** for the node group that was created. You need this when you configure your Amazon EKS Windows nodes.

**Step 2: To enable nodes to join your cluster**

1. Download, edit, and apply the AWS IAM Authenticator configuration map.

   a. Download the configuration map:

   ```bash
curl -o aws-auth-cm-windows.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/cloudformation/2020-10-29/aws-auth-cm-windows.yaml
```

   b. Open the file using your preferred text editor. Replace the ARN of instance role (not instance profile) of **Linux** node and ARN of instance role (not
instance profile) of **Windows** node snippets with the NodInstanceRole values that you recorded for your Linux and Windows nodes, and save the file.

**Important**

- Don’t modify any other lines in this file.
- Don’t use the same IAM role for both Windows and Linux nodes.

```yaml
apiVersion: v1
class: ConfigMap
metadata:
  name: aws-auth
  namespace: kube-system
data:
  mapRoles: |
    - rolearn: ARN of instance role (not instance profile) of **Linux** node
      username: system:node:{{EC2PrivateDNSName}}
      groups: 
        - system:bootstrappers
        - system:nodes
    - rolearn: ARN of instance role (not instance profile) of **Windows** node
      username: system:node:{{EC2PrivateDNSName}}
      groups: 
        - system:bootstrappers
        - system:nodes
        - eks:kube-proxy-windows
```

c. Apply the configuration. This command might take a few minutes to finish.

```bash
kubectl apply -f aws-auth-cm-windows.yaml
```

**Note**

If you receive any authorization or resource type errors, see Unauthorized or access denied (kubectl) (p. 509) in the troubleshooting section.

If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 508) in the Troubleshooting guide.

2. Watch the status of your nodes and wait for them to reach the **Ready** status.

```bash
kubectl get nodes --watch
```

3. (Optional) Deploy a sample application (p. 352) to test your cluster and Windows nodes.

4. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy (if you have an IPv4 cluster) or the AmazonEKS_CNI_IPv6_Policy (that you created yourself (p. 274) if you have an IPv6 cluster) is attached to your the section called “Node IAM role” (p. 452), we recommend assigning it to an IAM role that you associate to the Kubernetes aws-node service account instead. For more information, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).

5. (Optional) If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region, then we recommend blocking pod access to IMDS. For more information, see Restrict access to the instance profile assigned to the worker node.
Self-managed node updates

When a new Amazon EKS optimized AMI is released, consider replacing the nodes in your self-managed node group with the new AMI. Likewise, if you have updated the Kubernetes version for your Amazon EKS cluster, update the nodes to use nodes with the same Kubernetes version.

**Important**
This topic covers node updates for self-managed nodes. If you are using Managed node groups (p. 109), see Updating a managed node group (p. 119).

There are two basic ways to update self-managed node groups in your clusters to use a new AMI:

- **Migrating to a new node group (p. 145)** – Create a new node group and migrate your pods to that group. Migrating to a new node group is more graceful than simply updating the AMI ID in an existing AWS CloudFormation stack. This is because the migration process taints the old node group as `NoSchedule` and drains the nodes after a new stack is ready to accept the existing pod workload.
- **Updating an existing self-managed node group (p. 150)** – Update the AWS CloudFormation stack for an existing node group to use the new AMI. This method isn't supported for node groups that were created with `eksctl`.

Migrating to a new node group

This topic describes how you can create a new node group, gracefully migrate your existing applications to the new group, and remove the old node group from your cluster. You can migrate to a new node group using `eksctl` or the AWS Management Console.

**To migrate your applications to a new node group with eksctl**

This procedure requires `eksctl` version 0.92.0 or later. You can check your version with the following command:

```
 eksctl version
```

For instructions on how to install or upgrade `eksctl`, see Installing or upgrading eksctl (p. 11).

**Note**
This procedure only works for clusters and node groups that were created with `eksctl`.

1. Retrieve the name of your existing node groups, replacing `my-cluster` with your cluster name.

```
 eksctl get nodegroups --cluster=my-cluster
```

Example output:

```
<table>
<thead>
<tr>
<th>CLUSTER</th>
<th>NODEGROUP</th>
<th>CREATED</th>
<th>MIN SIZE</th>
<th>MAX SIZE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>t3.medium</td>
<td>ami-05a71d034119ffcc12</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

2. Launch a new node group with `eksctl` with the following command. In the command, replace every `example-value` with your own values. The version number can't be later than the Kubernetes version for your control plane. Also, it can't be more than two minor versions earlier than the Kubernetes version for your control plane. We recommend that you use the same version as your control plane. If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current AWS Region, then we recommend blocking pod access to IMDS. For more information, see Restrict...
access to the instance profile assigned to the worker node. To block pod access to IMDS, add the `--disable-pod-imds` option to the following command.

**Note**
For more available flags and their descriptions, see https://eksctl.io/.

```
eksctl create nodegroup \
  --cluster my-cluster \
  --version 1.22 \
  --name standard-nodes-new \
  --node-type t3.medium \
  --nodes 3 \
  --nodes-min 1 \
  --nodes-max 4 \
  --node-ami auto
```

3. When the previous command completes, verify that all of your nodes have reached the `Ready` state with the following command:

```
kubectl get nodes
```

4. Delete the original node group with the following command. In the command, replace every `example-value` with your cluster and node group names:

```
eksctl delete nodegroup --cluster my-cluster --name standard-nodes
```

**To migrate your applications to a new node group with the AWS Management Console and AWS CLI**

1. Launch a new node group by following the steps that are outlined in Launching self-managed Amazon Linux nodes (p. 132).
2. When your stack has finished creating, select it in the console and choose Outputs.
3. Record the `NodeInstanceRole` for the node group that was created. You need this to add the new Amazon EKS nodes to your cluster.

**Note**
If you attached any additional IAM policies to your old node group IAM role, attach those same policies to your new node group IAM role to maintain that functionality on the new group. This applies to you if you added permissions for the Kubernetes Cluster Autoscaler, for example.

4. Update the security groups for both node groups so that they can communicate with each other. For more information, see Amazon EKS security group considerations (p. 265).
   a. Record the security group IDs for both node groups. This is shown as the `NodeSecurityGroup` value in the AWS CloudFormation stack outputs.

   You can use the following AWS CLI commands to get the security group IDs from the stack names. In these commands, `oldNodes` is the AWS CloudFormation stack name for your older node stack, and `newNodes` is the name of the stack that you are migrating to. Replace every `example-value` with your own values.

   ```
oldSecGroup=$(aws cloudformation describe-stack-resources --stack-name $oldNodes \
  --query 'StackResources[? ResourceType=="AWS::EC2::SecurityGroup"].PhysicalResourceId' \
  --output text)
newSecGroup=$(aws cloudformation describe-stack-resources --stack-name $newNodes \
  --query 'StackResources[? ResourceType=="AWS::EC2::SecurityGroup"].PhysicalResourceId' \
  --output text)
   ```
b. Add ingress rules to each node security group so that they accept traffic from each other.

The following AWS CLI commands add inbound rules to each security group that allow all traffic on all protocols from the other security group. This configuration allows pods in each node group to communicate with each other while you're migrating your workload to the new group.

```bash
aws ec2 authorize-security-group-ingress --group-id $oldSecGroup --source-group $newSecGroup --protocol -1
aws ec2 authorize-security-group-ingress --group-id $newSecGroup --source-group $oldSecGroup --protocol -1
```

5. Edit the `aws-auth` configmap to map the new node instance role in RBAC.

```bash
ekubectl edit configmap -n kube-system aws-auth
```

Add a new `mapRoles` entry for the new node group. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

```yaml
apiVersion: v1
data:
  mapRoles: |
    - rolearn: ARN of instance role (not instance profile)
      username: system:node:{{EC2PrivateDNSName}}
      groups:
        - system:bootstrappers
        - system:nodes
    - rolearn: arn:aws:iam::111122223333:role/nodes-1-16-NodeInstanceRole-U11V27W93CX5
      username: system:node:{{EC2PrivateDNSName}}
      groups:
        - system:bootstrappers
        - system:nodes
```

Replace the `ARN of instance role (not instance profile)` snippet with the `NodeInstanceRole` value that you recorded in a previous step (p. 146). Then, save and close the file to apply the updated configmap.

6. Watch the status of your nodes and wait for your new nodes to join your cluster and reach the Ready status.

```bash
kubectl get nodes --watch
```

7. (Optional) If you're using the Kubernetes Cluster Autoscaler, scale the deployment down to zero (0) replicas to avoid conflicting scaling actions.

```bash
kubectl scale deployments/cluster-autoscaler --replicas=0 -n kube-system
```

8. Use the following command to taint each of the nodes that you want to remove with NoSchedule. This is so that new pods aren't scheduled or rescheduled on the nodes that you're replacing.

```bash
kubectl taint nodes node_name key=value:NoSchedule
```

If you're upgrading your nodes to a new Kubernetes version, you can identify and taint all of the nodes of a particular Kubernetes version (in this case, 1.20) with the following code snippet. The version number can't be later than the Kubernetes version of your control plane. It also can't
be more than two minor versions earlier than the Kubernetes version of your control plane. We recommend that you use the same version as your control plane.

```
K8S_VERSION=1.20
nodes=$(kubectl get nodes -o jsonpath="{.items[?(@.status.nodeInfo.kubeletVersion=="v
$K8S_VERSION")].metadata.name}")
for node in ${nodes[@]}
do
echo "Tainting $node"
kubectl taint nodes $node key=value:NoSchedule
done
```

9. Determine your cluster's DNS provider.

```
kubectl get deployments -l k8s-app=kube-dns -n kube-system
```

The following is the output. This cluster is using `coredns` for DNS resolution, but your cluster can return `kube-dns` instead):

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESIRED</th>
<th>CURRENT</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>coredns</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>31m</td>
</tr>
</tbody>
</table>

10. If your current deployment is running fewer than two replicas, scale out the deployment to two replicas. Replace `coredns` with `kubedns` if your previous command output returned that instead.

```
kubectl scale deployments/coredns --replicas=2 -n kube-system
```

11. Drain each of the nodes that you want to remove from your cluster with the following command:

```
kubectl drain node_name --ignore-daemonsets --delete-local-data
```

If you're upgrading your nodes to a new Kubernetes version, identify and drain all of the nodes of a particular Kubernetes version (in this case, 1.20) with the following code snippet.

```
K8S_VERSION=1.20
nodes=$(kubectl get nodes -o jsonpath="{.items[?(@.status.nodeInfo.kubeletVersion=="v
$K8S_VERSION")].metadata.name}")
for node in ${nodes[@]}
do
echo "Draining $node"
kubectl drain $node --ignore-daemonsets --delete-local-data
done
```

12. After your old nodes finished draining, revoke the security group inbound rules you authorized earlier. Then, delete the AWS CloudFormation stack to terminate the instances.

**Note**

If you attached any additional IAM policies to your old node group IAM role, such as adding permissions for the Kubernetes Cluster Autoscaler), detach those additional policies from the role before you can delete your AWS CloudFormation stack.

a. Revoke the inbound rules that you created for your node security groups earlier. In these commands, `oldNodes` is the AWS CloudFormation stack name for your older node stack, and `newNodes` is the name of the stack that you are migrating to.

```
oldNodes="old_node_CFN_stack_name"
newNodes="new_node_CFN_stack_name"
```
oldSecGroup=$(aws cloudformation describe-stack-resources --stack-name $oldNodes \ 
--query 'StackResources[?ResourceType==`AWS::EC2::SecurityGroup`].PhysicalResourceId' \ 
--output text)

newSecGroup=$(aws cloudformation describe-stack-resources --stack-name $newNodes \ 
--query 'StackResources[?ResourceType==`AWS::EC2::SecurityGroup`].PhysicalResourceId' \ 
--output text)

aws ec2 revoke-security-group-ingress --group-id $oldSecGroup \ 
--source-group $newSecGroup --protocol -1

aws ec2 revoke-security-group-ingress --group-id $newSecGroup \ 
--source-group $oldSecGroup --protocol -1

c. Select your old node stack.
d. Choose Delete.
e. In the Delete stack confirmation dialog box, choose Delete stack.

13. Edit the aws-auth configmap to remove the old node instance role from RBAC.

```bash
kubectl edit configmap -n kube-system aws-auth
```

Delete the mapRoles entry for the old node group. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace arn:aws: with arn:aws-us-gov:

```yaml
apiVersion: v1
data:
mapRoles: |
  - rolearn: arn:aws:iam::111122223333:role/nodes-1-16-NodeInstanceRole-W70725MZQFF8
    username: system:node:{{EC2PrivateDNSName}}
    groups:
      - system:bootstrappers
      - system:nodes
    username: system:node:{{EC2PrivateDNSName}}
    groups:
      - system:bootstrappers
      - system:nodes>
```

Save and close the file to apply the updated configmap.

14. (Optional) If you are using the Kubernetes Cluster Autoscaler, scale the deployment back to one replica.

**Note**
You must also tag your new Auto Scaling group appropriately (for example, k8s.io/cluster-autoscaler/enabled,k8s.io/cluster-autoscaler/my-cluster) and update the command for your Cluster Autoscaler deployment to point to the newly tagged Auto Scaling group. For more information, see Cluster Autoscaler on AWS.

```bash
kubectl scale deployments/cluster-autoscaler --replicas=1 -n kube-system
```

15. (Optional) Verify that you're using the latest version of the Amazon VPC CNI plugin for Kubernetes. You might need to update your CNI version to use the latest supported instance types. For more information, see Updating the Amazon VPC CNI self-managed add-on (p. 280).

16. If your cluster is using kube-dns for DNS resolution (see previous step (p. 148)), scale in the kube-dns deployment to one replica.

```bash
kubectl scale deployments/kube-dns --replicas=1 -n kube-system
```
Updating an existing self-managed node group

This topic describes how you can update an existing AWS CloudFormation self-managed node stack with a new AMI. You can use this procedure to update your nodes to a new version of Kubernetes following a cluster update. Otherwise, you can update to the latest Amazon EKS optimized AMI for an existing Kubernetes version.

**Important**
This topic covers node updates for self-managed nodes. For information about using Managed node groups (p. 109), see Updating a managed node group (p. 119).

The latest default Amazon EKS node AWS CloudFormation template is configured to launch an instance with the new AMI into your cluster before removing an old one, one at a time. This configuration ensures that you always have your Auto Scaling group's desired count of active instances in your cluster during the rolling update.

**Note**
This method isn't supported for node groups that were created with `eksctl`. If you created your cluster or node group with `eksctl`, see Migrating to a new node group (p. 145).

**To update an existing node group**

1. Determine the DNS provider for your cluster.

   ```bash
   kubectl get deployments -l k8s-app=kube-dns -n kube-system
   ```

   The output is as follows. This cluster is using `coredns` for DNS resolution, but your cluster might return `kube-dns` instead.

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESIRED</th>
<th>CURRENT</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>coredns</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>31m</td>
</tr>
</tbody>
</table>

2. If your current deployment is running fewer than two replicas, scale out the deployment to two replicas. Replace `coredns` with `kube-dns` if your previous command output returned that instead.

   ```bash
   kubectl scale deployments/coredns --replicas=2 -n kube-system
   ```

3. (Optional) If you're using the Kubernetes Cluster Autoscaler, scale the deployment down to zero (0) replicas to avoid conflicting scaling actions.

   ```bash
   kubectl scale deployments/clUSTER-autoscaler --replicas=0 -n kube-system
   ```

4. Determine the instance type and desired instance count of your current node group. You enter these values later when you update the AWS CloudFormation template for the group.

   a. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
   b. In the left navigation pane, choose Launch Configurations, and note the instance type for your existing node launch configuration.
   c. In the left navigation pane, choose Auto Scaling Groups, and note the Desired instance count for your existing node Auto Scaling group.

6. Select your node group stack, and then choose Update.

7. Select Replace current template and select Amazon S3 URL.

8. For Amazon S3 URL, paste the following URL into the text area to ensure that you're using the latest version of the node AWS CloudFormation template. Then, choose Next:
9. On the Specify stack details page, fill out the following parameters, and choose Next:

- **NodeAutoScalingGroupDesiredCapacity** – Enter the desired instance count that you recorded in a previous step (p. 150). Or, enter your new desired number of nodes to scale to when your stack is updated.

- **NodeAutoScalingGroupMaxSize** – Enter the maximum number of nodes to which your node Auto Scaling group can scale out. This value must be at least one node more than your desired capacity. This is so that you can perform a rolling update of your nodes without reducing your node count during the update.

- **NodeInstanceType** – Choose the instance type you recorded in a previous step (p. 150). Alternatively, choose a different instance type for your nodes. Before choosing a different instance type, review Choosing an Amazon EC2 instance type (p. 171). Each Amazon EC2 instance type supports a maximum number of elastic network interfaces (ENIs) and each ENI supports a maximum number of IP addresses. Because each worker node and pod is assigned its own IP address, it's important to choose an instance type that will support the maximum number of pods that you want to run on each worker node. For a list of the number of ENIs and IP addresses supported by instance types, see IP addresses per network interface per instance type. For example, the m5.large instance type supports a maximum of 30 IP addresses for the worker node and pods.

  **Note**
  The supported instance types for the latest version of the Amazon VPC CNI plugin for Kubernetes are shown in vpc_ip_resource_limit.go on GitHub. You might need to update your CNI version to use the latest supported instance types. For more information, see Updating the Amazon VPC CNI self-managed add-on (p. 280).

  **Important**
  Some instance types might not be available in all AWS Regions.

- **NodeImageIdSSMParam** – The Amazon EC2 Systems Manager parameter of the AMI ID that you want to update to. The following value uses the latest Amazon EKS optimized AMI for Kubernetes version 1.21.

  /aws/service/eks/optimized-ami/1.21/amazon-linux-2/recommended/image_id

  You can replace 1.21 with a supported Kubernetes version (p. 74) that's the same. Or, it should be up to one version earlier than the Kubernetes version running on your control plane. We recommend that you keep your nodes at the same version as your control plane. If you want to use the Amazon EKS optimized accelerated AMI, then replace amazon-linux-2 with amazon-linux-2-gpu.

  **Note**
  Using the Amazon EC2 Systems Manager parameter enables you to update your nodes in the future without having to look up and specify an AMI ID. If your AWS CloudFormation stack is using this value, any stack update always launches the latest recommended Amazon EKS optimized AMI for your specified Kubernetes version. This is even the case even if you don't change any values in the template.

- **NodeImageId** – To use your own custom AMI, enter the ID for the AMI to use.

  **Important**
  This value overrides any value specified for NodeImageIdSSMParam. If you want to use the NodeImageIdSSMParam value, ensure that the value for NodeImageId is blank.

- **DisableIMDSv1** – By default, each node supports the Instance Metadata Service Version 1 (IMDSv1) and IMDSv2. However, you can disable IMDSv1. Select true if you don't want any nodes
or any pods scheduled in the node group to use IMDSv1. For more information about IMDS, see Configuring the instance metadata service. If you've implemented IAM roles for service accounts, assign necessary permissions directly to all pods that require access to AWS services. This way, no pods in your cluster require access to IMDS for other reasons, such as retrieving the current AWS Region. Then, you can also disable access to IMDSv2 for pods that don't use host networking. For more information, see Restrict access to the instance profile assigned to the worker node.

10. (Optional) On the Options page, tag your stack resources. Choose Next.

11. On the Review page, review your information, acknowledge that the stack might create IAM resources, and then choose Update stack.

**Note**
The update of each node in the cluster takes several minutes. Wait for the update of all nodes to complete before performing the next steps.

12. If your cluster's DNS provider is kube-dns, scale in the kube-dns deployment to one replica.

```
kubectl scale deployments/kube-dns --replicas=1 -n kube-system
```

13. (Optional) If you are using the Kubernetes Cluster Autoscaler, scale the deployment back to your desired amount of replicas.

```
kubectl scale deployments/cluster-autoscaler --replicas=1 -n kube-system
```

14. (Optional) Verify that you're using the latest version of the Amazon VPC CNI plugin for Kubernetes. You might need to update your CNI version to use the latest supported instance types. For more information, see Updating the Amazon VPC CNI self-managed add-on (p. 280).

## AWS Fargate

This topic discusses using Amazon EKS to run Kubernetes pods on AWS Fargate.

AWS Fargate is a technology that provides on-demand, right-sized compute capacity for containers. With AWS Fargate, you don't have to provision, configure, or scale groups of virtual machines on your own to run containers. You also don't need to choose server types, decide when to scale your node groups, or optimize cluster packing. You can control which pods start on Fargate and how they run with Fargate profiles (p. 157). Fargate profiles are defined as part of your Amazon EKS cluster.

Amazon EKS integrates Kubernetes with AWS Fargate by using controllers that are built by AWS using the upstream, extensible model provided by Kubernetes. These controllers run as part of the Amazon EKS managed Kubernetes control plane and are responsible for scheduling native Kubernetes pods onto Fargate. The Fargate controllers include a new scheduler that runs alongside the default Kubernetes scheduler in addition to several mutating and validating admission controllers. When you start a pod that meets the criteria for running on Fargate, the Fargate controllers that are running in the cluster recognize, update, and schedule the pod onto Fargate.

This topic describes the different components of pods that run on Fargate, and calls out special considerations for using Fargate with Amazon EKS.

## AWS Fargate considerations

Here are some things to consider about using Fargate on Amazon EKS.

- AWS Fargate with Amazon EKS is available in all Amazon EKS Regions except China (Beijing), China (Ningxia), AWS GovCloud (US-East), and AWS GovCloud (US-West).
• Each pod that runs on Fargate has its own isolation boundary. They don't share the underlying kernel, CPU resources, memory resources, or elastic network interface with another pod.

• Network Load Balancers and Application Load Balancers (ALBs) can be used with Fargate with IP targets only. For more information, see Create a network load balancer (p. 367) and Application load balancing on Amazon EKS (p. 371).

• Fargate exposed services only run on target type IP mode, and not on node IP mode. The recommended way to check the connectivity from a service running on a managed node and a service running on Fargate is to connect via service name.

• Pods must match a Fargate profile at the time that they're scheduled to run on Fargate. Pods that don't match a Fargate profile might be stuck as Pending. If a matching Fargate profile exists, you can delete pending pods that you have created to reschedule them onto Fargate.

• You can only use Security groups for pods (p. 307) with pods that run on Fargate that are part of a 1.18 or later cluster.

• Daemonsets aren't supported on Fargate. If your application requires a daemon, reconfigure that daemon to run as a sidecar container in your pods.

• Privileged containers aren't supported on Fargate.

• Pods running on Fargate can't specify HostPort or HostNetwork in the pod manifest.

• The default nofile and nproc soft limit is 1024 and the hard limit is 65535 for Fargate pods.

• GPUs aren't currently available on Fargate.

• Pods that run on Fargate are only supported on private subnets (with NAT gateway access to AWS services, but not a direct route to an Internet Gateway), so your cluster's VPC must have private subnets available. For clusters without outbound internet access, see Private clusters (p. 100).

• You can use the Vertical Pod Autoscaler (p. 359) to initially right size the CPU and memory for your Fargate pods, and then use the Horizontal Pod Autoscaler (p. 363) to scale those pods. If you want the Vertical Pod Autoscaler to automatically re-deploy pods to Fargate with larger CPU and memory combinations, set the mode for the Vertical Pod Autoscaler to either Auto or Recreate to ensure correct functionality. For more information, see the Vertical Pod Autoscaler documentation on GitHub.

• DNS resolution and DNS hostnames must be enabled for your VPC. For more information, see Viewing and updating DNS support for your VPC.

• Amazon EKS Fargate adds defense-in-depth for Kubernetes applications by isolating each Pod within a Virtual Machine (VM). This VM boundary prevents access to host-based resources used by other Pods in the event of a container escape, which is a common method of attacking containerized applications and gain access to resources outside of the container.

Using Amazon EKS doesn't change your responsibilities under the shared responsibility model (p. 429). You should carefully consider the configuration of cluster security and governance controls. The safest way to isolate an application is always to run it in a separate cluster.

• Fargate profiles support specifying subnets from VPC secondary CIDR blocks. You might want to specify a secondary CIDR block. This is because there's a limited number of IP addresses available in a subnet. As a result, there's also a limited number of pods that can be created in the cluster. By using different subnets for pods, you can increase the number of available IP addresses. For more information, see Adding IPv4 CIDR blocks to a VPC.

• The Amazon EC2 instance metadata service (IMDS) isn't available to pods that are deployed to Fargate nodes. If you have pods that are deployed to Fargate that need IAM credentials, assign them to your pods using IAM roles for service accounts (p. 461). If your pods need access to other information available through IMDS, then you must hard code this information into your pod spec. This includes the AWS Region or Availability Zone that a pod is deployed to.

• You can't deploy Fargate pods to AWS Outposts, AWS Wavelength or AWS Local Zones.

• Amazon EKS must periodically patch AWS Fargate pods to keep them secure. We attempt the updates in a way that reduces impact, but there are times when pods must be deleted if they aren't successfully evicted. There are some actions you can take to minimize disruption. For more information, see Fargate pod patching (p. 161).
Getting started with AWS Fargate using Amazon EKS

This topic helps you to get started running pods on AWS Fargate with your Amazon EKS cluster.

If you restrict access to the public endpoint of your cluster using CIDR blocks, we recommend that you also enable private endpoint access so that Fargate pods can communicate with the cluster. Without the private endpoint enabled, the CIDR blocks that you specify for public access must include the egress sources from your VPC. For more information, see Amazon EKS cluster endpoint access control (p. 45).

Prerequisite

An existing cluster. AWS Fargate with Amazon EKS is available in all Amazon EKS Regions except China (Beijing), China (Ningxia), AWS GovCloud (US-East), and AWS GovCloud (US-West). If you don't already have an Amazon EKS cluster, see Getting started with Amazon EKS (p. 4).

Ensure that existing nodes can communicate with Fargate pods

If you're working with a new cluster with no nodes, or a cluster with only managed node groups (p. 109), you can skip to Create a Fargate pod execution role (p. 154).

Assume that you're working with an existing cluster that already has nodes that are associated with it. You should make sure that pods on these nodes can communicate freely with pods running on Fargate. Pods running on Fargate are automatically configured to use the cluster security group for the cluster that they're associated with. Ensure that any existing nodes in your cluster can send and receive traffic to and from the cluster security group. Managed node groups (p. 109) are automatically configured to use the cluster security group as well, so you don't need to modify or check them for this compatibility.

For existing node groups that were created with eksctl or the Amazon EKS managed AWS CloudFormation templates, you can add the cluster security group to the nodes manually. Or, alternatively, you can modify the Auto Scaling group launch template for the node group to attach the cluster security group to the instances. For more information, see Changing an instance's security groups in the Amazon VPC User Guide.

You can check for a cluster security group for your cluster in the AWS Management Console under the Networking section for the cluster. Or, you can do this using the following AWS CLI command. When using this command, replace my-cluster with the name of your cluster.

```
aws eks describe-cluster --name my-cluster --query
cluster.resourcesVpcConfig.clusterSecurityGroupId
```

Create a Fargate pod execution role

When your cluster creates pods on AWS Fargate, the components that run on the Fargate infrastructure must make calls to AWS APIs on your behalf. The Amazon EKS pod execution role provides the IAM permissions to do this. To create an AWS Fargate pod execution role, see Amazon EKS pod execution IAM role (p. 455).

**Note**

If you created your cluster with eksctl using the --fargate option, then your cluster already has a pod execution role. Similarly, if you use eksctl to create your Fargate profiles, eksctl creates your pod execution role if one isn't already created.

Create a Fargate profile for your cluster

Before you can schedule pods running on Fargate in your cluster, you must define a Fargate profile that specifies which pods should use Fargate when they are launched. For more information, see AWS Fargate profile (p. 157).
Note
If you created your cluster with `eksctl` using the `--fargate` option, then a Fargate profile has already been created for your cluster with selectors for all pods in the `kube-system` and `default` namespaces. Use the following procedure to create Fargate profiles for any other namespaces you would like to use with Fargate.

You can create a Fargate profile using `eksctl` or the AWS Management Console.

This procedure requires `eksctl` version 0.92.0 or later. You can check your version with the following command:

```
eksctl version
```

For instructions on how to install or upgrade `eksctl`, see Installing or upgrading `eksctl` (p. 11).

To create a Fargate profile with `eksctl`

Create your Fargate profile with the following `eksctl` command, replacing every `example-value` with your own values. You're required to specify a namespace. However, the `--labels` option isn't required.

```
eksctl create fargateprofile \
  --cluster my-cluster \
  --name fargate_profile_name \
  --namespace kubernetes_namespace \
  --labels key=value
```

AWS Management Console

To create a Fargate profile for a cluster with the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster to create a Fargate profile for.
3. Under Fargate profiles, choose Add Fargate profile.
4. On the Configure Fargate Profile page, do the following:
   a. For Name, enter a unique name for your Fargate profile.
   b. For Pod execution role, choose the pod execution role to use with your Fargate profile. Only the IAM roles with the `eks-fargate-pods.amazonaws.com` service principal are shown. If you don't see any roles listed, you must create one. For more information, see Amazon EKS pod execution IAM role (p. 455).
   c. Choose the Subnets dropdown and deselect any subnet with Public in its name. Only private subnets are supported for pods running on Fargate.
   d. For Tags, you can optionally tag your Fargate profile. These tags don't propagate to other resources associated with the profile such as pods.
   e. Choose Next.
5. On the Configure pod selection page, do the following:
   a. For Namespace, enter a namespace to match for pods, such as `kube-system` or `default`.
   b. (Optional) Add Kubernetes labels to the selector that pods in the specified namespace must have to match the selector. For example, you can add the label `infrastructure: fargate` to the selector. This is so that only the pods in the specified namespace that also have the `infrastructure: fargate` Kubernetes label match the selector.
   c. Choose Next.
Amazon EKS User Guide
Getting started with Fargate

6.

On the Review and create page, review the information for your Fargate proﬁle and choose
Create.

Update CoreDNS
By default, CoreDNS is conﬁgured to run on Amazon EC2 infrastructure on Amazon EKS clusters. If you
want to only run your pods on Fargate in your cluster, complete the following steps.

Note

If you created your cluster with eksctl using the --fargate option, then you can skip to Next
steps (p. 156).
1.

Create a Fargate proﬁle for CoreDNS. Replace my-cluster with your cluster name , 111122223333
with your account ID, AmazonEKSFargatePodExecutionRole with the name of your pod
execution role, and 0000000000000001, 0000000000000002, and 0000000000000003 with the
IDs of your private subnets. If you don't have a pod execution role, you must create one (p. 154)
ﬁrst. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then
replace arn:aws: with arn:aws-us-gov: before running the following command.

Important

The role ARN can't include a path. The format of the role ARN must be
arn:aws:iam::111122223333:role/role-name. For more information, see aws-auth
ConﬁgMap does not grant access to the cluster (p. 517).
aws eks create-fargate-profile \
--fargate-profile-name coredns \
--cluster-name my-cluster \
--pod-execution-role-arn
arn:aws:iam::111122223333:role/AmazonEKSFargatePodExecutionRole \
--selectors namespace=kube-system,labels={k8s-app=kube-dns} \
--subnets subnet-0000000000000001 subnet-0000000000000002 subnet-0000000000000003

2.

Run the following command to remove the eks.amazonaws.com/compute-type : ec2
annotation from the CoreDNS pods.
kubectl patch deployment coredns \
-n kube-system \
--type json \
-p='[{"op": "remove", "path": "/spec/template/metadata/annotations/
eks.amazonaws.com~1compute-type"}]'

Next steps
• You can start migrating your existing applications to run on Fargate with the following workﬂow.
1. Create a Fargate proﬁle (p. 158) that matches your application's Kubernetes namespace and
Kubernetes labels.
2. Delete and re-create any existing pods so that they are scheduled on Fargate. For example, the
following command triggers a rollout of the coredns deployment. You can modify the namespace
and deployment type to update your speciﬁc pods.
kubectl rollout restart -n kube-system deployment coredns

• Deploy the Application load balancing on Amazon EKS (p. 371) to allow Ingress objects for your pods
running on Fargate.
• You can use the Vertical Pod Autoscaler (p. 359) to initially right size the CPU and memory for your
Fargate pods, and then use the Horizontal Pod Autoscaler (p. 363) to scale those pods. If you want

156


the Vertical Pod Autoscaler to automatically re-deploy pods to Fargate with larger CPU and memory combinations, set the Vertical Pod Autoscaler's mode to either Auto or Recreate. This is to ensure correct functionality. For more information, see the Vertical Pod Autoscaler documentation on GitHub.

- You can set up the AWS Distro for OpenTelemetry (ADOT) collector for application monitoring by following these instructions.

**AWS Fargate profile**

Before you can schedule pods on Fargate in your cluster, you must define at least one Fargate profile that specifies which pods use Fargate when launched.

The Fargate profile allows an administrator to declare which pods run on Fargate. This declaration is done through the profile's selectors. Each profile can have up to five selectors that contain a namespace and optional labels. You must define a namespace for every selector. The label field consists of multiple optional key-value pairs. Pods that match a selector (by matching a namespace for the selector and all of the labels specified in the selector) are scheduled on Fargate. If a namespace selector is defined without any labels, Amazon EKS attempts to schedule all pods that run in that namespace onto Fargate using the profile. If a to-be-scheduled pod matches any of the selectors in the Fargate profile, then that pod is scheduled on Fargate.

If a pod matches multiple Fargate profiles, Amazon EKS picks one of the matches at random. In this case, you can specify which profile a pod should use by adding the following Kubernetes label to the pod specification:

```
eks.amazonaws.com/fargate-profile: fargate_profile_name
```

However, the pod must still match a selector in that profile in order to be scheduled onto Fargate. Kubernetes affinity/anti-affinity rules aren't taken into consideration and are unnecessary with Amazon EKS Fargate pods.

When you create a Fargate profile, you must specify a pod execution role for the Amazon EKS components that run on the Fargate infrastructure using the profile. This role is added to the cluster's Kubernetes Role Based Access Control (RBAC) for authorization so that the kubelet that's running on the Fargate infrastructure can register with your Amazon EKS cluster and appear in your cluster as a node. The pod execution role also provides IAM permissions to the Fargate infrastructure to allow read access to Amazon ECR image repositories. For more information, see Amazon EKS pod execution IAM role (p. 455).

Fargate profiles are immutable. However, you can create a new updated profile to replace an existing profile and then delete the original after the updated profile has finished creating.

**Note**

Any pods that are running using a Fargate profile will be stopped and put into pending when the profile is deleted.

If any Fargate profiles in a cluster are in the **DELETING** status, you must wait for that Fargate profile to finish deleting before you can create any other profiles in that cluster.

Amazon EKS and Fargate try to spread pods across each of the subnets defined in the Fargate profile, but you may end up with an uneven spread. If you must have an even spread (such as when deploying two replicas without any downtime), then you need to use two Fargate profiles. Each profile should have only one subnet.

**Fargate profile components**

The following components are contained in a Fargate profile.

- **Pod execution role** – When your cluster creates pods on AWS Fargate, the kubelet that's running on the Fargate infrastructure must make calls to AWS APIs on your behalf. This is, for example, to pull container images from Amazon ECR. The Amazon EKS pod execution role provides the IAM permissions to do this.
When you create a Fargate profile, you must specify a pod execution role to use with your pods. This role is added to the cluster’s Kubernetes Role Based Access Control (RBAC) for authorization. This is so that the kubelet that’s running on the Fargate infrastructure can register with your Amazon EKS cluster and appear in your cluster as a node. For more information, see Amazon EKS pod execution IAM role (p. 455).

- **Subnets** – The IDs of subnets to launch pods into that use this profile. At this time, pods that are running on Fargate aren’t assigned public IP addresses. Therefore, only private subnets (with no direct route to an Internet Gateway) are accepted for this parameter.
- **Selectors** – The selectors to match for pods to use this Fargate profile. Each selector must have an associated namespace. Optionally, you can also specify labels for a namespace. You may specify up to five selectors in a Fargate profile. A pod only must match one selector to run using the Fargate profile.
- **Namespace** – You must specify a namespace for a selector. The selector only matches pods that are created in this namespace, but you can create multiple selectors to target multiple namespaces.
- **Labels** – You can optionally specify Kubernetes labels to match for the selector. The selector only matches pods that have all of the labels that are specified in the selector.

### Creating a Fargate profile

This topic helps you to create a Fargate profile. AWS Fargate with Amazon EKS is available in all Amazon EKS Regions except China (Beijing), China (Ningxia), AWS GovCloud (US-East), and AWS GovCloud (US-West). You also must have created a pod execution role to use for your Fargate profile. For more information, see Amazon EKS pod execution IAM role (p. 455). Pods that are running on Fargate are only supported on private subnets (with NAT gateway access to AWS services, but not a direct route to an Internet Gateway), so your cluster’s VPC must have private subnets available. You can create a profile with eksctl or the AWS Management Console. Select the tab with the name of the tool that you want to create your Fargate profile with.

This procedure requires eksctl version 0.92.0 or later. You can check your version with the following command:

```
eksctl version
```

For instructions on how to install or upgrade eksctl, see Installing or upgrading eksctl (p. 11).

eksctl

**To create a Fargate profile with eksctl**

Create your Fargate profile with the following eksctl command, replacing every `example-value` with your own values. You’re required to specify a namespace. However, the `--labels` option isn’t required.

```
eksctl create fargateprofile \
  --cluster my-cluster \
  --name fargate_profile_name \
  --namespace kubernetes_namespace \
  --labels key=value
```

AWS Management Console

**To create a Fargate profile for a cluster with the AWS Management Console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster to create a Fargate profile for.
3. Choose the Configuration tab.
4. Choose the Compute tab.
5. Under Fargate Profiles, choose Add Fargate Profile.
6. On the Configure Fargate Profile page, do the following:
   a. For Name, enter a unique name for your Fargate profile, such as my-profile.
   b. For Pod execution role, choose the pod execution role to use with your Fargate profile. Only the IAM roles with the eks-fargate-pods.amazonaws.com service principal are shown. If you don’t see any roles listed, you must create one. For more information, see Amazon EKS pod execution IAM role (p. 455).
   c. Choose the Subnets dropdown and deselect any subnet with Public in its name. Only private subnets are supported for pods that are running on Fargate.
   d. For Tags, you can optionally tag your Fargate profile. These tags don’t propagate to other resources associated with the profile, such as pods.
   e. Choose Next.
7. On the Configure pod selection page, do the following:
   a. For Namespace, enter a namespace to match for pods, such as kube-system or default.
   b. (Optional) Add Kubernetes labels to the selector. Specifically add them to the one that the pods in the specified namespace need to match. For example, you could add the label infrastructure: fargate to the selector so that only pods in the specified namespace that also have the infrastructure: fargate Kubernetes label match the selector.
   c. Choose Next.
8. On the Review and create page, review the information for your Fargate profile and choose Create.

Deleting a Fargate profile

This topic helps you to delete a Fargate profile.

When you delete a Fargate profile, any pods that were scheduled onto Fargate with the profile are deleted. If those pods match another Fargate profile, then they are scheduled on Fargate with that profile. If they no longer match any Fargate profiles, then they aren’t scheduled onto Fargate and may remain as pending.

Only one Fargate profile in a cluster can be in the DELETING status at a time. Wait for a Fargate profile to finish deleting before you can delete any other profiles in that cluster.

You can delete a profile with eksctl, the AWS Management Console, or the AWS CLI. Select the tab with the name of the tool that you want to use to delete your profile.

eksctl

To delete a Fargate profile with eksctl

Use the following command to delete a profile from a cluster. Replace every example-value with your own values.

```bash
eksctl delete fargateprofile --name my-profile --cluster my-cluster
```

AWS Management Console

To delete a Fargate profile from a cluster with the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Amazon EKS Clusters. In the list of clusters, choose the cluster that you want to delete the Fargate profile from.

3. Choose the Configuration tab, and then choose the Compute tab.

4. Choose the Fargate profile to delete, and then choose Delete.

5. On the Delete Fargate Profile page, type the name of the profile and then choose Delete.

AWS CLI

To delete a Fargate profile with AWS CLI

Use the following command to delete a profile from a cluster. Replace every example-value with your own values.

```
aws eks delete-fargate-profile --fargate-profile-name my-profile --cluster-name my-cluster
```

Fargate pod configuration

This section describes some of the unique pod configuration details for running Kubernetes pods on AWS Fargate.

Pod CPU and memory

With Kubernetes, you can define requests, a minimum vCPU amount, and memory resources that are allocated to each container in a pod. Pods are scheduled by Kubernetes to ensure that at least the requested resources for each pod are available on the compute resource. For more information, see Managing compute resources for containers in the Kubernetes documentation.

**Note**

Since Amazon EKS Fargate runs only one pod per node, the scenario of evicting pods in case of fewer resources doesn't occur. All Amazon EKS Fargate pods run with guaranteed priority, so the requested CPU and memory must be equal to the limit for all of the containers. For more information, see Configure Quality of Service for Pods in the Kubernetes documentation.

When pods are scheduled on Fargate, the vCPU and memory reservations within the pod specification determine how much CPU and memory to provision for the pod.

- The maximum request out of any Init containers is used to determine the Init request vCPU and memory requirements.
- Requests for all long-running containers are added up to determine the long-running request vCPU and memory requirements.
- The larger of the above two values is chosen for the vCPU and memory request to use for your pod.
- Fargate adds 256 MB to each pod's memory reservation for the required Kubernetes components (kubelet, kube-proxy, and containerd).

Fargate rounds up to the compute configuration shown below that most closely matches the sum of vCPU and memory requests in order to ensure pods always have the resources that they need to run.

If you don't specify a vCPU and memory combination, then the smallest available combination is used (.25 vCPU and 0.5 GB memory).

The following table shows the vCPU and memory combinations that are available for pods running on Fargate.
**vCPU value** | **Memory value**
---|---
.25 vCPU | 0.5 GB, 1 GB, 2 GB
.5 vCPU | 1 GB, 2 GB, 3 GB, 4 GB
1 vCPU | 2 GB, 3 GB, 4 GB, 5 GB, 6 GB, 7 GB, 8 GB
2 vCPU | Between 4 GB and 16 GB in 1-GB increments
4 vCPU | Between 8 GB and 30 GB in 1-GB increments

The additional memory reserved for the Kubernetes components can cause a Fargate task with more vCPUs than requested to be provisioned. For example, a request for 1 vCPU and 8 GB memory will have 256 MB added to its memory request, and will provision a Fargate task with 2 vCPUs and 9 GB memory, since no task with 1 vCPU and 9 GB memory is available.

There is no correlation between the size of the pod running on Fargate and the node size reported by Kubernetes with `kubectl get nodes`. The reported node size is often larger than the pod's capacity. You can verify pod capacity with the following command. Replace `pod-name` with the name of your pod.

```
kubectl describe pod pod-name
```

Example output:

```
... annotations:
  CapacityProvisioned: 0.25vCPU 0.5GB
...
```

The `CapacityProvisioned` annotation represents the enforced pod capacity and it determines the cost of your pod running on Fargate. For pricing information for the compute configurations, see [AWS Fargate Pricing](https://aws.amazon.com/fargate/pricing/).

**Fargate storage**

When provisioned, each pod running on Fargate receives 20 GB of container image layer storage. Pod storage is ephemeral. After a pod stops, the storage is deleted. New pods launched onto Fargate on or after May 28, 2020, have encryption of the ephemeral storage volume enabled by default. The ephemeral pod storage is encrypted with an AES-256 encryption algorithm using AWS Fargate managed keys.

**Note**

The usable storage for Amazon EKS pods that run on Fargate is less than 20 GB because some space is used by the `kubelet` and other Kubernetes modules that are loaded inside the pod.

**Fargate pod patching**

Amazon EKS must periodically patch AWS Fargate pods to keep them secure. Updates are attempted in a way that creates the least impact on your services. However, if pods aren't successfully evicted, there are times when they must be deleted. The following are actions that you can take to minimize potential disruptions:

- Set appropriate pod disruption budgets (PDBs) to control the number of pods that are down simultaneously.
- Create event rules to react to failed evictions before the pods are deleted.
Amazon EKS works closely with the Kubernetes community to make bug fixes and security patches available as quickly as possible. New patch versions of Kubernetes are made available as part of Fargate platform versions. All Fargate pods start on the most recent Kubernetes patch version, which is available from Amazon EKS for the Kubernetes version of your cluster. If you have a pod with an older patch version, Amazon EKS might restart it to update it to the latest version. This ensures that your pods are equipped with the latest security updates. That way, if there's a critical Common Vulnerabilities and Exposures (CVE) issue, you're kept up to date to reduce security risks.

To limit the number of pods that are down at one time when pods are patched, you can set pod disruption budgets (PDBs). You can use PDBs to define minimum availability based on the requirements of each of your applications while still allowing updates to occur. For more information, see Specifying a Disruption Budget for your Application in the Kubernetes Documentation.

Amazon EKS uses the Eviction API to safely drain the pod while respecting the PDBs that you set for the application. Pods are evicted by Availability Zone to minimize impact. If the eviction succeeds, the new pod gets the latest patch and no further action is required.

When the eviction for a pod fails, Amazon EKS sends an event to your account with details about the pods that failed eviction. You can act on the message before the scheduled termination time. The specific time varies based on the urgency of the patch. When it's time, Amazon EKS attempts to evict the pods again. However, this time a new event isn't sent if the eviction fails. If the eviction fails again, your existing pods are deleted periodically so that the new pods can have the latest patch.

The following is a sample event received when the pod eviction fails. It contains details about the cluster, pod name, pod namespace, Fargate profile, and the scheduled termination time.

```json
{
    "version": "0",
    "id": "4c23a083-4d22-bd5b-a63f-75bc72df0062",
    "detail-type": "EKS Fargate Pod Scheduled Termination",
    "source": "aws.eks",
    "account": "619145827942",
    "time": "2021-06-27T12:52:44Z",
    "region": "us-east-1",
    "resources": [
        "default/database-deployment-8476fcc669-4s9jx"
    ],
    "detail": {
        "clusterName": "pdb-cluster",
        "fargateProfileName": "pdb-fargate-profile",
        "podName": "pdb-deployment-8476fcc669-4s9jx",
        "podNamespace": "default",
        "evictErrorMessage": "Cannot evict pod as it would violate the pod's disruption budget",
        "scheduledTerminationTime": "2021-06-30T12:52:44.832Z[UTC]"
    }
}
```

In addition, having multiple PDBs associated with a pod can cause an eviction failure event. This event returns the following error message.

```
"evictErrorMessage": "This pod has multiple PodDisruptionBudget, which the eviction subresource does not support",
```

You can create a desired action based on this event. For example, you can adjust your pod disruption budget (PDB) to control how the pods are evicted. More specifically, suppose that you start with a PDB that specifies the target percentage of pods that are available. Before your pods are force terminated during an upgrade, you can adjust the PDB to a different percentage of pods. To receive this event, you must create an Amazon EventBridge rule in the AWS account and Region that the cluster belongs to. The
rule must use the following **Custom pattern**. For more information, see Creating Amazon EventBridge rules that react to events in the *Amazon EventBridge User Guide*.

```json
{
  "source": ["aws.eks"],
  "detail-type": ["EKS Fargate Pod Scheduled Termination"]
}
```

A suitable target can be set for the event to capture it. For a complete list of available targets, see Amazon EventBridge targets in the *Amazon EventBridge User Guide*.

**Fargate metrics**

**Application metrics**

For applications running on Amazon EKS and AWS Fargate, you can use the AWS Distro for OpenTelemetry (ADOT). ADOT allows you to collect system metrics and send them to CloudWatch Container Insights dashboards. To get started with ADOT for applications running on Fargate, see Using CloudWatch Container Insights with AWS Distro for OpenTelemetry in the ADOT documentation.

**Usage metrics**

You can use CloudWatch usage metrics to provide visibility into your account's usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

AWS Fargate usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about Fargate service quotas, see Amazon EKS service quotas (p. 426).

AWS Fargate publishes the following metrics in the `AWS/Usage` namespace.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourceCount</td>
<td>The total number of the specified resource running on your account. The resource is defined by the dimensions associated with the metric.</td>
</tr>
</tbody>
</table>

The following dimensions are used to refine the usage metrics that are published by AWS Fargate.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service</td>
<td>The name of the AWS service containing the resource. For AWS Fargate usage metrics, the value for this dimension is Fargate.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of entity that's being reported. Currently, the only valid value for AWS Fargate usage metrics is Resource.</td>
</tr>
</tbody>
</table>
| Resource  | The type of resource that's running. Currently, AWS Fargate returns information on your Fargate On-Demand usage. The resource value for Fargate On-Demand usage is OnDemand. **Note** Fargate On-Demand usage combines Amazon EKS pods using Fargate, Amazon ECS tasks using the Fargate launch
### Fargate logging

Amazon EKS on Fargate offers a built-in log router based on Fluent Bit. This means that you don't explicitly run a Fluent Bit container as a sidecar, but Amazon runs it for you. All that you have to do is configure the log router. The configuration happens through a dedicated ConfigMap that must meet the following criteria:

- **Named**: `aws-logging`
- **Created in a dedicated namespace called**: `aws-observability`

Once you've created the ConfigMap, Amazon EKS on Fargate automatically detects it and configures the log router with it. Fargate uses a version of AWS for Fluent Bit, an upstream compliant distribution of Fluent Bit managed by AWS. For more information, see [AWS for Fluent Bit on GitHub](https://github.com/aws/aws-fluent-bit).

The log router allows you to use the breadth of services at AWS for log analytics and storage. You can stream logs from Fargate directly to Amazon CloudWatch, Amazon OpenSearch Service. You can also stream logs to destinations such as Amazon S3, Amazon Kinesis Data Streams, and partner tools through Amazon Kinesis Data Firehose.

### Prerequisites

- An existing Fargate profile that specifies an existing Kubernetes namespace that you deploy Fargate pods to. For more information, see Create a Fargate profile for your cluster (p. 154).
- An existing Fargate pod execution role. For more information, see Create a Fargate pod execution role (p. 154).

---

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type and Amazon ECS tasks using the FARGATE capacity provider.</td>
<td></td>
</tr>
<tr>
<td>Class</td>
<td>The class of resource being tracked. Currently, AWS Fargate doesn't use the class dimension.</td>
</tr>
</tbody>
</table>
Log router configuration

To configure the log router

In the following steps, replace every `example-value` with your own values.

1. Create a dedicated Kubernetes namespace named `aws-observability`.
   a. Save the following contents to a file named `aws-observability-namespace.yaml` on your computer. The value for `name` must be `aws-observability` and the `aws-observability: enabled` label is required.

   ```yaml
   kind: Namespace
   apiVersion: v1
   metadata:
     name: aws-observability
     labels:
       aws-observability: enabled
   ```
   b. Create the namespace.

   ```bash
   kubectl apply -f aws-observability-namespace.yaml
   ```

2. Create a ConfigMap with a Fluent Conf data value to ship container logs to a destination. Fluent Conf is Fluent Bit, which is a fast and lightweight log processor configuration language that’s used to route container logs to a log destination of your choice. For more information, see Configuration File in the Fluent Bit documentation.

   **Important**
   
   The main sections included in a typical Fluent Conf are Service, Input, Filter, and Output. The Fargate log router however, only accepts:
   
   - The Filter and Output sections and manages the Service and Input sections itself.
   - A Parser section.

   If you provide any sections other than Filter, Output, and Parser, the sections are rejected.

When creating the ConfigMap, take into account the following rules that Fargate uses to validate fields:

- `[FILTER], [OUTPUT], and [PARSER] are supposed to be specified under each corresponding key. For example, [FILTER] must be under `filters.conf`. You can have one or more [FILTER]s under `filters.conf`. The [OUTPUT] and [PARSER] sections should also be under their corresponding keys. By specifying multiple [OUTPUT] sections, you can route your logs to different destinations at the same time.
- Fargate validates the required keys for each section. Name and match are required for each [FILTER] and [OUTPUT]. Name and format are required for each [PARSER]. The keys are case-insensitive.
- Environment variables such as `${ENV_VAR}` aren't allowed in the ConfigMap.
- The indentation has to be the same for either directive or key-value pair within each `filters.conf`, `output.conf`, and `parsers.conf`. Key-value pairs have to be indented more than directives.
- Fargate validates against the following supported filters: `grep`, `parser`, `record_modifier`, `rewrite_tag`, `throttle`, `nest`, `modify`, and `kubernetes`.
- Fargate validates against the following supported output: `es`, `firehose`, `kinesis_firehose`, `cloudwatch`, `cloudwatch_logs`, `kinesis`, and `kubernetes`. 
• At least one supported Output plugin has to be provided in the ConfigMap to enable logging. Filter and Parser aren't required to enable logging.

You can also run Fluent Bit on Amazon EC2 using the desired configuration to troubleshoot any issues that arise from validation. Create your ConfigMap using one of the following examples.

Important
Amazon EKS Fargate logging doesn't support dynamic configuration of ConfigMaps. Any changes to ConfigMaps are applied to new pods only. Changes aren't applied to existing pods.

Create a ConfigMap using the example for your desired log destination.

CloudWatch

To create a ConfigMap for CloudWatch

You have two output options when using CloudWatch:

• An output plugin written in C
• An output plugin written in Golang

The following example shows you how to use the cloudwatch_logs plugin to send logs to CloudWatch.

1. Save the following contents to a file named aws-logging-cloudwatch-configmap.yaml. Replace region-code with the AWS Region that your cluster is in. The parameters under [OUTPUT] are required.

```yaml
kind: ConfigMap
apiVersion: v1
metadata:
  name: aws-logging
  namespace: aws-observability
data:
  output.conf: |
  [OUTPUT]
  Name cloudwatch_logs
  Match *
  region region-code
  log_group_name fluent-bit-cloudwatch
  log_stream_prefix from-fluent-bit-
  auto_create_group true
  log_key log

  parsers.conf: |
  [PARSER]
  Name crio
  Format Regex
  Regex ^(?<time>[^ ]+) (?<stream>stdout|stderr) (?<logtag>P|F) (?<log>.*)$
  Time_Key    time
  Time_Format %Y-%m-%dT%H:%M:%S.%L%z

  filters.conf: |
  [FILTER]
  Name parser
  Match *
  Key_name log
  Parser crio
```
2. Apply the manifest to your cluster.

```bash
kubectl apply -f aws-logging-cloudwatch-configmap.yaml
```

3. Download the CloudWatch IAM policy to your computer. You can also view the policy on GitHub.

```bash
curl -o permissions.json https://raw.githubusercontent.com/aws-samples/amazon-eks-fluent-logging-examples/mainline/examples/fargate/cloudwatchlogs/permissions.json
```

**Amazon OpenSearch Service**

**To create a ConfigMap for Amazon OpenSearch Service**

If you want to send logs to Amazon OpenSearch Service, you can use `es` output, which is a plugin written in C. The following example shows you how to use the plugin to send logs to OpenSearch.

1. Save the following contents to a file named `aws-logging-opensearch-configmap.yaml`. Replace every `example-value` with your own values.

```yaml
kind: ConfigMap
apiVersion: v1
metadata:
  name: aws-logging
  namespace: aws-observability
data:
  output.conf: |
      [OUTPUT]
      Name es
      Match *
      Host search-example-gjxdcilagiprbglqn42jst66y.region-code.es.amazonaws.com
      Port 443
      Index example
      Type example_type
      AWS_Auth On
      AWS_Region region-code
      tls On

2. Apply the manifest to your cluster.

```bash
kubectl apply -f aws-logging-opensearch-configmap.yaml
```

3. Download the OpenSearch IAM policy to your computer. You can also view the policy on GitHub.

```bash
curl -o permissions.json https://raw.githubusercontent.com/aws-samples/amazon-eks-fluent-logging-examples/mainline/examples/fargate/amazon-elasticsearch/permissions.json
```

Make sure that OpenSearch Dashboards' access control is configured properly. The `all_access` role in OpenSearch Dashboards needs to have the Fargate pod execution role and the IAM role mapped. The same mapping must be done for the `security_manager` role. You can add the previous mappings by selecting **Menu**, then **Security**, then **Roles**, and then select the respective roles. For more information, see How do I troubleshoot CloudWatch Logs so that it streams to my Amazon ES domain?
Kinesis Data Firehose

To create a ConfigMap for Kinesis Data Firehose

You have two output options when sending logs to Kinesis Data Firehose:

- **kinesis_firehose** – An output plugin written in C.
- **firehose** – An output plugin written in Golang.

The following example shows you how to use the `kinesis_firehose` plugin to send logs to Kinesis Data Firehose.

1. Save the following contents to a file named `aws-logging-firehose-configmap.yaml`. Replace `region-code` with the AWS Region that your cluster is in.

```yaml
kind: ConfigMap
apiVersion: v1
metadata:
  name: aws-logging
  namespace: aws-observability
data:
  output.conf: |
    [OUTPUT]
    Name  kinesis_firehose
    Match *
    region region-code
    delivery_stream my-stream-firehose
```

2. Apply the manifest to your cluster.

```
kubectl apply -f aws-logging-firehose-configmap.yaml
```

3. Download the Kinesis Data Firehose IAM policy to your computer. You can also view the policy on GitHub.

```
```

3. Create an IAM policy from the policy file you downloaded in a previous step.

```
aws iam create-policy --policy-name eks-fargate-logging-policy --policy-document file://permissions.json
```

4. Attach the IAM policy to the pod execution role specified for your Fargate profile. Replace `111122223333` with your account ID. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:` before running the following command.

```
aws iam attach-role-policy
  --policy-arn arn:aws:iam::111122223333:policy/eks-fargate-logging-policy
  --role-name your-pod-execution-role
```
Kubernetes filter support

This feature requires the following minimum Kubernetes version and platform level, or later. Any Kubernetes and platform versions later than those listed in the table are supported.

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Platform level</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.21</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.20</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.19</td>
<td>eks.7</td>
</tr>
<tr>
<td>1.18</td>
<td>eks.9</td>
</tr>
<tr>
<td>1.17</td>
<td>eks.10</td>
</tr>
</tbody>
</table>

The Fluent Bit Kubernetes filter allows you to add Kubernetes metadata to your log files. For more information about the filter, see Kubernetes in the Fluent Bit documentation. You can apply a filter using the API server endpoint.

```
filters.conf: |
[FILTER]         kubernetes
    Name            kube.*
    Merge_Log       On
    Buffer_Size     0
    Kube_Meta_Cache_TTL 300s
```

**Important**

- Kube_URL, Kube_CA_File, Kube_Token_Command, and Kube_Token_File are service owned configuration parameters and must not be specified. Amazon EKS Fargate populates these values.
- Kube_Meta_Cache_TTL is the time Fluent Bit waits until it communicates with the API server for the latest metadata. If Kube_Meta_Cache_TTL isn't specified then Amazon EKS Fargate appends a default value of 30 minutes to lessen the load on the API server, since Fluent Bit communicates with the API server to get the latest metadata.

**To ship Fluent-bit process logs to your account**

You can ship Fluent Bit process logs to Amazon CloudWatch using the following ConfigMap. Replace region-code with the AWS Region that your cluster is in.

```
kind: ConfigMap
apiVersion: v1
metadata:
    name: aws-logging
    namespace: aws-observability
    labels:
data:
    flb_log_cw: "true" #ships fluent-bit process logs to CloudWatch
output.conf: |
    [OUTPUT]
```
The logs are in the AWS Region that the cluster resides in under CloudWatch. The log group name is `my-cluster-fluent-bit-logs` and the Fluent Bit logstream name is `fluent-bit-podname-pod-namespace`.

**Note**

- The process logs are shipped only when the Fluent Bit process successfully starts. If there is a failure while starting Fluent Bit, the process logs are missed. You can only ship process logs to CloudWatch.
- To debug shipping process logs to your account, you can apply the previous ConfigMap to get the process logs. Fluent Bit failing to start is usually due to your ConfigMap not being parsed or accepted by Fluent Bit while starting.

**Test application**

1. Deploy a sample pod.
   a. Save the following contents to a file named `sample-app.yaml` on your computer.

```
apiVersion: apps/v1
kind: Deployment
metadata:
  name: sample-app
  namespace: same-namespace-as-your-fargate-profile
spec:
  replicas: 3
  selector:
    matchLabels:
      app: nginx
  template:
    metadata:
      labels:
        app: nginx
    spec:
      containers:
        - name: nginx
          image: nginx:latest
          ports:
            - name: http
              containerPort: 80
```

   b. Apply the manifest to the cluster.

```
kubectl apply -f sample-app.yaml
```

2. View the NGINX logs using the destination(s) that you configured in the ConfigMap.

**Size considerations**

We suggest that you plan for up to 50 MB of memory for the log router. If you expect your application to generate logs at very high throughput then you should plan for up to 100 MB.
Troubleshooting

To confirm whether the logging feature is enabled or disabled for some reason, such as an invalid ConfigMap, and why it's invalid, check your pod events with `kubectl describe pod pod_name`. The output might include pod events that clarify whether logging is enabled or not, such as the following example output.

```
... Annotations:          CapacityProvisioned: 0.25vCPU 0.5GB
                    Logging: LoggingDisabled: LOGGING_CONFIGMAP_NOT_FOUND
                    kubernetes.io/psp: eks.privileged
... Events:
   Type     Reason           Age       From                          Message
   ----     ------           ----       ----                          -------
   Warning  LoggingDisabled <unknown> fargate-scheduler
                      Disabled logging because aws-logging configmap was not found. configmap "aws-logging" not found
```

The pod events are ephemeral with a time period depending on the settings. You can also view a pod's annotations using `kubectl describe pod pod-name`. In the pod annotation, there is information about whether the logging feature is enabled or disabled and the reason.

Choosing an Amazon EC2 instance type

Each Amazon EC2 instance type offers different compute, memory, storage, and network capabilities, and is grouped in an instance family based on these capabilities.

Consider the following criteria before choosing an instance type for a node group.

- **Number of instances in a node group** – In general, fewer, larger instances are better, especially if you have a lot of Daemonsets. Each instance requires API calls to the API server, so the more instances you have, the more load on the API server.

- **Operating system** – Review the supported instance types for Linux, Windows, and Bottlerocket. Before creating Windows instances, review the section called “Windows support” (p. 90).

- **Hardware architecture** – Do you need x86 or Arm? You can only deploy Linux on Arm. Before deploying Arm instances, review the section called “Arm” (p. 184). Do you need instances built on the Nitro System (Linux or Windows) or that have Accelerated capabilities? If you need accelerated capabilities, you can only use Linux with Amazon EKS.

- **Maximum number of pods** – Since each pod is assigned its own IP address, the number of IP addresses supported by an instance type is a factor in determining the number of pods that can run on the instance. AWS Nitro System instance types optionally support significantly more IP addresses than non Nitro System instance types. Not all IP addresses assigned for an instance are available to pods however. To determine how many pods an instance type supports, see Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 172). To assign a significantly larger number of IP addresses to your instances, you must have version 1.9.0 or later of the Amazon VPC CNI add-on installed in your cluster and configured appropriately. For more information, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 303). To assign the largest number of IP addresses to your instances, you must have version 1.10.1 or later of the Amazon VPC CNI add-on installed in your 1.21 or later cluster and deploy the cluster with the IPv6 family.

- **IP family** – You can use any supported instance type when using the IPv4 family for a cluster, which allows your cluster to assign private IPv4 addresses to your pods and Services, but if you want to use the IPv6 family for your cluster, then you must use AWS Nitro System instance types that run Linux. Only IPv4 is supported for Windows instances. Your cluster must be a new 1.21 or later cluster running...
Maximum pods

version 1.10.1 or later of the Amazon VPC CNI add-on. For more information about using IPv6, see Assigning IPv6 addresses to pods and services (p. 288).

- **Version of the Amazon VPC CNI add-on that you're running** – The latest version of the Amazon VPC CNI plugin for Kubernetes supports these instance types. You may need to update your Amazon VPC CNI add-on version to take advantage of the latest supported instance types. For more information, see the section called “Updating the self-managed add-on” (p. 280). The latest version supports the latest features for use with Amazon EKS. Earlier versions don't support all features. You can view features supported by different versions in the Changelog on GitHub.

- **AWS Region that you're creating your nodes in** – Not all instance types are available in all AWS Regions.

- **Whether you're using security groups for pods** – If you're using security groups for Pods, only specific instance types are supported. For more information, see Security groups for pods (p. 307).

### Amazon EKS recommended maximum pods for each Amazon EC2 instance type

Amazon EKS provides a script that you can download and run to determine the Amazon EKS recommended maximum number of pods to run on each instance type. The script uses hardware attributes of each instance, and configuration options, to determine the maximum pods number. You can use the number returned in these steps to enable capabilities such as assigning IP addresses to pods from a different subnet than the instance's (p. 300) and significantly increasing the number of IP addresses for your instance (p. 303). If you're using a managed node group with multiple instance types, use a value that would work for all instance types.

1. Download a script that you can use to calculate the maximum number of pods for each instance type.

   ```
   ```

2. Mark the script as executable on your computer.

   ```
   chmod +x max-pods-calculator.sh
   ```

3. Run the script, replacing `m5.large` with the instance type that you plan to deploy and `1.9.0-eksbuild.1` with your Amazon VPC CNI add-on version. For a list of some possible instance types, see eni-max-pods.txt on GitHub. To determine your add-on version, see the update procedures in Managing the Amazon VPC CNI add-on (p. 275).

   ```
   ./max-pods-calculator.sh --instance-type m5.large --cni-version 1.9.0-eksbuild.1
   ```

   Example output:

   29

You can add the following options to the script to see the maximum pods supported when using optional capabilities.

- **--cni-custom-networking-enabled** – Use this option when you want to assign IP addresses from a different subnet than your instance's. For more information, see the section called “CNI custom networking” (p. 300). Adding this option to the previous script with the same example values yields 20.

- **--cni-prefix-delegation-enabled** – Use this option when you want to assign significantly more IP addresses to each elastic network interface. This capability requires an Amazon Linux
instance that run on the Nitro System and version 1.9.0 or later of the Amazon VPC CNI add-on. For more information, see the section called "Increase available IP addresses" (p. 303). Adding this option to the previous script with the same example values yields 110.

You can also run the script with the --help option to see all available options.

Amazon EKS optimized AMIs

You can deploy nodes with pre-built Amazon EKS optimized Amazon Machine Images (AMI), or your own custom AMIs. For more information about each type of Amazon EKS optimized AMI, see one of the following topics. For instructions on how to create your own custom AMI, see Amazon EKS optimized Amazon Linux AMI build script (p. 201).

Topics
- Amazon EKS is ending support for Dockershim (p. 173)
- Amazon EKS optimized Amazon Linux AMIs (p. 174)
- Amazon EKS optimized Ubuntu Linux AMIs (p. 202)
- Amazon EKS optimized Bottlerocket AMIs (p. 203)
- Amazon EKS optimized Windows AMIs (p. 208)

Amazon EKS is ending support for Dockershim

Kubernetes no longer supports Dockershim. Additionally, the Kubernetes team plans to completely remove the runtime in Kubernetes version 1.24. Amazon EKS is ending support for Dockershim starting with the Kubernetes version 1.23 launch. Amazon EKS AMIs that are officially published will have containerd as the only runtime starting with version 1.23. This is targeted for end of the second quarter of 2022.

There's a kubectl plugin you can use to see which of your Kubernetes workloads are mounting the Docker socket volume. For more information, see Detector for Docker Socket (DDS) on GitHub. Amazon EKS AMIs that run Kubernetes version 1.17 through 1.21 use Docker as the default runtime, but have a bootstrap flag option that you can use to test out your workloads on any supported cluster today with containerd. For more information, see Enable the containerd runtime bootstrap flag (p. 182).

We will continue to publish AMIs for existing Kubernetes versions until the end of their support date. For more information, see Amazon EKS Kubernetes release calendar (p. 72). If you require more time to test your workloads on containerd, you can stay on a supported version before 1.23 and still be fully supported. But, when version 1.23 is made available and you want to upgrade official Amazon EKS AMIs to that version or higher, make sure to validate that your workloads run on containerd.

If you will be upgrading to version 1.23 or higher but you still want to use Dockershim, build your own AMI with Docker installed. However, when Kubernetes removes Dockershim support, make sure that you migrate to containerd to remain on a supported version. For more information, see Kubernetes is Moving on From Dockershim: Commitments and Next Steps on the Kubernetes Blog.

The containerd runtime provides more reliable performance and security, and it's the runtime we're standardizing on across Amazon EKS (Fargate and Bottlerocket already use containerd only). containerd helps to minimize the number of Amazon EKS AMI releases that are required to address Dockershim Common Vulnerabilities and Exposures (CVES). As Dockershim already uses containerd internally, you might not need to make any changes. However, there are some situations where changes might or must be required:
• You must make changes for any application that mounts the Docker socket. For example, building container images using a container are impacted. Many monitoring tools also mount the Docker socket. You may have to wait for updates or re-deploy workloads for runtime monitoring.
• You might need to make changes for any application that’s reliant on specific Docker settings. For example, using \texttt{HTTPS\_PROXY} can require changes. For more information, see dockerd in the Docker Docs.
• If you’re using the Amazon ECR credential helper to pull images, you must switch to the kubelet image credential provider. For more information, see Configure a kubelet image credential provider in the Kubernetes documentation.

Amazon EKS optimized Amazon Linux AMIs

The Amazon EKS optimized Amazon Linux AMI is built on top of Amazon Linux 2, and is configured to serve as the base image for Amazon EKS nodes. The AMI is configured to work with Amazon EKS and it includes Docker, kubelet, and the AWS IAM Authenticator.

\textbf{Note}

• You can track security or privacy events for Amazon Linux 2 at the Amazon Linux security center or subscribe to the associated RSS feed. Security and privacy events include an overview of the issue, what packages are affected, and how to update your instances to correct the issue.
• Before deploying an accelerated or Arm AMI, review the information in Amazon EKS optimized accelerated Amazon Linux AMIs (p. 183) and Amazon EKS optimized Arm Amazon Linux AMIs (p. 184).
• Amazon EKS optimized Amazon Linux 2 contains an optional bootstrap flag to enable the containerd runtime. This feature provides a clear path to migrate to containerd. Amazon EKS is ending support for Docker starting with the Kubernetes version 1.23 launch. The containerd runtime is widely adopted in the Kubernetes community and is a graduated project with the CNCF. You can test it by adding a node group to a new or existing cluster. For more information, see Enable the containerd runtime bootstrap flag (p. 182). When bootstrapped in Amazon EKS optimized accelerated Amazon Linux AMIs for v1.21, AWS Inferentia workloads aren’t supported.

In the following tables, choose \textbf{View AMI ID} for the Kubernetes version, AWS Region, and processor type that are specific to your Amazon Linux instance. You can also retrieve the IDs with an AWS Systems Manager parameter. For more information, see Retrieving Amazon EKS optimized Amazon Linux AMI IDs (p. 201).

Important
These AMIs require the latest AWS CloudFormation node template. You can’t use these AMIs with a previous version of the node template. If you do, they fail to join your cluster. Make sure that you update any existing AWS CloudFormation node stacks with the latest template before you attempt to use these AMIs.

The AWS CloudFormation node template launches your nodes with Amazon EC2 user data that triggers a specialized bootstrap script. This script allows your nodes to discover and connect to your cluster's control plane automatically. For more information, see Launching self-managed Amazon Linux nodes (p. 132).

Enable the containerd runtime bootstrap flag

The Amazon EKS optimized Amazon Linux 2 AMI contains an optional bootstrap flag to enable the containerd runtime. This feature provides a clear path to migrate to containerd. Amazon EKS is ending support for Docker starting with the Kubernetes version 1.23 launch. For more information, see Amazon EKS is ending support for Dockershim (p. 173).

You can enable the bootstrap flag by creating one of the following types of node groups.

- **Self-managed** – Create the node group using the instructions in Launching self-managed Amazon Linux nodes (p. 132). Specify an Amazon EKS optimized AMI and the following text for the BootstrapArguments parameter.

  ```
  --container-runtime containerd
  ```

- **Managed** – If you use eksctl, create a file named `my-nodegroup.yaml` with the following contents. Replace every `example-value` with your own values.

  ```yaml
  apiVersion: eksctl.io/v1alpha5
  kind: ClusterConfig
  metadata:
    name: my-cluster
    region: region-code
  managedNodeGroups:
  - name: my-nodegroup
    ami: eks-optimized-AMI-ID
    overrideBootstrapCommand: |
      #!/bin/bash
      /etc/eks/bootstrap.sh my-cluster --container-runtime containerd
  ```

  Run the following command to create the node group.

  ```bash
  eksctl create nodegroup -f my-nodegroup.yaml --version 1.22
  ```

  If you prefer to use a different tool to create your managed node group, you must deploy the node group using a launch template. In your launch template, specify an Amazon EKS optimized AMI.
ID, then deploy the node group using a launch template (p. 124) and provide the following user data. This user data passes arguments into the `bootstrap.sh` file. For more information about the bootstrap file, see `bootstrap.sh` on GitHub.

```
/etc/eks/bootstrap.sh my-cluster \n   --container-runtime containerd
```

## Amazon EKS optimized accelerated Amazon Linux AMIs

The Amazon EKS optimized accelerated Amazon Linux AMI is built on top of the standard Amazon EKS optimized Amazon Linux AMI. It's configured to serve as an optional image for Amazon EKS nodes to support GPU and Inferentia based workloads.

In addition to the standard Amazon EKS optimized AMI configuration, the accelerated AMI includes the following:

- NVIDIA drivers
- The `nvidia-container-runtime` (as the default runtime)
- AWS Neuron container runtime

### Note

- The Amazon EKS optimized accelerated AMI only supports GPU and Inferentia based instance types. Make sure to specify these instance types in your node AWS CloudFormation template. By using the Amazon EKS optimized accelerated AMI, you agree to NVIDIA's user license agreement (EULA).
- The Amazon EKS optimized accelerated AMI was previously referred to as the Amazon EKS optimized AMI with GPU support.
- Previous versions of the Amazon EKS optimized accelerated AMI installed the `nvidia-docker` repository. The repository is no longer included in Amazon EKS AMI version v20200529 and later.

### To enable GPU based workloads

The following procedure describes how to run a workload on a GPU based instance with the Amazon EKS optimized accelerated AMI. For more information about using Inferentia based workloads, see Machine learning inference using AWS Inferentia (p. 390).

1. After your GPU nodes join your cluster, you must apply the NVIDIA device plugin for Kubernetes as a DaemonSet on your cluster with the following command.

   ```bash
   kubectl apply -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.9.0/nvidia-device-plugin.yml
   ```

2. You can verify that your nodes have allocatable GPUs with the following command.

   ```bash
   kubectl get nodes -o=custom-columns=NAME:.metadata.name,GPU:.status.allocatable.nvidia.com/gpu
   ```

### To deploy a pod to test that your GPU nodes are configured properly

1. Create a file named `nvidia-smi.yaml` with the following contents. This manifest launches a Cuda container that runs `nvidia-smi` on a node.
apiVersion: v1
kind: Pod
metadata:
  name: nvidia-smi
spec:
  restartPolicy: OnFailure
  containers:
  - name: nvidia-smi
    image: nvidia/cuda:9.2-devel
    args:
      - "nvidia-smi"
    resources:
      limits:
        nvidia.com/gpu: 1

2. Apply the manifest with the following command.

```bash
ekubectl apply -f nvidia-smi.yaml
```

3. After the pod has finished running, view its logs with the following command.

```bash
ekubectl logs nvidia-smi
```

The output as follows.

```

```

Amazon EKS optimized Arm Amazon Linux AMIs

Arm instances deliver significant cost savings for scale-out and Arm-based applications such as web servers, containerized microservices, caching fleets, and distributed data stores. When adding Arm nodes to your cluster, review the following considerations.

**Considerations**

- If your cluster was deployed before August 17, 2020, you must do a one-time upgrade of critical cluster add-on manifests. This is so that Kubernetes can pull the correct image for each hardware architecture in use in your cluster. For more information about updating cluster add-ons, see To update the Kubernetes version for your Amazon EKS cluster (p. 36). If you deployed your cluster on or after August 17, 2020, then your coredns, kube-proxy, and Amazon VPC CNI Plugin for Kubernetes add-ons are already multi-architecture capable.
• Applications deployed to Arm nodes must be compiled for Arm.
• You can’t use the Amazon FSx for Lustre CSI driver (p. 250) with Arm.
• If you have DaemonSets that are deployed in an existing cluster, or you want to deploy them to a new cluster that you also want to deploy Arm nodes in, then verify that your DaemonSet can run on all hardware architectures in your cluster.
• You can run Arm node groups and x86 node groups in the same cluster. If you do, consider deploying multi-architecture container images to a container repository such as Amazon Elastic Container Registry and then adding node selectors to your manifests so that Kubernetes knows what hardware architecture a pod can be deployed to. For more information, see Pushing a multi-architecture image in the Amazon ECR User Guide and the Introducing multi-architecture container images for Amazon ECR blog post.

Amazon EKS optimized Amazon Linux AMI versions

This topic lists versions of the Amazon EKS optimized Amazon Linux AMIs and their corresponding versions of kubectl, Docker, the Linux kernel, and the Packer build script (p. 201) configuration.

The Amazon EKS optimized AMI metadata, including the AMI ID, for each variant can be retrieved programmatically. For more information, see Retrieving Amazon EKS optimized Amazon Linux AMI IDs (p. 201).

AMIs are versioned by Kubernetes version and the release date of the AMI in the following format:

\[ k8s\_major\_version.k8s\_minor\_version.k8s\_patch\_version-release\_date \]

For a list of notable changes in each version, see Changelog on GitHub.

Amazon EKS optimized Amazon Linux AMI

The following tables list the current and previous versions of the Amazon EKS optimized Amazon Linux AMI.

Kubernetes version 1.22

Retrieving Amazon EKS optimized Amazon Linux AMI IDs

You can programmatically retrieve the Amazon Machine Image (AMI) ID for Amazon EKS optimized AMIs by querying the AWS Systems Manager Parameter Store API. This parameter eliminates the need for you to manually look up Amazon EKS optimized AMI IDs. For more information about the Systems Manager Parameter Store API, see GetParameter. Your user account must have the ssm:GetParameter IAM permission to retrieve the Amazon EKS optimized AMI metadata.

You can retrieve the AMI ID with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon EKS optimized Amazon Linux AMI with the following command by using the sub-parameter `image_id`. Replace `1.21` with a supported version (p. 74). Replace `region-code` with the AWS Region that your cluster is in. Replace `amazon-linux-2` with `amazon-linux-2-gpu` to see the accelerated AMI ID and `amazon-linux-2-arm64` to see the Arm ID.

  ```
  aws ssm get-parameter --name /aws/service/eks/optimized-ami/1.21/amazon-linux-2/recommended/image_id --region region-code --query "Parameter.Value" --output text
  ```

  Example output:

  ```
  ami-abcdef1234efgh5678i
  ```

- **AWS Management Console** – You can query for the recommended Amazon EKS optimized AMI ID using a URL. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, replace `1.21` with a supported version (p. 74) and `region-code` with an Amazon EKS supported Region for which you want the AMI ID. Replace `amazon-linux-2` with `amazon-linux-2-gpu` to see the accelerated AMI ID and `amazon-linux-2-arm64` to see the Arm ID.

  ```
  ```

Amazon EKS optimized Amazon Linux AMI build script

Amazon Elastic Kubernetes Service (Amazon EKS) has open-sourced the build scripts that are used to build the Amazon EKS optimized AMI. These build scripts are now available on GitHub.

The Amazon EKS optimized Amazon Linux AMI is built on top of Amazon Linux 2, specifically for use as a node in Amazon EKS clusters. You can use this repository to view the specifics of how the Amazon EKS team configures `kubelet`, Docker, the AWS IAM Authenticator for Kubernetes, and more.

The build scripts repository includes a HashiCorp `packer` template and build scripts to generate an AMI. These scripts are the source of truth for Amazon EKS optimized AMI builds, so you can follow the GitHub repository to monitor changes to our AMIs. For example, perhaps you want your own AMI to use the same version of Docker that the EKS team uses for the official AMI.

The GitHub repository also contains the specialized `bootstrap script` that runs at boot time to configure your instance’s certificate data, control plane endpoint, cluster name, and more.
Additionally, the GitHub repository contains our Amazon EKS node AWS CloudFormation templates. These templates make it easier to spin up an instance running the Amazon EKS optimized AMI and register it with a cluster.

For more information, see the repositories on GitHub at https://github.com/awslabs/amazon-eks-ami.

Amazon EKS optimized Amazon Linux 2 contains an optional bootstrap flag to enable the containerd runtime. When bootstrapped in Amazon EKS optimized accelerated Amazon Linux AMIs for v1.21, AWS Inferentia workloads are not supported.

**Configuring VT1 for your custom Amazon Linux AMI**

Custom Amazon Linux AMIs in Amazon EKS can support the VT1 video transcoding instance family for Amazon Linux 2, Ubuntu 18, and Ubuntu 20. VT1 supports the Xilinx U30 media transcoding cards with accelerated H.264/AVC and H.265/HEVC codecs. To get the benefit of these accelerated instances, you must follow these steps:

1. Create and launch a base AMI from Amazon Linux 2, Ubuntu 18, or Ubuntu 20.
2. After the based AMI is launched, Install the XRT driver and runtime on the node.
3. Create a cluster.
4. Install the Kubernetes FPGA plugin on your cluster.

```bash
kubectl apply -f fpga-device-plugin.yml
```

The plugin will now advertise Xilinx U30 devices per node on your Amazon EKS cluster. You can use the FFMPEG docker image to run example video transcoding workloads on your Amazon EKS cluster.

**Configuring DL1 for your custom Amazon Linux 2 AMI**

Custom Amazon Linux 2 AMIs in Amazon EKS can support deep learning workloads at scale through additional configuration and Kubernetes add-ons. This document describes the components required to set up a generic Kubernetes solution for an on-premise setup or as a baseline in a larger cloud configuration. To support this function, you will have to perform the following steps in your custom environment:

- SynapaseAI® Software drivers loaded on the system – These are included in the AMIs available on Github.

  The Habana device plugin -- A Daemonset that allows you to automatically enable the registration of Habana devices in your Kubernetes cluster and track device health.

- Kubernetes version between 1.19 to 1.21 (confirmed through testing).
- Helm 3.x
- Helm chart to install MPI Operator.
- MPI Operator

1. Create and launch a base AMI from Amazon Linux 2, Ubuntu 18, or Ubuntu 20.
2. Follow these instructions to set up the environment for DL1.

**Amazon EKS optimized Ubuntu Linux AMIs**

Canonical has partnered with Amazon EKS to create node AMIs that you can use in your clusters.
Canonical delivers a built-for-purpose Kubernetes Node OS image. This minimized Ubuntu image is optimized for Amazon EKS and includes the custom AWS kernel that is jointly developed with AWS. For more information, see Ubuntu and Amazon Elastic Kubernetes Service and Optimized support for Amazon EKS on Ubuntu 18.04.

Amazon EKS optimized Bottlerocket AMIs

The Amazon EKS optimized Bottlerocket AMI is built on top of Bottlerocket. Bottlerocket is a Linux based open-source operating system that is purpose built by AWS for running containers on virtual machines or bare metal hosts. It's secure and only includes the bare minimum packages required to run containers. This reduces the attack surface and impact of vulnerabilities. It also requires less effort to meet node compliance requirements. For more information about Bottlerocket, see the documentation and releases on GitHub.

The AMI is configured to work with Amazon EKS and it includes containerd and kubectl.

The following points are some considerations when using Bottlerocket for your AMI type:

- You can deploy to Amazon EC2 instances with x86 or Arm processors, but not to instances that have Inferentia chips.
- You can't deploy to the following regions: China (Beijing) (cn-north-1) or China (Ningxia) (cn-northwest-1).
- There is no AWS CloudFormation template to deploy nodes with.
- Bottlerocket images don't come with an SSH server or a shell. You can use out-of-band access methods to allow SSH enabling the admin container and to pass some bootstrapping configuration steps with user data. For more information, see these sections in the bottlerocket README.md on GitHub:
  - Exploration
  - Admin container
  - Kubernetes settings
- By default, Bottlerocket has a control container that's enabled. This container runs the AWS Systems Manager agent that you can use to run commands or start shell sessions on Amazon EC2 Bottlerocket instances. For more information, see Setting up Session Manager in the AWS Systems Manager User Guide.
- Bottlerocket also has an admin container that's enabled if an SSH key is given when creating the node group. We recommend using the admin container only for development and testing scenarios. We don't recommend using it for production environments.

Select a link in one of the following tables to view the latest Amazon EKS optimized Bottlerocket AMI ID for a region and Kubernetes version. You can also retrieve the IDs with an AWS Systems Manager parameter using different tools. For more information, see Retrieving Amazon EKS optimized Bottlerocket AMI IDs (p. 208).

Amazon EKS User Guide
Windows

Retrieving Amazon EKS optimized Bottlerocket AMI IDs

You can retrieve the Amazon Machine Image (AMI) ID for Amazon EKS optimized AMIs by querying the AWS Systems Manager Parameter Store API. Using this parameter, you don't need to manually look up Amazon EKS optimized AMI IDs. For more information about the Systems Manager Parameter Store API, see GetParameter. Your user account must have the ssm:GetParameter IAM permission to retrieve the Amazon EKS optimized AMI metadata.

