What is Amazon EKS?

Amazon EKS is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.

Amazon EKS runs Kubernetes control plane instances across multiple Availability Zones to ensure high availability. Amazon EKS automatically detects and replaces unhealthy control plane instances, and it provides automated version upgrades and patching for them.

Amazon EKS is integrated with many AWS services to provide scalability and security for your applications, including the following capabilities:

- Amazon ECR for container images
- Elastic Load Balancing for load distribution
- IAM for authentication
- Amazon VPC for isolation

Amazon EKS runs up-to-date versions of the open-source Kubernetes software, so you can use all of the existing plugins and tooling from the Kubernetes community. Applications that are running on Amazon EKS are fully compatible with applications running on any standard Kubernetes environment, no matter whether they're running in on-premises data centers or public clouds. This means that you can easily migrate any standard Kubernetes application to Amazon EKS without any code modification.

Amazon EKS control plane architecture

Amazon EKS runs a single tenant Kubernetes control plane for each cluster, and control plane infrastructure is not shared across clusters or AWS accounts.

This control plane consists of at least two API server nodes and three etcd nodes that run across three Availability Zones within a Region. Amazon EKS automatically detects and replaces unhealthy control plane instances, restarting them across the Availability Zones within the Region as needed. Amazon EKS leverages the architecture of AWS Regions in order to maintain high availability. Because of this, Amazon EKS is able to offer an SLA for API server endpoint availability.

Amazon EKS uses Amazon VPC network policies to restrict traffic between control plane components to within a single cluster. Control plane components for a cluster can't view or receive communication from other clusters or other AWS accounts, except as authorized with Kubernetes RBAC policies.

This secure and highly available configuration makes Amazon EKS reliable and recommended for production workloads.
How does Amazon EKS work?

Getting started with Amazon EKS is easy:

1. Create an Amazon EKS cluster in the AWS Management Console or with the AWS CLI or one of the AWS SDKs.
2. Launch managed or self-managed Amazon EC2 nodes, or deploy your workloads to AWS Fargate.
3. When your cluster is ready, you can configure your favorite Kubernetes tools, such as kubectl, to communicate with your cluster.
4. Deploy and manage workloads on your Amazon EKS cluster the same way that you would with any other Kubernetes environment. You can also view information about your workloads using the AWS Management Console.

To create your first cluster and its associated resources, see Getting started with Amazon EKS (p. 4).

Pricing

An Amazon EKS cluster consists of a control plane and the Amazon EC2 or AWS Fargate compute that you run pods on. For more information about pricing for the control plane, see Amazon EKS pricing. Both Amazon EC2 and Fargate provide:

- **On-Demand Instances** – Pay for the instances that you use by the second, with no long-term commitments or upfront payments. For more information, see Amazon EC2 On-Demand Pricing and AWS Fargate Pricing.
- **Savings Plans** – You can reduce your costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years. For more information, see Pricing with Savings Plans.

Aligning with Amazon EKS for your self-managed Kubernetes clusters

Amazon EKS Distro is a distribution of the same open-source Kubernetes software and dependencies deployed by Amazon EKS in the cloud. With Amazon EKS Distro, you can create reliable and secure clusters wherever your applications are deployed. You can rely on the same versions of Kubernetes deployed by Amazon EKS, etcd, CoreDNS, upstream CNI, and CSI sidecars with the latest updates, and extended security patching support. Amazon EKS Distro follows the same Kubernetes version release cycle as Amazon EKS and is provided as an open-source project.
Note
The source code for the Amazon EKS Distro is available on GitHub. The latest documentation is available on the Amazon EKS Distro website. If you find any issues, you can report them with Amazon EKS Distro by connecting with us on GitHub. There you can open issues, provide feedback, and report bugs.
Getting started with Amazon EKS

There are two getting started guides available for creating a new Kubernetes cluster with nodes in Amazon EKS:

- **Getting started with eksctl (p. 4)** – This getting started guide helps you to install all of the required resources to get started with Amazon EKS using eksctl, a simple command line utility for creating and managing Kubernetes clusters on Amazon EKS. At the end of the tutorial, you will have a running Amazon EKS cluster that you can deploy applications to. This is the fastest and simplest way to get started with Amazon EKS.

- **Getting started with the AWS Management Console (p. 15)** – This getting started guide helps you to create all of the required resources to get started with Amazon EKS using the AWS Management Console. At the end of the tutorial, you will have a running Amazon EKS cluster that you can deploy applications to. In this guide, you manually create each resource in the Amazon EKS or AWS CloudFormation consoles. The procedures give you complete visibility into how each resource is created and how they interact with each other.