You can retrieve the AMI ID with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon EKS optimized Bottlerocket AMI with the following AWS CLI command by using the sub-parameter image_id. Replace 1.21 with a supported version (p. 74) and region-code with an Amazon EKS supported Region for which you want the AMI ID.

  ```bash
  aws ssm get-parameter --name /aws/service/bottlerocket/aws-k8s-1.22/x86_64/latest/image_id --region region-code --query "Parameter.Value" --output text
  ``

  Example output:

  `ami-068ed1c8e99b4810c`

- **AWS Management Console** – You can query for the recommended Amazon EKS optimized AMI ID using a URL in the AWS Management Console. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, replace 1.21 with a supported version (p. 74) and region-code with an Amazon EKS supported Region for which you want the AMI ID.

  `https://console.aws.amazon.com/systems-manager/parameters/aws/service/bottlerocket/aws-k8s-1.22/x86_64/latest/image_id/description?region=region-code`

Amazon EKS optimized Windows AMIs

**Important**

Amazon EKS doesn't currently support Windows for Kubernetes 1.22, but support will be added soon.

The Amazon EKS optimized AMI is built on top of Windows Server 2019. It's configured to serve as the base image for Amazon EKS nodes. The AMI is configured to work with Amazon EKS and includes Docker, kubelet, and the AWS IAM Authenticator.

**Note**

You can track security or privacy events for Windows Server with the Microsoft security update guide.

The AMI IDs for the latest Amazon EKS optimized AMI are in the following tables. You can also retrieve the IDs with an AWS Systems Manager parameter using different tools. For more information, see Retrieving Amazon EKS optimized Windows AMI IDs (p. 221).
Windows Server 2019 is a Long-Term Servicing Channel (LTSC) release, whereas Versions 20H2 is a Semi-Annual Channel (SAC) release. For more information, see Windows Server servicing channels in the Microsoft documentation. Windows Server 20H2 support was added to Kubernetes in version 1.21. For more information about Windows OS version support, see Intro to Windows support in Kubernetes.

Bootstrap script configuration parameters

When you create a Windows node, there’s a script on the node that allows for configuring different parameters. Depending on your setup, this script can be found on the node at a location similar to: \Program Files\Amazon\EKS\EKSBootstrap.ps1. The script includes the following parameters:

- `-EKSClusterName` – Specifies the Amazon EKS cluster name for this worker node to join.
- `-KubeletExtraArgs` – Specifies extra arguments for kubelet (optional).
- `-KubeProxyExtraArgs` – Specifies extra arguments for kube-proxy (optional).
- `-APIServerEndpoint` – Specifies the Amazon EKS cluster API server endpoint (optional). Only valid when used with `-Base64ClusterCA`. Bypasses calling Get-EKSCluster.
- `-Base64ClusterCA` – Specifies the base64 encoded cluster CA content (optional). Only valid when used with `-APIServerEndpoint`. Bypasses calling Get-EKSCluster.
- `-DNSClusterIP` – Overrides the IP address to use for DNS queries within the cluster (optional). Defaults to 10.100.0.10 or 172.20.0.10 based on the IP address of the primary interface.
- `-ContainerRuntime` – Specifies the container runtime to be used on the node.

Enable the containerd runtime bootstrap flag

The Amazon EKS optimized Windows AMI contains an optional bootstrap flag to enable the containerd runtime. This feature gives you a clear path to migrate to containerd. Amazon EKS is
ending support for Docker starting with the Kubernetes version 1.23 launch. For more information, see Amazon EKS is ending support for Dockershim (p. 173).

Until Kubernetes version 1.23, the supported values for the container runtime are `docker` and `containerd`, specified when launching the Windows nodes using either `eksctl` or the AWS Management Console.

- If the specified value is `docker`, then Docker is used as the runtime on the node.
- If the specified value is `containerd` and the Amazon EKS version is greater than 1.20, then `containerd` is selected as the runtime. If the Amazon EKS version is less than 1.21, then the bootstrap fails and nodes are unable to join the cluster.
- If any other value is specified, then the bootstrap fails and the node isn’t able to join the cluster.
- If this flag itself isn’t specified, then the default value of the container runtime is selected. For Amazon EKS version 1.21 and lower, this would be Docker.

When launching Windows nodes in your Amazon EKS cluster, follow the steps in Launching self-managed Windows nodes (p. 139). Windows self-managed nodes with the `containerd` runtime can be launched using `eksctl` or the AWS Management Console.

**eksctl**

**To enable the containerd runtime with eksctl**

For Windows self-managed nodes, the container runtime can be specified in the configuration while creating new node groups. You can use the following `test-windows-with-containerd.yaml` as reference.

**Note**

You must use `eksctl` version 0.93.0 or later to use the `containerRuntime` setting in the configuration file.

```yaml
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: windows-containerd-cluster
  region: us-west-2
  version: '1.21'
nodeGroups:
  - name: windows-ng
    instanceType: m5.2xlarge
    amiFamily: WindowsServer2019FullContainer
    volumeSize: 100
    minSize: 2
    maxSize: 3
    containerRuntime: containerd
  - name: linux-ng
    amiFamily: AmazonLinux2
    minSize: 2
    maxSize: 3
```

The node groups can then be created using the following command.

```bash
eksctl create cluster -f test-windows-with-containerd.yaml
```

Alternatively, you can also specify the EKS_CONTAINER_RUNTIME environment variable as a pre-bootstrap command in the `eksctl` configuration file.
preBootstrapCommands:
- Invoke-Expression -Command
  '([Environment]::SetEnvironmentVariable("EKS_CONTAINER_RUNTIME", "containerd",
  [System.EnvironmentVariableTarget]::Machine)'

For more information, see Creating a nodegroup from a config file, defining containerd runtime, and Config file schema in the eksctl documentation.

AWS Management Console

To enable the containerd runtime with the AWS Management Console

In the AWS CloudFormation template, there's a parameter named BootstrapArguments which can be used to pass in additional arguments to the bootstrap script. A parameter named ContainerRuntime can be used to select a particular runtime on the node.

Specify the following in BootstrapArguments to enable the containerd runtime:

```
-ContainerRuntime containerd
```

Amazon EKS optimized Windows AMI versions

This topic lists versions of the Amazon EKS optimized Windows AMIs and their corresponding versions of kubelet and Docker.

The Amazon EKS optimized AMI metadata, including the AMI ID, for each variant can be retrieved programmatically. For more information, see Retrieving Amazon EKS optimized Windows AMI IDs (p. 221).

AMIs are versioned by Kubernetes version and the release date of the AMI in the following format:

`k8s_major_version.k8s_minor_version-release_date`

### Kubernetes version 1.17

The most recent version is the last version we're releasing for Amazon EKS 1.17 clusters. It will be available until the 1.17 end of support date. For more information, see Amazon EKS Kubernetes release calendar (p. 72). For newer AMI releases, update your cluster to a later Kubernetes version. For more information, see Updating a cluster (p. 32).

Kubernetes version 1.17

The most recent version is the last version we're releasing for Amazon EKS 1.17 clusters. It will be available until the 1.17 end of support date. For more information, see Amazon EKS Kubernetes release calendar (p. 72). For newer AMI releases, update your cluster to a later Kubernetes version. For more information, see Updating a cluster (p. 32).
## Retrieving Amazon EKS optimized Windows AMI IDs

You can programmatically retrieve the Amazon Machine Image (AMI) ID for Amazon EKS optimized AMIs by querying the AWS Systems Manager Parameter Store API. This parameter eliminates the need for you to manually look up Amazon EKS optimized AMI IDs. For more information about the Systems Manager Parameter Store API, see GetParameter. Your user account must have the `ssm:GetParameter` IAM permission to retrieve the Amazon EKS optimized AMI metadata.

You can retrieve the AMI ID with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon EKS optimized Windows AMI with the following command by using the sub-parameter `image_id`. You can replace **1.21** with any supported Amazon EKS version and can replace `region-code` with an Amazon EKS supported Region for which you want the AMI ID. Replace **Core** with **Full** to see the Windows Server full AMI ID. You can also replace **2019** with **20H2** for the **Core** version only. Furthermore, you can only use **20H2** for versions 1.21 and later.

```bash
```

Example output:

```bash
ami-ami-00a053f1635fffea0
```

- **AWS Management Console** – You can query for the recommended Amazon EKS optimized AMI ID using a URL. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, you can replace **1.21** with any supported Amazon EKS version and can replace `region-code` with an Amazon EKS supported Region for which you want the AMI ID. Replace **Core** with **Full** to see the Windows Server full AMI ID. You can also replace **2019** with **20H2** for the **Core** version only. Furthermore, you can only use **20H2** for versions 1.21 and later.
Amazon EKS optimized Windows AMI

You can use Amazon EC2 Image Builder to create custom Amazon EKS optimized Windows AMIs. You must create your own Image Builder recipe. For more information, see Create image recipes and versions in the EC2 Image Builder User Guide. When creating a recipe and selecting a Source image, you have the following options:

- **Select managed images** – If you select this option, you can choose one of the following options for Image origin.
  - **Quick start (Amazon-managed)** – In the Image name dropdown, select an Amazon EKS supported Windows Server version (p. 208).
  - **Images owned by me** – For Image name, select the ARN of your own image with your own license. The image that you provide can't already have Amazon EKS components installed.
  - **Enter custom AMI ID** – For AMI ID, enter the ID for your AMI with your own license. The image that you provide can't already have Amazon EKS components installed.

In the search box under Build components - Windows, select Amazon-managed in the dropdown list and then search on eks. Select the eks-optimized-ami-windows search result, even though the result returned may not be the version that you want. Under Selected components, select Versioning options, then select Specify component version. Enter version.x, replacing version with a supported Kubernetes version (p. 65). If you enter 1.21.x as the component version, your Image Builder pipeline builds an AMI with the latest 1.21.x kubelet version.

To determine which kubelet and Docker versions are installed with the component, select Components in the left navigation. Under Components, change Owned by me to Quick start (Amazon-managed). In the Find components by name box, enter eks. The search results show the kubelet and Docker version in the component returned for each supported Kubernetes version. The components go through functional testing on the Amazon EKS supported Windows versions. Any other Windows versions are not supported and might not be compatible with the component.

Also include the update-windows component for the latest Windows patches for the operating system.
Storage

This chapter covers storage options for Amazon EKS clusters.

The Storage classes (p. 223) topic uses the in-tree Amazon EBS storage provisioner.

Note
The existing in-tree Amazon EBS plugin is still supported, but by using a CSI driver, you benefit from the decoupling of Kubernetes upstream release cycle and CSI driver release cycle. Eventually, the in-tree plugin will be discontinued in favor of the CSI driver. However, the CSI driver isn’t supported on Fargate.

Topics
• Storage classes (p. 223)
• Amazon EBS CSI driver (p. 225)
• Amazon EFS CSI driver (p. 238)
• Amazon FSx for Lustre CSI driver (p. 250)
• Amazon FSx for NetApp ONTAP CSI driver (p. 255)

Storage classes

Amazon EKS clusters that were created prior to Kubernetes version 1.11 were not created with any storage classes. You must define storage classes for your cluster to use and you should define a default storage class for your persistent volume claims. For more information, see Storage classes in the Kubernetes documentation.

Note
This topic uses the in-tree Amazon EBS storage provisioner. The existing in-tree Amazon EBS plugin is still supported, but by using a CSI driver, you benefit from the decoupling of Kubernetes upstream release cycle and CSI driver release cycle. Eventually, the in-tree plugin will be discontinued in favor of the CSI driver. However, the CSI driver isn’t supported on Fargate.

To create an AWS storage class for your Amazon EKS cluster

1. Determine which storage classes your cluster already has.

```bash
to kubectl get storageclass
```

Example output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>PROVISIONER</th>
<th>RECLAIMPOLICY</th>
<th>VOLUMEBINDINGMODE</th>
</tr>
</thead>
<tbody>
<tr>
<td>gp2 (default)</td>
<td>kubernetes.io/aws-ebs</td>
<td>Delete</td>
<td>WaitForFirstConsumer true</td>
</tr>
</tbody>
</table>

34m

If your cluster returns the previous output, then it already has the storage class defined in the remaining steps. You can define other storage classes using the steps for deploying any of the CSI drivers in the Storage (p. 223) chapter. Once deployed, you can set one of the storage classes as your default (p. 224) storage class.
2. Create an AWS storage class manifest file for your storage class. The `gp2-storage-class.yaml` example below defines a storage class called `gp2` that uses the Amazon EBS gp2 volume type.

For more information about the options available for AWS storage classes, see AWS EBS in the Kubernetes documentation.

```yaml
kind: StorageClass
apiVersion: storage.k8s.io/v1
metadata:
  name: gp2
  annotations:
    storageclass.kubernetes.io/is-default-class: "true"
provisioner: kubernetes.io/aws-ebs
parameters:
  type: gp2
  fsType: ext4
```

3. Use `kubectl` to create the storage class from the manifest file.

```
kubectl create -f gp2-storage-class.yaml
```

Output:

```
storageclass "gp2" created
```

**To define a default storage class**

1. List the existing storage classes for your cluster. A storage class must be defined before you can set it as a default.

```
kubectl get storageclass
```

Output:

```
NAME      PROVISIONER             AGE
---------- ---------------------- -----
gp2       kubernetes.io/aws-ebs   8m
```

2. Choose a storage class and set it as your default by setting the `storageclass.kubernetes.io/is-default-class=true` annotation.

```
kubectl annotate storageclass gp2 storageclass.kubernetes.io/is-default-class=true
```

Output:

```
storageclass "gp2" patched
```

3. Verify that the storage class is now set as default.

```
kubectl get storageclass
```

Output:

```
gp2 (default)  kubernetes.io/aws-ebs   12m
```
Amazon EBS CSI driver

The Amazon Elastic Block Store (Amazon EBS) Container Storage Interface (CSI) driver allows Amazon Elastic Kubernetes Service (Amazon EKS) clusters to manage the lifecycle of Amazon EBS volumes for persistent volumes.

Here are some things to consider about using the Amazon EBS CSI driver.

- The Amazon EBS CSI plugin requires IAM permissions to make calls to AWS APIs on your behalf. For more information, see Creating the Amazon EBS CSI driver IAM role for service accounts (p. 225).
- You can run the Amazon EBS CSI controller on Fargate, but you can't mount volumes to Fargate pods.
- Alpha features of the Amazon EBS CSI driver aren't supported on Amazon EKS clusters.

The Amazon EBS CSI driver isn't installed when you first create a cluster. To use the driver, you must add it as an Amazon EKS add-on or as a self-managed add-on.

- For instructions on how to add it as an Amazon EKS add-on, see Managing the Amazon EBS CSI driver as an Amazon EKS add-on (p. 231).
- For instructions on how to add it as a self-managed add-on, see the Amazon EBS Container Storage Interface (CSI) driver project on GitHub.

After you installed the CSI driver with either method, you can test the functionality with a sample application. For more information, see Deploy a sample application and verify that the CSI driver is working (p. 236).

Creating the Amazon EBS CSI driver IAM role for service accounts

The Amazon EBS CSI plugin requires IAM permissions to make calls to AWS APIs on your behalf. For more information, see Set up driver permission on GitHub.

When the plugin is deployed, it creates and is configured to use a service account that's named ebs-csi-controller-sa. The service account is bound to a Kubernetes clusterrole that's assigned the required Kubernetes permissions.

**Note**

No matter if you configure the Amazon EBS CSI plugin to use IAM roles for service accounts, the pods have access to the permissions that are assigned to the IAM role. This is the case except when you block access to IMDS. For more information, see Security best practices for Amazon EKS (p. 492).

Prerequisites

- An existing cluster that's version 1.18 or later.
  - 1.18 requires eks.9 or later.
  - 1.19 requires eks.7 or later.
  - 1.20 requires eks.3 or later.
  - 1.21 requires eks.3 or later.
- An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Create an IAM OIDC provider for your cluster (p. 466).
Create an IAM role and attach the required AWS managed policy to it. You can use `eksctl`, the AWS Management Console, or the AWS CLI.

`eksctl`

**To create your Amazon EBS CSI plugin IAM role with `eksctl`**

1. Create an IAM role and attach the required AWS managed policy with the following command. Replace `my-cluster` with the name of your cluster. The command deploys an AWS CloudFormation stack that creates an IAM role, attaches the IAM policy to it, and annotates the existing `ebs-csi-controller-sa` service account with the Amazon Resource Name (ARN) of the IAM role. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:` before running the following command.

   ```bash
   eksctl create iamserviceaccount \
       --name ebs-csi-controller-sa \
       --namespace kube-system \
       --cluster my-cluster \
       --attach-policy-arn arn:aws:iam::aws:policy/service-role/AmazonEBSCSIDriverPolicy \
       --approve \
       --role-only \
       --role-name AmazonEKS_EBS_CSI_DriverRole
   ```

2. If you use a custom KMS key for encryption on your Amazon EBS volumes, customize the IAM role as needed. For example, do the following:
   a. Copy and paste the following code into a new `kms-key-for-encryption-on-ebs.json` file. Replace `custom-key-id` with the custom KMS key ID.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": [
           "kms:CreateGrant",
           "kms:ListGrants",
           "kms:RevokeGrant"
         ],
         "Resource": ["custom-key-id"],
         "Condition": {
           "Bool": {
             "kms:GrantIsForAWSResource": "true"
           }
         }
       },
       {
         "Effect": "Allow",
         "Action": [
           "kms:Encrypt",
           "kms:Decrypt",
           "kms:ReEncrypt*",
           "kms:GenerateDataKey*",
           "kms:DescribeKey"
         ],
         "Resource": ["custom-key-id"]
       }
     ]
   }
   ```
**b. Create the policy. You can change** KMS_Key_For_Encryption_On_EBS_Policy **to a different name. However, if you do, make sure to change it in later steps, too.**

```
aws iam create-policy \
--policy-name KMS_Key_For_Encryption_On_EBS_Policy \ 
--policy-document file://kms-key-for-encryption-on-ebs.json
```

c. **Attach the IAM policy to the role. Replace 111122223333 with your account ID. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace arn:aws: with arn:aws-us-gov: before running the following command.**

```
aws iam attach-role-policy \
--policy-arn arn:aws:iam::111122223333:policy/KMS_Key_For_Encryption_On_EBS_Policy \
--role-name AmazonEKS_EBS_CSI_DriverRole
```

AWS Management Console

**To create your Amazon EBS CSI plugin IAM role with the AWS Management Console**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose **Roles**.
3. On the **Roles** page, choose **Create role**.
4. On the **Select trusted entity** page, do the following:
   a. In the **Trusted entity type** section, choose **Web identity**.
   b. For **Identity provider**, choose the **OpenID Connect provider URL** for your cluster (as shown under **Configuration Details** in Amazon EKS).
   c. For **Audience**, choose sts.amazonaws.com.
   d. Choose **Next**.
5. On the **Add permissions** page, do the following:
   a. In the **Filter policies** box, enter AmazonEBSCSIDriverPolicy.
   b. Select the check box to the left of the AmazonEBSCSIDriverPolicy returned in the search.
   c. Choose **Next**.
6. On the **Name, review, and create** page, do the following:
   a. For **Role name**, enter a unique name for your role, such as AmazonEKS_EBS_CSI_DriverRole.
   b. Under **Add tags (Optional)**, add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see **Tagging IAM Entities** in the IAM User Guide.
   c. Choose **Create role**.
7. After the role is created, choose the role in the console to open it for editing.
8. Choose the **Trust relationships** tab, and then choose **Edit trust policy**.
9. Find the line that looks similar to the following line:

```
"oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:aud": "sts.amazonaws.com"
```
Add a comma to the end of the previous line, and then add the following line after the
previous line. Replace region-code with the AWS Region that your cluster is in. Replace
EXAMPLED539D4633E53DE1B71EXAMPLE with your cluster's OIDC provider ID.

```
"oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:sub":
"system:serviceaccount:kube-system:ebs-csi-controller-sa"
```

10. Choose **Update policy** to finish.

11. If you use a custom KMS key for encryption on your Amazon EBS volumes, customize the IAM
role as needed. For example, do the following:

   a. In the left navigation pane, choose **Policies**.
   b. On the **Policies** page, choose **Create Policy**.
   c. On the **Create policy** page, choose the **JSON** tab.
   d. Copy and paste the following code into the editor, replacing custom-key-id with the
custom KMS key ID:

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Action": [
   "kms:CreateGrant",
   "kms:ListGrants",
   "kms:RevokeGrant"
   ],
   "Resource": ["custom-key-id"],
   "Condition": {
   "Bool": {
   "kms:GrantIsForAWSResource": "true"
   }
   }
   },
   {
   "Effect": "Allow",
   "Action": [
   "kms:Encrypt",
   "kms:Decrypt",
   "kms:ReEncrypt*",
   "kms:GenerateDataKey*",
   "kms:DescribeKey"
   ],
   "Resource": ["custom-key-id"]
   }
   ]
   }
   
   e. Choose **Next: Tags**.
   f. On the **Add tags (Optional)** page, choose **Next: Review**.
   g. For **Name**, enter a unique name for your policy (for example,
**KMS_Key_For_Encryption_On_EBS_Policy**).
   h. Choose **Create policy**.
   i. In the left navigation pane, choose **Roles**.
   j. Choose the **AmazonEKS_EBS_CSI_DriverRole** in the console to open it for editing.
   k. From the **Add permissions** drop-down list, choose **Attach policies**.
   l. In the **Filter policies** box, enter **KMS_Key_For_Encryption_On_EBS_Policy**.
m. Select the check box to the left of the _KMS_Key_For_Encryption_On_EBS_Policy_ that was returned in the search.

n. Choose **Attach policies**.

---

**AWS CLI**

**To create your Amazon EBS CSI plugin IAM role with the AWS CLI**

1. View your cluster's OIDC provider URL. Replace `my-cluster` with your cluster name. If the output from the command is `None`, review the **Prerequisites**.

   ```bash
   aws eks describe-cluster \
   --name my-cluster \
   --query "cluster.identity.oidc.issuer" \
   --output text
   ```

   Example output:

   ```
   https://oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE
   ```

2. Create the IAM role.

   a. Copy the following contents to a file that's named `aws-ebs-csi-driver-trust-policy.json`. Replace `111122223333` with your account ID, `region-code` with your AWS Region, and `EXAMPLED539D4633E53DE1B71EXAMPLE` with the value that was returned in the previous step. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "Federated": "arn:aws:iam::111122223333:oidc-provider/oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE"
         },
         "Action": "sts:AssumeRoleWithWebIdentity",
         "Condition": {
           "StringEquals": {
             "oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:aud": "sts.amazonaws.com",
             "oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:sub": "system:serviceaccount:kube-system:csi-driver-controller-sa"
           }
         }
       }
     ]
   }
   ```

   b. Create the role. You can change `AmazonEKS_EBS_CSI_DriverRole` to a different name. If you change it, make sure to change it in later steps.

   ```bash
   aws iam create-role \
   --role-name AmazonEKS_EBS_CSI_DriverRole \
   --assume-role-policy-document file:"aws-ebs-csi-driver-trust-policy.json"
   ```
3. Attach the required AWS managed policy to the role. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace arn:aws: with arn:aws-us-gov: before running the following command.

```bash
aws iam attach-role-policy
  --policy-arn arn:aws:iam::aws:policy/service-role/AmazonEBSCSIDriverPolicy
  --role-name AmazonEKS_EBS_CSI_DriverRole
```

4. If you use a custom KMS key for encryption on your Amazon EBS volumes, customize the IAM role as needed. For example, do the following:

a. Copy and paste the following code into a new `kms-key-for-encryption-on-ebs.json` file. Replace `custom-key-id` with the custom KMS key ID.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:CreateGrant",
        "kms:ListGrants",
        "kms:RevokeGrant"
      ],
      "Resource": ["custom-key-id"],
      "Condition": {
        "Bool": {
          "kms:GrantIsForAWSResource": "true"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:DescribeKey"
      ],
      "Resource": ["custom-key-id"]
    }
  ]
}
```

b. Create the policy. You can change `KMS_Key_For_Encryption_On_EBS_Policy` to a different name. However, if you do, make sure to change it in later steps, too.

```bash
aws iam create-policy
  --policy-name KMS_Key_For_Encryption_On_EBS_Policy
  --policy-document file://kms-key-for-encryption-on-ebs.json
```

c. Attach the IAM policy to the role. Replace `111122223333` with your account ID. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace arn:aws: with arn:aws-us-gov: before running the following command.

```bash
aws iam attach-role-policy
  --policy-arn arn:aws:iam::111122223333:policy/KMS_Key_For_Encryption_On_EBS_Policy
  --role-name AmazonEKS_EBS_CSI_DriverRole
```
Managing the Amazon EBS CSI driver as an Amazon EKS add-on

To improve security and reduce the amount of work, you can manage the Amazon EBS CSI driver as an Amazon EKS add-on. For information about Amazon EKS add-ons, see Amazon EKS add-ons (p. 381). You can add the Amazon EBS CSI add-on by following the steps in Adding the Amazon EBS CSI add-on (p. 231).

If you added the Amazon EBS CSI add-on, you can manage it by following the steps in the Updating the Amazon EBS CSI driver as an Amazon EKS add-on (p. 232) and Removing the Amazon EBS CSI add-on (p. 235) sections.

Prerequisites

- An existing cluster that's version 1.18 or later. To see the required platform version, run the following command.

```
aws eks describe-addon-versions --addon-name aws-ebs-csi-driver
```

- An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Create an IAM OIDC provider for your cluster (p. 466).

- An Amazon EBS CSI driver IAM role. For more information, see Creating the Amazon EBS CSI driver IAM role for service accounts (p. 225).

Important

To use the snapshot functionality of the Amazon EBS CSI driver, you must install the external snapshotter before the installation of the add-on. The external snapshotter components must be installed in the following order:

- `CustomResourceDefinition` (CRD) for `volumesnapshotclasses`, `volumesnapshots`, and `volumesnapshotcontents`
- RBAC (`ClusterRole`, `ClusterRoleBinding`, and so on)
- controller deployment

For more information, see CSI Snapshotter on GitHub.

Adding the Amazon EBS CSI add-on

Important

Before adding the Amazon EBS CSI add-on, confirm that you don't self-manage any settings that Amazon EKS will start managing. To determine which settings Amazon EKS manages, see Amazon EKS add-on configuration (p. 382).

You can use `eksctl`, the AWS Management Console, or the AWS CLI to add the Amazon EBS CSI add-on to your cluster.

`eksctl`

To add the Amazon EBS CSI add-on using `eksctl`

Replace `my-cluster` with the name of your cluster, `111122223333` with your account ID, and `AmazonEKS_EBS_CSI_DriverRole` with the name of the role created earlier. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:` before running the following command.
manage the Amazon EKS add-on

```
eksctl create addon --name aws-ebs-csi-driver --cluster my-cluster --service-account-role-arn arn:aws::iam::111122223333:role/AmazonEKS_EBS_CSI_DriverRole --force
```

If you remove the `--force` option and there's a conflict with your existing settings, the command fails. You can use the resulting error message to troubleshoot the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage. This is because those settings are overwritten with this option. For more information about managing Amazon EKS add-ons, see Amazon EKS add-on configuration (p. 382).

**AWS Management Console**

**To add the Amazon EBS CSI add-on using the AWS Management Console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Amazon EKS Clusters.
3. Choose the name of the cluster that you want to configure the Amazon EBS CSI add-on for.
4. Choose the Configuration tab.
5. Choose the Add-ons tab.
6. Choose Add new.
   a. Select Amazon EBS CSI Driver for Name.
   b. Select the Version you'd like to use.
   c. For Service account role, select the name of an IAM role that you attached the IAM policy to.
   d. If you select Override existing configuration for this add-on on the cluster, one or more of the settings for the existing add-on can be overwritten with the Amazon EKS add-on settings. If you don't enable this option and there's a conflict with your existing settings, the operation fails. You can use the resulting error message to troubleshoot the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage. For more information about managing Amazon EKS add-ons, see Amazon EKS add-on configuration (p. 382).
   e. Choose Add.

**AWS CLI**

**To add the Amazon EBS CSI add-on using the AWS CLI**

Replace `my-cluster` with the name of your cluster, `111122223333` with your account ID, and `AmazonEKS_EBS_CSI_DriverRole` with the name of the role that was created earlier. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:` before running the following command.

```
aws eks create-addon \
  --cluster-name my-cluster \
  --addon-name aws-ebs-csi-driver \
  --service-account-role-arn arn:aws:iam::111122223333:role/AmazonEKS_EBS_CSI_DriverRole
```

**Updating the Amazon EBS CSI driver as an Amazon EKS add-on**

Amazon EKS doesn't automatically update Amazon EBS CSI for your cluster when new versions are released or after you update your cluster (p. 32) to a new Kubernetes minor version. To update Amazon EBS CSI on an existing cluster, you must initiate the update and then Amazon EKS updates the add-on for you.
Important
Update your cluster and nodes to a new Kubernetes minor version before you update Amazon EBS CSI to the same minor version.

To update the Amazon EBS CSI add-on using `eksctl`

1. Check the current version of your Amazon EBS CSI add-on. Replace `my-cluster` with your cluster name.

   ```
   eksctl get addon --name aws-ebs-csi-driver --cluster my-cluster
   ```

   Example output:

   ```
   NAME                    VERSION                      STATUS  ISSUES  IAMROLE
   AVAILABLE
   aws-ebs-csi-driver     v1.4.0-eksbuild.preview  ACTIVE  0
   ```

2. Update the add-on to the version returned under **UPDATE AVAILABLE** in the output of the previous step.

   ```
   eksctl update addon
   --name aws-ebs-csi-driver
   --version v1.5.1-eksbuild.1
   --cluster my-cluster
   --force
   ```

   If you remove the `--force` option and there's a conflict with your existing settings, the command fails. You can use the resulting error message to troubleshoot the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage. This is because those settings are overwritten with this option. For more information about managing Amazon EKS add-ons, see Amazon EKS add-on configuration (p. 382).

AWS Management Console

To update the Amazon EBS CSI add-on using the AWS Management Console

1. Open the Amazon EKS console at `https://console.aws.amazon.com/eks/home#/clusters`.
2. In the left navigation pane, choose Amazon EKS **Clusters**.
3. Choose the name of the cluster that you want to update the Amazon EBS CSI add-on for.
4. Choose the **Configuration** tab.
5. Choose the **Add-ons** tab.
6. Select the radio button in the upper right of the **aws-ebs-csi-driver** box.
7. Choose **Edit**.
   a. Select the **Version** of the Amazon EKS add-on that you want to use.
   b. For **Service account role**, select the name of the IAM role that you've attached the Amazon EBS CSI driver IAM policy to.
   c. If you select **Override existing configuration for this add-on on the cluster**, then one or more of the settings for the existing add-on can be overwritten with the Amazon EKS add-on settings. If you don't enable this option and there's a conflict with your existing settings,
the operation fails with an error message to help you resolve the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage. For more information about managing Amazon EKS add-ons, see Amazon EKS add-on configuration (p. 382).

d. Select Update.

**AWS CLI**

*To update the Amazon EBS CSI add-on using the AWS CLI*

1. Check the current version of your Amazon EBS CSI add-on. Replace `my-cluster` with your cluster name.

```bash
aws eks describe-addon
  --cluster-name my-cluster
  --addon-name aws-ebs-csi-driver
  --query "addon.addonVersion"
  --output text
```

Example output:

```
v1.4.0-eksbuild.preview
```

2. Determine which versions of the Amazon EBS CSI add-on are available for your cluster version.

```bash
aws eks describe-addon-versions
  --addon-name aws-ebs-csi-driver
  --kubernetes-version 1.20
  --query "addons[].addonVersions[].[addonVersion, compatibilities[].defaultVersion]"
  --output text
```

Example output:

```
v1.5.1-eksbuild.1 False
v1.4.0-eksbuild.preview True
```

The version with `True` underneath is the default version deployed with new clusters with the version that you specified.

3. Update the add-on to the version with `True` that was returned in the output of the previous step. If it was returned in the output, you can also update to a later version.

```bash
aws eks update-addon
  --cluster-name my-cluster
  --addon-name aws-ebs-csi-driver
  --addon-version v1.4.0-eksbuild.preview
  --resolve-conflicts OVERWRITE
```

If you remove the `--resolve-conflicts OVERWRITE` option and there's a conflict with your existing settings, then the command fails with an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage. This is because those settings are overwritten with this option. For more information about managing Amazon EKS add-ons, see Amazon EKS add-on configuration (p. 382).
Removing the Amazon EBS CSI add-on

You have two options for removing an Amazon EKS add-on.

- **Preserve add-on software on your cluster** – This option removes Amazon EKS management of any settings. It also removes the ability for Amazon EKS to notify you of updates and automatically update the Amazon EKS add-on after you initiate an update. However, it preserves the add-on software on your cluster. This option makes the add-on a self-managed add-on, rather than an Amazon EKS add-on. With this option, there's no downtime for the add-on. The commands in this procedure use this option.

- **Remove add-on software entirely from your cluster** – We recommend that you remove the Amazon EKS add-on from your cluster only if there are no resources on your cluster that are dependent on it. To do this option, delete `--preserve` from the command you use in this procedure.

If the add-on has an IAM account associated with it, the IAM account isn't removed.

You can use `eksctl`, the AWS Management Console, or the AWS CLI to remove the Amazon EBS CSI add-on.

### eksctl

**To remove the Amazon EBS CSI add-on using eksctl**

Replace `my-cluster` with the name of your cluster, and then run the following command.

```bash
eksctl delete addon --cluster my-cluster --name aws-ebs-csi-driver --preserve
```

### AWS Management Console

**To remove the Amazon EBS CSI add-on using the AWS Management Console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Amazon EKS Clusters.
3. Choose the name of the cluster that you want to remove the Amazon EBS CSI add-on for.
4. Choose the Configuration tab.
5. Choose the Add-ons tab.
6. Select the radio button in the upper right of the `aws-ebs-csi-driver` box.
7. Choose Remove.
8. Select Preserve on cluster if you want Amazon EKS to stop managing settings for the add-on. Do this if you want to retain the add-on software on your cluster. This is so that you can manage all of the settings of the add-on on your own.
9. Enter `aws-ebs-csi-driver`.
10. Select Remove.

### AWS CLI

**To remove the Amazon EBS CSI add-on using the AWS CLI**

Replace `my-cluster` with the name of your cluster, and then run the following command.

```bash
aws eks delete-addon --cluster-name my-cluster --addon-name aws-ebs-csi-driver --preserve
```
Deploy a sample application and verify that the CSI driver is working

You can test the CSI driver functionality with a sample application. This topic shows one example, but you can also do the following:

- Deploy a sample application that uses the external snapshotter to create volume snapshots. For more information, see Volume Snapshots on GitHub.
- Deploy a sample application that uses volume resizing. For more information, see Volume Resizing on GitHub.

This procedure uses the Dynamic volume provisioning example from the Amazon EBS Container Storage Interface (CSI) driver GitHub repository to consume a dynamically provisioned Amazon EBS volume.

1. Clone the Amazon EBS Container Storage Interface (CSI) driver GitHub repository to your local system.

   ```bash
   git clone https://github.com/kubernetes-sigs/aws-ebs-csi-driver.git
   ```

2. Navigate to the dynamic-provisioning example directory.

   ```bash
   cd aws-ebs-csi-driver/examples/kubernetes/dynamic-provisioning/
   ```

3. Deploy the ebs-sc storage class, ebs-claim persistent volume claim, and app sample application from the manifests directory.

   ```bash
   kubectl apply -f manifests/
   ```

4. Describe the ebs-sc storage class.

   ```bash
   kubectl describe storageclass ebs-sc
   ```

   Example output:

   ```plaintext
   Name:            ebs-sc
   IsDefaultClass:  No
   Annotations:     kubectl.kubernetes.io/last-applied-configuration={"apiVersion":"storage.k8s.io/v1","kind":"StorageClass","metadata":{"annotations":{},"name":"ebs-sc"},"provisioner":"ebs.csi.aws.com","volumeBindingMode":"WaitForFirstConsumer"}
   Provisioner:           ebs.csi.aws.com
   Parameters:            <none>
   AllowVolumeExpansion:  <unset>
   MountOptions:          <none>
   ReclaimPolicy:         Delete
   VolumeBindingMode:     WaitForFirstConsumer
   Events:                <none>
   ```

   **Note**
   
   The storage class uses the WaitForFirstConsumer volume binding mode. This means that volumes aren't dynamically provisioned until a pod makes a persistent volume claim. For more information, see Volume Binding Mode in the Kubernetes documentation.

5. Watch the pods in the default namespace. After a few minutes, the app pod's status changes to Running.
Amazon EKS User Guide
Deploy a sample application

**kubectl get pods --watch**

Enter Ctrl+C to return to a shell prompt.

6. List the persistent volumes in the default namespace. Look for a persistent volume with the default/ebs-claim claim.

**kubectl get pv**

Example output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>CAPACITY</th>
<th>ACCESS MODES</th>
<th>RECLAIM POLICY</th>
</tr>
</thead>
<tbody>
<tr>
<td>pvc-3771cd6-d0dc-11e9-b17f-06fad4858a5a</td>
<td>4Gi</td>
<td>RWO</td>
<td>Delete</td>
</tr>
<tr>
<td>Bound</td>
<td>default/ebs-claim</td>
<td>ebs-sc</td>
<td>30s</td>
</tr>
</tbody>
</table>

7. Describe the persistent volume. Replace `pvc-3771cd6-d0dc-11e9-b17f-06fad4858a5a` with the value from the output in the previous step.

**kubectl describe pv pvc-3771cd6-d0dc-11e9-b17f-06fad4858a5a**

Example output:

- **Name:** pvc-3771cd6-d0dc-11e9-b17f-06fad4858a5a
- **Labels:** <none>
- **Annotations:** pv.kubernetes.io/provisioned-by: ebs.csi.aws.com
- **Finalizers:** [kubernetes.io/pv-protection external-attacher/ebs-csi-aws-com]
- **StorageClass:** ebs-sc
- **Status:** Bound
- **Claim:** default/ebs-claim
- **Reclaim Policy:** Delete
- **Access Modes:** RWO
- **VolumeMode:** Filesystem
- **Capacity:** 4Gi
- **Node Affinity:**
  - **Required Terms:**
    - **Term 0:** topology.ebs.csi.aws.com/zone in [region-code]
- **Message:**
- **Source:**
  - **Type:** CSI (a Container Storage Interface (CSI) volume source)
  - **Driver:** ebs.csi.aws.com
  - **VolumeHandle:** vol-0d651e157c6d93445
  - **ReadOnly:** false
  - **VolumeAttributes:** storage.kubernetes.io/csiProvisionerIdentity=1567792483192-8081-ebs.csi.aws.com
- **Events:** <none>

The Amazon EBS volume ID is the value for VolumeHandle in the previous output.

8. Verify that the pod is writing data to the volume.

**kubectl exec -it app -- cat /data/out.txt**

Example output:

Wed May 5 16:17:03 UTC 2021
Wed May 5 16:17:08 UTC 2021
Wed May 5 16:17:13 UTC 2021
Amazon EFS CSI driver

The Amazon EFS Container Storage Interface (CSI) driver provides a CSI interface that allows Kubernetes clusters running on AWS to manage the lifecycle of Amazon EFS file systems.

This topic shows you how to deploy the Amazon EFS CSI Driver to your Amazon EKS cluster and verify that it works.

**Note**
Alpha features of the Amazon EFS CSI Driver aren't supported on Amazon EKS clusters.

For detailed descriptions of the available parameters and complete examples that demonstrate the driver's features, see the Amazon EFS Container Storage Interface (CSI) driver project on GitHub.

**Considerations**

- The Amazon EFS CSI Driver isn't compatible with Windows-based container images.
- You can't use dynamic persistent volume provisioning with Fargate nodes, but you can use static provisioning.
- Dynamic provisioning requires 1.2 or later of the driver, which requires a 1.17 or later cluster. You can statically provision persistent volumes using 1.1 of the driver on any supported Amazon EKS cluster version (p. 65).
- Version 1.3.2 or later of this driver supports the Arm64 architecture, including Amazon EC2 Graviton-based instances.

**Prerequisites**

- An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Create an IAM OIDC provider for your cluster (p. 466).
- Version 2.5.2 or later or 1.22.86 or later of the AWS CLI installed and configured on your computer or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with `aws configure` in the AWS Command Line Interface User Guide.
- The `kubectl` command line tool installed on your computer or AWS CloudShell. The version must be the same, or up to two versions later than your cluster version. To install or upgrade `kubectl`, see Installing `kubectl` (p. 4).

**Note**
A pod running on AWS Fargate automatically mounts an Amazon EFS file system, without needing the manual driver installation steps described on this page.

**Create an IAM policy and role**

Create an IAM policy and assign it to an IAM role. The policy will allow the Amazon EFS driver to interact with your file system.
To deploy the Amazon EFS CSI driver to an Amazon EKS cluster

1. Create an IAM policy that allows the CSI driver's service account to make calls to AWS APIs on your behalf.
   a. Download the IAM policy document from GitHub. You can also view the policy document.
      ```shell
      curl -o iam-policy-example.json https://raw.githubusercontent.com/kubernetes-sigs/aws-efs-csi-driver/v1.3.2/docs/iam-policy-example.json
      ```
   b. Create the policy. You can change `AmazonEKS_EFS_CSI_Driver_Policy` to a different name, but if you do, make sure to change it in later steps too.
      ```shell
      aws iam create-policy \
      --policy-name AmazonEKS_EFS_CSI_Driver_Policy \
      --policy-document file://iam-policy-example.json
      ```

2. Create an IAM role and attach the IAM policy to it. Annotate the Kubernetes service account with the IAM role ARN and the IAM role with the Kubernetes service account name. You can create the role using `eksctl` or the AWS CLI.

   **eksctl**
   Run the following command to create the IAM role and Kubernetes service account. It also attaches the policy to the role, annotates the Kubernetes service account with the IAM role ARN, and adds the Kubernetes service account name to the trust policy for the IAM role. Replace `my-cluster` with your cluster name and `111122223333` with your account ID. Replace `region-code` with the AWS Region that your cluster is in. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.
   ```shell
   eksctl create iamserviceaccount \
   --cluster my-cluster \
   --namespace kube-system \
   --name efs-csi-controller-sa \
   --attach-policy-arn arn:aws:iam::111122223333:policy/AmazonEKS_EFS_CSI_Driver_Policy \
   --approve \
   --region region-code
   ```

   **AWS CLI**
   1. Determine your cluster's OIDC provider URL. Replace `my-cluster` with your cluster name. If the output from the command is `None`, review the Prerequisites.
      ```shell
      aws eks describe-cluster --name my-cluster --query "cluster.identity.oidc.issuer" --output text
      ```
      Example output:
      ```
      https://oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE
      ```
   2. Create the IAM role, granting the Kubernetes service account the `AssumeRoleWithWebIdentity` action.
      a. Copy the following contents to a file named `trust-policy.json`. Replace `111122223333` with your account ID. Replace `EXAMPLED539D4633E53DE1B71EXAMPLE` and `region-code` with the values returned in the previous step. If your cluster is in
the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace arn:aws: with arn:aws-us-gov:.

```json
{
 "Version": "2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Principal": {
    "Action": "sts:AssumeRoleWithWebIdentity",
    "Condition": {
     "StringEquals": {
     }
    }
   }
  }
 ]
}
```

b. Create the role. You can change AmazonEKS_EFS_CSI_DriverRole to a different name, but if you do, make sure to change it in later steps too.

```
aws iam create-role \
   --role-name AmazonEKS_EFS_CSI_DriverRole \
   --assume-role-policy-document file://"trust-policy.json"
```

3. Attach the IAM policy to the role. Replace 111122223333 with your account ID. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace arn:aws: with arn:aws-us-gov: before running the following command.

```
aws iam attach-role-policy \
   --policy-arn arn:aws:iam::111122223333:policy/AmazonEKS_EFS_CSI_Driver_Policy \
   --role-name AmazonEKS_EFS_CSI_DriverRole
```

4. Create a Kubernetes service account that's annotated with the ARN of the IAM role that you created.

a. Save the following contents to a file named efs-service-account.yaml. Replace 111122223333 with your account ID. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace arn:aws: with arn:aws-us-gov:.

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  labels:
    app.kubernetes.io/name: aws-efs-csi-driver
name: efs-csi-controller-sa
namespace: kube-system
annotations:
  eks.amazonaws.com/role-arn:
    arn:aws:iam::111122223333:role/AmazonEKS_EFS_CSI_DriverRole
```

b. Create the Kubernetes service account on your cluster. The Kubernetes service account named efs-csi-controller-sa is annotated with the IAM role that you created named AmazonEKS_EFS_CSI_DriverRole.
Install the Amazon EFS driver

Install the Amazon EFS CSI driver using Helm or a manifest.

**Important**

- The following steps install the 1.3.2 version of the driver, which requires a 1.17 or later cluster. If you're installing the driver on a cluster that's earlier than version 1.17, you need to install version 1.1 of the driver. For more information, see Amazon EFS CSI driver on GitHub.
- Encryption of data in transit using TLS is enabled by default. Using encryption in transit, data is encrypted during its transition over the network to the Amazon EFS service. To disable it and mount volumes using NFSv4, set the `volumeAttributes` field `encryptInTransit` to "false" in your persistent volume manifest. For an example manifest, see Encryption in Transit example on GitHub.

**Helm**

This procedure requires Helm V3 or later. To install or upgrade Helm, see Using Helm with Amazon EKS (p. 421).

**To install the driver using Helm**

1. Add the Helm repo.

   ```bash
   ````

2. Update the repo.

   ```bash
   helm repo update
   ````

3. Install a release of the driver using the Helm chart. Replace the repository address with the cluster's container image address (p. 379).

   ```bash
   helm upgrade -i aws-efs-csi-driver aws-efs-csi-driver/aws-efs-csi-driver \
   --namespace kube-system \
   --set image.repository=602401143452.dkr.ecr.region-code.amazonaws.com/eks/aws-efs-csi-driver \
   --set controller.serviceAccount.create=false \
   --set controller.serviceAccount.name=efs-csi-controller-sa
   ````

**Manifest (private registry)**

If you want to download the image with a manifest, we recommend first trying these steps to pull secured images from the private Amazon ECR registry.

**To install the driver using images stored in the private Amazon ECR registry**

1. Download the manifest.

   ```bash
   kubectl kustomize \
   ```
Install the Amazon EFS driver

"github.com/kubernetes-sigs/aws-efs-csi-driver/deploy/kubernetes/overlays/stable/ecr?ref=release-1.3"  >  private-ecr-driver.yaml

**Note**
If you encounter an issue that you aren't able to resolve by adding IAM permissions, try the “Manifest (public registry)” steps instead.

2. Edit the file and remove the following lines that create a Kubernetes service account. These lines aren't needed because the service account was created in a previous step.

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  labels:
    app.kubernetes.io/name: aws-efs-csi-driver
    name: efs-csi-controller-sa
  namespace: kube-system
---
```

3. Find the following line. Replace the following address with the container image address (p. 379). Once you've made the change, save your modified manifest.

```yaml
image: 123456789012.dkr.ecr.region-code.amazonaws.com/eks/aws-efs-csi-driver:v1.3.2
```

4. Apply the manifest.

```shell
kubectl apply -f private-ecr-driver.yaml
```

---

**Manifest (public registry)**

For some situations, you may not be able to add the necessary IAM permissions to pull from the private Amazon ECR registry. One example of this scenario is if your IAM user or role isn't allowed to authenticate with someone else's account. When this is true, you can use the public Amazon ECR registry.

**To install the driver using images stored in the public Amazon ECR registry**

1. Download the manifest.

```shell
kubectl kustomize \\
```

2. Edit the file and remove the following lines that create a Kubernetes service account. This isn't necessary because the service account was created in a previous step.

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  labels:
    app.kubernetes.io/name: aws-efs-csi-driver
    name: efs-csi-controller-sa
  namespace: kube-system
---
```

3. Apply the manifest.

```shell
kubectl apply -f public-ecr-driver.yaml
```
Create an Amazon EFS file system

The Amazon EFS CSI driver supports Amazon EFS access points, which are application-specific entry points into an Amazon EFS file system that make it easier to share a file system between multiple pods. Access points can enforce a user identity for all file system requests that are made through the access point, and enforce a root directory for each pod. For more information, see Amazon EFS access points on GitHub.

Important
You must complete the following steps in the same terminal because variables are set and used across the steps.

To create an Amazon EFS file system for your Amazon EKS cluster

1. Retrieve the VPC ID that your cluster is in and store it in a variable for use in a later step. Replace my-cluster with your cluster name.

   ```bash
   vpc_id=$(aws eks describe-cluster
   --name my-cluster
   --query "cluster.resourcesVpcConfig.vpcId" 
   --output text)
   ```

2. Retrieve the CIDR range for your cluster's VPC and store it in a variable for use in a later step.

   ```bash
   cidr_range=$(aws ec2 describe-vpcs
   --vpc-ids $vpc_id 
   --query "Vpcs[].CidrBlock" 
   --output text)
   ```

3. Create a security group with an inbound rule that allows inbound NFS traffic for your Amazon EFS mount points.
   a. Create a security group. Replace the example values with your own.

      ```bash
      security_group_id=$(aws ec2 create-security-group
      --group-name MyEfsSecurityGroup
      --description "My EFS security group"
      --vpc-id $vpc_id 
      --output text)
      ```
   
   b. Create an inbound rule that allows inbound NFS traffic from the CIDR for your cluster's VPC.

      ```bash
      aws ec2 authorize-security-group-ingress 
      --group-id $security_group_id 
      --protocol tcp 
      --port 2049 
      --cidr $cidr_range
      ```

   Important
   To further restrict access to your file system, you can use the CIDR for your subnet instead of the VPC.

4. Create an Amazon EFS file system for your Amazon EKS cluster.
   a. Create a file system. Replace region-code with the AWS Region that your cluster is in.

      ```bash
      file_system_id=$(aws efs create-file-system
      --region region-code 
      --performance-mode generalPurpose 
      --query 'FileSystemId'
      ```
b. Create mount targets.
   i. Determine the IP address of your cluster nodes.

```
kubectl get nodes
```

Example output:

```
NAME                                      STATUS   ROLES    AGE              VERSION
ip-192-168-56-0.region-code.compute.internal   Ready   <none>   19m              v1.19.6-eks-4966c0
```

ii. Determine the IDs of the subnets in your VPC and which Availability Zone the subnet is in.

```
aws ec2 describe-subnets \  
   --filters "Name=vpc-id,Values=$vpc_id" \  
   --query 'Subnets[*].{SubnetId: SubnetId,AvailabilityZone: AvailabilityZone,CidrBlock: CidrBlock}' \  
   --output table
```

Example output:

```
<table>
<thead>
<tr>
<th>DescribeSubnets</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>AvailabilityZone</td>
<td>CidrBlock</td>
</tr>
<tr>
<td>region-code</td>
<td>192.168.128.0/19</td>
</tr>
<tr>
<td>region-code</td>
<td>192.168.96.0/19</td>
</tr>
<tr>
<td>region-code</td>
<td>192.168.32.0/19</td>
</tr>
<tr>
<td>region-code</td>
<td>192.168.0.0/19</td>
</tr>
<tr>
<td>region-code</td>
<td>192.168.60.0/19</td>
</tr>
</tbody>
</table>
```

iii. Add mount targets for the subnets that your nodes are in. From the output in the previous two steps, the cluster has one node with an IP address of 192.168.56.0. That IP address is within the CidrBlock of the subnet with the ID subnet-EXAMPLEe2ba886490. As a result, the following command creates a mount target for the subnet the node is in. If there were more nodes in the cluster, you’d run the command once for a subnet in each AZ that you had a node in, replacing subnet-EXAMPLEe2ba886490 with the appropriate subnet ID.

```
aws efs create-mount-target \  
   --file-system-id $file_system_id \  
   --subnet-id subnet-EXAMPLEe2ba886490 \  
   --security-groups $security_group_id
```

### Deploy a sample application

You can deploy a sample app that dynamically creates a persistent volume, or you can manually create a persistent volume. You can replace the examples given in this section with a different application.

**Dynamic**

**Important**

You can’t use dynamic provisioning with Fargate nodes.

**Prerequisite**
You must use version 1.2x or later of the Amazon EFS CSI driver, which requires a 1.17 or later cluster. To update your cluster, see the section called “Updating a cluster” (p. 32).

To deploy a sample application that uses a persistent volume that the controller creates

This procedure uses the Dynamic Provisioning example from the Amazon EFS Container Storage Interface (CSI) driver GitHub repository. It dynamically creates a persistent volume through Amazon EFS access points and a Persistent Volume Claim (PVC) that's consumed by a pod.

1. Create a storage class for EFS. For all parameters and configuration options, see Amazon EFS CSI Driver on GitHub.
   a. Retrieve your Amazon EFS file system ID. You can find this in the Amazon EFS console, or use the following AWS CLI command.

   ```bash
   aws efs describe-file-systems --query "FileSystems[*].FileSystemId" --output text
   ```

   Output:

   ```
   fs-582a03f3
   ```

   b. Download a StorageClass manifest for Amazon EFS.

   ```bash
   curl -o storageclass.yaml https://raw.githubusercontent.com/kubernetes-sigs/aws-efs-csi-driver/master/examples/kubernetes/dynamic_provisioning/specs/storageclass.yaml
   ```

   c. Edit the file. Find the following line, and replace the value for `fileSystemId` with your file system ID.

   ```yaml
   fileSystemId: fs-582a03f3
   ```

   d. Deploy the storage class.

   ```bash
   kubectl apply -f storageclass.yaml
   ```

2. Test automatic provisioning by deploying a Pod that makes use of the PersistentVolumeClaim:
   a. Download a manifest that deploys a pod and a PersistentVolumeClaim.

   ```bash
   ```

   b. Deploy the pod with a sample app and the PersistentVolumeClaim used by the pod.

   ```bash
   kubectl apply -f pod.yaml
   ```

3. Determine the names of the pods running the controller.

   ```bash
   kubectl get pods -n kube-system | grep efs-csi-controller
   ```

   Example output:

   ```
   efs-csi-controller-74ccf9f566-q5989  3/3  Running   0  40m
   efs-csi-controller-74ccf9f566-wswg9  3/3  Running   0  40m
   ```
4. After few seconds, you can observe the controller picking up the change (edited for readability). Replace `74ccf9f566-q5989` with a value from one of the pods in your output from the previous command.

```
kubectl logs efs-csi-controller-74ccf9f566-q5989 \
   -n kube-system \
   -c csi-provisioner \
   --tail 10
```

Example output:

```
... 1 controller.go:737] successfully created PV pvc-5983ffec-96cf-40c1-9cd6-e5686ca84eca
for PVC efs-claim and csi volume name fs-95bceec92::fsap-02a88145b865d3a87
```

If you don't see the previous output, run the previous command using one of the other controller pods.

5. Confirm that a persistent volume was created with a status of Bound to a `PersistentVolumeClaim`:

```
kubectl get pv
```

Example output:

```
NAME                                       CAPACITY   ACCESS MODES   RECLAIM POLICY
STATUS   CLAIM               STORAGECLASS   REASON   AGE
pvc-5983ffec-96cf-40c1-9cd6-e5686ca84eca   20Gi       RWX            Delete
Bound    default/efs-claim   efs-sc         7m57s
```

6. View details about the `PersistentVolumeClaim` that was created.

```
kubectl get pvc
```

Example output:

```
NAME        STATUS   VOLUME                                     CAPACITY   ACCESS MODES   STORAGECLASS   AGE
efs-claim   Bound   pvc-5983ffec-96cf-40c1-9cd6-e5686ca84eca 20Gi       RWX            9m7s
```

7. View the sample app pod's status until the STATUS becomes Running.

```
kubectl get pods -o wide
```

Example output:

```
NAME          READY   STATUS    RESTARTS   AGE   IP               NODE                   NOMINATED NODE   READINESS GATES
efs-example   1/1     Running   0          10m   192.168.78.156   ip-192-168-73-191.region-code.compute.internal   <none>           <none>
```

**Note**

If a pod doesn't have an IP address listed, make sure that you added a mount target for the subnet that your node is in (as described at the end of Create an Amazon EFS file).
system (p. 243)). Otherwise the pod won’t leave ContainerCreating status. When an IP address is listed, it may take a few minutes for a pod to reach the Running status.

8. Confirm that the data is written to the volume.

```
kubectl exec efs-app -- bash -c "cat data/out"
```

Example output:

```
... 
Tue Mar 23 14:29:16 UTC 2021 
Tue Mar 23 14:29:21 UTC 2021 
Tue Mar 23 14:29:26 UTC 2021 
Tue Mar 23 14:29:31 UTC 2021 
... 
```

9. (Optional) Terminate the Amazon EKS node that your pod is running on and wait for the pod to be re-scheduled. Alternately, you can delete the pod and redeploy it. Complete the previous step again, confirming that the output includes the previous output.

Static

To deploy a sample application that uses a persistent volume that you create

This procedure uses the Multiple Pods Read Write Many example from the Amazon EFS Container Storage Interface (CSI) driver GitHub repository to consume a statically provisioned Amazon EFS persistent volume and access it from multiple pods with the ReadWriteMany access mode.

1. Clone the Amazon EFS Container Storage Interface (CSI) driver GitHub repository to your local system.

```
git clone https://github.com/kubernetes-sigs/aws-efs-csi-driver.git
```

2. Navigate to the multiple_pods example directory.

```
cd aws-efs-csi-driver/examples/kubernetes/multiple_pods/
```

3. Retrieve your Amazon EFS file system ID. You can find this in the Amazon EFS console, or use the following AWS CLI command.

```
aws efs describe-file-systems --query "FileSystems[*].FileSystemId" --output text
```

Output:

```
fs-582a03f3
```

4. Edit the specs/pv.yaml file and replace the volumeHandle value with your Amazon EFS file system ID.

```
apiVersion: v1
kind: PersistentVolume
metadata: 
  name: efs-pv
spec: 
  capacity: 
    storage: 5Gi
  volumeMode: Filesystem
```
accessModes:
  - ReadWriteMany
persistentVolumeReclaimPolicy: Retain
storageClassName: efs-sc
csi:
  driver: efs.csi.aws.com
  volumeHandle: fs-582a03f3

**Note**
Because Amazon EFS is an elastic file system, it doesn't enforce any file system capacity limits. The actual storage capacity value in persistent volumes and persistent volume claims isn't used when creating the file system. However, because storage capacity is a required field in Kubernetes, you must specify a valid value, such as, 5Gi in this example. This value doesn't limit the size of your Amazon EFS file system.

5. Deploy the efs-sc storage class, efs-claim persistent volume claim, and efs-pv persistent volume from the specs directory.

```bash
kubectl apply -f specs/pv.yaml
kubectl apply -f specs/claim.yaml
kubectl apply -f specs/storageclass.yaml
```

6. List the persistent volumes in the default namespace. Look for a persistent volume with the default/efs-claim claim.

```bash
kubectl get pv -w
```

Output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>CAPACITY</th>
<th>ACCESS MODES</th>
<th>RECLAIM POLICY</th>
<th>STATUS</th>
<th>CLAIM</th>
</tr>
</thead>
<tbody>
<tr>
<td>efs-pv</td>
<td>5Gi</td>
<td>RWX</td>
<td>Retain</td>
<td>Bound</td>
<td>default/efs-claim</td>
</tr>
<tr>
<td>efs-sc</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Don't proceed to the next step until the STATUS is Bound.

7. Deploy the app1 and app2 sample applications from the specs directory.

```bash
kubectl apply -f specs/pod1.yaml
kubectl apply -f specs/pod2.yaml
```

8. Watch the pods in the default namespace and wait for the app1 and app2 pods' STATUS to become Running.

```bash
kubectl get pods --watch
```

**Note**
It may take a few minutes for the pods to reach the Running status.

9. Describe the persistent volume.

```bash
kubectl describe pv efs-pv
```

Output:

<table>
<thead>
<tr>
<th>Name</th>
<th>efs-pv</th>
</tr>
</thead>
<tbody>
<tr>
<td>Labels</td>
<td>none</td>
</tr>
<tr>
<td>Annotations</td>
<td>kubectl.kubernetes.io/last-applied-configuration:</td>
</tr>
</tbody>
</table>
10. Verify that the app1 pod is successfully writing data to the volume.

```bash
kubectl exec -ti app1 -- tail /data/out1.txt
```

Output:
```
...  
Mon Mar 22 18:18:22 UTC 2021  
Mon Mar 22 18:18:27 UTC 2021  
Mon Mar 22 18:18:32 UTC 2021  
Mon Mar 22 18:18:37 UTC 2021  
...
```

11. Verify that the app2 pod shows the same data in the volume that app1 wrote to the volume.

```bash
kubectl exec -ti app2 -- tail /data/out1.txt
```

Output:
```
...  
Mon Mar 22 18:18:22 UTC 2021  
Mon Mar 22 18:18:27 UTC 2021  
Mon Mar 22 18:18:32 UTC 2021  
Mon Mar 22 18:18:37 UTC 2021  
...
```

12. When you finish experimenting, delete the resources for this sample application to clean up.

```bash
kubectl delete -f specs/
```

You can also manually delete the file system and security group that you created.
Amazon FSx for Lustre CSI driver

The FSx for Lustre Container Storage Interface (CSI) driver provides a CSI interface that allows Amazon EKS clusters to manage the lifecycle of FSx for Lustre file systems.

This topic shows you how to deploy the FSx for Lustre CSI Driver to your Amazon EKS cluster and verify that it works. We recommend using version 0.4.0 of the driver.

**Note**
This driver is supported on Kubernetes version 1.22 and later Amazon EKS clusters and nodes. The driver isn’t supported on Fargate or Arm nodes. Alpha features of the FSx for Lustre CSI Driver aren’t supported on Amazon EKS clusters. The driver is in Beta release. It is well tested and supported by Amazon EKS for production use. Support for the driver will not be dropped, though details may change. If the schema or schematics of the driver changes, instructions for migrating to the next version will be provided.

For detailed descriptions of the available parameters and complete examples that demonstrate the driver’s features, see the FSx for Lustre Container Storage Interface (CSI) driver project on GitHub.

**Prerequisites**
You must have:

- Version 2.5.2 or later or 1.22.86 or later of the AWS CLI installed and configured on your computer or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with `aws configure` in the AWS Command Line Interface User Guide.
- An existing Amazon EKS cluster. To deploy one, see Getting started with Amazon EKS (p. 4).
- An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Create an IAM OIDC provider for your cluster (p. 466).
- Version 0.92.0 or later of the `eksctl` command line tool installed on your computer or AWS CloudShell. To install or update `eksctl`, see Installing `eksctl` (p. 10).
- The `kubectl` command line tool installed on your computer or AWS CloudShell. The version must be the same, or up to two versions later than your cluster version. To install or upgrade `kubectl`, see Installing `kubectl` (p. 4).

**To deploy the FSx for Lustre CSI driver to an Amazon EKS cluster**

1. Create an IAM policy and service account that allows the driver to make calls to AWS APIs on your behalf:
   
   a. Copy the following text and save it to a file named `fsx-csi-driver.json`. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`.

   ```json
   {
     "Version":"2012-10-17",
     "Statement":[
       {
         "Effect":"Allow",
         "Action": [
           "iam:CreateServiceLinkedRole",
           "iam:AttachRolePolicy",
           "iam:PutRolePolicy"
         ],
       }
   }
   ```
b. Create the policy. You can replace `Amazon_FSx_Lustre_CSI_Driver` with a different name.

```bash
aws iam create-policy \
  --policy-name Amazon_FSx_Lustre_CSI_Driver \
  --policy-document file://fsx-csi-driver.json
```

Take note of the policy Amazon Resource Name (ARN) that is returned.

2. Create a Kubernetes service account for the driver and attach the policy to the service account. Replacing the ARN of the policy with the ARN returned in the previous step. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace **arn:aws:** with **arn:aws-us-gov:** before running the following command.

```bash
eksctl create iamserviceaccount \
  --region region-code \
  --name fsx-csi-controller-sa \
  --namespace kube-system \
  --role-name "AmazonEKSfsxLustreCSIDriver" \
  --cluster prod \
  --attach-policy-arn arn:aws:iamb::111122223333:policy/Amazon_FSx_Lustre_CSI_Driver \
  --approve
```

Output:

You'll see several lines of output as the service account is created. The last line of output is similar to the following example line.

```
[✓] created serviceaccount "kube-system/fsx-csi-controller-sa"
```

Note the name of the AWS CloudFormation stack that was deployed. In the example output above, the stack is named `eksctl-prod-addon-iamserviceaccount-kube-system-fsx-csi-controller-sa`.
3. **Note the Role ARN** for the role that was created.
   
   b. Ensure that the console is set to the AWS Region that you created your IAM role in and then select **Stacks**.
   d. Select the **Outputs** tab. The **Role ARN** is listed on the **Output(1)** page.

4. **Deploy the driver with the following command.**

   **Note**
   To see or download the yaml file manually, you can find it on the [aws-fsx-csi-driver Github](https://github.com/kubernetes-sigs/aws-fsx-csi-driver).

   ```bash
   kubectl apply -k "github.com/kubernetes-sigs/aws-fsx-csi-driver/deploy/kubernetes/overlays/stable/?ref=master"
   ```

   **Example output:**

   ```
   Warning: kubectl apply should be used on resource created by either kubectl create --save-config or kubectl apply
   serviceaccount/fsx-csi-controller-sa configured
   clusterrole.rbac.authorization.k8s.io/fsx-csi-external-provisioner-role created
   clusterrolebinding.rbac.authorization.k8s.io/fsx-csi-external-provisioner-binding created
   deployment.apps/fsx-csi-controller created
   daemonset.apps/fsx-csi-node created
   csidriver.storage.k8s.io/fsx.csi.aws.com created
   ```

5. **Patch the driver deployment to add the service account that you created earlier, replacing the ARN with the ARN that you noted.** If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:` before running the following command.

   ```bash
   kubectl annotate serviceaccount -n kube-system fsx-csi-controller-sa
   eks.amazonaws.com/role-arn=arn:aws:iam::111122223333:role/AmazonEKSFSxLustreCSIDriver
   --overwrite=true
   ```

**To deploy a Kubernetes storage class, persistent volume claim, and sample application to verify that the CSI driver is working**

This procedure uses the [Dynamic volume provisioning for Amazon S3](https://github.com/kubernetes-sigs/aws-fsx-csi-driver) from the **FSx for Lustre Container Storage Interface (CSI) driver GitHub repository** to consume a dynamically-provisioned FSx for Lustre volume.

1. **Create an Amazon S3 bucket and a folder within it named `export` by creating and copying a file to the bucket.**

   ```bash
   aws s3 mb s3://fsx-csi
   echo test-file >> testfile
   aws s3 cp testfile s3://fsx-csi/export/testfile
   ```

2. **Download the storageclass manifest with the following command.**

   ```bash
   curl -o storageclass.yaml https://raw.githubusercontent.com/kubernetes-sigs/aws-fsx-csi-driver/master/examples/kubernetes/dynamic_provisioning_s3/specs/storageclass.yaml
   ```

3. **Edit the file and replace every `example-value` with your own values.**
parameters:

- subnetId: subnet-056da83524edbe641
- securityGroupIds: sg-086f61ea7388fb6b
- s3ImportPath: s3://ml-training-data-000
- s3ExportPath: s3://ml-training-data-000/export
- deploymentType: SCRATCH_2

- **subnetId** – The subnet ID that the Amazon FSx for Lustre file system should be created in. Amazon FSx for Lustre isn't supported in all Availability Zones. Open the Amazon FSx for Lustre console at https://console.aws.amazon.com/fsx/ to confirm that the subnet that you want to use is in a supported Availability Zone. The subnet can include your nodes, or can be a different subnet or VPC. If the subnet that you specify isn't the same subnet that you have nodes in, then your VPCs must be connected, and you must ensure that you have the necessary ports open in your security groups.

- **securityGroupIds** – The security group ID for your nodes.

  **Note**
  The security groups must allow inbound/outbound access to Lustre ports 988 and 1021–1023. For more information, see Lustre Client VPC Security Group Rules in the Amazon FSx for Lustre User Guide.

- **s3ImportPath** – The Amazon Simple Storage Service data repository that you want to copy data from to the persistent volume. Specify the `fsx-csi` bucket that you created earlier.

- **s3ExportPath** – The Amazon S3 data repository that you want to export new or modified files to. Specify the `fsx-csi/export` folder that you created earlier.

- **deploymentType** – The file system deployment type. Valid values are SCRATCH_1, SCRATCH_2, and PERSISTENT_1. For more information about deployment types, see Create your Amazon FSx for Lustre file system.

  **Note**
  The Amazon S3 bucket for s3ImportPath and s3ExportPath must be the same, otherwise the driver cannot create the FSx for Lustre file system. The s3ImportPath can stand alone. A random path will be created automatically like s3://ml-training-data-000/FSxLustre20190308T012310Z. The s3ExportPath cannot be used without specifying a value for s3ImportPath.

4. Create the storageclass.

```
kubectl apply -f storageclass.yaml
```

5. Download the persistent volume claim manifest.

```
curl -o claim.yaml https://raw.githubusercontent.com/kubernetes-sigs/aws-fsx-csi-driver/master/examples/kubernetes/dynamic_provisioning_s3/specs/claim.yaml
```

6. (Optional) Edit the `claim.yaml` file. Change **1200Gi** to one of the increment values listed below, based on your storage requirements and the deploymentType that you selected in a previous step.

```
storage: 1200Gi
```

- **SCRATCH_2** and **PERSISTENT** – 1.2 TiB, 2.4 TiB, or increments of 2.4 TiB over 2.4 TiB.
- **SCRATCH_1** – 1.2 TiB, 2.4 TiB, 3.6 TiB, or increments of 3.6 TiB over 3.6 TiB.

7. Create the persistent volume claim.

```
kubectl apply -f claim.yaml
```
8. Confirm that the file system is provisioned.

```shell
kubectl get pvc
```

Output.

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>VOLUME</th>
<th>CAPACITY</th>
<th>ACCESS MODES</th>
</tr>
</thead>
<tbody>
<tr>
<td>fsx-claim</td>
<td>Bound</td>
<td>pvc-15dad3c1-2365-11ea-a836-02468c18769e</td>
<td>1200Gi</td>
<td>RWX</td>
</tr>
<tr>
<td>fsx-sc</td>
<td>7m37s</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note**
The STATUS may show as Pending for 5-10 minutes, before changing to Bound. Don't continue with the next step until the STATUS is Bound.

9. Deploy the sample application.

```shell
```

10. Verify that the sample application is running.

```shell
kubectl get pods
```

Example output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>fsx-app</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>8s</td>
</tr>
</tbody>
</table>

**Access Amazon S3 files from the FSx for Lustre file system**

If you only want to import data and read it without any modification and creation, then you don't need a value for s3ExportPath in your storageclass.yaml file. Verify that data was written to the FSx for Lustre file system by the sample app.

```shell
kubectl exec -it fsx-app ls /data
```

Output.

```shell
export out.txt
```

The sample app wrote the out.txt file to the file system.

**Archive files to the s3ExportPath**

For new files and modified files, you can use the Lustre user space tool to archive the data back to Amazon S3 using the value that you specified for s3ExportPath.

1. Export the file back to Amazon S3.

```shell
kubectl exec -ti fsx-app -- lfs hsm_archive /data/out.txt
```
Note

- New files aren't synced back to Amazon S3 automatically. In order to sync files to the `s3ExportPath`, you need to install the Lustre client in your container image and manually run the `lfs hsm_archive` command. The container should run in privileged mode with the `CAP_SYS_ADMIN` capability.
- This example uses a lifecycle hook to install the Lustre client for demonstration purpose. A normal approach is building a container image with the Lustre client.

2. Confirm that the `out.txt` file was written to the `s3ExportPath` folder in Amazon S3.

```
aws s3 ls fsx-csi/export/
```

Example output:

```
2019-12-23 12:11:35       4553 out.txt
2019-12-23 11:41:21         10 testfile
```

Amazon FSx for NetApp ONTAP CSI driver

NetApp’s Astra Trident provides dynamic storage orchestration using a Container Storage Interface (CSI) compliant driver. This allows Amazon EKS clusters to manage the lifecycle of persistent volumes (PVs) backed by Amazon FSx for NetApp ONTAP file systems. To get started, see Use Astra Trident with Amazon FSx for NetApp ONTAP in the Astra Trident documentation.

Amazon FSx for NetApp ONTAP is a storage service that allows you to launch and run fully managed ONTAP file systems in the cloud. ONTAP is NetApp’s file system technology that provides a widely adopted set of data access and data management capabilities. Amazon FSx for NetApp ONTAP provides the features, performance, and APIs of on-premises NetApp file systems with the agility, scalability, and simplicity of a fully managed AWS service. For more information, see the FSx for ONTAP User Guide.
Amazon EKS networking

This chapter provides an overview of Amazon EKS networking. The following diagram shows key components of an Amazon EKS cluster, and the relationship of these components to a VPC.

The following explanations help you understand how components of the diagram relate to each other and which topics in this guide and other AWS guides that you can reference for more information.

- **Amazon VPC and subnets** – All Amazon EKS resources are deployed to one AWS Region in an existing subnet in an existing VPC. For more information, see VPCs and subnets in the Amazon VPC User Guide. Each subnet exists in one Availability Zone. The VPC and subnets must meet requirements such as the following:
  - VPCs and subnets must be tagged appropriately, so that Kubernetes knows that it can use them for deploying resources, such as load balancers. For more information, see Subnet tagging (p. 265). If you deploy the VPC using an Amazon EKS provided AWS CloudFormation template (p. 259) or using eksctl, then the VPC and subnets are tagged appropriately for you.
  - A subnet may or may not have internet access. If a subnet does not have internet access, the pods deployed within it must be able to access other AWS services, such as Amazon ECR, to pull container images. For more information about using subnets that don't have internet access, see Private clusters (p. 100).
  - Any public subnets that you use must be configured to auto-assign public IPv4 addresses or IPv6 addresses for Amazon EC2 instances launched within them. For more information, see VPC IP addressing (p. 263).
  - If using IPv6, each subnet must be configured to auto-assign IPv6 addresses. For more information, see Modify the IPv6 addressing attribute for your subnet in the Amazon VPC User Guide.
  - The nodes and control plane must be able to communicate over all ports through appropriately tagged security groups. For more information, see Amazon EKS security group considerations (p. 265).
• You can implement a network segmentation and tenant isolation network policy. Network policies are similar to AWS security groups in that you can create network ingress and egress rules. Instead of assigning instances to a security group, you assign network policies to pods using pod selectors and labels. For more information, see Installing the Calico add-on (p. 341).

You can deploy a VPC and subnets that meet the Amazon EKS requirements through manual configuration, or by deploying the VPC and subnets using eksctl (p. 10), or an Amazon EKS provided AWS CloudFormation template. Both eksctl and the AWS CloudFormation template create the VPC and subnets with the required configuration. For more information, see Creating a VPC for your Amazon EKS cluster (p. 259).

• Amazon EKS control plane – Deployed and managed by Amazon EKS in an Amazon EKS managed VPC. When you create the cluster, Amazon EKS creates and manages network interfaces in your account that have Amazon EKS <cluster name> in their description. These network interfaces allow AWS Fargate and Amazon EC2 instances to communicate with the control plane.

By default, the control plane exposes a public endpoint so that clients and nodes can communicate with the cluster. You can limit the internet client source IP addresses that can communicate with the public endpoint. Alternatively, you can enable a private endpoint and disable the public endpoint or enable both the public and private endpoints. To learn more about cluster endpoints, see Amazon EKS cluster endpoint access control (p. 45).

Clients in your on-premises network or other VPCs can communicate with the public or private-only endpoint, if you've configured connectivity between the VPC that the cluster is deployed to and the other networks. For more information about connecting your VPC to other networks, see the AWS Network-to-Amazon VPC connectivity options and Amazon VPC-to-Amazon VPC connectivity options technical papers.

• Amazon EC2 instances – Each Amazon EC2 node is deployed to one subnet. Each node is assigned a private IP address from a CIDR block assigned to the subnet. If the subnets were created using one of the Amazon EKS provided AWS CloudFormation templates (p. 259), then nodes deployed to public subnets are automatically assigned a public IPv4 address by the subnet. Each node is deployed with the Amazon VPC CNI add-on by default. The add-on assigns each pod a private IP address from the CIDR block assigned to the subnet that the node is in and adds an IPv4 address as a secondary IP address to one of the network interfaces attached to the instance. This AWS resource is referred to as a network interface in the AWS Management Console and the Amazon EC2 API. Therefore, we use "network interface" in this documentation instead of "elastic network interface". The term "network interface" in this documentation always means "elastic network interface".

You can change this behavior by assigning additional IPv4 CIDR blocks to your VPC and enabling CNI custom networking (p. 300), which assigns IP addresses to pods from different subnets than the node is deployed to. To use custom networking, you must enable it when you launch your nodes. You can also associate unique security groups with some of the pods running on many Amazon EC2 instance types. For more information, see Security groups for pods (p. 307).

By default, the source IPv4 address of each pod that communicates with resources outside of the VPC is translated through network address translation (NAT) to the primary IP address of the primary network interface attached to the node. You can change this behavior to instead have a NAT device in a private subnet translate each pod's IPv4 address to the NAT device's IPv4 address. For more information, see External source network address translation (SNAT) (p. 298).

If your instance is deployed to a cluster that uses the IPv6 family, you must assign an IPv6 CIDR block to your VPC and subnets. Outbound IPv6 traffic is not network address translated. For more information about using IPv6 with your cluster, see Assigning IPv6 addresses to pods and services (p. 288).

• Fargate pods – Deployed to private subnets only. Each pod is assigned a private IPv4 (and optionally, an IPv6) address from the CIDR block assigned to the subnet. Fargate does not support all pod networking options. For more information, see AWS Fargate considerations (p. 152).
Creating a VPC for your Amazon EKS cluster

Amazon Virtual Private Cloud (Amazon VPC) enables you to launch AWS resources into a virtual network that you’ve defined. This virtual network closely resembles a traditional network that you’d operate in your own data center, with the benefits of using the scalable infrastructure of AWS. For more information, see the Amazon VPC User Guide and De-mystifying cluster networking for Amazon EKS nodes.

If you want to use an existing VPC, then it must meet specific requirements for use with Amazon EKS. For more information, see Cluster VPC and subnet considerations (p. 262). This topic guides you through creating a VPC for your cluster using one of the following configurations:

- **Public and private subnets** – This VPC has two public and two private subnets. One public and one private subnet are deployed to the same Availability Zone. The other public and private subnets are deployed to a second Availability Zone in the same AWS Region. We recommend this option for all production deployments. This option allows you to deploy your nodes to private subnets and allows Kubernetes to deploy load balancers to the public subnets that can load balance traffic to pods running on nodes in the private subnets.

  Public IPv4 addresses are automatically assigned to nodes deployed to public subnets, but public IPv4 addresses are not assigned to nodes deployed to private subnets. If you choose, you can also assign IPv6 addresses to nodes in public and private subnets. The nodes in private subnets can communicate with the cluster and other AWS services, and pods can communicate outbound to the internet through a NAT gateway (IPv4) or egress-only Internet gateway (IPv6) that is deployed in each Availability Zone. A security group is deployed that denies all inbound traffic and allows all outbound traffic. The subnets are tagged so that Kubernetes is able to deploy load balancers to them. For more information about subnet tagging, see Subnet tagging (p. 265).

  For more information about this type of VPC, see VPC with public and private subnets (NAT).

- **Only public subnets** – This VPC has three public subnets that are deployed into different Availability Zones in the region. All nodes are automatically assigned public IPv4 addresses and can send and receive internet traffic through an internet gateway. A security group is deployed that denies all inbound traffic and allows all outbound traffic. The subnets are tagged so that Kubernetes can deploy load balancers to them. For more information about subnet tagging, see Subnet tagging (p. 265). For more information about this type of VPC, see VPC with a single public subnet.

- **Only private subnets** – This VPC has three private subnets that are deployed into different Availability Zones in the AWS Region. All nodes can optionally send and receive internet traffic through a NAT instance or NAT gateway. A security group is deployed that denies all inbound traffic and allows all outbound traffic. The subnets are tagged so that Kubernetes can deploy internal load balancers to them. For more information about subnet tagging, see Subnet tagging (p. 265). For more information about this type of VPC, see VPC with a private subnet only and AWS Site-to-Site VPN access.

  **Important**

  There are additional requirements if the VPC does not have outbound internet access, such as via a NAT Instance, NAT Gateway, Egress-only internet gateway, VPN, or Direct Connect. You must bypass the EKS cluster introspection by providing the cluster certificate authority and cluster API endpoint to the nodes. You also may need to configure VPC endpoints listed in Modifying cluster endpoint access (p. 46).

  **Important**

  If you deployed a VPC using `eksctl` or by using either of the Amazon EKS AWS CloudFormation VPC templates:

  - On or after March 26, 2020 – Public IPv4 addresses are automatically assigned by public subnets to new nodes deployed to public subnets.
• Before March 26, 2020 – Public IPv4 addresses are not automatically assigned by public subnets to new nodes deployed to public subnets.

This change impacts new node groups deployed to public subnets in the following ways:

• **Managed node groups (p. 113)** – If the node group is deployed to a public subnet on or after April 22, 2020, the public subnet must have automatic assignment of public IP addresses enabled. For more information, see Modifying the public IPv4 addressing attribute for your subnet.

• **Linux (p. 132), Windows (p. 139), or Arm (p. 184) self-managed node groups** – If the node group is deployed to a public subnet on or after March 26, 2020, the public subnet must have automatic assignment of public IP addresses enabled or the nodes must be launched with a public IP address. For more information, see Modifying the public IPv4 addressing attribute for your subnet or Assigning a public IPv4 address during instance launch.

**Prerequisite**

You must have the necessary IAM permissions to create Amazon VPC resources such as VPCs, subnets, security groups, route tables and routes, and internet and NAT gateways. For more information, see Create a VPC with a public subnet example policy in the Amazon VPC User Guide and the full list of Actions, resources, and condition keys for Amazon EC2 in the Service Authorization Reference.

**Creating a VPC for your Amazon EKS cluster**

You can create a VPC with public and private subnets, only public subnets, or only private subnets. Select the tab with the description of the type of VPC that you’d like to create.

**Public and private subnets**

**To create your cluster VPC with public and private subnets**

2. From the navigation bar, select an AWS Region that supports Amazon EKS.
3. Choose **Create stack, With new resources (standard)**.
4. Under **Prerequisite - Prepare template**, make sure that **Template is ready** is selected and then under **Specify template**, select **Amazon S3 URL**.
5. You can create an IPv4 network or an IPv6 network. Paste one of the following URLs into the text area under **Amazon S3 URL** and choose **Next**:
   - **IPv4**
     
   - **IPv6**
     

6. On the **Specify stack details** page, fill out the parameters accordingly, and then choose **Next**.

• **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it **eks-vpc**. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can’t be longer than 128 characters.
Creating a VPC for Amazon EKS

- **VpcBlock**: Choose an IPv4 CIDR range for your VPC. Each node, pod, and load balancer that you deploy is assigned an IPv4 address from this block. The default IPv4 values provide enough IP addresses for most implementations, but if it doesn't, then you can change it. For more information, see VPC and subnet sizing in the Amazon VPC User Guide. You can also add additional CIDR blocks to the VPC once it's created. If you're creating an IPv6 VPC, IPv6 CIDR ranges are automatically assigned for you from Amazon's Global Unicast Address space.

- **PublicSubnet01Block**: Specify an IPv4 CIDR block for public subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it. If you're creating an IPv6 VPC, this block is specified for you within the template.

- **PublicSubnet02Block**: Specify an IPv4 CIDR block for public subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it. If you're creating an IPv6 VPC, this block is specified for you within the template.

- **PrivateSubnet01Block**: Specify an IPv4 CIDR block for private subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it. If you're creating an IPv6 VPC, this block is specified for you within the template.

- **PrivateSubnet02Block**: Specify an IPv4 CIDR block for private subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it. If you're creating an IPv6 VPC, this block is specified for you within the template.

7. (Optional) On the **Configure stack options** page, tag your stack resources and then choose Next.

8. On the **Review** page, choose Create stack.

9. When your stack is created, select it in the console and choose Outputs.

10. Record the **SecurityGroups** value for the security group that was created. When you add nodes to your cluster, you must specify the ID of the security group. The security group is applied to the elastic network interfaces that are created by Amazon EKS in your subnets that allows the control plane to communicate with your nodes. These network interfaces have Amazon EKS cluster name in their description.

11. Record the **VpcId** for the VPC that was created. You need this when you launch your node group template.

12. Record the **SubnetIds** for the subnets that were created and whether you created them as public or private subnets. When you add nodes to your cluster, you must specify the IDs of the subnets that you want to launch the nodes into.

13. If you created an IPv4 VPC, skip this step. If you created an IPv6 VPC, then you must enable the auto-assign IPv6 address option for the public subnets that were created by the template. That setting is already enabled for the private subnets. To enable the setting, complete the following steps.

   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. In the left navigation pane, choose Subnets
   c. Select one of your public subnets (stack-name/SubnetPublic01 or stack-name/SubnetPublic02 contains the word public) and choose Actions, Edit subnet settings.
   d. Choose the Enable auto-assign IPv6 address check box and then choose Save.
   e. Complete the previous steps again for your other public subnet.

Only public subnets

**To create your cluster VPC with only public subnets**

2. From the navigation bar, select an AWS Region that supports Amazon EKS.
3. Choose Create stack, With new resources (standard).
4. Under **Prepare template**, make sure that **Template is ready** is selected and then under **Template source**, select **Amazon S3 URL**.

5. Paste the following URL into the text area under **Amazon S3 URL** and choose **Next**:

6. On the **Specify Details** page, fill out the parameters accordingly, and then choose **Next**.

   - **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it `eks-vpc`. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 128 characters.
   - **VpcBlock**: Choose a CIDR block for your VPC. Each node, pod, and load balancer that you deploy is assigned an IPv4 address from this block. The default IPv4 values provide enough IP addresses for most implementations, but if it doesn't, then you can change it. For more information, see [VPC and subnet sizing](https://docs.aws.amazon.com/vpc/userguide/vpc_overview.html) in the Amazon VPC User Guide. You can also add additional CIDR blocks to the VPC once it's created.
   - **Subnet01Block**: Specify a CIDR block for subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
   - **Subnet02Block**: Specify a CIDR block for subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
   - **Subnet03Block**: Specify a CIDR block for subnet 3. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.

7. (Optional) On the **Options** page, tag your stack resources. Choose **Next**.

8. On the **Review** page, choose **Create**.

9. When your stack is created, select it in the console and choose **Outputs**.

10. Record the **SecurityGroups** value for the security group that was created. When you add nodes to your cluster, you must specify the ID of the security group. The security group is applied to the elastic network interfaces that are created by Amazon EKS in your subnets that allows the control plane to communicate with your nodes. These network interfaces have `Amazon EKS cluster name` in their description.

11. Record the **VpcId** for the VPC that was created. You need this when you launch your node group template.

12. Record the **SubnetIds** for the subnets that were created. When you add nodes to your cluster, you must specify the IDs of the subnets that you want to launch the nodes into.

13. (Optional) Any cluster that you deploy to this VPC is able to assign private IPv4 addresses to your pods and services. If you want any clusters deployed to this VPC to assign private IPv6 addresses to your pods and services, then you must make updates to your VPC, subnet, route tables, and security groups. For more information, see [Migrate existing VPCs from IPv4 to IPv6](https://docs.aws.amazon.com/vpc/latest/userguide/migrate-existing-vpc-ipv6.html) in the Amazon VPC User Guide. Amazon EKS requires that your subnets have the Auto-assign IPv6 addresses option enabled (it's disabled by default).

**Only private subnets**

**To create your cluster VPC with only private subnets**

2. From the navigation bar, select an AWS Region that supports Amazon EKS.

3. Choose **Create stack**, With new resources (standard).

4. Under **Prepare template**, make sure that **Template is ready** is selected and then under **Template source**, select **Amazon S3 URL**.

5. Paste the following URL into the text area under **Amazon S3 URL** and choose **Next**:

6. On the **Specify Details** page, fill out the parameters accordingly, and then choose **Next**.

- **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it `eks-vpc`. The name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 128 characters.

- **VpcBlock**: Choose a CIDR block for your VPC. Each node, pod, and load balancer that you deploy is assigned an IPv4 address from this block. The default IPv4 values provide enough IP addresses for most implementations, but if it doesn't, then you can change it. For more information, see *VPC and subnet sizing* in the Amazon VPC User Guide. You can also add additional CIDR blocks to the VPC once it's created.

- **PrivateSubnet01Block**: Specify a CIDR block for subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.

- **PrivateSubnet02Block**: Specify a CIDR block for subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.

- **PrivateSubnet03Block**: Specify a CIDR block for subnet 3. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.

7. (Optional) On the **Options** page, tag your stack resources. Choose **Next**.
8. On the **Review** page, choose **Create**.
9. When your stack is created, select it in the console and choose **Outputs**.
10. Record the **SecurityGroups** value for the security group that was created. When you add nodes to your cluster, you must specify the ID of the security group. The security group is applied to the elastic network interfaces that Amazon EKS creates in your subnets to allow the control plane to communicate with your nodes. These network interfaces have Amazon EKS cluster name in their description.
11. Record the **VpcId** for the VPC that was created. You need this when you launch your node group template.
12. Record the **SubnetIds** for the subnets that were created. When you add nodes to your cluster, you must specify the IDs of the subnets that you want to launch the nodes into.
13. (Optional) Any cluster that you deploy to this VPC is able to assign private IPv4 addresses to your pods and services. If you want any clusters deployed to this VPC to assign private IPv6 addresses to your pods and services, then you must make updates to your VPC, subnet, route tables, and security groups. For more information, see *Migrate existing VPCs from IPv4 to IPv6* in the Amazon VPC User Guide. Amazon EKS requires that your subnets have the Auto-assign IPv6 addresses option enabled (it's disabled by default).

## Cluster VPC and subnet considerations

Amazon EKS recommends running a cluster in a VPC with public and private subnets so that Kubernetes can create public load balancers in the public subnets that load balance traffic to pods running on nodes that are in private subnets. This configuration is not required, however. You can run a cluster in a VPC with only private or only public subnets, depending on your networking and security requirements. For more information about clusters deployed to a VPC with only private subnets, see Private clusters (p. 100).

When you create an Amazon EKS cluster, you specify the VPC subnets where Amazon EKS can place Elastic network interfaces. Amazon EKS requires subnets in at least two Availability Zone, and creates up to four network interfaces across these subnets to facilitate control plane communication to your nodes. This communication channel supports Kubernetes functionality such as **kubectl exec** and **kubectl logs**. The Amazon EKS created **cluster security group** (p. 265) and any additional security groups that
you specify when you create your cluster are applied to these network interfaces. Each Amazon EKS created network interface has Amazon EKS `cluster name` in its description.

Make sure that the subnets that you specify during cluster creation have enough available IP addresses for the Amazon EKS created network interfaces. If you're going to deploy a cluster that uses the IPv4 family, we recommend creating small (/28), dedicated subnets for Amazon EKS created network interfaces, and only specifying these subnets as part of cluster creation. Other resources, such as nodes and load balancers, should be launched in separate subnets from the subnets specified during cluster creation.

**Important**

- Nodes and load balancers can be launched in any subnet in your cluster’s VPC, including subnets not registered with Amazon EKS during cluster creation. Subnets do not require any tags for nodes. For Kubernetes load balancing auto discovery to work, subnets must be tagged as described in Subnet tagging (p. 265).
- Subnets associated with your cluster cannot be changed after cluster creation. If you need to control exactly which subnets the Amazon EKS created network interfaces are placed in, then specify only two subnets during cluster creation, each in a different Availability Zone.
- Do not select a subnet in AWS Outposts, AWS Wavelength, or an AWS Local Zone when creating your cluster.
- Clusters created using v1.14 or earlier contain a `kubernetes.io/cluster/cluster-name` tag on your VPC. This tag was only used by Amazon EKS and can be safely removed.
- It can take a cluster as long as five hours to recognize a CIDR block added to an existing VPC. Each of the subnets from the new CIDR block must have at least five free IP addresses for the control plane to reconcile.
- Amazon EC2 resource-based naming is not supported with Amazon EKS. You must use IP address-based naming for your subnets and instances.
- If you want Kubernetes to assign IPv6 addresses to pods and services, then you must have IPv4 and IPv6 CIDR blocks assigned to your VPC and subnets. For more information, see Associate an IPv6 CIDR block with your VPC in the Amazon VPC User Guide. Your route tables and security groups must also include IPv6 addresses. For more information, see Migrate to IPv6 in the Amazon VPC User Guide.
- Nodes must be able to communicate with the control plane and other AWS services. If your nodes are deployed in a private subnet and you want pods to have outbound access to the internet, then the private subnet must meet one of the following requirements:
  - Subnets with only IPv4 CIDR blocks must have a default route to a NAT gateway. The NAT gateway must be assigned a public IPv4 address to provide internet access for the nodes.
  - Subnets with IPv6 CIDR blocks must have a default route to an egress-only internet gateway.
- Your VPC must have DNS hostname and DNS resolution support, or your nodes can’t register with your cluster. For more information, see Using DNS with Your VPC in the Amazon VPC User Guide.

**VPC IP addressing**

If you want pods deployed to nodes in public subnets to have outbound internet access, then your public subnets must be configured to auto-assign public IPv4 addresses or IPv6 addresses. Determine whether your public subnets are configured to auto-assign public IPv4 addresses or IPv6 addresses with the following command. Replace the `example values` with your own values.
IPv4