---

**Getting started with eksctl**

This getting started guide helps you to create all of the required resources to get started with Amazon EKS using eksctl, a simple command line utility for creating and managing Kubernetes clusters on Amazon EKS. At the end of this tutorial, you will have a running Amazon EKS cluster that you can deploy applications to.

The procedures in this guide create several resources for you automatically, that you have to create manually when you create your cluster using the AWS Management Console. If you'd rather manually create most of the resources to better understand how they interact with each other, then use the AWS Management Console to create your cluster and compute. For more information, see **Getting started with the AWS Management Console (p. 15)**.

**Prerequisites**

This section helps you to install and configure the following tools that you need to create and manage an Amazon EKS cluster.

- **AWS CLI (p. 4)** – Command line tools for working with AWS services, including Amazon EKS.
- **eksctl (p. 6)** – A command line tool for working with EKS clusters that automates many individual tasks.
- **kubectl (p. 7)** – A command line tool for working with Kubernetes clusters.

**Install the AWS CLI**

You can install the latest version of the AWS CLI for macOS (p. 4), Linux (p. 5), or Windows (p. 5).

[To install the AWS CLI for macOS]

1. If you currently have the AWS CLI installed, determine which version that you have installed.
2. If you don't have version 1.18.190 or later, or version 2.1.7 or later installed, then install the AWS CLI version 2. For other installation options, or to upgrade your currently installed version 2, see Upgrading the AWS CLI version 2 on macOS.

```bash
curl "https://awscli.amazonaws.com/AWSCLIV2.pkg" -o "AWSCLIV2.pkg"
sudo installer -pkg AWSCLIV2.pkg -target /
```

If you're unable to use the AWS CLI version 2, then ensure that you have the latest version of the AWS CLI version 1 installed using the following command.

```bash
pip3 install awscli --upgrade --user
```

[To install the AWS CLI for Linux]

1. If you currently have the AWS CLI installed, determine which version that you have installed.

```bash
aws --version
```

2. If you don't have version 1.18.190 or later, or version 2.1.7 or later installed, then install the AWS CLI version 2. For other installation options, or to upgrade your currently installed version 2, see Upgrading the AWS CLI version 2 on Linux.

```bash
curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip"
unzip awscliv2.zip
sudo ./aws/install
```

If you're unable to use the AWS CLI version 2, then ensure that you have the latest version of the AWS CLI version 1 installed using the following command.

```bash
pip3 install --upgrade --user awscli
```

[To install the AWS CLI for Windows]

1. If you currently have the AWS CLI installed, determine which version that you have installed.

```bash
aws --version
```

2. If you don't have either version 1.18.190 or later, or version 2.1.7 or later installed, then install the AWS CLI version 2 using the following steps. For other installation options, or to upgrade your currently installed version 2, see Upgrading the AWS CLI version 2 on Windows.

   a. Download the AWS CLI MSI installer for Windows (64-bit) at https://awscli.amazonaws.com/AWSCLIV2.msi
   b. Run the downloaded MSI installer and follow the onscreen instructions. By default, the AWS CLI installs to C:\Program Files\Amazon\AWSCLIV2.

3. (Optional) If you're unable to use the AWS CLI version 2, then ensure that you have the latest version of the AWS CLI version 1 installed using the following command.

```bash
pip3 install --user --upgrade awscli
```
Configure your AWS CLI credentials

Both eksctl and the AWS CLI require that you have AWS credentials configured in your environment. The aws configure command is the fastest way to set up your AWS CLI installation for general use.

```
$ aws configure
AWS Access Key ID [None]: <AKIAIOSFODNN7EXAMPLE>
AWS Secret Access Key [None]: <wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY>
Default region name [None]: <region-code>
Default output format [None]: <json>
```

When you type this command, the AWS CLI prompts you for four pieces of information: access key, secret access key, AWS Region, and output format. This information is stored in a profile (a collection of settings) named default. This profile is used when you run commands, unless you specify another one.

For more information, see Configuring the AWS CLI in the AWS Command Line Interface User Guide.

Install eksctl

You can install 0.35.0 version or later of the eksctl command line utility on macOS (p. 6), Linux (p. 7), or Windows (p. 7). For more information, see https://eksctl.io/.

[ To install or upgrade eksctl on macOS using Homebrew ]

The easiest way to get started with Amazon EKS and macOS is by installing eksctl with Homebrew. The eksctl Homebrew recipe installs eksctl and any other dependencies that are required for Amazon EKS, such as kubectl. The recipe also installs the aws-iam-authenticator (p. 271), which is required if you don't have the AWS CLI version 1.16.156 or higher installed.