```
aws ec2 describe-subnets
   --filters "Name=vpc-id,Values=VPC-ID" | grep 'SubnetId\|MapPublicIpOnLaunch'
```

IPv6

```
aws ec2 describe-subnets
   --filters "Name=vpc-id,Values=VPC-ID" | grep 'SubnetId\|AssignIpv6AddressOnCreation'
```

Example output:

IPv4

```
"MapPublicIpOnLaunch": true,
"SubnetId": "subnet-ID1",
"MapPublicIpOnLaunch": false,
"SubnetId": "subnet-ID2",
...
```

IPv6

```
"SubnetId": "subnet-ID1",
"AssignIpv6AddressOnCreation": true,
"SubnetId": "subnet-ID2",
"AssignIpv6AddressOnCreation": false,
...
```

For any subnets that have MapPublicIpOnLaunch or AssignIpv6AddressOnCreation set to false, change the setting to true.

IPv4

```
aws ec2 modify-subnet-attribute --subnet-id subnet-ID2 --map-public-ip-on-launch
```

IPv6

```
aws ec2 modify-subnet-attribute --subnet-id subnet-ID2 --assign-ipv6-address-on-creation
```

**Important**

If you used an Amazon EKS AWS CloudFormation template (p. 258) to deploy your VPC before March 26, 2020, then you need to change the setting for your public subnets. You can define both private (RFC 1918), and public (non-RFC 1918) classless inter-domain routing (CIDR) IPv4 ranges within the VPC used for your Amazon EKS cluster. For more information, see Adding IPv4 CIDR blocks to a VPC in the Amazon VPC User Guide. When choosing the CIDR blocks for your VPC and subnets, make sure that the blocks contain enough IPv4 addresses for all of the Amazon EC2 nodes and pods that you plan to deploy. There should be at least one IP address for each of your pods. You can conserve IP address use by implementing a transit gateway with a shared services VPC. For more information, see Isolated VPCs with shared services and Amazon EKS VPC routable IP address conservation patterns in a hybrid network.
Subnet tagging

For 1.18 and earlier clusters, Amazon EKS adds the following tag to all subnets passed in during cluster creation. Amazon EKS does not add the tag to subnets passed in when creating 1.19 clusters. If the tag exists on subnets used by a cluster created on a version earlier than 1.19, and you update the cluster to 1.19, the tag is not removed from the subnets.

- **Key**: kubernetes.io/cluster/cluster-name
- **Value**: shared

You can optionally use this tag to control where Elastic Load Balancers are provisioned, in addition to the required subnet tags for using automatically provisioned Elastic Load Balancers. For more information about load balancer subnet tagging, see Application load balancing on Amazon EKS (p. 371) and Network load balancing on Amazon EKS (p. 365).

Increase available IPv4 addresses for your VPC

If your Amazon VPC is running out of IPv4 addresses, you can associate a secondary CIDR to an existing VPC. For more information, see Associate a secondary IP address CIDR block with your VPC in the Amazon VPC User Guide. With the new associated CIDR, you can create subnets using a subset of the newly associated CIDR. After creating the new subnet or subnets, you can create additional node groups, either managed or self-managed, that use the newly associated CIDR and subnets.

Amazon EKS security group considerations

The following sections describe the recommended or minimum required security group settings for the cluster, control plane, and node security groups of your cluster. These considerations are dependent on which Kubernetes version and Amazon EKS platform version you use.

**Important**

If you've configured your cluster to use IPv6 (p. 288), then your security groups must allow communication to and from all IPv4 and IPv6 addresses that Pods communicate with or are communicated with from.

Cluster security group

Amazon EKS clusters, starting with Kubernetes version 1.14 and platform version (p. 74) eks.3, create a cluster security group when they are created. This also happens when a cluster of an earlier version is upgraded to this Kubernetes version and platform version. A cluster security group is designed to allow all traffic from the control plane and managed node groups (p. 109) to flow freely between each other. By assigning the cluster security group to the elastic network interfaces created by Amazon EKS that allow the control plane to communicate with the managed node group instances, you don't need to configure complex security group rules to allow this communication. Any instance or network interface that is assigned this security group can freely communicate with other resources with this security group.

You can check for a cluster security group for your cluster in the AWS Management Console under the cluster's **Networking** section, or with the following AWS CLI command:

```bash
aws eks describe-cluster --name my-cluster --query cluster.resourcesVpcConfig.clusterSecurityGroupId
```

We recommend that you add the cluster security group to all existing and future node groups. For more information, see Security Groups for Your VPC in the Amazon VPC User Guide. Amazon EKS managed node groups (p. 109) are automatically configured to use the cluster security group.
Control plane and node security groups

Restricting cluster traffic

If you need to limit the open ports between the control plane and nodes, the default cluster security group can be modified to allow only the following required minimum ports. The required minimum ports are the same as they were in previous Amazon EKS versions.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Source</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum inbound traffic</td>
<td>TCP</td>
<td>443</td>
<td>Cluster security group</td>
</tr>
<tr>
<td>Minimum inbound traffic*</td>
<td>TCP</td>
<td>10250</td>
<td>Cluster security group</td>
</tr>
<tr>
<td>CoreDNS</td>
<td>TCP and UDP</td>
<td>53</td>
<td>Cluster security group</td>
</tr>
<tr>
<td>Minimum outbound traffic</td>
<td>TCP</td>
<td>443</td>
<td>Cluster security group</td>
</tr>
<tr>
<td>Minimum outbound traffic*</td>
<td>TCP</td>
<td>10250</td>
<td>Cluster security group</td>
</tr>
<tr>
<td>DNS</td>
<td>TCP and UDP</td>
<td>53</td>
<td>Cluster security group</td>
</tr>
</tbody>
</table>

*Any protocol and ports that you expect your nodes to use for inter-node communication should be included, if required. Nodes also require outbound internet access to the Amazon EKS APIs for cluster introspection and node registration at launch time, or that you’ve implemented the required necessary settings in Private clusters (p. 100). To pull container images, they require access to Amazon S3, Amazon ECR APIs, and any other container registries that they need to pull images from, such as DockerHub. For more information, see AWS IP address ranges in the AWS General Reference.

Control plane and node security groups

For Amazon EKS clusters created earlier than Kubernetes version 1.14 and platform version (p. 74) eks . 3, control plane to node communication was configured by manually creating a control plane security group and specifying that security group when you created the cluster. At cluster creation, this security group was then attached to the network interfaces created by Amazon EKS that allow communication between the control plane and the nodes. These network interfaces have Amazon EKS cluster name in their description.

Note

If you used the API directly, or a tool such as AWS CloudFormation to create your cluster and didn't specify a security group, then the default security group for the VPC was applied to the control plane cross-account network interfaces.
You can check the control plane security group for your cluster in the AWS Management Console under the cluster's Networking section (listed as Additional security groups), or with the following AWS CLI command:

```bash
code
aws eks describe-cluster --name my-cluster --query cluster.resourcesVpcConfig.securityGroupIds
```

If you launch nodes with the AWS CloudFormation template in the Getting started with Amazon EKS (p. 4) walkthrough, AWS CloudFormation modifies the control plane security group to allow communication with the nodes. Amazon EKS strongly recommends that you use a dedicated security group for each control plane (one for each cluster). If you share a control plane security group with other Amazon EKS clusters or resources, you may block or disrupt connections to those resources.

The security group for the nodes and the security group for the control plane communication to the nodes have been set up to prevent communication to privileged ports in the nodes. If your applications require added inbound or outbound access from the control plane or nodes, you must add these rules to the security groups associated with your cluster. For more information, see Security Groups for Your VPC in the Amazon VPC User Guide.

**Note**
To allow proxy functionality on privileged ports or to run the CNCF conformance tests yourself, you must edit the security groups for your control plane and the nodes. The security group on the nodes' side needs to allow inbound access for ports 0-65535 from the control plane, and the control plane side needs to allow outbound access to the nodes on ports 0-65535.

**Control Plane Security Group**

<table>

</tr>
<tr>
<td>Recommended outbound traffic</td>
<td>All</td>
<td>All</td>
<td>0.0.0.0/0 (IPv4) or ::/0 (IPv6)</td>
</tr>
</tbody>
</table>

*Nodes also require access to the Amazon EKS APIs for cluster introspection and node registration at launch time either through the internet or VPC endpoints. To pull container images, they require access to the Amazon S3 and Amazon ECR APIs (and any other container registries, such as DockerHub). For more information, see AWS IP address ranges in the AWS General Reference and Private clusters (p. 100).

One, and only one, of the security groups associated to your nodes should have the following tag applied: For more information about tagging, see Working with tags using the console (p. 424).

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/cluster/cluster-name</td>

</table>
Pod networking (CNI)

Amazon EKS supports native VPC networking with the Amazon VPC Container Network Interface (CNI) plugin for Kubernetes. This plugin assigns a private IPv4 or IPv6 address from your VPC to each pod. The plugin is an open-source project that is maintained on GitHub. For more information, see `amazon-vpc-cni-k8s` and Proposal: CNI plugin for Kubernetes networking over Amazon VPC on GitHub. The Amazon VPC CNI plugin is fully supported for use on Amazon EKS and self-managed Kubernetes clusters on AWS.

Note

Kubernetes can use the Container Networking Interface (CNI) for configurable networking setups. The Amazon VPC CNI plugin might not meet requirements for all use cases. Amazon EKS maintains a network of partners that offer alternative CNI solutions with commercial support options. For more information, see Alternate compatible CNI plugins (p. 320).

When you create an Amazon EKS node, it has one network interface. All Amazon EC2 instance types support more than one network interface. The network interface attached to the instance when the instance is created is called the primary network interface. Any additional network interface attached to the instance is called a secondary network interface. Each network interface can be assigned multiple private IP addresses. One of the private IP addresses is the primary IP address, whereas all other addresses assigned to the network interface are secondary IP addresses. For more information about network interfaces, see Elastic network interfaces in the Amazon EC2 User Guide for Linux Instances. For more information about how many network interfaces and private IP addresses are supported for each network interface, see IP addresses per network interface per instance type in the Amazon EC2 User Guide for Linux Instances. For example, an m5.large instance type supports three network interfaces and ten private IP addresses for each network interface.

The Amazon VPC Container Network Interface (CNI) plugin for Kubernetes is deployed with each of your Amazon EC2 nodes in a Daemonset with the name `aws-node`. The plugin consists of two primary components:

- **L-IPAM daemon** – Responsible for creating network interfaces and attaching the network interfaces to Amazon EC2 instances, assigning secondary IP addresses to network interfaces, and maintaining a warm pool of IP addresses on each node for assignment to Kubernetes pods when they are scheduled. When the number of pods running on the node exceeds the number of addresses that can be assigned to a single network interface, the plugin starts allocating a new network interface, as long as the maximum number of network interfaces for the instance aren't already attached. There are configuration variables that allow you to change the default value for when the plugin creates new network interfaces. For more information, see `WARM_ENI_TARGET`, `WARM_IP_TARGET` and `MINIMUM_IP_TARGET` on GitHub.

Each pod that you deploy is assigned one secondary private IP address from one of the network interfaces attached to the instance. Previously, it was mentioned that an m5.large instance supports three network interfaces and ten private IP addresses for each network interface. Even though an m5.large instance supports 30 private IP addresses, you can't deploy 30 pods to that node. To determine how many pods you can deploy to a node, use the following formula:

\[(\text{Number of network interfaces for the instance type} \times (\text{the number of IP addresses per network interface} - 1)) + 2\]

Using this formula, an m5.large instance type can support a maximum of 29 pods. For a list of the maximum number of pods supported by each instance type, see `eni-max-pods.txt` on GitHub. System pods count towards the maximum pods. For example, the CNI plugin and `kube-proxy` pods run on every node in a cluster, so you're only able to deploy 27 additional pods to an m5.large instance, not 29. Further, CoreDNS runs on some of the nodes in the cluster, which decrements the maximum pods by another one for the nodes it runs on.
By default, all pods deployed to a node are assigned the same security groups and are assigned private IP addresses from a CIDR block that is assigned to the subnet that one of the instance's network interfaces is connected to. You can assign IP addresses from a different CIDR block than the subnet that the primary network interface is connected to by configuring CNI custom networking (p. 300). You can also use CNI custom networking to assign all pods on a node the same security groups. The security groups assigned to all pods can be different than the security groups assigned to the primary network interface. You can assign unique security groups to pods deployed to many Amazon EC2 instance types using security groups for pods. For more information, see Security groups for pods (p. 307).

- **CNI plugin** – Responsible for wiring the host network (for example, configuring the network interfaces and virtual Ethernet pairs) and adding the correct network interface to the pod namespace.

If you use custom pod security policies with your cluster, be sure to review the Pod security policy (p. 493) topic for important information.

### Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts

The **Amazon VPC CNI plugin for Kubernetes** is the networking plugin for pod networking in Amazon EKS clusters. The plugin is responsible for allocating VPC IP addresses to Kubernetes nodes and configuring the necessary networking for pods on each node. The plugin:

- Requires AWS Identity and Access Management (IAM) permissions. If your cluster uses the IPv4 family, the permissions are specified in the `AmazonEKS_CNI_Policy` AWS managed policy. If your cluster uses the IPv6 family, then the permissions must be added to an IAM policy that you create (p. 274). You can attach the policy to the Amazon EKS node IAM role (p. 452), or to a separate IAM role. We recommend that you assign it to a separate role, as detailed in this topic.
- Creates and is configured to use a Kubernetes service account named `aws-node` when it's deployed. The service account is bound to a Kubernetes clusterrole named `aws-node`, which is assigned the required Kubernetes permissions.

**Note**

The pods for the Amazon VPC CNI plugin have access to the permissions assigned to the Amazon EKS node IAM role (p. 452), unless you block access to IMDS. For more information, see Restrict access to the instance profile assigned to the worker node.

### Prerequisites

- An existing Amazon EKS cluster. To deploy one, see Getting started with Amazon EKS (p. 4).
- An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Create an IAM OIDC provider for your cluster (p. 466).

### Step 1: Create the Amazon VPC CNI plugin IAM role

**To create the IAM role**

1. Determine the IP family of your cluster.

   ```bash
   aws eks describe-cluster --name my-cluster | grep ipFamily
   ```

   **Output**
"ipFamily": "ipv4"

The output may return ipv6 instead.

2. Create the IAM role. You can use eksctl or kubectl and the AWS CLI to create your CNI plugin IAM role.

**eksctl**

Create an IAM role and attach the IAM policy to the role with the command that matches the IP family of your cluster. The command creates and deploys an AWS CloudFormation stack that creates an IAM role, attaches the policy that you specify to it, and annotates the existing aws-node Kubernetes service account with the ARN of the IAM role that is created.

- **IPv4**

  Replace *my-cluster* with your own value.

  ```
  eksctl create iamserviceaccount \
  --name aws-node \
  --namespace kube-system \
  --cluster my-cluster \
  --role-name "AmazonEKSVPCCNIRole" \
  --attach-policy-arn arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy \
  --override-existing-serviceaccounts \
  --approve
  ```

- **IPv6**

  Replace *my-cluster* with your own value. Replace 111122223333 with your account ID and replace *AmazonEKS_CNI_IPv6_Policy* with the name of your IPv6 policy. If you don’t have an IPv6 policy, see Create IAM policy for clusters that use the IPv6 family (p. 274) to create one. To use IPv6 with your cluster, it must meet several requirements. For more information, see Assigning IPv6 addresses to pods and services (p. 288).

  ```
  eksctl create iamserviceaccount \
  --name aws-node \
  --namespace kube-system \
  --cluster my-cluster \
  --role-name "AmazonEKSVPCCNIRole" \
  --attach-policy-arn arn:aws:iam::111122223333:policy/AmazonEKS_CNI_IPv6_Policy \
  --override-existing-serviceaccounts \
  --approve
  ```

**kubectl and the AWS CLI**

1. View your cluster’s OIDC provider URL.

   ```
   aws eks describe-cluster --name my-cluster --query "cluster.identity.oidc.issuer" --output text
   ```

   Example output:

   https://oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE
If no output is returned, then you must create an IAM OIDC provider for your cluster (p. 466).

2. Copy the following contents to a file named `vpc-cni-trust-policy.json`. Replace `111122223333` with your account ID and `EXAMPLED539D4633E53DE1B71EXAMPLE` from the output returned in the previous step. Replace `region-code` with the AWS Region that your cluster is in.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::111122223333:oidc-provider/oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE"
      },
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
        "StringEquals": {
          "oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:aud": "sts.amazonaws.com",
          "oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:sub": "system:serviceaccount:kube-system:aws-node"
        }
      }
    }
  ]
}
```

3. Create the role. You can replace `AmazonEKSVPCCNIRole` with any name that you choose.

```bash
aws iam create-role \
  --role-name AmazonEKSVPCCNIRole \
  --assume-role-policy-document file://"vpc-cni-trust-policy.json"
```

4. Attach the required IAM policy to the role. Run the command that matches the IP family of your cluster.
   - IPv4

```bash
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy \
  --role-name AmazonEKSVPCCNIRole
```

   - IPv6

Replace `111122223333` with your account ID and `AmazonEKS_CNI_IPv6_Policy` with the name of your IPv6 policy. If you don't have an IPv6 policy, see Create IAM policy for clusters that use the IPv6 family (p. 274) to create one. To use IPv6 with your cluster, it must meet several requirements. For more information, see Assigning IPv6 addresses to pods and services (p. 288).

```bash
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::111122223333:policy/AmazonEKS_CNI_IPv6_Policy \
  --role-name AmazonEKSVPCCNIRole
```

5. Run the following command to annotate the `aws-node` service account with the ARN of the IAM role that you created previously. Replace the `example values` with your own values.
3. (Optional) Annotate your service account to use the AWS Security Token Service AWS Regional endpoint if your cluster's Kubernetes version is listed in the following table and its platform version is the same or later than the version listed in the table. If your cluster's Kubernetes version is listed in the following table and you have a platform version that is earlier than the version listed in the following table, then you can't enable your service accounts to use the AWS Security Token Service AWS Regional endpoint. You must use the global endpoint. If your cluster is 1.22 or later, the AWS Regional endpoint is used by default, so you don't need to annotate your Kubernetes service accounts to use it.

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Platform version</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.21</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.20</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.19</td>
<td>eks.7</td>
</tr>
<tr>
<td>1.18</td>
<td>eks.9</td>
</tr>
</tbody>
</table>

Add the following annotation to your service accounts.

```
kubectl annotate serviceaccount -n kube-system aws-node \
  eks.amazonaws.com/sts-regional-endpoints=true
```

AWS recommends using the AWS Regional AWS STS endpoints instead of the global endpoint to reduce latency, build in redundancy, and increase session token validity. The AWS Security Token Service must be active in the AWS Region where the pod is running and your application should have redundancy built in to pick a different AWS Region in the event of a failure of the service in the AWS Region. For more information, see Managing AWS STS in an AWS Region in the IAM User Guide.

### Step 2: Re-deploy VPC CNI pods

1. Delete and re-create any existing pods that are associated with the service account to apply the credential environment variables. The annotation is not applied to pods that are currently running without the annotation. The following command deletes the existing `aws-node` DaemonSet pods and deploys them with the service account annotation.

   ```
kubectl delete pods -n kube-system -l k8s-app=aws-node
```

2. Confirm that the pods all restarted.

   ```
kubectl get pods -n kube-system -l k8s-app=aws-node
```

3. Describe one of the pods and verify that the `AWS_WEB_IDENTITY_TOKEN_FILE` and `AWS_ROLE_ARN` environment variables exist. Replace `9rgzw` with the name of one of your pods returned in the output of the previous step.

   ```
kubectl exec -n kube-system aws-node-9rgzw -c aws-node -- env | grep AWS
```
Output:

```
...  
AWS_WEB_IDENTITY_TOKEN_FILE=/var/run/secrets/eks.amazonaws.com/serviceaccount/token
...  
AWS_ROLE_ARN=arn:arn:aws::111122223333:role/AmazonEKSVPCCNIRole
...  
```

If your pod is using the AWS Regional endpoint, then the following line is also returned in the previous output.

```
AWS_STS_REGIONAL_ENDPOINTS=regional
```

### Step 3: Remove the CNI policy from the node IAM role

If your `Amazon EKS node IAM role` currently has the `AmazonEKS_CNI_Policy` IAM (IPv4) policy or an IPv6 policy attached to it, and you've created a separate IAM role, attached the policy to it instead, and assigned it to the `aws-node` Kubernetes service account, then we recommend that you remove the policy from your role with the the AWS CLI command that matches the IP family of your cluster. Replace `AmazonEKSNodeRole` with the name of your node role.

- **IPv4**

  ```
  aws iam detach-role-policy --role-name AmazonEKSNodeRole --policy-arn arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy
  ```

- **IPv6**

  Replace `111122223333` with your account ID and `AmazonEKS_CNI_IPv6_Policy` with the name of your IPv6 policy.

  ```
  aws iam detach-role-policy --role-name AmazonEKSNodeRole --policy-arn arn:aws:iam::111122223333:policy/AmazonEKS_CNI_IPv6_Policy
  ```

### Create IAM policy for clusters that use the IPv6 family

If you created a 1.21 or later cluster that uses the IPv6 family and the cluster has version 1.10.1 or later of the VPC CNI add-on configured, then you need to create an IAM policy that you can assign to an IAM role. If you have an existing 1.21 or later cluster that you didn't configure with the IPv6 family when you created it, then to use IPv6, you must create a new cluster. For more information about using IPv6 with your cluster, see the section called “IPv6” (p. 288).

1. Copy the following text and save it to a file named `vpc-cni-ipv6-policy.json`.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Action": [
   "ec2:AssignIpv6Addresses",
   "ec2:DescribeInstances",
   "ec2:DescribeTags",
   "ec2:DescribeNetworkInterfaces",
   ```
Managing VPC CNI add-on

Amazon EKS supports native VPC networking with the Amazon VPC Container Network Interface (CNI) plugin for Kubernetes. Using this plugin allows Kubernetes pods to have the same IP address inside the pod as they do on the VPC network. For more information, see Pod networking (CNI) (p. 269).

If you created a 1.18 or later cluster using the AWS Management Console, then Amazon EKS installed the Amazon EKS add-on for you. If you created a 1.18 or later cluster using any method other than the AWS Management Console, then Amazon EKS installed the self-managed add-on for you. You can migrate the self-managed add-on to the Amazon EKS add-on using the procedure in Adding the Amazon VPC CNI Amazon EKS add-on (p. 276). If you have a cluster that you've already added the Amazon VPC CNI Amazon EKS add-on to, you can manage it using the procedures in the Updating the Amazon VPC CNI Amazon EKS add-on (p. 277) and Removing the Amazon VPC CNI Amazon EKS add-on (p. 279) sections. For more information about Amazon EKS add-ons, see Amazon EKS add-ons (p. 381).

Recommended version of the Amazon VPC CNI add-on for each cluster version

<table>
<thead>
<tr>
<th>Add-on version</th>
<th>1.22</th>
<th>1.21</th>
<th>1.20</th>
<th>1.19</th>
<th>1.18</th>
<th>1.17</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add-on version</td>
<td>1.10.2-eksbuild.1</td>
<td>1.10.2-eksbuild.1</td>
<td>1.10.2-eksbuild.1</td>
<td>1.10.2-eksbuild.1</td>
<td>1.10.2-eksbuild.1</td>
<td>1.10.2-eksbuild.1</td>
</tr>
</tbody>
</table>

To update your Amazon EKS add-on version, see Updating the Amazon VPC CNI Amazon EKS add-on (p. 277). To update your self-managed add-on version using container images in the Amazon EKS Amazon Elastic Container Registry or your own repository, see Updating the Amazon VPC CNI self-managed add-on (p. 280).

**Important**

The version of the add-on that was deployed when you created your cluster may be earlier than the recommended version. If you've updated the self-managed add-on using a manifest, then the version doesn't include -eksbuild.1.

**Prerequisites**

- An existing Amazon EKS cluster. To deploy one, see Getting started with Amazon EKS (p. 4).
• An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Create an IAM OIDC provider for your cluster (p. 466).

• An IAM role with the AmazonEKS_CNI_Policy IAM policy (if your cluster uses the IPv4 family) or an IPv6 policy (p. 274) (if your cluster uses the IPv6 family) attached to it. For more information, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).

• If you are using version 1.7.0 or later of the CNI plugin and you use custom pod security policies, see the section called “Delete default policy” (p. 493).Pod security policy (p. 492).

Adding the Amazon VPC CNI Amazon EKS add-on

You can add the Amazon VPC CNI Amazon EKS add-on to your 1.18 or later cluster with eksctl, the AWS Management Console, or the AWS CLI.

Important
Before adding the Amazon VPC CNI Amazon EKS add-on, confirm that you do not self-manage any settings that Amazon EKS will start managing. To determine which settings Amazon EKS manages, see Amazon EKS add-on configuration (p. 382).

_eksctl_

To add the **recommended version** (p. 275) of the Amazon EKS add-on using _eksctl_

Replace `my-cluster` with the name of your cluster and `arn:aws:iam::111122223333:role/AmazonEKSVPCCNIRole` with your existing IAM role (see Prerequisites (p. 275)).

```
eksctl create addon \
  --name vpc-cni \
  --version v1.10.1-eksbuild.1 \
  --cluster my-cluster \
  --service-account-role-arn arn:aws:iam::111122223333:role/AmazonEKSVPCCNIRole \
  --force
```

If any of the Amazon EKS add-on settings conflict with the existing settings for the self-managed add-on, then adding the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict.

If you want to add a different version of the add-on instead, then you can view all versions available for the add-on and your cluster's version with the following command. Replace `1.22` with your cluster's version.

```
eksctl utils describe-addon-versions --name vpc-cni --kubernetes-version 1.22 | grepAddonVersion:
```

Replace `v1.10.1-eksbuild.1` in the `create addon` command with the version returned in the output that you want to add and then run the `create addon` command.

AWS Management Console

To add the **recommended version** (p. 275) of the Amazon EKS add-on using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, select Amazon EKS Clusters, and then select the name of the cluster that you want to configure the Amazon VPC CNI Amazon EKS add-on for.
3. Choose the **Configuration** tab and then choose the **Add-ons** tab.

4. Select **Add new**.
   - Select **vpc-cni** for **Name**.
   - Select the **Version** you'd like to use. We recommend the **1.10.1-eksbuild.1** version, but you can select a different version if necessary.
   - For **Service account role**, select the name of an IAM role that you've attached the `AmazonEKS_CNI_Policy` IAM policy to (see Prerequisites (p. 275)).
   - Select **Override existing configuration for this add-on on the cluster**. If any of the Amazon EKS add-on settings conflict with the existing settings for the self-managed add-on, then adding the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict.
   - Select **Add**.

**AWS CLI**

To add the recommended version (p. 275) of the Amazon EKS add-on using the AWS CLI, replace `my-cluster` with the name of your cluster, `arn:aws:iam::AWS_ACCOUNT_ID:role/AmazonEKS_CNI_Role` with the ARN of an IAM role that you've attached the `AmazonEKS_CNI_Policy` IAM policy to (see Prerequisites (p. 275)), and then run the command.

```bash
aws eks create-addon
  --cluster-name my-cluster
  --addon-name vpc-cni
  --addon-version v1.10.1-eksbuild.1
  --service-account-role-arn arn:aws:iam::AWS_ACCOUNT_ID:role/AmazonEKS_CNI_Role
  --resolve-conflicts OVERWRITE
```

If any of the Amazon EKS add-on settings conflict with the existing settings for the self-managed add-on, then adding the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict.

If you want to add a different version of the add-on instead, then you can view all versions available for the add-on and your cluster's version with the following command. Replace **1.22** with your cluster's version.

```bash
aws eks describe-addon-versions
  --addon-name vpc-cni
  --kubernetes-version 1.22
  --query "addons[].addonVersions[].addonVersion, compatibilities[].Version"
  --output text
```

Replace `v1.10.1-eksbuild.1` in the `create-addon` command with the version returned in the output that you want to add and then run the `create-addon` command.

**Updating the Amazon VPC CNI Amazon EKS add-on**

**Important**

Before updating the Amazon VPC CNI Amazon EKS add-on, confirm that you do not self-manage any settings that Amazon EKS manages. To determine which settings Amazon EKS manages, see **Amazon EKS add-on configuration (p. 382)**.

This procedure is for updating the Amazon VPC CNI Amazon EKS add-on. If you haven't added the Amazon VPC CNI Amazon EKS add-on, complete the procedure in **Updating the Amazon VPC CNI self-**
managed add-on (p. 280) instead. Amazon EKS does not automatically update the Amazon VPC CNI add-on when new versions are released or after you update your cluster (p. 32) to a new Kubernetes minor version. To update the Amazon VPC CNI add-on for an existing cluster, you must initiate the update and then Amazon EKS updates the add-on for you.

We recommend that you update one minor version at a time. For example, if your current minor version is 1.8 and you want to update to 1.10, you should update to the latest patch version of 1.9 first, then update to the latest patch version of 1.10.

You can update the Amazon VPC CNI Amazon EKS add-on on your 1.18 or later cluster using eksctl, the AWS Management Console, or the AWS CLI.

eksctl

To update the Amazon EKS add-on to the recommended version (p. 275) using eksctl

1. Check the current version of your vpc-cni Amazon EKS add-on. Replace my-cluster with your cluster name.

   ```bash
   eksctl get addon --name vpc-cni --cluster my-cluster
   ```

   Example output:

   ```
   NAME    VERSION                 STATUS  ISSUES  IAMROLE
   UPDATE
   AVAILABLE
   vpc-cni v1.7.5-eksbuild.2       ACTIVE  0
   arn:aws:iam::111122223333:role/AmazonEKSVPCCNIRole v1.10.1-eksbuild.1
   ```

2. Update the add-on to the recommended version (p. 275).

   ```bash
   eksctl update addon
   --name vpc-cni
   --version 1.10.1-eksbuild.1
   --cluster my-cluster
   --force
   ```

   If you want to update to a different version of the add-on instead, then you can view all versions available for the add-on and your cluster’s version with the following command. Replace 1.22 with your cluster’s version.

   ```bash
   eksctl utils describe-addon-versions --name vpc-cni --kubernetes-version 1.22 | grep AddonVersion:
   ```

   Replace v1.10.1-eksbuild.1 in the update addon command with the version returned in the output that you want to add and then run the update addon command.

AWS Management Console

To update the Amazon EKS add-on to the recommended version (p. 275) using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, select Amazon EKS Clusters, and then select the name of the cluster that you want to update the Amazon VPC CNI add-on for.
3. Choose the Configuration tab and then choose the Add-ons tab.
4. Select the box in the top right of the vpc-cni box and then choose Edit.

- Select the Version of the Amazon EKS add-on that you want to use. We recommend the 1.10.1-eksbuild.1 version, but you can select a different version if necessary.
- For Service account role, select the name of an IAM role that you’ve attached the AmazonEKS_CNI_Policy IAM policy to (see Prerequisites (p. 275)), if one isn’t already selected.
- Select Override existing configuration for this add-on on the cluster.
- Select Update.

AWS CLI

**To update the Amazon EKS add-on to the recommended version (p. 275) using the AWS CLI**

1. Check the current version of your Amazon VPC CNI Amazon EKS add-on. Replace my-cluster with your cluster name.

   ```bash
   aws eks describe-addon
   --cluster-name my-cluster
   --addon-name vpc-cni
   --query "addon.addonVersion"
   --output text
   ```

   Example output:

   ```
   v1.7.5-eksbuild.2
   ```

   The version returned for you may be different.

2. Update the add-on to the recommended version (p. 275). Replace my-cluster with your cluster name.

   ```bash
   aws eks update-addon
   --cluster-name my-cluster
   --addon-name vpc-cni
   --addon-version v1.10.1-eksbuild.1
   --resolve-conflicts OVERWRITE
   ```

   If you want to update to a different version of the add-on instead, then you can view all versions available for the add-on and your cluster's version with the following command. Replace 1.22 with your cluster's version.

   ```bash
   aws eks describe-addon-versions
   --addon-name vpc-cni
   --kubernetes-version 1.22
   --query "addons[].addonVersions[].addonVersion, compatibilities[].Version"
   --output text
   ```

   Replace v1.10.1-eksbuild.1 in the update-addon command with the version returned in the output that you want to add and then run the update-addon command.

**Removing the Amazon VPC CNI Amazon EKS add-on**

You have two options when removing an Amazon EKS add-on:
• **Preserve the add-on's software on your cluster** – This option removes Amazon EKS management of any settings and the ability for Amazon EKS to notify you of updates and automatically update the Amazon EKS add-on after you initiate an update, but preserves the add-on's software on your cluster. This option makes the add-on a self-managed add-on, rather than an Amazon EKS add-on. There is no downtime for the add-on.

• **Removing the add-on software entirely from your cluster** – You should only remove the Amazon EKS add-on from your cluster if there are no resources on your cluster are dependent on the functionality that the add-on provides. After removing the Amazon EKS add-on, you can add it again if you want to.

If the add-on has an IAM account associated with it, the IAM account is not removed.

You can remove the Amazon VPC CNI Amazon EKS add-on from your 1.18 or later cluster with `eksctl`, the AWS Management Console, or the AWS CLI.

### eksctl

To remove the Amazon EKS add-on using `eksctl`

Replace `my-cluster` with the name of your cluster and then run the following command. Removing `--preserve` removes the add-on software from your cluster.

```
eksctl delete addon --cluster my-cluster --name vpc-cni --preserve
```

### AWS Management Console

To remove the Amazon EKS add-on using the AWS Management Console

1. Open the Amazon EKS console at [https://console.aws.amazon.com/eks/home#/clusters](https://console.aws.amazon.com/eks/home#/clusters).
2. In the left navigation pane, select Amazon EKS Clusters, and then select the name of the cluster that you want to remove the Amazon VPC CNI Amazon EKS add-on for.
3. Choose the Configuration tab, and then choose the Add-ons tab.
4. Select the check box in the top right of the vpc-cni box and then choose Remove. Select Preserve on cluster if you want Amazon EKS to stop managing settings for the add-on, but want to retain the add-on software on your cluster so that you can self-managed all of the add-on's settings. Type `vpc-cni` and then select Remove.

### AWS CLI

To remove the Amazon EKS add-on using the AWS CLI

Replace `my-cluster` with the name of your cluster and then run the following command. Removing `--preserve` removes the add-on software from your cluster.

```
aws eks delete-addon --cluster-name my-cluster --addon-name vpc-cni --preserve
```

### Updating the Amazon VPC CNI self-managed add-on

If you have a 1.17 cluster, or a 1.18 or later cluster that you haven't added the Amazon VPC CNI Amazon EKS add-on to, complete the following steps to update the add-on. If you've added the Amazon VPC CNI Amazon EKS add-on, complete the procedure in Updating the Amazon VPC CNI Amazon EKS add-on (p. 277) instead.
To update the self-managed add-on to the recommended version (p. 275)

1. To view the available versions and familiarize yourself with the changes in the version that you want to update to, see the releases on GitHub.

2. Use the following command to determine your cluster's current Amazon VPC CNI add-on version:

```bash
kubectl describe daemonset aws-node --namespace kube-system | grep Image | cut -d "/" - f 2
```

Example output:

```plaintext
amazon-k8s-cni-init:v1.7.5-eksbuild.1
amazon-k8s-cni:v1.7.5-eksbuild.1
```

Your output might look different than the example output. In this example output, the Amazon VPC CNI add-on version is 1.7.5-eksbuild.1, which is earlier than the recommended version (p. 275). The version that Amazon EKS originally deployed with your cluster looks similar to the previous output. If you've already updated the add-on at least once using a manifest however, your output doesn't include -eksbuild.1.

3. Update the daemonset using Helm V3 (p. 421) or later, or by using a manifest.

Helm

a. Add the eks-charts repository to Helm.

```
helm repo add eks https://aws.github.io/eks-charts
```

b. Update your local repository to make sure that you have the most recent charts.

```
helm repo update
```

c. Backup your current settings so that you can determine which settings you need to specify values for in a later step.

```
kubectl get daemonset aws-node -n kube-system -o yaml > aws-k8s-cni-old.yaml
```

d. If you installed the existing AWS VPC CNI daemonset using Helm, then skip to the next step.

Complete one of the following options so that Helm can manage the daemonset's resources:

- Add the Helm annotations and labels to your existing resources.

  i. Save the following contents to a file named `helm-cni.sh`. Replace `aws-vpc-cni` if you want to use a different release name.

```
#!/usr/bin/env bash
set -euo pipefail
for kind in daemonSet clusterRole clusterRoleBinding serviceAccount; do
done
echo "setting annotations and labels on $kind/aws-node"
kubectl --namespace=kube-system annotate --overwrite $kind aws-node meta.helm.sh/release-name=aws-vpc-cni
kubectl --namespace=kube-system annotate --overwrite $kind aws-node meta.helm.sh/release-namespace=kube-system
kubectl --namespace=kube-system label --overwrite $kind app.kubernetes.io/managed-by=Helm
```

ii. Make the script executable.

```
chmod +x helm-cni.sh
```

iii. Run the script

```
./helm-cni.sh
```

- Remove the existing daemonset's resources.

  **Important**
  
  Your cluster will experience downtime between completing this step and the next step.

  ```
  kubectl delete serviceaccount aws-node -n kube-system
  kubectl delete customresourcedefinition eniconfigs.crd.k8s.amazonaws.com
  kubectl delete clusterrole aws-node
  kubectl delete clusterrolebinding aws-node
  kubectl delete daemonset aws-node -n kube-system
  ```

e. Install the chart using one of the following options. Before running the installation, review the backup you made of the settings for your daemonset in a previous step and then review the configuration settings to determine if you need to set any of them. We recommend using the version in the following commands, but if necessary, you can replace it with any release version.

  **Important**
  
  - You should only update one minor version at a time. For example, if your current minor version is 1.8 and you want to update to 1.10, you should update to 1.9 first, then update to 1.10 by changing the version number in the one of the following commands.
  - The latest and recommended versions work with all Amazon EKS supported Kubernetes versions.

  If you have an existing IAM role to use with the daemonset, then add the following line at the end of the install options that follow. If you don't have an IAM role associated to the aws-node Kubernetes service account, then we recommend creating one. Replace `111122223333` with your account ID and `AmazonEKSVPCCNIRole` with the name of your role. To create a role, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).

  ```
  --set serviceAccount.annotations."eks\.amazonaws\.com/role-arn"=arn:aws:iam::111122223333:role/AmazonEKSVPCCNIRole
  ```

  If you added the Helm annotations and labels in the previous step, then add the following settings to any of the following options.

  ```
  --set originalMatchLabels=true
  --set crd.create=false
  ```

  - If your nodes have access to the Amazon EKS Amazon ECR repositories and are in the us-west-2 AWS Region, then install the chart with the release name `aws-vpc-cni` and default configuration.

  ```
  helm upgrade -i aws-vpc-cni eks/aws-vpc-cni 
  --namespace kube-system 
  --set image.tag=v1.10.1
  ```
If your nodes have access to the Amazon EKS Amazon ECR repositories and are in an AWS Region other than us-west-2, then install the chart with the release name `aws-vpc-cni`. Replace `eks-ecr-account` with the value from the section called “Amazon container image registries” (p. 379) for the AWS Region that your cluster is in. Replace `region-code` with the AWS Region that your cluster is in.

```
helm upgrade -i aws-vpc-cni eks/aws-vpc-cni 
--namespace kube-system 
--set image.account=eks-ecr-account 
--set image.region=region-code 
--set image.tag=v1.10.1 
--set init.image.account=eks-ecr-account 
--set init.image.region=region-code 
--set init.image.tag=v1.10.1
```

If your nodes don’t have access to the Amazon EKS Amazon ECR repositories

1. Pull the following container images and push them to a repository that your nodes have access to. For more information on how to pull, tag, and push an image to your own repository, see Copy a container image from one repository to another repository (p. 377). We recommend using the version in the following commands, but if necessary, you can replace it with any release version. Replace `602401143452` and `region-code` with values from the section called “Amazon container image registries” (p. 379) for the AWS Region that your cluster is in.

```
602401143452.dkr.ecr.region-code.amazonaws.com/amazon-k8s-cni-init:v1.10.1
602401143452.dkr.ecr.region-code.amazonaws.com/amazon-k8s-cni:v1.10.1
```

2. Install the chart with the release name `aws-vpc-cni` and default configuration. Before running the installation, review the backup you made of the settings for your daemonset in a previous step and then review the configuration settings to determine if you need to set any of them. Replace `registry/repo:tag` with your registry, repository, and tag.

```
helm upgrade -i aws-vpc-cni eks/aws-vpc-cni 
--namespace kube-system 
--set image.override=registry/repo:tag 
--set init.image.override=registry/repo:tag
```

Manifest

a. If you've changed any default settings for your current VPC CNI daemonset or you need to pull the container image from your own repository to update it, then skip to the next step.

Update your Amazon VPC CNI add-on. We recommend using the version in the following commands, but if necessary, you can replace it with any release version.

Important

- You should only update one minor version at a time. For example, if your current minor version is 1.8 and you want to update to 1.10, you should update to 1.9 first, then update to 1.10 by changing the version number in the one of the following commands.
- The latest and recommended versions work with all Amazon EKS supported Kubernetes versions.
Complete the instruction for the AWS Region that your cluster is in to update your Amazon
VPC CNI add-on to the recommended version (p. 275).

- If your cluster is in the AWS GovCloud (US-East) (us-gov-east-1) AWS Region then run
the following command.

```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.10.1/config/master/aws-k8s-cni-us-gov-east-1.yaml
```

- If your cluster is in the AWS GovCloud (US-West) (us-gov-west-1) AWS Region then run
the following command.

```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.10.1/config/master/aws-k8s-cni-us-gov-west-1.yaml
```

- If your cluster is in the US West (Oregon) (us-west-2) AWS Region then run the following
command.

```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.10.1/config/master/aws-k8s-cni.yaml
```

- If your cluster is in any other AWS Region, then complete the following steps.
  a. Download the manifest file.

```
curl -o aws-k8s-cni.yaml https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.10.1/config/master/aws-k8s-cni.yaml
```

  b. Modify the file:
     i. In the following command, replace `region-code` with the AWS Region that your
        cluster is in and then run the modified command to replace `us-west-2` in the file
        with your AWS Region.

```
sed -i.bak -e 's|us-west-2|region-code|' aws-k8s-cni.yaml
```

     ii. Replace `account` in the following command with the account from Amazon container
         image registries (p. 379) for the AWS Region that your cluster is in and then run
         the modified command to replace 602401143452 in the file.

```
sed -i.bak -e 's|602401143452|account|' aws-k8s-cni.yaml
```

  c. Apply the manifest file to your cluster.

```
kubectl apply -f aws-k8s-cni.yaml
```

b. If you've changed any default settings for your current VPC CNI daemonset or need to
pull the container image from your own repository when updating it, then complete the
following steps to update your Amazon VPC CNI add-on to 1.10.1, which is the recommended
version (p. 275).

**Important**
- You should only update one minor version at a time. For example, if your current
  minor version is 1.8 and you want to update to 1.10, you should update to
  1.9 first, then update to 1.10 by changing the version number in the following
  commands.
- The latest and recommended versions work with all Amazon EKS supported
  Kubernetes versions.
i. If your nodes have access to the Amazon EKS Amazon ECR image repositories, then skip to the next sub-step.

Pull the following container images and push them to a repository that your nodes have access to. For more information on how to pull, tag, and push an image to your own repository, see Copy a container image from one repository to another repository (p. 377). We recommend using the version in the following commands, but if necessary, you can replace it with any release version. Replace 602401143452 and region-code with values from the section called “Amazon container image registries” (p. 379) for the AWS Region that your cluster is in.

| 602401143452.dkr.ecr.region-code.amazonaws.com/amazon-k8s-cni-init:v1.10.1 |
| 602401143452.dkr.ecr.region-code.amazonaws.com/amazon-k8s-cni:v1.10.1 |

ii. Backup your current settings so that you can compare your settings to the default settings in the new manifest.

```bash
toolctl get daemonset aws-node -n kube-system -o yaml > aws-k8s-cni-old.yaml
```

iii. Download the manifest for the Amazon VPC CNI add-on for your AWS Region. We recommend using the version in the following commands, but if necessary, you can replace it with any release version.

- AWS GovCloud (US-East) (us-gov-east-1)

```bash
```

- AWS GovCloud (US-West) (us-gov-west-1)

```bash
```

- Any other AWS Region, or if you copied the images to your own repository in a previous step

```bash
curl -o aws-k8s-cni.yaml https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.10.1/config/master/aws-k8s-cni.yaml
```

iv. Modify the file with one of the following options:

- If you didn't copy the container images to your own repository in a previous step, then run the following commands:
  
  A. In the following command, replace region-code with the AWS Region that your cluster is in and then run the modified command to replace us-west-2 in the file with your AWS Region.

  ```bash
  sed -i.bak -e 's|us-west-2|region-code|' aws-k8s-cni.yaml
  ```

  B. Replace account in the following command with the account from Amazon container image registries (p. 379) for the AWS Region that your cluster is in and then run the modified command to replace 602401143452 in the file.

  ```bash
  sed -i.bak -e 's|602401143452|account|' aws-k8s-cni.yaml
  ```

- If you copied the container images to your own repository in a previous step, then make the following replacements and run the following commands:
Choosing pod networking use cases

The Amazon VPC CNI plugin provides networking for pods. The following table helps you understand which networking use cases you can use together and the capabilities and Amazon VPC CNI plugin settings that you can use with different Amazon EKS node types. All information in the table applies to Linux IPv4 nodes only.
### Amazon EKS node type (p. 104)

<table>
<thead>
<tr>
<th></th>
<th>Amazon EC2</th>
<th>Fargate</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Amazon EC2</strong></td>
<td>Yes</td>
<td>Yes (subnets controlled through Fargate profile)</td>
</tr>
<tr>
<td><strong>Fargate</strong></td>
<td>Yes (true only)</td>
<td>Yes (true only)</td>
</tr>
</tbody>
</table>

#### CNI custom networking (p. 300)
- Assign IP addresses from a different subnet than the node's subnet

#### External source network address translation (SNAT) (p. 298)
- Yes (default is false)

### Capabilities

<table>
<thead>
<tr>
<th>Security group scope</th>
<th>Node</th>
<th>Node</th>
<th>Pod</th>
<th>Pod</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Amazon VPC subnet types</strong></td>
<td>Private and public</td>
<td>Private and public</td>
<td>Private only</td>
<td>Private only</td>
</tr>
<tr>
<td><strong>Network policy (p. 341) (Calico)</strong></td>
<td>Compatible</td>
<td>Compatible</td>
<td>Not supported</td>
<td>Not supported</td>
</tr>
<tr>
<td>Pod density per node</td>
<td>Medium</td>
<td>High</td>
<td>Low</td>
<td>One</td>
</tr>
<tr>
<td>Pod launch time</td>

</tr>
<tr>
<td>MINIMUM_IP_TARGET</td>
<td>Yes</td>
<td>Yes</td>
<td>Not applicable</td>
</tr>
<tr>
<td>WARM_PREFIX_TARGET</td>
<td>Not applicable</td>
<td>Yes</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

### Note

- You can't use IPv6 with custom networking.
- IPv6 addresses are not translated, so SNAT doesn't apply.
- You can use Calico network policy with IPv6.
- Traffic flow to and from pods with associated security groups are not subjected to Calico network policy enforcement and are limited to Amazon VPC security group enforcement only.
- IP prefixes and IP addresses are associated with standard Amazon EC2 elastic network interfaces. Pods requiring specific security groups are assigned the primary IP address of a branch network interface. You can mix pods getting IP addresses, or IP addresses from IP prefixes with pods getting branch network interfaces on the same node.
Windows nodes

Each Windows node only supports one network interface and secondary IPv4 addresses for pods. As a result, you can't use IP address prefixes or IPv6 with Windows nodes. The maximum number of pods for each node is equal to the number of IP addresses that you can assign to each Elastic network interface, minus one. Calico network policies are supported on Windows. For more information, see Open Source Calico for Windows Containers on Amazon EKS. You can't use security groups for pods (p. 307) on Windows.

Assigning IPv6 addresses to pods and services

By default, Kubernetes assigns IPv4 addresses to your pods and services. Instead of assigning IPv4 addresses to your pods and services, you can configure your cluster to assign IPv6 addresses to them. Amazon EKS doesn't support dual-stacked pods or services. As a result, you can't assign both IPv4 and IPv6 addresses to your pods and services.

You select which IP family you want to use for your cluster when you create it. You can't change the family after you create the cluster.

Considerations for using the IPv6 family for your cluster:

- You must create a new cluster that's version 1.21 or later and specify that you want to use the IPv6 family for that cluster. You can't enable the IPv6 family for a cluster that you updated from a previous version. For instructions on how to create a new cluster, see Creating an Amazon EKS cluster (p. 24).
- The version of the Amazon VPC CNI add-on that you deploy to your cluster must be version 1.10.1 or later. This version or later is deployed by default with a new 1.21 or later cluster. After you deploy the add-on, you can't downgrade your Amazon VPC CNI add-on to a version lower than 1.10.1 without first removing all nodes in all node groups in your cluster.
- Windows pods and services aren't supported.
- If you use Amazon EC2 nodes, you must configure the Amazon VPC CNI add-on with IP prefix delegation and IPv6. If you choose the IPv6 family when creating your cluster, the 1.10.1 version of the add-on defaults to this configuration. This is the case for both a self-managed or Amazon EKS add-on. For more information about IP prefix delegation, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 303).
- When you create a cluster, the VPC and subnets that you specify must have an IPv6 CIDR block that's assigned to the VPC and subnets that you specify. They must also have an IPv4 CIDR block assigned to them. This is because, even if you only want to use IPv6, a VPC still requires an IPv4 CIDR block to function. For more information, see Associate an IPv6 CIDR block with your VPC in the Amazon VPC User Guide.
- When you create your cluster and nodes, you must specify subnets that are configured to auto-assign IPv6 addresses. Otherwise, you can't deploy your cluster and nodes. By default, this configuration is disabled. For more information, see Modify the IPv6 addressing attribute for your subnet in the Amazon VPC User Guide.
- The route tables that are assigned to your subnets must have routes for IPv6 addresses. For more information, see Migrate to IPv6 in the Amazon VPC User Guide.
- Your security groups must allow IPv6 addresses. For more information, see Migrate to IPv6 in the Amazon VPC User Guide.
- You can only use IPv6 with AWS Nitro-based Amazon EC2 or Fargate nodes.
- You can't use IPv6 with Security groups for pods (p. 307) with Amazon EC2 nodes. However, you can use it with Fargate nodes. If you need separate security groups for individual pods, continue using the IPv4 family with Amazon EC2 nodes, or use Fargate nodes instead.
- If you previously used custom networking (p. 300) to help alleviate IP address exhaustion, you can use IPv6 instead. You can't use custom networking with IPv6. If you use custom networking for network isolation, then you might need to continue to use custom networking and the IPv4 family for your clusters.
• You can’t use IPv6 with nodes that are deployed on AWS Outposts.
• Pods and services are only assigned an IPv6 address. They aren’t assigned an IPv4 address. Because pods are able to communicate to IPv4 endpoints through NAT on the instance itself, DNS64 and NAT64 aren’t needed. If the traffic needs a public IP address, the traffic is then source network address translated to a public IP.
• The source IPv6 address of a pod isn’t source network address translated to the IPv6 address of the node when communicating outside of the VPC. It is routed using an internet gateway or egress-only internet gateway.
• All nodes are assigned an IPv4 and IPv6 address.
• The Amazon FSx for Lustre CSI driver (p. 250) is not supported.
• You can use version 2.3.1 or later of the AWS Load Balancer Controller to load balance application (p. 371) or network (p. 365) traffic to IPv6 pods in IP mode, but not instance mode. For more information, see Installing the AWS Load Balancer Controller add-on (p. 320).
• You must attach an IPv6 IAM policy to your node IAM or CNI IAM role. Between the two, we recommend that you attach it to a CNI IAM role. For more information, see Create IAM policy for clusters that use the IPv6 family (p. 274) and Step 1: Create the Amazon VPC CNI plugin IAM role (p. 270).
• Each Fargate pod receives an IPv6 address from the CIDR that’s specified for the subnet that it’s deployed in. The underlying hardware unit that runs Fargate pods gets a unique IPv4 and IPv6 address from the CIDRs that are assigned to the subnet that the hardware unit is deployed in.
• We recommend that you perform a thorough evaluation of your applications, Amazon EKS add-ons, and AWS services that you integrate with before deploying IPv6 clusters. This is to ensure that everything works as expected with IPv6.
• You can’t use IPv6 with AWS App Mesh.
• Use of the Amazon EC2 Instance Metadata Service IPv6 endpoint is not supported with Amazon EKS.

Deploy an IPv6 cluster and nodes

In this topic, you deploy an IPv6 Amazon VPC, an Amazon EKS cluster with the IPv6 family, and a managed node group with Amazon EC2 Amazon Linux nodes. You can’t deploy Amazon EC2 Windows nodes in an IPv6 cluster. You can also deploy Fargate nodes to your cluster, though those instructions aren’t provided in this topic for simplicity.

Before creating a cluster for production use, we recommend that you familiarize yourself with all settings and deploy a cluster with the settings that meet your requirements. For more information, see Creating an Amazon EKS cluster (p. 24), Managed node groups (p. 109) and the considerations (p. 288) for this topic. You can only enable some settings when creating your cluster.

Prerequisites

Before starting this tutorial, you must install and configure the following tools and resources that you need to create and manage an Amazon EKS cluster.

• The kubectl command line tool installed on your computer or AWS CloudShell. The version must be the same, or up to two versions later than your cluster version. To install or upgrade kubectl, see Installing kubectl (p. 4). For this tutorial, the version must be 1.21 or later.
• The IAM security principal that you’re using must have permissions to work with Amazon EKS IAM roles and service linked roles, AWS CloudFormation, and a VPC and related resources. For more information, see Actions, resources, and condition keys for Amazon Elastic Kubernetes Service and Using service-linked roles in the IAM User Guide.

Procedures are provided to create the resources with either eksctl or the AWS CLI. You can also deploy the resources using the AWS Management Console, but those instructions aren’t provided in this topic for simplicity.
eksctl

**Prerequisite**

*eksctl* version 0.92.0 or later installed on your computer. To install or update to it, see the section called “Installing *eksctl*” (p. 10).

**To deploy an IPv6 cluster with *eksctl***

1. Copy the following contents to a file named `ipv6-cluster.yaml`. Replace the *example values* with your own. Replace `region-code` with any AWS Region that is supported by Amazon EKS. For a list of AWS Regions, see Amazon EKS endpoints and quotas in the AWS General Reference guide. You can replace `t3.medium` with any AWS Nitro System instance type. The value for `version` must be `1.21` or a later supported Amazon EKS Kubernetes version (p. 65). The cluster name can contain only alphanumeric characters (case-sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 128 characters.

```yaml
---
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: my-cluster
  region: region-code
  version: "1.21"

kubernetesNetworkingConfig:
  ipFamily: IPv6

addons:
- name: vpc-cni
  version: latest
- name: coredns
  version: latest
- name: kube-proxy
  version: latest

iam:
  withOIDC: true

managedNodeGroups:
- name: my-nodegroup
  instanceType: t3.medium
```

2. Create your cluster.

```
eksctl create cluster -f ipv6-cluster.yaml
```

Cluster creation takes several minutes. Don't proceed until you see the last line of output, which looks similar to the following output.

```
[✓]  EKS cluster "my-cluster" in "region-code" region is ready
```

3. Confirm that default pods are assigned IPv6 addresses.

```
kubectl get pods -n kube-system -o wide
```

Example output:
4. Confirm that default services are assigned IPv6 addresses.

```
kubectl get services -n kube-system -o wide
```

Example output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>kube-dns</td>
<td>ClusterIP</td>
<td>fd30:3087:bc6c2::a</td>
<td>&lt;none&gt;</td>
<td>53/UDP,53/TCP</td>
<td>57m</td>
</tr>
</tbody>
</table>

5. (Optional) Deploy a sample application (p. 352) or deploy the AWS Load Balancer Controller (p. 320) and a sample application to load balance application (p. 371) or network (p. 365) traffic to IPv6 pods.

6. After you've finished with the cluster and nodes that you created for this tutorial, you should clean up the resources that you created with the following command.

```
eksctl delete cluster my-cluster
```

AWS CLI

**Prerequisite**

Version 2.5.2 or later or 1.22.86 or later of the AWS CLI installed and configured on your computer or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with `aws configure` in the AWS Command Line Interface User Guide. If you use the AWS CloudShell, you may need to install version 2.5.2 or later or 1.22.86 or later of the AWS CLI, because the default AWS CLI version installed in the AWS CloudShell may be an earlier version.

**Important**

- You must complete all steps in this procedure as the same user.
- You must complete all steps in this procedure in the same shell. Several steps use variables set in previous steps. Steps that use variables won't function properly if the variable values are set in a different shell. If you use the AWS CloudShell to complete the following procedure, remember that if you don't interact with it using your keyboard or...
pointer for approximately 20–30 minutes, your shell session ends. Running processes do
not count as interactions.

- The instructions are written for the Bash shell, and may need adjusting in other shells.

To create your cluster with the AWS CLI

Replace all example values in the steps of this procedure with your own values.

1. Run the following commands to set some variables used in later steps. Replace region-code
with the AWS Region that you want to deploy your resources in. The value can be any AWS
Region that is supported by Amazon EKS. For a list of AWS Regions, see Amazon EKS endpoints
and quotas in the AWS General Reference guide. Replace my-cluster and my-nodegroup with
the names for your cluster and node group. Replace 111122223333 with your account ID.

```bash
export region_code=region-code
export cluster_name=my-cluster
export nodegroup_name=my-nodegroup
export account_id=111122223333
```

2. Create an Amazon VPC with public and private subnets that meets Amazon EKS and IPv6
requirements.

   a. Run the following command to set a variable for your AWS CloudFormation stack name.
      You can replace my-eks-ipv6-vpc with any name you choose.

   ```bash
   export vpc_stack_name=my-eks-ipv6-vpc
   ```

   b. Create an IPv6 VPC using an AWS CloudFormation template.

   ```bash
   aws cloudformation create-stack \
     --region $region_code \
     --stack-name $vpc_stack_name \
   ```

   The stack takes a few minutes to create. Run the following command. Don’t continue to the
   next step until the output of the command is CREATE_COMPLETE.

   ```bash
   aws cloudformation describe-stacks \
     --region $region_code \
     --stack-name $vpc_stack_name \
     --query Stacks[].StackStatus \
     --output text
   ```

   c. Retrieve the IDs of the public subnets that were created.

   ```bash
   aws cloudformation describe-stacks \
     --region $region_code \
     --stack-name $vpc_stack_name \
     --query='StagesPublic'.Outputs[].OutputValue' \
     --output text
   ```

   Example output:

   ```text
   subnet-0a1a56c486EXAMPLE, subnet-099e6ca77aEXAMPLE
   ```

d. Enable the auto-assign IPv6 address option for the public subnets that were created.
Use cases

aws ec2 modify-subnet-attribute
  --region $region_code
  --subnet-id subnet-0a1a56c486EXAMPLE
  --assign-ipv6-address-on-creation
aws ec2 modify-subnet-attribute
  --region $region_code
  --subnet-id subnet-099e6c077eEXAMPLE
  --assign-ipv6-address-on-creation

e. Retrieve the names of the subnets and security groups created by the template from the deployed AWS CloudFormation stack and store them in variables for use in a later step.

security_groups=$(aws cloudformation describe-stacks
  --region $region_code
  --stack-name $vpc_stack_name
  --query='Stacks[].Outputs[?OutputKey==`SecurityGroups`].OutputValue'
  --output text)
public_subnets=$(aws cloudformation describe-stacks
  --region $region_code
  --stack-name $vpc_stack_name
  --query='Stacks[].Outputs[?OutputKey==`SubnetsPublic`].OutputValue'
  --output text)
private_subnets=$(aws cloudformation describe-stacks
  --region $region_code
  --stack-name $vpc_stack_name
  --query='Stacks[].Outputs[?OutputKey==`SubnetsPrivate`].OutputValue'
  --output text)
subnets=${public_subnets},${private_subnets}

3. Create a cluster IAM role and attach the required Amazon EKS IAM managed policy to it. Kubernetes clusters managed by Amazon EKS make calls to other AWS services on your behalf to manage the resources that you use with the service.

a. Copy the following contents to a file named eks-cluster-role-trust-policy.json.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "eks.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

b. Run the following command to set a variable for your role name. You can replace myAmazonEKSClusterRole with any name you choose.

```
export cluster_role_name=myAmazonEKSClusterRole
```
c. Create the role.

```
aws iam create-role
  --role-name $cluster_role_name
```
d. Retrieve the ARN of the IAM role and store it in a variable for a later step.

```bash
cluster_iam_role=$(aws iam get-role
   --role-name $cluster_role_name
   --query="Role.Arn"
   --output text)
```

e. Attach the required Amazon EKS managed IAM policy to the role.

```bash
aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonEKSClusterPolicy
   --role-name $cluster_role_name
```

4. Create your cluster.

a. The version must be 1.21 or a later supported Amazon EKS Kubernetes version (p. 65).

```bash
aws eks create-cluster
   --region $region_code
   --name $cluster_name
   --kubernetes-version 1.21
   --role-arn $cluster_iam_role
   --resources-vpc-config subnetIds=$subnets,securityGroupIds=$security_groups
   --kubernetes-network-config ipFamily=ipv6
```

**Note**

You might receive an error that one of the Availability Zones in your request doesn't have sufficient capacity to create an Amazon EKS cluster. If this happens, the error output contains the Availability Zones that can support a new cluster. Retry creating your cluster with at least two subnets that are located in the supported Availability Zones for your account. For more information, see Insufficient capacity (p. 508).

b. The cluster takes several minutes to create. Run the following command. Don't continue to the next step until the output from the command is `ACTIVE`.

```bash
aws eks describe-cluster
   --region $region_code
   --name $cluster_name
   --query cluster.status
```

5. Create or update a `kubeconfig` file for your cluster so that you can communicate with your cluster.

```bash
aws eks update-kubeconfig
   --region $region_code
   --name $cluster_name
```

By default, the `config` file is created in `~/.kube` or the new cluster's configuration is added to an existing `config` file in `~/.kube`.

6. Create a node IAM role.

a. Copy the following text and save it to a file named `vpc-cni-ipv6-policy.json`.

```json
{
   "Version": "2012-10-17",
```
Use cases

```json
"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "ec2:AssignIpv6Addresses",
      "ec2:DescribeInstances",
      "ec2:DescribeTags",
      "ec2:DescribeNetworkInterfaces",
      "ec2:DescribeInstanceTypes"
    ],
    "Resource": "*"
  },
  {
    "Effect": "Allow",
    "Action": [
      "ec2:CreateTags"
    ],
    "Resource": [
      "arn:aws:ec2:*:*:network-interface/*"
    ]
  }
]
```

b. Create the IAM policy.

```bash
aws iam create-policy \
  --policy-name AmazonEKS_CNI_IPv6_Policy \
  --policy-document file://vpc-cni-ipv6-policy.json
```

c. Save the following contents to a file named `node-role-trust-relationship.json`.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "ec2.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

d. Run the following command to set a variable for your role name. You can replace `AmazonEKSNodeRole` with any name you choose.

```bash
export node_role_name=AmazonEKSNodeRole
```

e. Create the IAM role.

```bash
aws iam create-role \
  --role-name $node_role_name \
  --assume-role-policy-document file://"node-role-trust-relationship.json"
```

f. Attach the IAM policy to the IAM role.

```bash
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::$account_id:policy/AmazonEKS_CNI_IPv6_Policy \
  --role-name $node_role_name
```
### Important
For simplicity in this tutorial, the policy is attached to this IAM role. In a production cluster however, we recommend attaching the policy to a separate IAM role. For more information, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).

#### g. Attach two required IAM managed policies to the IAM role.

```bash
aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy
   --role-name $node_role_name
aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly
   --role-name $node_role_name
```

#### h. Retrieve the ARN of the IAM role and store it in a variable for a later step.

```bash
node_iam_role=$(aws iam get-role
   --role-name $node_role_name
   --query="Role.Arn"
   --output text)
```

7. Create a managed node group.

#### a. View the IDs of the subnets that you created in a previous step.

```bash
echo $subnets
```

Example output:

```
subnet-0a1a56c486EXAMPLE, subnet-099e6ca77aEXAMPLE, subnet-0377963d69EXAMPLE, subnet-0c05f819d5EXAMPLE
```

#### b. Create the node group. Replace `0a1a56c486EXAMPLE, 099e6ca77aEXAMPLE, 0377963d69EXAMPLE, and 0c05f819d5EXAMPLE` with the values returned in the output of the previous step. Be sure to remove the commas between subnet IDs from the previous output in the following command. You can replace `t3.medium` with any AWS Nitro System instance type.

```bash
aws eks create-nodegroup
   --region $region_code
   --cluster-name $cluster_name
   --nodegroup-name $nodegroup_name
   --subnets subnet-0a1a56c486EXAMPLE subnet-099e6ca77aEXAMPLE
   --instance-types t3.medium
   --node-role $node_iam_role
```

The node group takes a few minutes to create. Run the following command. Don't proceed to the next step until the output returned is `ACTIVE`.

```bash
aws eks describe-nodegroup
   --region $region_code
   --cluster-name $cluster_name
   --nodegroup-name $nodegroup_name
   --query nodegroup.status
   --output text
```
8. Confirm that the default pods are assigned IPv6 addresses in the IP column.

```
kubectl get pods -n kube-system -o wide
```

Example output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws-node-rslts</td>
<td>1/1</td>
<td>Running</td>
<td>1</td>
<td>5m36s</td>
<td>2600:1f13:b66:8200:11a5:ode0:c590:6ac8</td>
</tr>
<tr>
<td>aws-node-t74jh</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>5m32s</td>
<td>2600:1f13:b66:8203:4516:2080:8ced:1ca9</td>
</tr>
<tr>
<td>coredns-85d5b4454c-cw7w2</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>56m</td>
<td>2600:1f13:b66:8203:34e5:1</td>
</tr>
<tr>
<td>coredns-85d5b4454c-6m8</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>56m</td>
<td>2600:1f13:b66:8203:34e5:1</td>
</tr>
<tr>
<td>kube-proxy-btpbk</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>5m36s</td>
<td>2600:1f13:b66:8200:11a5:ode0:c590:6ac8</td>
</tr>
<tr>
<td>kube-proxy-3jkk2g</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>5m32s</td>
<td>2600:1f13:b66:8203:4516:2080:8ced:1ca9</td>
</tr>
</tbody>
</table>

9. Confirm that the default services are assigned IPv6 addresses in the IP column.

```
kubectl get services -n kube-system -o wide
```

Example output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
</table>
| kube-dns | ClusterIP  | fd30:3087:b6c2:2a | <none>      | 53/UDP, 53/TCP | 57m   | k8s-

10. **(Optional)** Deploy a sample application (p. 352) or deploy the AWS Load Balancer Controller (p. 320) and a sample application to load balance application (p. 371) or network (p. 365) traffic to IPv6 pods.

11. After you've finished with the cluster and nodes that you created for this tutorial, you should clean up the resources that you created with the following commands. Make sure that you're not using any of the resources outside of this tutorial before deleting them.

   a. If you're completing this step in a different shell than you completed the previous steps in, set the values of all the variables used in previous steps, replacing the example values with the values you specified when you completed the previous steps. If you're completing this step in the same shell that you completed the previous steps in, skip to the next step.

```
export region_code=region-code
export vpc_stack_name=my-eks-ipv6-vpc
export cluster_name=my-cluster
export nodegroup_name=my-nodegroup
export account_id=111122223333
export node_role_name=AmazonEKSNodeRole
export cluster_role_name=AmazonEKSClusterRole
```
b. Delete your node group.

```bash
aws eks delete-nodegroup --region $region_code --cluster-name $cluster_name --nodegroup-name $nodegroup_name
```

Deletion takes a few minutes. Run the following command. Don't proceed to the next step if any output is returned.

```bash
aws eks list-nodegroups --region $region_code --cluster-name $cluster_name --query nodegroups --output text
```

c. Delete the cluster.

```bash
aws eks delete-cluster --region $region_code --name $cluster_name
```

The cluster takes a few minutes to delete. Before continuing make sure that the cluster is deleted with the following command.

```bash
aws eks describe-cluster --region $region_code --name $cluster_name
```

Don't proceed to the next step until your output is similar to the following output.

```text
An error occurred (ResourceNotFoundException) when calling the DescribeCluster operation: No cluster found for name: my-cluster.
```

d. Delete the IAM resources that you created. Replace `AmazonEKS_CNI_IPv6_Policy` with the name you chose, if you chose a different name than the one used in previous steps.

```bash
aws iam detach-role-policy --role-name $cluster_role_name --policy-arn arn:aws:iam::aws:policy/AmazonEKSClusterPolicy
aws iam detach-role-policy --role-name $node_role_name --policy-arn arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy
aws iam detach-role-policy --role-name $node_role_name --policy-arn arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly
aws iam detach-role-policy --role-name $node_role_name --policy-arn arn:aws:iam::$account_id:policy/AmazonEKS_CNI_IPv6_Policy
aws iam delete-policy --policy-arn arn:aws:iam::$account_id:policy/AmazonEKS_CNI_IPv6_Policy
aws iam delete-role --role-name $cluster_role_name
aws iam delete-role --role-name $node_role_name
```

e. Delete the AWS CloudFormation stack that created the VPC.

```bash
aws cloudformation delete-stack --region $region_code --stack-name $vpc_stack_name
```

### External source network address translation (SNAT)

Communication within a VPC (such as pod to pod) is direct between private IP addresses and requires no source network address translation (SNAT). When IP traffic is destined for an IPv4 address outside of the VPC, the Amazon VPC CNI plugin for Kubernetes translates the private IP address of each pod to the primary private IP address assigned to the primary elastic network interface of the Amazon EC2 node that the pod is running on, by default. IPv6 traffic is not source network address translated, so neither of the options in this topic apply to IPv6 traffic.
Elastic network interface is referred to as a *network interface* in the AWS Management Console and the Amazon EC2 API. Therefore, we use "network interface" in this documentation instead of "elastic network interface". The term "network interface" in this documentation always means "elastic network interface".

**SNAT:**

- Enables pods to communicate bi-directionally with the internet. The node must be in a *public subnet* and have a *public* or Elastic IP address assigned to the primary private IP address of its primary network interface. The traffic is translated to and from the public or Elastic IP address and routed to and from the internet by an *internet gateway*, as shown in the following picture.

SNAT is necessary because the internet gateway can only translate between the primary private and public or Elastic IP address assigned to the primary network interface of the Amazon EC2 instance node that pods are running on.

- Prevents a device in other private IP address spaces (for example, VPC peering, Transit VPC, or Direct Connect) from communicating directly to a pod that is not assigned the primary private IP address of the primary network interface of the Amazon EC2 instance node.

If the internet or devices in other private IP address spaces need to communicate with a pod that isn't assigned the primary private IP address assigned to the primary network interface of the Amazon EC2 instance node that the pod is running on, then:

- The node must be deployed in a private subnet that has a route to a *NAT device* in a public subnet.
- You need to enable external SNAT in the CNI plugin `aws-node` DaemonSet with the following command:

  ```
  kubectl set env daemonset -n kube-system aws-node AWS_VPC_K8S_CNI_EXTERNALSNAT=true
  ```

  After external SNAT is enabled, the CNI plugin doesn't translate a pod's private IP address to the primary private IP address assigned to the primary network interface of the Amazon EC2 instance node that the pod is running on when traffic is destined for an address outside of the VPC. Traffic from the pod's private IP address is translated by a NAT device to the public IP address of the NAT device and routed to and from the internet by an internet gateway, as shown in the following picture.
CNI custom networking

By default, when new network interfaces are allocated for pods, `ipamD` uses the security groups and subnet of the node's primary network interface. You might want your pods to use a different security group or subnet, within the same VPC as your control plane security group. For example:

- There are a limited number of IP addresses available in a subnet. This might limit the number of pods that can be created in the cluster. Using different subnets for pods allows you to increase the number of available IP addresses.
- For security reasons, your pods must use different security groups or subnets than the node's primary network interface.
- The nodes are configured in public subnets and you want the pods to be placed in private subnets using a NAT Gateway. For more information, see External source network address translation (SNAT) (p. 298).

Considerations

- The procedures in this topic require the Amazon VPC CNI plugin for Kubernetes version 1.6.3-eksbuilt.1 or later.
- Enabling a custom network effectively removes an available network interface (and all of its available IP addresses for pods) from each node that uses it. The primary network interface for the node is not used for pod placement when a custom network is enabled.
- The procedure in this topic instructs the Amazon VPC CNI plugin to associate different security groups to secondary network interfaces than are associated to the primary network interface in the instance. All pods using the secondary network interfaces still share use of the secondary network interfaces and all use the same security groups.

If you want to assign different security groups to individual pods, then you can use the section called “Security groups for pods” (p. 307). Security groups for pods create additional network interfaces that can each be assigned a unique security group. Security groups for pods can be used with or without custom networking.

- You can't use custom networking if you created your cluster to use the IPv6 family. If you plan to use custom networking to help alleviate IP address exhaustion, you can use IPv6 instead. For more information, see Assigning IPv6 addresses to pods and services (p. 288).
To configure CNI custom networking

1. Confirm that your currently-installed Amazon VPC CNI plugin version is 1.6.3-eksbuild.1 or later.

   ```bash
   kubectl describe daemonset aws-node
   --namespace kube-system | grep Image | cut -d "/" -f 2
   ```

   Output:

   ```
   amazon-k8s-cni:1.6.3-eksbuild.1
   ```

   If your version is earlier than 1.6.3-eksbuild.1, then you must update it. For more information, see the updating sections of Managing the Amazon VPC CNI add-on (p. 275).

2. Associate a secondary CIDR block to your cluster's VPC. For more information, see Associating a Secondary IPv4 CIDR Block with Your VPC in the Amazon VPC User Guide.

3. Create a subnet in your VPC for each Availability Zone, using your secondary CIDR block. Your custom subnets must be from a different VPC CIDR block than the subnet that your nodes were launched into. For more information, see Creating a subnet in your VPC in the Amazon VPC User Guide.

4. Set the `AWS_VPC_K8S_CNI_CUSTOM_NETWORK_CFG` environment variable to `true` in the `aws-node` DaemonSet:

   ```bash
   kubectl set env daemonset aws-node
   -n kube-system AWS_VPC_K8S_CNI_CUSTOM_NETWORK_CFG=true
   ```

5. Create an `ENIConfig` custom resource for each subnet that you want to schedule pods in.

   a. Create a unique file for each network interface configuration. Each file must include the following contents with a unique value for `name`. We highly recommend using a value for `name` that matches the Availability Zone of the subnet because this makes deployment of multi-Availability Zone Auto Scaling groups simpler (see step 5c below).

   In this example, a file named `us-west-2a.yaml` is created. Replace the example values with your own values. In this example, we follow best practices and set the value for `name` to the Availability Zone that the subnet is in. If you don't have a specific security group that you want to attach for your pods, you can leave that value empty for now. Later, you specify the node security group in the ENIConfig.

   ```yaml
   apiVersion: crd.k8s.amazonaws.com/v1alpha1
   kind: ENIConfig
   metadata:
     name: us-west-2a
   spec:
     securityGroups:
     - sg-0dfff111a1d11c11c1
     subnet: subnet-011b111c1f11fd11
   ```

   Note

   - Each subnet and security group combination requires its own custom resource. If you have multiple subnets in the same Availability Zone, use the following command to annotate the nodes in each subnet with the matching config name.

   ```bash
   kubectl annotate node
   node-name.region-code.compute.internal
   k8s.amazonaws.com/eniConfig=subnet1ConfigName
   ```
• If you don't specify a valid security group for the VPC, and you're using version 1.8.0 or later of the VPC CNI plugin, then the security groups associated with the node's primary elastic network interface are used. If you're using a version of the plugin that is earlier than 1.8.0, then the default security group for the VPC is assigned to secondary elastic network interfaces.

• If you specified a security group, ensure that the recommended or minimum required security group settings for the cluster, control plane and node security groups are met. For more information, see Amazon EKS security group considerations (p. 265).

b. Apply each custom resource file that you created to your cluster with the following command:

```
kubectl apply -f us-west-2a.yaml
```

c. (Optional, but recommended for multi-Availability Zone node groups) By default, Kubernetes applies the Availability Zone of a node to the `topology.kubernetes.io/zone` label. If you named your ENIConfig custom resources after each Availability Zone in your VPC, as recommended in step 5a, then you can enable Kubernetes to automatically apply the corresponding ENIConfig for the node's Availability Zone with the following command.

```
kubectl set env daemonset aws-node -n kube-system ENI_CONFIG_LABEL_DEF=topology.kubernetes.io/zone
```

**Note**

Ensure that an annotation with the key `k8s.amazonaws.com/eniConfig` for the `ENI_CONFIG_ANNOTATION_DEF` environment variable doesn't exist in the container spec for the `aws-node` daemonset. If it exists, it overrides the `ENI_CONFIG_LABEL_DEF` value, and should be removed. You can check to see if the variable is set with the `kubectl describe daemonset aws-node -n kube-system | grep ENI_CONFIG_ANNOTATION_DEF` command. If no output is returned, then the variable is not set.

6. If you plan to deploy a managed node group without a launch template, or with a launch template that you haven't specified an AMI ID in, then skip to step 7 and use the Managed, Without a launch template or with a launch template without an AMI ID specified option. Managed node groups automatically calculates the maximum pods value for you.

If you're deploying a self-managed node group or a managed node group with a launch template that you have specified an AMI ID in, then you must determine the Amazon EKS recommend number of maximum pods for your nodes. Follow the instructions in Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 172), adding `--cni-custom-networking-enabled` to step 3. Note the output for use in a later step.

7. Create one of the following types of node groups. For additional instance selection criteria, see Choosing an Amazon EC2 instance type (p. 171). For the options that include 20, replace it with either the value from the previous step (recommended) or your own value.

- **Self-managed** – Deploy the node group using the instructions in Launching self-managed Amazon Linux nodes (p. 132). Don't specify the subnets that you specified in the ENIConfig resources that you deployed. Specify the following text for the `BootstrapArguments` parameter:

  ```
  --use-max-pods false --kubelet-extra-args '--max-pods=20'
  ```

- **Managed** – Deploy your node group using one of the following options:

  - **Without a launch template or with a launch template without an AMI ID specified** – Complete the procedure in Creating a managed node group (p. 113). Managed node groups automatically calculates the Amazon EKS recommended `max-pods` value for you.

  - **With a launch template with a specified AMI ID** – In your launch template, specify an Amazon EKS optimized AMI ID, or a custom AMI built off the Amazon EKS optimized AMI, then deploy
the node group using a launch template (p. 124) and provide the following user data in the launch template. This user data passes arguments into the bootstrap.sh file. For more information about the bootstrap file, see bootstrap.sh on GitHub.

```
/etc/eks/bootstrap.sh my-cluster \
   --use-max-pods false \
   --kubelet-extra-args '--max-pods=20'
```

If you've created a custom AMI that is not built off the Amazon EKS optimized AMI, then you need to custom create the configuration yourself.

**Note**
If you want your nodes to support a significantly higher number of pods, run the script in Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 172) again, adding the `--cni-prefix-delegation-enabled` option to the command. For example, `110` is returned for an `m5.large` instance type. To enable this capability, see Increase the amount of available IP addresses for your Amazon EC2 nodes (p. 303). You can use this capability with custom networking.

8. After your node group is created, record the security group that was created for the subnet and apply the security group to the associated ENIConfig. Edit each ENIConfig with the following command, replacing `eniconfig-name` with your value:

```
kubectl edit eniconfig.crd.k8s.amazonaws.com/eniconfig-name
```

If you followed best practices in step 5, the `eniconfig-name` corresponds to the Availability Zone name.

The `spec` section should look like the following example spec:

```
spec:
  securityGroups:
  - sg-0dff222a2d22c2c22
  subnet: subnet-022b222c2f22f422
```

**Note**
If you use the security group that was created, ensure that the recommended or minimum required security group settings for the cluster, control plane and node security groups are met. For more information, see Amazon EKS security group considerations (p. 265).

9. If you had any nodes in your cluster with running pods before you switched to the custom CNI networking feature, you should cordon and drain the nodes to gracefully shutdown the pods and then terminate the nodes. Only new nodes that are registered with the `k8s.amazonaws.com/eniConfig` label use the custom networking feature.

### Increase the amount of available IP addresses for your Amazon EC2 nodes

By default, the number of IP addresses available to assign to pods is based on the number of IP addresses assigned to Elastic network interfaces, and the number of network interfaces attached to your Amazon EC2 node. You can configure version 1.9.0 or later of the Amazon VPC CNI add-on to assign /28 IPv4 address prefixes. With 1.10.1 or later of the add-on, you can still assign /28 IPv4 address prefixes, but if your cluster is version 1.21 or later, and you've configured it for IPv6 (p. 288), you can assign /80 IPv6 address prefixes instead.
When configured for prefix assignment, the CNI add-on can assign significantly more IP addresses to a network interface than it can when you assign individual IP addresses. The node can then assign significantly more available IP addresses to pods. For more information about the Amazon EC2 capability that enables the add-on to do this, see Assigning prefixes to Amazon EC2 network interfaces in the Amazon EC2 User Guide for Linux Instances.

Without enabling this capability, the add-on must make more Amazon EC2 application programming interface (API) calls to configure the network interfaces and IP addresses necessary for pod connectivity. The frequency of these API calls combined with a high number of network interfaces in each VPC can lead to longer pod and instance launch times as clusters grow to larger sizes. This results in scaling delays to meet the demand of large and spiky workloads, and adds cost and management overhead because you need to provision additional clusters and VPCs to meet scaling requirements. See the Kubernetes scalability thresholds for more information.

Considerations

- AWS Nitro-based nodes use this capability. Instances that aren't Nitro-based continue to allocate individual secondary IP addresses, but have a significantly lower number of IP addresses to assign to pods than Nitro-based instances.
- Once you configure the add-on to assign prefixes to network interfaces, you can't downgrade your Amazon VPC CNI add-on to a version lower than 1.9.0 (or 1.10.1) without removing all nodes in all node groups in your cluster.
- Your VPC must have enough available contiguous /28 IPv4 address blocks to support this capability.
- Each instance type supports a maximum number of pods. If your managed node group consists of multiple instance types, the smallest number of maximum pods for an instance in the cluster is applied to all nodes in the cluster.
- If you have an existing managed node group, the next AMI or launch template update of your node group results in new worker nodes coming up with the new IP address prefix assignment-enabled max-pod value.

Prerequisites

- An existing cluster. To deploy one, see Creating an Amazon EKS cluster (p. 24).
- Version 1.9.0 or later (for version 1.20 or earlier clusters or 1.21 or later clusters configured for IPv4) or 1.10.1 or later (for version 1.21 or later clusters configured for IPv6) of the Amazon VPC CNI add-on deployed to your cluster.

To increase the amount of available IP addresses for your Amazon EC2 nodes

1. Confirm that your currently-installed Amazon VPC CNI version is 1.9.0 or 1.10.1 or later.

```
kubectl describe daemonset aws-node --namespace kube-system | grep Image | cut -d "/" - f 2
```

Output:

```
amazon-k8s-cni:v1.10.1-eksbuild.1
```

If your version is earlier than 1.9.0, then you must update it. For more information, see the updating sections of Managing the Amazon VPC CNI add-on (p. 275).

2. Enable the parameter to assign prefixes to network interfaces for the Amazon VPC CNI daemonset. When you deploy a 1.21 or later cluster, version 1.10.1 or later of the VPC CNI add-on is deployed with it. If you created the cluster with the IPv6 family, this setting was set to true by default. If you created the cluster with the IPv4 family, this setting was set to false by default.
Important

Even if your subnet has free IP addresses, if the subnet does not have any contiguous /28 blocks available, you will see the following error in the VPC CNI logs:

"failed to allocate a private IP/Prefix address: InsufficientCidrBlocks: The specified subnet does not have enough free cidr blocks to satisfy the request"

This can happen due to fragmentation of existing secondary IP addresses spread out across a subnet. To resolve this error, either create a new subnet and launch pods there, or use an Amazon EC2 subnet CIDR reservation to reserve space within a subnet for use with prefix assignment. For more information, see Subnet CIDR reservations in the Amazon VPC User Guide.

3. If you plan to deploy a managed node group without a launch template, or with a launch template that you haven't specified an AMI ID in, and you're using a version of the VPC add-on at or later than the versions listed in the prerequisites, then skip to the next step. Managed node groups automatically calculates the maximum number of pods for you.

If you're deploying a self-managed node group or a managed node group with a launch template that you have specified an AMI ID in, then you must determine the Amazon EKS recommend number of maximum pods for your nodes. Follow the instructions in Amazon EKS recommended maximum pods for each Amazon EC2 instance type (p. 172), adding --cni-prefix-delegation-enabled to step 3. Note the output for use in a later step.

Important

Managed node groups enforces a maximum number on the value of maxPods. For instances with less than 30 vCPUs the maximum number is 110 and for all other instances the maximum number is 250. This maximum number is applied whether prefix delegation is enabled or not.

4. If you're using a 1.21 or later cluster configured for IPv6, skip to the next step.

Specify the parameters in one of the following options. To determine which option is right for you and what value to provide for it, see WARM_PREFIX_TARGET, WARM_IP_TARGET, and MINIMUM_IP_TARGET on GitHub.

You can replace the example values with a value greater than zero.

• WARM_PREFIX_TARGET

```
kubectl set env ds aws-node -n kube-system WARM_PREFIX_TARGET=1
```

• WARM_IP_TARGET or MINIMUM_IP_TARGET – If either value is set, it overrides any value set for WARM_PREFIX_TARGET.

```
kubectl set env ds aws-node -n kube-system WARM_IP_TARGET=5
```

```
kubectl set env ds aws-node -n kube-system MINIMUM_IP_TARGET=2
```

5. Create one of the following types of node groups with at least one Amazon EC2 Nitro Amazon Linux 2 instance type. For a list of Nitro instance types, see instances built on the Nitro System in the Amazon EC2 User Guide for Linux Instances. This capability is not supported on Windows. For the options that include 110, replace it with either the value from step 3 (recommended), or your own value.

305
• **Self-managed** – Deploy the node group using the instructions in Launching self-managed Amazon Linux nodes (p. 132). Specify the following text for the `BootstrapArguments` parameter.

```
--use-max-pods false --kubelet-extra-args '--max-pods=110'
```

If you're using `eksctl` to create the node group, you can use the following command.

```
eksctl create nodegroup --cluster my-cluster --managed=false --max-pods-per-node 110
```

• **Managed** – Deploy your node group using one of the following options:

  • **Without a launch template or with a launch template without an AMI ID specified** – Complete the procedure in Creating a managed node group (p. 113). Managed node groups automatically calculates the Amazon EKS recommended `max-pods` value for you.

  • **With a launch template with a specified AMI ID** – In your launch template, specify an Amazon EKS optimized AMI ID, or a custom AMI built off the Amazon EKS optimized AMI, then deploy the node group using a launch template (p. 124) and provide the following user data in the launch template. This user data passes arguments into the `bootstrap.sh` file. For more information about the bootstrap file, see `bootstrap.sh` on GitHub.

```
/etc/eks/bootstrap.sh my-cluster
--use-max-pods false
--kubelet-extra-args '--max-pods=110'
```

If you're using `eksctl` to create the node group, you can use the following command.

```
eksctl create nodegroup --cluster my-cluster --max-pods-per-node 110
```

If you've created a custom AMI that is not built off the Amazon EKS optimized AMI, then you need to custom create the configuration yourself.

**Note**

If you also want to assign IP addresses to pods from a different subnet than the instance's, then you need to enable the capability in this step. For more information, see CNI custom networking (p. 300).

6. Once your nodes are deployed, view the nodes in your cluster.

```
kubectl get nodes
```

Example output:

```
NAME                                           STATUS     ROLES    AGE   VERSION
ip-192-168-22-103.region-code.compute.internal Ready <none> 19m   v1.20.4-eks-6b7464
ip-192-168-97-94.region-code.compute.internal Ready <none> 19m   v1.20.4-eks-6b7464
```

7. Describe one of the nodes to determine the `max-pods` for the node.

```
kubectl describe node node-name ip-192-168-22-103.region-code.compute.internal
```

Example output:

```
...
Security groups for pods

Security groups for pods integrate Amazon EC2 security groups with Kubernetes pods. You can use Amazon EC2 security groups to define rules that allow inbound and outbound network traffic to and from pods that you deploy to nodes running on many Amazon EC2 instance types and Fargate. For a detailed explanation of this capability, see the Introducing security groups for pods blog post.

Considerations

Before deploying security groups for pods, consider the following limits and conditions:

- Traffic flow to and from pods with associated security groups are not subjected to Calico network policy enforcement and are limited to Amazon EC2 security group enforcement only. Community effort is underway to remove this limitation.
- Pods running on Amazon EC2 nodes can be in any Amazon EKS supported Kubernetes version, but pods running on Fargate must be in a 1.18 or later cluster.
- Security groups for pods can’t be used with Windows nodes.
- Security groups for pods can’t be used with clusters configured for the IPv6 family that contain Amazon EC2 nodes. You can however, use security groups for pods with clusters configured for the IPv6 family that contain only Fargate nodes. For more information, see Assigning IPv6 addresses to pods and services.
- Security groups for pods are supported by most Nitro-based Amazon EC2 instance families, including the m5, c5, r5, p3, m6g, c6g, and r6g instance families. The t3 instance family is not supported. For a complete list of supported instances, see the limits.go file on Github. Your nodes must be one of the listed instance types that have IsTrunkingCompatible: true in that file.
- Source NAT is disabled for outbound traffic from pods with assigned security groups so that outbound security group rules are applied. To access the internet, pods with assigned security groups must be launched on nodes that are deployed in a private subnet configured with a NAT gateway or instance. Pods with assigned security groups deployed to public subnets are not able to access the internet.
- Kubernetes services of type NodePort and LoadBalancer using instance targets with an externalTrafficPolicy set to Local are not supported with pods that you assign security groups to. For more information about using a load balancer with instance targets, see Network load balancing on Amazon EKS.
- If you’re also using pod security policies to restrict access to pod mutation, then the eks-vpc-resource-controller and vpc-resource-controller Kubernetes service accounts must be specified in the Kubernetes ClusterRoleBinding for the the Role that your psp is assigned to. If you’re using the default Amazon EKS psp, Role, and ClusterRoleBinding, this is the eks:podsecuritypolicy:authenticated ClusterRoleBinding. For example, you would add the service accounts to the subjects: section, as shown in the following example:

```yaml
... subjects:
  - kind: Group
```
• If you're using custom networking (p. 300) and security groups for pods together, the security group specified by security groups for pods is used instead of the security group specified in the ENI config.

• Pods using security groups must contain terminationGracePeriodSeconds in their pod spec. This is because the Amazon EKS VPC CNI plugin queries the API server to retrieve the pod IP address before deleting the pod network on the host. Without this setting, the plugin doesn't remove the pod network on the host.

• Pods using security groups are not supported in clusters using Nodelocal DNSCache.

Configure the Amazon VPC CNI add-on for security groups for pods

To deploy security groups for pods

If you're using security groups for Fargate pods only, and don't have any Amazon EC2 nodes in your cluster, skip to Deploy an example application (p. 309).

1. Check your current CNI plugin version with the following command.

   kubectl describe daemonset aws-node --namespace kube-system | grep Image | cut -d "/" - f 2

   Example output:

   amazon-k8s-cni-init:1.7.5-eksbuild.1
   amazon-k8s-cni:1.7.5-eksbuild.1

   If your CNI plugin version is earlier than 1.7.7, then update your CNI plugin to version 1.7.7 or later. For more information, see Updating the Amazon VPC CNI Amazon EKS add-on (p. 277).

2. Add the AmazonEKSVPCResourceController managed policy to the cluster role (p. 450) that is associated with your Amazon EKS cluster. The policy allows the role to manage network interfaces, their private IP addresses, and their attachment and detachment to and from network instances.

   a. Determine the ARN of your cluster IAM role. Replace my-cluster with the name of your cluster.

      aws eks describe-cluster --name my-cluster --query cluster.roleArn --output text

      Output

      arn:aws:iam::111122223333:role/eksClusterRole

   b. The following command adds the policy to a cluster role named eksClusterRole. Replace eksClusterRole with the name of your role.

      aws iam attach-role-policy
      --policy-arn arn:aws:iam::aws:policy/AmazonEKSVPCResourceController
      --role-name eksClusterRole

3. Enable the Amazon VPC CNI add-on to manage network interfaces for pods by setting the ENABLE_POD_ENI variable to true in the aws-node daemonset. Once this setting is set to true,
for each node in the cluster the add-on adds a label with the value `vpc.amazonaws.com/has-trunk-attached=true`. The VPC resource controller creates and attaches one special network interface called a `trunk network interface` with the description `aws-k8s-trunk-eni`.

```
kubectl set env daemonset aws-node -n kube-system ENABLE_POD_ENI=true
```

**Note**
The trunk network interface is included in the maximum number of network interfaces supported by the instance type. For a list of the maximum number of network interfaces supported by each instance type, see [IP addresses per network interface per instance type](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/instance-network-interfaces.html) in the *Amazon EC2 User Guide for Linux Instances*. If your node already has the maximum number of standard network interfaces attached to it then the VPC resource controller will reserve a space. You will have to scale down your running pods enough for the controller to detach and delete a standard network interface, create the trunk network interface, and attach it to the instance.

You can see which of your nodes have `aws-k8s-trunk-eni` set to `true` with the following command. If `No resources found` is returned, then wait several seconds and try again. The previous step requires restarting the CNI pods, which takes several seconds.

```
kubectl get nodes -o wide -l vpc.amazonaws.com/has-trunk-attached=true
```

Once the trunk network interface is created, pods are assigned secondary IP addresses from the trunk or standard network interfaces. The trunk interface is automatically deleted if the node is deleted.

When you deploy a security group for a pod in a later step, the VPC resource controller creates a special network interface called a `branch network interface` with a description of `aws-k8s-branch-eni` and associates the security groups to it. Branch network interfaces are created in addition to the standard and trunk network interfaces attached to the node. If you are using liveness or readiness probes, then you also need to disable TCP early demux, so that the `kubelet` can connect to pods on branch network interfaces using TCP. To disable TCP early demux, run the following command:

```
kubectl patch daemonset aws-node \
  -n kube-system \
  -p "{"spec": {"template": {"spec": {"initContainers": [{"env": [{"name":"DISABLE_TCP_EARLY_DEMUX","value":"true"}],"name":"aws-vpc-cni-init"}]}}}}"
```

**Deploy an example application**

To use security groups for pods, you must have an existing security group and [Deploy an Amazon EKS SecurityGroupPolicy](https://docs.aws.amazon.com/eks/latest/userguide/deploy-security-group.html) to your cluster, as described in the following procedure. The following steps show you how to use the security group policy for a pod. Unless otherwise noted, complete all steps from the same terminal because variables are used in the following steps that don't persist across terminals.

**To deploy an example pod with a security group**

1. Create a security group to use with your pod. The steps that follow help you create a simple security group for illustrative purposes only. In a production cluster, your rules will likely be different.
   
   a. Retrieve the IDs of your cluster's VPC and cluster security group. Replace `my-cluster` with the name of your cluster.

```
my_cluster_name=my-cluster
```
Use cases

b. Create the security group for your pod. Replace `my-pod-security-group` with your own.
Note the ID of the security group returned in the output after running the commands. You'll use it in a later step.

```bash
my_pod_security_group_name=my-pod-security-group
aws ec2 create-security-group
  --vpc-id $my_cluster_vpc_id
  --group-name $my_pod_security_group_name
  --description "My pod security group"
my_pod_security_group_id=$(aws ec2 describe-security-groups
  --filters Name=group-name,Values=$my_pod_security_group_name
  --query 'SecurityGroups[].GroupId'
  --output text)
echo $my_pod_security_group_id
```

c. Allow TCP and UDP port 53 traffic from the pod security group that you created in the previous step to your cluster security group. If you want the DNS traffic from your pod to flow to a different security group than your cluster security group, then replace `$my_cluster_security_group_id` with your own security group ID. Note the value returned for `SecurityGroupRuleId` in the output returned for each of the commands. You'll use them in a later step.

```bash
aws ec2 authorize-security-group-ingress
  --group-id $my_cluster_security_group_id
  --protocol tcp --port 53 --source-group $my_pod_security_group_id
aws ec2 authorize-security-group-ingress
  --group-id $my_cluster_security_group_id
  --protocol udp --port 53 --source-group $my_pod_security_group_id
```

d. Allow inbound traffic to your pod security group from any pod the security group is associated to over any protocol and port. The security group has a default outbound rule that allows outbound traffic from the pods that your security group is associated with to any destination over any protocol and port.

```bash
aws ec2 authorize-security-group-ingress
  --group-id $my_pod_security_group_id
  --protocol -1 --port -1 --source-group $my_pod_security_group_id
```

2. Create a Kubernetes namespace to deploy resources to.

```bash
kubectl create namespace my-namespace
```

3. Deploy an Amazon EKS SecurityGroupPolicy to your cluster.

   a. Save the following example security policy to a file named `my-security-group-policy.yaml`. You can replace `podSelector` with `serviceAccountSelector` if you'd rather select pods based on service account labels. You must specify one selector or the other. An empty `podSelector` (example: `podSelector: {}`) selects all pods in the namespace. An empty `serviceAccountSelector` selects all service accounts in the namespace. You must specify 1-5 security group IDs for `groupIds`. If you specify more than one ID, then the
combination of all the rules in all the security groups are effective for the selected pods. Replace *sg-05b1d815d1EXAMPLE* with the ID of the security group that you noted in a previous step when you created the security group for your pod.

```yaml
apiVersion: vpcresources.k8s.aws/v1beta1
class: SecurityGroupPolicy
metadata:
  name: my-security-group-policy
  namespace: my-namespace
spec:
  podSelector:
    matchLabels:
      role: my-role
  securityGroups:
    groupIds:
    - sg-05b1d815d1EXAMPLE
```

**Important**

The security group or groups that you specify for your pods must meet the following criteria:

- They must exist. If they don't exist, then, when you deploy a pod that matches the selector, your pod remains stuck in the creation process. If you describe the pod, you'll see an error message similar to the following one: An error occurred (InvalidSecurityGroupID.NotFound) when calling the CreateNetworkInterface operation: The securityGroup ID 'sg-05b1d815d1EXAMPLE' does not exist.

- They must allow inbound communication from the cluster security group (p. 265) (for kubelet) over any ports that you've configured probes for.

- They must allow outbound communication over TCP and UDP ports 53 to a security group assigned to pods running CoreDNS. The security group for your CoreDNS pods must allow inbound TCP and UDP port 53 traffic from your security group.

- They must have necessary inbound and outbound rules to communicate with other pods that they need to communicate with.

- They must have rules that allow the pods to communicate with the Kubernetes control plane if you're using the security group with Fargate. The easiest way to do this is to specify the cluster security group as one of the security groups.

Security group policies only apply to newly scheduled pods. They do not affect running pods.

b. Deploy the policy.

```
kubectl apply -f my-security-group-policy.yaml
```

4. Deploy a sample application with a label that matches the *my-role* value for *podSelector* that you specified in the previous step.

a. Save the following contents to a file named *sample-application.yaml*.

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: my-deployment
  namespace: my-namespace
labels:
  app: my-app
```
b. Deploy the application with the following command. When you deploy the application, the CNI plugin matches the role label and the security groups that you specified in the previous step are applied to the pod.

```bash
kubectl apply -f sample-application.yaml
```

**Note**

- If your pod is stuck in the Waiting state and you see Insufficient permissions: Unable to create Elastic Network Interface. when you describe the pod, confirm that you added the IAM policy to the IAM cluster role in a previous step.

- If your pod is stuck in the Pending state, confirm that your node instance type is listed in `limits.go` and that the maximum number of branch network interfaces supported by the instance type multiplied times the number of nodes in your node group hasn't already been met. For example, an `m5.large` instance supports nine branch network interfaces. If your node group has five nodes, then a maximum of 45 branch network interfaces can be created for the node group. The 46th pod that you attempt to deploy will sit in Pending state until another pod that has associated security groups is deleted.

If you run `kubectl describe pod my-deployment-xxxxxxxxxxxx-xxxxx` -n `my-namespace` and see a message similar to the following message, then it can be safely ignored. This message might appear when the CNI plugin tries to set up host networking and fails while the network interface is being created. The CNI plugin logs this event until the network interface is created.
Failed to create pod sandbox: rpc error: code = Unknown desc = failed to set up sandbox container
"e2426832ee55c8185721f32df6493684f6c2c3bf4fd59c9c121fd4c894579f" network for pod "my-deployment-5df6f7687b-4fbjm": networkPlugin
cni failed to set up pod "my-deployment-5df6f7687b-4fbjm-c89wx_my-namespace"
network: add cmd: failed to assign an IP address to container

You can't exceed the maximum number of pods that can be run on the instance type. For a list
of the maximum number of pods that you can run on each instance type, see eni-max-pods.txt
on GitHub. When you delete a pod that has associated security groups, or delete the node that
the pod is running on, the VPC resource controller deletes the branch network interface. If you
delete a cluster with pods using pods for security groups, then the controller does not delete
the branch network interfaces, so you'll need to delete them yourself.

5. View the pods deployed with the sample application. For the remainder of this topic, this terminal is
referred to as TerminalA.

```
kubectl get pods -n my-namespace -o wide
```

```
NAME                             READY   STATUS    RESTARTS   AGE     IP                    NODE                                            NOMINATED NODE   READINESS GATES
my-deployment-5df6f7687b-4fbjm  1/1     Running   0          7m51s  192.168.53.48           ip-192-168-33-28.region-code.compute.internal   <none>           <none>
my-deployment-5df6f7687b-j9fl4  1/1     Running   0          7m51s  192.168.70.145           ip-192-168-92-33.region-code.compute.internal   <none>           <none>
my-deployment-5df6f7687b-rjxcz  1/1     Running   0          7m51s  192.168.73.207           ip-192-168-92-33.region-code.compute.internal   <none>           <none>
my-deployment-5df6f7687b-zmb42  1/1     Running   0          7m51s  192.168.63.27            ip-192-168-33-28.region-code.compute.internal   <none>           <none>
```

6. In a separate terminal, shell into one of the pods. For the remainder of this topic, this terminal is
referred to as TerminalB. Replace 5df6f7687b-4fbjm with the ID of one of the pods returned in
your output from the previous step.

```
kubectl exec -it -n my-namespace my-deployment-5df6f7687b-4fbjm -- /bin/bash
```

7. From the shell in TerminalB, confirm that the sample application works.

```
curl my-app
```

```
<!DOCTYPE html>
<html>
<head>
<title>Welcome to nginx!</title>
...</n```

You received the output because all pods running the application are associated with the security
group that you created. That group contains a rule that allows all traffic between all pods that the
security group is associated to. DNS traffic is allowed outbound from that security group to the
cluster security group, which is associated with your nodes. The nodes are running the CoreDNS
pods, which your pods did a name lookup to.
8. From TerminalA, remove the security group rules that allow DNS communication to the cluster security group from your security group. If you didn’t add the DNS rules to the cluster security group in a previous step, then replace $my_cluster_security_group_id with the ID of the security group that you created the rules in. Replace sgr-0407e21efdEXAMPLE and sgr-04dedf9701EXAMPLE with the IDs of the security group rules that you noted in a previous step.

```
aws ec2 revoke-security-group-ingress --group-id $my_cluster_security_group_id --security-group-rule-ids sgr-0407e21efdEXAMPLE
aws ec2 revoke-security-group-ingress --group-id $my_cluster_security_group_id --security-group-rule-ids sgr-04dedf9701EXAMPLE
```

9. From TerminalB, attempt to access the application again.

```
curl my-app
```

The attempt fails because the pod is no longer able to access the CoreDNS pods, which have the cluster security group associated to them. The cluster security group no longer has the security group rules that allow DNS communication from the security group associated to your pod.

If you attempt to access the application using the IP addresses returned for one of the pods in a previous step, you still receive a response because all ports are allowed between pods that have the security group associated to them and a name lookup isn't required.

10. Once you've finished experimenting, you can remove the sample security group policy, application, and security group that you created with the following commands.

```
kubectl delete namespace my-namespace
aws ec2 delete-security-group --group-id $my_pod_security_group_id
```

### Multiple network interfaces for pods

Multus CNI is a container network interface (CNI) plugin for Amazon EKS that enables attaching multiple network interfaces to a pod. For more information, see the Multus-CNI documentation on GitHub.

In Amazon EKS, each pod has one network interface assigned by the Amazon VPC CNI plugin. With Multus, you can create a multi-homed pod that has multiple interfaces. This is accomplished by Multus acting as a "meta-plugin"; a CNI plugin that can call multiple other CNI plugins. AWS support for Multus comes configured with the Amazon VPC CNI plugin as the default delegate plugin.

### Considerations

- Amazon EKS won't be building and publishing single root I/O virtualization (SR-IOV) and Data Plane Development Kit (DPDK) CNI plugins. However, you can achieve packet acceleration by connecting directly to Amazon EC2 Elastic Network Adapters (ENA) through Multus managed host-device and ipvlan plugins.
- Amazon EKS is supporting Multus, which provides a generic process that enables simple chaining of additional CNI plugins. Multus and the process of chaining is supported, but AWS won't provide support for all compatible CNI plugins that can be chained, or issues that may arise in those CNI plugins that are unrelated to the chaining configuration.
- Amazon EKS is providing support and life cycle management for the Multus plugin, but isn't responsible for any IP address or additional management associated with the additional network interfaces. The IP address and management of the default network interface utilizing the Amazon VPC CNI plugin remains unchanged.
• Only the Amazon VPC CNI plugin is officially supported as the default delegate plugin. You need to modify the published Multus installation manifest to reconfigure the default delegate plugin to an alternate CNI if you choose not to use the Amazon VPC CNI plugin for primary networking.
• Multus is only supported when using the Amazon VPC CNI as the primary CNI. We do not support the Amazon VPC CNI when used for higher order interfaces, secondary or otherwise.
• To prevent the Amazon VPC CNI plugin from trying to manage additional network interfaces assigned to pods, you can tag the network interfaces with `node.k8s.amazonaws.com/no_manage`.
• Multus is compatible with network policies, but the policy has to be enriched to include ports and IP addresses that may be part of additional network interfaces attached to pods.

For an implementation walk through, see the Multus Setup Guide on GitHub.

CNI metrics helper

The CNI metrics helper is a tool that you can use to scrape network interface and IP address information, aggregate metrics at the cluster level, and publish the metrics to Amazon CloudWatch. To learn more about the metrics helper, see cni-metrics-helper on GitHub.

When managing an Amazon EKS cluster, you may want to know how many IP addresses have been assigned and how many are available. The CNI metrics helper helps you to:

• Track these metrics over time
• Troubleshoot and diagnose issues related to IP assignment and reclamation
• Provide insights for capacity planning

When a node is provisioned, the CNI plugin automatically allocates a pool of secondary IP addresses from the node's subnet to the primary network interface (`eth0`). This pool of IP addresses is known as the *warm pool*, and its size is determined by the node's instance type. For example, a `c4.large` instance can support three network interfaces and nine IP addresses per interface. The number of IP addresses available for a given pod is one less than the maximum (of ten) because one of the IP addresses is reserved for the elastic network interface itself. For more information, see IP Addresses Per Network Interface Per Instance Type in the Amazon EC2 User Guide for Linux Instances.

As the pool of IP addresses is depleted, the plugin automatically attaches another elastic network interface to the instance and allocates another set of secondary IP addresses to that interface. This process continues until the node can no longer support additional elastic network interfaces.

The following metrics are collected for your cluster and exported to CloudWatch:

• The maximum number of network interfaces that the cluster can support
• The number of network interfaces have been allocated to pods
• The number of IP addresses currently assigned to pods
• The total and maximum numbers of IP addresses available
• The number of ipamD errors

Prerequisites

• An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Create an IAM OIDC provider for your cluster (p. 466).
• Version 2.5.2 or later or 1.22.86 or later of the AWS CLI installed and configured on your computer or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with `aws configure` in the AWS Command Line Interface User Guide.
- The `kubectl` command line tool installed on your computer or AWS CloudShell. The version must be the same, or up to two versions later than your cluster version. To install or upgrade `kubectl`, see Installing `kubectl` (p. 4).

**Deploy the CNI metrics helper**

Create an IAM policy and role and deploy the metrics helper.

**To deploy the CNI metrics helper**

1. Create an IAM policy that grants the CNI metrics helper `cloudwatch:PutMetricData` permissions to send metric data to CloudWatch.
   a. Copy the following contents to a file named `cni-metrics-helper-policy.json`.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
     "Effect": "Allow",
     "Action": [
     "cloudwatch:PutMetricData"
     ],
     "Resource": "*"
   }
   ]
   }
   ```

   b. Create an IAM policy named `AmazonEKSVPCCNIMetricsHelperPolicy`.

   ```bash
   aws iam create-policy --policy-name AmazonEKSVPCCNIMetricsHelperPolicy \
   --description "Grants permission to write metrics to CloudWatch" \
   --policy-document file://cni-metrics-helper-policy.json
   ```

2. Create an IAM role and attach the IAM policy to it. Create a Kubernetes service account. Annotate the Kubernetes service account with the IAM role ARN and the IAM role with the Kubernetes service account name. You can create the role using `eksctl` or the AWS CLI.

   **eksctl**

   Run the following command to create the IAM role. Replace `my-cluster` with your cluster name, `111122223333` with your account ID, and `region-code` with the AWS Region that your cluster is in.

   ```bash
   eksctl create iamserviceaccount \
   --name cni-metrics-helper \
   --namespace kube-system \
   --cluster my-cluster \
   --role-name "AmazonEKSVPCCNIMetricsHelperRole" \
   --attach-policy-arn arn:aws:iam::111122223333:policy/AmazonEKSVPCCNIMetricsHelperPolicy \
   --approve
   ```

   **AWS CLI**

   1. Determine your cluster's OIDC provider URL. Replace `my-cluster` with your cluster name. If the output from the command is `None`, review the Prerequisites.
aws eks describe-cluster --name my-cluster --query "cluster.identity.oidc.issuer" --output text

Example output:

oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE

2. Create the IAM role, granting the Kubernetes service account the AssumeRoleWithWebIdentity action.
   a. Copy the following contents to a file named trust-policy.json. Replace 111122223333 with your account ID. Replace EXAMPLED539D4633E53DE1B71EXAMPLE and region-code with the values returned in the previous step.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "Federated": "arn:aws:iam::111122223333:oidc-provider/oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE"
         },
         "Action": "sts:AssumeRoleWithWebIdentity",
         "Condition": {
           "StringEquals": {
             "oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:aud": "sts.amazonaws.com",
             "oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:sub": "system:serviceaccount:kube-system:cni-metrics-helper"
           }
         }
       }
     ]
   }
   ```
   b. Create the role.

   ```bash
   aws iam create-role \
   --role-name AmazonEKSVPCCNIMetricsHelperRole \
   --assume-role-policy-document file://"trust-policy.json"
   ```

   3. Attach the IAM policy to the role. Replace 111122223333 with your account ID.

   ```bash
   aws iam attach-role-policy \
   --policy-arn arn:aws:iam::111122223333:policy/AmazonEKSVPCCNIMetricsHelperPolicy \
   --role-name AmazonEKSVPCCNIMetricsHelperRole
   ```

   3. Use the following command for the AWS Region that your cluster is in to add the recommended version of the CNI metrics helper to your cluster.

   **Important**
   You should only update one minor version at a time. For example, if your current minor version is 1.8 and you want to update to 1.10, you should update to 1.9 first, then update to 1.10 by changing the version number in one of the following commands.
   The recommended and latest version work with all Amazon EKS supported Kubernetes versions.
China (Beijing) (cn-north-1) or China (Ningxia) (cn-northwest-1)

```bash
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.10.1/config/master/cni-metrics-helper-cn.yaml
```

AWS GovCloud (US-East) (us-gov-east-1)

```bash
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.10.1/config/master/cni-metrics-helper-us-gov-east-1.yaml
```

AWS GovCloud (US-West) (us-gov-west-1)

```bash
```

All other AWS Regions

1. Download the manifest file.

```bash
```

2. If your cluster isn't in us-west-2, then replace `region-code` in the following command with the AWS Region that your cluster is in and then run the modified command to replace `us-west-2` in the file with your AWS Region.

```bash
sed -i.bak -e 's/us-west-2/region-code/' cni-metrics-helper.yaml
```

3. If your cluster isn't in us-west-2, then replace `602401143452` in the following command with the account from Amazon container image registries (p. 379) for the AWS Region that your cluster is in and then run the modified command to replace `602401143452` in the file.

```bash
sed -i.bak -e 's/602401143452/602401143452/' cni-metrics-helper.yaml
```

4. Apply the manifest file to your cluster.

```bash
kubectl apply -f cni-metrics-helper.yaml
```

4. Annotate the `cni-metrics-helper` Kubernetes service account created in a previous step with the ARN of the IAM role that you created previously. Replace `111122223333` with your account ID, `my-cluster` with your cluster name, and `AmazonEKSVPCCNIMetricsHelperRole` with the name of the IAM role that you created in a previous step.

```bash
kubectl annotate serviceaccount cni-metrics-helper \
   -n kube-system \
   eks.amazonaws.com/role-arn=arn:aws:iam::111122223333:role/AmazonEKSVPCCNIMetricsHelperRole
```

5. (Optional) Annotate your service account to use the AWS Security Token Service AWS Regional endpoint if your cluster’s Kubernetes version is listed in the following table and its platform version is the same or later than the version listed in the table. If your cluster’s Kubernetes version is listed in the following table and you have a platform version that is earlier than the version listed in the following table, then you can’t enable your service accounts to use the AWS Security Token Service AWS Regional endpoint. You must use the global endpoint. If your cluster is 1.22 or later, the
AWS Regional endpoint is used by default, so you don't need to annotate your Kubernetes service accounts to use it.

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Platform version</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.21</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.20</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.19</td>
<td>eks.7</td>
</tr>
<tr>
<td>1.18</td>
<td>eks.9</td>
</tr>
</tbody>
</table>

Add the following annotation to your service accounts.

```
kubectl annotate serviceaccount -n kube-system cni-metrics-helper eks.amazonaws.com/sts-regional-endpoints=true
```

AWS recommends using the AWS Regional AWS STS endpoints instead of the global endpoint to reduce latency, build in redundancy, and increase session token validity. The AWS Security Token Service must be active in the AWS Region where the pod is running and your application should have redundancy built in to pick a different AWS Region in the event of a failure of the service in the AWS Region. For more information, see Managing AWS STS in an AWS Region in the IAM User Guide.

6. Restart the `cni-metrics-helper` deployment.

```
kubectl rollout restart deployment cni-metrics-helper -n kube-system
```

Creating a metrics dashboard

After you have deployed the CNI metrics helper, you can view the CNI metrics in the CloudWatch console. This topic helps you to create a dashboard for viewing your cluster's CNI metrics.

To create a CNI metrics dashboard

2. In the left navigation pane, choose Metrics and then select All metrics.
3. Under Custom Namespaces, select Kubernetes.
4. Select CLUSTER_ID.
5. On the Metrics tab, select the metrics you want to add to the dashboard.
6. At the upper right of the console, select Actions, and then Add to dashboard.
7. In the Select a dashboard section, select Create new, enter a name for your dashboard, such as EKS-CNI-metrics, and then select Create.
8. In the Widget type section, select Number.
9. In the Customize widget title section, enter a logical name for your dashboard title, such as EKS CNI metrics.
10. Select Add to dashboard to finish. Now your CNI metrics are added to a dashboard that you can monitor, as shown below.
Alternate compatible CNI plugins

Amazon EKS only officially supports the Amazon VPC CNI plugin (p. 269). Amazon EKS runs upstream Kubernetes and is certified Kubernetes conformant however, so alternate CNI plugins will work with Amazon EKS clusters. If you plan to use an alternate CNI plugin in production, then we strongly recommend that you either obtain commercial support, or have the in-house expertise to troubleshoot and contribute fixes to the open source CNI plugin project.

Amazon EKS maintains relationships with a network of partners that offer support for alternate compatible CNI plugins. See the following partners' documentation for details on supported Kubernetes versions and qualifications and testing performed.

<table>
<thead>
<tr>
<th>Partner</th>
<th>Product</th>
<th>Documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tigera</td>
<td>Calico</td>
<td>Installation instructions</td>
</tr>
<tr>
<td>Isovalent</td>
<td>Cilium</td>
<td>Installation instructions</td>
</tr>
<tr>
<td>Weaveworks</td>
<td>Weave Net</td>
<td>Installation instructions</td>
</tr>
<tr>
<td>VMware</td>
<td>Antrea</td>
<td>Installation instructions</td>
</tr>
</tbody>
</table>

Amazon EKS aims to give you a wide selection of options to cover all use cases. If you develop a commercially supported Kubernetes CNI plugin that is not listed here, then please contact our partner team at aws-container-partners@amazon.com for more information.

Installing the AWS Load Balancer Controller add-on

The AWS Load Balancer Controller manages AWS Elastic Load Balancers for a Kubernetes cluster. The controller provisions the following resources.

- An AWS Application Load Balancer (ALB) when you create a Kubernetes Ingress.
- An AWS Network Load Balancer (NLB) when you create a Kubernetes service of type LoadBalancer.

In the past, the Kubernetes network load balancer was used for *instance* targets, but the AWS Load balancer Controller was used for *IP* targets. With the AWS Load Balancer Controller version 2.3.0 or later, you can create NLBs using either target type. For more information about NLB target types, see Target type in the User Guide for Network Load Balancers.
The AWS Load Balancer Controller controller was formerly named the AWS ALB Ingress Controller. It's an open-source project managed on GitHub. This topic describes how to install the controller using default options. You can view the full documentation for the controller on GitHub. Before deploying the controller, we recommend that you review the prerequisites and considerations in Application load balancing on Amazon EKS (p. 371) and Network load balancing on Amazon EKS (p. 365). Those topics also include steps on how to deploy a sample application that require the AWS Load Balancer Controller to provision AWS ALBs and NLBs.

Prerequisites

- An existing Amazon EKS cluster. To deploy one, see Getting started with Amazon EKS (p. 4). To use version 2.4.1 of the controller, which is the version used in this topic, your cluster must be 1.19 or later. If your cluster is earlier than 1.19, then we recommend using version 2.3.1.
- An existing AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. To determine whether you already have one, or to create one, see Create an IAM OIDC provider for your cluster (p. 466).

To deploy the AWS Load Balancer Controller to an Amazon EKS cluster

In the following steps, replace the example values with your own values. If your cluster is earlier than 1.19, then change all instances of 2.4.1 to 2.3.1 and all instances of v2_4_1_full.yaml to v2_3_1_full.yaml.

1. Create an IAM policy.
   a. Download an IAM policy for the AWS Load Balancer Controller that allows it to make calls to AWS APIs on your behalf. You can view the policy document on GitHub. Download the policy for your AWS Region
      - AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions
      - All other AWS Regions
        curl -o iam_policy.json https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.4.1/docs/install/iam_policy.json
   b. Create an IAM policy using the policy downloaded in the previous step. If you downloaded iam_policy_us-gov.json, change iam_policy.json to iam_policy_us-gov.json before running the command.

      aws iam create-policy
      --policy-name AWSLoadBalancerControllerIAMPolicy
      --policy-document file://iam_policy.json

      Note
      If you view the policy in the AWS Management Console, you may see warnings for ELB. These can be safely ignored because some of the actions only exist for ELB v2. You do not see warnings for ELB v2.

2. Create an IAM role. Create a Kubernetes service account named aws-load-balancer-controller in the kube-system namespace for the AWS Load Balancer Controller and annotate the Kubernetes service account with the name of the IAM role.
   You can use eksctl or the AWS CLI and kubectl to create the IAM role and Kubernetes service account.
eksctl

Replace my-cluster with the name of your cluster, 111122223333 with your account ID, and then run the command. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace arn:aws: with arn:aws-us-gov: before running the following command.

```bash
docker run --rm -it -e AWS_DEFAULT_REGION=us-west-2 -e AWS_PROFILE=default eksctl --version
```

AWS CLI and kubectl

**Using the AWS CLI and kubectl**

**a. View your cluster's OIDC provider URL.**

```bash/aws eks describe-cluster --name my-cluster --query "cluster.identity.oidc.issuer" --output text
```

Example output:

```
oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE
```

If no output is returned, then you must create an IAM OIDC provider for your cluster (p. 466).

**b. Copy the following contents to a file named load-balancer-role-trust-policy.json.** Replace 111122223333 with your account ID. Replace region-code with the AWS Region that your cluster is in. Replace EXAMPLED539D4633E53DE1B71EXAMPLE with the output returned in the previous step. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace arn:aws: with arn:aws-us-gov:.

```json
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Principal": {
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
        "StringEquals": {
          "oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:aud": "sts.amazonaws.com",
          "oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE:sub": "system:serviceaccount:kube-system:aws-load-balancer-controller"
        }
      }
    }
  }
}
```
Installing the AWS Load Balancer Controller add-on

c. Create the IAM role.

```bash
aws iam create-role
  --role-name AmazonEKSLoadBalancerControllerRole
  --assume-role-policy-document file://"load-balancer-role-trust-policy.json"
```

d. Attach the required Amazon EKS managed IAM policy to the IAM role. Replace 111122223333 with your account ID.

```bash
aws iam attach-role-policy
  --policy-arn arn:aws:iam::111122223333:policy/AWSLoadBalancerControllerIAMPolicy
  --role-name AmazonEKSLoadBalancerControllerRole
```

e. Save the following contents to a file that's named `aws-load-balancer-controller-service-account.yaml`, replacing 111122223333 with your account ID. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace `arn:aws:` with `arn:aws-us-gov:`

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  labels:
    - app.kubernetes.io/component: controller
    - app.kubernetes.io/name: aws-load-balancer-controller
  name: aws-load-balancer-controller
  namespace: kube-system
  annotations:
    eks.amazonaws.com/role-arn:
      - arn:aws:::111122223333:role/AmazonEKSLoadBalancerControllerRole
```

f. Create the Kubernetes service account on your cluster. The Kubernetes service account named `aws-load-balancer-controller` is annotated with the IAM role that you created named `AmazonEKSLoadBalancerControllerRole`.

```bash
kubectl apply -f aws-load-balancer-controller-service-account.yaml
```

3. (Optional) Annotate your service account to use the AWS Security Token Service AWS Regional endpoint if your cluster's Kubernetes version is listed in the following table and its platform version is the same or later than the version listed in the table. If your cluster's Kubernetes version is listed in the following table and you have a platform version that is earlier than the version listed in the following table, then you can't enable your service accounts to use the AWS Security Token Service AWS Regional endpoint. You must use the global endpoint. If your cluster is 1.22 or later, the AWS Regional endpoint is used by default, so you don't need to annotate your Kubernetes service accounts to use it.

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Platform version</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.21</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.20</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.19</td>
<td>eks.7</td>
</tr>
<tr>
<td>1.18</td>
<td>eks.9</td>
</tr>
</tbody>
</table>
Add the following annotation to your service accounts.

```bash
kubectl annotate serviceaccount -n kube-system aws-load-balancer-controller eks.amazonaws.com/sts-regional-endpoints=true
```

AWS recommends using the AWS Regional AWS STS endpoints instead of the global endpoint to reduce latency, build in redundancy, and increase session token validity. The AWS Security Token Service must be active in the AWS Region where the pod is running and your application should have redundancy built in to pick a different AWS Region in the event of a failure of the service in the AWS Region. For more information, see Managing AWS STS in an AWS Region in the IAM User Guide.

4. If you don't currently have the AWS ALB Ingress Controller for Kubernetes installed, skip to the next step.

Uninstall the AWS ALB Ingress Controller for Kubernetes. The AWS Load Balancer Controller replaces the functionality of the AWS ALB Ingress Controller for Kubernetes.

a. Check to see if the controller is currently installed.

```bash
kubectl get deployment -n kube-system alb-ingress-controller
```

This is the output if the controller isn't installed. Skip to the install controller (p. 325) step.

```
Error from server (NotFound): deployments.apps "alb-ingress-controller" not found
```

This is the output if the controller is installed.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>alb-ingress-controller</td>
<td>1/1</td>
<td>1</td>
<td>1</td>
<td>122d</td>
</tr>
</tbody>
</table>

b. Enter the following commands to remove the controller.

```bash
kubectl delete -f https://raw.githubusercontent.com/kubernetes-sigs/aws-alb-ingress-controller/v1.1.8/docs/examples/rbac-role.yaml
```

c. Add the following IAM policy to the IAM role created in a previous step (p. 321). The policy allows the AWS Load Balancer Controller access to the resources that were created by the ALB Ingress Controller for Kubernetes.

1. Download the IAM policy. You can also view the policy.

   ```bash
curl -o iam_policy_v1_to_v2_additional.json https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.4.1/docs/install/iam_policy_v1_to_v2_additional.json
```

2. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-West) AWS Regions, then replace `arn:aws:` in the file with `arn:aws-us-gov:`.

   ```bash
   sed -i.bak -e 's|arn:aws:|arn:aws-us-gov:|' iam_policy_v1_to_v2_additional.json
   ```

3. Create the IAM policy and note the ARN that is returned.

   ```bash
   aws iam create-policy
   ```
4. Attach the IAM policy to the IAM role that you created in a previous step (p. 321). Replace your-role-name with the name of the role. If you created the role using eksctl, then to find the role name that was created, open the AWS CloudFormation console and select the eksctl-your-cluster-name-addon-iamserviceaccount-kube-system-aws-load-balancer-controller stack. Select the Resources tab. The role name is in the Physical ID column. If you used the AWS Management Console to create the role, then the role name is whatever you named it, such as AmazonEKSLoadBalancerControllerRole. If your cluster is in the AWS GovCloud (US-East) or AWS GovCloud (US-East) AWS Regions, then replace arn:aws: with arn:aws-us-gov: before running the command.

```
aws iam attach-role-policy
  --role-name your-role-name
  --policy-arn arn:aws:iam::111122223333:policy/AWSLoadBalancerControllerAdditionalIAMPolicy
```

5. Install the AWS Load Balancer Controller using Helm V3 (p. 421) or later or by applying a Kubernetes manifest. If you want to deploy the controller on Fargate, use the Helm procedure because it doesn’t depend on cert-manager.

Helm V3 or later

a. Add the eks-charts repository.

```
helm repo add eks https://aws.github.io/eks-charts
```

b. Update your local repo to make sure that you have the most recent charts.

```
helm repo update
```

c. If your nodes don’t have access to Amazon EKS Amazon ECR image repositories, then you need to pull the following container image and push it to a repository that your nodes have access to. For more information on how to pull, tag, and push an image to your own repository, see Copy a container image from one repository to another repository (p. 377). Replace 602401143452 and region-code with the values for your AWS Region listed in Amazon container image registries (p. 379).

```
602401143452.dkr.ecr.region-code.amazonaws.com/amazon/aws-load-balancer-controller:v2.4.1
```

d. Install the AWS Load Balancer Controller. If you’re deploying the controller to Amazon EC2 nodes that have restricted access to the Amazon EC2 instance metadata service (IMDS), or if you’re deploying to Fargate, then add the following flags to the helm command that follows:

- --set region=region-code
- --set vpcId=vpc-xxxxxxxx

If you’re deploying to any AWS Region other than us-west-2, then add the following flag to the helm command, replacing 602401143452 and region-code with the values for your AWS Region listed in Amazon container image registries (p. 379). If you pulled the image and pushed it to your own repository, then replace the full registry and repository with your own.

```
--set image.repository=602401143452.dkr.ecr.region-code.amazonaws.com/amazon/aws-load-balancer-controller
```
Replace `cluster-name` with your own. In the following command, `aws-load-balancer-controller` is the Kubernetes service account that you created in a previous step.

```shell
code
helm install aws-load-balancer-controller eks/aws-load-balancer-controller 
  --set clusterName=cluster-name 
  --set serviceAccount.create=false 
  --set serviceAccount.name=aws-load-balancer-controller
```

**Important**
The deployed chart doesn't receive security updates automatically. You need to manually upgrade to a newer chart when it becomes available. When upgrading, change `install` to `upgrade` in the previous command, but run the following command to install the TargetGroupBinding custom resource definitions before running the previous command.

```shell
code
```

**Kubernetes manifest**

a. Install `cert-manager` using one of the following methods to inject certificate configuration into the webhooks.

- If your nodes have access to the `quay.io` container registry, install `cert-manager` to inject certificate configuration into the webhooks.

```shell
code
kubectl apply 
  --validate=false 
  -f https://github.com/jetstack/cert-manager/releases/download/v1.5.4/cert-manager.yaml
```

- If your nodes don't have access to the `quay.io` container registry, then complete the following tasks:
  i. Download the manifest.

```shell
code
curl -Lo cert-manager.yaml https://github.com/jetstack/cert-manager/releases/download/v1.5.4/cert-manager.yaml
```

  ii. Pull the following images and push them to a repository that your nodes have access to. For more information on how to pull, tag, and push the images to your own repository, see Copy a container image from one repository to another repository (p. 377).

```markdown
- quay.io/jetstack/cert-manager-cainjector:v1.5.4
- quay.io/jetstack/cert-manager-controller:v1.5.4
- quay.io/jetstack/cert-manager-webhook:v1.5.4
```

  iii. Replace `quay.io` in the manifest for the three images with your own registry name. The following command assumes that your private repository's name is the same as the source repository. Replace 11112223333.dkr.ecr.region-code.amazonaws.com with your private registry.

```shell
code
sed -i.bak -e 's|quay.io|11112223333.dkr.ecr.region-code.amazonaws.com|' cert-manager.yaml
```

iv. Apply the manifest.
b. Install the controller.
   i. Download the controller specification. For more information about the controller, see the documentation on GitHub.

```bash
kubectl apply \
  --validate=false \
  -f ./cert-manager.yaml
```

ii. Make the following edits to the file.
   • Replace `your-cluster-name` in the Deployment spec section of the file with the name of your cluster by replacing `my-cluster` with the name of your cluster.

   ```bash
   sed -i.bak -e 's|your-cluster-name|my-cluster|' ./v2_4_1_full.yaml
   ```

   • If your nodes don't have access to the Amazon EKS Amazon ECR image repositories, then you need to pull the following image and push it to a repository that your nodes have access to. For more information on how to pull, tag, and push an image to your own repository, see Copy a container image from one repository to another repository (p. 377).

   ```plaintext
   amazon/aws-alb-ingress-controller:v2.4.1
   ```

   Add your registry's name to the manifest. The following command assumes that your private repository's name is the same as the source repository and adds your private registry's name to the file. In the source file there is no registry specified because Kubernetes pulls from `docker.io`, by default. Replace 111122223333.dkr.ecr.region-code.amazonaws.com with your registry. This line assumes that you named your private repository the same as the source repository. If not, change the `amazon/aws-alb-ingress-controller` text after your private registry name to your repository name.

   ```bash
   sed -i.bak -e 's|amazon/aws-alb-ingress-controller|111122223333.dkr.ecr.region-code.amazonaws.com/amazon/aws-alb-ingress-controller|' ./v2_4_1_full.yaml
   ```

   • Open the file in an editor and remove the following lines. Removing this section prevents the annotation with the IAM role that was added to the aws-load-balancer-controller Kubernetes service account that you created in a previous step from being overwritten when the controller is deployed. It also preserves the service account that you created in a previous step if you delete the controller.

   ```yaml
   apiVersion: v1
   kind: ServiceAccount
   metadata:
     labels:
       app.kubernetes.io/component: controller
       app.kubernetes.io/name: aws-load-balancer-controller
     name: aws-load-balancer-controller
   namespace: kube-system
   ```
• If you're deploying the controller to Amazon EC2 nodes that have restricted access to the Amazon EC2 instance metadata service (IMDS), or if you're deploying to Fargate, then add the following parameters under `--args`:

```yaml
... spec:
  containers:
    - args:
      - --cluster-name=your-cluster-name
      - --ingress-class=alb
      - --aws-vpc-id=vpc-xxxxxxxx
      - --aws-region=region-code
...```

iii. Apply the file.

```bash
kubectl apply -f v2_4_1_full.yaml
```

6. Verify that the controller is installed.

```bash
cubectl get deployment -n kube-system aws-load-balancer-controller
```

Example output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws-load-balancer-controller</td>
<td>2/2</td>
<td>2</td>
<td>2</td>
<td>84s</td>
</tr>
</tbody>
</table>

You receive the previous output if you deployed using Helm. If you deployed using the Kubernetes manifest, you only have one replica.

7. Before using the controller to provision AWS resources, your cluster must meet specific requirements. For more information, see Application load balancing on Amazon EKS (p. 371) and Network load balancing on Amazon EKS (p. 365).

### Managing the CoreDNS add-on

CoreDNS is a flexible, extensible DNS server that can serve as the Kubernetes cluster DNS. When you launch an Amazon EKS cluster with at least one node, two replicas of the CoreDNS image are deployed by default, regardless of the number of nodes deployed in your cluster. The CoreDNS pods provide name resolution for all pods in the cluster. The CoreDNS pods can be deployed to Fargate nodes if your cluster includes an AWS Fargate profile (p. 157) with a namespace that matches the namespace for the CoreDNS Deployment. For more information about CoreDNS, see Using CoreDNS for Service Discovery in the Kubernetes documentation.

The following table lists the version of the CoreDNS add-on that is deployed with each Amazon EKS cluster version.

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>1.22</th>
<th>1.21</th>
<th>1.20</th>
<th>1.19</th>
<th>1.18</th>
<th>1.17</th>
</tr>
</thead>
<tbody>
<tr>
<td>CoreDNS</td>
<td>1.8.7</td>
<td>1.8.4</td>
<td>1.8.3</td>
<td>1.8.0</td>
<td>1.7.0</td>
<td>1.6.6</td>
</tr>
</tbody>
</table>
If you have a 1.18 or later cluster that you have not added the CoreDNS Amazon EKS add-on to, you can add it using the procedure in Adding the CoreDNS Amazon EKS add-on (p. 329). If you created your 1.18 or later cluster using the AWS Management Console on or after May 19, 2021, the CoreDNS Amazon EKS add-on is already on your cluster. If you created your 1.18 or later cluster using any other tool, and want to use the CoreDNS Amazon EKS add-on, then you must add it to your cluster yourself.

If you've added the CoreDNS Amazon EKS add-on to your 1.18 or later cluster, you can manage it using the procedures in the Updating the CoreDNS Amazon EKS add-on (p. 330) and Removing the CoreDNS Amazon EKS add-on (p. 332) sections. For more information about Amazon EKS add-ons, see Amazon EKS add-ons (p. 381).

If you have not added the CoreDNS Amazon EKS add-on, the CoreDNS self-managed add-on is still running on your cluster. You can update the CoreDNS self-managed add-on using the procedure in Updating the CoreDNS self-managed add-on (p. 333).

Adding the CoreDNS Amazon EKS add-on

Select the tab with the name of the tool that you want to use to add the CoreDNS Amazon EKS add-on to your cluster with.

Important
Before adding the CoreDNS Amazon EKS add-on, confirm that you do not self-manage any settings that Amazon EKS will start managing. To determine which settings Amazon EKS manages, see Amazon EKS add-on configuration (p. 382).

eksctl

To add the CoreDNS Amazon EKS add-on using eksctl

Replace my-cluster with the name of your cluster and then run the following command.

```
eksctl create addon --name coredns --cluster my-cluster --force
```

If you remove the --force option and any of the Amazon EKS add-on settings conflict with your existing settings, then adding the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 382).

AWS Management Console

To add the CoreDNS Amazon EKS add-on using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Amazon EKS Clusters, and then select the name of the cluster that you want to configure the CoreDNS Amazon EKS add-on for.
3. Choose the Configuration tab and then choose the Add-ons tab.
4. Select Add new.
   a. Select CoreDNS for Name.
   b. Select the Version you'd like to use.
   c. If you select Override existing configuration for this add-on on the cluster, then any setting for the existing add-on can be overwritten with the Amazon EKS add-on's settings. If you don't enable this option and any of the Amazon EKS add-on settings conflict with your existing settings, then adding the Amazon EKS add-on fails, and you receive an error.
message to help you resolve the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn’t manage settings that you need to manage. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 382).

d. Select Add.

AWS CLI

To add the CoreDNS Amazon EKS add-on using the AWS CLI

Replace my-cluster with the name of your cluster and then run the following command.

```bash
aws eks create-addon \
  --cluster-name my-cluster \
  --addon-name coredns \
  --resolve-conflicts OVERWRITE
```

If you remove the --resolve-conflicts OVERWRITE option and any of the Amazon EKS add-on settings conflict with your existing settings, then creating the add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn’t manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 382).

Updating the CoreDNS Amazon EKS add-on

This procedure is for updating the CoreDNS Amazon EKS add-on. If you haven’t added the CoreDNS Amazon EKS add-on, complete the procedure in Updating the CoreDNS self-managed add-on (p. 333) instead, or add the CoreDNS Amazon EKS add-on (p. 329). Amazon EKS does not automatically update CoreDNS on your cluster when new versions are released or after you update your cluster (p. 32) to a new Kubernetes minor version. To update CoreDNS on an existing cluster, you must initiate the update and then Amazon EKS updates the Amazon EKS add-on for you.

eksctl

To update the CoreDNS Amazon EKS add-on using eksctl

1. Check the current version of your coredns Amazon EKS add-on. Replace my-cluster with your cluster name.

   ```bash
   eksctl get addon --name coredns --cluster my-cluster
   ```

   Example output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>STATUS</th>
<th>ISSUES</th>
<th>IAMROLE</th>
<th>UPDATE AVAILABLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>coredns</td>
<td>v1.8.0-eksbuild.1</td>
<td>ACTIVE</td>
<td>0</td>
<td></td>
<td>v1.8.3-eksbuild.1</td>
</tr>
</tbody>
</table>

2. Update the add-on to the version returned under UPDATE AVAILABLE in the output of the previous step.

   ```bash
   eksctl update addon \
     --name coredns \ 
     --version v1.8.3-eksbuild.1 \ 
     --cluster my-cluster \ 
     --force
   ```
If you remove the \texttt{--force} option and any of the Amazon EKS add-on settings conflict with your existing settings, then updating the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see \textit{Amazon EKS add-on configuration (p. 382)}.

\section*{AWS Management Console}

\textbf{To update the CoreDNS Amazon EKS add-on using the AWS Management Console}

1. Open the Amazon EKS console at \url{https://console.aws.amazon.com/eks/home#/clusters}.
2. In the left navigation pane, choose Amazon EKS \textbf{Clusters}, and then select the name of the cluster that you want to update the CoreDNS Amazon EKS add-on for.
3. Choose the \textit{Configuration} tab and then choose the \textbf{Add-ons} tab.
4. Select the radio button in the upper right of the \textbf{coredns} box and then choose \textit{Edit}.
   a. Select the \textbf{Version} of the Amazon EKS add-on that you want to use.
   b. If you select \textit{Override existing configuration for this add-on on the cluster}, then any setting for the existing add-on can be overwritten with the Amazon EKS add-on's settings. If you don't enable this option and any of the Amazon EKS add-on settings conflict with your existing settings, then updating the add-on to an Amazon EKS add-on fail, and you receive an error message to help you resolve the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage. For more information about Amazon EKS add-on configuration management, see \textit{Amazon EKS add-on configuration (p. 382)}.
   c. Select \textbf{Update}.

\section*{AWS CLI}

\textbf{To update the CoreDNS Amazon EKS add-on using the AWS CLI}

1. Check the current version of your CoreDNS add-on. Replace \textit{my-cluster} with your cluster name.

   \begin{verbatim}
   aws eks describe-addon \
   --cluster-name my-cluster \
   --addon-name coredns \
   --query "addon.addonVersion" \
   --output text
   \end{verbatim}

   Output:

   \begin{verbatim}
   1.7.0
   \end{verbatim}

2. Determine which versions of the CoreDNS add-on are available for your cluster's version.

   \begin{verbatim}
   aws eks describe-addon-versions \
   --addon-name coredns \
   --kubernetes-version 1.19 \
   --query "addons[].addonVersions[].addonVersion, compatibilities[].defaultVersion" \
   --output text
   \end{verbatim}
Removing the Amazon EKS add-on

Example output:

```
1.8.0
True
1.7.0
False
```

The version with `True` underneath is the default version deployed with new clusters.

3. Update the add-on to the version with `True` returned in the output of the previous step. You can also update to a later version, if returned in the output.

```
aws eks update-addon
  --cluster-name my-cluster
  --addon-name coredns
  --addon-version 1.8.0
  --resolve-conflicts OVERWRITE
```

If you remove the `--resolve-conflicts OVERWRITE` option and any of the Amazon EKS add-on settings conflict with your existing settings, then updating the add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn’t manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 382).

Removing the CoreDNS Amazon EKS add-on

You have two options when removing an Amazon EKS add-on:

- **Preserve the add-on’s software on your cluster** – This option removes Amazon EKS management of any settings and the ability for Amazon EKS to notify you of updates and automatically update the Amazon EKS add-on after you initiate an update, but preserves the add-on’s software on your cluster. This option makes the add-on a self-managed add-on, rather than an Amazon EKS add-on. There is no downtime for the add-on.

- **Removing the add-on software entirely from your cluster** – You should only remove the Amazon EKS add-on from your cluster if there are no resources on your cluster dependent on the functionality that the add-on provides. After removing the Amazon EKS add-on, you can add it again if you want to.

If the add-on has an IAM account associated with it, the IAM account is not removed.

Select the tab with the name of the tool that you want to use to remove the CoreDNS Amazon EKS add-on from your 1.18 or later cluster with.

`eksctl`

To remove the CoreDNS Amazon EKS add-on using `eksctl`

Replace `my-cluster` with the name of your cluster and then run the following command. Removing `--preserve` removes the add-on software from your cluster.

```
eksctl delete addon --cluster my-cluster --name coredns --preserve
```
AWS Management Console

To remove the CoreDNS Amazon EKS add-on using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Amazon EKS Clusters, and then select the name of the cluster that you want to remove the CoreDNS Amazon EKS add-on for.
3. Choose the Configuration tab and then choose the Add-ons tab.
4. Select the radio button in the upper right of the coredns box and then choose Remove. Type coredns and then select Remove.

AWS CLI

To remove the CoreDNS Amazon EKS add-on using the AWS CLI

Replace my-cluster with the name of your cluster and then run the following command. Removing --preserve removes the add-on software from your cluster.

```
aws eks delete-addon --cluster-name my-cluster --addon-name coredns --preserve
```

Updating the CoreDNS self-managed add-on

If you have a 1.17 or earlier cluster, or a 1.18 or later cluster that you have not added the CoreDNS Amazon EKS add-on to, complete the following steps to update the add-on. If you’ve added the CoreDNS Amazon EKS add-on, complete the procedure in Updating the CoreDNS Amazon EKS add-on (p. 330) instead.

To update the CoreDNS self-managed add-on using kubectl

1. Check the current version of your CoreDNS add-on.

```
kubectl describe deployment coredns \
   --namespace kube-system \
   | grep Image \
   | cut -d "/" -f 3
```

Output:

```
coredns:v1.8.0
```

2. If your current CoreDNS version is 1.5.0 or later, but earlier than the version listed in the CoreDNS versions (p. 328) table, then skip this step. If your current version is earlier than 1.5.0, then you need to modify the ConfigMap for CoreDNS to use the forward add-on, rather than the proxy add-on.

   a. Open the configmap with the following command.

```
kubectl edit configmap coredns -n kube-system
```

   b. Replace proxy in the following line with forward. Save the file and exit the editor.

```
proxy . /etc/resolv.conf
```
3. If you originally deployed your cluster on Kubernetes 1.17 or earlier, then you may need to remove a discontinued term from your CoreDNS manifest.

   Important
   You must complete this before upgrading to CoreDNS version 1.7.0, but it's recommended that you complete this step even if you're upgrading to an earlier version.

   a. Check to see if your CoreDNS manifest has the line.

      ```shell
      kubectl get configmap coredns -n kube-system -o jsonpath='{$.data.Corefile}' | grep upstream
      ```

      If no output is returned, your manifest doesn't have the line and you can skip to the next step to update CoreDNS. If output is returned, then you need to remove the line.

   b. Edit the ConfigMap with the following command, removing the line in the file that has the word `upstream` in it. Do not change anything else in the file. Once the line is removed, save the changes.

      ```shell
      kubectl edit configmap coredns -n kube-system -o yaml
      ```

4. Retrieve your current CoreDNS image:

   ```shell
   kubectl get deployment coredns -n kube-system -o jsonpath='{$.spec.template.spec.containers[0].image}'
   ```

5. If you're updating to CoreDNS 1.8.3 or later, then you need to add the `endpointslices` permission to the `system:coredns` Kubernetes clusterrole.

   ```shell
   kubectl edit clusterrole system:coredns -n kube-system
   ```

   Add the following lines under the existing permissions lines in the rules section of the file.

   ```yaml
   ...  
   - apiGroups:
     - discovery.k8s.io
   resources:
     - endpointslices
   verbs:
     - list
     - watch
   ...
   ```

6. Update the CoreDNS add-on by replacing `602401143452` and `region-code` with the values from the output returned in a previous step. Replace `1.8.7` with your cluster's recommended CoreDNS version (p. 328) or later:

   ```shell
   kubectl set image --namespace kube-system deployment.apps/coredns \
   coredns=602401143452.dkr.ecr.region-code.amazonaws.com/eks/coredns:v1.8.7-eksbuild.1
   ```

---

Managing the `kube-proxy` add-on

Kube-proxy maintains network rules on each Amazon EC2 node. It enables network communication to your pods. Kube-proxy is not deployed to Fargate nodes. For more information, see `kube-proxy` in the
Kubernetes documentation. Two versions of the `kube-proxy` image are available for each Kubernetes version.

- **Default** – The version deployed by default with new clusters. This is the only version that you can use with the Amazon EKS add-on.

- **Minimal** – Unlike the default version, this image version is based on a minimal base image maintained by Amazon EKS Distro, which contains minimal packages and doesn’t have shells. For more information, see Amazon EKS Distro. This version is available as a self-managed add-on, but not as an Amazon EKS add-on. If you choose to install this version, complete the steps in Step 2 of the section called “Updating the self-managed add-on” (p. 339), specifying this version.

### `kube-proxy` image version for each Amazon EKS supported cluster version

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>1.22</th>
<th>1.21</th>
<th>1.20</th>
<th>1.19</th>
<th>1.18</th>
<th>1.17</th>
</tr>
</thead>
<tbody>
<tr>
<td>kube-proxy (default version)</td>
<td>1.22.6-eksbuild.1</td>
<td>1.21.2-eksbuild.2</td>
<td>1.20.4-eksbuild.2</td>
<td>1.19.6-eksbuild.2</td>
<td>1.18.8-eksbuild.1</td>
<td>1.17.9-eksbuild.1</td>
</tr>
<tr>
<td>kube-proxy (minimal)</td>
<td>1.22.6-minimal-eksbuild.1</td>
<td>1.21.2-minimal-eksbuild.1</td>
<td>1.20.7-minimal-eksbuild.1</td>
<td>1.19.13-minimal-eksbuild.1</td>
<td>1.18.20-minimal-eksbuild.1</td>
<td>1.17.17-minimal-eksbuild.1</td>
</tr>
</tbody>
</table>

If you have a 1.18 or later cluster that you have not added the `kube-proxy` Amazon EKS add-on to, you can add it using the procedure in Adding the `kube-proxy` Amazon EKS add-on (p. 335). If you created your 1.18 or later cluster using the AWS Management Console after May 3, 2021, the `kube-proxy` Amazon EKS add-on is already on your cluster. If you created your 1.18 or later cluster using any other tool, and want to use the `kube-proxy` Amazon EKS add-on, then you must add it to your cluster yourself.

If you’ve added the `kube-proxy` Amazon EKS add-on to your 1.18 or later cluster, you can manage it using the procedures in the Updating the `kube-proxy` Amazon EKS add-on (p. 336) and Removing the `kube-proxy` Amazon EKS add-on (p. 338) sections. For more information about Amazon EKS add-ons, see Amazon EKS add-ons (p. 381).

If you have not added the `kube-proxy` Amazon EKS add-on, the `kube-proxy` self-managed add-on is still running on your cluster. You can manually update the `kube-proxy` self-managed add-on using the procedure in Updating the `kube-proxy` self-managed add-on (p. 339).

### Adding the `kube-proxy` Amazon EKS add-on

Select the tab with the name of the tool that you want to use to add the `kube-proxy` Amazon EKS add-on to your cluster with.

**Important**

Before adding the `kube-proxy` Amazon EKS add-on, confirm that you do not self-manage any settings that Amazon EKS will start managing. To determine which settings Amazon EKS manages, see Amazon EKS add-on configuration (p. 382).

**eksctl**

To add the `kube-proxy` Amazon EKS add-on using `eksctl`

Replace `my-cluster` with the name of your cluster and then run the following command.

```
$ eksctl create addon --name kube-proxy --cluster my-cluster --force
```
If you remove the `--force` option and any of the Amazon EKS add-on settings conflict with your existing settings, then adding the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 382).

AWS Management Console

**To add the `kube-proxy` Amazon EKS add-on using the AWS Management Console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, select Amazon EKS Clusters, and then select the name of the cluster that you want to configure the `kube-proxy` Amazon EKS add-on for.
3. Choose the Configuration tab and then choose the Add-ons tab.
4. Select Add new.
   a. Select `kube-proxy` for Name.
   b. Select the Version you'd like to use.
   c. If you select Override existing configuration for this add-on on the cluster, then any setting for the existing add-on can be overwritten with the Amazon EKS add-on's settings. If you don't enable this option and any of the Amazon EKS add-on settings conflict with your existing settings, then adding the Amazon EKS add-on fails, and you receive an error message to help you resolve the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 382).
   d. Select Add.

AWS CLI

**To add the `kube-proxy` Amazon EKS add-on using the AWS CLI**

Replace `my-cluster` with the name of your cluster and then run the following command.

```bash
aws eks create-addon \
--cluster-name my-cluster \
--addon-name kube-proxy \
--resolve-conflicts OVERWRITE
```

If you remove the `--resolve-conflicts` OVERWRITE option and any of the Amazon EKS add-on settings conflict with your existing settings, then creating the add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 382).

**Updating the `kube-proxy` Amazon EKS add-on**

This procedure is for updating the `kube-proxy` Amazon EKS add-on. If you haven't added the `kube-proxy` Amazon EKS add-on, complete the procedure in Updating the `kube-proxy` self-managed add-on (p. 339) instead. Amazon EKS does not automatically update `kube-proxy` on your cluster when new versions are released or after you update your cluster (p. 32) to a new Kubernetes minor version. To update `kube-proxy` on an existing cluster, you must initiate the update and then Amazon EKS updates the add-on for you.
Important
Update your cluster and nodes to a new Kubernetes minor version before updating kube-proxy to the same minor version as your updated cluster’s minor version.

**eksctl**

**To update the kube-proxy Amazon EKS add-on using eksctl**

1. Check the current version of your kube-proxy Amazon EKS add-on. Replace `my-cluster` with your cluster name.

   ```
   eksctl get addon --name kube-proxy --cluster my-cluster
   ```

   **Output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>STATUS</th>
<th>ISSUES</th>
<th>IAMROLE</th>
<th>UPDATE</th>
<th>AVAILABLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>kube-proxy</td>
<td>v1.19.6-eksbuild.2</td>
<td>ACTIVE</td>
<td>0</td>
<td></td>
<td>v1.20.4-eksbuild.2</td>
<td></td>
</tr>
</tbody>
</table>

2. Update the add-on to the version returned under `UPDATE AVAILABLE` in the output of the previous step.

   ```
   eksctl update addon
     --name kube-proxy
     --version v1.20.4-eksbuild.2
     --cluster my-cluster
     --force
   ```

   If you remove the `--force` option and any of the Amazon EKS add-on settings conflict with your existing settings, then updating the add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn’t manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 382).

**AWS Management Console**

**To update the kube-proxy Amazon EKS add-on using the AWS Management Console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, select Amazon EKS Clusters, and then select the name of the cluster that you want to update the kube-proxy Amazon EKS add-on for.
3. Choose the Configuration tab and then choose the Add-ons tab.
4. Select the box in the top right of the kube-proxy box and then choose Edit.
   a. Select the Version of the Amazon EKS add-on that you want to use.
   b. If you select Override existing configuration for this add-on on the cluster, then any setting for the existing add-on can be overwritten with the Amazon EKS add-on’s settings. If you don’t enable this option and any of the Amazon EKS add-on settings conflict with your existing settings, then updating the add-on to an Amazon EKS add-on fail, and you receive an error message to help you resolve the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn’t manage settings that you need to manage. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 382).
   c. Select Update.
### AWS CLI

**To update the kube-proxy Amazon EKS add-on using the AWS CLI**

1. Check the current version of your kube-proxy Amazon EKS add-on. Replace `my-cluster` with your cluster name.

```
aws eks describe-addon
--cluster-name my-cluster
--addon-name kube-proxy
--query "addon.addonVersion"
--output text
```

Output:

```
v1.19.6-eksbuild.2
```

2. Determine which versions of the kube-proxy add-on are available for your cluster version.

```
aws eks describe-addon-versions
--addon-name kube-proxy
--kubernetes-version 1.20
--query "addons[].addonVersions[].[addonVersion, compatibilities[].defaultVersion]"
--output text
```

Output

```
v1.20.4-eksbuild.2 True
v1.19.6-eksbuild.2 False
v1.18.8-eksbuild.1 False
```

The version with `True` underneath is the default version deployed with new clusters with the version that you specified.

3. Update the add-on to the version with `True` returned in the output of the previous step. You can also update to a later version, if returned in the output.

```
aws eks update-addon
--cluster-name my-cluster
--addon-name kube-proxy
--addon-version v1.20.4-eksbuild.2
--resolve-conflicts OVERWRITE
```

If you remove the `--resolve-conflicts OVERWRITE` option and any of the Amazon EKS add-on settings conflict with your existing settings, then updating the add-on fails, and you receive an error message to help you resolve the conflict. Before specifying this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to manage, because those settings are overwritten with this option. For more information about Amazon EKS add-on configuration management, see Amazon EKS add-on configuration (p. 382).

### Removing the kube-proxy Amazon EKS add-on

You have two options when removing an Amazon EKS add-on:
Updating the self-managed add-on

- **Preserve the add-on's software on your cluster** – This option removes Amazon EKS management of any settings and the ability for Amazon EKS to notify you of updates and automatically update the Amazon EKS add-on after you initiate an update, but preserves the add-on's software on your cluster. This option makes the add-on a self-managed add-on, rather than an Amazon EKS add-on. There is no downtime for the add-on.

- **Removing the add-on software entirely from your cluster** – You should only remove the Amazon EKS add-on from your cluster if there are no resources on your cluster that are dependent on the functionality that the add-on provides. After removing the Amazon EKS add-on, you can add it again if you want to.

If the add-on has an IAM account associated with it, the IAM account is not removed.

Select the tab with the name of the tool that you want to use to remove the kube-proxy Amazon EKS add-on from your 1.18 or later cluster with.

**eksctl**

To remove the kube-proxy Amazon EKS add-on using eksctl

Replace `my-cluster` with the name of your cluster and then run the following command. Removing --preserve removes the add-on software from your cluster.

```
eksctl delete addon --cluster my-cluster --name kube-proxy --preserve
```

**AWS Management Console**

To remove the kube-proxy Amazon EKS add-on using the AWS Management Console

1. Open the Amazon EKS console at [https://console.aws.amazon.com/eks/home#/clusters](https://console.aws.amazon.com/eks/home#/clusters).
2. In the left navigation pane, select Amazon EKS Clusters, and then select the name of the cluster that you want to remove the kube-proxy Amazon EKS add-on for.
3. Choose the Configuration tab and then choose the Add-ons tab.
4. Select the check box in the top right of the kube-proxy box and then choose Remove. Type kube-proxy and then select Remove.

**AWS CLI**

To remove the kube-proxy Amazon EKS add-on using the AWS CLI

Replace `my-cluster` with the name of your cluster and then run the following command. Removing --preserve removes the add-on software from your cluster.

```
aws eks delete-addon --cluster-name my-cluster --addon-name kube-proxy --preserve
```

**Updating the kube-proxy** self-managed add-on

If you have a 1.17 or earlier cluster, or a 1.18 or later cluster that you have not added the kube-proxy Amazon EKS add-on to, complete the following steps to update the self-managed add-on. If you've added the kube-proxy Amazon EKS add-on, complete the procedure in Updating the kube-proxy Amazon EKS add-on (p. 336) instead.

**Important**

Update your cluster and nodes to a new Kubernetes minor version before updating kube-proxy to the same minor version as your updated cluster's minor version.
To update the kube-proxy self-managed add-on using kubectl

1. Check the current version of your kube-proxy deployment.

```
kubectl get daemonset kube-proxy \  
   --namespace kube-system \  
   -o=jsonpath='{$.spec.template.spec.containers[0].image}'
```

Example output:

```
602401143452.dkr.ecr.region-code.amazonaws.com/eks/kube-proxy:v1.21.2-eksbuild.2
```

2. Update the kube-proxy add-on by replacing 602401143452 and region-code with the values from your output. Replace 1.22.6-eksbuild.1 with the kube-proxy version listed in the kube-proxy version deployed with each Amazon EKS supported cluster version (p. 335) table for your cluster version.

```
kubectl set image daemonset.apps/kube-proxy \ 
   -n kube-system \  
   kube-proxy=602401143452.dkr.ecr.region-code.amazonaws.com/eks/kube-proxy:v1.22.6-eksbuild.1
```

3. (Optional) If you're using x86 and Arm nodes in the same cluster and your cluster was deployed before August 17, 2020. Then, edit your kube-proxy manifest to include a node selector for multiple hardware architectures with the following command. This is a one-time operation. After you've added the selector to your manifest, you don't need to add it each time you update. If your cluster was deployed on or after August 17, 2020, then kube-proxy is already multi-architecture capable.

```
kubectl edit -n kube-system daemonset/kube-proxy
```

Add the following node selector to the file in the editor and then save the file. For an example of where to include this text in the editor, see the CNI manifest file on GitHub. This enables Kubernetes to pull the correct hardware image based on the node's hardware architecture.

```
- key: "kubernetes.io/arch"
  operator: In
  values:
  - amd64
  - arm64
```

4. (Optional) If your cluster was originally created with Kubernetes v1.14 or later, then you can skip this step because kube-proxy already includes this Affinity Rule. If you originally created an Amazon EKS cluster with Kubernetes version 1.13 or earlier and intend to use Fargate nodes, then edit your kube-proxy manifest to include a NodeAffinity rule to prevent kube-proxy pods from scheduling on Fargate nodes. This is a one-time edit. Once you've added the Affinity Rule to your manifest, you don't need to add it each time you upgrade your cluster. Edit your kube-proxy Daemonset.

```
kubectl edit -n kube-system daemonset/kube-proxy
```

Add the following Affinity Rule to the Daemonset spec section of the file in the editor and then save the file. For an example of where to include this text in the editor, see the CNI manifest file on GitHub.

```
- key: eks.amazonaws.com/compute-type
```

340
Installing the Calico add-on

Project Calico is a network policy engine for Kubernetes. With Calico network policy enforcement, you can implement network segmentation and tenant isolation. This is useful in multi-tenant environments where you must isolate tenants from each other or when you want to create separate environments for development, staging, and production. Network policies are similar to AWS security groups in that you can create network ingress and egress rules. Instead of assigning instances to a security group, you assign network policies to pods using pod selectors and labels.

Considerations

- Calico is not supported when using Fargate with Amazon EKS.
- Calico adds rules to `iptables` on the node that may be higher priority than existing rules that you've already implemented outside of Calico. Consider adding existing `iptables` rules to your Calico policies to avoid having rules outside of Calico policy overridden by Calico.
- If you're using security groups for pods (p. 307), traffic flow to pods on branch network interfaces is not subjected to Calico network policy enforcement and is limited to Amazon EC2 security group enforcement only. Community effort is underway to remove this limitation.

Prerequisites

- An existing Amazon EKS cluster. To deploy one, see Getting started with Amazon EKS (p. 4).
- The `kubectl` command line tool installed on your computer or AWS CloudShell. The version must be the same, or up to two versions later than your cluster version. To install or upgrade `kubectl`, see Installing `kubectl` (p. 4).

The following procedure shows you how to install Calico on Linux nodes in your Amazon EKS cluster. To install Calico on Windows nodes, see Using Calico on Amazon EKS Windows Containers.

Install Calico on your Amazon EKS Linux nodes

You can install Calico using the procedure for Helm or manifests. The manifests are not updated by Amazon EKS, so we recommend using Helm, because the charts are maintained by Tigera.

Amazon EKS doesn't test and verify new Tigera operator and Calico functionality on Amazon EKS clusters. If you encounter issues during installation and usage of Calico, submit issues to Tigera Operator and Calico Project directly. You should always contact Tigera for compatibility of any new Tigera operator and Calico versions before installing them on your cluster.

Helm

Prerequisite

Helm version 3.0 or later installed on your computer. To install or upgrade Helm, see Using Helm with Amazon EKS (p. 421).

To install Calico with Helm

1. Add Project Calico into your Helm repository.
Install Calico

2. If you already have Calico added, you may want to update it to get the latest released version.

   helm repo add projectcalico https://docs.projectcalico.org/charts

   helm repo update

3. Install version 3.21.4 or later of the Tigera Calico operator and custom resource definitions.

   helm install calico projectcalico/tigera-operator --version v3.21.4

4. View the resources in the tigera-operator namespace.

   kubectl get all -n tigera-operator

Example output:

The values in the DESIRED and READY columns for the replicaset should match. The values returned for you are different than the values in the following output.

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESIRED</th>
<th>CURRENT</th>
<th>READY</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>pod/tigera-operator-c4b9549c7-h4zp5</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>110m</td>
</tr>
<tr>
<td>replicaset.apps/tigera-operator-c4b9549c7</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>2m35s</td>
</tr>
</tbody>
</table>

5. View the resources in the calico-system namespace.

   kubectl get all -n calico-system

Example output:

The values in the DESIRED and READY columns for the calico-node daemonset should match. The values in the DESIRED and READY columns for the two replicas should also match. The values returned for you are different than the values in the following output.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>pod/calico-kube-controllers-579b45dcf-z5tsf</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>100m</td>
</tr>
<tr>
<td>pod/calico-node-v9dhf</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>100m</td>
</tr>
<tr>
<td>pod/calico-typha-6f9c6786d-f2mc7</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>100m</td>
</tr>
<tr>
<td>replicaet.apps/calico-kube-controllers</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>100m</td>
</tr>
<tr>
<td>replicaet.apps/calico-typha</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>100m</td>
</tr>
</tbody>
</table>

6. Confirm that the logs for one of your calico-node, calico-typha, and tigera-operator pods don't contain ERROR. Replace the values in the following commands with the values returned in your output for the previous steps.

   kubectl logs tigera-operator-c4b9549c7-h4zp5 -n tigera-operator | grep ERROR
   kubectl logs calico-node-v9dhf -n calico-system | grep ERROR
kubectl logs calico-typha-6f9c6786d-f2mc7 -n calico-system | grep ERROR

If no output is returned from the previous commands, then ERROR doesn't exist in your logs and everything should be running correctly.

**Manifests**

**Important**

These charts won't be maintained in the future. We recommend that you install using Helm instead, because the Helm charts are maintained.

**To install Calico using manifests**

1. Apply the Calico manifests to your cluster. These manifests create a DaemonSet in the calico-system namespace.

```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/master/config/master/calico-operator.yaml
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/master/config/master/calico-crs.yaml
```

2. View the resources in the calico-system namespace.

```
kubectl get daemonset calico-node --namespace calico-system
```

Example output:

The values in the DESIRED and READY columns should match. The values returned for you are different than the values in the following output.