1. If you do not already have Homebrew installed on macOS, install it with the following command.

   ```bash
   /bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/master/install.sh)"
   ```

2. Install the Weaveworks Homebrew tap.

   ```bash
   brew tap weaveworks/tap
   ```

3. Install or upgrade eksctl.

   - Install eksctl with the following command:

     ```bash
     brew install weaveworks/tap/eksctl
     ```

   - If eksctl is already installed, run the following command to upgrade:

     ```bash
     brew upgrade eksctl && brew link --overwrite eksctl
     ```

4. Test that your installation was successful with the following command.

   ```bash
   eksctl version
   ```

   **Note**
   The GitTag version should be at least 0.35.0. If not, check your terminal output for any installation or upgrade errors, or manually download an archive of the release from https://github.com/weaveworks/eksctl/releases/download/0.35.0/eksctl_Darwin_amd64.tar.gz, extract eksctl, and then execute it.
Prerequisites

[To install or upgrade eksctl on Linux using curl]
1. Download and extract the latest release of eksctl with the following command.

```bash
curl --silent --location "https://github.com/weaveworks/eksctl/releases/latest/download/eksctl_$(uname -s)_amd64.tar.gz" | tar xz -C /tmp
```

2. Move the extracted binary to /usr/local/bin.

```bash
sudo mv /tmp/eksctl /usr/local/bin
```

3. Test that your installation was successful with the following command.

```bash
eksctl version
```

**Note**
The GitTag version should be at least 0.35.0. If not, check your terminal output for any installation or upgrade errors, or replace the address in step 1 with https://github.com/weaveworks/eksctl/releases/download/0.35.0/eksctl_Linux_amd64.tar.gz and complete steps 1-3 again.

[To install or upgrade eksctl on Windows using Chocolatey]
1. If you do not already have Chocolatey installed on your Windows system, see Installing Chocolatey.
2. Install or upgrade eksctl.
   - Install the binaries with the following command:

```bash
choco install -y eksctl
```
   - If they are already installed, run the following command to upgrade:

```bash
choco upgrade -y eksctl
```
3. Test that your installation was successful with the following command.

```bash
eksctl version
```

**Note**
The GitTag version should be at least 0.35.0. If not, check your terminal output for any installation or upgrade errors, or manually download an archive of the release from https://github.com/weaveworks/eksctl/releases/download/0.35.0/eksctl_Windows_amd64.zip, extract eksctl, and then execute it.

Install and configure kubectl

Kubernetes uses the kubectl command-line utility for communicating with the cluster API server.

**Note**
If you used the preceding Homebrew instructions to install eksctl on macOS, then kubectl has already been installed on your system. You can skip to Create your Amazon EKS cluster and compute (p. 11).
You can install version 1.18 of the kubectl command line utility for macOS (p. 8), Linux (p. 9), or Windows (p. 10). If you need to install a different version to use with a different cluster version, then see Installing kubectl (p. 283).

[To install kubectl on macOS]

1. Download the Amazon EKS vended kubectl binary that corresponds to the Region that your cluster is in.
   - All Regions other than China Regions.

   ```bash
   curl -o kubectl https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/darwin/amd64/kubectl
   ```

   - Beijing and Ningxia China Regions.

   ```bash
   curl -o kubectl https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/darwin/amd64/kubectl
   ```

2. (Optional) Verify the downloaded binary with the SHA-256 sum.
   a. Download the SHA-256 sum that corresponds to the Region that your cluster is in.
      - All Regions other than China Regions.

      ```bash
      curl -o kubectl.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/darwin/amd64/kubectl.sha256
      ```

      - Beijing and Ningxia China Regions.

      ```bash
      curl -o kubectl.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/darwin/amd64/kubectl.sha256
      ```

   b. Check the SHA-256 sum.

      ```bash
      openssl sha1 -sha256 kubectl
      ```

   c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match.

3. Apply execute permissions to the binary.

   ```bash
   chmod +x ./kubectl
   ```

4. Move kubectl to a folder that is in your path.
   - If you don't already have a version of kubectl installed, then move the binary to a folder that's already in your PATH.

   ```bash
   sudo mv ./kubectl /usr/local/bin
   ```

   - If you already have a version of kubectl installed, then we recommend creating a $HOME/bin/kubectl folder, moving the binary to that folder, and ensuring that $HOME/bin comes first in your $PATH.