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESIRED</th>
<th>CURRENT</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
<th>NODE_SELECTOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>calico-node</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td></td>
<td>kubernetes.io/os=linux</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>26m</td>
<td></td>
</tr>
</tbody>
</table>

**Stars policy demo**

This section walks through the Stars policy demo provided by the Project Calico documentation and isn't necessary for Calico functionality on your cluster. The demo creates a front-end, back-end, and client service on your Amazon EKS cluster. The demo also creates a management graphical user interface that shows the available ingress and egress paths between each service. We recommend that you complete the demo on a cluster that you don't run production workloads on.

Before you create any network policies, all services can communicate bidirectionally. After you apply the network policies, you can see that the client can only communicate with the front-end service, and the back-end only accepts traffic from the front-end.

**To run the Stars policy demo**

1. Apply the front-end, back-end, client, and management user interface services:

```
kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/00-namespace.yaml
kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/01-management-ui.yaml
```
2. View all pods on the cluster.

```
kubectl get pods --all-namespaces
```

Example output:

In your output, you should see pods in the namespaces shown in the following output. Your pod `NAMESPACE` and the number of pods in the `READY` column are different than those in the following output. Don't continue until you see pods with similar names and they all have `Running` in the `STATUS` column.

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>client</td>
<td>client-xlfffc</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>5m19s</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>management-ui</td>
<td>management-ui-qrb2g</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>5m24s</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>stars</td>
<td>backend-sz87q</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>5m23s</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>stars</td>
<td>frontend-cscnf</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>5m21s</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

3. To connect to the management user interface, forward your local port 9001 to the `management-ui` service running on your cluster:

```
kubectl port-forward service/management-ui -n management-ui 9001
```

4. Open a browser on your local system and point it to `http://localhost:9001/`. You should see the management user interface. The `C` node is the client service, the `F` node is the front-end service, and the `B` node is the back-end service. Each node has full communication access to all other nodes, as indicated by the bold, colored lines.
5. Apply the following network policies to isolate the services from each other:

```
kubectl apply -n stars -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/policies/default-deny.yaml
kubectl apply -n client -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/policies/default-deny.yaml
```

6. Refresh your browser. You see that the management user interface can no longer reach any of the nodes, so they don’t show up in the user interface.

7. Apply the following network policies to allow the management user interface to access the services:

```
kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/policies/allow-ui.yaml
kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/policies/allow-ui-client.yaml
```

8. Refresh your browser. You see that the management user interface can reach the nodes again, but the nodes cannot communicate with each other.
9. Apply the following network policy to allow traffic from the front-end service to the back-end service:

    kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/policies/backend-policy.yaml

10. Refresh your browser. You see that the front-end can communicate with the back-end.
11. Apply the following network policy to allow traffic from the client to the front-end service.

```bash
kubectl apply -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/policies/frontend-policy.yaml
```

12. Refresh your browser. You see that the client can communicate to the front-end service. The front-end service can still communicate to the back-end service.
13. (Optional) When you are done with the demo, you can delete its resources.

```
kubectl delete -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/04-client.yaml
kubectl delete -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/03-frontend.yaml
kubectl delete -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/02-backend.yaml
kubectl delete -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/01-management-ui.yaml
kubectl delete -f https://docs.projectcalico.org/v3.5/getting-started/kubernetes/tutorials/stars-policy/manifests/00-namespace.yaml
```

Even after deleting the resources, there can still be `iptables` rules on the nodes that might interfere in unexpected ways with networking in your cluster. The only sure way to remove Calico is to terminate all of the nodes and recycle them. To terminate all nodes, either set the Auto Scaling Group desired count to 0, then back up to the desired number, or just terminate the nodes. If you are unable to recycle the nodes, then see Disabling and removing Calico Policy in the Calico GitHub repository for a last resort procedure.
Remove Calico

Remove Calico using the method that you installed Calico with.

Helm

Remove Calico from your cluster.

```
helm uninstall calico
```

Manifests

Remove Calico from your cluster.

```
kubectl delete -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/master/config/master/calico-cr

kubectl delete -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/master/config/master/calico-operator.yaml
```
Workloads

Your workloads are deployed in containers, which are deployed in pods in Kubernetes. A pod includes one or more containers. Typically, one or more pods that provide the same service are deployed in a Kubernetes service. Once you've deployed multiple pods that provide the same service, you can:

- View information about the workloads (p. 350) running on each of your clusters using the AWS Management Console.
- Vertically scale pods up or down with the Kubernetes Vertical Pod Autoscaler (p. 359).
- Horizontally scale the number of pods needed to meet demand up or down with the Kubernetes Horizontal Pod Autoscaler (p. 363).
- Create an external (for internet-accessible pods) or an internal (for private pods) network load balancer (p. 365) to balance network traffic across pods. The load balancer routes traffic at Layer 4 of the OSI model.
- Create an Application load balancing on Amazon EKS (p. 371) to balance application traffic across pods. The application load balancer routes traffic at Layer 7 of the OSI model.
- If you're new to Kubernetes, this topic helps you Deploy a sample application (p. 352).
- You can restrict IP addresses that can be assigned to a service (p. 376) with externalIPs.

View workloads

Workloads define applications running on a Kubernetes cluster. Every workload controls pods. Pods are the fundamental unit of computing within a Kubernetes cluster and represent one or more containers that run together.

You can use the Amazon EKS console to view information about the Kubernetes workloads and pods running on your cluster.

Prerequisites

The IAM user or IAM role that you sign into the AWS Management Console with must meet the following requirements.

- Has the eks:AccessKubernetesApi and other necessary IAM permissions to view workloads attached to it. For an example IAM policy, see View nodes and workloads for all clusters in the AWS Management Console (p. 440).
- For nodes in connected clusters, the Amazon EKS Connector Service account should be able to impersonate the IAM or role in the cluster. This allows the eks-connector to map the IAM user or role to a Kubernetes user.
- Is mapped to Kubernetes user or group in the aws-auth configmap. For more information, see Enabling IAM user and role access to your cluster (p. 395).
- The Kubernetes user or group that the IAM user or role is mapped to in the configmap must be bound to a Kubernetes role or clusterrole that has permissions to view the resources in the namespaces that you want to view. For more information, see Using RBAC Authorization in the Kubernetes documentation. You can download the following example manifests that create a clusterrole and clusterrolebinding or a role and rolebinding:
  - View Kubernetes resources in all namespaces – The group name in the file is eks-console-dashboard-full-access-group, which is the group that your IAM user or role needs to be
mapped to in the `aws-auth` configmap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the `ConfigMap`. To download the file, run the following command.

```bash
curl -o eks-console-full-access.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-full-access.yaml
```

- **View Kubernetes resources in a specific namespace** – The namespace in this file is `default`, so if you want to specify a different namespace, edit the file before applying it to your cluster. The group name in the file is `eks-console-dashboard-restricted-access-group`, which is the group that your IAM user or role needs to be mapped to in the `aws-auth` configmap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the `ConfigMap`. To download the file, run the following command.

```bash
curl -o eks-console-restricted-access.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-restricted-access.yaml
```

### To view workloads using the AWS Management Console

1. Open the Amazon EKS console at [https://console.aws.amazon.com/eks/home#/clusters](https://console.aws.amazon.com/eks/home#/clusters).
2. In the **Clusters** list, select the cluster that you want to view workloads for.
3. On the **Workloads** tab, you see a list of **Names** of all the Kubernetes workloads that are currently deployed to your cluster, the **Pod count**, and **Status** for each workload.

   **Important**

   If you can't see any workloads, or you see a **Your current user or role does not have access to Kubernetes objects on this EKS cluster**, you may need to select a different namespace from the **All Namespaces** dropdown list. If you're still having problems, see the prerequisites for this topic. If you don't resolve the issue, you can still view and manage your Amazon EKS cluster on the **Configuration** tab, but you won't be able to see information about your workloads.

You can deploy the following types of workloads on a cluster:

- **Deployment** – Ensures that a specific number of pods run and includes logic to deploy changes.
- **ReplicaSet** – Ensures that a specific number of pods run. Can be controlled by deployments.
- **StatefulSet** – Manages the deployment of stateful applications.
- **DaemonSet** – Ensures that a copy of a pod runs on all (or some) nodes in the cluster.
- **Job** – Creates one or more pods and ensures that a specified number of them run to completion.

For more information, see **Workloads** in the Kubernetes documentation.

By default, all Amazon EKS clusters have the following workloads:

- **coredns** – A **Deployment** that deploys two replicas of the `coredns` pods. The pods provide name resolution for all pods in the cluster. Two pods are deployed by default for high availability, regardless of the number of nodes deployed in your cluster. For more information, see **Managing the CoreDNS add-on** (p. 328). The pods can be deployed to any node type. However, they can be deployed to Fargate nodes only if your cluster includes a Fargate profile with a namespace that matches the namespace for the workload.

- **aws-node** – A **DaemonSet** that deploys one pod to each Amazon EC2 node in your cluster. The pod runs the Amazon Virtual Private Cloud (Amazon VPC) CNI controller, which provides VPC networking functionality to the pods and nodes in your cluster. For more information, see **Pod networking (CNI)** (p. 269). This workload isn't deployed to Fargate nodes because Fargate already contains the Amazon VPC CNI controller.
• **kube-proxy** – A DaemonSet that deploys one pod to each Amazon EC2 node in your cluster. The pods maintain network rules on nodes that enable networking communication to your pods. For more information, see `kube-proxy` in the Kubernetes documentation. This workload isn't deployed to Fargate nodes.

**View workload details**

Selecting the link in the **Name** column for one of the **Workloads** shows you the following information:

- The **Status**, **Namespace**, and **Selectors** (if any) assigned to the workload.
- The list of **Pods** managed by the workload, their **Status** and **Created** date and time.
- The Kubernetes **Labels** and **Annotations** assigned to the workload. These could have been assigned by you, by Kubernetes, or by the Amazon EKS API when the workload was created.

Some of the detailed information that you see when inspecting a workload might be different depending on the type of workload. To learn more about the unique properties of each workload type, see **Workloads** in the Kubernetes documentation.

**View pod details**

Pods are the fundamental unit of computing within a Kubernetes cluster and represent one or more containers that run together. Each workload controls one or more pods running on the cluster. Pods are designed as relatively ephemeral and immutable objects. Over time it's normal to have pods start and stop while your cluster is running. Pods starting or stopping reflect changes in your workloads as well as changes in the scale of your cluster. For more information, see **Pods** in the Kubernetes documentation.

When viewing a workload, select a link in the **Name** column for one of the **Pods** to see the following information about the pod:

- The Kubernetes **Namespace** that the pod is in and the pod's **Status**.
- The node on which the pod is running. The node might be an Amazon EC2 instance or a Fargate pod. For more information about viewing nodes, see **View nodes** (p. 107).
- The **Containers** in the pod. Selecting the name of a container provides the **Image**, **Ports**, **Mounts**, and **Arguments** provided when the pod was started. Pods can define two types of containers. The first is **application** containers, which are containers that run as long as the pod is running. The second is **init** containers, which are containers that serve as processes that run during pod startup. You can see both types of containers on the pod detail page.
- The Kubernetes **Labels** and **Annotations** assigned to the pod.

### Deploy a sample application

In this topic, you deploy a sample application to your cluster.

**Prerequisites**

- An existing Kubernetes cluster. If you don't have an existing Amazon EKS cluster, you can deploy one using one of the **Getting started with Amazon EKS** (p. 4) guides. If you're deploying a Windows application, then you must have **Windows support** (p. 90) enabled for your cluster and at least one Amazon EC2 Windows node.
- **Kubectl** installed on your computer. For more information, see **Installing kubectl** (p. 4).
• Kubectl configured to communicate with your cluster. For more information, see Create a kubeconfig for Amazon EKS (p. 403).

• If you plan to deploy your sample workload to Fargate, then you must have an existing Fargate profile (p. 157) that includes the same namespace created in this tutorial, which is eks-sample-app, unless you change the name. If you used one of the getting started guides (p. 4) to create your cluster, then you'll have to create a new profile, or add the namespace to your existing profile, because the profile created in the getting started guides doesn't specify the namespace used in this tutorial. Your VPC must also have at least one private subnet.

To deploy a sample application

Though many variables are changeable in the following steps, we recommend only changing variable values where specified. Once you have a better understanding of Kubernetes pods, deployments, and services, you can experiment with changing other values.

1. Create a namespace. A namespace allows you to group resources in Kubernetes. For more information, see Namespaces in the Kubernetes documentation. If you plan to deploy your sample application to AWS Fargate (p. 152), make sure that the value for namespace in your AWS Fargate profile (p. 157) is eks-sample-app.

```bash
kubectl create namespace eks-sample-app
```

2. Create a Kubernetes deployment. This sample deployment pulls a container image from a public repository and deploys three replicas (individual pods) of it to your cluster. To learn more, see Deployments in the Kubernetes documentation. You can deploy the application to Linux or Windows nodes. If you're deploying to Fargate, then you can only deploy a Linux application.

   a. Save the following contents to a file named eks-sample-deployment.yaml. The containers in the sample application don't use network storage, but you might have applications that need to. For more information, see Storage (p. 223).

   Linux

   The amd64 or arm64 values under the kubernetes.io/arch key mean that the application can be deployed to either hardware architecture (if you have both in your cluster). This is possible because this image is a multi-architecture image, but not all are. You can determine the hardware architecture that the image is supported on by viewing the image details in the repository that you're pulling it from. When deploying images that don't support a hardware architecture type, or that you don't want the image deployed to, remove that type from the manifest. For more information, see Well-Known Labels, Annotations and Taints in the Kubernetes documentation.

   The kubernetes.io/os: linux nodeSelector means that if you had Linux and Windows nodes (for example) in your cluster, the image would only be deployed to Linux nodes. For more information, see Well-Known Labels, Annotations and Taints in the Kubernetes documentation.

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: eks-sample-linux-deployment
  namespace: eks-sample-app
  labels:
    app: eks-sample-linux-app
spec:
  replicas: 3
  selector:
    matchLabels:
```
Sample application deployment

```yaml
app: eks-sample-linux-app
template:
  metadata:
    labels:
      app: eks-sample-linux-app
  spec:
    affinity:
      nodeAffinity:
        requiredDuringSchedulingIgnoredDuringExecution:
          nodeSelectorTerms:
            - matchExpressions:
              - key: kubernetes.io/arch
                operator: In
                values:
                  - amd64
                  - arm64
        containers:
          - name: nginx
            image: public.ecr.aws/nginx/nginx:1.21
            ports:
              - name: http
                containerPort: 80
            imagePullPolicy: IfNotPresent
            nodeSelector:
              kubernetes.io/os: linux

Windows

The `kubernetes.io/os: windows` nodeSelector means that if you had Windows and Linux nodes (for example) in your cluster, the image would only be deployed to Windows nodes. For more information, see Well-Known Labels, Annotations and Taints in the Kubernetes documentation.

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: eks-sample-windows-deployment
  namespace: eks-sample-app
  labels:
    app: eks-sample-windows-app
spec:
  replicas: 3
  selector:
    matchLabels:
      app: eks-sample-windows-app
  template:
    metadata:
      labels:
        app: eks-sample-windows-app
    spec:
      affinity:
        nodeAffinity:
          requiredDuringSchedulingIgnoredDuringExecution:
            nodeSelectorTerms:
              - matchExpressions:
                - key: beta.kubernetes.io/arch
                  operator: In
                  values:
                    - amd64
        containers:
          - name: windows-server-iis
            image: mcr.microsoft.com/windows/servercore:ltsc2019
            ports:
              - name: http
```

354
Sample application deployment

containerPort: 80
imagePullPolicy: IfNotPresent
command:
  - powershell.exe
  - -command
  - "Add-WindowsFeature Web-Server; Invoke-WebRequest -UseBasicParsing -Uri 'https://dotnetbinaries.blob.core.windows.net/servicemonitor/2.0.1.6/ServiceMonitor.exe' -OutFile 'C:\ServiceMonitor.exe'; echo '<html><body><br/><br/><marquee><H1>Hello EKS!!!</H1><marquee></body><html>' > C:\inetpub\wwwroot\default.html; C:\ServiceMonitor.exe 'w3svc'; "
nodeSelector:
  kubernetes.io/os: windows

b. Apply the deployment manifest to your cluster.

| kubectl apply -f eks-sample-deployment.yaml |

3. Create a service. A service allows you to access all replicas through a single IP address or name. For more information, see Service in the Kubernetes documentation. Though not implemented in the sample application, if you have applications that need to interact with other AWS services, we recommend that you create Kubernetes service accounts for your pods, and associate them to AWS IAM accounts. By specifying service accounts, your pods have only the minimum permissions that you specify for them to interact with other services. For more information, see IAM roles for service accounts (p. 461).

a. Save the following contents to a file named eks-sample-service.yaml. Kubernetes assigns the service its own IP address that is accessible only from within the cluster. To access the service from outside of your cluster, deploy the AWS Load Balancer Controller (p. 320) to load balance application (p. 371) or network (p. 365) traffic to the service.

Linux

```yaml
apiVersion: v1
class: Service
metadata:
  name: eks-sample-linux-service
  namespace: eks-sample-app
spec:
  selector:
    app: eks-sample-linux-app
  ports:
    - protocol: TCP
      port: 80
      targetPort: 80
```

Windows

```yaml
apiVersion: v1
kind: Service
metadata:
  name: eks-sample-windows-service
  namespace: eks-sample-app
spec:
  selector:
    app: eks-sample-windows-app
  ports:
    - protocol: TCP
      port: 80
```

355
b. Apply the service manifest to your cluster.

```bash
kubectl apply -f eks-sample-service.yaml
```

4. View all resources that exist in the eks-sample-app namespace.

```bash
kubectl get all -n eks-sample-app
```

Example output:

If you deployed Windows resources, then all instances of `linux` in the following output are `windows`. The other example values may be different from your output.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>pod/eks-sample-linux-deployment-65b7669776-m6qxz</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>27m</td>
</tr>
<tr>
<td>pod/eks-sample-linux-deployment-65b7669776-mmxd6</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>27m</td>
</tr>
<tr>
<td>pod/eks-sample-linux-deployment-65b7669776-qzn22</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>27m</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
</tr>
</thead>
<tbody>
<tr>
<td>service/eks-sample-linux-service</td>
<td>ClusterIP</td>
<td>10.100.74.8</td>
<td>&lt;none&gt;</td>
<td>80/TCP</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>deployment.apps/eks-sample-linux-deployment</td>
<td>3/3</td>
<td>3</td>
<td>3</td>
<td>27m</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESIRED</th>
<th>CURRENT</th>
<th>READY</th>
</tr>
</thead>
<tbody>
<tr>
<td>replicaset.apps/eks-sample-linux-deployment-776d8f8fd8</td>
<td>3</td>
<td>3</td>
<td>27m</td>
</tr>
</tbody>
</table>

In the output, you see the service and deployment that were specified in the sample manifests deployed in previous steps. You also see three pods. This is because 3 replicas were specified in the sample manifest. For more information about pods, see Pods in the Kubernetes documentation. Kubernetes automatically creates the replicaset resource, even though it isn't specified in the sample manifests. For more information about ReplicaSets, see ReplicaSet in the Kubernetes documentation.

**Note**

Kubernetes maintains the number of replicas that are specified in the manifest. If this were a production deployment and you wanted Kubernetes to horizontally scale the number of replicas or vertically scale the compute resources for the pods, use the Horizontal Pod Autoscaler (p. 363) and the Vertical Pod Autoscaler (p. 359) to do so.

5. View the details of the deployed service. If you deployed a Windows service, replace `linux` with `windows`.

```bash
kubectl -n eks-sample-app describe service eks-sample-linux-service
```

Example output:

If you deployed Windows resources, then all instances of `linux` in the following output are `windows`. The other example values may be different from your output.

<table>
<thead>
<tr>
<th>Name:</th>
<th>eks-sample-linux-service</th>
</tr>
</thead>
<tbody>
<tr>
<td>Namespace:</td>
<td>eks-sample-app</td>
</tr>
<tr>
<td>Labels:</td>
<td>app=eks-sample-linux-app</td>
</tr>
</tbody>
</table>
Annotations: <none>
Selector: app=eks-sample-linux-app
Type: ClusterIP
IP Families: <none>
IP: 10.100.74.8
IPs: 10.100.74.8
Port: <unset> 80/TCP
TargetPort: 80/TCP
Session Affinity: None
Events: <none>

In the previous output, the value for IP: is a unique IP address that can be reached from any node or pod within the cluster, but it can't be reached from outside of the cluster. The values for Endpoints are IP addresses assigned from within your VPC to the pods that are part of the service.

6. View the details of one of the pods listed in the output when you viewed the namespace (p. 356) in a previous step. If you deployed a Windows app, replace linux with windows and replace 776d8f8fd8-78w66 with the value returned for one of your pods.

```bash
kubectl -n eks-sample-app describe pod eks-sample-linux-deployment-65b7669776-m6qxz
```

**Abbreviated output**

If you deployed Windows resources, then all instances of linux in the following output are windows. The other example values may be different from your output.

<table>
<thead>
<tr>
<th>Name:</th>
<th>eks-sample-linux-deployment-65b7669776-m6qxz</th>
</tr>
</thead>
<tbody>
<tr>
<td>Namespace:</td>
<td>eks-sample-app</td>
</tr>
<tr>
<td>Priority:</td>
<td>0</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>IP:</td>
<td>192.168.63.93</td>
</tr>
<tr>
<td>IPs:</td>
<td>192.168.63.93</td>
</tr>
<tr>
<td>Controlled By:</td>
<td>ReplicaSet/eks-sample-linux-deployment-65b7669776</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>Conditions:</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Status</td>
</tr>
<tr>
<td>Initialized</td>
<td>True</td>
</tr>
<tr>
<td>Ready</td>
<td>True</td>
</tr>
<tr>
<td>ContainersReady</td>
<td>True</td>
</tr>
<tr>
<td>PodScheduled</td>
<td>True</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>

<p>| Events: |</p>
<table>
<thead>
<tr>
<th>Type</th>
<th>Reason</th>
<th>Age</th>
<th>From</th>
</tr>
</thead>
<tbody>
<tr>
<td>---</td>
<td>------</td>
<td>---</td>
<td>----</td>
</tr>
<tr>
<td>Normal</td>
<td>Scheduled</td>
<td>3m20s</td>
<td>default-scheduler</td>
</tr>
<tr>
<td>Successfully assigned eks-sample-app/eks-sample-linux-deployment-65b7669776-m6qxz to ip-192-168-45-132.us-west-2.compute.internal</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In the previous output, the value for IP: is a unique IP that's assigned to the pod from the CIDR block assigned to the subnet that the node is in. If you prefer to assign pods IP addresses from different CIDR blocks, you can change the default behavior. For more information, see CNI custom networking (p. 300). You can also see that the Kubernetes scheduler scheduled the pod on the Node with the IP address 192.168.45.132.
Tip
Rather than using the command line, you can view many details about pods, services, deployments, and other Kubernetes resources in the AWS Management Console. For more information, see View workloads (p. 350).

7. Run a shell on the pod that you described in the previous step, replacing `65b7669776-m6qxz` with the ID of one of your pods.

Linux

```
kubectl exec -it eks-sample-linux-deployment-65b7669776-m6qxz -n eks-sample-app -- /bin/bash
```

Windows

```
kubectl exec -it eks-sample-windows-deployment-65b7669776-m6qxz -n eks-sample-app -- powershell.exe
```

8. From the pod shell, view the output from the web server that was installed with your deployment in a previous step. You only need to specify the service name. It is resolved to the service's IP address by CoreDNS, which is deployed with an Amazon EKS cluster, by default.

Linux

```
curl eks-sample-linux-service
```

Example output:

```
<!DOCTYPE html>
<html>
<head>
<title>Welcome to nginx!</title>
...
```

Windows

```
Invoke-WebRequest -uri eks-sample-windows-service/default.html -UseBasicParsing
```

Example output:

```
StatusCode : 200
StatusDescription : OK
Content : <html><body><br/><br/><marquee><h1>Hello EKS!!!</h1><marquee><br/><br/></body></html>
```

9. From the pod shell, view the DNS server for the pod.

Linux

```
cat /etc/resolv.conf
```

Example output:

```
nameserver 10.100.0.10
```
search eks-sample-app.svc.cluster.local svc.cluster.local cluster.local us-west-2.compute.internal
options ndots:5

In the previous output, 10.100.0.10 is automatically assigned as the nameserver for all pods deployed to the cluster.

Windows

```
Get-NetIPConfiguration
```

Abbreviated output

<table>
<thead>
<tr>
<th>InterfaceAlias</th>
<th>vEthernet</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv4Address</td>
<td>192.168.63.14</td>
</tr>
<tr>
<td>DNSServer</td>
<td>10.100.0.10</td>
</tr>
</tbody>
</table>

In the previous output, 10.100.0.10 is automatically assigned as the DNS server for all pods deployed to the cluster.

10. Disconnect from the pod by typing `exit`.

11. Once you're finished with the sample application, you can remove the sample namespace, service, and deployment with the following command.

```
kubectl delete namespace eks-sample-app
```

---

Vertical Pod Autoscaler

The Kubernetes Vertical Pod Autoscaler automatically adjusts the CPU and memory reservations for your pods to help "right size" your applications. This adjustment can improve cluster resource utilization and free up CPU and memory for other pods. This topic helps you to deploy the Vertical Pod Autoscaler to your cluster and verify that it is working.

Prerequisites

- You have an existing Amazon EKS cluster. If you don't, see Getting started with Amazon EKS (p. 4).
- You have the Kubernetes Metrics Server installed. For more information, see Installing the Kubernetes Metrics Server (p. 417).
- You are using a kubectl client that is configured to communicate with your Amazon EKS cluster (p. 18).
- OpenSSL 1.1.1 or later installed on your device.

Deploy the Vertical Pod Autoscaler

In this section, you deploy the Vertical Pod Autoscaler to your cluster.

To deploy the Vertical Pod Autoscaler

1. Open a terminal window and navigate to a directory where you would like to download the Vertical Pod Autoscaler source code.
2. Clone the `kubernetes/autoscaler` GitHub repository.

   ```shell
git clone https://github.com/kubernetes/autoscaler.git
   ```

3. Change to the `vertical-pod-autoscaler` directory.

   ```shell
cd autoscaler/vertical-pod-autoscaler/
   ```

4. (Optional) If you have already deployed another version of the Vertical Pod Autoscaler, remove it with the following command.

   ```shell
./hack/vpa-down.sh
   ```

5. If your nodes don't have internet access to the `k8s.gcr.io` container registry, then you need to pull the following images and push them to your own private repository. For more information about how to pull the images and push them to your own private repository, see Copy a container image from one repository to another repository (p. 377).

   ```
   k8s.gcr.io/autoscaling/vpa-admission-controller:0.10.0
   k8s.gcr.io/autoscaling/vpa-recommender:0.10.0
   k8s.gcr.io/autoscaling/vpa-updater:0.10.0
   ```

   If you're pushing the images to a private Amazon ECR repository, then replace `k8s.gcr.io` in the manifests with your registry. Replace `111122223333` with your account ID. Replace `region-code` with the AWS Region that your cluster is in. The following commands assume that you named your repository the same as the repository name in the manifest. If you named your repository something different, then you'll need to change it too.

   ```
   sed -i.bak -e 's/k8s.gcr.io/111122223333.dkr.ecr.region-code.amazonaws.com/ .deploy/admission-controller-deployment.yaml
   sed -i.bak -e 's/k8s.gcr.io/111122223333.dkr.ecr..dkr.ecr.region-code.amazonaws.com/ .deploy/recommender-deployment.yaml
   sed -i.bak -e 's/k8s.gcr.io/111122223333.dkr.ecr..dkr.ecr.region-code.amazonaws.com/ .deploy/updater-deployment.yaml
   ```

6. Deploy the Vertical Pod Autoscaler to your cluster with the following command.

   ```shell
./hack/vpa-up.sh
   ```

7. Verify that the Vertical Pod Autoscaler pods have been created successfully.

   ```shell
kubectl get pods -n kube-system
   ```

   ```
NAME                           READY STATUS    RESTARTS AGE
---                            ----- -------- -------- -----
metrics-server-8459fc497-kfj8w 1/1    Running   0        83m
vpa-admission-controller-68c748777d-pppspd 1/1    Running   0        7s
vpa-recommender-6fc8c67d85-gljp 1/1    Running   0        8s
vpa-updater-786b96955c-bgp9d    1/1    Running   0        8s
   ```

---

Test your Vertical Pod Autoscaler installation

In this section, you deploy a sample application to verify that the Vertical Pod Autoscaler is working.
To test your Vertical Pod Autoscaler installation

1. Deploy the hamster.yaml Vertical Pod Autoscaler example with the following command.

```bash
kubectl apply -f examples/hamster.yaml
```

2. Get the pods from the hamster example application.

```bash
kubectl get pods -l app=hamster
```

Output:

```
hamster-c7d89d6db-rglf5  1/1  Running  0  48s
hamster-c7d89d6db-znvw5  1/1  Running  0  48s
```

3. Describe one of the pods to view its cpu and memory reservation. Replace `c7d89d6db-rglf5` with one of the IDs returned in your output from the previous step.

```bash
kubectl describe pod hamster-c7d89d6db-rglf5
```

Output:

```
...Containers:
hamster:
  Container ID:  docker://e76c2413fc720ac395c33b64588c82094fc8e5d590e373d5f818f3978f577e24
  Image:         k8s.gcr.io/ubuntu-slim:0.1
  Image ID:      docker-pullable://k8s.gcr.io/ubuntu-slim@sha256:b6f8c3885f588a4f1a7cf717c07242eb4858fdd5a84b5ffe35b1cf680ea17b1
  Port:          <none>
  Host Port:     <none>
  Command:       /bin/sh
  Args:          -c
                  while true; do timeout 0.5s yes >/dev/null; sleep 0.5s; done
  State:         Running
  Started:       Fri, 27 Sep 2019 10:35:16 -0700
  Ready:         True
  Restart Count: 0
  Requests:
                  cpu:     100m
                  memory: 50Mi
```

You can see that the original pod reserves 100 millipu of CPU and 50 mebibytes of memory. For this example application, 100 millipu is less than the pod needs to run, so it is CPU-constrained. It also reserves much less memory than it needs. The Vertical Pod Autoscaler vpa-recommender deployment analyzes the hamster pods to see if the CPU and memory requirements are appropriate. If adjustments are needed, the vpa-updater relaunches the pods with updated values.

4. Wait for the vpa-updater to launch a new hamster pod. This should take a minute or two. You can monitor the pods with the following command.

```
...```

**Note**

If you are not sure that a new pod has launched, compare the pod names with your previous list. When the new pod launches, you will see a new pod name.
5. When a new `hamster` pod is started, describe it and view the updated CPU and memory reservations.

```
kubectl describe pod hamster-c7d89d6db-jxgfv
```

Output:

```
... Containers:
  hamster:  Container ID: docker:///2c3e7b6fb7ce0d8c86444334df654af6fb3fc88aaad4c5d710eac3b1e7c58f7db
          Image: k8s.gcr.io/ubuntu-slim:0.1
          Image ID: docker-pullable://k8s.gcr.io/ubuntu-slim@sha256:b6f8c33885f5880a4f1a7cf717c07242eb858fd5a84b5ffe35b1cf680ea17b1
          Port: <none>
          Host Port: <none>
          Command: /bin/sh
          Args:
            -c
              while true; do timeout 0.5s yes >/dev/null; sleep 0.5s; done
          State: Running
          Started: Fri, 27 Sep 2019 10:37:08 -0700
          Ready: True
          Restart Count: 0
          Requests:
            cpu: 587m
            memory: 262144k
...```

In the previous output, you can see that the `cpu` reservation increased to 587 millicpu, which is over five times the original value. The `memory` increased to 262,144 Kilobytes, which is around 250 mebibytes, or five times the original value. This pod was under-resourced, and the Vertical Pod Autoscaler corrected the estimate with a much more appropriate value.

6. Describe the `hamster-vpa` resource to view the new recommendation.

```
kubectl describe vpa/hamster-vpa
```

Output:

```
Name:         hamster-vpa
Namespace:    default
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration: ("apiVersion":"autoscaling.k8s.io/v1beta2","kind":"VerticalPodAutoscaler","metadata":{"annotations":{},"name":"hamster-vpa","namespace":"default"},"spec":{"minReplicas":1,"maxReplicas":3,"targetCPUUtilizationPercentage":80,"targetMemoryUtilizationPercentage":80},"status":{... API Version: autoscaling.k8s.io/v1beta2
Kind:         VerticalPodAutoscaler
Metadata:
  Generation: 23
  Resource Version: 14411
  Self Link: /apis/autoscaling.k8s.io/v1beta2/namespaces/default/verticalpodautoscalers/hamster-vpa
```

362
7. When you finish experimenting with the example application, you can delete it with the following command.

```
kubectl delete -f examples/hamster.yaml
```

# Horizontal Pod Autoscaler

The Kubernetes Horizontal Pod Autoscaler automatically scales the number of pods in a deployment, replication controller, or replica set based on that resource's CPU utilization. This can help your applications scale out to meet increased demand or scale in when resources are not needed, thus freeing up your nodes for other applications. When you set a target CPU utilization percentage, the Horizontal Pod Autoscaler scales your application in or out to try to meet that target.

The Horizontal Pod Autoscaler is a standard API resource in Kubernetes that simply requires that a metrics source (such as the Kubernetes metrics server) is installed on your Amazon EKS cluster to work. You do not need to deploy or install the Horizontal Pod Autoscaler on your cluster to begin scaling your applications. For more information, see Horizontal Pod Autoscaler in the Kubernetes documentation.

Use this topic to prepare the Horizontal Pod Autoscaler for your Amazon EKS cluster and to verify that it is working with a sample application.

**Note**

This topic is based on the Horizontal pod autoscaler walkthrough in the Kubernetes documentation.

**Prerequisites**

- You have an existing Amazon EKS cluster. If you don't, see Getting started with Amazon EKS (p. 4).
- You have the Kubernetes Metrics Server installed. For more information, see Installing the Kubernetes Metrics Server (p. 417).
Run a Horizontal Pod Autoscaler test application

In this section, you deploy a sample application to verify that the Horizontal Pod Autoscaler is working.

**Note**
This example is based on the Horizontal pod autoscaler walkthrough in the Kubernetes documentation.

**To test your Horizontal Pod Autoscaler installation**

1. Deploy a simple Apache web server application with the following command.

   ```bash
   kubectl apply -f https://k8s.io/examples/application/php-apache.yaml
   ```

   This Apache web server pod is given a 500 millicpu CPU limit and it is serving on port 80.

2. Create a Horizontal Pod Autoscaler resource for the `php-apache` deployment.

   ```bash
   kubectl autoscale deployment php-apache --cpu-percent=50 --min=1 --max=10
   ```

   This command creates an autoscaler that targets 50 percent CPU utilization for the deployment, with a minimum of one pod and a maximum of ten pods. When the average CPU load is below 50 percent, the autoscaler tries to reduce the number of pods in the deployment, to a minimum of one. When the load is greater than 50 percent, the autoscaler tries to increase the number of pods in the deployment, up to a maximum of ten. For more information, see How does the Horizontal Pod Autoscaler work? in the Kubernetes documentation.

3. Describe the autoscaler with the following command to view its details.

   ```bash
   kubectl get hpa
   ```

   Output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS</th>
<th>MINPODS</th>
<th>MAXPODS</th>
<th>REPLICAS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>0%/50%</td>
<td>1</td>
<td>10</td>
<td>1</td>
<td>51s</td>
</tr>
</tbody>
</table>

   As you can see, the current CPU load is 0%, because there's no load on the server yet. The pod count is already at its lowest boundary (one), so it cannot scale in.

4. Create a load for the web server by running a container.

   ```bash
   kubectl run -i --tty load-generator --rm --image=busybox --restart=Never -- /bin/sh -c "while sleep 0.01; do wget -q -O- http://php-apache; done"
   ```

5. To watch the deployment scale out, periodically run the following command in a separate terminal from the terminal that you ran the previous step in.

   ```bash
   kubectl get hpa php-apache
   ```

   Output:
It may take over a minute for the replica count to increase. As long as actual CPU percentage is higher than the target percentage, then the replica count increases, up to 10. In this case, it’s 250%, so the number of REPLICAS continues to increase.

**Note**
It may take a few minutes before you see the replica count reach its maximum. If only 6 replicas, for example, are necessary for the CPU load to remain at or under 50%, then the load won’t scale beyond 6 replicas.

6. Stop the load. In the terminal window you’re generating the load in, stop the load by holding down the Ctrl+C keys. You can watch the replicas scale back to 1 by running the following command again in the terminal that you’re watching the scaling in.

```
kubectl get hpa
```

Example output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS</th>
<th>MINPODS</th>
<th>MAXPODS</th>
<th>REPLICAS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>0%/50%</td>
<td>1</td>
<td>10</td>
<td>1</td>
<td>25m</td>
</tr>
</tbody>
</table>

**Note**
The default timeframe for scaling back down is five minutes, so it will take some time before you see the replica count reach 1 again, even when the current CPU percentage is 0 percent. The timeframe is modifiable. For more information, see Horizontal Pod Autoscaler in the Kubernetes documentation.

7. When you are done experimenting with your sample application, delete the php-apache resources.

```
kubectl delete deployment.apps/php-apache service/php-apache horizontalpodautoscaler.autoscaling/php-apache
```

### Network load balancing on Amazon EKS

Network traffic is load balanced at L4 of the OSI model. To load balance application traffic at L7, you deploy a Kubernetes ingress, which provisions an AWS Application Load Balancer. For more information, see Application load balancing on Amazon EKS (p. 371). To learn more about the differences between the two types of load balancing, see Elastic Load Balancing features on the AWS website.

When you create a Kubernetes Service of type LoadBalancer, the AWS cloud provider load balancer controller creates AWS Classic Load Balancers by default, but can also create AWS Network Load Balancers. This controller is only receiving critical bug fixes in the future. For more information about using the AWS cloud provider load balancer, see AWS cloud provider load balancer controller in the Kubernetes documentation. Its use is not covered in this topic.

For new services deployed to 1.19 or later clusters, we recommend that you use version 2.4.1 or later of the the section called "Installing the AWS Load Balancer Controller add-on" (p. 320) instead of the AWS cloud provider load balancer controller. If your cluster is earlier than 1.19, then we recommend that you use version 2.3.1 of the controller. The AWS Load Balancer Controller creates AWS Network Load Balancers, but doesn't create AWS Classic Load Balancers. The remainder of this topic is about using the AWS Load Balancer Controller.
An AWS Network Load Balancer can load balance network traffic to pods deployed to Amazon EC2 IP and instance targets or to AWS Fargate IP targets. For more information, see AWS Load Balancer Controller on GitHub.

**Prerequisites**

Before you can load balance network traffic using the AWS Load Balancer Controller, you must meet the following requirements.

- **Have an existing cluster.** If you don't have an existing cluster, see Getting started with Amazon EKS (p. 4). If you need to update the version of an existing cluster, see Updating a cluster (p. 32).

- **Have the AWS Load Balancer Controller deployed on your cluster.** For more information, see Installing the AWS Load Balancer Controller add-on (p. 320). We recommend version 2.4.1 or later for 1.19 or later clusters. If your cluster is earlier than 1.19, then we recommend using version 2.3.1.

- **At least one subnet.** If multiple tagged subnets are found in an Availability Zone, the controller chooses the first subnet whose subnet ID comes first lexicographically. The subnet must have at least eight available IP addresses.

- **If you're using the AWS Load Balancer Controller version v2.1.1 or earlier,** subnets must be tagged as follows. If using version 2.1.2 or later, this tag is optional. You might want to tag a subnet if you have multiple clusters running in the same VPC, or multiple AWS services sharing subnets in a VPC, and want more control over where load balancers are provisioned for each cluster. If you explicitly specify subnet IDs as an annotation on a service object, then Kubernetes and the AWS Load Balancer Controller use those subnets directly to create the load balancer. Subnet tagging isn't required if you choose to use this method for provisioning load balancers and you can skip the following private and public subnet tagging requirements. Replace `cluster-name` with your cluster name.
  
  - **Key** – `kubernetes.io/cluster/cluster-name`
  - **Value** – *shared* or *owned*

- **Your public and private subnets must meet the following requirements,** unless you explicitly specify subnet IDs as an annotation on a service or ingress object. If you provision load balancers by explicitly specifying subnet IDs as an annotation on a service or ingress object, then Kubernetes and the AWS Load Balancer Controller use those subnets directly to create the load balancer and the following tags aren't required.

  - **Private subnets** – Must be tagged in the following format. This is so that Kubernetes and the AWS Load Balancer Controller know that the subnets can be used for internal load balancers. If you use `eksctl` or an Amazon EKS AWS CloudFormation template to create your VPC after March 26, 2020, then the subnets are tagged appropriately when they're created. For more information about the Amazon EKS AWS CloudFormation VPC templates, see Creating a VPC for your Amazon EKS cluster (p. 258).
    
    - **Key** – `kubernetes.io/role/internal-elb`
    - **Value** – 1

  - **Public subnets** – Must be tagged in the following format. This is so that Kubernetes knows to use only those subnets for external load balancers instead of choosing a public subnet in each Availability Zone (based on the lexicographical order of the subnet IDs). If you use `eksctl` or an Amazon EKS AWS CloudFormation template to create your VPC after March 26, 2020, then the subnets are tagged appropriately when they're created. For more information about the Amazon EKS AWS CloudFormation VPC templates, see Creating a VPC for your Amazon EKS cluster (p. 258).
    
    - **Key** – `kubernetes.io/role/elb`
    - **Value** – 1

If the subnet role tags aren't explicitly added, the Kubernetes service controller examines the route table of your cluster VPC subnets to determine if the subnet is private or public. We recommend that you don't rely on this behavior, and instead explicitly add the private or public role tags. The AWS Load Balancer Controller doesn't examine route tables, and requires the private and public tags to be present for successful auto discovery.
Considerations

- The configuration of your load balancer is controlled by annotations that are added to the manifest for your service. Service annotations are different when using the AWS Load Balancer Controller than they are when using the AWS cloud provider load balancer controller. Make sure to review the annotations for the AWS Load Balancer Controller before deploying services.

- When using the Amazon EKS VPC CNI plugin (p. 269), the AWS Load Balancer Controller can load balance to Amazon EC2 IP or instance targets and Fargate IP targets. When using Alternate compatible CNI plugins (p. 320), the controller can only load balance to instance targets. For more information about Network Load Balancer target types, see Target type in the User Guide for Network Load Balancers.

- If you want to add tags to the load balancer when or after it's created, add the following annotation in your service specification. For more information, see AWS Resource Tags in the AWS Load Balancer Controller documentation.

  ```
  service.beta.kubernetes.io/aws-load-balancer-additional-resource-tags
  ```

- You can assign Elastic IP addresses to the Network Load Balancer by adding the following annotation. Replace the `example-values` with the Allocation IDs of your Elastic IP addresses. The number of Allocation IDs must match the number of subnets that are used for the load balancer. For more information, see the AWS Load Balancer Controller documentation.

  ```
  service.beta.kubernetes.io/aws-load-balancer-eip-allocations:
  eipalloc-xxxxxxxxxxxxxxxxx,eipalloc-yyyyyyyyyyyyyyyyy
  ```

- Amazon EKS adds one inbound rule to the node's security group for client traffic and one rule for each load balancer subnet in the VPC for health checks for each Network Load Balancer that you create. Deployment of a service of type `LoadBalancer` can fail if Amazon EKS attempts to create rules that exceed the quota for the maximum number of rules allowed for a security group. For more information, see Security groups in Amazon VPC quotas in the Amazon VPC User Guide. Consider the following options to minimize the chances of exceeding the maximum number of rules for a security group:

  - Request an increase in your rules per security group quota. For more information, see Requesting a quota increase in the Service Quotas User Guide.

  - Use IP targets, rather than instance targets. With IP targets, you can share rules for the same target ports. You can manually specify load balancer subnets with an annotation. For more information, see Annotations on GitHub.

  - Use an ingress, instead of a service of type `LoadBalancer`, to send traffic to your service. The AWS Application Load Balancer requires fewer rules than Network Load Balancers. You can share an ALB across multiple ingresses. For more information, see Application load balancing on Amazon EKS (p. 371). You can't share a Network Load Balancer across multiple services.

  - Deploy your clusters to multiple accounts.

  - If your pods run on Windows in an Amazon EKS cluster, a single service with a load balancer can support up to 64 backend pods. Each pod has its own unique IP address. This is a limitation of the Windows OS on the Amazon EC2 nodes.

  - We recommend only creating new Network Load Balancers with the AWS Load Balancer Controller. Attempting to replace existing Network Load Balancers created with the AWS cloud provider load balancer controller can result in multiple Network Load Balancers that might cause application downtime.

## Create a network load balancer

You can create a network load balancer with IP or instance targets.
Create a network load balancer

IP targets

You can use IP targets with pods deployed to Amazon EC2 nodes or Fargate. Your Kubernetes service must be created as type LoadBalancer. For more information, see Type LoadBalancer in the Kubernetes documentation.

To create a load balancer that uses IP targets, add the following annotations to a service manifest and deploy your service. The external value for aws-load-balancer-type is what causes the AWS Load Balancer Controller, rather than the AWS cloud provider load balancer controller, to create the Network Load Balancer. You can view a sample service manifest (p. 370) with the annotations.

```
service.beta.kubernetes.io/aws-load-balancer-type: "external"
service.beta.kubernetes.io/aws-load-balancer-nlb-target-type: "ip"
```

**Note**

If you’re load balancing to IPv6 pods, add the following annotation. You can only load balance over IPv6 to IP targets, not instance targets. Without this annotation, load balancing is over IPv4.

```
service.beta.kubernetes.io/aws-load-balancer-ip-address-type: dualstack
```

Network Load Balancers are created with the internal aws-load-balancer-scheme, by default. For internal Network Load Balancers, your Amazon EKS cluster must be configured to use at least one private subnet in your VPC. Kubernetes examines the route table for your subnets to identify whether they are public or private. Public subnets have a route directly to the internet using an internet gateway, but private subnets do not.

If you want to create a Network Load Balancer in a public subnet to load balance to Amazon EC2 nodes (Fargate can only be private), specify internet-facing with the following annotation:

```
service.beta.kubernetes.io/aws-load-balancer-scheme: "internet-facing"
```

**Note**

The service.beta.kubernetes.io/aws-load-balancer-type: "nlb-ip" annotation is still supported for backwards compatibility. However, we recommend using the previous annotations for new load balancers instead of service.beta.kubernetes.io/aws-load-balancer-type: "nlb-ip".

**Important**

Do not edit the annotations after creating your service. If you need to modify it, delete the service object and create it again with the desired value for this annotation.

Instance targets

The AWS cloud provider load balancer controller creates Network Load Balancers with instance targets only. Version 2.2.0 and later of the AWS Load Balancer Controller also creates Network Load Balancers with instance targets. We recommend using it, rather than the AWS cloud provider load balancer controller, to create new Network Load Balancers. You can use Network Load Balancer instance targets with pods deployed to Amazon EC2 nodes, but not to Fargate. To load balance network traffic across pods deployed to Fargate, you must use IP targets.

To deploy a Network Load Balancer to a private subnet, your service specification must have the following annotations. You can view a sample service manifest (p. 370) with the annotations. The external value for aws-load-balancer-type is what causes the AWS Load Balancer Controller, rather than the AWS cloud provider load balancer controller, to create the Network Load Balancer.

```
service.beta.kubernetes.io/aws-load-balancer-type: "external"
service.beta.kubernetes.io/aws-load-balancer-nlb-target-type: "instance"
```
Network Load Balancers are created with the **internal aws-load-balancer-scheme**, by default. For internal Network Load Balancers, your Amazon EKS cluster must be configured to use at least one private subnet in your VPC. Kubernetes examines the route table for your subnets to identify whether they are public or private. Public subnets have a route directly to the internet using an internet gateway, but private subnets do not.

If you want to create an Network Load Balancer in a public subnet to load balance to Amazon EC2 nodes, specify **internet-facing** with the following annotation:

```
service.beta.kubernetes.io/aws-load-balancer-scheme: "internet-facing"
```

**Important**
Do not edit the annotations after creating your service. If you need to modify it, delete the service object and create it again with the desired value for this annotation.

---

### (Optional) Deploy a sample application

**Prerequisites**

- At least one public or private subnet in your cluster VPC.
- Have the AWS Load Balancer Controller deployed on your cluster. For more information, see [Installing the AWS Load Balancer Controller add-on](p. 320). We recommend version 2.4.1 or later.

**To deploy a sample application**

1. If you're deploying to Fargate, make sure you have an available private subnet in your VPC and create a Fargate profile. If you're not deploying to Fargate, skip this step. You can create the profile by running the following command or in the AWS Management Console (p. 158) using the same values for `name` and `namespace` that are in the command. Replace the example values with your own.

   ```bash
   eksctl create fargateprofile \
   --cluster my-cluster \
   --region region-code \
   --name nlb-sample-app \
   --namespace nlb-sample-app
   ```

2. Deploy a sample application.
   
   a. Create a namespace for the application.

   ```bash
   kubectl create namespace nlb-sample-app
   ```

   b. Save the following contents to a file named `sample-deployment.yaml` file on your computer.

   ```yaml
   apiVersion: apps/v1
   kind: Deployment
   metadata:
     name: nlb-sample-app
     namespace: nlb-sample-app
   spec:
     replicas: 3
     selector:
       matchLabels:
         app: nginx
     template:
   ```
metadata:
  labels:
    app: nginx
spec:
  containers:
  - name: nginx
    image: public.ecr.aws/nginx/nginx:1.21
    ports:
    - name: tcp
      containerPort: 80

3. Create a service with an internal Network Load Balancer that load balances to IP targets.
   a. Save the following contents to a file named sample-service.yaml file on your computer. If you're deploying to Fargate nodes, remove the service.beta.kubernetes.io/aws-load-balancer-scheme: internet-facing line.

apiVersion: v1
kind: Service
metadata:
  name: nlb-sample-service
  namespace: nlb-sample-app
  annotations:
    service.beta.kubernetes.io/aws-load-balancer-type: external
    service.beta.kubernetes.io/aws-load-balancer-nlb-target-type: ip
    service.beta.kubernetes.io/aws-load-balancer-scheme: internet-facing
spec:
  ports:
  - port: 80
    targetPort: 80
    protocol: TCP
  type: LoadBalancer
  selector:
    app: nginx

b. Apply the manifest to the cluster.

   kubectl apply -f sample-service.yaml

4. Verify that the service was deployed.

   kubectl get svc nlb-sample-service -n nlb-sample-app

Example output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>sample-service</td>
<td>LoadBalancer</td>
<td>10.100.240.137</td>
<td>k8s-nlbso1-nlbso1-xxxxxxxxxx-xxxxx-xxxxx.region-code.amazonaws.com</td>
<td>16h</td>
</tr>
</tbody>
</table>

Note
The values for 10.100.240.137 and xxxxxxxxxx-xxxxxxxxxxxxxxxxxxx will be different than the example output (they will be unique to your load balancer) and us-west-2 may be different for you, depending on which AWS Region that your cluster is in.
5. Open the Amazon EC2 AWS Management Console. Select Target Groups (under Load Balancing) in the left navigation pane. In the Name column, select the target group's name where the value in the Load balancer column matches a portion of the name in the EXTERNAL-IP column of the output in the previous step. For example, you'd select the target group named k8s-default-samples-e-xxxxxxxxxxx if your output were the same as the output above. The Target type is IP because that was specified in the sample service manifest.

6. Select the Target group and then select the Targets tab. Under Registered targets, you should see three IP addresses of the three replicas deployed in a previous step. Wait until the status of all targets is healthy before continuing. It might take several minutes before all targets are healthy. The targets might be in an unhealthy state before changing to a healthy state.

7. Send traffic to the service replacing xxxxxxxxxx-xxxxxxxxxxxxxxx and us-west-2 with the values returned in the output for a previous step (p. 370) for EXTERNAL-IP. If you deployed to a private subnet, then you'll need to view the page from a device within your VPC, such as a bastion host. For more information, see Linux Bastion Hosts on AWS.

   curl k8s-default-samples-e-xxxxxxxxxxx-xxxxxxxxxxxxxxx.elb.region-code.amazonaws.com

   Example output:

   ```html
   <!DOCTYPE html>
   <html>
   <head>
   <title>Welcome to nginx!</title>
   ...
   ```

8. When you're finished with the sample deployment, service, and namespace, remove them.

   kubectl delete namespace mlb-sample-app

## Application load balancing on Amazon EKS

When you create a Kubernetes ingress, an AWS Application Load Balancer (ALB) is provisioned that load balances application traffic. To learn more, see What is an Application Load Balancer? in the Application Load Balancers User Guide and Ingress in the Kubernetes documentation. ALBs can be used with pods that are deployed to nodes or to AWS Fargate. You can deploy an ALB to public or private subnets.

Application traffic is balanced at L7 of the OSI model. To load balance network traffic at L4, you deploy a Kubernetes service of the LoadBalancer type. This type provisions an AWS Network Load Balancer. For more information, see Network load balancing on Amazon EKS (p. 365). To learn more about the differences between the two types of load balancing, see Elastic Load Balancing features on the AWS website.

### Prerequisites

Before you can load balance application traffic to an application, you must meet the following requirements.

- Have an existing cluster. If you don't have an existing cluster, see Getting started with Amazon EKS (p. 4). If you need to update the version of an existing cluster, see Updating a cluster (p. 32).
- Have the AWS Load Balancer Controller deployed on your cluster. For more information, see Installing the AWS Load Balancer Controller add-on (p. 320). We recommend version 2.4.1 or later for 1.19 or later clusters. If your cluster is earlier than 1.19, then we recommend using version 2.3.1.
- At least two subnets in different Availability Zones. The AWS load balancer controller chooses one subnet from each Availability Zone. When multiple tagged subnets are found in an Availability Zone,
the controller chooses the subnet whose subnet ID comes first lexicographically. Each subnet must have at least eight available IP addresses.

If you’re using multiple security groups attached to worker node, exactly one security group must be tagged as follows. Replace `cluster-name` with your cluster name.

- **Key** – `kubernetes.io/cluster/cluster-name`
- **Value** – `shared` or `owned`

If you’re using the AWS Load Balancer controller version v2.1.1 or earlier, subnets must be tagged in the format that follows. If you’re using version 2.1.2 or later, tagging is optional. However, we recommend that you tag a subnet if any of the following is the case. You have multiple clusters that are running in the same VPC, or have multiple AWS services that share subnets in a VPC. Or, you want more control over where load balancers are provisioned for each cluster. Replace `cluster-name` with your cluster name.

- **Key** – `kubernetes.io/cluster/cluster-name`
- **Value** – `shared` or `owned`

Your public and private subnets must meet the following requirements. This is unless you explicitly specify subnet IDs as an annotation on a service or ingress object. Assume that you provision load balancers by explicitly specifying subnet IDs as an annotation on a service or ingress object. In this situation, Kubernetes and the AWS load balancer controller use those subnets directly to create the load balancer and the following tags aren’t required.

- **Private subnets** – Must be tagged in the following format. This is so that Kubernetes and the AWS load balancer controller know that the subnets can be used for internal load balancers. If you use `eksctl` or an Amazon EKS AWS CloudFormation template to create your VPC after March 26, 2020, the subnets are tagged appropriately when created. For more information about the Amazon EKS AWS CloudFormation VPC templates, see Creating a VPC for your Amazon EKS cluster (p. 258).
  - **Key** – `kubernetes.io/role/internal-elb`
  - **Value** – `1`

- **Public subnets** – Must be tagged in the following format. This is so that Kubernetes knows to use only the subnets that were specified for external load balancers. This way, Kubernetes doesn’t choose a public subnet in each Availability Zone (lexicographically based on their subnet ID). If you use `eksctl` or an Amazon EKS AWS CloudFormation template to create your VPC after March 26, 2020, the subnets are tagged appropriately when created. For more information about the Amazon EKS AWS CloudFormation VPC templates, see Creating a VPC for your Amazon EKS cluster (p. 258).
  - **Key** – `kubernetes.io/role/elb`
  - **Value** – `1`

If the subnet role tags aren’t explicitly added, the Kubernetes service controller examines the route table of your cluster VPC subnets. This is to determine if the subnet is private or public. We recommend that you don’t rely on this behavior. Rather, explicitly add the private or public role tags. The AWS load balancer controller doesn’t examine route tables. It also requires the private and public tags to be present for successful auto discovery.

**Considerations**

- The **AWS Load Balancer Controller** creates ALBs and the necessary supporting AWS resources whenever a Kubernetes ingress resource is created on the cluster with the `kubernetes.io/ingress.class: alb` annotation. The ingress resource configures the ALB to route HTTP or HTTPS traffic to different pods within the cluster. To ensure that your ingress objects use the AWS Load Balancer Controller, add the following annotation to your Kubernetes ingress specification. For more information, see Ingress specification on GitHub.

```
.annotations:
  kubernetes.io/ingress.class: alb
```
Note
If you’re load balancing to IPv6 pods, add the following annotation to your ingress spec. You can only load balance over IPv6 to IP targets, not instance targets. Without this annotation, load balancing is over IPv4.

```
alb.ingress.kubernetes.io/ip-address-type: dualstack
```

- The AWS Load Balancer Controller supports the following traffic modes:
  - **Instance** – Registers nodes within your cluster as targets for the ALB. Traffic reaching the ALB is routed to NodePort for your service and then proxied to your pods. This is the default traffic mode. You can also explicitly specify it with the `alb.ingress.kubernetes.io/target-type: instance` annotation.
    
    **Note**
    
    Your Kubernetes service must specify the `NodePort` or "LoadBalancer" type to use this traffic mode.
  - **IP** – Registers pods as targets for the ALB. Traffic reaching the ALB is directly routed to pods for your service. You must specify the `alb.ingress.kubernetes.io/target-type: ip` annotation to use this traffic mode. The IP target type is required when target pods are running on Fargate.

- To tag ALBs created by the controller, add the following annotation to the controller:
  
  `alb.ingress.kubernetes.io/tags` For a list of all available annotations supported by the AWS Load Balancer Controller, see Ingress annotations on GitHub.

- Upgrading or downgrading the ALB controller version can introduce breaking changes for features that rely on it. For more information about the breaking changes that are introduced in each release, see the ALB controller release notes on GitHub.

To share an application load balancer across multiple service resources using IngressGroups

To join an ingress to a group, add the following annotation to a Kubernetes ingress resource specification.

```
alb.ingress.kubernetes.io/group.name: my-group
```

The group name must:

- Be 63 or fewer characters in length.
- Consist of lower case letters, numbers, -, and .
- Start and end with a letter or number.

The controller automatically merges ingress rules for all ingresses in the same ingress group. It supports them with a single ALB. Most annotations that are defined on an ingress only apply to the paths defined by that ingress. By default, ingress resources don't belong to any ingress group.

**Warning**

**Potential security risk**: Specify an ingress group for an ingress only when all the Kubernetes users that have RBAC permission to create or modify ingress resources are within the same trust boundary. If you add the annotation with a group name, other Kubernetes users might create or modify their ingresses to belong to the same ingress group. Doing so can cause undesirable behavior, such as overwriting existing rules with higher priority rules.

You can add an order number of your ingress resource.

```
alb.ingress.kubernetes.io/group.order: '10'
```
The number can be 1-1000. The lowest number for all ingresses in the same ingress group is evaluated first. All ingresses without this annotation are evaluated with a value of zero. Duplicate rules with a higher number can overwrite rules with a lower number. By default, the rule order between ingresses within the same ingress group is determined lexicographically based namespace and name.

**Important**

Ensure that each ingress in the same ingress group has a unique priority number. You can't have duplicate order numbers across ingresses.

(Optional) Deploy a sample application

Prerequisites

- At least one public or private subnet in your cluster VPC.
- Have the AWS Load Balancer Controller deployed on your cluster. For more information, see Installing the AWS Load Balancer Controller add-on (p. 320). We recommend version 2.4.1 or later.

To deploy a sample application

You can run the sample application on a cluster that has Amazon EC2 nodes, Fargate pods, or both.

1. If you're not deploying to Fargate, skip this step. If you're deploying to Fargate, create a Fargate profile. You can create the profile by running the following command or in the AWS Management Console (p. 158) using the same values for `name` and `namespace` that are in the command. Replace the example values with your own.

   ```bash
   eksctl create fargateprofile \
   --cluster my-cluster \
   --region region-code \
   --name alb-sample-app \
   --namespace game-2048
   ```

2. Deploy the game 2048 as a sample application to verify that the AWS Load Balancer Controller creates an AWS ALB as a result of the ingress object. Complete the steps for the type of subnet you're deploying to.

   a. If you're deploying to pods in a cluster that you created with the IPv6 family, skip to the next step.

   - **Public**

     ```bash
     kubectl apply -f https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.4.1/docs/examples/2048/2048_full.yaml
     ```

   - **Private**

     1. Download the manifest.

     ```bash
     curl -o 2048_full.yaml https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.4.1/docs/examples/2048/2048_full.yaml
     ```

     2. Edit the file and find the line that says `alb.ingress.kubernetes.io/scheme: internet-facing`.

     3. Change `internet-facing` to `internal` and save the file.

     4. Apply the manifest to your cluster.

     ```bash
     kubectl apply -f 2048_full.yaml
     ```
b. If you're deploying to pods in a cluster that you created with the IPv6 family (p. 288), complete the following steps.

1. Download the manifest.

```bash
curl -o 2048_full.yaml https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.4.1/docs/examples/2048/2048_full.yaml
```

2. Open the file in an editor and add the following line to the annotations in the ingress spec.

```yaml
alb.ingress.kubernetes.io/ip-address-type: dualstack
```

3. If you're load balancing to internal pods, rather than internet facing pods, change the line that says

```yaml
alb.ingress.kubernetes.io/scheme: internet-facing
```

   to

```yaml
alb.ingress.kubernetes.io/scheme: internal
```

4. Save the file.

5. Apply the manifest to your cluster.

```bash
cubectl apply -f 2048_full.yaml
```

3. After a few minutes, verify that the ingress resource was created with the following command.

```bash
cubectl get ingress/ingress-2048 -n game-2048
```

Output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>CLASS</th>
<th>HOSTS</th>
<th>ADDRESS</th>
</tr>
</thead>
<tbody>
<tr>
<td>ingress-2048</td>
<td>&lt;none&gt;</td>
<td>*</td>
<td>k8s-game2048-ingress2-xxxxxxxxxx-yyyyyyyyy.region-code.elb.amazonaws.com</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>80</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>2m32s</td>
</tr>
</tbody>
</table>

Note

If you created the load balancer in a private subnet, the value under ADDRESS in the previous output is prefaced with internal-.

If your ingress wasn't successfully created after several minutes, run the following command to view the Load Balancer Controller logs. These logs might contain error messages that you can use to diagnose issues with your deployment.

```bash
cubectl logs -n kube-system deployment.apps/aws-load-balancer-controller
```

4. If you deployed to a public subnet, open a browser and navigate to the ADDRESS URL from the previous command output to see the sample application. If you don't see anything, refresh your browser and try again. If you deployed to a private subnet, then you'll need to view the page from a device within your VPC, such as a bastion host. For more information, see Linux Bastion Hosts on AWS.

5. When you finish experimenting with your sample application, delete it by running one of the following commands.

   - If you applied the manifest, rather than applying a copy that you downloaded, use the following command.

     ```bash
cubectl delete -f https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.4.1/docs/examples/2048/2048_full.yaml
```

   - If you downloaded and edited the manifest, use the following command.

     ```bash
ckubectl apply -f 2048_full.yaml
```
Restricting external IP addresses that can be assigned to services

Kubernetes services can be reached from inside of a cluster through:

- A cluster IP address that is assigned automatically by Kubernetes
- Any IP address that you specify for the `externalIPs` property in a service spec. External IP addresses are not managed by Kubernetes and are the responsibility of the cluster administrator. External IP addresses specified with `externalIPs` are different than the external IP address assigned to a service of type `LoadBalancer` by a cloud provider.

To learn more about Kubernetes services, see Service in the Kubernetes documentation. You can restrict the IP addresses that can be specified for `externalIPs` in a service spec.

To restrict the IP addresses that can be specified for `externalIPs` in a service spec

1. Deploy cert-manager to manage webhook certificates. For more information, see the cert-manager documentation.

   ```
   kubectl apply -f https://github.com/jetstack/cert-manager/releases/download/v1.5.4/cert-manager.yaml
   ```

2. Verify that the cert-manager pods are running.

   ```
   kubectl get pods -n cert-manager
   ```

   Example output:

   ```
   NAME                                       READY   STATUS    RESTARTS   AGE
   cert-manager-58c8844bb8-nlx7q              1/1     Running   0          15s
   cert-manager-cainjector-745768f6ff-696h5   1/1     Running   0          15s
   cert-manager-webhook-67cc76975b-4v4nk      1/1     Running   0          14s
   ```

3. Review your existing services to ensure that none of them have external IP addresses assigned to them that aren't contained within the CIDR block you want to limit addresses to.

   ```
   kubectl get services --all-namespaces
   ```

   Example output:

   ```
   NAMESPACE                     NAME                                    PORT(S)         AGE
   cert-manager                   cert-manager                            9402/TCP        20m
   cert-manager                   cert-manager-webhook                    443/TCP         20m
   default                       kubernetes                              443/TCP         2d1h
   externalip-validation-system  externalip-validation-webhook-service   443/TCP         16s
   ```
If any of the values are IP addresses that are not within the block you want to restrict access to, you'll need to change the addresses to be within the block, and redeploy the services. For example, the `my-service` service in the previous output has an external IP address assigned to it that isn't within the CIDR block example in step 5.

4. Download the external IP webhook manifest. You can also view the [source code for the webhook on GitHub](https://s3.us-west-2.amazonaws.com/amazon-eks/docs/externalip-webhook.yaml).

   ```bash
curl -o externalip-webhook.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/externalip-webhook.yaml
   ```

5. Specify CIDR blocks. Open the downloaded file in your editor and remove the # at the start of the following lines.

   ```yaml
   #args:
   #--allowed-external-ip-cidrs=10.0.0.0/8
   ```

   Replace `10.0.0.0/8` with your own CIDR block. You can specify as many blocks as you like. If specifying multiple blocks, add a comma between blocks.

6. If your cluster is not in the `us-west-2` AWS Region, then replace `us-west-2`, `602401143452`, and `amazonaws.com` in the file with the following commands. Before running the commands, replace `region-code` and `account-id` with the value for your AWS Region from the list in Amazon container image registries (p. 379).

   ```bash
   sed -i.bak -e 's|602401143452|account-id|' externalip-webhook.yaml
   sed -i.bak -e 's|us-west-2|region-code|' externalip-webhook.yaml
   sed -i.bak -e 's|amazonaws.com||' externalip-webhook.yaml
   ```

7. Apply the manifest to your cluster.

   ```bash
   kubectl apply -f externalip-webhook.yaml
   ```

   An attempt to deploy a service to your cluster with an IP address specified for `externalIPs` that is not contained in the blocks that you specified in the Specify CIDR blocks (p. 377) step will fail.

### Copy a container image from one repository to another repository

This topic describes how to pull a container image from a repository that your nodes don't have access to and push the image to a repository that your nodes have access to. You can push the image to Amazon ECR or an alternative repository that your nodes have access to.

**Prerequisites**

- The Docker engine installed and configured on your computer. For instructions, see [Install Docker Engine](https://docs.docker.com/engine/install/) in the Docker documentation.
Copy an image to a repository

Complete the following steps to pull a container image from a repository and push it to your own repository. In the following examples that are provided in this topic, the image for the CNI metrics helper (p. 315) is pulled. When you follow these steps, make sure to replace the example values with your own values.

To copy a container image from one repository to another repository

1. If you don’t already have an Amazon ECR repository or another repository, then create one that your nodes have access to. The following command creates an Amazon ECR private repository. An Amazon ECR private repository name must start with a letter. It can only contain lowercase letters, numbers, hyphens (-), underscores (_), and forward slashes (/). For more information, see Creating a private repository in the Amazon Elastic Container Registry User Guide.

   ```
   aws ecr create-repository --region region-code --repository-name cni-metrics-helper
   ```

2. Determine the registry, repository, and tag (optional) of the image that your nodes need to pull. This information is in the registry/repository[:tag] format.

   Many of the Amazon EKS topics about installing images require that you apply a manifest file or install the image using a Helm chart. However, before you apply a manifest file or install a Helm chart, first view the contents of the manifest or chart's values.yaml file. That way, you can determine the registry, repository, and tag to pull.

   For example, you can find the following line in the manifest file for the CNI metrics helper (p. 315). The registry is 602401143452.dkr.ecr.us-west-2.amazonaws.com, which is an Amazon ECR private registry. The repository is cni-metrics-helper.

   ```
   image: "602401143452.dkr.ecr.us-west-2.amazonaws.com/cni-metrics-helper:v1.10.1"
   ```

   You may see the following variations for an image location:

   - Only repository-name:tag. In this case, docker.io is usually the registry, but not specified since Kubernetes prepends it to a repository name by default if no registry is specified.
   - repository-name/repository-namespace/repository:tag. A repository namespace is optional, but is sometimes specified by the repository owner for categorizing images. For example, all Amazon EC2 images in the Amazon ECR Public Gallery use the aws-ec2 namespace.

   Before installing an image with Helm, view the Helm values.yaml file to determine the image location. For example, the values.yaml file for the CNI metrics helper (p. 315) includes the following lines.

   ```
   image:
     region: us-west-2
     tag: v1.10.2
   ```
3. Pull the container image specified in the manifest file.

   a. If you're pulling from a public registry, such as the Amazon ECR Public Gallery, you can skip to the next sub-step, because authentication isn't required. In this example, you authenticate to an Amazon ECR private registry that contains the repository for the CNI metrics helper image. Amazon EKS maintains the image in each registry listed in Amazon container image registries (p. 379). You can authenticate to any of the registries by replacing 602401143452 and region-code with the information for a different registry. A separate registry exists for each AWS Region that Amazon EKS is supported in.

   ```bash
   aws ecr get-login-password --region region-code | docker login --username AWS --password-stdin 602401143452.dkr.ecr.region-code.amazonaws.com
   
   docker pull 602401143452.dkr.ecr.region-code.amazonaws.com/cni-metrics-helper:v1.10.2
   
   b. Pull the image. In this example, you pull from the registry that you authenticated to in the previous sub-step. Replace 602401143452 and region-code with the information that you provided in the previous sub-step.

   ```bash
   docker pull 602401143452.dkr.ecr.region-code.amazonaws.com/cni-metrics-helper:v1.10.2
   ```

4. Tag the image that you pulled with your registry, repository, and tag. The following example assumes that you pulled the image from the manifest file and are going to push it to the Amazon ECR private repository that you created in the first step. Replace 111122223333 with your account ID. Replace region-code with the AWS Region that you created your Amazon ECR private repository in.

   ```bash
   docker tag cni-metrics-helper:v1.10.2 111122223333.dkr.ecr.region-code.amazonaws.com/cni-metrics-helper:v1.10.2
   ```

5. Authenticate to your registry. In this example, you authenticate to the Amazon ECR private registry that you created in the first step. For more information, see Registry authentication in the Amazon Elastic Container Registry User Guide.

   ```bash
   aws ecr get-login-password --region region-code | docker login --username AWS --password-stdin 111122223333.dkr.ecr.region-code.amazonaws.com
   ```

6. Push the image to your repository. In this example, you push the image to the Amazon ECR private repository that you created in the first step. For more information, see Pushing a Docker image in the Amazon Elastic Container Registry User Guide.

   ```bash
   docker push 111122223333.dkr.ecr.region-code.amazonaws.com/cni-metrics-helper:v1.10.2
   ```

7. Update the manifest file that you used to determine the image in a previous step with the registry/repository:tag for the image that you pushed. If you're installing with a Helm chart, there's often an option to specify the registry/repository:tag. When installing the chart, specify the registry/repository:tag for the image that you pushed to your repository.

---

**Amazon container image registries**

When you deploy add-ons such as the Installing the AWS Load Balancer Controller add-on (p. 320), the Amazon VPC CNI (p. 280), kube-proxy (p. 339), or storage drivers (p. 223) to your cluster, your nodes might pull the container image from an Amazon EKS Amazon ECR private repository. The image's registry, repository, and tag are specified in a manifest or Helm values.yaml file referenced in the topics for each add-on that you deploy.
Amazon EKS replicates the images to a repository in each Amazon EKS supported AWS Region. Your nodes can pull the container image over the internet from any of the following registries. Alternatively, your nodes can pull the image over Amazon's network if you created an interface VPC endpoint for Amazon ECR (AWS PrivateLink) in your VPC. The registries require authentication with an AWS IAM account. Your nodes authenticate using the Amazon EKS node IAM role (p. 452), which has the permissions in the AmazonEC2ContainerRegistryReadOnly managed IAM policy associated to it.

</table>
Amazon EKS add-ons

An add-on is software that provides supporting operational capabilities to Kubernetes applications, but is not specific to the application. This includes software like observability agents or Kubernetes drivers that allow the cluster to interact with underlying AWS resources for networking, compute, and storage. Add-on software is typically built and maintained by the Kubernetes community, cloud providers like AWS, or third-party vendors. Amazon EKS automatically installs self-managed add-ons such as the Amazon VPC CNI, kube-proxy, and CoreDNS for every cluster. You can change the default configuration of the add-ons and update them when desired.

Amazon EKS add-ons provide installation and management of a curated set of add-ons for Amazon EKS clusters. All Amazon EKS add-ons include the latest security patches, bug fixes, and are validated by AWS to work with Amazon EKS. Amazon EKS add-ons allow you to consistently ensure that your Amazon EKS clusters are secure and stable and reduce the amount of work that you need to do in order to install, configure, and update add-ons. If a self-managed add-on, such as kube-proxy is already running on your cluster and is available as an Amazon EKS add-on, then you can install the kube-proxy Amazon EKS add-on to start benefiting from the capabilities of Amazon EKS add-ons.

You can update specific Amazon EKS managed configuration fields for Amazon EKS add-ons through the Amazon EKS API. You can also modify configuration fields not managed by Amazon EKS directly within the Kubernetes cluster once the add-on starts. This includes defining specific configuration fields for an add-on where applicable. These changes are not overridden by Amazon EKS once they are made. This is made possible using the Kubernetes server-side apply feature. For more information, see Amazon EKS add-on configuration (p. 382).

Amazon EKS add-ons can be used with any 1.18 or later Amazon EKS cluster. The cluster can include self-managed and Amazon EKS managed node groups, and Fargate.

Considerations

- To configure add-ons for the cluster your IAM user must have IAM permissions to work with add-ons. For more information, see the actions with Addon in their name in Actions defined by Amazon Elastic Kubernetes Service.
- Amazon EKS add-ons are only available with Amazon EKS clusters running Kubernetes version 1.18 and later.
- Amazon EKS add-ons run on the nodes that you provision or configure for your cluster. Node types include Amazon EC2 instances and Fargate.
- You can modify fields that aren’t managed by Amazon EKS to customize the installation of an Amazon EKS add-on. For more information, see Amazon EKS add-on configuration (p. 382).
• If you create a cluster with the AWS Management Console, the Amazon EKS `kube-proxy`, Amazon VPC CNI, and CoreDNS Amazon EKS add-ons are automatically added to your cluster. If you use `eksctl` to create your cluster with a `config` file, `eksctl` can also create the cluster with Amazon EKS add-ons. If you create your cluster using `eksctl` without a `config` file or with any other tool, the self-managed `kube-proxy`, Amazon VPC CNI, and CoreDNS add-ons are installed, rather than the Amazon EKS add-ons. You can either manage them yourself or add the Amazon EKS add-ons manually after cluster creation.

You can add, update, or delete Amazon EKS add-ons using the Amazon EKS API, AWS Management Console, AWS CLI, and `eksctl`. For detailed steps when using the AWS Management Console, AWS CLI, and `eksctl`, see the topics for the following add-ons:

- Amazon VPC CNI (p. 275)
- CoreDNS (p. 328)
- `kube-proxy` (p. 334)
- Amazon EBS CSI (p. 231)

You can also create Amazon EKS add-ons using AWS CloudFormation.

**Amazon EKS add-on configuration**

Amazon EKS add-ons are installed to your cluster using standard, best practice configurations. For more information about Amazon EKS add-ons, see Amazon EKS add-ons (p. 381).

You may want to customize the configuration of an Amazon EKS add-on to enable advanced features. Amazon EKS uses the Kubernetes server-side apply feature to enable management of an add-on by Amazon EKS without overwriting your configuration for settings that aren't managed by Amazon EKS. For more information, see Server-Side Apply in the Kubernetes documentation. To achieve this, Amazon EKS manages a minimum set of fields for every add-on that it installs. You can modify all fields that aren't managed by Amazon EKS, or another Kubernetes control plane process such as `kube-controller-manager`, without issue.

**Important**

Modifying a field managed by Amazon EKS prevents Amazon EKS from managing the add-on and may result in your changes being overwritten when an add-on is updated.

**Prerequisites**

- An existing 1.18 or later Amazon EKS cluster.
- An Amazon EKS add-on added to the cluster. For more information about adding an Amazon EKS add-on to your cluster, see Amazon EKS add-ons (p. 381).

**View field management status**

You can use `kubectl` to see which fields are managed by Amazon EKS for any Amazon EKS add-on.

**To see the management status of a field**

1. Determine which add-on that you want to examine. To see all of the Deployments and Daemonsets deployed to your cluster, see View workloads (p. 350).
2. View the managed fields for an add-on by running the following command:

```bash
cubectl get <type>/<add-on-name> -n <add-on-namespace> -o yaml
```
For example, you can see the managed fields for the CoreDNS add-on with the following command.

```
kubectl get deployment/coredns -n kube-system -o yaml
```

Field management is listed in the following section in the returned output.

```
... 
managedFields:   
- apiVersion: apps/v1
  fieldsType: FieldsV1
  fieldsV1: 
    ...
```

**Note**

If you don't see `managedFields` in the output, add `--show-managed-fields` to the command and run it again. The version of `kubectl` that you're using determines whether managed fields are returned by default.

### Understanding field management syntax in the Kubernetes API

When you view details for a Kubernetes object, both managed and unmanaged fields are returned in the output. Managed fields can be either of the following types:

- **Fully managed** – All keys for the field are managed by Amazon EKS. Modifications to any value causes a conflict.
- **Partially managed** – Some keys for the field are managed by Amazon EKS. Only modifications to the keys explicitly managed by Amazon EKS cause a conflict.

Both types of fields are tagged with `manager: eks`.

Each key is either a `f:<name>` representing the field itself, which always maps to an empty set, or a string that represents a sub-field or item. The output for field management consists of the following types of declarations:

- `f:<name>`, where `<name>` is the name of a field in a list.
- `k:<keys>`, where `<keys>` is a map of a list item's fields.
- `v:<value>`, where `<value>` is the exact json formatted value of a list item.
- `i:<index>`, where `<index>` is position of an item in the list.

For more information, see [FieldsV1 v1 meta](https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.22/) in the Kubernetes documentation.

The following portions of output for the CoreDNS add-on illustrate the previous declarations:

- **Fully managed fields** – If a managed field has an `f:` (field) specified, but no `k:` (key), then the entire field is managed. Modifications to any values in this field cause a conflict.

  In the following output, you can see that the container named `coredns` is managed by `eks`. The `args`, `image`, and `imagePullPolicy` sub-fields are also managed by `eks`. Modifications to any values in these fields cause a conflict.

```
... 
f:containers:
  k: {"name":"coredns":
    i: ()
```
Machine learning training using Elastic Fabric Adapter

This topic describes how to integrate Elastic Fabric Adapter (EFA) with pods deployed in your Amazon EKS cluster. Elastic Fabric Adapter (EFA) is a network interface for Amazon EC2 instances that enables you to run applications requiring high levels of inter-node communications at scale on AWS. Its custom-built operating system bypass hardware interface enhances the performance of inter-instance communications, which is critical to scaling these applications. With EFA, High Performance Computing (HPC) applications using the Message Passing Interface (MPI) and Machine Learning (ML) applications using NVIDIA Collective Communications Library (NCCL) can scale to thousands of CPUs or GPUs. As a result, you get the application performance of on-premises HPC clusters with the on-demand elasticity and flexibility of the AWS cloud. Integrating EFA with applications running on Amazon EKS clusters can
reduce the time to complete large scale distributed training workloads without having to add additional instances to your cluster. For more information about EFA, Elastic Fabric Adapter.

The EFA plugin described in this topic fully supports Amazon EC2 P4d instances, which represent the current state of the art in distributed machine learning in the cloud. Each p4d.24xlarge instance has eight NVIDIA A100 GPUs, and 400 Gbps GPUDirectRDMA over EFA. GPUDirectRDMA enables you to have direct GPU-to-GPU communication across nodes with CPU bypass, increasing collective communication bandwidth and lowering latency. Amazon EKS and EFA integration with P4d instances provides a seamless method to take advantage of the highest performing Amazon EC2 computing instance for distributed machine learning training.

Prerequisites

- An existing 1.19 or later Amazon EKS cluster. If you don’t have an existing cluster, use one of our Getting started with Amazon EKS (p. 4) guides to create one. Your cluster must be deployed in a VPC that has at least one private subnet with enough available IP addresses to deploy nodes in. The private subnet must have outbound internet access provided by an external device, such as a NAT gateway.

  If you plan to use eksctl to create your node group, eksctl can also create a 1.19 cluster for you.

- Version 2.5.2 or later or 1.22.86 or later of the AWS CLI installed and configured on your computer or AWS CloudShell. For more information, see Installing, updating, and uninstalling the AWS CLI and Quick configuration with aws configure in the AWS Command Line Interface User Guide.

- The kubectl command line tool installed on your computer or AWS CloudShell. The version must be the same, or up to two versions later than your cluster version. To install or upgrade kubectl, see Installing kubectl (p. 4).

- You must have the VPC CNI version 1.7.10 installed before launching worker nodes that support multiple Elastic Fabric Adapters, such as the p4d.24xlarge. For more information about updating your CNI version, see Updating the Amazon VPC CNI self-managed add-on (p. 280).

Create node group

The following procedure helps you create a node group with a p4d.24xlarge backed node group with EFA interfaces and GPUDirect RDMA, and run an example NVIDIA Collective Communications Library (NCCL) test for multi-node NCCL Performance using EFAs. The example can be used a template for distributed deep learning training on Amazon EKS using EFAs.

1. Determine which Availability Zones that Amazon EC2 instances that support EFA are available in for the region that your cluster is in

   a. Determine which Amazon EC2 instance types that support EFA are available in the AWS Region that your cluster is in.

      ```bash
      aws ec2 describe-instance-types
      --region region-code
      --filters Name=network-info.efa-supported,Values=true
      --query "InstanceTypes[*].[InstanceType]"
      --output text
      
      The Availability Zone name is listed in the Location column of the output returned from the previous command.
      