   ```bash
   mkdir -p $HOME/bin & & mv ./kubectl $HOME/bin/kubectl & & export PATH=$PATH:$HOME/bin
   ```
Prerequisites

(Optional) Add the \$HOME/bin path to your shell initialization file so that it is configured when you open a shell.

```bash
echo 'export PATH=\$PATH:\$HOME/bin' >> ~/.bash_profile
```

5. After you install kubectl, you can verify its version with the following command:

```bash
cubectl version --short --client
```

[To install kubectl on Linux]

1. Download the Amazon EKS vended kubectl binary that corresponds to the Region that your cluster is in.
   - All Regions other than China Regions.
     ```bash
curl -o kubectl https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/linux/amd64/kubectl
```
   - Beijing and Ningxia China Regions.
     ```bash
curl -o kubectl https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/linux/amd64/kubectl
```

2. (Optional) Verify the downloaded binary with the SHA-256 sum.
   a. Download the SHA-256 sum that corresponds to the Region that your cluster is in.
      - All Regions other than China Regions.
        ```bash
curl -o kubectl.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/linux/amd64/kubectl.sha256
```
      - Beijing and Ningxia China Regions.
        ```bash
curl -o kubectl.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/linux/amd64/kubectl.sha256
```
   b. Check the SHA-256 sum.
     ```bash
     openssl sha1 -sha256 kubectl
     ```
   c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match.

3. Apply execute permissions to the binary.

```bash
chmod +x ./kubectl
```

4. Move kubectl to a folder that is in your path.
   - If you don't already have a version of kubectl installed, then move the binary to a folder in your PATH.
     ```bash
     sudo mv ./kubectl /usr/local/bin
     ```
• If you already have a version of kubectl installed, then we recommend creating a $HOME/bin/kubectl folder, moving the binary to that folder, and ensuring that $HOME/bin comes first in your $PATH.

```bash
mkdir -p $HOME/bin && mv ./kubectl $HOME/bin/kubectl && export PATH=$PATH:$HOME/bin
```

(Optional) Add the $HOME/bin path to your shell initialization file so that it is configured when you open a shell.

```bash
echo 'export PATH=$PATH:$HOME/bin' >> ~/.bash_profile
```

**Note**
This step assumes you are using the Bash shell; if you are using another shell, change the command to use your specific shell initialization file.

5. After you install kubectl, you can verify its version with the following command:

```bash
kubectl version --short --client
```

**To install kubectl on Windows**

1. Open a PowerShell terminal.
2. Download the Amazon EKS vended kubectl binary that corresponds to the region that your cluster is in.

   • All Regions other than China Regions.

   ```bash
curl -o kubectl.exe https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/windows/amd64/kubectl.exe
```

   • Beijing and Ningxia China Regions.

   ```bash
curl -o kubectl.exe https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/windows/amd64/kubectl.exe
```

3. (Optional) Verify the downloaded binary with the SHA-256 sum.

   a. Download the SHA-256 sum that corresponds to the region that your cluster is in.

      • All Regions other than China Regions.

      ```bash
curl -o kubectl.exe.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/windows/amd64/kubectl.exe.sha256
```

      • Beijing and Ningxia China Regions.

      ```bash
curl -o kubectl.exe.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/windows/amd64/kubectl.exe.sha256
```

   b. Check the SHA-256 sum.

   ```bash
   Get-FileHash kubectl.exe
   ```

   c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match, although the PowerShell output will be uppercase.
Create your Amazon EKS cluster and compute

This section helps you to create an Amazon EKS cluster with a compute option to run your applications. The latest Kubernetes version available in Amazon EKS is installed so that you can take advantage of the latest Kubernetes and Amazon EKS features. Some features are not available on older versions of Kubernetes.

**Important**
Make sure that the AWS Security Token Service (STS) endpoint for the Region that your cluster is in is enabled for your account. If the endpoint is not enabled, then nodes will fail to join the cluster during cluster creation. For more information, see Activating and deactivating AWS STS in an AWS Region.

Select one of the following compute options. To learn more about each option, see Amazon EKS nodes (p. 96). After your cluster is deployed, you can add other options, if you choose.

- **Fargate – Linux (p. 11)** – Select this option if you want to run Linux applications on AWS Fargate.
- **Managed nodes – Linux (p. 12)** – Select this option if you want to run Amazon Linux applications on Amazon EC2 instances.
- **Self-managed nodes – Windows (p. 13)** – Select this option if you want to run Windows applications on Amazon EC2 instances. You can also run Linux applications using this option because even if you only need to run Windows applications, your cluster must still have at least one Linux node.

Though not covered in this guide, you can also add Bottlerocket nodes to your cluster. For more information, see Launching self-managed Bottlerocket nodes (p. 122).