      2. Create a node group using either eksctl or the AWS CLI and AWS CloudFormation.
      
      eksctl

      Prerequisite
Version 0.92.0 or later of the `eksctl` command line tool installed on your computer or AWS CloudShell. To install or update `eksctl`, see Installing `eksctl` (p. 10).

a. Copy the following contents to a file named `efa-cluster.yaml`. Replace the example values with your own. You can replace `p4d.24xlarge` with a different instance, but if you do, make sure that the values for `availabilityZones` are Availability Zones that were returned for the instance type in step 1.

```yaml
apiversion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: my-efa-cluster
  region: region-code
  version: "1.19"

iam:
  withOIDC: true

availabilityZones: ["us-west-2a", "us-west-2c"]

managedNodeGroups:
  - name: my-efa-ng
    instanceType: p4d.24xlarge
    minSize: 1
    desiredCapacity: 2
    maxSize: 3
    availabilityZones: ["us-west-2a"]
    volumeSize: 300
    privateNetworking: true
    efaEnabled: true
```

b. Create a managed node group in an existing cluster.

```bash
ekubectl create nodegroup -f efa-cluster.yaml
```

If you don't have an existing cluster, you can run the following command to create a cluster and the node group.

```bash
ekubectl create cluster -f efa-cluster.yaml
```

AWS CLI and AWS CloudFormation

There are several requirements for EFA networking, including creating an EFA specific security group, creating an Amazon EC2 placement group, and creating a launch template that specifies one or more EFA interfaces, and includes EFA driver installation as part of Amazon EC2 user data. To learn more about EFA requirements, see Get started with EFA and MPI in the Amazon EC2 User Guide for Linux Instances. The following steps create all of this for you. Replace all example values with your own.

a. Set a few variables used in later steps. Replace all of the example values with your own. Replace `my-cluster` with the name of your existing cluster. The value for `node_group_resources_name` is later used to create an AWS CloudFormation stack. The value for `node_group_name` is later used to create the node group in your cluster.

```bash
cluster_name="my-cluster"
cluster_region="region-code"
node_group_resources_name="my-efa-nodegroup-resources"
node_group_name="my-efa-nodegroup"
```
b. Identify a private subnet in your VPC that is in the same Availability Zone as the instance type that you want to deploy is available in.

i. Retrieve the version of your cluster and store it in a variable for use in a later step.

```bash
cluster_version=$(aws eks describe-cluster --name $cluster_name --query "cluster.version" --output text)
```

ii. Retrieve the VPC ID that your cluster is in and store it in a variable for use in a later step.

```bash
vpc_id=$(aws eks describe-cluster --name $cluster_name --query "cluster.resourcesVpcConfig.vpcId" --output text)
```

iii. Retrieve the ID of the control plane security group for your cluster and store it in a variable for use in a later step.

```bash
control_plane_security_group=$(aws eks describe-cluster --name $cluster_name --query "cluster.resourcesVpcConfig.clusterSecurityGroupId" --output text)
```

iv. Get the list of subnet IDs in your VPC that are in an Availability Zone returned in step 1.

```bash
aws ec2 describe-subnets --filters "Name=vpc-id,Values=$vpc_id" "Name=availability-zone,Values=us-west-2a" --query 'Subnets[*].SubnetId' --output text
```

If no output is returned, try a different Availability Zone returned in step 1. If none of your subnets are in an Availability Zone returned in step 1, then you need to create a subnet in an Availability Zone returned in step 1. If you have no room in your VPC to create another subnet, then you may need to create a new cluster in a new VPC.

v. Determine whether the subnet is a private subnet by checking the route table for the subnet.

```bash
aws ec2 describe-route-tables --filter Name=association.subnet-id,Values=subnet-0d403852a65210a29 --query "RouteTables[].Routes[].GatewayId" --output text
```

Example output:

```
local
```

If the output is local `igw-02adc64c1b727272e2`, then the subnet is a public subnet. You must select a private subnet in an Availability Zone returned in step 1. Once you've identified a private subnet, note its ID for use in a later step.

vi. Set a variable with the private subnet ID from the previous step for use in later steps.

```bash
subnet_id=your-subnet-id
```

c. Download the AWS CloudFormation template.
d. Copy the following text to your computer. Replace *p4d.24xlarge* with an instance type from step 1. Replace *subnet-0d403852a65210a29* with the ID of the private subnet that you identified in step 2.b.v. Replace *path-to-downloaded-cfn-template* with the path to the *efa-p4d-managed-nodegroup.yaml* that you downloaded in the previous step. Replace *your-public-key-name* with the name of your public key. Once you’ve made the replacements, run the modified command.

```bash
aws cloudformation create-stack \
--stack-name ${node_group_resources_name} \
--capabilities CAPABILITY_IAM \
--template-body file://path-to-downloaded-cfn-template \
--parameters \
  ParameterKey=ClusterName,ParameterValue=${cluster_name} \
  ParameterKey=ClusterControlPlaneSecurityGroup,ParameterValue=${control_plane_security_group} \
  ParameterKey=VpcId,ParameterValue=${vpc_id} \
  ParameterKey=SubnetId,ParameterValue=${subnet_id} \
  ParameterKey=NodeGroupName,ParameterValue=${node_group_name} \
  ParameterKey=NodeImageIdSSMParam,ParameterValue=/aws/service/eks/optimized-ami/${cluster_version}/amazon-linux-2-gpu/recommended/image_id \
  ParameterKey=KeyName,ParameterValue=your-public-key-name \
  ParameterKey=NodeInstanceType,ParameterValue=p4d.24xlarge
```

e. Determine when the stack that you deployed in the previous step is deployed.

```bash
aws cloudformation wait stack-create-complete --stack-name
#node_group_resources_name
```

There is no output from the previous command, but your shell prompt doesn’t return until the stack is created.

f. Create your node group using the resources created by the AWS CloudFormation stack in the previous step.

i. Retrieve information from the deployed AWS CloudFormation stack and store it in variables.

```bash
node_instance_role=$(aws cloudformation describe-stacks \
  --stack-name #node_group_resources_name \
  --query='Stacks[].Outputs[?OutputKey==`NodeInstanceRole`].OutputValue' \
  --output text)
launch_template=$(aws cloudformation describe-stacks \
  --stack-name #node_group_resources_name \
  --query='Stacks[].Outputs[?OutputKey==`LaunchTemplateID`].OutputValue' \
  --output text)
```

ii. Create a managed node group that uses the launch template and node IAM role that were created in the previous step.

```bash
aws eks create-nodegroup \
  --cluster-name #cluster_name \
  --nodegroup-name #node_group_name \
  --node-role #node_instance_role \
  --subnets #subnet_id \
  --launch-template id=$launch_template,version=1
```

iii. Confirm that the nodes were created.
(Optional) Deploy a sample EFA compatible application

Deploy the Kubeflow MPI Operator

For the NCCL tests you can apply the Kubeflow MPI Operator. The MPI Operator makes it easy to run Allreduce-style distributed training on Kubernetes. For more information, see MPI Operator on GitHub.

Run the multi-node NCCL Performance Test to verify GPUDirectRDMA/EFA

To verify NCCL Performance with GPUDirectRDMA over EFA, run the standard NCCL Performance test. For more information, see the official NCCL-Tests repo on GitHub. You can use the sample Dockerfile that comes with this test already built for both CUDA 11.2 and the latest version of EFA.

Alternately, you can download an AWS Docker image available from an Amazon ECR repo.

Important
An important consideration required for adopting EFA with Kubernetes is configuring and managing Huge Pages as a resource in the cluster. For more information, see Manage Huge Pages in the Kubernetes documentation. Amazon EC2 instances with the EFA driver installed pre-allocate 5128 2M Huge Pages, which you can request as resources to consume in your job specifications.

Complete the following steps to run a two node NCCL Performance Test. In the example NCCL test job, each worker requests eight GPUs, 5210Mi of hugepages-2Mi, four EFAs, and 8000Mi of memory, which effectively means each worker consumes all the resources of a p4d.24xlarge instance.

1. Create the NCCL-tests job.
### Machine learning inference using AWS Inferentia

This topic describes how to create an Amazon EKS cluster with nodes running Amazon EC2 Inf1 instances and (optionally) deploy a sample application. Amazon EC2 Inf1 instances are powered by AWS Inferentia chips, which are custom built by AWS to provide high performance and lowest cost inference in the cloud. Machine learning models are deployed to containers using AWS Neuron, a specialized software development kit (SDK) consisting of a compiler, runtime, and profiling tools that optimize the machine learning inference performance of Inferentia chips. AWS Neuron supports popular machine learning frameworks such as TensorFlow, PyTorch, and MXNet.

**Note**

Neuron device logical IDs must be contiguous. If a pod requesting multiple Neuron devices is scheduled on an inf1.6xlarge or inf1.24xlarge instance type (which have more than one Neuron device), that pod will fail to start if the Kubernetes scheduler selects non-contiguous device IDs. For more information, see Device logical IDs must be contiguous on GitHub.

### Prerequisites

- Have eksctl installed on your computer. If you don't have it installed, see Installing eksctl (p. 10) for installation instructions.
- Have kubectl installed on your computer. For more information, see Installing kubectl (p. 4).
- (Optional) Have python3 installed on your computer. If you don't have it installed, then see Python downloads for installation instructions.
Create a cluster

To create a cluster with Inf1 Amazon EC2 instance nodes

1. Create a cluster with Inf1 Amazon EC2 instance nodes. You can replace `inf1.2xlarge` with any Inf1 instance type. The eksctl utility detects that you are launching a node group with an Inf1 instance type and will start your nodes using one of the Amazon EKS optimized accelerated Amazon Linux AMI (p. 192).

   **Note**
   You can't use IAM roles for service accounts (p. 461) with TensorFlow Serving.

   ```shell
   eksctl create cluster \
   --name inferentia \
   --region region-code \
   --nodegroup-name ng-inf1 \
   --node-type inf1.2xlarge \
   --nodes 2 \
   --nodes-min 1 \
   --nodes-max 4 \
   --ssh-access \ 
   --ssh-public-key your-key \ 
   --with-oidc
   ```

   **Note**
   Note the value of the following line of the output. It's used in a later (optional) step.

   ```shell
   ```

   When launching a node group with Inf1 instances, eksctl automatically installs the AWS Neuron Kubernetes device plugin. This plugin advertises Neuron devices as a system resource to the Kubernetes scheduler, which can be requested by a container. In addition to the default Amazon EKS node IAM policies, the Amazon S3 read only access policy is added so that the sample application, covered in a later step, can load a trained model from Amazon S3.

2. Make sure that all pods have started correctly.

   ```shell
   kubectl get pods -n kube-system
   ```

   Abbreviated output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>neuron-device-plugin-daemonset-6djhp</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>5m</td>
</tr>
<tr>
<td>neuron-device-plugin-daemonset-hwjsj</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>5m</td>
</tr>
</tbody>
</table>

(Optional) Deploy a TensorFlow Serving application image

A trained model must be compiled to an Inferentia target before it can be deployed on Inferentia instances. To continue, you will need a Neuron optimized TensorFlow model saved in Amazon S3. If you don't already have a SavedModel, please follow the tutorial for creating a Neuron compatible ResNet50 model and upload the resulting SavedModel to S3. ResNet-50 is a popular machine learning model.
used for image recognition tasks. For more information about compiling Neuron models, see The AWS Inferentia Chip With DLAMI in the AWS Deep Learning AMI Developer Guide.

The sample deployment manifest manages a pre-built inference serving container for TensorFlow provided by AWS Deep Learning Containers. Inside the container is the AWS Neuron Runtime and the TensorFlow Serving application. A complete list of pre-built Deep Learning Containers optimized for Neuron is maintained on GitHub under Available Images. At start-up, the DLC will fetch your model from Amazon S3, launch Neuron TensorFlow Serving with the saved model, and wait for prediction requests.

The number of Neuron devices allocated to your serving application can be adjusted by changing the `aws.amazon.com/neuron` resource in the deployment yaml. Please note that communication between TensorFlow Serving and the Neuron runtime happens over GRPC, which requires passing the `IPC_LOCK` capability to the container.

1. Add the `AmazonS3ReadOnlyAccess` IAM policy to the node instance role that was created in step 1 of Create a cluster (p. 391). This is necessary so that the sample application can load a trained model from Amazon S3.

   ```bash
   aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonS3ReadOnlyAccess
   --role-name eksctl-inferentia-nodegroup-ng-inode-instance-role-FI7H1Y3BS09
   ```

2. Create a file named `rn50_deployment.yaml` with the contents below. Update the region-code and model path to match your desired settings. The model name is for identification purposes when a client makes a request to the TensorFlow server. This example uses a model name to match a sample ResNet50 client script that will be used in a later step for sending prediction requests.

   ```yaml
   kind: Deployment
   apiVersion: apps/v1
   metadata:
     name: eks-neuron-test
   spec:
     replicas: 2
     selector:
       matchLabels:
         app: eks-neuron-test
         role: master
     template:
       metadata:
         labels:
           app: eks-neuron-test
           role: master
     spec:
       containers:
         - name: eks-neuron-test
           image: 763104351884.dkr.ecr.us-east-1.amazonaws.com/tensorflow-inference-neuron:1.15.4-neuron-py37-ubuntu18.04
           command:
             /usr/local/bin/entrypoint.sh
           args:
             - --port=8500
             - --rest_api_port=9000
             - --model_name=resnet50_neuron
             - --model_base_path=s3://<your-bucket-of-models>/resnet50_neuron/
```
3. Deploy the model.

```
kubectl apply -f rn50_deployment.yaml
```

4. Create a file named `rn50_service.yaml` with the following contents. The HTTP and gRPC ports are opened for accepting prediction requests.

```
kind: Service
apiVersion: v1
metadata:
  name: <eks-neuron-test>
  labels:
    app: <eks-neuron-test>
spec:
  type: ClusterIP
  ports:
    - name: http-tf-serving
      port: 8500
      targetPort: 8500
    - name: grpc-tf-serving
      port: 9000
      targetPort: 9000
  selector:
    app: <eks-neuron-test>
    role: master
```

5. Create a Kubernetes service for your TensorFlow model Serving application.

```
kubectl apply -f rn50_service.yaml
```
(Optional) Make predictions against your TensorFlow Serving service

1. To test locally, forward the gRPC port to the eks-neuron-test service.
   
   ```bash
   kubectl port-forward service/eks-neuron-test 8500:8500 &
   ```

2. Create a Python script called `tensorflow-model-server-infer.py` with the following content. This script runs inference via gRPC, which is service framework.

   ```python
   import numpy as np
   import grpc
   import tensorflow as tf
   from tensorflow.keras.preprocessing import image
   from tensorflow.keras.applications.resnet50 import preprocess_input
   from tensorflow_serving.apis import predict_pb2
   from tensorflow_serving.apis import prediction_service_pb2_grpc
   from tensorflow.keras.applications.resnet50 import decode_predictions

   if __name__ == '__main__':
       channel = grpc.insecure_channel('localhost:8500')
       stub = prediction_service_pb2_grpc.PredictionServiceStub(channel)
       img_file = tf.keras.utils.get_file("./kitten_small.jpg",
         "https://raw.githubusercontent.com/awslabs/mxnet-model-server/master/docs/images/kitten_small.jpg")
       img = image.load_img(img_file, target_size=(224, 224))
       img_array = preprocess_input(image.img_to_array(img)[None, ...])
       request = predict_pb2.PredictRequest()
       request.model_spec.name = 'resnet50_inf1'
       request.inputs['input'].CopyFrom(tf.make_tensor_proto(img_array, shape=img_array.shape))
       result = stub.Predict(request)
       prediction = tf.make_ndarray(result.outputs['output'])
       print(decode_predictions(prediction))
   ```

3. Run the script to submit predictions to your service.
   
   ```bash
   python3 tensorflow-model-server-infer.py
   ```

   Example output:

   ```
   [[[('u'n02123045', 'u'tabby', 0.68817204), ('u'n02127052', 'u'lynx', 0.12701613),
    ('u'n02123159', 'u'tiger_cat', 0.08736559), ('u'n02124075', 'u'Egyptian_cat',
    0.063844085), ('u'n02128757', 'u'snow_leopard', 0.009240591)]]
   ```
Cluster authentication

Amazon EKS uses IAM to provide authentication to your Kubernetes cluster (through the `aws eks get-token` command, available in version 1.16.156 or later of the AWS CLI, or the AWS IAM Authenticator for Kubernetes), but it still relies on native Kubernetes Role Based Access Control (RBAC) for authorization. This means that IAM is only used for authentication of valid IAM entities. All permissions for interacting with your Amazon EKS cluster’s Kubernetes API is managed through the native Kubernetes RBAC system. The following picture shows this relationship.

![Cluster authentication diagram]

**Note**
Amazon EKS uses the authentication token to make the `sts:GetCallerIdentity` call. As a result, AWS CloudTrail events with the name `GetCallerIdentity` from the source `sts.amazonaws.com` can have Amazon EKS service IP addresses for their source IP address.

**Topics**
- Enabling IAM user and role access to your cluster (p. 395)
- Authenticating users for your cluster from an OpenID Connect identity provider (p. 400)
- Create a kubeconfig for Amazon EKS (p. 403)
- Installing `aws-iam-authenticator` (p. 408)
- Default Amazon EKS Kubernetes roles and users (p. 411)

**Enabling IAM user and role access to your cluster**

Access to your cluster using AWS IAM entities is enabled by the AWS IAM Authenticator for Kubernetes, which runs on the Amazon EKS control plane. The authenticator gets its configuration information from the `aws-auth` ConfigMap. For all `aws-auth` ConfigMap settings, see Full Configuration Format on GitHub.
Add IAM users or roles to your Amazon EKS cluster

When you create an Amazon EKS cluster, the AWS Identity and Access Management (IAM) entity user or role, such as a federated user that creates the cluster, is automatically granted system:masters permissions in the cluster's role-based access control (RBAC) configuration in the Amazon EKS control plane. This IAM entity doesn't appear in any visible configuration, so make sure to keep track of which IAM entity originally created the cluster. To grant additional AWS users or roles the ability to interact with your cluster, you must edit the aws-auth ConfigMap within Kubernetes and create a Kubernetes rolebinding or clusterrolebinding with the name of a group that you specify in the aws-auth ConfigMap.

Note
For more information about different IAM identities, see Identities (Users, Groups, and Roles) in the IAM User Guide. For more information on Kubernetes role-based access control (RBAC) configuration, see Using RBAC Authorization.

To add an IAM user or role to an Amazon EKS cluster

1. Determine which credentials kubectl is using to access your cluster. On your computer, you can see which credentials kubectl uses with the following command. Replace `~/.kube/config` with the path to your kubeconfig file if you don't use the default path.

```
cat ~/.kube/config
```

Example output:

```
...
contexts:
- context:
  cluster: my-cluster.region-code.eksctl.io
  user: admin@my-cluster.region-code.eksctl.io
  name: admin@my-cluster.region-code.eksctl.io
  current-context: admin@my-cluster.region-code.eksctl.io
...
```

In the previous example output the credentials for a user named `admin` are configured for a cluster named `my-cluster`. If this is the user that created the cluster, then it already has access to your cluster. If it's not the user that created the cluster, then you need to complete the remaining steps to enable cluster access for the user, if you haven't already.

2. Ensure that you have an existing Kubernetes role or clusterrole with the permissions (rules) that you want your IAM users to have access to in your cluster and that you have an existing Kubernetes rolebinding or clusterrolebinding that binds a Kubernetes group to the role or clusterrole. For more information, see Using RBAC Authorization in the Kubernetes documentation. You can view all of your existing roles, clusterroles, rolebindings, and clusterrolebindings using the following commands.

```
kubectl get roles --all-namespaces
```

```
kubectl get clusterroles
```

```
kubectl get rolebindings --all-namespaces
```

```
kubectl get clusterrolebindings
```
You can then view the details of any of the resources using the following command. You can replace _role_ with _clusterrole, rolebinding_, or _clusterrolebinding_, replace _role-name_ with the resource name (from the previous output), and replace _kube-system_ with the namespace of the resource (from the previous output).

```
kubectl describe role role-name -n kube-system
```

3. (Optional) Create a _clusterrole_ and _clusterrolebinding_ or _role_ and _rolebinding_ to enable IAM users to view nodes (p. 107) and workloads (p. 350) in the AWS Management Console.

   a. You can enable users to view Kubernetes resources for:

      - **The cluster** – This manifest creates a _clusterrole_ and _clusterrolebinding_. The group name in the file is _eks-console-dashboard-full-access-group_, which is the group that your IAM user or role needs to be mapped to in the _aws-auth_ ConfigMap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the ConfigMap.

        ```
curl -o eks-console-full-access.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-full-access.yaml
        
        curl -o eks-console-restricted-access.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-restricted-access.yaml
        ```

      - **A specific namespace** – This manifest creates a _role_ and _rolebinding_. The namespace in this file is _default_, so if you want to specify a different namespace, edit the file before applying it to your cluster. The group name in the file is _eks-console-dashboard-restricted-access-group_, which is the group that your IAM user or role needs to be mapped to in the _aws-auth_ ConfigMap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the ConfigMap.

        ```
curl -o eks-console-restricted-access.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-restricted-access.yaml
        ```

   b. Apply the appropriate manifest using one of the following commands.

   ```
kubectl apply -f eks-console-full-access.yaml

kubectl apply -f eks-console-restricted-access.yaml
```

4. Edit the _aws-auth_ ConfigMap.

   a. Open the ConfigMap for editing.

      ```
kubectl edit -n kube-system configmap/aws-auth
```

      **Note**

      If you receive an error stating "Error from server (NotFound): configmaps "aws-auth" not found", then use the procedure in **Apply the _aws-auth_ ConfigMap to your cluster (p. 399)** to apply the stock ConfigMap.

   b. Add your IAM users, roles, or AWS accounts to the ConfigMap. You cannot add IAM groups to the ConfigMap.

   ```
To add an IAM role (for example, for federated users): Add the role details to the mapRoles section of the ConfigMap, under data. Add this section if it does not already exist in the file. Each entry supports the following parameters:
```
• **rolearn**: The ARN of the IAM role to add. This value can't include a path. The format of the value you provide must be `arn:aws:iam::111122223333:role/role-name`. For more information, see [aws-auth ConfigMap does not grant access to the cluster](p. 517).

• **username**: The user name within Kubernetes to map to the IAM role.

• **groups**: A list of groups within Kubernetes to which the role is mapped. For more information, see [Default Roles and Role Bindings](https://kubernetes.io/docs/concepts/roles/roles/) in the Kubernetes documentation.

**To add an IAM user**: Add the user details to the `mapUsers` section of the ConfigMap, under `data`. Add this section if it does not already exist in the file. Each entry supports the following parameters:

- **userarn**: The ARN of the IAM user to add.
- **username**: The user name within Kubernetes to map to the IAM user.
- **groups**: A list of groups within Kubernetes to which the user is mapped to. For more information, see [Default Roles and Role Bindings](https://kubernetes.io/docs/concepts/roles/roles/) in the Kubernetes documentation.

For example, the block below contains:

- A `mapRoles` section that adds the node instance role so that nodes can register themselves with the cluster.
- A `mapUsers` section with the AWS users `admin` from the default AWS account, and two operations users from a different AWS account. The `admin` user is added to the `system:masters` Kubernetes group.

The operations users are added to Kubernetes groups that are used by the `role` and `rolebinding` and `clusterrole` and `clusterrolebinding` created by the manifests in the previous step, but you can replace them with whatever group you like. To enable users to view nodes (p. 107) and workloads (p. 350) in the AWS Management Console, they must have the mapping in the following example and the `role` and `rolebinding` or the `clusterrole` and `clusterrolebinding` created by the manifests in the previous step.

Replace all *example-values* with your own values.

```yaml
# Please edit the object below. Lines beginning with a '#' will be ignored, # and an empty file will abort the edit. If an error occurs while saving this file # will be # reopened with the relevant failures.
#
apiVersion: v1
data:
  mapRoles: |
  username: system:node:{{EC2PrivateDNSName}}
  groups:
  - system:bootstrappers
  - system:nodes

mapUsers: |
- userarn: arn:aws:iam::111122223333:user/admin
  username: admin
  groups:
  - system:masters
- userarn: arn:aws:iam::444455556666:user/ops-user
  username: ops-user
  groups:
  - eks-console-dashboard-full-access-group
- userarn: arn:aws:iam::444455556666:user/ops-user2
  username: ops-user2
```
Apply the `aws-auth` ConfigMap to your cluster

The `aws-auth` ConfigMap is automatically created and applied to your cluster when you create a managed node group or when you create a node group using `eksctl`. It is initially created to allow nodes to join your cluster, but you also use this ConfigMap to add role-based access control (RBAC) access to IAM users and roles. If you have not launched self-managed nodes and applied the `aws-auth` ConfigMap to your cluster, you can do so with the following procedure.

To apply the `aws-auth` ConfigMap to your cluster

1. Check to see if you have already applied the `aws-auth` ConfigMap.

   ```bash
   kubectl describe configmap -n kube-system aws-auth
   ```

   If you receive an error stating "Error from server (NotFound): configmaps "aws-auth" not found", then proceed with the following steps to apply the stock ConfigMap.

2. Download, edit, and apply the AWS authenticator configuration map.

   a. Download the configuration map.

      ```bash
      curl -o aws-auth-cm.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/cloudformation/2020-10-29/aws-auth-cm.yaml
      ```

   b. Open the file with a text editor. Replace `<ARN of instance role (not instance profile)>` with the Amazon Resource Name (ARN) of the IAM role associated with your nodes, and save the file. Do not modify any other lines in this file.

      **Important**
      The role ARN cannot include a path. The format of the role ARN must be `arn:aws:iam::111122223333:role/<role-name>`. For more information, see `aws-auth` ConfigMap does not grant access to the cluster (p. 517).

      ```yaml
      apiVersion: v1
      kind: ConfigMap
      metadata:
        name: aws-auth
        namespace: kube-system
      data:
        mapRoles:
          - roleArn: <ARN of instance role (not instance profile)>
            username: system:node:{{EC2PrivateDNSName}}
        groups:
          - system:bootstrappers
          - system:nodes
      ```

   c. Apply the configuration. This command may take a few minutes to finish.
Authenticating users for your cluster from an OpenID Connect identity provider

Amazon EKS supports using OpenID Connect (OIDC) identity providers as a method to authenticate users to your cluster. OIDC identity providers can be used with, or as an alternative to AWS Identity and Access Management (IAM). For more information about using IAM, see Enabling IAM user and role access to your cluster (p. 395). After configuring authentication to your cluster, you can create Kubernetes roles and clusterroles to assign permissions to the roles, and then bind the roles to the identities using Kubernetes rolebindings and clusterrolebindings. For more information, see Using RBAC Authorization in the Kubernetes documentation.

Considerations

- You can associate one OIDC identity provider to your cluster.
- Kubernetes doesn't provide an OIDC identity provider. You can use an existing public OIDC identity provider, or you can run your own identity provider. For a list of certified providers, see OpenID Certification on the OpenID site.
- The issuer URL of the OIDC identity provider must be publicly accessible, so that Amazon EKS can discover the signing keys. Amazon EKS does not support OIDC identity providers with self-signed certificates.
- You can't disable the AWS IAM authenticator on your cluster, because it is still required for joining nodes to a cluster. For more information, see AWS IAM Authenticator for Kubernetes on GitHub.
- An Amazon EKS cluster must still be created by an AWS IAM user, rather than an OIDC identity provider user. This is because the cluster creator interacts with the Amazon EKS APIs, rather than the Kubernetes APIs.
- OIDC identity provider-authenticated users are listed in the cluster's audit log if CloudWatch logs are turned on for the control plane. For more information, see Enabling and disabling control plane logs (p. 63).
- You can't sign in to the AWS Management Console with an account from an OIDC provider. You can only View nodes (p. 107) and Workloads (p. 350) in the console by signing into the AWS Management Console with an AWS Identity and Access Management account.

Associate an OIDC identity provider

Before you can associate an OIDC identity provider with your cluster, you need the following information from your provider:

- **Issuer URL** – The URL of the OIDC identity provider that allows the API server to discover public signing keys for verifying tokens. The URL must begin with `https://` and should correspond to the `iss` claim in the provider's OIDC ID tokens. In accordance with the OIDC standard, path components
Associate an OIDC identity provider

are allowed but query parameters are not. Typically the URL consists of only a host name, like https://server.example.org or https://example.com. This URL should point to the level below .well-known/openid-configuration and must be publicly accessible over the internet.

- **Client ID (also known as audience)** – The ID for the client application that makes authentication requests to the OIDC identity provider.

You can associate an identity provider using eksctl or the AWS Management Console.

**eksctl**

**To associate an OIDC identity provider to your cluster using eksctl**

1. Create a file named associate-identity-provider.yaml with the following contents. Replace the example values with your own. The values in the identityProviders section are obtained from your OIDC identity provider. Values are only required for the name, type, issuerUrl, and clientId settings under identityProviders.

   ```yaml
   ---
   apiVersion: eksctl.io/v1alpha5
   kind: ClusterConfig
   metadata:
     name: my-cluster
     region: your-region-code
   identityProviders:
     - name: my-provider
       type: oidc
       issuerUrl: https://example.com
       clientId: kubernetes
       usernameClaim: email
       usernamePrefix: my-username-prefix
       groupsClaim: my-claim
       groupsPrefix: my-groups-prefix
       requiredClaims:
         string: string
       tags:
         env: dev
   ```

   **Important**
   
   Don’t specify `system:` or any portion of that string, for groupsPrefix or usernamePrefix.

2. Create the provider.

   ```bash
   eksctl associate identityprovider -f associate-identity-provider.yaml
   ```

3. To use kubectl to work with your cluster and OIDC identity provider, see Using kubectl in the Kubernetes documentation.

**AWS Management Console**

**To associate an OIDC identity provider to your cluster using the AWS Management Console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Select your cluster.
3. Select the **Configuration** tab, and then select the **Authentication** tab.
4. On the **OIDC Identity Providers** page, select **Associate Identity Provider**.

5. On the **Associate OIDC Identity Provider** page, enter or select the following options, and then select **Associate**.
   
   • For **Name**, enter a unique name for the provider.
   
   • For **Issuer URL**, enter the URL for your provider. This URL must be accessible over the internet.
   
   • For **Client ID**, enter the OIDC identity provider's client ID (also known as **audience**).
   
   • For **Username claim**, enter the claim to use as the username.
   
   • For **Groups claim**, enter the claim to use as the user's group.
   
   • (Optional) Select **Advanced options**, enter or select the following information.
     
     • **Username prefix** – Enter a prefix to prepend to username claims. The prefix is prepended to username claims to prevent clashes with existing names. If you do not provide a value, and the username is a value other than email, the prefix defaults to the value for **Issuer URL**. You can use the value – to disable all prefixing. Don't specify system: or any portion of that string.
     
     • **Groups prefix** – Enter a prefix to prepend to groups claims. The prefix is prepended to group claims to prevent clashes with existing names (such as system: groups). For example, the value oidc: creates group names like oidc:engineering and oidc:infra. Don't specify system: or any portion of that string.
     
     • **Required claims** – Select **Add claim** and enter one or more key value pairs that describe required claims in the client ID token. The pairs describe required claims in the ID Token. If set, each claim is verified to be present in the ID token with a matching value.

6. To use **kubectl** to work with your cluster and OIDC identity provider, see **Using kubectl** in the Kubernetes documentation.

**Disassociate an OIDC identity provider from your cluster**

If you disassociate an OIDC identity provider from your cluster, users included in the provider can no longer access the cluster. However, you can still access the cluster with AWS IAM users.

**To disassociate an OIDC identity provider from your cluster using the AWS Management Console**

1. Open the Amazon EKS console at [https://console.aws.amazon.com/eks/home#/clusters](https://console.aws.amazon.com/eks/home#/clusters).
2. In the **OIDC Identity Providers** section, select **Disassociate**, enter the identity provider name, and then select **Disassociate**.

**Example IAM policy**

If you want to prevent an OIDC identity provider from being associated with a cluster, create and associate the following IAM policy to the IAM accounts of your Amazon EKS administrators. For more information, see **Creating IAM policies** and **Adding IAM identity permissions** in the IAM User Guide and **Actions, resources, and condition keys for Amazon Elastic Kubernetes Service** in the Service Authorization Reference.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "denyOIDC",
```
Create a kubeconfig for Amazon EKS

In this section, you create a kubeconfig file for your cluster (or update an existing one).

This section offers two procedures to create or update your kubeconfig file. You can quickly create or update a kubeconfig file with the AWS CLI update-kubeconfig command automatically by
using the AWS CLI, or you can create a `kubeconfig` file manually using the AWS CLI or the `aws-iam-authenticator`.

Amazon EKS uses the `aws eks get-token` command, available in version 1.16.156 or later of the AWS CLI or the AWS IAM Authenticator for Kubernetes with `kubectl` for cluster authentication. If you have installed the AWS CLI on your system, then by default the AWS IAM Authenticator for Kubernetes uses the same credentials that are returned with the following command:

```bash
aws sts get-caller-identity
```

For more information, see Configuring the AWS CLI in the AWS Command Line Interface User Guide.

Create `kubeconfig` file automatically

To create your `kubeconfig` file with the AWS CLI

1. Ensure that you have version 1.16.156 or later of the AWS CLI installed. To install or upgrade the AWS CLI, see Installing the AWS CLI in the AWS Command Line Interface User Guide.

   **Note**
   Your system’s Python version must be 2.7.9 or later. Otherwise, you receive `hostname` doesn’t match errors with AWS CLI calls to Amazon EKS.

   You can check your AWS CLI version with the following command:

   ```bash
   aws --version
   ```

   **Important**
   Package managers such as `yum`, `apt-get`, or Homebrew for macOS are often behind several versions of the AWS CLI. To ensure that you have the latest version, see Installing the AWS CLI in the AWS Command Line Interface User Guide.

2. Create or update a `kubeconfig` file for your cluster. Replace the example values with your own.

   • By default, the resulting configuration file is created at the default `kubeconfig` path (`.kube`) in your home directory or merged with an existing `config` file at that location. You can specify another path with the `--kubeconfig` option.

   • You can specify an IAM role ARN with the `--role-arn` option to use for authentication when you issue `kubectl` commands. Otherwise, the IAM entity in your default AWS CLI or SDK credential chain is used. You can view your default AWS CLI or SDK identity by running the `aws sts get-caller-identity` command.

   • For more information, see the help page with the `aws eks update-kubeconfig` help command or see `update-kubeconfig` in the AWS CLI Command Reference.

   **Note**
   To run the following command, you must have permission to use the `eks:DescribeCluster` API action with the cluster that you specify. For more information, see Amazon EKS identity-based policy examples (p. 438).

   ```bash
   aws eks update-kubeconfig --region region-code --name cluster-name
   ```

3. Test your configuration.

   ```bash
   kubectl get svc
   ```
Create kubeconfig manually

To create your kubeconfig file manually

1. Set values for a few variables by replacing the example values with your own and then running the modified commands.

   ```bash
   export region_code=region-code
   export cluster_name=my-cluster
   export account_id=111122223333
   ```

2. Retrieve the endpoint for your cluster and store the value in a variable.

   ```bash
   cluster_endpoint=$(aws eks describe-cluster \
   --region $region_code \
   --name $cluster_name \
   --query "cluster.endpoint" \
   --output text)
   ```

3. Retrieve the Base64-encoded certificate data required to communicate with your cluster and store the value in a variable.

   ```bash
   certificate_data=$(aws eks describe-cluster \
   --region $region_code \
   --name $cluster_name \
   --query "cluster.certificateAuthority.data" \
   --output text)
   ```

4. Create the default ~/.kube directory if it doesn't already exist.

   ```bash
   mkdir -p ~/.kube
   ```

5. Run the command for your preferred client token method (AWS CLI or AWS IAM authenticator for Kubernetes) to create the config file in the ~/.kube directory. You can specify the following before running one of the commands by modifying the command to include the following:

   - **An IAM role** – Remove the # at the start of the lines under args:. Replace my-role with the name of the IAM role that you want to perform cluster operations with instead of the default AWS credential provider chain. For more information, see Set up kubectl to use authentication tokens provided by AWS IAM Authenticator for Kubernetes on GitHub.

   - **An AWS CLI named profile** – Remove the # at the start of the env: line, and remove # at the start of the lines under it. Replace aws-profile with the name of the profile to use. If you don't specify a profile, then the default profile is used. For additional information, see Specifying Credentials & Using AWS Profiles on GitHub.
AWS CLI

**Prerequisite**

Version 1.16.156 or later of the AWS CLI must be installed on your device.

```bash
read -r -d '' KUBECONFIG <<EOF
apiVersion: v1
clusters:
  - cluster:
      certificate-authority-data: $certificate_data
      server: $cluster_endpoint
      name: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
      contexts:
        - context:
            cluster: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
            user: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
            name: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
            current-context: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
            kind: Config
            preferences: {} users:
              - name: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
                user:
                  exec:
                    apiVersion: client.authentication.k8s.io/v1alpha1
                    command: aws
                    args:
                      - --region
                      - $region_code
                      - eks
                      - get-token
                      - --cluster-name
                      - $cluster_name
                      # - "$r"
                      # - "arn:aws:iam::$account_id:role/my-role"
                      # env:
                      #   - name: "AWS_PROFILE"
                      #   value: "aws-profile"
EOF

echo "${KUBECONFIG}" > ~/.kube/config
```

AWS IAM Authenticator for Kubernetes

**Prerequisite**

The AWS IAM Authenticator for Kubernetes must be installed on your device. To install it, see [Installing aws-iam-authenticator](p. 408).

```bash
read -r -d '' KUBECONFIG <<EOF
apiVersion: v1
clusters:
  - cluster:
      server: $cluster_endpoint
      certificate-authority-data: $certificate_data
      name: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
      contexts:
        - context:
            cluster: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
            user: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
            name: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
EOF
```
current-context: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
kind: Config
preferences: {}
users:
- name: arn:aws:eks:$region_code:$account_id:cluster/$cluster_name
  user:
    exec:
      apiVersion: client.authentication.k8s.io/v1alpha1
      command: aws-iam-authenticator
      args:
      - "token"
      - "-i"
      - "$cluster_name"
      # - "-r"
      # - "arn:aws:iam::$account_id:role/my-role"
      env:
      # - name: "AWS_PROFILE"
      # value: "aws-profile"
EOF

6. Add the file path to your KUBECONFIG environment variable so that kubectl knows where to look for your cluster configuration.

   • For Bash shells on macOS or Linux:

     ```bash
     export KUBECONFIG=$KUBECONFIG:~/.kube/config
     ```

   • For PowerShell on Windows:

     ```bash
     $ENV:KUBECONFIG="(0);(1)" -f $ENV:KUBECONFIG, "$ENV:userprofile\.kube\config"
     ```

7. (Optional) Add the configuration to your shell initialization file so that it is configured when you open a shell.

   • For Bash shells on macOS:

     ```bash
     echo 'export KUBECONFIG=$KUBECONFIG:~/.kube/config' >> ~/.bash_profile
     ```

   • For Bash shells on Linux:

     ```bash
     echo 'export KUBECONFIG=$KUBECONFIG:~/.kube/config' >> ~/.bashrc
     ```

   • For PowerShell on Windows:

     ```bash
     [System.Environment]::SetEnvironmentVariable('KUBECONFIG', $ENV:KUBECONFIG, 'Machine')
     ```

8. Test your configuration.

   ```bash
   kubectl get svc
   ```

   **Note**

   If you receive any authorization or resource type errors, see Unauthorized or access denied (kubectl) (p. 509) in the troubleshooting section.

   **Output:**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>407</td>
<td></td>
<td></td>
<td></td>

Installing aws-iam-authenticator

Amazon EKS uses IAM to provide authentication to your Kubernetes cluster through the AWS IAM authenticator for Kubernetes. You can configure the stock kubectl client to work with Amazon EKS by installing the AWS IAM authenticator for Kubernetes and modifying your kubectl configuration file (p. 403) to use it for authentication.

Note
If you're running the AWS CLI version 1.16.156 or later, then you don't need to install the authenticator. Instead, you can use the aws eks get-token command. For more information, see Create kubeconfig manually (p. 405).

If you're unable to use the AWS CLI version 1.16.156 or later to create the kubeconfig file, then you can install the AWS IAM authenticator for Kubernetes on macOS, Linux, or Windows.

macOS

To install aws-iam-authenticator with Homebrew

The easiest way to install the aws-iam-authenticator is with Homebrew.

1. If you do not already have Homebrew installed on your Mac, install it with the following command.

   `/bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/master/install.sh)"

2. Install the aws-iam-authenticator with the following command.

   `brew install aws-iam-authenticator`

3. Test that the aws-iam-authenticator binary works.

   `aws-iam-authenticator help`

To install aws-iam-authenticator on macOS

You can also install the AWS-vended version of the aws-iam-authenticator by following these steps.

1. Download the Amazon EKS vended aws-iam-authenticator binary from Amazon S3.

2. (Optional) Verify the downloaded binary with the SHA-256 sum provided in the same bucket prefix.
   a. Download the SHA-256 sum for your system.

b. Check the SHA-256 sum for your downloaded binary.

```bash
openssl sha1 -sha256 aws-iam-authenticator
```

c. Compare the generated SHA-256 sum in the command output against your downloaded `aws-iam-authenticator.sha256` file. The two should match.

3. Apply execute permissions to the binary.

```bash
chmod +x ./aws-iam-authenticator
```

4. Copy the binary to a folder in your `$PATH`. We recommend creating a `$HOME/bin/aws-iam-authenticator` and ensuring that `$HOME/bin` comes first in your `$PATH`.

```bash
mkdir -p $HOME/bin && cp ./aws-iam-authenticator $HOME/bin/aws-iam-authenticator && export PATH=$PATH:$HOME/bin
```

5. Add `$HOME/bin` to your `PATH` environment variable.

```bash
echo 'export PATH=$PATH:$HOME/bin' >> ~/.bash_profile
```

6. Test that the `aws-iam-authenticator` binary works.

```bash
aws-iam-authenticator help
```

### Linux

**To install `aws-iam-authenticator` on Linux**

1. Download the Amazon EKS vended `aws-iam-authenticator` binary from Amazon S3 for your hardware platform.

```bash
curl -o aws-iam-authenticator https://s3.us-west-2.amazonaws.com/amazon-eks/1.21.2/2021-07-05/bin/linux/amd64/aws-iam-authenticator
```

```bash
curl -o aws-iam-authenticator https://s3.us-west-2.amazonaws.com/amazon-eks/1.21.2/2021-07-05/bin/linux/arm64/aws-iam-authenticator
```

2. (Optional) Verify the downloaded binary with the SHA-256 sum provided in the same bucket prefix for your hardware platform.

a. Download the SHA-256 sum for your system.

```bash
```

```bash
```

b. Check the SHA-256 sum for your downloaded binary.

```bash
openssl sha1 -sha256 aws-iam-authenticator
```

c. Compare the generated SHA-256 sum in the command output against your downloaded `aws-iam-authenticator.sha256` file. The two should match.
3. Apply execute permissions to the binary.

```
chmod +x ./aws-iam-authenticator
```

4. Copy the binary to a folder in your $PATH. We recommend creating a $HOME/bin/aws-iam-authenticator and ensuring that $HOME/bin comes first in your $PATH.

```
mkdir -p $HOME/bin && cp ./aws-iam-authenticator $HOME/bin/aws-iam-authenticator && export PATH=$PATH:$HOME/bin
```

5. Add $HOME/bin to your PATH environment variable.

```
echo 'export PATH=$PATH:$HOME/bin' >> ~/.bashrc
```

6. Test that the aws-iam-authenticator binary works.

```
aws-iam-authenticator help
```

Windows

To install aws-iam-authenticator on Windows with Chocolatey

1. If you do not already have Chocolatey installed on your Windows system, see Installing chocolatey.
2. Open a PowerShell terminal window and install the aws-iam-authenticator package with the following command:

```
choco install -y aws-iam-authenticator
```
3. Test that the aws-iam-authenticator binary works.

```
aws-iam-authenticator help
```

To install aws-iam-authenticator on Windows

1. Open a PowerShell terminal window and download the Amazon EKS vended aws-iam-authenticator binary from Amazon S3.

```
```
2. (Optional) Verify the downloaded binary with the SHA-256 sum provided in the same bucket prefix.
   a. Download the SHA-256 sum for your system.
      
      ```
```
   b. Check the SHA-256 sum for your downloaded binary.
      
      ```
Get-FileHash aws-iam-authenticator.exe
```
   c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match, although the PowerShell output will be uppercase.
3. Copy the binary to a folder in your PATH. If you have an existing directory in your PATH that you use for command line utilities, copy the binary to that directory. Otherwise, complete the following steps.
   
a. Create a new directory for your command line binaries, such as C:\bin.
b. Copy the aws-iam-authenticator.exe binary to your new directory.
c. Edit your user or system PATH environment variable to add the new directory to your PATH.
d. Close your PowerShell terminal and open a new one to pick up the new PATH variable.

4. Test that the aws-iam-authenticator binary works.

    aws-iam-authenticator help

If you have an existing Amazon EKS cluster, create a kubeconfig file for that cluster. For more information, see Create a kubeconfig for Amazon EKS (p. 403). Otherwise, see Creating an Amazon EKS cluster (p. 24) to create a new Amazon EKS cluster.

Default Amazon EKS Kubernetes roles and users

Amazon EKS creates identities for each of the Kubernetes components in 1.20 and later clusters. The following objects have been created by the Amazon EKS team to provide RBAC permissions for the components:

Roles

- eks:authenticator
- eks:certificate-controller-approver
- eks:certificate-controller
- eks:cluster-event-watcher
- eks:fargate-scheduler
- eks:k8s-metrics
- eks:nodewatcher
- eks:pod-identity-mutating-webhook

RoleBindings

- eks:authenticator
- eks:certificate-controller-approver
- eks:certificate-controller
- eks:cluster-event-watcher
- eks:fargate-scheduler
- eks:k8s-metrics
- eks:nodewatcher
- eks:pod-identity-mutating-webhook

Users

- eks:authenticator
- eks:certificate-controller
• eks:cluster-event-watcher
• eks:fargate-scheduler
• eks:k8s-metrics
• eks:nodewatcher
• eks:pod-identity-mutating-webhook

In addition to the objects above, Amazon EKS uses a special user identity eks:cluster-bootstrap for kubectl operations during cluster bootstrap. Amazon EKS also uses a special user identity eks:support-engineer for cluster management operations. All the user identities will appear in the kube audit logs available to customers through CloudWatch.

Run kubectl describe clusterrole <rolename> to see the permissions for each role.
Cluster management

This chapter includes the following topics to help you manage your cluster. You can also view information about your nodes (p. 107) and workloads (p. 350) using the AWS Management Console.

- Tutorial: Deploy the Kubernetes Dashboard (web UI) (p. 413) – Learn how to install the dashboard, a web-based user interface for your Kubernetes cluster and applications.
- Installing the Kubernetes Metrics Server (p. 417) – The Kubernetes Metrics Server is an aggregator of resource usage data in your cluster. It is not deployed by default in your cluster, but is used by Kubernetes add-ons, such as the Kubernetes Dashboard and Horizontal Pod Autoscaler (p. 363). In this topic you learn how to install the Metrics Server.
- Control plane metrics with Prometheus (p. 418) – The Kubernetes API server exposes a number of metrics that are useful for monitoring and analysis. This topic explains how to deploy Prometheus and some of the ways that you can use it to view and analyze what your cluster is doing.
- Using Helm with Amazon EKS (p. 421) – The Helm package manager for Kubernetes helps you install and manage applications on your Kubernetes cluster. This topic helps you install and run the Helm binaries so that you can install and manage charts using the Helm CLI on your local computer.
- Tagging your Amazon EKS resources (p. 422) – To help you manage your Amazon EKS resources, you can assign your own metadata to each resource in the form of tags. This topic describes tags and shows you how to create them.
- Amazon EKS service quotas (p. 426) – Your AWS account has default quotas, formerly referred to as limits, for each AWS service. Learn about the quotas for Amazon EKS and how to increase them.

Tutorial: Deploy the Kubernetes Dashboard (web UI)

This tutorial guides you through deploying the Kubernetes Dashboard to your Amazon EKS cluster, complete with CPU and memory metrics. It also helps you to create an Amazon EKS administrator service account that you can use to securely connect to the dashboard to view and control your cluster.
Prerequisites

This tutorial assumes the following:

- You have created an Amazon EKS cluster by following the steps in Getting started with Amazon EKS (p. 4).
- You have the Kubernetes Metrics Server installed. For more information, see Installing the Kubernetes Metrics Server (p. 417).
- The security groups for your control plane elastic network interfaces and nodes follow the recommended settings in Amazon EKS security group considerations (p. 265).
- You are using a kubectl client that is configured to communicate with your Amazon EKS cluster (p. 18).

Step 1: Deploy the Kubernetes dashboard

- For Regions other than Beijing and Ningxia China, apply the Kubernetes dashboard.

  ```bash
  kubectl apply -f https://raw.githubusercontent.com/kubernetes/dashboard/v2.0.5/aio/deploy/recommended.yaml
  ```

- For the Beijing and Ningxia China Region, download, modify, and apply the Calico manifests to your cluster.

  1. Download the Kubernetes Dashboard manifest with the following command.

     ```bash
     curl -o recommended.yaml https://raw.githubusercontent.com/kubernetes/dashboard/blob/master/aio/deploy/recommended.yaml
     ```

  2. Modify the manifest files.

     a. View the manifest file or files that you downloaded and note the name of the image. Download the image locally with the following command.

        ```bash
        docker pull image:<tag>
        ```

     b. Tag the image to be pushed to an Amazon Elastic Container Registry repository in China with the following command.

        ```bash
        docker tag image:<tag> <aws_account_id>.dkr.ecr.<cn-north-1>.amazonaws.com.cn/image:<tag>
        ```

     c. Update the recommended.yaml to reference the Amazon ECR image URL in your Region.

     d. Update the recommended.yaml file to reference the Amazon ECR image repository in your Region by adding the following to the spec.

        ```bash
        registry: <aws_account_id>.dkr.ecr.<cn-north-1>.amazonaws.com.cn
        ```

     e. Apply the Kubernetes Dashboard manifest.

        ```bash
        kubectl apply -f recommended.yaml
        ```

  3. Apply the manifest to your cluster with the following command.

        ```bash
        kubectl apply -f recommended.yaml
        ```
Step 2: Create an eks-admin service account and cluster role binding

By default, the Kubernetes Dashboard user has limited permissions. In this section, you create an eks-admin service account and cluster role binding that you can use to securely connect to the dashboard with admin-level permissions. For more information, see Managing Service Accounts in the Kubernetes documentation.

To create the eks-admin service account and cluster role binding

**Important**
The example service account created with this procedure has full cluster-admin (superuser) privileges on the cluster. For more information, see Using RBAC authorization in the Kubernetes documentation.

1. Create a file called eks-admin-service-account.yaml with the text below. This manifest defines a service account and cluster role binding called eks-admin.

   ```yaml
   apiVersion: v1
   kind: ServiceAccount
   metadata:
     name: eks-admin
     namespace: kube-system

   apiVersion: rbac.authorization.k8s.io/v1beta1
   kind: ClusterRoleBinding
   metadata:
     name: eks-admin
   roleRef:
     apiGroup: rbac.authorization.k8s.io
     kind: ClusterRole
     name: cluster-admin
   subjects:
     - kind: ServiceAccount
       name: eks-admin
       namespace: kube-system
   ```

2. Apply the service account and cluster role binding to your cluster.

   ```bash
   kubectl apply -f eks-admin-service-account.yaml
   ```

   Output:
Step 3: Connect to the dashboard

Now that the Kubernetes Dashboard is deployed to your cluster, and you have an administrator service account that you can use to view and control your cluster, you can connect to the dashboard with that service account.

To connect to the Kubernetes dashboard

1. Retrieve an authentication token for the eks-admin service account. Copy the <authentication_token> value from the output. You use this token to connect to the dashboard.

   ```sh
ekubectl -n kube-system describe secret $(kubectl -n kube-system get secret | grep eks-admin | awk '{print $1}')
```

   Output:

   ```
   Name:         eks-admin-token-b5zv4
   Namespace:    kube-system
   Labels:       <none>
   Annotations:  kubernetes.io/service-account.name=eks-admin
                  kubernetes.io/service-account.uid=bcfe66ac-39be-11e8-97e8-026dce96b6e8
   Type:  kubernetes.io/service-account-token
   Data
   ====
   ca.crt:     1025 bytes
   namespace:  11 bytes
   token:      <authentication_token>
   ```

2. Start the kubectl proxy.

   ```sh
ekubectl proxy
```

   To access the dashboard endpoint, open the following link with a web browser: http://localhost:8001/api/v1/namespaces/kubernetes-dashboard/services/https:kubernetes-dashboard:/proxy/#!/login.

3. Choose Token, paste the <authentication_token> output from the previous command into the Token field, and choose SIGN IN.
After you have connected to your Kubernetes Dashboard, you can view and control your cluster using your eks-admin service account. For more information about using the dashboard, see the project documentation on GitHub.

Installing the Kubernetes Metrics Server

The Kubernetes Metrics Server is an aggregator of resource usage data in your cluster, and it is not deployed by default in Amazon EKS clusters. For more information, see Kubernetes Metrics Server on GitHub. The Metrics Server is commonly used by other Kubernetes add ons, such as the Horizontal Pod Autoscaler (p. 363) or the Kubernetes Dashboard (p. 413). For more information, see Resource metrics pipeline in the Kubernetes documentation. This topic explains how to deploy the Kubernetes Metrics Server on your Amazon EKS cluster.

**Important**
Don't use Metrics Server when you need an accurate source of resource usage metrics or as a monitoring solution.

**Deploy the Metrics Server**

1. Deploy the Metrics Server with the following command:
Prometheus metrics

1. Apply the metrics-server components to your EKS cluster:

```
kubectl apply -f https://github.com/kubernetes-sigs/metrics-server/releases/latest/download/components.yaml
```

2. Verify that the metrics-server deployment is running the desired number of pods with the following command:

```
kubectl get deployment metrics-server -n kube-system
```

Example output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>metrics-server</td>
<td>1/1</td>
<td>1</td>
<td>1</td>
<td>6m</td>
</tr>
</tbody>
</table>

Control plane metrics with Prometheus

The Kubernetes API server exposes a number of metrics that are useful for monitoring and analysis. These metrics are exposed internally through a metrics endpoint that refers to the `/metrics` HTTP API. Like other endpoints, this endpoint is exposed on the Amazon EKS control plane. This topic explains some of the ways you can use this endpoint to view and analyze what your cluster is doing.

Viewing the raw metrics

To view the raw metrics output, use `kubectl` with the `--raw` flag. This command allows you to pass any HTTP path and returns the raw response.

```
kubectl get --raw /metrics
```

Example output:

```
...  # HELP rest_client_requests_total Number of HTTP requests, partitioned by status code, method, and host.
# TYPE rest_client_requests_total counter
rst_client_requests_total{code="200",host="127.0.0.1:21362",method="POST"} 4994  # HELP ssh_tunnel_open_count Counter of ssh tunnel total open attempts
rst_client_requests_total{code="200",host="127.0.0.1:443",method="DELETE"} 1  # TYPE ssh_tunnel_open_count counter
rst_client_requests_total{code="200",host="127.0.0.1:443",method="GET"} 1.326086e+06
rst_client_requests_total{code="200",host="127.0.0.1:443",method="PUT"} 862173
rst_client_requests_total{code="404",host="127.0.0.1:443",method="GET"} 2
rst_client_requests_total{code="409",host="127.0.0.1:443",method="DELETE"} 1
rst_client_requests_total{code="409",host="127.0.0.1:443",method="GET"} 3
rst_client_requests_total{code="409",host="127.0.0.1:443",method="PUT"} 8
# HELP ssh_tunnel_open_count Counter of ssh tunnel total open attempts
# TYPE ssh_tunnel_open_count counter
ssh_tunnel_open_count 0  # HELP ssh_tunnel_open_fail_count Counter of ssh tunnel failed open attempts
# TYPE ssh_tunnel_open_fail_count counter
ssh_tunnel_open_fail_count 0  # HELP rest_client_requests_total Number of HTTP requests, partitioned by status code, method, and host.
```

This raw output returns verbatim what the API server exposes. These metrics are represented in a Prometheus format. This format allows the API server to expose different metrics broken down by line. Each line includes a metric name, tags, and a value.
While this endpoint is useful if you are looking for a specific metric, you typically want to analyze these metrics over time. To do this, you can deploy Prometheus into your cluster. Prometheus is a monitoring and time series database that scrapes exposed endpoints and aggregates data, allowing you to filter, graph, and query the results.

## Deploying Prometheus

This topic helps you deploy Prometheus into your cluster with Helm V3. If you already have Helm installed, you can check your version with the `helm version` command. Helm is a package manager for Kubernetes clusters. For more information about Helm and how to install it, see Using Helm with Amazon EKS (p. 421).

After you configure Helm for your Amazon EKS cluster, you can use it to deploy Prometheus with the following steps.

### To deploy Prometheus using Helm

1. Create a Prometheus namespace.
   
   ```bash
   kubectl create namespace prometheus
   ```

2. Add the prometheus-community chart repository.
   
   ```bash
   helm repo add prometheus-community https://prometheus-community.github.io/helm-charts
   ```

3. Deploy Prometheus.
   
   ```bash
   helm upgrade -i prometheus prometheus-community/prometheus \
   --namespace prometheus \
   --set
   alertmanager.persistentVolume.storageClass="gp2",server.persistentVolume.storageClass="gp2"
   ```

   **Note**
   If you get the error `Error: failed to download "stable/prometheus" (hint: running `helm repo update` may help)` when executing this command, run `helm repo update`, and then try running the Step 2 command again.
   If you get the error `Error: rendered manifests contain a resource that already exists`, run `helm uninstall your-release-name -n namespace`, then try running the Step 3 command again.

4. Verify that all of the pods in the `prometheus` namespace are in the `READY` state.
   
   ```bash
   kubectl get pods -n prometheus
   ```

   Output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>prometheus-alertmanager-59b4c8c744-r7bgp</td>
<td>1/2</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-kube-state-metrics-7cfd87cf99-jkz2f</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-node-exporter-jcjqz</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-node-exporter-jxv2h</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-node-exporter-vbdks</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-pushgateway-76c444b68c-82tnw</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-server-775957f748-mmht9</td>
<td>1/2</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
</tbody>
</table>

5. Use `kubectl` to port forward the Prometheus console to your local machine.
6. Point a web browser to `localhost:9090` to view the Prometheus console.
7. Choose a metric from the `- insert metric at cursor` menu, then choose **Execute**. Choose the **Graph** tab to show the metric over time. The following image shows `container_memory_usage_bytes` over time.

8. From the top navigation bar, choose **Status**, then **Targets**.
All of the Kubernetes endpoints that are connected to Prometheus using service discovery are displayed.

Store your Prometheus metrics in Amazon Managed Service for Prometheus

Amazon Managed Service for Prometheus is a Prometheus-compatible monitoring and alerting service that makes it easy to monitor containerized applications and infrastructure at scale. It is a fully-managed service that automatically scales the ingestion, storage, querying, and alerting of your metrics. It also integrates with AWS security services to enable fast and secure access to your data. You can use the open-source PromQL query language to query your metrics and alert on them.

For more information, see Getting started with Amazon Managed Service for Prometheus.

Using Helm with Amazon EKS

The Helm package manager for Kubernetes helps you install and manage applications on your Kubernetes cluster. For more information, see the Helm documentation. This topic helps you install and run the Helm binaries so that you can install and manage charts using the Helm CLI on your local system.

Important
Before you can install Helm charts on your Amazon EKS cluster, you must configure kubectl to work for Amazon EKS. If you have not already done this, see Create a kubect1 config for Amazon EKS (p. 403) before proceeding. If the following command succeeds for your cluster, you're properly configured.

kubectl get svc
To install the Helm binaries on your local system

1. Run the appropriate command for your client operating system.
   - If you're using macOS with Homebrew, install the binaries with the following command.
     
     ```
     brew install helm
     ```
   - If you're using Windows with Chocolatey, install the binaries with the following command.
     
     ```
     choco install kubernetes-helm
     ```
   - If you're using Linux, install the binaries with the following commands.
     
     ```
     get_helm.sh
     chmod 700 get_helm.sh
     ./get_helm.sh
     ```

     **Note**
     If you get a message that `openssl` must first be installed, one method to install it would be:
     
     ```
     sudo yum install openssl
     ```

2. To pick up the new binary in your `PATH`, Close your current terminal window and open a new one.
3. Confirm that Helm is running with the following command.
   
   ```
   helm help
   ```

4. At this point, you can run any Helm commands (such as `helm install <chart_name>`) to install, modify, delete, or query Helm charts in your cluster. If you're new to Helm and don't have a specific chart to install, you can:
   - Experiment by installing an example chart. See Install an example chart in the Helm Quickstart guide.
   - Create an example chart and push it to Amazon ECR. For more information, see Pushing a Helm chart in the Amazon Elastic Container Registry User Guide.
   - Install an Amazon EKS chart from the eks-charts GitHub repo or from ArtifactHub.

Tagging your Amazon EKS resources

To help you manage your Amazon EKS resources, you can assign your own metadata to each resource using tags. This topic provides an overview of the tags function and shows how you can create tags.

Contents

- Tag basics (p. 423)
- Tagging your resources (p. 423)
- Tag restrictions (p. 424)
- Working with tags using the console (p. 424)
- Working with tags using the CLI, API, or eksctl (p. 425)
Tag basics

A tag is a label that you assign to an AWS resource. Each tag consists of a key and an optional value, both of which you define.

Tags enable you to categorize your AWS resources by, for example, purpose, owner, or environment. When you have many resources of the same type, you can quickly identify a specific resource based on the tags you've assigned to it. For example, you can define a set of tags for your Amazon EKS clusters to help you track each cluster's owner and stack level. We recommend that you devise a consistent set of tag keys for each resource type. You can then search and filter the resources based on the tags that you add.

Tags are not automatically assigned to your resources. After you add a tag, you can edit tag keys and values or remove tags from a resource at any time. If you delete a resource, any tags for the resource are also deleted.

Tags don't have any semantic meaning to Amazon EKS and are interpreted strictly as a string of characters. You can set the value of a tag to an empty string, but you can't set the value of a tag to null. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the earlier value.

You can tag new or existing cluster resources using the AWS Management Console, the AWS CLI, or the Amazon EKS API. You can tag only new cluster resources using eksctl.

If you use AWS Identity and Access Management (IAM), you can control which users in your AWS account have permission to manage tags.

Tagging your resources

You can tag new or existing Amazon EKS clusters and managed node groups.

If you're using the Amazon EKS console, then you can apply tags to new or existing resources at any time. You can do this by using the Tags tab on the relevant resource page. If you're using eksctl, then you can apply tags to resources when they are created using the --tags option.

If you're using the Amazon EKS API, the AWS CLI, or an AWS SDK, you can apply tags to new resources using the tags parameter on the relevant API action. You can apply tags to existing resources using the TagResource API action. For more information, see TagResource.

Some resource-creating actions enable you to specify tags for a resource when the resource is created. If tags cannot be applied while a resource is being created, the resource fails to be created. This mechanism ensures that resources you intended to tag on creation are either created with specified tags or not created at all. If you tag resources at the time of creation, you don't need to run custom tagging scripts after creating a resource.

The following table describes the Amazon EKS resources that can be tagged and the resources that can be tagged on creation.

Tagging support for Amazon EKS resources

<table>
<thead>
<tr>
<th>Resource</th>
<th>Supports tags</th>
<th>Supports tag propagation</th>
<th>Supports tagging on creation (Amazon EKS API, AWS CLI, AWS SDK, and eksctl)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon EKS clusters</td>
<td>Yes</td>
<td>No. Cluster tags do not propagate to any other</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Amazon EKS User Guide
Tag restrictions

<table>
<thead>
<tr>
<th>Resource</th>
<th>Supports tags</th>

</thead>
<tbody>
<tr>
<td>Amazon EKS managed node groups</td>
<td>Yes</td>
<td>No. Managed node group tags do not propagate to any other resources associated with the node group.</td>
<td>Yes</td>
</tr>
<tr>
<td>Amazon EKS Fargate profiles</td>
<td>Yes</td>
<td>No. Fargate profile tags do not propagate to any other resources associated with the Fargate profile, such as the pods that are scheduled with it.</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Tag restrictions**

The following basic restrictions apply to tags:

- Maximum number of tags per resource – 50
- For each resource, each tag key must be unique, and each tag key can have only one value.
- Maximum key length – 128 Unicode characters in UTF-8
- Maximum value length – 256 Unicode characters in UTF-8
- If your tagging schema is used across multiple AWS services and resources, remember that other services may have restrictions on allowed characters. Generally allowed characters are letters, numbers, spaces representable in UTF-8, and the following characters: + - = . _ : / @.
- Tag keys and values are case sensitive.
- Don't use `aws:`, `AWS:`, or any upper or lowercase combination of such as a prefix for either keys or values. These are reserved only for AWS use. You can't edit or delete tag keys or values with this prefix. Tags with this prefix do not count against your tags-per-resource limit.

**Working with tags using the console**

Using the Amazon EKS console, you can manage the tags associated with new or existing clusters and managed node groups.

When you select a resource-specific page in the Amazon EKS console, it displays a list of those resources. For example, if you select Amazon EKS Clusters from the left navigation pane, the console displays a list of Amazon EKS clusters. When you select a resource from one of these lists (for example, a specific cluster) that supports tags, you can view and manage its tags on the Tags tab.

**Adding tags on an individual resource on creation**

You can add tags to Amazon EKS clusters, managed node groups, and Fargate profiles when you create them. For more information, see Creating an Amazon EKS cluster (p. 24).
Adding and deleting tags on an individual resource

Amazon EKS allows you to add or delete tags associated with your clusters directly from the resource's page.

To add or delete a tag on an individual resource

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. From the navigation bar, select the Region to use.
3. In the left navigation pane, choose Amazon EKS Clusters.
5. On the Update tags page, add or delete your tags as necessary.
   - To add a tag — choose Add tag and then specify the key and value for each tag.
   - To delete a tag — choose Remove tag.
6. Repeat this process for each tag you want to add or delete, and then choose Update to finish.

Working with tags using the CLI, API, or eksctl

Use the following AWS CLI commands or Amazon EKS API operations to add, update, list, and delete the tags for your resources. You can only use eksctl to add tags to new resources.

Tagging support for Amazon EKS resources

<table>
<thead>
<tr>
<th>Task</th>
<th>AWS CLI</th>
<th>AWS Tools for Windows PowerShell</th>
<th>API action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add or overwrite one or more tags.</td>
<td>tag-resource</td>
<td>Add-EKSResourceTag</td>
<td>TagResource</td>
</tr>
<tr>
<td>Delete one or more tags.</td>
<td>untag-resource</td>
<td>Remove-EKSResourceTag</td>
<td>UntagResource</td>
</tr>
</tbody>
</table>

The following examples show how to tag or untag resources using the AWS CLI.

Example 1: Tag an existing cluster

The following command tags an existing cluster.

```
aws eks tag-resource --resource-arn <resource_ARN> --tags <team>=<devs>
```

Example 2: Untag an existing cluster

The following command deletes a tag from an existing cluster.

```
aws eks untag-resource --resource-arn <resource_ARN> --tag-keys <tag_key>
```

Example 3: List tags for a resource

The following command lists the tags associated with an existing resource.

```
aws eks list-tags-for-resource --resource-arn <resource_ARN>
```
Some resource-creating actions enable you to specify tags when you create the resource. The following actions support tagging when creating a resource.

<table>
<thead>
<tr>
<th>Task</th>
<th>AWS CLI</th>
<th>AWS Tools for Windows PowerShell</th>
<th>API action</th>
<th>eksctl</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a cluster</td>
<td>create-cluster</td>
<td>New-EKSCluster</td>
<td>CreateCluster</td>
<td>create cluster</td>
</tr>
<tr>
<td>Create a managed node group*</td>
<td>create-nodegroup</td>
<td>New-EKSNodegroup</td>
<td>CreateNodegroup</td>
<td>create nodegroup</td>
</tr>
<tr>
<td>Create a Fargate profile</td>
<td>create-fargate-profile</td>
<td>New-EKSFargateProfile</td>
<td>CreateFargateprofile</td>
<td>create fargateprofile</td>
</tr>
</tbody>
</table>

*If you want to also tag the Amazon EC2 instances when creating a managed node group, create the managed node group using a launch template. For more information, see Tagging Amazon EC2 instances (p. 126). If your instances already exist, you can manually tag the instances. For more information, see Tagging your resources in the Amazon EC2 User Guide for Linux Instances.

Amazon EKS service quotas

Amazon EKS has integrated with Service Quotas, an AWS service that enables you to view and manage your quotas from a central location. For more information, see What Is Service Quotas? in the Service Quotas User Guide. Service Quotas makes it easy to look up the value of your Amazon EKS and AWS Fargate service quotas using the AWS Management Console and AWS CLI.

AWS Management Console

To view Amazon EKS and Fargate service quotas using the AWS Management Console

2. In the left navigation pane, choose AWS services.
3. From the AWS services list, search for and select Amazon Elastic Kubernetes Service (Amazon EKS) or AWS Fargate.

   In the Service quotas list, you can see the service quota name, applied value (if it is available), AWS default quota, and whether the quota value is adjustable.
4. To view additional information about a service quota, such as the description, choose the quota name.
5. (Optional) To request a quota increase, select the quota that you want to increase, select Request quota increase, enter or select the required information, and select Request.

To work more with service quotas using the AWS Management Console see the Service Quotas User Guide. To request a quota increase, see Requesting a Quota Increase in the Service Quotas User Guide.

AWS CLI

To view Amazon EKS and Fargate service quotas using the AWS CLI

Run the following command to view your Amazon EKS quotas.

```bash
aws service-quotas list-aws-default-service-quotas
```
Run the following command to view your Fargate quotas.

```bash
aws service-quotas list-aws-default-service-quotas
--query 'Quotas[*].{Adjustable:Adjustable,Name:QuotaName,Value:Value,Code:QuotaCode}'
--service-code fargate
--output table
```

**Note**

The quota returned is the maximum number of Amazon ECS tasks or Amazon EKS pods running concurrently on Fargate in this account in the current AWS Region.

To work more with service quotas using the AWS CLI, see the Service Quotas AWS CLI Command Reference. To request a quota increase, see the `request-service-quota-increase` command in the AWS CLI Command Reference.

## Service quotas

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clusters</td>
<td>Each supported Region: 100</td>
<td>Yes</td>
<td>The maximum number of EKS clusters in this account in the current Region.</td>
</tr>
<tr>
<td>Control plane security groups per cluster</td>
<td>Each supported Region: 4</td>
<td>No</td>
<td>The maximum number of control plane security groups per cluster (these are specified when you create the cluster).</td>
</tr>
<tr>
<td>Fargate profiles per cluster</td>
<td>Each supported Region: 10</td>
<td>Yes</td>
<td>The maximum number of Fargate profiles per cluster.</td>
</tr>
<tr>
<td>Label pairs per Fargate profile selector</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
<td>The maximum number of label pairs per Fargate profile selector.</td>

</tr>
</thead>
<tbody>
<tr>
<td>Fargate On-Demand resource count</td>
<td>The maximum number of Amazon ECS tasks and Amazon EKS pods running concurrently on Fargate in this account in the current AWS Region.</td>
<td>1,000</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Security in Amazon EKS

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. For Amazon EKS, AWS is responsible for the Kubernetes control plane, which includes the control plane nodes and etcd database. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon EKS, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility includes the following areas.
  - The security configuration of the data plane, including the configuration of the security groups that allow traffic to pass from the Amazon EKS control plane into the customer VPC
  - The configuration of the nodes and the containers themselves
  - The node's operating system (including updates and security patches)
  - Other associated application software:
    - Setting up and managing network controls, such as firewall rules
    - Managing platform-level identity and access management, either with or in addition to IAM
    - The sensitivity of your data, your company's requirements, and applicable laws and regulations

This documentation helps you understand how to apply the shared responsibility model when using Amazon EKS. The following topics show you how to configure Amazon EKS to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Amazon EKS resources.

**Note**

Linux containers are made up of control groups (cgroups) and namespaces that help limit what a container can access, but all containers share the same Linux kernel as the host Amazon EC2 instance. Running a container as the root user (UID 0) or granting a container access to host resources or namespaces such as the host network or host PID namespace are strongly discouraged, because doing so reduces the effectiveness of the isolation that containers provide.

- Amazon EKS Connector considerations (p. 495)
Certificate signing

The Kubernetes Certificates API enables automation of X.509 credential provisioning. It features a command line interface for Kubernetes API clients to request and obtain X.509 certificates from a Certificate Authority (CA). A CertificateSigningRequest (CSR) resource is used to request that a denoted signer sign the certificate. Then, the request is either approved or denied before it's signed. Kubernetes supports both build-in signers and custom signers with well-defined behaviors. This way, clients can predict what happens to their CSRs. To learn more about certificate signing, see signing requests.

One of the built-in signers is kubernetes.io/legacy-unknown. The v1beta1 API of CSR resource honored this legacy-unknown signer. However, the stable v1 API of CSR doesn't allow the signerName to be set to kubernetes.io/legacy-unknown.

Amazon EKS version 1.21 and earlier versions allowed the value legacy-unknown as the signerName in v1beta1 CSR API. This API enables the Amazon EKS Certificate Authority (CA) to generate certificates. However, in Kubernetes version 1.22, the v1beta1 CSR API is replaced by the v1 CSR API. This API doesn't support the signerName of “legacy-unknown.” Given this, if you want to use Amazon EKS CA for generating certificates on version 1.22 and later, you need to use a custom signer. It was introduced in Amazon EKS version 1.22. To use the CSR v1 API version and generate a new certificate, you must migrate any existing manifests and API clients. Existing certificates that were created with the older v1beta1 API are valid and function until the certificate expires. This includes the following:

1. Trust distribution: None. There’s no standard trust or distribution for this signer in a Kubernetes cluster.
2. Permitted subjects: Any
3. Permitted x509 extensions: Honors subjectAltName and key usage extensions and discards other extensions
4. Permitted key usages: Must not include usages beyond ["key encipherment", "digital signature", "server auth"]
5. Expiration/certificate lifetime: 1 year (default and maximum)
6. CA bit allowed/disallowed: Not allowed

Example CSR generation with signerName

These steps shows how to generate a serving certificate for DNS name myserver.default.svc using signerName: beta.eks.amazonaws.com/app-serving. Use this as a guide for your own environment.

1. Run the openssl genrsa -out myserver.key 2048 command to generate an RSA private key.

   ```bash
   openssl genrsa -out myserver.key 2048
   ```

2. Run the following command to generate a certificate request.

   ```bash
   openssl req -new -key myserver.key -out myserver.csr -subj "/CN=myserver.default.svc"
   ```

3. Run the cat myserver.csr | base64 -w 0 # command to generate a base64 value for the CSR request. Later, use this value for the request value in your CSR.

   ```bash
   cat myserver.csr | base64 -w 0 | tr -d "\n"
   ```

4. Create a CertificateSigningRequest YAML file. In the following example, beta.eks.amazonaws.com/app-serving is the signerName.
Identity and access management

### Identity and access management for Amazon EKS

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Amazon EKS resources. IAM is an AWS service that you can use with no additional charge.

### Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in Amazon EKS.

---

```yaml
apiVersion: certificates.k8s.io/v1
kind: CertificateSigningRequest
metadata:
  name: myserver
spec:
  request: [your-base64-value]
  signerName: beta.eks.amazonaws.com/app-serving
  usages:
  - digital signature
  - key encipherment
  - server auth

5. Run the `kubectl apply -f myserver.yaml` command to submit the CSR.

```kubectl apply -f myserver.yaml```

6. Run the `kubectl certificate approve myserver` command to approve the serving certificate.

```kubectl certificate approve myserver```

7. Run the `kubectl get csr myserver` command verify that the certificate has been issued.

The output is as follows.

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>SIGNERNAME</th>
<th>REQUESTOR</th>
<th>REQUESTEDDURATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>myserver</td>
<td>96s</td>
<td>beta.eks.amazonaws.com/app-serving</td>
<td>kubernetes-admin</td>
<td>&lt;none&gt;</td>
</tr>
</tbody>
</table>

8. Run the following command to verify that a certificate has been issued:

```kubectl get csr myserver -o jsonpath='{.status.certificate}'| base64 -d > myserver.crt```

Example output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>SIGNERNAME</th>
<th>REQUESTOR</th>
<th>REQUESTEDDURATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>myserver</td>
<td>96s</td>
<td>beta.eks.amazonaws.com/app-serving</td>
<td>kubernetes-admin</td>
<td>&lt;none&gt;</td>
</tr>
</tbody>
</table>

9. Export the issued certificate to the signed certificate `myserver.crt`.

```kubectl get csr myserver -o jsonpath='{.status.certificate}'| base64 -d > myserver.crt```

---

431
Service user – If you use the Amazon EKS service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Amazon EKS features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon EKS, see Troubleshooting Amazon EKS identity and access (p. 489).

Service administrator – If you’re in charge of Amazon EKS resources at your company, you probably have full access to Amazon EKS. It’s your job to determine which Amazon EKS features and resources your employees should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Amazon EKS, see How Amazon EKS works with IAM (p. 435).

IAM administrator – If you’re an IAM administrator, you might want to learn details about how you can write policies to manage access to Amazon EKS. To view example Amazon EKS identity-based policies that you can use in IAM, see Amazon EKS identity-based policy examples (p. 438).

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. For more information about signing in using the AWS Management Console, see Signing in to the AWS Management Console as an IAM user or root user in the IAM User Guide.

You must be authenticated (signed in to AWS) as the AWS account root user, an IAM user, or by assuming an IAM role. You can also use your company’s single sign-on authentication or even sign in using Google or Facebook. In these cases, your administrator previously set up identity federation using IAM roles. When you access AWS using credentials from another company, you are assuming a role indirectly.

To sign in directly to the AWS Management Console, use your password with your root user email address or your IAM user name. You can access AWS programmatically using your root user or IAM users access keys. AWS provides SDK and command line tools to cryptographically sign your request using your credentials. If you don’t use AWS tools, you must sign the request yourself. Do this using Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 signing process in the AWS General Reference.

Regardless of the authentication method that you use, you might also be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

AWS account root user

When you first create an AWS account, you begin with a single sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you do not use the root user for your everyday tasks, even the administrative ones. Instead, adhere to the best practice of using the root user only to create your first IAM user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks.

IAM users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. An IAM user can have long-term credentials such as a user name and password or a set of access keys. To learn how to generate access keys, see Managing access keys for IAM users in the IAM User Guide. When you generate access keys for an IAM user, make sure you view and securely save the key pair. You cannot recover the secret access key in the future. Instead, you must generate a new access key pair.
An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary IAM user permissions** – An IAM user can assume an IAM role to temporarily take on different permissions for a specific task.

- **Federated user access** – Instead of creating an IAM user, you can use existing identities from AWS Directory Service, your enterprise user directory, or a web identity provider. These are known as federated users. AWS assigns a role to a federated user when access is requested through an identity provider. For more information about federated users, see Federated users and roles in the IAM User Guide.

- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.

- **Principal permissions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see Actions, Resources, and Condition Keys for Amazon Elastic Kubernetes Service in the Service Authorization Reference.

- **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.
Managing access using policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. You can sign in as the root user or an IAM user, or you can assume an IAM role. When you then make a request, AWS evaluates the related identity-based or resource-based policies. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

Every IAM entity (user or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the iam:GetRole action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

Identity-based policies can be further categorized as inline policies or managed policies. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the IAM User Guide.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

Access control lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.
Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the Amazon Simple Storage Service Developer Guide.

Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the IAM User Guide.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the AWS Organizations User Guide.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the IAM User Guide.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the IAM User Guide.

How Amazon EKS works with IAM

Before you use IAM to manage access to Amazon EKS, you should understand what IAM features are available to use with Amazon EKS. To get a high-level view of how Amazon EKS and other AWS services work with IAM, see AWS services that work with IAM in the IAM User Guide.

Topics

- Amazon EKS identity-based policies (p. 435)
- Amazon EKS resource-based policies (p. 437)
- Authorization based on Amazon EKS tags (p. 437)
- Amazon EKS IAM roles (p. 438)

Amazon EKS identity-based policies

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. Amazon EKS supports specific actions, resources, and condition keys. To learn about all of the elements that you use in a JSON policy, see IAM JSON policy elements reference in the IAM User Guide.
Actions

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as permission-only actions that don’t have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called dependent actions.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Amazon EKS use the following prefix before the action: eks:. For example, to grant someone permission to get descriptive information about an Amazon EKS cluster, you include the DescribeCluster action in their policy. Policy statements must include either an Action or NotAction element.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": ["eks:<action1>", "eks:<action2>"
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action:

```
"Action": "eks:Describe*"
```

To see a list of Amazon EKS actions, see Actions Defined by Amazon Elastic Kubernetes Service in the Service Authorization Reference.

Resources

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as resource-level permissions.

For actions that don’t support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*
```

The Amazon EKS cluster resource has the following ARN:

```
arn:#{Partition}:eks:#{Region}:#{Account}:cluster/#{ClusterName}
```

For more information about the format of ARNs, see Amazon resource names (ARNs) and AWS service namespaces.

For example, to specify the dev cluster in your statement, use the following ARN:

```
"Resource": "arn:aws:eks:<region-code>:123456789012:cluster/dev"
```
To specify all clusters that belong to a specific account and AWS Region, use the wildcard (*):

```
```

Some Amazon EKS actions, such as those for creating resources, cannot be performed on a specific resource. In those cases, you must use the wildcard (*):

```
"Resource": "*
```

To see a list of Amazon EKS resource types and their ARNs, see Resources Defined by Amazon Elastic Kubernetes Service in the Service Authorization Reference. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon Elastic Kubernetes Service.

**Condition keys**

Amazon EKS defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS Global Condition Context Keys in the IAM User Guide.

You can set condition keys when associating an OpenID Connect provider to your cluster. For more information, see Example IAM policy (p. 402).

All Amazon EC2 actions support the `aws:RequestedRegion` and `ec2:Region` condition keys. For more information, see Example: Restricting Access to a Specific AWS Region.

For a list of Amazon EKS condition keys, see Condition Keys for Amazon Elastic Kubernetes Service in the Service Authorization Reference. To learn which actions and resources you can use a condition key with, see Actions Defined by Amazon Elastic Kubernetes Service.

**Examples**

To view examples of Amazon EKS identity-based policies, see Amazon EKS identity-based policy examples (p. 438).

When you create an Amazon EKS cluster, the AWS Identity and Access Management (IAM) entity user or role, such as a federated user that creates the cluster, is automatically granted `system:masters` permissions in the cluster's role-based access control (RBAC) configuration in the Amazon EKS control plane. This IAM entity doesn't appear in any visible configuration, so make sure to keep track of which IAM entity originally created the cluster. To grant additional AWS users or roles the ability to interact with your cluster, you must edit the `aws-auth` ConfigMap within Kubernetes and create a Kubernetes rolebinding or clusterrolebinding with the name of a group that you specify in the `aws-auth` ConfigMap.

For additional information about working with the ConfigMap, see Enabling IAM user and role access to your cluster (p. 395).

**Amazon EKS resource-based policies**

Amazon EKS does not support resource-based policies.

**Authorization based on Amazon EKS tags**

You can attach tags to Amazon EKS resources or pass tags in a request to Amazon EKS. To control access based on tags, you provide tag information in the condition element of a policy using the `eks:ResourceTag/<key-name>`, `aws:RequestTag/<key-name>`, or `aws:TagKeys` condition keys. For more information about tagging Amazon EKS resources, see Tagging your Amazon EKS resources (p. 422).
Amazon EKS IAM roles

An IAM role is an entity within your AWS account that has specific permissions.

Using temporary credentials with Amazon EKS

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling AWS STS API operations such as AssumeRole or GetFederationToken.

Amazon EKS supports using temporary credentials.

Service-linked roles

Service-linked roles allow AWS services to access resources in other services to complete an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view but not edit the permissions for service-linked roles.

Amazon EKS supports service-linked roles. For details about creating or managing Amazon EKS service-linked roles, see Using service-linked roles for Amazon EKS (p. 442).

Service roles

This feature allows a service to assume a service role on your behalf. This role allows the service to access resources in other services to complete an action on your behalf. Service roles appear in your IAM account and are owned by the account. This means that an IAM administrator can change the permissions for this role. However, doing so might break the functionality of the service.

Amazon EKS supports service roles. For more information, see Amazon EKS cluster IAM role (p. 450) and Amazon EKS node IAM role (p. 452).

Choosing an IAM role in Amazon EKS

When you create a cluster resource in Amazon EKS, you must choose a role to allow Amazon EKS to access several other AWS resources on your behalf. If you have previously created a service role, then Amazon EKS provides you with a list of roles to choose from. It’s important to choose a role that has the Amazon EKS managed policies attached to it. For more information, see Check for an existing cluster role (p. 450) and Check for an existing node role (p. 452).

Amazon EKS identity-based policy examples

By default, IAM users and roles don’t have permission to create or modify Amazon EKS resources. They also can’t perform tasks using the AWS Management Console, AWS CLI, or AWS API. An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating policies on the JSON tab in the IAM User Guide.

When you create an Amazon EKS cluster, the AWS Identity and Access Management (IAM) entity user or role, such as a federated user that creates the cluster, is automatically granted system:masters permissions in the cluster’s role-based access control (RBAC) configuration in the Amazon EKS control plane. This IAM entity doesn’t appear in any visible configuration, so make sure to keep track of which IAM entity originally created the cluster. To grant additional AWS users or roles the ability to interact with your cluster, you must edit the aws-auth ConfigMap within Kubernetes and create a Kubernetes rolebinding or clusterrolebinding with the name of a group that you specify in the aws-auth ConfigMap.
For additional information about working with the ConfigMap, see Enabling IAM user and role access to your cluster (p. 395).

Topics
• Policy best practices (p. 439)
• Using the Amazon EKS console (p. 439)
• View nodes and workloads for all clusters in the AWS Management Console (p. 440)
• Allow users to view their own permissions (p. 441)
• Update a Kubernetes cluster (p. 442)
• List or describe all clusters (p. 442)

Policy best practices

Identity-based policies are very powerful. They determine whether someone can create, access, or delete Amazon EKS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

• Get started using AWS managed policies – To start using Amazon EKS quickly, use AWS managed policies to give your employees the permissions they need. These policies are already available in your account and are maintained and updated by AWS. For more information, see Get started using permissions with AWS managed policies in the IAM User Guide.

• Grant least privilege – When you create custom policies, grant only the permissions required to perform a task. Start with a minimum set of permissions and grant additional permissions as necessary. Doing so is more secure than starting with permissions that are too lenient and then trying to tighten them later. For more information, see Grant least privilege in the IAM User Guide.

• Enable MFA for sensitive operations – For extra security, require IAM users to use multi-factor authentication (MFA) to access sensitive resources or API operations. For more information, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

• Use policy conditions for extra security – To the extent that it’s practical, define the conditions under which your identity-based policies allow access to a resource. For example, you can write conditions to specify a range of allowable IP addresses that a request must come from. You can also write conditions to allow requests only within a specified date or time range, or to require the use of SSL or MFA. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

Using the Amazon EKS console

To access the Amazon EKS console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon EKS resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won’t function as intended for entities (IAM users or roles) with that policy.

Important
If you see an Error loading Namespaces error in the console, or don’t see anything on the Overview or Workloads tabs, see Can't see workloads or nodes and receive an error in the AWS Management Console (p. 516) to resolve the issue. If you don’t resolve the issue, you can still view and manage aspects of your Amazon EKS cluster on the Configuration tab.

To ensure that those entities can still use the Amazon EKS console, create a policy with your own unique name, such as AmazonEKSAdminPolicy. Attach the policy to the entities. For more information, see Adding permissions to a user in the IAM User Guide.

Important
The following example policy will allow you to view information on the Configuration tab in the console. To view information on the Nodes and Workloads in the AWS Management Console,
Identity-based policy examples

you need additional IAM permissions, as well as Kubernetes permissions. For more information, see the View nodes and workloads for all clusters in the AWS Management Console (p. 440) example policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [ "eks:*" ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [ "iam:PassRole", "**" ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "iam:PassedToService": "eks.amazonaws.com"
        }
      }
    }
  ]
}
```

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

**View nodes and workloads for all clusters in the AWS Management Console**

This example shows how you can create a policy that allows a user to View nodes (p. 107) and View workloads (p. 350) for all clusters.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

**Important**
The policy must be attached to a user or role that is mapped to a Kubernetes user or group in the aws-auth configmap. The user or group must be a subject in a rolebinding or
clusterrolebinding that is bound to a Kubernetes role or clusterrole that has the necessary permissions to view the Kubernetes resources. For more information about adding IAM users or roles to the aws-auth configmap, see Enabling IAM user and role access to your cluster (p. 395). To create roles and role bindings, see Using RBAC Authorization in the Kubernetes documentation. You can download the following example manifests that create a clusterrole and clusterrolebinding or a role and rolebinding:

- **View Kubernetes resources in all namespaces** – The group name in the file is eks-console-dashboard-full-access-group, which is the group that your IAM user or role needs to be mapped to in the aws-auth configmap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the ConfigMap. To download the file, run the following command.