### [ Fargate – Linux ]

**Note**

- You can only use AWS Fargate with Amazon EKS in some Regions. Before using Fargate with Amazon EKS, ensure that the Region that you want to use is supported. For more information, see Getting started with AWS Fargate using Amazon EKS (p. 139).
- Do not use eksctl to create a cluster or nodes in an AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled. Create a cluster and self-managed nodes using the Amazon EC2 API or AWS CloudFormation instead. For more information, see To launch self-managed Linux nodes using the AWS Management Console (p. 119) and To launch self-managed Windows nodes using the AWS Management Console (p. 126).

Create your Amazon EKS cluster with Fargate support with the following command. Replace the `<example values>` (including `<`) with your own values. You can replace `<us-west-2>` with any Amazon EKS supported Region. You can replace `<us-west-2>` with any Amazon EKS Fargate supported
**Region (p. 137).** We recommend that you deploy version 1.18, but if you replace it with an earlier version, then read the important Amazon EKS release notes (p. 68) for the version and install the corresponding version of kubectl (p. 283).

```
eksctl create cluster \
--name <my-cluster> \
--version <1.18> \
--region <us-west-2> \
--fargate
```

Your new Amazon EKS cluster is created without a node group. Eksctl creates a pod execution role, a Fargate profile (p. 143) for the default and kube-system namespaces, and it patches the coredns deployment so that it can run on Fargate. For more information see AWS Fargate (p. 137).

### [Managed nodes – Linux ]

1. You can create the nodes with or without a launch template. A launch template allows for greater customization, to include the ability to deploy a custom AMI. For either option, replace the `<example values>` (including `<>`) with your own values.

   You can replace `<us-west-2>` with any Amazon EKS supported Region. We recommend that you deploy version 1.18, but if you replace it with an earlier version, then read the important Amazon EKS release notes (p. 68) for the version and install the corresponding version of kubectl (p. 283).

   Though `--ssh-public-key` is optional, we highly recommend that you specify it when you create your node group with a cluster. This option enables SSH access to the nodes in your managed node group. Enabling SSH access allows you to connect to your instances and gather diagnostic information if there are issues. You cannot enable remote access after the node group is created. If you don’t have a public key, then you can create a key pair for Amazon EC2 to specify for `--ssh-public-key`. Ensure that you create the key in the same Region that you create the cluster in.

   **Important**
   Do not use eksctl to create a cluster or nodes in an AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled. Create a cluster and self-managed nodes using the Amazon EC2 API or AWS CloudFormation instead. For more information, see To launch self-managed Linux nodes using the AWS Management Console (p. 119) and To launch self-managed Windows nodes using the AWS Management Console (p. 126).

   **Important**
   Amazon EKS nodes are standard Amazon EC2 instances, and you are billed for them based on normal Amazon EC2 instance prices. For more information, see Amazon EC2 pricing.

   - **Without** a launch template.

   **Note**
   Even when you don’t specify your own launch template, the Amazon EKS API creates a default launch template and deploys the nodes using the launch template.

```
eksctl create cluster \
--name <my-cluster> \
--version <1.18> \
--region <us-west-2> \
--nodegroup-name <linux-nodes> \
--nodes <3> \
--nodes-min <1> \n--nodes-max <4> \n--with-oidc \
--ssh-access \
```
--ssh-public-key <name-of-ec2-keypair> \
--managed

- **With a launch template** -- Create your Amazon EKS cluster and Amazon Linux nodes with a launch template. The launch template must already exist and must meet the requirements specified in Launch template configuration basics (p. 113). Create a file with the following contents, replacing the `<example values>` (including `<`) with your own values. Several settings that you specify when deploying without a launch template are moved into the launch template. If you don't specify a version, the template's default version is used.

```yaml
---
apiversion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: <my-cluster>
  region: <us-west-2>
  version: '<1.18>'
iam:
  withOIDC: true
managedNodeGroups:
- name: <ng-linux>
  launchTemplate:
    id: lt-<id>
    version: "<1>"
```

2. Create the cluster and node group with the following command.

```
eksctl create cluster --config-file <filename-you-used-in-previous-step.yaml>
```

Output:

You'll see several lines of output as the cluster and nodes are created. The last line of output is similar to the following example line.

```
[✓]  EKS cluster "<my-cluster>" in "<us-west-2>" region is ready
```

If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 366) in the Troubleshooting guide.

### [ Self-managed nodes – Windows ]

Familiarize yourself with the Windows support considerations (p. 80), which include supported values for `instanceType` in the example text below. Replace the example `<values>` with your own values.

We recommend that you deploy version 1.18. If you must deploy an earlier version, then you can only replace it with version 1.16 or later. If you change 1.18, then read the important Amazon EKS release notes (p. 68) for the version and install the corresponding version of `kubectl` (p. 283).

**Important**

Do not use `eksctl` to create a cluster or nodes in an AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled. Create a cluster and self-managed nodes using the Amazon EC2 API or AWS CloudFormation instead. For more information, see To launch self-managed Linux nodes using the AWS Management Console (p. 119) and To launch self-managed Windows nodes using the AWS Management Console (p. 126).

**Important**

Amazon EKS nodes are standard Amazon EC2 instances, and you are billed for them based on normal Amazon EC2 instance prices. For more information, see Amazon EC2 pricing.
1. Create a file with the following contents, replacing the `<example values>` (including `<>`) with your own values. The file will be used to create a cluster with a self-managed Windows node group and a managed Linux node group. Even if you only want to run Windows applications in your cluster, all Amazon EKS clusters must contain at least one Linux node, though we recommend that you create at least two Linux nodes for availability purposes. For more information about using a config file with `eksctl`, the config file schema, and config file samples, see the `eksctl` documentation. We recommend that you deploy version 1.18 (but first remove the `<>`). If you replace 1.18, then read the important Amazon EKS release notes (p. 68) for the version and install the corresponding version of `kubectl` (p. 283).

```yaml
---
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: <my-cluster>
  region: <us-west-2>
  version: '<1.18>'
iam:
  withOIDC: true
managedNodeGroups:
- name: <linux-ng>
  instanceType: <m5.large>
  minSize: <2>
nodeGroups:
- name: <windows-ng>
  instanceType: <m5.large>
  minSize: <2>
  volumeSize: <100>
  amiFamily: <WindowsServer2019FullContainer>
```

2. Create your Amazon EKS cluster and Windows and Linux nodes with the following command.

`eksctl create cluster -f <filename-you-used-in-previous-step.yaml> --install-vpc-controllers`

**Note**
For more information about the available options for `eksctl create cluster`, see the project README on GitHub or view the help page with the following command.

`eksctl create cluster --help`

**Output:**

You'll see several lines of output as the cluster and nodes are created. The last line of output is similar to the following example line.

```
[✓]  EKS cluster "<my-cluster>" in "<us-west-2>" region is ready
```

If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 366) in the Troubleshooting guide.

Cluster provisioning usually takes between 10 and 15 minutes.

3. When your cluster is ready, test that your `kubectl` configuration is correct.
Next steps

Now that you have a working Amazon EKS cluster with nodes, you are ready to start installing Kubernetes add-ons and deploying applications to your cluster. The following documentation topics help you to extend the functionality of your cluster.

- **Restrict access to IMDS (p. 349)** – If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current Region, then we recommend blocking pod access to IMDS. For more information, see the section called “IAM roles for service accounts” (p. 330) and the section called “Restricting access to the instance profile” (p. 349).
- **Cluster Autoscaler (p. 61)** – Configure the Kubernetes Cluster Autoscaler to automatically adjust the number of nodes in your node groups.
- **Deploy a sample Linux workload (p. 249)** – Deploy a sample application to test your cluster and Linux nodes.
- **Deploy a Windows sample application (p. 85)** – Deploy a sample application to test your cluster and Windows nodes.
- **Cluster management (p. 283)** – Learn how to use important tools for managing your cluster.

Getting started with the AWS Management Console

This getting started guide helps you to create all of the required resources to get started with Amazon EKS using the AWS Management Console. In this guide, you manually create each resource in the Amazon EKS or AWS CloudFormation consoles. At the end of this tutorial, you will have a running Amazon EKS cluster that you can deploy applications to.

The procedures in this guide give you complete visibility into how each resource is created and how the resources interact with each other. If you'd rather have most of the resources created for you automatically, use the `eksctl` CLI to create your cluster and nodes. For more information, see Getting started with `eksctl` (p. 4).

Note

If you receive any authorization or resource type errors, see Unauthorized or access denied (`kubectl`) (p. 367) in the troubleshooting section.

Output:

```
NAME             TYPE        CLUSTER-IP   EXTERNAL-IP   PORT(S)   AGE
svc/kubernetes   ClusterIP   10.100.0.1   <none>        443/TCP   1m
```

4. (Linux accelerated AMI nodes only) If you chose an accelerated AMI instance type and the Amazon EKS optimized accelerated AMI, then you must apply the NVIDIA device plugin for Kubernetes as a DaemonSet on your cluster with the following command.

```
kubectl apply -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.6.0/nvidia-device-plugin.yml
```
Prerequisites

This section helps you to install and configure the following tools and resources that you need to create and manage an Amazon EKS cluster.

- The AWS CLI (p. 16) – A command line tools for working with AWS services, including Amazon EKS.
- kubectl (p. 17) – A command line tool for working with Kubernetes clusters.
- Cluster IAM role (p. 21) – A role allows Kubernetes clusters managed by Amazon EKS to make calls to other AWS services on your behalf to manage the resources that you use with the service.