  ```bash
curl -o eks-console-full-access.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-full-access.yaml
  
  curl -o eks-console-restricted-access.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-restricted-access.yaml
  ```

- **View Kubernetes resources in a specific namespace** – The namespace in this file is default, so if you want to specify a different namespace, edit the file before applying it to your cluster. The group name in the file is eks-console-dashboard-restricted-access-group, which is the group that your IAM user or role needs to be mapped to in the aws-auth ConfigMap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the configmap. To download the file, run the following command.

  ```bash
curl -o eks-console-restricted-access.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/eks-console-restricted-access.yaml
  ```

### Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies"
            ]
        }
    ]
}
```
Using service-linked roles

Amazon Elastic Kubernetes Service uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.

Topics

- Using roles for Amazon EKS clusters (p. 443)
- Using roles for Amazon EKS node groups (p. 444)
- Using roles for Amazon EKS Fargate profiles (p. 446)
- Using roles to connect a Kubernetes cluster to Amazon EKS (p. 448)
Using roles for Amazon EKS clusters

Amazon Elastic Kubernetes Service uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon EKS easier because you don't have to manually add the necessary permissions. Amazon EKS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon EKS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Amazon EKS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-linked role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-Linked Role Permissions for Amazon EKS

Amazon EKS uses the service-linked role named AWSServiceRoleForAmazonEKS – The role allows Amazon EKS to manage clusters in your account. The attached policies allow the role to manage the following resources: network interfaces, security groups, logs, and VPCs.

**Note**
The AWSServiceRoleForAmazonEKS service-linked role is distinct from the role required for cluster creation. For more information, see Amazon EKS cluster IAM role (p. 450).

The AWSServiceRoleForAmazonEKS service-linked role trusts the following services to assume the role:

- eks.amazonaws.com

The role permissions policy allows Amazon EKS to complete the following actions on the specified resources:

- AmazonEKSServiceRolePolicy

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the IAM User Guide.

Creating a Service-Linked Role for Amazon EKS

You don't need to manually create a service-linked role. When you create a cluster in the AWS Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a cluster, Amazon EKS creates the service-linked role for you again.

Editing a service-linked role for Amazon EKS

Amazon EKS does not allow you to edit the AWSServiceRoleForAmazonEKS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might
reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting a service-linked role for Amazon EKS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can manually delete it.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first delete any resources used by the role.

Note

If the Amazon EKS service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete Amazon EKS resources used by the AWSServiceRoleForAmazonEKS role.

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Amazon EKS Clusters.
3. If your cluster has any node groups or Fargate profiles, you must delete them before you can delete the cluster. For more information, see Deleting a managed node group (p. 130) and Deleting a Fargate profile (p. 159).
4. On the Clusters page, choose the cluster that you want to delete and choose Delete.
5. Type the name of the cluster in the deletion confirmation window, and then choose Delete.
6. Repeat this procedure for any other clusters in your account. Wait for all of the delete operations to finish.

Manually delete the service-linked role

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForAmazonEKS service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.

Supported regions for Amazon EKS service-linked roles

Amazon EKS supports using service-linked roles in all of the regions where the service is available. For more information, see Amazon EKS Service Endpoints and Quotas.

Using roles for Amazon EKS node groups

Amazon EKS uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon EKS easier because you don't have to manually add the necessary permissions. Amazon EKS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon EKS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Amazon EKS resources because you can't inadvertently remove permission to access the resources.
For information about other services that support service-linked roles, see AWS services that work with
IAM and look for the services that have Yes in the Service-linked role column. Choose a Yes with a link
to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon EKS

Amazon EKS uses the service-linked role named AWSServiceRoleForAmazonEKSNodegroup – The
role allows Amazon EKS to manage node groups in your account. The attached policies allow the role
to manage the following resources: Auto Scaling groups, security groups, launch templates and IAM
instance profiles.

The AWSServiceRoleForAmazonEKSNodegroup service-linked role trusts the following services to
assume the role:

- eks-nodegroup.amazonaws.com

The role permissions policy allows Amazon EKS to complete the following actions on the specified
resources:

- AWSServiceRoleForAmazonEKSNodegroup

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or
delete a service-linked role. For more information, see Service-Linked Role Permissions in the IAM User
Guide.

Creating a service-linked role for Amazon EKS

You don't need to manually create a service-linked role. When you CreateNodegroup in the AWS
Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.

Important

This service-linked role can appear in your account if you completed an action in another service
that uses the features supported by this role. If you were using the Amazon EKS service before
January 1, 2017, when it began supporting service-linked roles, then Amazon EKS created the
AWSServiceRoleForAmazonEKSNodegroup role in your account. To learn more, see A New Role
Appeared in My IAM Account.

Creating a service-linked role in Amazon EKS (AWS API)

You don't need to manually create a service-linked role. When you create a managed node group in the
AWS Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to
recreate the role in your account. When you create another managed node group, Amazon EKS creates
the service-linked role for you again.

Editing a service-linked role for Amazon EKS

Amazon EKS does not allow you to edit the AWSServiceRoleForAmazonEKSNodegroup service-linked
role. After you create a service-linked role, you cannot change the name of the role because various
entities might reference the role. However, you can edit the description of the role using IAM. For more
information, see Editing a service-linked role in the IAM User Guide.

Deleting a service-linked role for Amazon EKS

If you no longer need to use a feature or service that requires a service-linked role, we recommend
that you delete that role. That way you don't have an unused entity that is not actively monitored or
maintained. However, you must clean up your service-linked role before you can manually delete it.
Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first delete any resources used by the role.

**Note**
If the Amazon EKS service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

**To delete Amazon EKS resources used by the AWSServiceRoleForAmazonEKSNodegroup role.**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Amazon EKS Clusters.
3. Select the Configuration tab and then choose the Compute tab.
4. In the Node Groups section, choose the node group to delete.
5. Type the name of the node group in the deletion confirmation window, and then choose Delete.
6. Repeat this procedure for any other node groups in the cluster. Wait for all of the delete operations to finish.

Manually delete the service-linked role

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForAmazonEKSNodegroup service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.

Supported regions for Amazon EKS service-linked roles

Amazon EKS supports using service-linked roles in all of the regions where the service is available. For more information, see Amazon EKS Service Endpoints and Quotas.

Using roles for Amazon EKS Fargate profiles

Amazon EKS uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon EKS easier because you don't have to manually add the necessary permissions. Amazon EKS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon EKS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Amazon EKS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-linked role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon EKS

Amazon EKS uses the service-linked role named AWSServiceRoleForAmazonEKSForFargate – The role allows Amazon EKS Fargate to configure VPC networking required for Fargate Pods. The attached
policies allow the role to create and delete Elastic Network Interfaces and describe Elastic Network Interfaces and resources.

The AWSServiceRoleForAmazonEKSForFargate service-linked role trusts the following services to assume the role:

• eks-fargate.amazonaws.com

The role permissions policy allows Amazon EKS to complete the following actions on the specified resources:

• AmazonEKSForFargateServiceRolePolicy

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the IAM User Guide.

Creating a service-linked role for Amazon EKS

You don't need to manually create a service-linked role. When you create a Fargate profile in the AWS Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.

Important
This service-linked role can appear in your account if you completed an action in another service that uses the features supported by this role. If you were using the Amazon EKS service before December 13, 2019, when it began supporting service-linked roles, then Amazon EKS created the AWSServiceRoleForAmazonEKSForFargate role in your account. To learn more, see A New Role Appeared in My IAM Account.

Creating a service-linked role in Amazon EKS (AWS API)

You don't need to manually create a service-linked role. When you create a Fargate profile in the AWS Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create another managed node group, Amazon EKS creates the service-linked role for you again.

Editing a service-linked role for Amazon EKS

Amazon EKS does not allow you to edit the AWSServiceRoleForAmazonEKSForFargate service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting a service-linked role for Amazon EKS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can manually delete it.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first delete any resources used by the role.

Note
If the Amazon EKS service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.
To delete Amazon EKS resources used by the AWSServiceRoleForAmazonEKSForFargate role.

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Amazon EKS Clusters.
3. On the Clusters page, select your cluster.
4. Select the Configuration tab and then select the Compute tab.
5. If there are any Fargate profiles in the Fargate Profiles section, select each one individually, and then choose Delete.
6. Type the name of the profile in the deletion confirmation window, and then choose Delete.
7. Repeat this procedure for any other Fargate profiles in the cluster and for any other clusters in your account.

Manually delete the service-linked role

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForAmazonEKSForFargate service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.

Supported regions for Amazon EKS service-linked roles

Amazon EKS supports using service-linked roles in all of the regions where the service is available. For more information, see Amazon EKS Service Endpoints and Quotas.

Using roles to connect a Kubernetes cluster to Amazon EKS

Amazon EKS uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon EKS easier because you don't have to manually add the necessary permissions. Amazon EKS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon EKS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Amazon EKS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS services that work with IAM and look for the services that have Yes in the Service-linked role column. Choose a Yes with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon EKS

Amazon EKS uses the service-linked role named AWSServiceRoleForAmazonEKSCluster – The role allows Amazon EKS to connect Kubernetes clusters. The attached policies allow the role to to manage necessary resources to connect to your registered Kubernetes cluster.

The AWSServiceRoleForAmazonEKSCluster service-linked role trusts the following services to assume the role:

- eks-connector.amazonaws.com

The role permissions policy allows Amazon EKS to complete the following actions on the specified resources:
Amazon EKS User Guide
Using service-linked roles

- AmazonEKSServiceRolePolicy

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the IAM User Guide.

Creating a service-linked role for Amazon EKS

You don't need to manually create a service-linked role to connect a cluster. When you connect a cluster in the AWS Management Console, the AWS CLI, eksctl, or the AWS API, Amazon EKS creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you connect a cluster, Amazon EKS creates the service-linked role for you again.

Editing a service-linked role for Amazon EKS

Amazon EKS does not allow you to edit the AWSServiceRoleForAmazonEKSConnector service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

Deleting a service-linked role for Amazon EKS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can manually delete it.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first delete any resources used by the role.

Note
If the Amazon EKS service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete Amazon EKS resources used by the AWSServiceRoleForAmazonEKSConnector role.

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation pane, choose Amazon EKS Clusters.
3. On the Clusters page, select your cluster.
4. Select the Deregister tab and then select the Ok tab.

Manually delete the service-linked role

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForAmazonEKSConnector service-linked role. For more information, see Deleting a service-linked role in the IAM User Guide.

Supported regions for Amazon EKS service-linked roles

Amazon EKS supports using service-linked roles in all of the regions where the service is available. For more information, see Amazon EKS Service Endpoints and Quotas.
Amazon EKS cluster IAM role

Kubernetes clusters managed by Amazon EKS make calls to other AWS services on your behalf to manage the resources that you use with the service. Before you can create Amazon EKS clusters, you must create an IAM role with the following IAM policies:

- AmazonEKSClusterPolicy

**Note**
Prior to April 16, 2020, AmazonEKSServicePolicy was also required and the suggested name was eksServiceRole. With the AWSServiceRoleForAmazonEKS service-linked role, that policy is no longer required for clusters created on or after April 16, 2020.

Check for an existing cluster role

You can use the following procedure to check and see if your account already has the Amazon EKS cluster role.

**To check for the eksClusterRole in the IAM console**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Roles.
3. Search the list of roles for eksClusterRole. If a role that includes eksClusterRole doesn’t exist, then see Creating the Amazon EKS cluster role (p. 450) to create the role. If a role that includes eksClusterRole does exist, then select the role to view the attached policies.
4. Choose Permissions.
5. Ensure that the AmazonEKSClusterPolicy managed policy is attached to the role. If the policy is attached, your Amazon EKS cluster role is properly configured.
6. Choose Trust relationships, and then choose Edit trust policy.
7. Verify that the trust relationship contains the following policy. If the trust relationship matches the policy below, choose Cancel. If the trust relationship doesn’t match, copy the policy into the Edit trust policy window and choose Update policy. If you’re using the same role for clusters in all AWS Regions, then region-code may have an *. If you’re using the same role for all clusters, then cluster-name may have an *. The SourceArn condition isn’t required, but we recommend it to prevent the confused deputy problem (p. 473).

```json
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Principal": {
            "Service": "eks.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
            "ArnLike": {
                "aws:SourceArn": "arn:aws:eks:region-code:your-account-id:cluster/cluster-name"
            }
        }
    }
}
```

Creating the Amazon EKS cluster role

You can use the AWS Management Console or the AWS CLI to create the cluster role.
To create your Amazon EKS cluster role in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Roles, then Create role.
3. Under Trusted entity type, select AWS service.
4. Under Use cases for other AWS services, select EKS.
5. Under Use case, choose EKS from the list of services under Use cases for other AWS services.
6. Choose EKS - Cluster for your use case, and then choose Next.
7. On the Add permissions tab, choose Next.
8. For Role name, enter a unique name for your role, such as eksClusterRole.
9. For Description, enter descriptive text such as Amazon EKS - Cluster role.
10. Choose Create role.
11. Choose the role that you just created.
12. Choose the Trust relationships page.
13. Choose Edit trust policy.
14. Update the policy to match the following policy. Replace region-code with the AWS Region that your cluster is in. If you want to use the same role for clusters in all AWS Regions in your account, replace region-code with *. Replace 123456789012 with your account ID, and cluster-name with your cluster's name. Since you need the role to create the cluster, the cluster-name is the name of the cluster you will create and use this role with. If you want to use the same role for all clusters in your account, replace cluster-name with *. The SourceArn condition isn't required, but we recommend it to prevent the confused deputy problem (p. 473).

```json
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Principal": {
            "Service": "eks.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
            " ArnLike": {
                "aws:SourceArn": "arn:aws:eks:region-code:123456789012:cluster/cluster-name"
            }
        }
    }
}
```
15. Choose Update policy.

AWS CLI

1. Copy the following contents to a file named cluster-trust-policy.json. Replace region-code with the AWS Region that your cluster is in. If you want to use the same role for clusters in all AWS Regions in your account, replace region-code with *. Replace 123456789012 with your account ID, and cluster-name with your cluster's name. Since you need the role to create the cluster, the cluster-name is the name of the cluster you will create and use this role with. If you want to use the same role for all clusters in your account, replace cluster-name with *. The SourceArn condition isn't required, but we recommend it to prevent the confused deputy problem (p. 473).

```json
{
}
```
Amazon EKS User Guide
Node IAM role

2. Create the role. You can replace \texttt{eksClusterRole} with any name that you choose.

\texttt{aws iam create-role \--role-name \texttt{eksClusterRole} \--assume-role-policy-document file://cluster-trust-policy.json}

3. Attach the required IAM policy to the role.

\texttt{aws iam attach-role-policy \--policy-arn arn:aws:iam::aws:policy/AmazonEKSClusterPolicy \--role-name \texttt{eksClusterRole}}

Amazon EKS node IAM role

The Amazon EKS node \texttt{kubelet} daemon makes calls to AWS APIs on your behalf. Nodes receive permissions for these API calls through an IAM instance profile and associated policies. Before you can launch nodes and register them into a cluster, you must create an IAM role for those nodes to use when they are launched. This requirement applies to nodes launched with the Amazon EKS optimized AMI provided by Amazon, or with any other node AMIs that you intend to use. Before you create nodes, you must create an IAM role with the following IAM policies:

- \texttt{AmazonEKSWorkerNodePolicy}
- \texttt{AmazonEC2ContainerRegistryReadOnly}
- Either the \texttt{AmazonEKS\_CNI\_Policy} managed policy (if you created your cluster with the IPv4 family) or an IPv6 policy that you create (p. 274) (if you created your cluster with the IPv6 family). Rather than attaching the policy to this role however, we recommend that you attach the policy to a separate role used specifically for the Amazon VPC CNI add-on. For more information about creating a separate role for the Amazon VPC CNI add-on, see the section called “Configure plugin for IAM account” (p. 270).

\textbf{Note}

The Amazon EC2 node groups must have a different IAM role than the Fargate profile. For more information, see Amazon EKS pod execution IAM role (p. 455).

Check for an existing node role

You can use the following procedure to check and see if your account already has the Amazon EKS node role.

\textbf{To check for the \texttt{eksNodeRole} in the IAM console}

1. Open the IAM console at \url{https://console.aws.amazon.com/iam/}.  

452
2. In the left navigation pane, choose Roles.
3. Search the list of roles for eksNodeRole, AmazonEKSNodeRole, or NodeInstanceRole. If a role with one of those names doesn't exist, then see Creating the Amazon EKS node IAM role (p. 453) to create the role. If a role that contains eksNodeRole, AmazonEKSNodeRole, or NodeInstanceRole does exist, then select the role to view the attached policies.
4. Choose Permissions.
5. Ensure that the AmazonEKSWorkerNodePolicy and AmazonEC2ContainerRegistryReadOnly managed policies are attached to the role. If the policies are attached, your Amazon EKS node role is properly configured.

   **Note**
   If the AmazonEKS_CNI_Policy policy is attached to the role, we recommend removing it and attaching it to an IAM role that is mapped to the aws-node Kubernetes service account instead. For more information, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).
6. Choose Trust relationships, and then choose Edit trust policy.
7. Verify that the trust relationship contains the following policy. If the trust relationship matches the policy below, choose Cancel. If the trust relationship doesn't match, copy the policy into the Edit trust policy window and choose Update policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "ec2.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
      }
   ]
}
```

**Creating the Amazon EKS node IAM role**

You can create the node IAM role with the AWS Management Console or the AWS CLI. Select the tab with the name of the tool that you want to create the role with.

**AWS Management Console**

**To create your Amazon EKS node IAM role in the IAM console**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Roles, then Create role.
3. Under Use case, choose EC2 and then choose Next.
4. In the Filter policies box Add permissions page, enter AmazonEKSWorkerNodePolicy and then select the check box to the left of AmazonEKSWorkerNodePolicy in the search results.
5. Choose Clear filters.
6. In the Filter policies box, enter AmazonEC2ContainerRegistryReadOnly. Then select the check box to the left of AmazonEC2ContainerRegistryReadOnly in the search results.

   Either the AmazonEKS_CNI_Policy managed policy, or an IPv6 policy (p. 274) that you create must also be attached to either this role or to a different role that's mapped to the aws-node Kubernetes service account. We recommend assigning the policy to the role associated to
the Kubernetes service account instead of assigning it to this role. For more information, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).

7. Choose Next.
8. For Role name, enter a unique name for your role, such as AmazonEKSNodeRole.
9. For Description, replace the current text with descriptive text such as Amazon EKS – Node role.
10. Choose Create role.

AWS CLI

1. Save the following contents to a file named node-role-trust-relationship.json.

```json
{
   "Version": "2012-10-17",
   "Statement": [
   {
      "Effect": "Allow",
      "Principal": {
         "Service": "ec2.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
   }
   ]
}
```

2. Create the IAM role.

```bash
aws iam create-role
   --role-name AmazonEKSNodeRole
   --assume-role-policy-document file://"node-role-trust-relationship.json"
```

3. Attach two required IAM managed policies to the IAM role.

```bash
aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy
   --role-name AmazonEKSNodeRole

aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly
   --role-name AmazonEKSNodeRole
```

4. Attach one of the following IAM policies to the IAM role depending on which IP family you created your cluster with. The policy must be attached to this role or to a role associated to the Kubernetes aws-node service account that's used for the Amazon EKS VPC CNI plugin. We recommend assigning the policy to the role associated to the Kubernetes service account. To assign the policy to the role associated to the Kubernetes service account, see Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).

   - IPv4

   ```bash
   aws iam attach-role-policy
      --policy-arn arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy
      --role-name AmazonEKSNodeRole
   ```

   - IPv6

   1. Copy the following text and save it to a file named vpc-cni-ipv6-policy.json.

   ```json
   {
      "Version": "2012-10-17",
   }"
Amazon EKS pod execution IAM role

The Amazon EKS pod execution role is required to run pods on AWS Fargate infrastructure.

When your cluster creates pods on AWS Fargate infrastructure, the components running on the Fargate infrastructure must make calls to AWS APIs on your behalf. This is so that they can do actions such as pull container images from Amazon ECR or route logs to other AWS services. The Amazon EKS pod execution role provides the IAM permissions to do this.

When you create a Fargate profile, you must specify a pod execution role for the Amazon EKS components that run on the Fargate infrastructure using the profile. This role is added to the cluster's Kubernetes Role based access control (RBAC) for authorization. This allows the kubelet that's running on the Fargate infrastructure to register with your Amazon EKS cluster so that it can appear in your cluster as a node.

**Note**
The Fargate profile must have a different IAM role than Amazon EC2 node groups.

**Important**
The containers running in the Fargate pod can't assume the IAM permissions associated with a pod execution role. To give the containers in your Fargate pod permissions to access other AWS services, you must use IAM roles for service accounts (p. 461).

Before you create a Fargate profile, you must create an IAM role with the AmazonEKSFargatePodExecutionRolePolicy.
Check for a correctly configured existing pod execution role

You can use the following procedure to check and see if your account already has a correctly configured Amazon EKS pod execution role. To avoid a confused deputy security problem, it's important that the role restricts access based on SourceArn. You can modify the execution role as needed to include support for Fargate profiles on other clusters.

To check for an Amazon EKS pod execution role in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Roles.
3. On the Roles page, search the list of roles for AmazonEKSFargatePodExecutionRole. If the role doesn't exist, see Creating the Amazon EKS pod execution role (p. 457) to create the role. If the role does exist, choose the role.
4. On the AmazonEKSFargatePodExecutionRole page, do the following:
   a. Choose Permissions.
   b. Ensure that the AmazonEKSFargatePodExecutionRolePolicy Amazon managed policy is attached to the role.
   c. Choose Trust relationships.
   d. Choose Edit trust policy.
5. On the Edit trust policy page, verify that the trust relationship contains the following policy and has a line for Fargate profiles on your cluster. If so, choose Cancel.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Condition": {
        "ArnLike": {
        }
      },
      "Principal": {
        "Service": "eks-fargate-pods.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

If the policy matches but doesn't have a line specifying the Fargate profiles on your cluster, you can add the following line at the top of the ArnLike object. Replace region-code with the AWS Region that your cluster is in, 111122223333 with your account ID, and my-cluster with the name of your cluster.

```
```

If the policy doesn't match, copy the full previous policy into the form and choose Update policy. Replace region-code with the AWS Region that your cluster is in. If you want to use the same role in all AWS Regions in your account, replace region-code with *. Replace 111122223333 with your account ID and my-cluster with the name of your cluster. If you want to use the same role for all clusters in your account, replace my-cluster with *.
Creating the Amazon EKS pod execution role

If you don’t already have the Amazon EKS pod execution role for your cluster, you can use the AWS Management Console or the AWS CLI to create it.

AWS Management Console

To create an AWS Fargate pod execution role with the AWS Management Console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Roles.
3. On the Roles page, choose Create role.
4. On the Select trusted entity page, do the following:
   a. In the Trusted entity type section, choose AWS service.
   b. From the Use cases for other AWS services dropdown list, choose EKS.
   c. Choose EKS - Fargate pod.
   d. Choose Next.
5. On the Add permissions page, choose Next.
6. On the Name, review, and create page, do the following:
   a. For Role name, enter a unique name for your role, such as AmazonEKSFargatePodExecutionRole.
   b. Under Add tags (Optional), add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM Entities in the IAM User Guide
   c. Choose Create role.
7. On the Roles page, search the list of roles for AmazonEKSFargatePodExecutionRole. Choose the role.
8. On the AmazonEKSFargatePodExecutionRole page, do the following:
   a. Choose Trust relationships.
   b. Choose Edit trust policy.
9. On the Edit trust policy page, do the following:
   a. Copy and paste the following contents into the Edit trust policy form. Replace region-code with the AWS Region that your cluster is in. If you want to use the same role in all AWS Regions in your account, replace region-code with *. Replace 111122223333 with your account ID and my-cluster with the name of your cluster. If you want to use the same role for all clusters in your account, replace my-cluster with *.
   b. Choose Next.

```json
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Effect": "Allow",
        "Condition": {
            "ArnLike": {
            }
        },
        "Principal": {
            "Service": "eks-fargate-pods.amazonaws.com"
        }
    }
    ]
}
```
Amazon EKS User Guide
Connector IAM role

"Action": "sts:AssumeRole"
}
]
}

b. Choose Update policy.

AWS CLI

To create an AWS Fargate pod execution role with the AWS CLI

1. Copy and paste the following contents to a file named pod-execution-role-trust-policy.json. Replace region-code with the AWS Region that your cluster is in. If you want to use the same role in all AWS Regions in your account, replace region-code with *. Replace 111122223333 with your account ID and my-cluster with the name of your cluster. If you want to use the same role for all clusters in your account, replace my-cluster with *.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Condition": {
        "ArnLike": {
        }
      },
      "Principal": {
        "Service": "eks-fargate-pods.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

2. Create a pod execution IAM role.

```
aws iam create-role \
  --role-name AmazonEKSFargatePodExecutionRole \
  --assume-role-policy-document file://pod-execution-role-trust-policy.json
```

3. Attach the required Amazon EKS managed IAM policy to the role.

```
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::aws:policy/AmazonEKSFargatePodExecutionRolePolicy \
  --role-name AmazonEKSFargatePodExecutionRolePolicy
```

Amazon EKS connector IAM role

You can connect Kubernetes clusters to view them in your AWS Management Console. To connect to a Kubernetes cluster, create an IAM role.

Check for an existing connector role

You can use the following procedure to check and see if your account already has the Amazon EKS connector role.
To check for the AmazonEKSConnectorAgentRole in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Roles.
3. Search the list of roles for AmazonEKSConnectorAgentRole. If a role that includes AmazonEKSConnectorAgentRole doesn't exist, then see Creating the Amazon EKS connector agent role (p. 459) to create the role. If a role that includes AmazonEKSConnectorAgentRole does exist, then select the role to view the attached policies.
4. Choose Permissions.
5. Ensure that the AmazonEKSClusterPolicy managed policy is attached to the role. If the policy is attached, your Amazon EKS cluster role is properly configured.
6. Choose Trust relationships, and then choose Edit trust policy.
7. Verify that the trust relationship contains the following policy. If the trust relationship matches the policy below, choose Cancel. If the trust relationship doesn't match, copy the policy into the Edit trust policy window and choose Update policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Creating the Amazon EKS connector agent role

You can use the AWS Management Console or AWS CloudFormation to create the connector agent role. Select the tab with the name of the tool that you want to use to create the role.

AWS CLI

1. Create a file named eks-connector-agent-trust-policy.json that contains the following JSON to use for the IAM role.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": ["ssm.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

2. Create a file named eks-connector-agent-policy.json that contains the following JSON to use for the IAM role.

```
```
3. Create the Amazon EKS Connector agent role using the trust policy and policy you created in the previous list items.

```
aws iam create-role \
  --role-name AmazonEKSConnectorAgentRole \
  --assume-role-policy-document file://eks-connector-agent-trust-policy.json
```

4. Attach the policy to your Amazon EKS Connector agent role.

```
aws iam put-role-policy \
  --role-name AmazonEKSConnectorAgentRole \
  --policy-name AmazonEKSConnectorAgentPolicy \
  --policy-document file://eks-connector-agent-policy.json
```

**AWS CloudFormation**

To create your Amazon EKS connector agent role with AWS CloudFormation.

1. Save the following AWS CloudFormation template to a text file on your local system.

   **Note**
   This template also creates the service-linked role that would otherwise be created when the registerCluster API is called. See Using roles to connect a Kubernetes cluster to Amazon EKS (p. 448) for details.

   ```yaml
AWSTemplateFormatVersion: '2010-09-09'
Description: 'Provisions necessary resources needed to register clusters in EKS'
Parameters: {}
Resources:
  EKSConnectorSLR:
    Type: AWS::IAM::ServiceLinkedRole
    Properties:
      AWSServiceName: eks-connector.amazonaws.com
  EKSConnectorAgentRole:
```
IAM roles for service accounts

You can associate an IAM role with a Kubernetes service account. This service account can then provide AWS permissions to the containers in any pod that uses that service account. With this feature, you no longer need to provide extended permissions to the Amazon EKS node IAM role (p. 452) so that pods on that node can call AWS APIs.

Applications must sign their AWS API requests with AWS credentials. This feature provides a strategy for managing credentials for your applications, similar to the way that Amazon EC2 instance profiles provide credentials to Amazon EC2 instances. Instead of creating and distributing your AWS credentials to the containers or using the Amazon EC2 instance's role, you can associate an IAM role with a Kubernetes service account. The applications in the pod's containers can then use an AWS SDK or the AWS CLI to make API requests to authorized AWS services.
Important
Even if you assign an IAM role to a Kubernetes service account, the pod still also has the permissions assigned to the Amazon EKS node IAM role (p. 452), unless you block pod access to the IMDS. For more information, see Restrict access to the instance profile assigned to the worker node.

The IAM roles for service accounts feature provides the following benefits:

- **Least privilege** — By using the IAM roles for service accounts feature, you no longer need to provide extended permissions to the node IAM role so that pods on that node can call AWS APIs. You can scope IAM permissions to a service account, and only pods that use that service account have access to those permissions. This feature also eliminates the need for third-party solutions such as kiam or kube2iam.

- **Credential isolation** — A container can only retrieve credentials for the IAM role that is associated with the service account to which it belongs. A container never has access to credentials that are intended for another container that belongs to another pod.

- **Auditability** — Access and event logging is available through CloudTrail to help ensure retrospective auditing.

Enable service accounts to access AWS resources in three steps

1. Create an IAM OIDC provider for your cluster (p. 466) – You only need to do this once for a cluster.
2. Create an IAM role and attach an IAM policy to it with the permissions that your service accounts need (p. 467) – We recommend creating separate roles for each unique collection of permissions that pods need.
3. Associate an IAM role with a service account (p. 470) – Complete this task for each Kubernetes service account that needs access to AWS resources.

Technical overview

In 2014, AWS Identity and Access Management added support for federated identities using OpenID Connect (OIDC). This feature allows you to authenticate AWS API calls with supported identity providers and receive a valid OIDC JSON web token (JWT). You can pass this token to the AWS STS AssumeRoleWithWebIdentity API operation and receive IAM temporary role credentials. You can use these credentials to interact with any AWS service, like Amazon S3 and DynamoDB.

Kubernetes has long used service accounts as its own internal identity system. Pods can authenticate with the Kubernetes API server using an auto-mounted token (which was a non-OIDC JWT) that only the Kubernetes API server could validate. These legacy service account tokens do not expire, and rotating the signing key is a difficult process. In Kubernetes version 1.12, support was added for a new ProjectedServiceAccountToken feature, which is an OIDC JSON web token that also contains the service account identity, and supports a configurable audience.

Amazon EKS now hosts a public OIDC discovery endpoint per cluster containing the signing keys for the ProjectedServiceAccountToken JSON web tokens so external systems, like IAM, can validate and accept the OIDC tokens issued by Kubernetes.

IAM role configuration

In IAM, you create an IAM role with a trust relationship that is scoped to your cluster’s OIDC provider, the service account namespace, and (optionally) the service account name, and then attach the IAM policy that you want to associate with the service account. You can add multiple entries in the StringEquals and StringLike conditions below to use multiple service accounts or namespaces with the role.

- To scope a role to a specific service account:
IAM roles for service accounts

Service account configuration

In Kubernetes, you define the IAM role to associate with a service account in your cluster by adding the eks.amazonaws.com/role-arn annotation to the service account.

```yaml
apiVersion: v1
category: ServiceAccount
metadata:
  annotations:
    eks.amazonaws.com/role-arn: arn:aws:iam::ACCOUNT_ID:role/IAM_ROLE_NAME
```

Pod configuration

The Amazon EKS Pod Identity Webhook on the cluster watches for pods that are associated with service accounts with this annotation and applies the following environment variables to them.

```
AWS_ROLE_ARN=arn:aws:iam::ACCOUNT_ID:role/IAM_ROLE_NAME
AWS_WEB_IDENTITY_TOKEN_FILE=/var/run/secrets/eks.amazonaws.com/serviceaccount/token
```
Note
Your cluster does not need to use the mutating web hook to configure the environment variables and token file mounts; you can choose to configure pods to add these environment variables manually.

Supported versions of the AWS SDK (p. 472) look for these environment variables first in the credential chain provider. The role credentials are used for pods that meet this criteria.

Note
When a pod uses AWS credentials from an IAM role associated with a service account, the AWS CLI or other SDKs in the containers for that pod use the credentials provided by that role. The pod still has access to the credentials provided to the Amazon EKS node IAM role (p. 452) too, unless you restrict access to those credentials. For more information, see Restrict access to the instance profile assigned to the worker node.

By default, only containers that run as root have the proper file system permissions to read the web identity token file. You can provide these permissions by having your containers run as root, or by providing the following security context for the containers in your manifest. The fsGroup ID is arbitrary, and you can choose any valid group ID. For more information about the implications of setting a security context for your pods, see Configure a Security Context for a Pod or Container in the Kubernetes documentation.

Note
Providing this security context is not required for 1.19 or later clusters.

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: my-app
spec:
template:
  metadata:
    labels:
      app: my-app
  spec:
    serviceAccountName: my-app
    containers:
    - name: my-app
      image: my-app:latest
      securityContext:
        fsGroup: 1337
... 
```

The kubelet requests and stores the token on behalf of the pod. By default, the kubelet refreshes the token if it is older than 80 percent of its total TTL, or if the token is older than 24 hours. You can modify the expiration duration for any account, except the default service account, with settings in your pod spec. For more information, see Service Account Token Volume Projection in the Kubernetes documentation.

Cross-account IAM permissions
You can configure cross-account IAM permissions either by creating an identity provider from another account's cluster or by using chained AssumeRole operations. In the following examples, Account A owns an Amazon EKS cluster that supports IAM roles for service accounts. Pods running on that cluster need to assume IAM permissions from Account B.

**Example: Create an identity provider from another account's cluster**

**Example**

In this example, Account A would provide Account B with the OIDC issuer URL from their cluster. Account B follows the instructions in Create an IAM OIDC provider for your cluster (p. 466) and Creating an IAM
role and policy for your service account (p. 467) using the OIDC issuer URL from Account A's cluster. Then a cluster administrator annotates the service account in Account A's cluster to use the role from Account B.

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  annotations:
    eks.amazonaws.com/role-arn: arn:aws:iam::ACCOUNT_B_ID:role/IAM_ROLE_NAME
```

**Example: Use chained AssumeRole operations**

**Example**

In this example, Account B creates an IAM policy with the permissions to give to pods in Account A's cluster. Account B attaches that policy to an IAM role with a trust relationship that allows AssumeRole permissions to Account A (111111111111), as shown below.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111111111111:root"
      },
      "Action": "sts:AssumeRole",
      "Condition": {}
    }
  ]
}
```

Account A creates a role with a trust policy that gets credentials from the identity provider created with the cluster's OIDC issuer URL, as shown below.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::111111111111:oidc-provider/oidc.eks.region-code.amazonaws.com/id/EXAMPLEDE53994633E573DE1B71EXAMPLE"
      },
      "Action": "sts:AssumeRoleWithWebIdentity"
    }
  ]
}
```

Account A attaches a policy to that role with the following permissions to assume the role that Account B created.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Resource": "arn:aws:iam::222222222222:role/account-b-role"
    }
  ]
}
```
The application code for pods to assume Account B's role uses two profiles: `account_b_role` and `account_a_role`. The `account_b_role` profile uses the `account_a_role` profile as its source. For the AWS CLI, the `~/.aws/config` file would look like the following example.

```
[profile account_b_role]
source_profile = account_a_role
role_arn=arn:aws:iam::222222222222:role/account-b-role

[profile account_a_role]
web_identity_token_file = /var/run/secrets/eks.amazonaws.com/serviceaccount/token
role_arn=arn:aws:iam::111111111111:role/account-a-role
```

To specify chained profiles for other AWS SDKs, consult their documentation.

## Create an IAM OIDC provider for your cluster

Your cluster has an OpenID Connect issuer URL associated with it. To use IAM roles for service accounts, an IAM OIDC provider must exist for your cluster.

### Prerequisites

An existing cluster. If you don’t have one, you can create one using one of the Getting started with Amazon EKS (p. 4) guides.

You can create an OIDC provider for your cluster using `eksctl` or the AWS Management Console.

### eksctl

#### To create an IAM OIDC identity provider for your cluster with `eksctl`

1. Determine whether you have an existing IAM OIDC provider for your cluster.
   - View your cluster's OIDC provider URL.

   ```
   aws eks describe-cluster --name my-cluster --query "cluster.identity.oidc.issuer" --output text
   
   Example output:
   
   https://oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE
   
   List the IAM OIDC providers in your account. Replace `EXAMPLED539D4633E53DE1B71EXAMPLE` with the value returned from the previous command.

   ```

   ```
   aws iam list-open-id-connect-providers | grep EXAMPLED539D4633E53DE1B71EXAMPLE
   
   Example output:
   
   "Arn": "arn:aws:iam::111122223333:oidc-provider/oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE"
   
   If output is returned from the previous command, then you already have a provider for your cluster. If no output is returned, then you must create an IAM OIDC provider.

   2. Create an IAM OIDC identity provider for your cluster with the following command. Replace `my-cluster` with your own value.

   ```
   
   Example output:
   
   "Arn": "arn:aws:iam::111122223333:oidc-provider/oidc.eks.region-code.amazonaws.com/id/EXAMPLED539D4633E53DE1B71EXAMPLE"
   ```
AWS Management Console

To create an IAM OIDC identity provider for your cluster with the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Select the name of your cluster and then select the Configuration tab.
3. In the Details section, note the value of the OpenID Connect provider URL.
5. In the left navigation pane, choose Identity Providers under Access management. If a Provider is listed that matches the URL for your cluster, then you already have a provider for your cluster. If a provider isn't listed that matches the URL for your cluster, then you must create one.
6. To create a provider, choose Add Provider.
7. For Provider Type, choose OpenID Connect.
8. For Provider URL, paste the OIDC issuer URL for your cluster, and then choose Get thumbprint.
9. For Audience, enter sts.amazonaws.com and choose Add provider.

Creating an IAM role and policy for your service account

You must create an IAM policy that specifies the permissions that you would like the containers in your pods to have. You have several ways to create a new IAM permission policy. One way is to copy a complete AWS managed policy that already does some of what you're looking for and then customize it to your specific requirements. For more information, see Creating a New Policy in the IAM User Guide.

You must also create an IAM role for your Kubernetes service accounts to use before you associate it with a service account. The trust relationship is scoped to your cluster and service account so that each cluster and service account combination requires its own role. You can then attach a specific IAM policy to the role that gives the containers in your pods the permissions you desire. The following procedures describe how to do this.

Create an IAM policy

In this procedure, we offer two example policies that you can use for your application:

- A policy to allow read-only access to an Amazon S3 bucket. You could store configuration information or a bootstrap script in this bucket, and the containers in your pod can read the file from the bucket and load it into your application.
- A policy to allow paid container images from AWS Marketplace.

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Policies and then choose Create policy.
3. Choose the JSON tab.
4. In the Policy Document field, paste one of the following policies to apply to your service accounts, or paste your own policy document into the field. You can also use the visual editor to construct your own policy.

The example below allows permission to the my-pod-secrets-bucket Amazon S3 bucket. You can modify the policy document to suit your specific needs.
The example below gives the required permissions to use a paid container image from AWS Marketplace.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["s3:GetObject"],
         "Resource": ["arn:aws:s3:::my-pod-secrets-bucket/*"]
      }
   ]
}
```

5. Choose **Review policy**.
6. Enter a name and description for your policy and then choose **Create policy**.
7. Record the Amazon Resource Name (ARN) of the policy to use later when you create your role.

## Create an IAM role for a service account

Create an IAM role for your Kubernetes service account. You can use `eksctl`, the AWS Management Console, or the AWS CLI to create the role.

### Prerequisites

- An existing cluster. If you don't have one, you can create one using one of the Getting started with Amazon EKS (p. 4) guides.
- If using the AWS Management Console or AWS CLI to create the role, then you must have an existing IAM OIDC provider for your cluster. For more information, see Create an IAM OIDC provider for your cluster (p. 466).
- An existing IAM policy that includes the permissions for the AWS resources that your service account needs access to. For more information, see Create an IAM policy (p. 467).

You can create the IAM role with `eksctl` or the AWS CLI.

`eksctl`

Create the service account and IAM role with the following command. Replace `my-service-account` and `my-namespace` with the Kubernetes service account and namespace that you want to...
associate the IAM role to. Replace $my-cluster$ with the name of your cluster and replace $my-role-name$ with the name you want for the IAM role. Replace $111122223333$ with your account ID (or with $aws$, if you’re attaching an AWS managed policy) and replace $my-iam-policy$ with the name of an existing IAM policy that you created or with the name of a managed AWS IAM policy.

```
eksctl create iamserviceaccount
   --name $my-service-account$
   --namespace $my-namespace$
   --cluster $my-cluster$
   --role-name "$my-role-name"
   --attach-policy-arn arn:aws:iam::$ACCOUNT_ID::policy/$my-iam-policy
   --approve
   --override-existing-serviceaccounts
```

The `eksctl` utility creates and deploys an AWS CloudFormation template. The template creates an IAM role and attaches the IAM policy that you specified to it. The role is associated with the Kubernetes service account that you specified. If the Kubernetes service account didn’t exist, `eksctl` created it in the namespace that you specified and annotated it with `eks.amazonaws.com/role-arn:arn:aws:iam::$ACCOUNT_ID::role/$my-role-name`. This is the name of the IAM role created by the AWS CloudFormation template.

If the Kubernetes service account existed before running the command, but wasn’t created with `eksctl`, then `eksctl` annotated the existing service account with `eks.amazonaws.com/role-arn:arn:aws:iam::$ACCOUNT_ID::role/$my-role-name`. If the Kubernetes service account existed before running the command and was created by `eksctl`, the command fails. To update a service account created by `eksctl`, use `eksctl update iamserviceaccount`.

**AWS CLI**

1. Set your AWS account ID to an environment variable with the following command.

   ```bash
   ACCOUNT_ID=$(aws sts get-caller-identity --query "Account" --output text)
   ```

2. Set your OIDC identity provider to an environment variable with the following command.

   Replace $my-cluster$ with the name of your cluster.

   **Important**
   You must use at least version 1.22.86 or 2.5.2 of the AWS CLI to receive the proper output from this command. For more information, see Installing the AWS CLI in the AWS Command Line Interface User Guide.

   ```bash
   OIDC_PROVIDER=$(aws eks describe-cluster --name $my-cluster --query "cluster.identity.oidc.issuer" --output text | sed -e "s/^https:/\///")
   ```

3. Copy the following code block to your computer. Replace $my-namespace$ and $my-service-account$ with the Kubernetes namespace and service account that you want to associate the role to.

   ```bash
   read -r -d '' TRUST_RELATIONSHIP <<EOF
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Principal": {
   "Federated": "arn:aws:iam::$ACCOUNT_ID:oidc-provider/$OIDC_PROVIDER"},
   "Action": "sts:AssumeRoleWithWebIdentity",
   "Condition": {
   "StringEquals": {
   "$OIDC_PROVIDER":aud": "sts.amazonaws.com",
   ```
Associate an IAM role to a service account

In Kubernetes, you define the IAM role to associate with a service account in your cluster by adding the following annotation to the service account.

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  annotations:
    eks.amazonaws.com/role-arn: arn:aws:iam::account-id:role/iam-role-name
```

**Note**

If you created an IAM role to use with your service account (p. 468) using eksctl, eksctl annotated the service account that you specified when creating the role.

**Prerequisites**

- An existing cluster. If you don’t have one, you can create one using one of the Getting started with Amazon EKS (p. 4) guides.
- An existing IAM OIDC provider for your cluster. For more information, see Create an IAM OIDC provider for your cluster (p. 466).
- An existing Kubernetes service account. If you don’t have one, see Configure Service Accounts for Pods in the Kubernetes documentation.
- An existing IAM role with an attached IAM policy. If you don’t have one, see Creating an IAM role and policy for your service account (p. 467).

**To annotate a service account with an IAM role**

1. Use the following command to annotate your service account with the ARN of the IAM role that you want to use with your service account. Replace `service-account-namespace` with the Kubernetes namespace of your service account, `service-account-name` with the name of your...
existing Kubernetes service account. Replace `account-id` with your AWS account ID and `iam-role-name` with the name of your existing AWS Identity and Access Management (IAM) role.

```
kubectl annotate serviceaccount -n service-account-namespace service-account-name eks.amazonaws.com/role-arn=arn:aws:iam::account-id:role/iam-role-name
```

**Note**
If you don't have an existing service account, then you need to create one. For more information, see Configure Service Accounts for Pods in the Kubernetes documentation. For the service account to be able to use Kubernetes permissions, you must create a Role, or ClusterRole and then bind the role to the service account. For more information, see Using RBAC Authorization in the Kubernetes documentation. When the AWS VPC CNI plugin (p. 269) is deployed, for example, the deployment manifest creates a service account, cluster role, and cluster role binding. You can view the manifest on GitHub to use as an example.

2. (Optional) Annotate your service account to use the AWS Security Token Service AWS Regional endpoint if your cluster's Kubernetes version is listed in the following table and its platform version is the same or later than the version listed in the table. If your cluster's Kubernetes version is listed in the following table and you have a platform version that is earlier than the version listed in the table, then you can't enable your service accounts to use the AWS Security Token Service AWS Regional endpoint. You must use the global endpoint. If your cluster is 1.22 or later, the AWS Regional endpoint is used by default, so you don't need to annotate your Kubernetes service accounts to use it.

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Platform version</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.21</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.20</td>
<td>eks.3</td>
</tr>
<tr>
<td>1.19</td>
<td>eks.7</td>
</tr>
<tr>
<td>1.18</td>
<td>eks.9</td>
</tr>
</tbody>
</table>

Add the following annotation to your service accounts.

```
kubectl annotate serviceaccount -n service-account-namespace service-account-name eks.amazonaws.com/sts-regional-endpoints=true
```

AWS recommends using the AWS Regional AWS STS endpoints instead of the global endpoint to reduce latency, build in redundancy, and increase session token validity. The AWS Security Token Service must be active in the AWS Region where the pod is running and your application should have redundancy built in to pick a different AWS Region in the event of a failure of the service in the AWS Region. For more information, see Managing AWS STS in an AWS Region in the IAM User Guide.

3. (Optional) In Amazon EKS v1.22 and later, the default AWS STS endpoint used for the IAM Role for Service Account (IRSA) to be the regional endpoint instead of the global endpoint. To use the global STS endpoint, add the following annotation to your service account:

```
kubectl annotate serviceaccount -n service-account-namespace service-account-name eks.amazonaws.com/sts-regional-endpoints=false
```

4. Delete and re-create any existing pods that are associated with the service account to apply the credential environment variables. The mutating web hook does not apply them to pods that are
already running. For example, if you added the annotation to the service account used for the Amazon VPC CNI DaemonSet in a previous step, the following command deletes the existing aws-node DaemonSet pods and deploys them with the service account annotation. You can replace pods, kube-system, and -l k8s-app=aws-node with the information for the pods that you set your annotation for.

```
kubectl delete pods -n kube-system -l k8s-app=aws-node
```

5. Confirm that the pods all restarted.

```
kubectl get pods -n kube-system -l k8s-app=aws-node
```

6. View the environment variables for one of the pods and verify that the AWS_WEB_IDENTITY_TOKEN_FILE and AWS_ROLE_ARN environment variables exist. The following example command returns the variables for one of the pods created by the Amazon VPC CNI DaemonSet. The pod named aws-node-5v6ws was returned in the output of the example used in the previous step.

```
kubectl exec -n kube-system aws-node-5v6ws -- env | grep AWS
```

Output:

```
...  
AWS_WEB_IDENTITY_TOKEN_FILE=/var/run/secrets/eks.amazonaws.com/serviceaccount/token
...
AWS_ROLE_ARN=arn:aws:iam::account-id:role/iam-role-name
...
```

If your pod is using the AWS Regional endpoint, then the following line is also returned in the previous output.

```
AWS_STS_REGIONAL_ENDPOINTS=regional
```

**Using a supported AWS SDK**

The containers in your pods must use an AWS SDK version that supports assuming an IAM role via an OIDC web identity token file. AWS SDKs that are included in Linux distribution package managers may not be new enough to support this feature. Be sure to use at least the minimum SDK versions listed below:

- **Java (Version 2)** — 2.10.11
- **Java** — 1.11.704
- **Go** — 1.23.13
- **Python (Boto3)** — 1.9.220
- **Python (botocore)** — 1.12.200
- **AWS CLI** — 1.16.232
- **Node** — 3.27.0
- **Ruby** — 3.58.0
- **C++** — 1.7.174
- **.NET** — 3.3.659.1
- **PHP** — 3.110.7

472
Many popular Kubernetes add-ons, such as the Cluster Autoscaler and the Installing the AWS Load Balancer Controller add-on (p. 320), support IAM roles for service accounts. The Amazon VPC CNI plugin for Kubernetes also supports IAM roles for service accounts.

To ensure that you are using a supported SDK, follow the installation instructions for your preferred SDK at Tools for Amazon Web Services when you build your containers.

## Cross-service confused deputy prevention

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the calling service) calls another service (the called service). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it shouldn't otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account.

We recommend using the `aws:SourceArn` or `aws:SourceAccount` global condition context keys in resource policies to limit the permissions that Amazon Elastic Kubernetes Service gives another service to the resource. Use `aws:SourceArn` if you want only one resource to be associated with the cross-service access. Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. If you don't know the full ARN of the resource or if you are specifying multiple resources, use the `aws:SourceArn` global context condition key with wild card characters (*) for the unknown portions of the ARN. For example, `arn:aws:eks:*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` global condition context key in Amazon EKS to prevent the confused deputy problem. This example is for the trust policy of the Amazon EKS cluster IAM role (p. 450). Replace `region-code` with the AWS Region that your cluster is in, `123456789012` with your account ID, and `cluster-name` with your cluster's name. If you want to use the same role for clusters in all AWS Regions in your account, replace `region-code` with `*`. If you want to use the same role for all clusters in your account, replace `cluster-name` with `*`.

```json
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Principal": {
            "Service": "eks.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
            "ArnLike": {
                "aws:SourceArn": "arn:aws:eks:region-code:123456789012:cluster/cluster-name"
            }
        }
    }
}
```

See Amazon EKS pod execution IAM role (p. 455) for an example of a trust policy for that role.

## AWS managed policies for Amazon Elastic Kubernetes Service

---

473
To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ReadOnlyAccess AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

AWS managed policy: AmazonEKS_CNI_Policy

You can attach the AmazonEKS_CNI_Policy to your IAM entities. Before you create an Amazon EC2 node group, this policy must be attached to either the node IAM role (p. 452), or to an IAM role that's used specifically by the AWS VPC CNI plugin. This is so that it can perform actions on your behalf. We recommend that you attach the policy to a role that's used only by the CNI plugin. For more information, see Pod networking (CNI) (p. 269) and Configuring the Amazon VPC CNI plugin to use IAM roles for service accounts (p. 270).

Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks:

- **ec2** – Allows the Amazon VPC CNI plugin to perform actions such as provisioning Elastic Network Interfaces and IP addresses for pods to provide networking for applications that run in Amazon EKS.

```json
{
   "Version": "2012-10-17",
   "Statement": [
   {
      "Effect": "Allow",
      "Action": [
         "ec2:AssignPrivateIpAddresses",
         "ec2:AttachNetworkInterface",
         "ec2:CreateNetworkInterface",

         "ec2:DescribeInstanceTypes",
         "ec2:DetachNetworkInterface",
         "ec2:ModifyNetworkInterfaceAttribute",
         "ec2:UnassignPrivateIpAddresses"
      ],
      "Resource": "*"
   },
   {
      "Effect": "Allow",
      "Action": [
You can attach AmazonEKSClusterPolicy to your IAM entities. Before creating a cluster, you must have a cluster IAM role (p. 450) with this policy attached. Kubernetes clusters that are managed by Amazon EKS make calls to other AWS services on your behalf. They do this to manage the resources that you use with the service.

This policy includes the following permissions that allow Amazon EKS to complete the following tasks:

- **autoscaling** – Read and update the configuration of an Auto Scaling group. These permissions aren’t used by Amazon EKS but remain in the policy for backwards compatibility.
- **ec2** – Work with volumes and network resources that are associated to Amazon EC2 nodes. This is required so that the Kubernetes control plane can join instances to a cluster and dynamically provision and manage Amazon EBS volumes that are requested by Kubernetes persistent volumes.
- **elasticloadbalancing** – Work with Elastic Load Balancers and add nodes to them as targets. This is required so that the Kubernetes control plane can dynamically provision Elastic Load Balancers requested by Kubernetes services.
- **iam** – Create a service-linked role. This is required so that the Kubernetes control plane can dynamically provision Elastic Load Balancers that are requested by Kubernetes services.
- **kms** – Read a key from AWS KMS. This is required for the Kubernetes control plane to support secrets encryption of Kubernetes secrets stored in etcd.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "autoscaling:DescribeAutoScalingGroups",
                "autoscaling:UpdateAutoScalingGroup",
                "ec2:AttachVolume",
                "ec2:AuthorizeSecurityGroupIngress",
                "ec2:CreateRoute",
                "ec2:CreateSecurityGroup",
                "ec2:CreateTags",
                "ec2:CreateVolume",
                "ec2:DeleteRoute",
                "ec2:DeleteSecurityGroup",
                "ec2:DeleteVolume",
                "ec2:DescribeInstances",
                "ec2:DescribeRouteTables",
                "ec2:DescribeSecurityGroups",
                "ec2:DescribeSubnets",
                "ec2:DescribeVolumes",
                "ec2:DescribeVolumesModifications",
                "ec2:DescribeVpcs",
                "ec2:DescribeDhcpOptions",
                "ec2:DescribeNetworkInterfaces",
                "ec2:DetachVolume",
                "ec2:CreateTags"
            ],
            "Resource": [
                "arn:aws:ec2:*
```
AWS managed policy:
AmazonEKSFargatePodExecutionRolePolicy

You can attach AmazonEKSFargatePodExecutionRolePolicy to your IAM entities. Before you can create a Fargate profile, you must create a Fargate pod execution role and attach this policy to it. For more information, see Create a Fargate pod execution role (p. 154) and AWS Fargate profile (p. 157).

This policy grants the role the permissions that provide access to other AWS service resources that are required to run Amazon EKS pods on Fargate.
Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks:

- **ecr** – Allows Pods that are running on Fargate to pull container images that are stored in Amazon ECR.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecr:GetAuthorizationToken",
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage"
      ],
      "Resource": "*"
    }
  ]
}
```

**AWS managed policy: AmazonEKSForFargateServiceRolePolicy**

You can't attach AmazonEKSForFargateServiceRolePolicy to your IAM entities. This policy is attached to a service-linked role that allows Amazon EKS to perform actions on your behalf. For more information, see AWSServiceRoleforAmazonEKSForFargate.

This policy grants necessary permissions to Amazon EKS to run Fargate tasks. The policy is only used if you have Fargate nodes.

Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks.

- **ec2** – Create and delete Elastic Network Interfaces and describe Elastic Network Interfaces and resources. This is required so that the Amazon EKS Fargate service can configure the VPC networking that's required for Fargate Pods.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateNetworkInterface",
        "ec2:CreateNetworkInterfacePermission",
        "ec2:DeleteNetworkInterface",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeSubnets",
        "ec2:DescribeVpcs",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeRouteTables"
      ],
      "Resource": "*"
    }
  ]
}
```
AWS managed policy: AmazonEKSServicePolicy

You can attach AmazonEKSServicePolicy to your IAM entities. Clusters that were created before April 16, 2020, required you to create an IAM role and attach this policy to it. Clusters that were created on or after April 16, 2020, don't require you to create a role and don't require you to assign this policy. When you create a cluster using an IAM principal that has the iam:CreateServiceLinkedRole permission, the AWSServiceRoleForAmazonEKS (p. 443) service-linked role is automatically created for you. The service-linked role has the AWS managed policy: AmazonEKSServiceRolePolicy (p. 479) attached to it.

This policy allows Amazon EKS to create and manage the necessary resources to operate Amazon EKS clusters.

Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks.

- **eks** – Update the Kubernetes version of your cluster after you initiate an update. This permission isn't used by Amazon EKS but remains in the policy for backwards compatibility.
- **ec2** – Work with Elastic Network Interfaces and other network resources and tags. This is required by Amazon EKS to configure networking that facilitates communication between nodes and the Kubernetes control plane.
- **route53** – Associate a VPC with a hosted zone. This is required by Amazon EKS to enable private endpoint networking for your Kubernetes cluster API server.
- **logs** – Log events. This is required so that Amazon EKS can ship Kubernetes control plane logs to CloudWatch.
- **iam** – Create a service-linked role. This is required so that Amazon EKS can create the AWSServiceRoleForAmazonEKS (p. 443) service-linked role on your behalf.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ec2:CreateNetworkInterface",
            "ec2:CreateNetworkInterfacePermission",
            "ec2:DeleteNetworkInterface",
            "ec2:DescribeInstances",
            "ec2:DescribeNetworkInterfaces",
            "ec2:DetachNetworkInterface",
            "ec2:DescribeSecurityGroups",
            "ec2:DescribeSubnets",
            "ec2:DescribeVpcs",
            "ec2:ModifyNetworkInterfaceAttribute",
            "iam:ListAttachedRolePolicies",
            "eks:UpdateClusterVersion"
         ],
         "Resource": "*
      },
      {
         "Effect": "Allow",
         "Action": [
            "ec2:CreateTags",
            "ec2:DeleteTags"
         ],
         "Resource": [
            "arn:aws:ec2::*:*:vpc/*",
            "arn:aws:ec2::*:*:subnet/*"
         ]
      }
   ]
}
```
AWS managed policy: AmazonEKSServiceRolePolicy

You can't attach AmazonEKSServiceRolePolicy to your IAM entities. This policy is attached to a service-linked role that allows Amazon EKS to perform actions on your behalf. For more information, see Service-Linked Role Permissions for Amazon EKS (p. 443). When you create a cluster using an IAM principal that has the `iam:CreateServiceLinkedRole` permission, the AWSServiceRoleforAmazonEKS (p. 443) service-linked role is automatically created for you and this policy is attached to it.

This policy allows the service-linked role to call AWS services on your behalf.

Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks.

- **ec2** – Create and describe Elastic Network Interfaces and Amazon EC2 instances, the cluster security group (p. 265), and VPC that are required to create a cluster.
- **iam** – List all of the managed policies that attached to an IAM role. This is required so that Amazon EKS can list and validate all managed policies and permissions required to create a cluster.
- **Associate a VPC with a hosted zone** – This is required by Amazon EKS to enable private endpoint networking for your Kubernetes cluster API server.
- **Log event** – This is required so that Amazon EKS can ship Kubernetes control plane logs to CloudWatch.

  ]
}
AWS managed policies

AWS managed policy: AmazonEKSVPCResourceController

You can attach the AmazonEKSVPCResourceController policy to your IAM identities. If you're using security groups for pods (p. 307), you must attach this policy to your Amazon EKS cluster IAM role (p. 450) to perform actions on your behalf.

This policy grants the cluster role permissions to manage Elastic Network Interfaces and IP addresses for nodes.

Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks:

- ec2 – Manage Elastic Network Interfaces and IP addresses to support pod security groups and Windows nodes.
AWS managed policy: AmazonEKSWorkerNodePolicy

You can attach the AmazonEKSWorkerNodePolicy to your IAM entities. You must attach this policy to a node IAM role (p. 452) that you specify when you create Amazon EC2 nodes that allow Amazon EKS to perform actions on your behalf. If you create a node group using eksctl, it creates the node IAM role and attaches this policy to the role automatically.

This policy grants Amazon EKS Amazon EC2 nodes permissions to connect to Amazon EKS clusters.

Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks:

- **ec2** – Read instance volume and network information. This is required so that Kubernetes nodes can describe information about Amazon EC2 resources that are required for the node to join the Amazon EKS cluster.
- **eks** – Optionally describe the cluster as part of node bootstrapping.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeInstances",
        "ec2:DescribeInstanceTypes",
        "ec2:DescribeRouteTables",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeSubnets",
        "ec2:DescribeVolumes",
        "ec2:DescribeVolumesModifications",
        "ec2:DescribeVpcs",
        "eks:DescribeCluster"
      ],
      "Resource": "*"
    }
  ]
}
```
AWS managed policy:
AWSServiceRoleForAmazonEKSNodegroup

You can't attach AWSServiceRoleForAmazonEKSNodegroup to your IAM entities. This policy is
attached to a service-linked role that allows Amazon EKS to perform actions on your behalf. For more
information, see Service-linked role permissions for Amazon EKS (p. 445).

This policy grants the AWSServiceRoleForAmazonEKSNodegroup role permissions that allow it to
create and manage Amazon EC2 node groups in your account.

Permissions details

This policy includes the following permissions that allow Amazon EKS to complete the following tasks:

- **ec2** – Work with security groups, tags, and launch templates. This is required for Amazon EKS
managed node groups to enable remote access configuration. Additionally, Amazon EKS managed
node groups create a launch template on your behalf. This is to configure the Amazon EC2 Auto
Scaling group that backs each managed node group.

- **iam** – Create a service-linked role and pass a role. This is required by Amazon EKS managed
node groups to manage instance profiles for the role being passed when creating a managed node group.
This instance profile is used by Amazon EC2 instances launched as part of a managed node group.
Amazon EKS needs to create service-linked roles for other services such as Amazon EC2 Auto Scaling
groups. These are used in the creation of a managed node group.

- **autoscaling** – Work with security Auto Scaling groups. This is required by Amazon EKS managed
node groups to manage the Amazon EC2 Auto Scaling group that backs each managed node group. It's
also used to support functionality such as evicting pods when nodes are terminated or recycled during
node group updates.

AWS managed policy: AmazonEBSCSIDriverPolicy

The AmazonEBSCSIDriverPolicy allows the Amazon EBS Container Storage Interface (CSI) driver to create, modify, attach, detach, and delete volumes on your behalf. It also grants the EBS CSI driver permissions to create and delete snapshots, and to list your instances, volumes, and snapshots.

The AmazonEBSCSIDriverPolicy includes the following permissions:

```json
{"Version": "2012-10-17",
 "Statement": [
   {
     "Effect": "Allow",
     "Action": [
       "ec2:CreateSnapshot",

Troubleshooting Amazon EKS identity and access

To diagnose and fix common issues that you might encounter when working with Amazon EKS and IAM see Troubleshooting IAM (p. 516).

Logging and monitoring in Amazon EKS

Amazon EKS control plane logging provides audit and diagnostic logs directly from the Amazon EKS control plane to CloudWatch Logs in your account. These logs make it easy for you to secure and run your clusters. You can select the exact log types you need, and logs are sent as log streams to a group for each Amazon EKS cluster in CloudWatch. For more information, see Amazon EKS Control Plane Logging (p. 62).

**Note**
When you check the Amazon EKS authenticator logs in Amazon CloudWatch, you'll see entries that contain text similar to the following example text.

```
level=info msg="mapping IAM role" groups="[]"
role="arn:aws:iam::<111122223333>:role/<XXXXXXXXXXXXXXXXXX>-NodeManagerRole-<XXXXXXXXXX>" username="eks:node-manager"
```

Entries that contain this text are expected. The `username` is an Amazon EKS internal service role that performs specific operations for managed node groups and Fargate.

Amazon EKS is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Amazon EKS. CloudTrail captures all API calls for Amazon EKS as events. The calls captured include calls from the Amazon EKS console and code calls to the Amazon EKS API operations. For more information, see Logging Amazon EKS API calls with AWS CloudTrail (p. 498).

The Kubernetes API server exposes a number of metrics that are useful for monitoring and analysis. For more information, see Control plane metrics with Prometheus (p. 418).

To configure Fluent Bit for custom Amazon CloudWatch logs, see this page.

Compliance validation for Amazon Elastic Kubernetes Service

Third-party auditors assess the security and compliance of AWS services as part of multiple AWS compliance programs, such as SOC, PCI, FedRAMP, and HIPAA.
To learn whether Amazon EKS or other AWS services are in scope of specific compliance programs, see AWS Services in Scope by Compliance Program. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- Security and Compliance Quick Start Guides – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.
- Architecting for HIPAA Security and Compliance Whitepaper – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.
  
  **Note**
  Not all AWS services are HIPAA eligible. For more information, see the HIPAA Eligible Services Reference.
- AWS Compliance Resources – This collection of workbooks and guides might apply to your industry and location.
- Evaluating Resources with Rules in the AWS Config Developer Guide – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- AWS Security Hub – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.
- AWS Audit Manager – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

## Resilience in Amazon EKS

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

Amazon EKS runs and scales the Kubernetes control plane across multiple AWS Availability Zones to ensure high availability. Amazon EKS automatically scales control plane instances based on load, detects and replaces unhealthy control plane instances, and automatically patches the control plane. After you initiate a version update, Amazon EKS updates your control plane for you, maintaining high availability of the control plane during the update.

This control plane consists of at least two API server instances and three etcd instances that run across three Availability Zones within an AWS Region. Amazon EKS:

- Actively monitors the load on control plane instances and automatically scales them to ensure high performance.
- Automatically detects and replaces unhealthy control plane instances, restarting them across the Availability Zones within the AWS Region as needed.
- Leverages the architecture of AWS Regions in order to maintain high availability. Because of this, Amazon EKS is able to offer an SLA for API server endpoint availability.

For more information about AWS Regions and Availability Zones, see AWS global infrastructure.
Infrastructure security in Amazon EKS

As a managed service, Amazon EKS is protected by the AWS global network security procedures that are described in the Amazon Web Services: Overview of security processes paper.

You use AWS published API calls to access Amazon EKS through the network. Clients must support Transport Layer Security (TLS) 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

When you create an Amazon EKS cluster, you specify the VPC subnets for your cluster to use. Amazon EKS requires subnets in at least two Availability Zones. We recommend a VPC with public and private subnets so that Kubernetes can create public load balancers in the public subnets that load balance traffic to pods running on nodes that are in private subnets.

For more information about VPC considerations, see Cluster VPC and subnet considerations (p. 262).

If you create your VPC and node groups with the AWS CloudFormation templates provided in the Getting started with Amazon EKS (p. 4) walkthrough, then your control plane and node security groups are configured with our recommended settings.

For more information about security group considerations, see Amazon EKS security group considerations (p. 265).

When you create a new cluster, Amazon EKS creates an endpoint for the managed Kubernetes API server that you use to communicate with your cluster (using Kubernetes management tools such as kubectl). By default, this API server endpoint is public to the internet, and access to the API server is secured using a combination of AWS Identity and Access Management (IAM) and native Kubernetes Role Based Access Control (RBAC).

You can enable private access to the Kubernetes API server so that all communication between your nodes and the API server stays within your VPC. You can limit the IP addresses that can access your API server from the internet, or completely disable internet access to the API server.

For more information about modifying cluster endpoint access, see Modifying cluster endpoint access (p. 46).

You can implement network policies with tools such as Project Calico (p. 341). Project Calico is a third party open source project. For more information, see the Project Calico documentation.

Configuration and vulnerability analysis in Amazon EKS

Security is a critical consideration for configuring and maintaining Kubernetes clusters and applications. The Center for Internet Security (CIS) Kubernetes Benchmark provides guidance for Amazon EKS node security configurations. The benchmark:

- Is applicable to Amazon EC2 nodes (both managed and self-managed) where you are responsible for security configurations of Kubernetes components.
- Provides a standard, community-approved way to ensure that you have configured your Kubernetes cluster and nodes securely when using Amazon EKS.
• Consists of four sections; control plane logging configuration, node security configurations, policies, and managed services.
• Supports all of the Kubernetes versions currently available in Amazon EKS and can be run using `kube-bench`, a standard open source tool for checking configuration using the CIS benchmark on Kubernetes clusters.

To learn more, see Introducing The CIS Amazon EKS Benchmark.

Amazon EKS platform versions represent the capabilities of the cluster control plane, including which Kubernetes API server flags are enabled and the current Kubernetes patch version. New clusters are deployed with the latest platform version. For details, see Amazon EKS platform versions (p. 74).

You can update an Amazon EKS cluster (p. 32) to newer Kubernetes versions. As new Kubernetes versions become available in Amazon EKS, we recommend that you proactively update your clusters to use the latest available version. For more information about Kubernetes versions in EKS, see Amazon EKS Kubernetes versions (p. 65).

Track security or privacy events for Amazon Linux 2 at the Amazon Linux Security Center or subscribe to the associated RSS feed. Security and privacy events include an overview of the issue affected, packages, and instructions for updating your instances to correct the issue.

You can use Amazon Inspector to check for unintended network accessibility of your nodes and for vulnerabilities on those Amazon EC2 instances.

Security best practices for Amazon EKS

Amazon EKS security best practices are maintained on Github: [https://aws.github.io/aws-eks-best-practices/security/docs/](https://aws.github.io/aws-eks-best-practices/security/docs/)

Pod security policy

The Kubernetes pod security policy admission controller validates pod creation and update requests against a set of rules. By default, Amazon EKS clusters ship with a fully permissive security policy with no restrictions. For more information, see Pod Security Policies in the Kubernetes documentation.

**Note**
As of Kubernetes v1.21, this feature is deprecated. PodSecurityPolicy will be functional for several more releases, following Kubernetes deprecation guidelines. To learn more, read PodSecurityPolicy Deprecation: Past, Present, and Future and the AWS blog.

Amazon EKS default pod security policy

Amazon EKS clusters with Kubernetes version 1.13 and higher have a default pod security policy named `eks.privileged`. This policy has no restriction on what kind of pod can be accepted into the system, which is equivalent to running Kubernetes with the PodSecurityPolicy controller disabled.

**Note**
This policy was created to maintain backwards compatibility with clusters that did not have the PodSecurityPolicy controller enabled. You can create more restrictive policies for your cluster and for individual namespaces and service accounts and then delete the default policy to enable the more restrictive policies.

You can view the default policy with the following command.
Delete default Amazon EKS pod security policy

If you create more restrictive policies for your pods, then after doing so, you can delete the default Amazon EKS eks.privileged pod security policy to enable your custom policies.

Important

If you are using version 1.7.0 or later of the CNI plugin and you assign a custom pod security policy to the aws-node Kubernetes service account used for the aws-node pods deployed by the Daemonset, then the policy must have NET_ADMIN in its allowedCapabilities section along with hostNetwork: true and privileged: true in the policy's spec.

To delete the default pod security policy

1. Create a file named privileged-podsecuritypolicy.yaml with the contents in the example file in Install or restore the default pod security policy (p. 494).
Install or restore default policy

If you are upgrading from an earlier version of Kubernetes, or have modified or deleted the default Amazon EKS eks.privileged pod security policy, you can restore it with the following steps.

To install or restore the default pod security policy

1. Create a file called privileged-podsecuritypolicy.yaml with the following contents.

```yaml
apiVersion: policy/v1beta1
kind: PodSecurityPolicy
metadata:
  name: eks.privileged
  annotations:
    kubernetes.io/description: 'privileged allows full unrestricted access to
    pod features, as if the PodSecurityPolicy controller was not enabled.'
    seccomp.security.alpha.kubernetes.io/allowedProfileNames: '*'
  labels:
    kubernetes.io/cluster-service: "true"
    eks.amazonaws.com/component: pod-security-policy
spec:
  privileged: true
  allowPrivilegeEscalation: true
  allowedCapabilities:
  - '*'
  volumes:
  - '*'
  hostNetwork: true
  hostPorts:
    - min: 0
    - max: 65535
  hostIPC: true
  hostPID: true
  runAsUser:
    rule: 'RunAsAny'
  seLinux:
    rule: 'RunAsAny'
  supplementalGroups:
    rule: 'RunAsAny'
  fsGroup:
    rule: 'RunAsAny'
  readOnlyRootFilesystem: false
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: eks:podsecuritypolicy:privileged
  labels:
    kubernetes.io/cluster-service: "true"
    eks.amazonaws.com/component: pod-security-policy
rules:
- apiGroups:
  - policy
  resourceNames:
  - eks.privileged
```

2. Delete the YAML with the following command. This deletes the default pod security policy, the ClusterRole, and the ClusterRoleBinding associated with it.

```
kubectl delete -f privileged-podsecuritypolicy.yaml
```
Managing Kubernetes secrets

resources:
  - podsecuritypolicies
verbs:
  - use

---

apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: eks:podsecuritypolicy:authenticated
  annotations:
    kubernetes.io/description: 'Allow all authenticated users to create privileged pods.'
    labels:
      kubernetes.io/cluster-service: "true"
      eks.amazonaws.com/component: pod-security-policy

roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: eks:podsecuritypolicy:privileged

subjects:
  - kind: Group
    apiGroup: rbac.authorization.k8s.io
    name: system:authenticated

2. Apply the YAML with the following command.

```bash
kubectl apply -f privileged-podsecuritypolicy.yaml
```

Using AWS Secrets Manager secrets with Kubernetes

To show secrets from Secrets Manager and parameters from Parameter Store as files mounted in Amazon EKS pods, you can use the AWS Secrets and Configuration Provider (ASCP) for the Kubernetes Secrets Store CSI Driver. The ASCP works with Amazon Elastic Kubernetes Service (Amazon EKS) version 1.17 or later.

With the ASCP, you can store and manage your secrets in Secrets Manager and then retrieve them through your workloads running on Amazon EKS. You can use IAM roles and policies to limit access to your secrets to specific Kubernetes pods in a cluster. The ASCP retrieves the pod identity and exchanges the identity for an IAM role. ASCP assumes the IAM role of the pod, and then it can retrieve secrets from Secrets Manager that are authorized for that role.

If you use Secrets Manager automatic rotation for your secrets, you can also use the Secrets Store CSI Driver rotation reconciler feature to ensure you are retrieving the latest secret from Secrets Manager.

For more information, see Using Secrets Manager secrets in Amazon EKS in the AWS Secrets Manager User Guide.

Amazon EKS Connector considerations

The Amazon EKS Connector is an open source component that runs on your Kubernetes cluster. This cluster can be located outside of the AWS environment. This creates additional considerations for security responsibilities. This configuration can be illustrated by the following diagram. Orange represents AWS responsibilities, and blue represents customer responsibilities:
This topic describes the differences in the responsibility model if the connected cluster is outside of AWS.

**AWS responsibilities**

- Maintaining, building, and delivering Amazon EKS Connector, which is an open source component that runs on a customer's Kubernetes cluster and communicates with AWS.
- Maintaining transport and application layer communication security between the connected Kubernetes cluster and AWS services.

**Customer responsibilities**

- Kubernetes cluster specific security, specifically along the following lines:
  - Kubernetes Secrets must be properly encrypted and protected.
  - Lock down access to the eks-connector namespace.
  - Configuring role-based access control (RBAC) permissions to manage user access from AWS. For instructions, see Granting access to a user to view a cluster.
- Installing and upgrading Amazon EKS Connector.
- Maintaining the hardware, software, and infrastructure that supports the connected Kubernetes cluster.
- Securing their AWS accounts (for example, through using secure root user credentials).
AWS services integrated with Amazon EKS

Amazon EKS works with other AWS services to provide additional solutions for your business challenges. This topic identifies services that either use Amazon EKS to add functionality, or services that Amazon EKS uses to perform tasks.

Contents
- Creating Amazon EKS resources with AWS CloudFormation (p. 497)
- Logging Amazon EKS API calls with AWS CloudTrail (p. 498)
- Use AWS App Mesh with Kubernetes (p. 500)
- Amazon EKS on AWS Outposts (p. 501)
- Amazon EKS on AWS Local Zones (p. 507)
- Deep Learning Containers (p. 507)

Creating Amazon EKS resources with AWS CloudFormation

Amazon EKS is integrated with AWS CloudFormation, a service that helps you model and set up your AWS resources so that you can spend less time creating and managing your resources and infrastructure. You create a template that describes all the AWS resources that you want, for example an Amazon EKS cluster, and AWS CloudFormation takes care of provisioning and configuring those resources for you.

When you use AWS CloudFormation, you can reuse your template to set up your Amazon EKS resources consistently and repeatedly. Just describe your resources once, and then provision the same resources over and over in multiple AWS accounts and Regions.

Amazon EKS and AWS CloudFormation templates

To provision and configure resources for Amazon EKS and related services, you must understand AWS CloudFormation templates. Templates are formatted text files in JSON or YAML. These templates describe the resources that you want to provision in your AWS CloudFormation stacks. If you're unfamiliar with JSON or YAML, you can use AWS CloudFormation Designer to help you get started with AWS CloudFormation templates. For more information, see What is AWS CloudFormation Designer? in the AWS CloudFormation User Guide.

Amazon EKS supports creating clusters and node groups in AWS CloudFormation. For more information, including examples of JSON and YAML templates for your Amazon EKS resources, see Amazon EKS resource type reference in the AWS CloudFormation User Guide.

Learn more about AWS CloudFormation

To learn more about AWS CloudFormation, see the following resources:
Logging Amazon EKS API calls with AWS CloudTrail

Amazon EKS is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Amazon EKS. CloudTrail captures all API calls for Amazon EKS as events, including calls from the Amazon EKS console and from code calls to the Amazon EKS API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Amazon EKS. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request that was made to Amazon EKS, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Amazon EKS information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Amazon EKS, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing events with CloudTrail event history.

For an ongoing record of events in your AWS account, including events for Amazon EKS, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple regions and Receiving CloudTrail log files from multiple accounts

All Amazon EKS actions are logged by CloudTrail and are documented in the Amazon EKS API Reference. For example, calls to the CreateCluster, ListClusters and DeleteCluster sections generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.
For more information, see the CloudTrail userIdentity element.

Understanding Amazon EKS log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the CreateCluster action.

```json
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AKIAIOSFODNN7EXAMPLE",
    "arn": "arn:aws:iam::your-account-id:user/username",
    "accountId": "your-account-id",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "userName": "username"
  },
  "eventSource": "eks.amazonaws.com",
  "eventName": "CreateCluster",
  "awsRegion": "region-code",
  "sourceIPAddress": "205.251.233.178",
  "userAgent": "PostmanRuntime/6.4.0",
  "requestParameters": {
    "resourcesVpcConfig": {
      "subnetIds": [
        "subnet-a670c2df",
        "subnet-4f8c5004"
      ]
    },
    "roleArn": "arn:aws:iam::your-account-id:role/AWSServiceRoleForAmazonEKS-CAC1G1VH3ZKZ",
    "clusterName": "test"
  },
  "responseElements": {
    "cluster": {
      "clusterName": "test",
      "status": "CREATING",
      "createdAt": 1527535003.208,
      "certificateAuthority": {},
      "roleArn": "arn:aws:iam::your-account-id:role/AWSServiceRoleForAmazonEKS-CAC1G1VH3ZKZ",
      "version": "1.10",
      "resourcesVpcConfig": {
        "securityGroupIds": [],
        "vpcId": "vpc-21277358",
        "subnetIds": [
          "subnet-a670c2df",
          "subnet-4f8c5004"
        ]
      }
    }
  },
  "requestID": "a7a0735d-62ab-11e8-9f79-81ce5b2b7d37",
  "eventID": "eab22523-174a-499c-9dd6-91e7be3ff8e3",
  "readOnly": false,
  "eventType": "AwsApiCall",
  "recipientAccountId": "your-account-id"
}
```
Log Entries for Amazon EKS Service Linked Roles

The Amazon EKS service linked roles make API calls to AWS resources. You will see CloudTrail log entries with username: AWSServiceRoleForAmazonEKS and username: AWSServiceRoleForAmazonEKSNodegroup for calls made by the Amazon EKS service linked roles. For more information about Amazon EKS and service linked roles, see Using service-linked roles for Amazon EKS (p. 442).

The following example shows a CloudTrail log entry that demonstrates a $\texttt{DeleteInstanceProfile}$ action made by the AWSServiceRoleForAmazonEKSNodegroup service linked role, noted in the sessionContext.

```json
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "AROA3WHGPEZ7SJ2CW55C5:EKS",
    "arn": "arn:aws:sts::your-account-id:assumed-role/AWSServiceRoleForAmazonEKSNodegroup/EKS",
    "accountId": "your-account-id",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "sessionIssuer": {
        "type": "Role",
        "principalId": "AROA3WHGPEZ7SJ2CW55C5",
        "arn": "arn:aws:iam::your-account-id:role/aws-service-role/eks-nodegroup.amazonaws.com/AWSServiceRoleForAmazonEKSNodegroup",
        "accountId": "your-account-id",
        "userName": "AWSServiceRoleForAmazonEKSNodegroup"
      },
      "webIdFederationData": {},
      "attributes": {
        "mfaAuthenticated": "false",
        "creationDate": "2020-02-26T00:56:33Z"
      }
    },
    "invokedBy": "eks-nodegroup.amazonaws.com"
  },
  "eventTime": "2020-02-26T00:56:34Z",
  "eventSource": "iam.amazonaws.com",
  "eventName": "DeleteInstanceProfile",
  "awsRegion": "region-code",
  "sourceIPAddress": "eks-nodegroup.amazonaws.com",
  "userId": "eks-nodegroup.amazonaws.com",
  "requestParameters": {
    "instanceProfileName": "eks-1111111-2222-3333-4444-abcd123456"
  },
  "responseElements": null,
  "requestId": "1111111-2222-3333-4444-abcd123456",
  "eventType": "AwsApiCall",
  "recipientAccountId": "your-account-id"
}
```

Use AWS App Mesh with Kubernetes

AWS App Mesh (App Mesh) is a service mesh that makes it easy to monitor and control services. App Mesh standardizes how your services communicate, giving you end-to-end visibility and helping to
ensure high availability for your applications. App Mesh gives you consistent visibility and network traffic controls for every service in an application. You can get started using App Mesh with Kubernetes by completing the Getting started with AWS App Mesh and Kubernetes tutorial in the AWS App Mesh User Guide. The tutorial recommends that you have existing services deployed to Kubernetes that you want to use App Mesh with.

**Amazon EKS on AWS Outposts**

You can create and run Amazon EKS nodes on AWS Outposts. AWS Outposts enables native AWS services, infrastructure, and operating models in on-premises facilities for low latency, local data processing, and data residency needs. In AWS Outposts environments, you can use the same AWS APIs, tools, and infrastructure that you use in the AWS Cloud. For more information about AWS Outposts, see the AWS Outposts User Guide.

You can use Amazon EKS to run Kubernetes applications on-premises with AWS Outposts. Amazon EKS on AWS Outposts supports extended clusters, with the Kubernetes control plane running in the parent AWS Region, and worker nodes running on AWS Outposts. The Kubernetes control plane is fully managed by AWS, and you can use the same Amazon EKS APIs, tools, and console to create and run Amazon EKS worker nodes on AWS Outposts.

**Prerequisites**

The following are the prerequisites for using Amazon EKS nodes on AWS Outposts:

- You must have installed and configured an Outpost in your on-premises data center. For more information, see Create an Outpost and order Outpost capacity in the AWS Outposts User Guide.

- You must have a reliable network connection between your Outpost and its parent AWS Region. We recommend that you provide highly available, low-latency connectivity between your Outpost and its parent AWS Region. For more information, see Outpost connectivity to the local network in the AWS Outposts User Guide.

- The AWS Region for the Outpost must support Amazon EKS. For a list of supported AWS Regions, see Amazon EKS service endpoints in the AWS General Reference.

**Outpost considerations**

**Architecture**

- AWS Outposts are available in a variety of form factors including 1U and 2U Outposts servers and 42U Outposts racks. Amazon EKS is supported on the 42U Outposts racks only.

- A single subnet cannot span multiple logical Outposts, and inter-Outposts traffic must use customer-owned IP addresses and traverse the local network. Because of this, it is recommended to run a single Amazon EKS cluster per logical Outpost.
• Traffic from Amazon EKS worker nodes running on AWS Outposts to the control plane in an AWS Region stays within your VPC and traverses the service link connection. You can use private or public connectivity for your service link connection. For more information about the service link, see Outposts Connectivity to AWS Regions in the AWS Outposts User Guide.

• If network connectivity between your Outpost and its parent AWS Region is lost, your Amazon EKS worker nodes will continue to run. However, you cannot create new nodes or perform mutating management actions on existing deployments until connectivity is restored. The recommended course of action during network disconnects is to attempt to reconnect your AWS Outposts to the parent AWS Region following the network connectivity checklist. In case of instance failures during periods of network disconnect, the instances will not be replaced automatically. The Amazon EKS Kubernetes control plane runs in the parent AWS Region, and missing kubelet heartbeats can lead to the following:
  • Pods on the AWS Outposts being marked as unhealthy
  • the Node status times out
  • the Pods will be marked for eviction

For more information, see Node Controller in the Kubernetes documentation.

Operational

• When you create your Amazon EKS cluster, you must use subnets that run in the AWS Region because these are used for the creation of the Amazon EKS Kubernetes control plane. During cluster creation, do not use subnets that run on your AWS Outposts.

• You can run self-managed nodes on AWS Outposts only, managed nodes and Fargate are not supported. When you create a self-managed node group, you must pass the subnets that exist on your AWS Outposts.

• The Amazon EKS worker nodes’ VPC must be associated with an LGW route table for Services running on the worker nodes to be accessible over the local network. If you are using customer-owned IPs, then the subnet in which the worker nodes run must have a route to the LGW.

• IPv6 cannot be used for service link or local network traffic on AWS Outposts. You shouldn’t create your Amazon EKS cluster with the IPv6 IP family if you plan to run Amazon EKS worker nodes on AWS Outposts.

• The Kubernetes components for Amazon EKS worker nodes are pulled from Amazon Elastic Container Registry (Amazon ECR) in the parent AWS Region. When bootstrapping new Amazon EC2 instances to your Amazon EKS cluster, expect an increase in traffic over your service link connection.

• You can use Amazon ECR in the parent AWS Region to host your application container images. The size of your application container images will affect the service link bandwidth usage and the startup time when deploying new Pods that are not already cached. If you need to reduce your application deployment time, consider hosting a local container registry or cache for your application container images. If you have “isolated” subnets that do not have a path to the internet, you must set up VPC Endpoints for Amazon S3 and Amazon ECR to create Amazon EKS worker nodes on AWS Outposts.

• When creating your Amazon EKS worker nodes, you must use the gp2 volume type.

Application

• With AWS Outposts, you can run some AWS services locally, and you can connect to a broad range of services available in the parent AWS Region. The locally available AWS services will have lower latency response times compared to those running in the parent AWS Region. The AWS services that you use in the AWS Region will not be available during periods of network disconnect to the parent AWS Region. For information on the AWS services available locally, see the AWS Outposts User Guide.

• You can connect to your applications running on Amazon EKS on AWS Outposts over your local network using the normal methods for Kubernetes Services and Ingress. Application Load Balancer
(ALB) is available for Kubernetes Ingress on Outposts racks. Network Load Balancer (Network Load Balancer) is not available on AWS Outposts. A common practice to conserve capacity on AWS Outposts is to use a single ALB deployment with path-based routing for each Kubernetes Service. For more information, see the Application Load Balancer documentation.

- Amazon EBS volumes do not span physical or logical AWS Outposts, similar to the multi-Availability Zone behavior in AWS Regions. For example, if a Node running on physical Outpost A moves to physical Outpost B, the EBS volume will not move with it. If you are running stateful workloads on Amazon EKS with Pods backed by EBS volumes, consider implementing dual writes at the application layer or using an alternative storage mechanism if your application and its data must remain available during single-rack failures.

Deploy an Amazon EKS cluster with worker nodes on AWS Outposts

This section describes how to create an Amazon EKS cluster and deploy Amazon EKS worker nodes on AWS Outposts using eksctl and the AWS CLI. You must have permissions to create and manage subnets on AWS Outposts. Click here to learn more about shareable Outpost resources [https://docs.aws.amazon.com/outposts/latest/userguide/sharing-outposts.html#sharing-resources](https://docs.aws.amazon.com/outposts/latest/userguide/sharing-outposts.html#sharing-resources).

1. Create a public Amazon EKS cluster using a YAML file:

   ```bash
   eksctl create cluster -f cluster-config.yaml
   ```

   An example YAML file is shown below:

   ```yaml
   apiVersion: eksctl.io/v1alpha5
   kind: ClusterConfig
   metadata:
     name: my-outposts-cluster
     version: 1.21
     region: us-west-2
   cloudWatch:
     clusterLogging:
       enableTypes: [ "api", "audit", "authenticator", "controllerManager", "scheduler" ]
   iam:
     withOIDC: true
   addons:
     - name: vpc-cni
     - name: coredns
     - name: kube-proxy
   
   To create a fully private cluster, add the following to your config YAML file:

   ```yaml
   privateCluster:
     enabled: true
   ```

   Your output should looks similar to this:

   ```bash
   eksctl version 0.80.0
   using region us-west-2
   ```
Deploy an Amazon EKS cluster with worker nodes on AWS Outposts

Creating an EKS cluster with worker nodes on AWS Outposts

1. Create subnets for your Outpost. You can find your VPC with the command:

   eksctl get cluster --name my-outposts-cluster

2. Identify the VPC created with your new cluster. This VPC will host the subnet that contains your worker nodes. You can find your vpc-id with the command:

   eksctl get cluster --name my-outposts-cluster

3. Identify the subnet and CIDR for your Outpost. The CIDR shouldn't conflict with other IP addresses in use on your local network. This can be done by using a subnet calculator and determining the appropriate settings for your environment. Once you have calculated the CIDR, you can use this value in the next step. Your availability-zone is visible in the AWS Management Console.