Install the AWS CLI

You can install the latest version of the AWS CLI, for macOS (p. 16), Linux (p. 16), or Windows (p. 17).

[ To install the AWS CLI for macOS ]

1. If you currently have the AWS CLI installed, determine which version that you have installed.

   ```shell
   aws --version
   ```

2. If you don't have version 1.18.190 or later, or version 2.1.7 or later installed, then install the AWS CLI version 2. For other installation options, or to upgrade your currently installed version 2, see Upgrading the AWS CLI version 2 on macOS.

   ```shell
curl "https://awscli.amazonaws.com/AWSCLIV2.pkg" -o "AWSCLIV2.pkg"
sudo installer -pkg AWSCLIV2.pkg -target /
   ```

   If you're unable to use the AWS CLI version 2, then ensure that you have the latest version of the AWS CLI version 1 installed using the following command.

   ```shell
   pip3 install awscli --upgrade --user
   ```

[ To install the AWS CLI for Linux ]

1. If you currently have the AWS CLI installed, determine which version that you have installed.

   ```shell
   aws --version
   ```

2. If you don't have version 1.18.190 or later, or version 2.1.7 or later installed, then install the AWS CLI version 2. For other installation options, or to upgrade your currently installed version 2, see Upgrading the AWS CLI version 2 on Linux.

   ```shell
curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip"
unzip awscliv2.zip
sudo ./aws/install
   ```

   If you're unable to use the AWS CLI version 2, then ensure that you have the latest version of the AWS CLI version 1 installed using the following command.

   ```shell
   pip3 install --upgrade --user awscli
   ```
[To install the AWS CLI for Windows]

1. If you currently have the AWS CLI installed, determine which version that you have installed.

   ```bash
   aws --version
   ```

2. If you don't have either version 1.18.190 or later, or version 2.1.7 or later installed, then install the AWS CLI version 2 using the following steps. For other installation options, or to upgrade your currently installed version 2, see Upgrading the AWS CLI version 2 on Windows.

   a. Download the AWS CLI MSI installer for Windows (64-bit) at https://awscli.amazonaws.com/AWSCLIV2.msi
   b. Run the downloaded MSI installer and follow the onscreen instructions. By default, the AWS CLI installs to C:\Program Files\Amazon\AWSCLIV2.

3. (Optional) If you're unable to use the AWS CLI version 2, then ensure that you have the latest version of the AWS CLI version 1 installed using the following command.

   ```bash
   pip3 install --user --upgrade awscli
   ```

**Configure your AWS CLI credentials**

The AWS CLI requires that you have AWS credentials configured in your environment. The `aws configure` command is the fastest way to set up your AWS CLI installation for general use.

```bash
# aws configure
AWS Access Key ID [None]: <AKIAIOSFODNN7EXAMPLE>
AWS Secret Access Key [None]: <wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY>
Default region name [None]: <region-code>
Default output format [None]: <json>
```

When you type this command, the AWS CLI prompts you for four pieces of information: access key, secret access key, AWS Region, and output format. This information is stored in a profile (a collection of settings) named default. This profile is used when you run commands, unless you specify another one.

For more information, see Configuring the AWS CLI in the AWS Command Line Interface User Guide.

**Install and configure kubectl**

Kubernetes uses the `kubectl` command-line utility for communicating with the cluster API server.

You can install version 1.18 of the `kubectl` command line utility for macOS (p. 17), Linux (p. 18), or Windows (p. 20).

[To install `kubectl` on macOS]

1. Download the Amazon EKS vended `kubectl` binary that corresponds to the Region that your cluster is in.

   - All Regions other than China Regions.
   ```bash
   curl -o kubectl https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/darwin/amd64/kubectl
   ```
   - Beijing and Ningxia China Regions.
curl -o kubectl https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/darwin/amd64/kubectl

2. (Optional) Verify the downloaded binary with the SHA-256 sum.
   a. Download the SHA-256 sum that corresponds to the Region that your cluster is in.
      • All Regions other than China Regions.
      
curl -o kubectl.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/darwin/amd64/kubectl.sha256
   
      • Beijing and Ningxia China Regions.
      
curl -o kubectl.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/darwin/amd64/kubectl.sha256

   b. Check the SHA-256 sum.
   
      openssl sha1 -sha256 kubectl
   
   c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match.