4. Create a subnet on AWS Outposts using AWS CLI to host your worker nodes. Use the vpc-id that you retrieved in the previous step in the following command:

   aws ec2 create-subnet \
     --region us-west-2 \ 
     --availability-zone us-west-2 \ 
     --outpost-arn your-outpost-arn\ 
     --vpc-id your-vpc-id \ 
     --cidr-block your-cidr-block

Note the subnet id that appears in the message after creation.

Your output should look similar to this:

```json
{
  "Subnet": {
    "AvailabilityZone": "us-west-2b",
    "AvailabilityZoneId": "usw2-az1",
    "AvailableIpAddressCount": 11,
    ...
  }
}```
Deploy an Amazon EKS cluster with worker nodes on AWS Outposts

You can verify the subnet creation in the AWS Management Console under your cluster details.

5. Create worker nodes by using a YAML file. Replace the `vpc-id` with the value created in step 1 and `subnet-id` created in step 2. The `security-group-id` was created in step 1 and can be retrieved with the command:

```bash
eksctl get cluster --name my-outposts-cluster
```

The nodes can be created with a YAML file by using the command:

```bash
eksctl create nodegroup -f worker-nodes-config.yaml
```

The following is an example YAML file to include in this step. For `instanceType`, select the instance size that is:

- slotted on your Outpost
- available for your workload

```yaml
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig

metadata:
  name: my-outposts-cluster
  region: us-west-2

nodeGroups:
  - name: outpost-worker-nodes
    instanceType: m5.large
    desiredCapacity: 1
    minSize: 1
    maxSize: 1
    volumeSize: 50
    volumeType: gp2
    volumeEncrypted: true
    subnets:
      - subnet-042e2c531a5713a5b
    privateNetworking: true
```
To create private worker nodes, add this to the end of the YAML file:

```
subnets:
  - outpost-subnet
  volumeType: gp2
  privateNetworking: true
```

Your output should look similar to this:

```
all nodegroups have up-to-date cloudformation templates
eksctl version 0.80.0
using region us-west-2
will use version 1.21 for new nodegroup(s) based on control plane version
nodegroup "outpost-worker-nodes" will use "ami-085e8e02353a59de5" [AmazonLinux2/1.21]
  nodegroup (outpost-worker-nodes) was included (based on the include/exclude rules)
will create a CloudFormation stack for each of 1 nodegroups in cluster "my-outpost-cluster"
2 sequential tasks: { fix cluster compatibility, 1 task: { 1 task: { create nodegroup
  "outpost-worker-nodes" } } }
  checking cluster stack for missing resources
  cluster stack has all required resources
  building nodegroup stack "eksctl-my-outpost-cluster-nodegroup-outpost-worker-nodes"
  deploying stack "eksctl-my-outpost-cluster-nodegroup-outpost-worker-nodes"
  waiting for CloudFormation stack "eksctl-my-outpost-cluster-nodegroup-outpost-worker-nodes"
  waiting for CloudFormation stack "eksctl-my-outpost-cluster-nodegroup-outpost-worker-nodes"...
  no tasks
  adding identity "arn:aws:iam::601017151385:role/eksctl-my-outpost-cluster-nodegro-
  NodeInstanceRole-LHYFK4K4DV8S" to auth ConfigMap
  nodegroup "outpost-worker-nodes" has 0 node(s)
  waiting for at least 1 node(s) to become ready in "outpost-worker-nodes"
  nodegroup "outpost-worker-nodes" has 2 node(s)
  node "ip-192-168-192-5.us-west-2.compute.internal" is not ready
  node "ip-192-168-192-9.us-west-2.compute.internal" is ready
  created 1 nodegroup(s) in cluster "my-outpost-cluster"
  created 0 managed nodegroup(s) in cluster "my-outpost-cluster"
  checking security group configuration for all nodegroups
```

6. (Optional) To expose worker nodes over your local network, see [How local gateways work](#).

Now that you have a configured Amazon EKS cluster with worker nodes running on AWS Outposts, you can install add-ons and deploying applications to your cluster. See the following for more information on how to extend your cluster's functionality:

- The IAM entity (user or role) that created the cluster is the only IAM user that can make calls to the API server using `kubectl`. To grant access to other users or roles, see [Apply the `aws-auth` ConfigMap to your cluster](#) (p. 399).
- Deploy a sample application (p. 352) to your cluster.
- Learn about important [Cluster management](#) (p. 413) tools.
- Deploy a containerized application on AWS Outposts.
- Build a modern application on AWS Outposts with [Terraform examples](#).
Amazon EKS on AWS Local Zones

An AWS Local Zone is an extension of an AWS Region in geographic proximity to your users. Local Zones have their own connections to the internet and support AWS Direct Connect. Resources created in a Local Zone can serve local users with low-latency communications. For more information, see Local Zones.

Amazon EKS supports running certain infrastructure. This includes Amazon EC2 instances, Amazon EBS volumes, and Application Load Balancers (ALBs) from a Local Zone as part of your cluster. We recommend that you consider the following when using Local Zone infrastructure as part of your Amazon EKS cluster.

**Kubernetes versions**

Only Amazon EKS clusters that run Kubernetes versions 1.17 and later can use Local Zone compute resources.

**Nodes**

You can't create managed node groups in AWS Local Zones with Amazon EKS. You must create self-managed nodes using the Amazon EC2 API or AWS CloudFormation. **Do not use eksctl to create your cluster or nodes in Local Zones.** For more information, see Self-managed nodes (p. 131).

**Network architecture**

The Amazon EKS managed Kubernetes control plane always runs in the AWS Region. The Amazon EKS managed Kubernetes control plane can't run in the Local Zone. Because Local Zones appear as a subnet within your VPC, Kubernetes sees your Local Zone resources as part of that subnet.

The Amazon EKS Kubernetes cluster communicates with the Amazon EC2 instances you run in the AWS Region or Local Zone using Amazon EKS managed elastic network interfaces. To learn more about Amazon EKS networking architecture, see Amazon EKS networking (p. 256).

Unlike regional subnets, Amazon EKS can't place network interfaces into your Local Zone subnets. This means that you must not specify Local Zone subnets when you create your cluster.

After the cluster is created, tag your Local Zone subnets with the Amazon EKS cluster name. For more information, see Subnet tagging (p. 265). You can then deploy self-managed nodes to the Local Zone subnets and the nodes join your Amazon EKS cluster.

Deep Learning Containers

AWS Deep Learning Containers are a set of Docker images for training and serving models in TensorFlow on Amazon EKS and Amazon Elastic Container Service (Amazon ECS). Deep Learning Containers provide optimized environments with TensorFlow, Nvidia CUDA (for GPU instances), and Intel MKL (for CPU instances) libraries and are available in Amazon ECR.

To get started using AWS Deep Learning Containers on Amazon EKS, see AWS Deep Learning Containers on Amazon EKS in the AWS Deep Learning AMI Developer Guide.
Amazon EKS troubleshooting

This chapter covers some common errors that you may see while using Amazon EKS and how to work around them.

Insufficient capacity

If you receive the following error while attempting to create an Amazon EKS cluster, then one of the Availability Zones you specified does not have sufficient capacity to support a cluster.

Cannot create cluster 'example-cluster' because region-1d, the targeted Availability Zone, does not currently have sufficient capacity to support the cluster. Retry and choose from these Availability Zones: region-1a, region-1b, region-1c

Retry creating your cluster with subnets in your cluster VPC that are hosted in the Availability Zones returned by this error message.

Nodes fail to join cluster

There are a few common reasons that prevent nodes from joining the cluster:

- The aws-auth-cm.yaml (p. 395) file does not have the correct IAM role ARN for your nodes. Ensure that the node IAM role ARN (not the instance profile ARN) is specified in your aws-auth-cm.yaml file. For more information, see Launching self-managed Amazon Linux nodes (p. 132).
- The ClusterName in your node AWS CloudFormation template does not exactly match the name of the cluster you want your nodes to join. Passing an incorrect value to this field results in an incorrect configuration of the node's /var/lib/kubelet/kubeconfig file, and the nodes will not join the cluster.
- The node is not tagged as being owned by the cluster. Your nodes must have the following tag applied to them, where cluster-name is replaced with the name of your cluster.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/cluster/cluster-name</td>
<td>owned</td>
</tr>
</tbody>
</table>

- The nodes may not be able to access the cluster using a public IP address. Ensure that nodes deployed in public subnets are assigned a public IP address. If not, you can associate an Elastic IP address to a node after it’s launched. For more information, see Associating an Elastic IP address with a running instance or network interface. If the public subnet is not set to automatically assign public IP addresses to instances deployed to it, then we recommend enabling that setting. For more information, see Modifying the public IPv4 addressing attribute for your subnet. If the node is deployed to a private subnet, then the subnet must have a route to a NAT gateway that has a public IP address assigned to it.
- The STS endpoint for the AWS Region that you’re deploying the nodes to is not enabled for your account. To enable the region, see Activating and deactivating AWS STS in an AWS Region.
- The worker node does not have a private DNS entry, resulting in the kubelet log containing a node "" not found error. Ensure that the VPC where the worker node is created has values set for domain-name and domain-name-servers as Options in a DHCP options set. The default values are domain-name:<region>.compute.internal and domain-name-
servers: AmazonProvidedDNS. For more information, see DHCP options sets in the Amazon VPC User Guide.

Unauthorized or access denied (kubectl)

If you receive one of the following errors while running kubectl commands, then your kubectl is not configured properly for Amazon EKS or the IAM user or role credentials that you are using do not map to a Kubernetes RBAC user with sufficient permissions in your Amazon EKS cluster.

- could not get token: AccessDenied: Access denied
- error: You must be logged in to the server (Unauthorized)
- error: the server doesn't have a resource type "svc"

This could be because the cluster was created with one set of AWS credentials (from an IAM user or role), and kubectl is using a different set of credentials.

When an Amazon EKS cluster is created, the IAM entity (user or role) that creates the cluster is added to the Kubernetes RBAC authorization table as the administrator (with system:masters permissions). Initially, only that IAM user can make calls to the Kubernetes API server using kubectl. For more information, see Enabling IAM user and role access to your cluster (p. 395). If you use the console to create the cluster, you must ensure that the same IAM user credentials are in the AWS SDK credential chain when you are running kubectl commands on your cluster.

If you install and configure the AWS CLI, you can configure the IAM credentials for your user. For more information, see Configuring the AWS CLI in the AWS Command Line Interface User Guide.

If you assumed a role to create the Amazon EKS cluster, you must ensure that kubectl is configured to assume the same role. Use the following command to update your kubeconfig file to use an IAM role.

For more information, see Create a kubeconfig for Amazon EKS (p. 403).

```bash
aws eks update-kubeconfig \
  --region region-code \
  --name my-cluster \
  --role-arn arn:aws:iam::aws_account_id:role/role_name
```

To map an IAM user to a Kubernetes RBAC user, see Enabling IAM user and role access to your cluster (p. 395).

aws-iam-authenticator Not found

If you receive the error "aws-iam-authenticator": executable file not found in $PATH, then your kubectl is not configured for Amazon EKS. For more information, see Installing aws-iam-authenticator (p. 408).

Note
The aws-iam-authenticator isn't required if you have the AWS CLI version 1.16.156 or higher installed.

hostname doesn't match

Your system's Python version must be 2.7.9 or later. Otherwise, you receive hostname doesn't match errors with AWS CLI calls to Amazon EKS. For more information, see What are "hostname doesn't match" errors? in the Python Requests FAQ.
getsockopt: no route to host

Docker runs in the 172.17.0.0/16 CIDR range in Amazon EKS clusters. We recommend that your cluster's VPC subnets do not overlap this range. Otherwise, you will receive the following error:

```
```

Managed node group errors

If you receive the error "Instances failed to join the kubernetes cluster" in the AWS Management Console, ensure that either the cluster's private endpoint access is enabled, or that you have correctly configured CIDR blocks for public endpoint access. For more information, see Amazon EKS cluster endpoint access control (p. 45).

If your managed node group encounters a hardware health issue, Amazon EKS returns an error message to help you to diagnose the issue. These health checks don't detect software issues because they are based on Amazon EC2 health checks. The following error messages and their associated descriptions are shown below.

- **AccessDenied**: Amazon EKS or one or more of your managed nodes is failing to authenticate or authorize with your Kubernetes cluster API server. For more information about resolving this error, see Fixing AccessDenied errors for managed node groups (p. 511).
- **AmiIdNotFound**: We couldn't find the AMI Id associated with your Launch Template. Make sure that the AMI exists and is shared with your account.
- **AutoScalingGroupNotFound**: We couldn't find the Auto Scaling group associated with the managed node group. You may be able to recreate an Auto Scaling group with the same settings to recover.
- **ClusterUnreachable**: Amazon EKS or one or more of your managed nodes is unable to communicate with your Kubernetes cluster API server. This can happen if there are network disruptions or if API servers are timing out processing requests.
- **Ec2SecurityGroupNotFound**: We couldn't find the cluster security group for the cluster. You must recreate your cluster.
- **Ec2SecurityGroupDeletionFailure**: We could not delete the remote access security group for your managed node group. Remove any dependencies from the security group.
- **Ec2LaunchTemplateNotFound**: We couldn't find the Amazon EC2 launch template for your managed node group. You must recreate your node group to recover.
- **Ec2LaunchTemplateVersionMismatch**: The Amazon EC2 launch template version for your managed node group does not match the version that Amazon EKS created. You may be able to revert to the version that Amazon EKS created to recover.
- **IamInstanceProfileNotFound**: We couldn't find the IAM instance profile for your managed node group. You may be able to recreate an instance profile with the same settings to recover.
- **IamNodeRoleNotFound**: We couldn't find the IAM role for your managed node group. You may be able to recreate an IAM role with the same settings to recover.
- **AsgInstanceLaunchFailures**: Your Auto Scaling group is experiencing failures while attempting to launch instances.
- **NodeCreationFailure**: Your launched instances are unable to register with your Amazon EKS cluster. Common causes of this failure are insufficient node IAM role (p. 452) permissions or lack of outbound internet access for the nodes. Your nodes must be able to access the internet using a public IP address to function properly. For more information, see VPC IP addressing (p. 263). Your nodes
must also have ports open to the internet. For more information, see Amazon EKS security group considerations (p. 265).

- **InstanceLimitExceeded**: Your AWS account is unable to launch any more instances of the specified instance type. You may be able to request an Amazon EC2 instance limit increase to recover.
- **InsufficientFreeAddresses**: One or more of the subnets associated with your managed node group does not have enough available IP addresses for new nodes.
- **InternalFailure**: These errors are usually caused by an Amazon EKS server-side issue.

**Fixing AccessDenied errors for managed node groups**

The most common cause of AccessDenied errors when performing operations on managed node groups is missing the eks:node-manager ClusterRole or ClusterRoleBinding. Amazon EKS sets up these resources in your cluster as part of onboarding with managed node groups, and these are required for managing the node groups.

The ClusterRole may change over time, but it should look similar to the following example:

```yaml
apiVersion: rbac.authorization.k8s.io/v1
class: ClusterRole
metadata:
  name: eks:node-manager
rules:
- apiGroups:
  - 
    resources:
    - pods
    verbs:
    - get
    - list
    - watch
    - delete
- apiGroups:
  - 
    resources:
    - nodes
    verbs:
    - get
    - list
    - watch
    - patch
- apiGroups:
  - 
    resources:
    - pods/eviction
    verbs:
    - create
```

The ClusterRoleBinding may change over time, but it should look similar to the following example:

```yaml
apiVersion: rbac.authorization.k8s.io/v1
class: ClusterRoleBinding
metadata:
  name: eks:node-manager
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: eks:node-manager
subjects:
```
Verify that the eks:node-manager ClusterRole exists.

```
kubectl describe clusterrole eks:node-manager
```

If present, compare the output to the previous ClusterRole example.

Verify that the eks:node-manager ClusterRoleBinding exists.

```
kubectl describe clusterrolebinding eks:node-manager
```

If present, compare the output to the previous ClusterRoleBinding example.

If you've identified a missing or broken ClusterRole or ClusterRoleBinding as the cause of an AccessDenied error while requesting managed node group operations, you can restore them. Save the following contents to a file named `eks-node-manager-role.yaml`.

```yaml
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: eks:node-manager
rules:
- apiGroups: 
  - ''
  resources: 
  - pods
  verbs: 
  - get
  - list
  - watch
  - delete
- apiGroups: 
  - ''
  resources: 
  - nodes
  verbs: 
  - get
  - list
  - watch
  - patch
- apiGroups: 
  - ''
  resources: 
  - pods/eviction
  verbs: 
  - create
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: eks:node-manager
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: eks:node-manager
subjects:
- apiGroup: rbac.authorization.k8s.io
  kind: User
```
Apply the file.

```shell
kubectl apply -f eks-node-manager-role.yaml
```

Retry the node group operation to see if that resolved your issue.

## CNI log collection tool

The Amazon VPC CNI plugin for Kubernetes has its own troubleshooting script that is available on nodes at `/opt/cni/bin/aws-cni-support.sh`. You can use the script to collect diagnostic logs for support cases and general troubleshooting.

Use the following command to run the script on your node:

```bash
sudo bash /opt/cni/bin/aws-cni-support.sh
```

**Note**

If the script is not present at that location, then the CNI container failed to run. You can manually download and run the script with the following command:

```bash
sudo bash eks-log-collector.sh
```

The script collects the following diagnostic information. The CNI version that you have deployed can be earlier than the script version.

```text
This is version 0.6.1. New versions can be found at https://github.com/awslabs/amazon-eks-ami

- Trying to collect common operating system logs...
- Trying to collect kernel logs...
- Trying to collect mount points and volume information...
- Trying to collect SELinux status...
- Trying to collect iptables information...
- Trying to collect installed packages...
- Trying to collect active system services...
- Trying to collect Docker daemon information...
- Trying to collect kubectl information...
- Trying to collect L-IPAMD information...
- Trying to collect sysctls information...
- Trying to collect networking information...
- Trying to collect CNI configuration information...
- Trying to collect running Docker containers and gather container data...
- Trying to collect Docker daemon logs...
- Trying to archive gathered information...

Done... your bundled logs are located in /var/log/eks_i-0717c9d54b6cfa019_2020-03-24_0103-UTC_0.6.1.tar.gz
```

The diagnostic information is collected and stored at:

```bash
/var/log/eks_i-0717c9d54b6cfa019_2020-03-24_0103-UTC_0.6.1.tar.gz
```
Container runtime network not ready

You may receive a Container runtime network not ready error and authorization errors similar to the following:

```
4191 kubelet_node_status.go:106] Unable to register node "ip-10-40-175-122.ec2.internal" with API server: Unauthorized
```

The errors are most likely because the AWS IAM Authenticator (aws-auth) configuration map isn't applied to the cluster. The configuration map provides the system:bootstrappers and system:nodes Kubernetes RBAC permissions for nodes to register to the cluster. To apply the configuration map to your cluster, see Apply the aws-auth ConfigMap to your cluster (p. 399).

The authenticator does not recognize a Role ARN if it includes a path other than /, such as the following example:

```
arn:aws:iam::111122223333:role/development/apps/prod-iam-role-NodeInstanceRole-621LVEXAMPLE
```

When specifying a Role ARN in the configuration map that includes a path other than /, you must drop the path. The ARN above should be specified as the following:

```
arn:aws:iam::111122223333:role/prod-iam-role-NodeInstanceRole-621LVEXAMPLE
```

TLS handshake timeout

When a node is unable to establish a connection to the public API server endpoint, you may see an error similar to the following error.

```
server.go:233] failed to run Kubelet: could not init cloud provider "aws": error finding instance i-1111f222f333e44c: "error listing AWS instances: "\"RequestError: send request failed\ncaused by: Post  net/http: TLS handshake timeout\""
```

The kubelet process will continually respawn and test the API server endpoint. The error can also occur temporarily during any procedure that performs a rolling update of the cluster in the control plane, such as a configuration change or version update.

To resolve the issue, check the route table and security groups to ensure that traffic from the nodes can reach the public endpoint.

InvalidClientTokenId

If you're using IAM roles for service accounts for a pod or daemonset deployed to a cluster in a China AWS Region, and haven't set the AWS_DEFAULT_REGION environment variable in the spec, the pod or daemonset may receive the following error:
An error occurred (InvalidClientTokenId) when calling the GetCallerIdentity operation: The security token included in the request is invalid

To resolve the issue, you need to add the `AWS_DEFAULT_REGION` environment variable to your pod or daemonset spec, as shown in the following example pod spec.

```yaml
apiVersion: v1
kind: Pod
metadata:
  name: envar-demo
labels:
  purpose: demonstrate-envvars
spec:
  containers:
  - name: envar-demo-container
    image: gcr.io/google-samples/node-hello:1.0
    env:
      - name: AWS_DEFAULT_REGION
        value: "region-code"
```

**VPC admission webhook certificate expiration**

If the certificate used to sign the VPC admission webhook expires, the status for new Windows pod deployments stays at ContainerCreating.

To resolve the issue if you have legacy Windows support on your data plane, see the section called "Renew VPC admission webhook certificate" (p. 98). If your cluster and platform version are later than a version listed in the Windows support prerequisites (p. 91), then we recommend that you remove legacy Windows support on your data plane and enable it for your control plane. Once you do, you don't need to manage the webhook certificate. For more information, see Windows support (p. 90).

**Node groups must match Kubernetes version before updating control plane**

Before you update a control plane to a new Kubernetes version, the minor version of the managed and Fargate nodes in your cluster must be the same as the version of your control plane's current version. The EKS update-cluster-version API rejects requests until you update all EKS managed nodes to the current cluster version. EKS provides APIs to update managed nodes. For information on updating managed node group Kubernetes versions, see Updating a managed node group (p. 119). To update the version of a Fargate node, delete the pod that's represented by the node and redeploy the pod after you update your control plane. For more information, see Updating a cluster (p. 32).

**When launching many nodes, there are Too Many Requests errors**

If you launch many nodes simultaneously, you may see an error message that says Waiter ClusterActive failed: Too Many Requests. This can occur because the control plane is being overloaded with describeCluster calls. The overloading results in throttling, nodes failing to run the bootstrap script, and nodes failing to join the cluster altogether.
Make sure that you are setting the values for the --apiserver-endpoint, --b64-cluster-ca, and --dns-cluster-ip arguments. When including these arguments, there’s no need for the bootstrap script to make a describeCluster call, which helps prevent the control plane from being overloaded. For more information, see Specifying an AMI (p. 128).

Troubleshooting IAM

This topic covers some common errors that you may see while using Amazon EKS with IAM and how to work around them.

AccessDeniedException

If you receive an AccessDeniedException when calling an AWS API operation, then the AWS Identity and Access Management (IAM) user or role credentials that you are using do not have the required permissions to make that call.

An error occurred (AccessDeniedException) when calling the DescribeCluster operation:
User: arn:aws:iam::111122223333:user/user_name is not authorized to perform:

In the above example message, the user does not have permissions to call the Amazon EKS DescribeCluster API operation. To provide Amazon EKS admin permissions to a user, see Amazon EKS identity-based policy examples (p. 438).

For more general information about IAM, see Controlling access using policies in the IAM User Guide.

Can’t see workloads or nodes and receive an error in the AWS Management Console

You may see a console error message that says Your current user or role does not have access to Kubernetes objects on this EKS cluster. Make sure that the IAM entity (user or role) that you’re signed into the AWS Management Console with meets all of the following requirements:

- Has an IAM policy attached to it that includes the eks:AccessKubernetesApi action. For an example IAM policy, see View nodes and workloads for all clusters in the AWS Management Console (p. 440). If you’re using the IAM policy visual editor in the AWS Management Console and you don’t see the eks:AccessKubernetesApi Permission listed, edit the policy’s JSON and add eks:AccessKubernetesApi to the list of Actions in the JSON.

- Has a mapping to a Kubernetes user or group in the aws-auth configmap. For more information about adding IAM users or roles to the aws-auth configmap, see Enabling IAM user and role access to your cluster (p. 395). If the user or role isn’t mapped, the console error may include Unauthorized: Verify you have access to the Kubernetes cluster.

- The Kubernetes user or group that the IAM account or role is mapped to in the configmap must be a subject in a rolebinding or clusterrolebinding that is bound to a Kubernetes role or clusterrole that has the necessary permissions to view the Kubernetes resources. If the user or group doesn’t have the necessary permissions, the console error may include Unauthorized: Verify you have access to the Kubernetes cluster. To create roles and bindings, see Using RBAC Authorization in the Kubernetes documentation. You can download the example manifests that create a clusterrole and clusterrolebinding or a role and rolebinding by following the instructions in the Important section of View nodes and workloads for all clusters in the AWS Management Console (p. 440).
aws-auth ConfigMap does not grant access to the cluster

AWS IAM Authenticator does not permit a path in the role ARN used in the configuration map. Therefore, before you specify roleARN, remove the path. For example, change

arn:aws:iam::123456789012:role/team/developers/eks-admin to

arn:aws:iam::123456789012:role/eks-admin.

I Am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password. Ask that person to update your policies to allow you to pass a role to Amazon EKS.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in Amazon EKS. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole
```

In this case, Mary asks her administrator to update her policies to allow her to perform the iam:PassRole action.

I want to view my access keys

After you create your IAM user access keys, you can view your access key ID at any time. However, you can't view your secret access key again. If you lose your secret key, you must create a new access key pair.

Access keys consist of two parts: an access key ID (for example, AKIAIOSFODNN7EXAMPLE) and a secret access key (for example, wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY). Like a user name and password, you must use both the access key ID and secret access key together to authenticate your requests. Manage your access keys as securely as you do your user name and password.

**Important**

Do not provide your access keys to a third party, even to help find your canonical user ID. By doing this, you might give someone permanent access to your account.

When you create an access key pair, you are prompted to save the access key ID and secret access key in a secure location. The secret access key is available only at the time you create it. If you lose your secret access key, you must add new access keys to your IAM user. You can have a maximum of two access keys. If you already have two, you must delete one key pair before creating a new one. To view instructions, see Managing access keys in the IAM User Guide.

I'm an administrator and want to allow others to access Amazon EKS

To allow others to access Amazon EKS, you must create an IAM entity (user or role) for the person or application that needs access. They will use the credentials for that entity to access AWS. You must then attach a policy to the entity that grants them the correct permissions in Amazon EKS.
To get started right away, see Creating your first IAM delegated user and group in the IAM User Guide.

I want to allow people outside of my AWS account to access my Amazon EKS resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon EKS supports these features, see How Amazon EKS works with IAM (p. 435).
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the IAM User Guide.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the IAM User Guide.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the IAM User Guide.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

Troubleshooting issues in Amazon EKS Connector

This topic covers some of the common errors that you might encounter while using the Amazon EKS Connector, including instructions on how to resolve them, workarounds, and frequently asked questions.

Common issues

This section describes how you can troubleshoot some functional issues that you might encounter while using Amazon EKS Connector. It provides solutions and workarounds for these issues.

Console error: the cluster is stuck in the Pending state

If, after you registered the cluster, the cluster gets stuck in the Pending state on the Amazon EKS console, it might be because Amazon EKS Connector didn't successfully connect the cluster to AWS yet. For a registered cluster, the Pending state means that the connection wasn't already successfully established. To resolve this issue, make sure that you have applied the manifest to the target Kubernetes cluster. If you did apply it to the cluster but the cluster is still in the Pending state, then most likely Amazon EKS Connector might be unhealthy in your cluster. To troubleshoot this issue, see the section that's named Amazon EKS connector pods are crash looping (p. 519) in this topic.

Console error: User “system:serviceaccount:eks-connector:eks-connector” can't impersonate resource “users” in API group “” at cluster scope

Amazon EKS Connector uses Kubernetes user impersonation to act on behalf of users from the AWS Management Console. For each IAM identity that accesses the Kubernetes API from the AWS eks-connector service account, they must be granted permission to impersonate the corresponding Kubernetes user with an IAM ARN as their user name. In the following examples, the IAM ARN is mapped to a Kubernetes user.
• IAM user jeff from AWS account 123456789012 is mapped to a Kubernetes user:

arn:aws:iam::123456789012:user/jeff

• IAM role admin from AWS account 123456789012 is mapped to a Kubernetes user:

arn:aws:iam::123456789012:role/admin

The result is an IAM role ARN, instead of the STS session ARN.

For instructions on how to configure the ClusterRole and ClusterRoleBinding to grant eks-connector service account privilege to impersonate the mapped user, see Granting access to a user to view a cluster (p. 528). Make sure that, in the template, %IAM_ARN% is replaced with IAM ARN of the AWS Management Console user.

Console error: ... is forbidden: User ... cannot list resource “... in API group” at the cluster scope

Consider the following problem. The Amazon EKS Connector has successfully impersonated the requesting AWS Management Console user in the target Kubernetes cluster. However, the impersonated user doesn't have RBAC permission on Kubernetes API operations.

To resolve this issues, as the cluster administrator, you must grant the appropriate level of RBAC privileges to individual Kubernetes users. For more information and examples, see Granting access to a user to view a cluster (p. 528).

Console error: Amazon EKS can't communicate with your Kubernetes cluster API server. The cluster must be in an ACTIVE state for successful connection. Try again in few minutes.

If the Amazon EKS service can't communicate with Amazon EKS connector in the target cluster, it might be because of one of the following reasons:

• Amazon EKS Connector in the target cluster is unhealthy.
• Poor connectivity or an interrupted connection between the target cluster and the AWS Region.

To resolve this, check the Inspect logs of Amazon EKS Connector (p. 522). If you don't see an error for the Amazon EKS connector, retry the connection after a few minutes. If you regularly experience high latency or intermittent connectivity for the target cluster, consider re-registering the cluster to an AWS Region that's located closer to you.

Amazon EKS connector pods are crash looping

There are many reasons that can cause an EKS connector pod to enter the CrashLoopBackOff status. This issue likely involves the connector-init container. In the following example, it was the connector-init container that entered the CrashLoopBackOff status.

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>eks-connector-0</td>
<td>0/2</td>
<td>Init:CrashLoopBackOff</td>
<td>1</td>
<td>7s</td>
</tr>
</tbody>
</table>

To troubleshoot this issue, Inspect logs of Amazon EKS Connector (p. 522).
failed to initiate eks-connector: InvalidActivation

When you start Amazon EKS Connector for the first time, it registers an activationId and activationCode with Amazon Web Services. The registration might fail, which can cause the connector-init container to crash.

To troubleshoot this issue, consider the following causes and recommended fixes:

- Registration might have failed because the activationId and activationCode aren't in your manifest file. If this is the case, make sure that they are the correct values that were returned from the RegisterCluster API operation, and that the activationCode is in the manifest file. The activationCode is added to Kubernetes secrets, so it must be base64 encoded. For more information, see Step 1: Registering the cluster (p. 525).
- Registration might have failed because your activation expired. This is because, for security reasons, you must activate the EKS connector within 3 days after registering the cluster. To resolve this issue, make sure that the EKS connector manifest is applied to the target Kubernetes cluster before the expiry date and time. To confirm your activation expiry date, call the DescribeCluster API operation. In the following example response, the expiry date and time is recorded as 2021-11-12T22:28:51.101000-08:00.

```
aws eks describe-cluster --name my-cluster
{
  "cluster": {
    "name": "my-cluster",
    "arn": "arn:aws:eks:us-east-1:123456789012:cluster/my-cluster",
    "createdAt": "2021-11-09T22:28:51.449000-08:00",
    "status": "FAILED",
    "tags": {
      },
    "connectorConfig": {
      "activationId": "00000000-0000-0000-0000-000000000000",
      "activationExpiry": "2021-11-12T22:28:51.101000-08:00",
      "provider": "OTHER",
      "roleArn": "arn:aws:iam::123456789012:role/my-connector-role"
    }
  }
}
```

If the activationExpiry passed, deregister the cluster and register it again. Do this generates a new activation.

Cluster worker node is missing outbound connectivity

To work properly, EKS connector requires outbound connectivity to several AWS endpoints. You can't connect a private cluster without outbound connectivity to a target AWS Region. To resolve this issue, you must add the necessary outbound connectivity. For information about connector requirements, see Amazon EKS Connector considerations (p. 524).

Amazon EKS connector pods are in ImagePullBackOff state

If you run the getpods command and pods are in the ImagePullBackOff state, they can't work properly. If EKS Connector pod is in ImagePullBackOff state, they can't work properly. See the example below:
The default Amazon EKS Connector manifest file references images from Amazon ECR Public Registry. It is possible that the target Kubernetes cluster cannot pull images from Amazon ECR Public. Either resolve the Amazon ECR Public image pull issue, or consider mirroring the images in the private container registry of your choice.

Frequently asked questions

Q: How does the underlying technology behind Amazon EKS Connector work?
A: The Amazon EKS Connector is based on the System Manager (SSM) Agent. The EKS Connector runs as a StatefulSet on your Kubernetes cluster. It establishes a connection and proxies the communication between the API server of your cluster and Amazon Web Services. It does this to display cluster data in the Amazon EKS console until you disconnect the cluster from AWS. SSM agent is an open source project. For more information about this project, see the GitHub project page.

Q: I have an on-premises Kubernetes cluster that I want to connect. Do I need to open firewall ports to connect it?
A: No, you don't need to open any firewall ports. The Kubernetes cluster only requires outbound connection to AWS Regions. AWS services never access resources in your on-premises network. The Amazon EKS Connector runs on your cluster and initiates the connection to AWS. When the cluster registration completes, AWS only issues commands to the Amazon EKS Connector after you start an action from the Amazon EKS console that requires information from the Kubernetes API server on your cluster.

Q: What data is sent from my cluster to AWS by the Amazon EKS Connector?
A: The Amazon EKS Connector sends technical information that's necessary for your cluster to be registered on AWS. It also sends cluster and workload metadata for the Amazon EKS console features that customers request. Amazon EKS Connector only gathers or sends this data if you start an action from the Amazon EKS console or the Amazon EKS API that necessitates the data to be sent to AWS. Other than the Kubernetes version number, AWS doesn't store any data by default. It stores them only if you authorize it.

Q: Can I connect a cluster outside of an AWS Region?
A: Yes, you can connect a cluster from any location to Amazon EKS. Moreover, your EKS service can be located in any AWS public commercial AWS Region. This works with a valid network connection from your cluster to the target AWS Region. We recommend that you pick an AWS Region, which is the closest to your cluster location for UI performance optimization. For example, if you have a cluster running in Tokyo, connect your cluster to the AWS Region in Tokyo (that is, the ap-northeast-1 AWS Region) for low latency. You can connect a cluster from any location to the Amazon EKS in any of the public commercial AWS Regions, except the China or GovCloud AWS Regions.

Basic troubleshooting

This section describes steps to diagnose the issue if it's unclear.

Check Amazon EKS Connector status

Check the Amazon EKS Connector status by using the following commands.
There are two eks-connector-x pods in the Running state.

**Inspect logs of Amazon EKS Connector**

The Amazon EKS Connector Pod consists of three containers. You can inspect the logs of all three of them.

- connector-init
- connector-proxy
- connector-agent

To retrieve full logs for all of these containers so that you can inspect them, run the following commands.

```bash
# Retrieve log for connector-init container
kubectl logs eks-connector-0 --container connector-init -n eks-connector
kubectl logs eks-connector-1 --container connector-init -n eks-connector

# Retrieve log for connector-proxy container
kubectl logs eks-connector-0 --container connector-proxy -n eks-connector
kubectl logs eks-connector-1 --container connector-proxy -n eks-connector

# Retrieve log for connector-agent container
kubectl exec eks-connector-0 --container connector-agent -n eks-connector -- cat /var/log/amazon/ssm/amazon-ssm-agent.log
kubectl exec eks-connector-1 --container connector-agent -n eks-connector -- cat /var/log/amazon/ssm/amazon-ssm-agent.log
```

**Get the effective cluster name**

Amazon EKS clusters are uniquely identified by `clusterName` within a single AWS account and AWS Region. If you have multiple connected clusters in Amazon EKS, you can confirm which Amazon EKS cluster that the current Kubernetes cluster is registered. To do this, enter the following to find out the `clusterName` of the current cluster.

```bash
kubectl exec eks-connector-0 --container connector-agent -n eks-connector -- cat /var/log/amazon/ssm/amazon-ssm-agent.log | grep -m1 -oE "eks_c:\[a-zA-Z0-9-\_\-\]+\_[a-zA-Z0-9]+.*$/|" | sed -E "s/^[^\s]*eks_c:\[a-zA-Z0-9-\_\-\]+\_[a-zA-Z0-9]+.*$/\1/"
kubectl exec eks-connector-1 --container connector-agent -n eks-connector -- cat /var/log/amazon/ssm/amazon-ssm-agent.log | grep -m1 -oE "eks_c:\[a-zA-Z0-9-\_\-\]+\_[a-zA-Z0-9]+.*$/|" | sed -E "s/^[^\s]*eks_c:\[a-zA-Z0-9-\_\-\]+\_[a-zA-Z0-9]+.*$/\1/"
```

**Miscellaneous commands**

The following commands are useful to retrieve information that you need to troubleshoot issues.

- Use the following command to gather images that's used by pods in Amazon EKS Connector.

  ```bash
  kubectl get pods -n eks-connector -o jsonpath="{.items[\*].spec.containers[\*].image}" | tr -s ' ' '[[:space:]]' '\n'
  ```

- Use the following command to gather worker node names that Amazon EKS Connector is running on.
**Basic troubleshooting**

- Run the following command to get your Kubernetes client and server versions.

```
kubectl version
```

- Run the following command to get information about your worker nodes.

```
kubectl get nodes -o wide --show-labels
```
Amazon EKS Connector

You can use Amazon EKS Connector to register and connect any conformant Kubernetes cluster to AWS and visualize it in the Amazon EKS console. After a cluster is connected, you can see the status, configuration, and workloads for that cluster in the Amazon EKS console. You can use this feature to view connected clusters in Amazon EKS console, but you can't manage them. The Amazon EKS Connector can connect the following types of Kubernetes clusters to Amazon EKS. The Amazon EKS Connector is also an open source project on Github. For additional technical content, including frequently asked questions and troubleshooting, see Troubleshooting issues in Amazon EKS Connector (p. 518)

• On-premises Kubernetes clusters
• Self-managed clusters that are running on Amazon EC2
• Managed clusters from other cloud providers

Amazon EKS Connector considerations

Before you use Amazon EKS Connector, understand the following:

• You must have administrative privileges to the Kubernetes cluster to connect the cluster to Amazon EKS.
• The Kubernetes cluster must have Linux 64-bit (x86) worker nodes present before connecting. ARM worker nodes aren’t supported.
• You must have worker nodes in your Kubernetes cluster that have outbound access to the ssm and ssmmessages Systems Manager endpoints. For more information, see Systems Manager endpoints in the AWS General Reference.
• By default, you can connect up to 10 clusters in a Region. You can request an increase through the service quota console. See Requesting a quota increase for more information.
• Only the Amazon EKS RegisterCluster, ListClusters, DescribeCluster, and DeregisterCluster APIs are supported for external Kubernetes clusters.
• You must have the following permissions to register a cluster:
  • eks:RegisterCluster
  • ssm:CreateActivation
  • ssm:DeleteActivation
  • iam:PassRole
• You must have the following permissions to deregister a cluster:
  • eks:DeregisterCluster
  • ssm:DeleteActivation
  • ssm:DeregisterManagedInstance

Required IAM roles for Amazon EKS Connector

Using the Amazon EKS Connector requires the following two IAM roles:

• The Amazon EKS Connector service-linked role is created when you register the cluster.
• The Amazon EKS Connector agent IAM role must be created manually. See Amazon EKS connector IAM role (p. 458) for details.
To enable cluster and workload view permission for another user, you must apply the eks-connector and Amazon EKS Connector cluster roles to your cluster. Follow the steps in Granting access to a user to view a cluster (p. 528).

Connecting a cluster

**Step 1: Registering the cluster**

You can connect an external Kubernetes cluster to Amazon EKS with AWS CLI and the AWS Management Console. This process involves two steps: registering the cluster with Amazon EKS and applying a YAML manifest file to enable connectivity. To allow another user to view the cluster, follow the instructions in Granting access to a user to view a cluster (p. 528).

You must have the following permissions to register a cluster:

- eks:RegisterCluster
- ssm:CreateActivation
- ssm:DeleteActivation
- iam:PassRole

**eksctl**

**Prerequisites**

- eksctl v0.68 or above must be installed. To install or upgrade it, see Getting started with eksctl.
- The Amazon EKS Connector agent IAM role was created. For more information, see Connector IAM role.

**To register your cluster with eksctl**

1. Register the cluster by providing a name, provider, and region.

   ```bash
   eksctl register cluster --name <my-first-registered-cluster> --provider <provider> --region <region>
   ```

   This creates two files on your local drive: my-first-registered-cluster.yaml and eks-connector-binding.yaml files. These two files must be applied to the external cluster within three days, or the registration expires.

2. In the cluster's native environment, apply the eks-connector-binding.yaml file:

   ```bash
   kubectl apply -f eks-connector-binding.yaml
   ```

**AWS CLI**

**Prerequisites**

- AWS CLI must be installed. To install or upgrade it, see Installing the AWS CLI.
- Ensure the Amazon EKS Connector agent role was created.
To register your cluster with the AWS CLI

1. For the Connector configuration, specify your Amazon EKS Connector agent IAM role. For more information, see Required IAM roles for Amazon EKS Connector (p. 524).

```bash
aws eks register-cluster \
  --name my-first-registered-cluster \
  --connector-config roleArn=arn:aws:iam::111122223333:role/AmazonEKSConnectorAgentRole,provider="OTHER" \
  --region AWS_REGION
```

Output:

```json
{
  "cluster": {
    "name": "my-first-registered-cluster",
    "createdAt": 1627669203.531,
    "ConnectorConfig": {
      "activationId": "xxxxxxxxACTIVATION_IDxxxxxxxx",
      "activationCode": "xxxxxxxxACTIVATION_CODExxxxxxxx",
      "activationExpiry": 1627672543.0,
      "provider": "OTHER",
      "roleArn": "arn:aws:iam::111122223333:role/AmazonEKSConnectorAgentRole"
    },
    "status": "CREATING"
  }
}
```

You use the `region`, `activationId`, and `activationCode` values in a later step.

2. Download the Amazon EKS Connector YAML file.

```bash
```

3. Edit the Amazon EKS Connector YAML file to replace all references of `%AWS_REGION%`, `%EKS_ACTIVATION_ID%`, `%EKS_ACTIVATION_CODE%` with the `region`, `activationId`, and `activationCode` from the output of your registration command.

The following example command can replace these values.

```bash
sed -i "s~%AWS_REGION%~$AWS_REGION~g; s~%EKS_ACTIVATION_ID%~$EKS_ACTIVATION_ID~g; s~%EKS_ACTIVATION_CODE%~$(echo -n $EKS_ACTIVATION_CODE | base64)~g" eks-connector.yaml
```

**Important**

Ensure that your activation code is in the base64 format.

AWS Management Console

**Prerequisites**

- Ensure the Amazon EKS Connector agent role was created.

**To register your Kubernetes cluster with the console.**

1. Open the Amazon EKS console at [https://console.aws.amazon.com/eks/home#/clusters](https://console.aws.amazon.com/eks/home#/clusters).
2. Choose **Add cluster** and select **Register** to bring up the configuration page.

3. On the **Configure cluster** section, fill in the following fields:

   - **Name** – A unique name for your cluster.
   - **Provider** – Choose to display the dropdown list of Kubernetes cluster providers. If you don’t know the specific provider, select Other.
   - **EKS Connector role** – Select the role to use for connecting the cluster.

4. Select **Register cluster**.

5. The Cluster overview page displays. Choose **Download YAML file** to download the manifest file to your local drive.

   **Important**

   - This is your only opportunity to download this file. Don’t navigate away from this page, as the link will not be accessible and you must deregister the cluster and start the steps from the beginning.
   - The manifest file can be used only once for the registered cluster. If you delete resources from the Kubernetes cluster, you must re-register the cluster and obtain a new manifest file.

Continue to the next step to apply the manifest file to your Kubernetes cluster.

---

**Step 2: Applying the manifest file**

Complete the connection by applying the Amazon EKS Connector manifest file to your Kubernetes cluster. To do this, you must use the AWS CLI or eksctl for the registration methods described previously. If the manifest is applied within three days, the Amazon EKS Connector registration expires. If the cluster connection expires, the cluster must be deregistered before connecting the cluster again.

1. In the native environment of the cluster, you can apply the updated manifest file by running the following command:

   ```bash
   kubectl apply -f eks-connector.yaml
   ```

2. After the Amazon EKS Connector manifest and role binding YAML files are applied to your Kubernetes cluster, confirm that the cluster is now connected.

   ```bash
   aws eks describe-cluster \ 
   --name "my-first-registered-cluster" \ 
   --region AWS_REGION
   ```

   The output should include `status=ACTIVE`.

3. You can now add Tags to your cluster (optional). See [Tagging your Amazon EKS resources for more information](#).

   To grant additional IAM users access to the Amazon EKS console to view the connected clusters, see [Granting access to a user to view a cluster](p. 528). Your clusters will now be viewable in the AWS Management Console, as well as your connected **nodes** and **workloads**.
Granting access to a user to view a cluster

Grant additional IAM users access to the Amazon EKS console to view information about the Kubernetes workloads and pods running on your connected cluster.

Prerequisites

The IAM user or role that you use to access the AWS Management Console must meet the following requirements.

- It has the `eks:AccessKubernetesApi` permission.
- The Amazon EKS Connector Service account can impersonate the IAM or role in the cluster. This allows the eks-connector to map the IAM user or role to a Kubernetes user.

To create and apply the Amazon EKS Connector cluster role

1. Download the `eks-connector` cluster role template.

   ```bash
   ```

2. Edit the cluster role template YAML file. Replace references of `%IAM_ARN%` with the Amazon Resource Name (ARN) of your IAM user or role.

3. Apply the Amazon EKS Connector cluster role YAML to your Kubernetes cluster.

   ```bash
   kubectl apply -f eks-connector-clusterrole.yaml
   ```

For an IAM user or role to visualize the workloads on the Amazon EKS console, they must be associated with a Kubernetes `role` or `clusterrole` with necessary permissions to read these resources. For more information, see Using RBAC Authorization in the Kubernetes documentation.

To configure an IAM user to access the connected cluster

1. You can download the example manifest file to create a `clusterrole` and `clusterrolebinding` or a `role` and `rolebinding`:

   - **View Kubernetes resources in all namespaces** – The `eks-connector-console-dashboard-full-access-clusterrole` cluster role gives access to all namespaces and resources that can be visualized in the console. You can change the name of the role, clusterrole and their corresponding binding before applying it to your cluster. Use the following command to download a sample file.

     ```bash
     ```

   - **View Kubernetes resources in a specific namespace** – The namespace in this file is `default`, so if you want to specify a different namespace, edit the file before applying it to your cluster. Use the following command to download a sample file.

     ```bash
     ```
2. Edit the full access or restricted access YAML file to replace references of %IAM_ARN% with the Amazon Resource Name (ARN) of your IAM user or role.

3. Apply the full access or restricted access YAML files to your Kubernetes cluster. Replace the YAML file value with your own.

```
kubectl apply -f eks-connector-console-dashboard-full-access-group.yaml
```

To view your connected cluster and nodes, see View nodes (p. 107). To view workloads, see View workloads (p. 350). Keep in mind that some node and workload data aren't populated for connected clusters.

## Deregistering a cluster

If you are finished using a connected cluster, you can deregister it. After it’s deregistered, the cluster is no longer visible in the Amazon EKS console.

You must have the following permissions to call the deregisterCluster API:

- eks:DeregisterCluster
- ssm:DeleteActivation
- ssm:DeregisterManagedInstance

```
# eksctl
eksctl deregister cluster --name
```

**Prerequisites**

- eksctl v0.68 or above must be installed. To install or upgrade it, see Getting started with eksctl.
- Ensure the Amazon EKS Connector agent role was created.

**To deregister your cluster with eksctl**

- For the Connector configuration, specify your Amazon EKS Connector agent IAM role. For more information, see Required IAM roles for Amazon EKS Connector (p. 524).

```
aws eks deregister-cluster --name
```

**AWS CLI**

**Prerequisites**

- AWS CLI must be installed. To install or upgrade it, see Installing the AWS CLI.
- Ensure the Amazon EKS Connector agent role was created.

Deregister the connected cluster.

```
aws eks deregister-cluster \
--name "my-first-registered-cluster" \
--region AWS_REGION
```
AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose Clusters.
3. On the Clusters page, select the connected cluster and select Deregister.
4. Confirm that you want to deregister the cluster.

To clean up the resources on your Kubernetes cluster.

1. Delete the Amazon EKS Connector YAML file from your Kubernetes cluster.

   kubectl delete -f eks-connector.yaml

2. If you created clusterrole or clusterrolebinding for an additional IAM user to access the cluster, ensure that you delete them from your Kubernetes cluster.
Related projects

These open-source projects extend the functionality of Kubernetes clusters running on or outside of AWS, including clusters managed by Amazon EKS.

Management tools

Related management tools for Amazon EKS and Kubernetes clusters.

**eksctl**

Eksctl is a simple CLI tool for creating clusters on Amazon EKS.

- Project URL
- Project documentation
- AWS open source blog: eksctl: Amazon EKS cluster with one command

**AWS controllers for Kubernetes**

With AWS Controllers for Kubernetes, you can create and manage AWS resources directly from your Kubernetes cluster.

- Project URL
- AWS open source blog: AWS service operator for Kubernetes now available

**Flux CD**

Flux is a tool that you can use to manage your cluster configuration using Git. It uses an operator in the cluster to trigger deployments inside of Kubernetes. For more information about operators, see Awesome Operators in the Wild on GitHub.

- Project URL
- Project documentation

**CDK for Kubernetes**

With the CDK for Kubernetes (cdk8s), you can define Kubernetes apps and components using familiar programming languages. cdk8s apps synthesize into standard Kubernetes manifests, which can be applied to any Kubernetes cluster.

- Project URL
- Project documentation
- AWS containers blog: Introducing cdk8s+: Intent-driven APIs for Kubernetes objects
Networking

Related networking projects for Amazon EKS and Kubernetes clusters.

Amazon VPC CNI plugin for Kubernetes

Amazon EKS supports native VPC networking through the Amazon VPC CNI plugin for Kubernetes. The plugin assigns an IP address from your VPC to each pod.

• Project URL
• Project documentation

AWS Load Balancer Controller for Kubernetes

The AWS Load Balancer Controller helps manage AWS Elastic Load Balancers for a Kubernetes cluster. It satisfies Kubernetes Ingress resources by provisioning AWS Application Load Balancers. It satisfies Kubernetes Service resources by provisioning AWS Network Load Balancers.

• Project URL
• Project documentation

ExternalDNS

ExternalDNS synchronizes exposed Kubernetes services and ingresses with DNS providers including Amazon Route 53 and AWS Service Discovery.

• Project URL
• Project documentation

App Mesh Controller

The App Mesh Controller for Kubernetes helps to manage App Mesh for your cluster. With the controller, you can manage the service mesh using custom resources within your cluster. The controller manages the injection of networking proxy sidecars to pods to enable the mesh.

Security

Related security projects for Amazon EKS and Kubernetes clusters.

AWS IAM authenticator

A tool to use AWS IAM credentials to authenticate to a Kubernetes cluster if you're not using the AWS CLI version 1.16.156 or higher. For more information, see Installing aws-iam-authenticator (p. 408).
Machine learning

Related machine learning projects for Amazon EKS and Kubernetes clusters.

**Kubeflow**

A machine learning toolkit for Kubernetes.

- **Project URL**
- **Project documentation**
- **AWS open source blog:** [Kubeflow on Amazon EKS](https://aws.amazon.com/blogs/open-source/kubeflow-on-amazon-eks/)

Auto Scaling

Related auto scaling projects for Amazon EKS and Kubernetes clusters.

**Cluster autoscaler**

Cluster Autoscaler is a tool that automatically adjusts the size of the Kubernetes cluster based on CPU and memory pressure.

- **Project URL**
- **Project documentation**
- **Amazon EKS workshop:** [https://eksworkshop.com/scaling/deploy_ca/](https://eksworkshop.com/scaling/deploy_ca/)

**Escalator**

Escalator is a batch or job optimized horizontal autoscaler for Kubernetes.

- **Project URL**
- **Project documentation**

Monitoring

Related monitoring projects for Amazon EKS and Kubernetes clusters.

**Prometheus**

Prometheus is an open-source systems monitoring and alerting toolkit.

- **Project URL**
- **Project documentation**
Continuous integration / continuous deployment

Related CI/CD projects for Amazon EKS and Kubernetes clusters.

**Jenkins X**

CI/CD solution for modern cloud applications on Amazon EKS and Kubernetes clusters.

Amazon EKS new features and roadmap

You can learn about new Amazon EKS features by scrolling to the What's New feed on the What's New with AWS page. You can also review the roadmap on GitHub, which lets you know about upcoming features and priorities so that you can plan how you want to use Amazon EKS in the future. You can provide direct feedback to us about the roadmap priorities.
## Document history for Amazon EKS

The following table describes the major updates and new features for the Amazon EKS User Guide. We also update the documentation frequently to address the feedback that you send us.

<table>
<thead>
<tr>
<th>update-history-change</th>
<th>update-history-description</th>
<th>update-history-date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes version 1.22</td>
<td>Added Kubernetes version 1.22 support for new clusters and version upgrades.</td>
<td>April 4, 2022</td>
</tr>
<tr>
<td>Added Fargate pod patching details</td>
<td>When upgrading Fargate pods, Amazon EKS first tries to evict pods based on your pod disruption budgets. You can create event rules to react to failed evictions before the pods are deleted.</td>
<td>April 1, 2022</td>
</tr>
<tr>
<td>Full release: Add-on support for Amazon EBS CSI driver</td>
<td>You can now use the AWS Management Console, AWS CLI, and API to manage the Amazon EBS CSI driver.</td>
<td>March 31, 2022</td>
</tr>
<tr>
<td>AWS Outposts content update</td>
<td>Instructions to deploy an Amazon EKS cluster on AWS Outposts.</td>
<td>March 22, 2022</td>
</tr>
<tr>
<td>Windows containerd support</td>
<td>You can now select the containerd runtime for Windows nodes.</td>
<td>March 14, 2022</td>
</tr>
<tr>
<td>Added EKS Connector considerations to security documentation</td>
<td>Describes the shared responsibility model as it related to connected clusters.</td>
<td>February 25, 2022</td>
</tr>
<tr>
<td>Assign IPv6 addresses to your Pods and Services</td>
<td>You can now create a 1.21 or later cluster that assigns IPv6 addresses to your Pods and Services.</td>
<td>January 6, 2022</td>
</tr>
<tr>
<td>Preview release: Add-on support for Amazon EBS CSI driver</td>
<td>You can now preview using the AWS Management Console, AWS CLI, and API to manage the Amazon EBS CSI driver.</td>
<td>December 9, 2021</td>
</tr>
<tr>
<td>Karpenter autoscaler support</td>
<td>You can now use the Karpenter open-source project to autoscale your nodes.</td>
<td>November 29, 2021</td>
</tr>
<tr>
<td>Fluent Bit Kubernetes filter support in Fargate logging</td>
<td>You can now use the Fluent Bit Kubernetes filter with Fargate logging.</td>
<td>November 10, 2021</td>
</tr>
<tr>
<td>Windows support available in the control plane</td>
<td>Windows support is now available in your control plane.</td>
<td>November 9, 2021</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>----------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------</td>
</tr>
<tr>
<td>Bottlerocket added as an AMI type for managed node groups</td>
<td>Previously, Bottlerocket was only available as a self-managed node option. Now it can be configured as a managed node group, reducing the effort that's required to meet node compliance requirements.</td>
<td>October 28, 2021</td>
</tr>
<tr>
<td>DL1 driver support</td>
<td>Custom Amazon Linux AMIs now support deep learning workloads for AWS Linux 2. This enablement allows a generic on-premises or cloud baseline configuration.</td>
<td>October 25, 2021</td>
</tr>
<tr>
<td>VT1 video support</td>
<td>Custom Amazon Linux AMIs now support VT1 for some distributions. This enablement advertises Xilinx U30 devices on your Amazon EKS cluster.</td>
<td>September 13, 2021</td>
</tr>
<tr>
<td>Amazon EKS Connector is now available</td>
<td>You can use Amazon EKS Connector to register and connect any conformant Kubernetes cluster to AWS and visualize it in the Amazon EKS console.</td>
<td>September 8, 2021</td>
</tr>
<tr>
<td>Amazon EKS Anywhere is now available</td>
<td>Amazon EKS Anywhere is a new deployment option for Amazon EKS that you can use to create and operate Kubernetes clusters on-premises.</td>
<td>September 8, 2021</td>
</tr>
<tr>
<td>Amazon FSx for NetApp ONTAP CSI driver</td>
<td>Added topic that summarizes the Amazon FSx for NetApp ONTAP CSI driver and gives links to other references.</td>
<td>September 2, 2021</td>
</tr>
<tr>
<td>Managed node groups now auto-calculates the Amazon EKS maximum pods for nodes</td>
<td>Managed node groups now auto-calculate the Amazon EKS maximum pods for nodes that you deploy without a launch template, or with a launch template that you haven’t specified an AMI ID in.</td>
<td>August 30, 2021</td>
</tr>
<tr>
<td>Remove Amazon EKS management of add-on settings without removing the Amazon EKS add-on software</td>
<td>You can now remove an Amazon EKS add-on without removing the add-on software from your cluster.</td>
<td>August 20, 2021</td>
</tr>
<tr>
<td>Create multi-homed Pods using Multus</td>
<td>You can now add multiple network interfaces to a Pod using Multus.</td>
<td>August 2, 2021</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
<td>------</td>
</tr>
<tr>
<td>Add more IP addresses to your Linux Amazon EC2 nodes</td>
<td>You can now add significantly more IP addresses to your Linux Amazon EC2 nodes. This means that you can run a higher density of pods on each node.</td>
<td>July 27, 2021</td>
</tr>
<tr>
<td>Kubernetes version 1.21</td>
<td>Added Kubernetes version 1.21 support.</td>
<td>July 19, 2021</td>
</tr>
<tr>
<td>Containerd runtime bootstrap</td>
<td>The Amazon EKS optimized accelerated Amazon Linux Amazon Machine Image (AMI) now contains a bootstrap flag that you can use to enable the containerd runtime in Amazon EKS optimized and Bottlerocket AMIs. This flag is available in all supported Kubernetes versions of the AMI.</td>
<td>July 19, 2021</td>
</tr>
<tr>
<td>Added managed policies topic</td>
<td>A list of all Amazon EKS IAM managed policies and changes that were made to them since June 17, 2021.</td>
<td>June 17, 2021</td>
</tr>
<tr>
<td>Use security groups for pods with Fargate</td>
<td>You can now use security groups for pods with Fargate, in addition to using them with Amazon EC2 nodes.</td>
<td>June 1, 2021</td>
</tr>
<tr>
<td>Added CoreDNS and kubeproxy Amazon EKS add-ons</td>
<td>Amazon EKS can now help you manage the CoreDNS and kubeproxy Amazon EKS add-ons for your cluster.</td>
<td>May 19, 2021</td>
</tr>
<tr>
<td>Kubernetes version 1.20</td>
<td>Added Kubernetes version 1.20 support for new clusters and version upgrades.</td>
<td>May 18, 2021</td>
</tr>
<tr>
<td>AWS Load Balancer Controller 2.2.0 released</td>
<td>You can now use the AWS Load Balancer Controller to create Elastic Load Balancers using instance or IP targets.</td>
<td>May 14, 2021</td>
</tr>
<tr>
<td>Node taints for managed node groups</td>
<td>Amazon EKS now supports adding note taints to managed node groups.</td>
<td>May 11, 2021</td>
</tr>
<tr>
<td>Secrets encryption for existing clusters</td>
<td>Amazon EKS now supports adding secrets encryption to existing clusters.</td>
<td>February 26, 2021</td>
</tr>
<tr>
<td>Kubernetes version 1.19</td>
<td>Added Kubernetes version 1.19 support for new clusters and version upgrades.</td>
<td>February 16, 2021</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Amazon EKS now supports OpenID Connect (OIDC) identity providers as a method to authenticate users to your cluster that's version 1.16 or later.</td>
<td>OIDC identity providers can be used with, or as an alternative to AWS Identity and Access Management (IAM).</td>
<td>February 12, 2021</td>
</tr>
<tr>
<td>View node and workload resources in the AWS Management Console</td>
<td>You can now view details about your managed, self-managed, and Fargate nodes and your deployed Kubernetes workloads in the AWS Management Console.</td>
<td>December 1, 2020</td>
</tr>
<tr>
<td>Deploy Spot Instance types in a managed node group</td>
<td>You can now deploy multiple Spot or On-Demand Instance types to a managed node group.</td>
<td>December 1, 2020</td>
</tr>
<tr>
<td>Amazon EKS can now manage specific add-ons for your cluster</td>
<td>You can manage add-ons yourself, or allow Amazon EKS control the launch and version of an add-on through the Amazon EKS API for clusters that are running Kubernetes version 1.18 with platform version eks.3 or later.</td>
<td>December 1, 2020</td>
</tr>
<tr>
<td>Share an ALB across multiple Ingresses</td>
<td>You can now share an AWS Application Load Balancer (ALB) across multiple Kubernetes Ingresses. In the past, you had to deploy a separate ALB for each Ingress.</td>
<td>October 23, 2020</td>
</tr>
<tr>
<td>NLB IP target support</td>
<td>You can now deploy a network load balancer (NLB) with IP targets. This means that you can use an NLB to load balance network traffic to Fargate pods and directly to pods that are running on Amazon EC2 nodes.</td>
<td>October 23, 2020</td>
</tr>
<tr>
<td>Kubernetes version 1.18</td>
<td>Added Kubernetes version 1.18 support for new clusters and version upgrades.</td>
<td>October 13, 2020</td>
</tr>
<tr>
<td>Specify a custom CIDR block for Kubernetes service IP address assignment</td>
<td>You can now specify a custom CIDR block that Kubernetes assigns service IP addresses from.</td>
<td>September 29, 2020</td>
</tr>
<tr>
<td>Assign security groups to individual pods</td>
<td>You can now associate different security groups to some of the individual pods that are running on many Amazon EC2 instance types.</td>
<td>September 9, 2020</td>
</tr>
<tr>
<td>Deploy Bottlerocket on your nodes</td>
<td>You can now deploy nodes that are running Bottlerocket.</td>
<td>August 31, 2020</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
<td>------</td>
</tr>
<tr>
<td>The ability to launch Arm nodes is generally available</td>
<td>You can now launch Arm nodes in managed and self-managed node groups.</td>
<td>August 17, 2020</td>
</tr>
<tr>
<td>Managed node group launch templates and custom AMI</td>
<td>You can now deploy a managed node group that uses an Amazon EC2 launch template. The launch template can specify a custom AMI, if you choose.</td>
<td>August 17, 2020</td>
</tr>
<tr>
<td>EFS support for AWS Fargate</td>
<td>You can now use Amazon EFS with AWS Fargate.</td>
<td>August 17, 2020</td>
</tr>
<tr>
<td>Amazon EKS platform version update</td>
<td>This is a new platform version with security fixes and enhancements. This includes UDP support for services of type LoadBalancer when using NLB with Kubernetes 1.15 or later. For more information, see the Allow UDP for AWS NLB issue on GitHub.</td>
<td>August 12, 2020</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 536)</td>
<td>Amazon EKS is now available in the Africa (Cape Town) (af-south-1) and Europe (Milan) (eu-south-1) AWS Regions.</td>
<td>August 6, 2020</td>
</tr>
<tr>
<td>Fargate usage metrics</td>
<td>AWS Fargate provides CloudWatch usage metrics that provide visibility into your account's usage of Fargate On-Demand resources.</td>
<td>August 3, 2020</td>
</tr>
<tr>
<td>Kubernetes version 1.17</td>
<td>Added Kubernetes version 1.17 support for new clusters and version upgrades.</td>
<td>July 10, 2020</td>
</tr>
<tr>
<td>Create and manage App Mesh resources from within Kubernetes with the App Mesh controller for Kubernetes</td>
<td>You can create and manage App Mesh resources from within Kubernetes. The controller also automatically injects the Envoy proxy and init containers into pods that you deploy.</td>
<td>June 18, 2020</td>
</tr>
<tr>
<td>Amazon EKS now supports Amazon EC2 Inf1 nodes</td>
<td>You can add Amazon EC2 Inf1 nodes to your cluster.</td>
<td>June 4, 2020</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 536)</td>
<td>Amazon EKS is now available in the AWS GovCloud (US-East) (us-gov-east-1) and AWS GovCloud (US-West) (us-gov-west-1) AWS Regions.</td>
<td>May 13, 2020</td>
</tr>
<tr>
<td>Kubernetes 1.12 is no longer supported on Amazon EKS</td>
<td>Kubernetes version 1.12 is no longer supported on Amazon EKS. Update any 1.12 clusters to version 1.13 or later to avoid service interruption.</td>
<td>May 12, 2020</td>
</tr>
<tr>
<td>Kubernetes version 1.16 (p. 536)</td>
<td>Added Kubernetes version 1.16 support for new clusters and version upgrades.</td>
<td>April 30, 2020</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-----------------------------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>Added the <strong>AWSServiceRoleForAmazonEKS</strong> service-linked role</td>
<td>Added the <strong>AWSServiceRoleForAmazonEKS</strong> service-linked role.</td>
<td>April 16, 2020</td>
</tr>
<tr>
<td>Kubernetes version 1.15 (p. 536)</td>
<td>Added Kubernetes version 1.15 support for new clusters and version upgrades.</td>
<td>March 10, 2020</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 536)</td>
<td>Amazon EKS is now available in the Beijing (cn-north-1) and Ningxia (cn-northwest-1) AWS Regions.</td>
<td>February 26, 2020</td>
</tr>
<tr>
<td><strong>FSx for Lustre CSI driver</strong></td>
<td>Added topic for installing the FSx for Lustre CSI Driver on Kubernetes 1.14 Amazon EKS clusters.</td>
<td>December 23, 2019</td>
</tr>
<tr>
<td><strong>Restrict network access to the public access endpoint of a cluster</strong></td>
<td>With this update, you can use Amazon EKS to restrict the CIDR ranges that can communicate to the public access endpoint of the Kubernetes API server.</td>
<td>December 20, 2019</td>
</tr>
<tr>
<td><strong>Resolve the private access endpoint address for a cluster from outside of a VPC</strong></td>
<td>With this update, you can use Amazon EKS to resolve the private access endpoint of the Kubernetes API server from outside of a VPC.</td>
<td>December 13, 2019</td>
</tr>
<tr>
<td><strong>(Beta) Amazon EC2 A1 Amazon EC2 instance nodes</strong></td>
<td>Launch <strong>Amazon EC2 A1 Amazon EC2 instance nodes</strong> that register with your Amazon EKS cluster.</td>
<td>December 4, 2019</td>
</tr>
<tr>
<td><strong>Creating a cluster on AWS Outposts</strong></td>
<td>Amazon EKS now supports creating clusters on AWS Outposts.</td>
<td>December 3, 2019</td>
</tr>
<tr>
<td><strong>AWS Fargate on Amazon EKS</strong></td>
<td>Amazon EKS Kubernetes clusters now support running pods on Fargate.</td>
<td>December 3, 2019</td>
</tr>
<tr>
<td><strong>Amazon EKS Region expansion (p. 536)</strong></td>
<td>Amazon EKS is now available in the Canada (Central) (ca-central-1) AWS Region.</td>
<td>November 21, 2019</td>
</tr>
<tr>
<td><strong>Managed node groups</strong></td>
<td>Amazon EKS managed node groups automate the provisioning and lifecycle management of nodes (Amazon EC2 instances) for Amazon EKS Kubernetes clusters.</td>
<td>November 18, 2019</td>
</tr>
<tr>
<td><strong>Amazon EKS platform version update</strong></td>
<td>New platform versions to address <strong>CVE-2019-11253.</strong></td>
<td>November 6, 2019</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>Kubernetes 1.11 is no longer supported on Amazon EKS</td>
<td>Kubernetes version 1.11 is no longer supported on Amazon EKS. Please update any 1.11 clusters to version 1.12 or higher to avoid service interruption.</td>
<td>November 4, 2019</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 536)</td>
<td>Amazon EKS is now available in the South America (São Paulo) (sa-east-1) AWS Region.</td>
<td>October 16, 2019</td>
</tr>
<tr>
<td>Windows support</td>
<td>Amazon EKS clusters running Kubernetes version 1.14 now support Windows workloads.</td>
<td>October 7, 2019</td>
</tr>
<tr>
<td>Autoscaling</td>
<td>Added a chapter to cover some of the different types of Kubernetes autoscaling that are supported on Amazon EKS clusters.</td>
<td>September 30, 2019</td>
</tr>
<tr>
<td>Kubernetes Dashboard update</td>
<td>Updated topic for installing the Kubernetes Dashboard on Amazon EKS clusters to use the beta 2.0 version.</td>
<td>September 28, 2019</td>
</tr>
<tr>
<td>Amazon EFS CSI driver</td>
<td>Added topic for installing the Amazon EFS CSI Driver on Kubernetes 1.14 Amazon EKS clusters.</td>
<td>September 19, 2019</td>
</tr>
<tr>
<td>Amazon EC2 Systems Manager parameter for Amazon EKS optimized AMI ID</td>
<td>Added topic for retrieving the Amazon EKS optimized AMI ID using an Amazon EC2 Systems Manager parameter. The parameter eliminates the need for you to look up AMI IDs.</td>
<td>September 18, 2019</td>
</tr>
<tr>
<td>Amazon EKS resource tagging</td>
<td>You can manage the tagging of your Amazon EKS clusters.</td>
<td>September 16, 2019</td>
</tr>
<tr>
<td>Amazon EBS CSI driver</td>
<td>Added topic for installing the Amazon EBS CSI driver on Kubernetes 1.14 Amazon EKS clusters.</td>
<td>September 9, 2019</td>
</tr>
<tr>
<td>New Amazon EKS optimized AMI patched for CVE-2019-9512 and CVE-2019-9514</td>
<td>Amazon EKS has updated the Amazon EKS optimized AMI to address CVE-2019-9512 and CVE-2019-9514.</td>
<td>September 6, 2019</td>
</tr>
<tr>
<td>Announcing deprecation of Kubernetes 1.11 in Amazon EKS</td>
<td>Amazon EKS discontinued support for Kubernetes version 1.11 on November 4, 2019.</td>
<td>September 4, 2019</td>
</tr>
<tr>
<td>Kubernetes version 1.14 (p. 536)</td>
<td>Added Kubernetes version 1.14 support for new clusters and version upgrades.</td>
<td>September 3, 2019</td>
</tr>
<tr>
<td>IAM roles for service accounts</td>
<td>With IAM roles for service accounts on Amazon EKS clusters, you can associate an IAM role with a Kubernetes service account. With this feature, you no longer need to provide extended permissions to the node IAM role. This way, pods on that node can call AWS APIs.</td>
<td>September 3, 2019</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 536)</td>
<td>Amazon EKS is now available in the Middle East (Bahrain) (me-south-1) AWS Region.</td>
<td>August 29, 2019</td>
</tr>
<tr>
<td>Amazon EKS platform version update</td>
<td>New platform versions to address CVE-2019-9512 and CVE-2019-9514.</td>
<td>August 28, 2019</td>
</tr>
<tr>
<td>Amazon EKS platform version update</td>
<td>New platform versions to address CVE-2019-11247 and CVE-2019-11249.</td>
<td>August 5, 2019</td>
</tr>
<tr>
<td>Amazon EKS Region expansion (p. 536)</td>
<td>Amazon EKS is now available in the Asia Pacific (Hong Kong) (ap-east-1) AWS Region.</td>
<td>July 31, 2019</td>
</tr>
<tr>
<td>Kubernetes 1.10 no longer supported on Amazon EKS</td>
<td>Kubernetes version 1.10 is no longer supported on Amazon EKS. Update any 1.10 clusters to version 1.11 or higher to avoid service interruption.</td>
<td>July 30, 2019</td>
</tr>
<tr>
<td>Added topic on ALB ingress controller</td>
<td>The AWS ALB Ingress Controller for Kubernetes is a controller that causes an ALB to be created when ingress resources are created.</td>
<td>July 11, 2019</td>
</tr>
<tr>
<td>New Amazon EKS optimized AMI</td>
<td>Removing unnecessary kubectl binary from AMIs.</td>
<td>July 3, 2019</td>
</tr>
<tr>
<td>Kubernetes version 1.13 (p. 536)</td>
<td>Added Kubernetes version 1.13 support for new clusters and version upgrades.</td>
<td>June 18, 2019</td>
</tr>
<tr>
<td>New Amazon EKS optimized AMI patched for AWS-2019-005</td>
<td>Amazon EKS has updated the Amazon EKS optimized AMI to address the vulnerabilities that are described in AWS-2019-005.</td>
<td>June 17, 2019</td>
</tr>
<tr>
<td>Announcing discontinuation of support of Kubernetes 1.10 in Amazon EKS</td>
<td>Amazon EKS stopped supporting Kubernetes version 1.10 on July 22, 2019.</td>
<td>May 21, 2019</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------</td>
</tr>
<tr>
<td>Amazon EKS platform version update</td>
<td>New platform version for Kubernetes 1.11 and 1.10 clusters to support custom DNS names in the Kubelet certificate and improve etcd performance.</td>
<td>May 21, 2019</td>
</tr>
<tr>
<td>AWS CLI get-token command (p. 536)</td>
<td>The <code>aws eks get-token</code> command was added to the AWS CLI. You no longer need to install the AWS IAM Authenticator for Kubernetes to create client security tokens for cluster API server communication. Upgrade your AWS CLI installation to the latest version to use this new functionality. For more information, see Installing the AWS Command Line Interface in the AWS Command Line Interface User Guide.</td>
<td>May 10, 2019</td>
</tr>
<tr>
<td>Getting started with eksctl</td>
<td>This getting started guide describes how you can install all of the required resources to get started with Amazon EKS using eksctl. This is a simple command line utility for creating and managing Kubernetes clusters on Amazon EKS.</td>
<td>May 10, 2019</td>
</tr>
<tr>
<td>Amazon EKS platform version update</td>
<td>New platform version for Kubernetes 1.12 clusters to support custom DNS names in the Kubelet certificate and improve etcd performance. This fixes a bug that caused node Kubelet daemons to request a new certificate every few seconds.</td>
<td>May 8, 2019</td>
</tr>
<tr>
<td>Prometheus tutorial</td>
<td>Added topic for deploying Prometheus to your Amazon EKS cluster.</td>
<td>April 5, 2019</td>
</tr>
<tr>
<td>Amazon EKS control plane logging</td>
<td>With this update, you can get audit and diagnostic logs directly from the Amazon EKS control pane. You can use these CloudWatch logs in your account as reference for securing and running clusters.</td>
<td>April 4, 2019</td>
</tr>
<tr>
<td>Kubernetes version 1.12 (p. 536)</td>
<td>Added Kubernetes version 1.12 support for new clusters and version upgrades.</td>
<td>March 28, 2019</td>
</tr>
<tr>
<td>Added App Mesh getting started guide</td>
<td>Added documentation for getting started with App Mesh and Kubernetes.</td>
<td>March 27, 2019</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>---------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>Amazon EKS API server endpoint private access</td>
<td>Added documentation for disabling public access for your Amazon EKS cluster's Kubernetes API server endpoint.</td>
<td>March 19, 2019</td>
</tr>
<tr>
<td>Added topic for installing the Kubernetes Metrics Server</td>
<td>The Kubernetes Metrics Server is an aggregator of resource usage data in your cluster.</td>
<td>March 18, 2019</td>
</tr>
<tr>
<td>Added list of related open source projects</td>
<td>These open source projects extend the functionality of Kubernetes clusters running on AWS, including clusters that are managed by Amazon EKS.</td>
<td>March 15, 2019</td>
</tr>
<tr>
<td>Added topic for installing Helm locally</td>
<td>The helm package manager for Kubernetes helps you install and manage applications on your Kubernetes cluster. This topic shows how to install and run the helm and tiller binaries locally. That way, you can install and manage charts using the helm CLI on your local system.</td>
<td>March 11, 2019</td>
</tr>
<tr>
<td>Amazon EKS platform version update</td>
<td>New platform version that updates Amazon EKS Kubernetes 1.11 clusters to patch level 1.11.8 to address CVE-2019-1002100.</td>
<td>March 8, 2019</td>
</tr>
<tr>
<td>Increased cluster limit</td>
<td>Amazon EKS has increased the number of clusters that you can create in an AWS Region from 3 to 50.</td>
<td>February 13, 2019</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 536)</td>
<td>Amazon EKS is now available in the Europe (London) (eu-west-2), Europe (Paris) (eu-west-3), and Asia Pacific (Mumbai) (ap-south-1) AWS Regions.</td>
<td>February 13, 2019</td>
</tr>
<tr>
<td>New Amazon EKS optimized AMI patched for ALAS-2019-1156</td>
<td>Amazon EKS has updated the Amazon EKS optimized AMI to address the vulnerability that's described in ALAS-2019-1156.</td>
<td>February 11, 2019</td>
</tr>
<tr>
<td>New Amazon EKS optimized AMI patched for ALAS2-2019-1141</td>
<td>Amazon EKS has updated the Amazon EKS optimized AMI to address the CVEs that are referenced in ALAS2-2019-1141.</td>
<td>January 9, 2019</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 536)</td>
<td>Amazon EKS is now available in the Asia Pacific (Seoul) (ap-northeast-2) AWS Region.</td>
<td>January 9, 2019</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>---------------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 536)</td>
<td>Amazon EKS is now available in the following additional AWS Regions: Europe (Frankfurt) (eu-central-1), Asia Pacific (Tokyo) (ap-northeast-1), Asia Pacific (Singapore) (ap-southeast-1), and Asia Pacific (Sydney) (ap-southeast-2).</td>
<td>December 19, 2018</td>
</tr>
<tr>
<td>Amazon EKS cluster updates</td>
<td>Added documentation for Amazon EKS cluster Kubernetes version updates and node replacement.</td>
<td>December 12, 2018</td>
</tr>
<tr>
<td>Amazon EKS AWS Region expansion (p. 536)</td>
<td>Amazon EKS is now available in the Europe (Stockholm) (eu-north-1) AWS Region.</td>
<td>December 11, 2018</td>
</tr>
<tr>
<td>Amazon EKS platform version update</td>
<td>New platform version updating Kubernetes to patch level 1.10.11 to address CVE-2018-1002105.</td>
<td>December 4, 2018</td>
</tr>
<tr>
<td>Added version 1.0.0 support for the ALB ingress controller</td>
<td>The ALB ingress controller releases version 1.0.0 with formal support from AWS.</td>
<td>November 20, 2018</td>
</tr>
<tr>
<td>Added support for CNI network configuration</td>
<td>The Amazon VPC CNI plugin for Kubernetes version 1.2.1 now supports custom network configuration for secondary pod network interfaces.</td>
<td>October 16, 2018</td>
</tr>
<tr>
<td>Added support for MutatingAdmissionWebhook and ValidatingAdmissionWebhook</td>
<td>Amazon EKS platform version 1.10-eks.2 now supports MutatingAdmissionWebhook and ValidatingAdmissionWebhook admission controllers.</td>
<td>October 10, 2018</td>
</tr>
<tr>
<td>Added partner AMI information</td>
<td>Canonical has partnered with Amazon EKS to create node AMIs that you can use in your clusters.</td>
<td>October 3, 2018</td>
</tr>
<tr>
<td>Added instructions for AWS CLI update-kubeconfig command</td>
<td>Amazon EKS has added the update-kubeconfig to the AWS CLI to simplify the process of creating a kubeconfig file for accessing your cluster.</td>
<td>September 21, 2018</td>
</tr>
<tr>
<td>New Amazon EKS optimized AMIs</td>
<td>Amazon EKS has updated the Amazon EKS optimized AMIs (with and without GPU support) to provide various security fixes and AMI optimizations.</td>
<td>September 13, 2018</td>
</tr>
<tr>
<td>Event Description</td>

<tr>
<td><strong>Amazon EKS AWS Region expansion (p. 536)</strong></td>
<td>Amazon EKS is now available in the Europe (Ireland) (eu-west-1) Region.</td>
<td>September 5, 2018</td>
</tr>
<tr>
<td><strong>Amazon EKS platform version update</strong></td>
<td>New platform version with support for Kubernetes aggregation layer and the Horizontal Pod Autoscaler (HPA).</td>
<td>August 31, 2018</td>
</tr>
<tr>
<td><strong>New Amazon EKS optimized AMIs and GPU support</strong></td>
<td>Amazon EKS has updated the Amazon EKS optimized AMI to use a new AWS CloudFormation node template and bootstrap script. In addition, a new Amazon EKS optimized AMI with GPU support is available.</td>
<td>August 22, 2018</td>
</tr>
<tr>
<td><strong>New Amazon EKS optimized AMI patched for ALAS2-2018-1058</strong></td>
<td>Amazon EKS has updated the Amazon EKS optimized AMI to address the CVEs that are referenced in ALAS2-2018-1058.</td>
<td>August 14, 2018</td>
</tr>
<tr>
<td><strong>Amazon EKS optimized AMI build scripts</strong></td>
<td>Amazon EKS has open-sourced the build scripts that are used to build the Amazon EKS optimized AMI. These build scripts are now available on GitHub.</td>
<td>July 10, 2018</td>
</tr>
<tr>
<td><strong>Amazon EKS initial release (p. 536)</strong></td>
<td>Initial documentation for service launch</td>
<td>June 5, 2018</td>
</tr>