3. Apply execute permissions to the binary.

   chmod +x ./kubectl

4. Move kubectl to a folder that is in your path.
   a. If you don't already have a version of kubectl installed, then move the binary to a folder that's already in your PATH.
      
      sudo mv ./kubectl /usr/local/bin
   
      • If you already have a version of kubectl installed, then we recommend creating a $HOME/bin/kubectl folder, moving the binary to that folder, and ensuring that $HOME/bin comes first in your $PATH.
      
      mkdir -p $HOME/bin && mv ./kubectl $HOME/bin/kubectl && export PATH=$PATH:$HOME/bin
   
   (Optional) Add the $HOME/bin path to your shell initialization file so that it is configured when you open a shell.

   echo 'export PATH=$PATH:$HOME/bin' >> ~/.bash_profile

5. After you install kubectl, you can verify its version with the following command:

   kubectl version --short --client

[ To install kubectl on Linux ]

1. Download the Amazon EKS vended kubectl binary that corresponds to the Region that your cluster is in.
   • All Regions other than China Regions.
curl -o kubectl https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/linux/amd64/kubectl

- Beijing and Ningxia China Regions.

```
curl -o kubectl https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/linux/amd64/kubectl
```

2. (Optional) Verify the downloaded binary with the SHA-256 sum.
   a. Download the SHA-256 sum that corresponds to the Region that your cluster is in.
      - All Regions other than China Regions.
        ```
curl -o kubectl.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/linux/amd64/kubectl.sha256
```
      - Beijing and Ningxia China Regions.
        ```
curl -o kubectl.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/linux/amd64/kubectl.sha256
```
   b. Check the SHA-256 sum.
      ```
      openssl sha1 -sha256 kubectl
      ```
   c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match.

3. Apply execute permissions to the binary.

   ```
   chmod +x ./kubectl
   ```

4. Move kubectl to a folder that is in your path.
   - If you don't already have a version of kubectl installed, then move the binary to a folder in your PATH.
     ```
sudo mv ./kubectl /usr/local/bin
```
   - If you already have a version of kubectl installed, then we recommend creating a $HOME/bin/kubectl folder, moving the binary to that folder, and ensuring that $HOME/bin comes first in your PATH.
     ```
     mkdir -p $HOME/bin && mv ./kubectl $HOME/bin/kubectl && export PATH=$PATH:$HOME/bin
     ```
   (Optional) Add the $HOME/bin path to your shell initialization file so that it is configured when you open a shell.
   ```
   echo 'export PATH=$PATH:$HOME/bin' >> ~/.bash_profile
   ```

**Note**

This step assumes you are using the Bash shell; if you are using another shell, change the command to use your specific shell initialization file.

5. After you install kubectl, you can verify its version with the following command:
**[To install kubectl on Windows]**

1. Open a PowerShell terminal.
2. Download the Amazon EKS vended **kubectl** binary that corresponds to the Region that your cluster is in.
   - All Regions other than China Regions.
     
     ```
     curl -o kubectl.exe https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/windows/amd64/kubectl.exe
     ```
   
   - Beijing and Ningxia China Regions.
     
     ```
     curl -o kubectl.exe https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/windows/amd64/kubectl.exe
     ```
3. (Optional) Verify the downloaded binary with the SHA-256 sum.
   a. Download the SHA-256 sum that corresponds to the Region that your cluster is in.
      
      - All Regions other than China Regions.
       
       ```
       curl -o kubectl.exe.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/windows/amd64/kubectl.exe.sha256
       ```
      
      - Beijing and Ningxia China Regions.
       
       ```
       curl -o kubectl.exe.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/windows/amd64/kubectl.exe.sha256
       ```
   b. Check the SHA-256 sum.
     
     ```
     Get-FileHash kubectl.exe
     ```
   c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match, although the PowerShell output will be uppercase.
4. Copy the binary to a folder in your **PATH**. If you have an existing directory in your PATH that you use for command line utilities, copy the binary to that directory. Otherwise, complete the following steps.
   a. Create a new directory for your command line binaries, such as **C:\bin**.
   b. Copy the **kubectl.exe** binary to your new directory.
   c. Edit your user or system **PATH** environment variable to add the new directory to your **PATH**.
   d. Close your PowerShell terminal and open a new one to pick up the new **PATH** variable.
5. After you install **kubectl**, you can verify its version with the following command:

```
kubectl version --short --client
```
Create your Amazon EKS cluster IAM role

You can create the role using the AWS Management Console (p. 21) or AWS CloudFormation (p. 21).

[ To create your Amazon EKS cluster role in the IAM console ]

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Roles, then Create role.
3. Choose EKS from the list of services, then EKS - Cluster for your use case, and then Next: Permissions.
4. Choose Next: Tags.
5. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM Entities in the IAM User Guide.
6. Choose Next: Review.
7. For Role name, enter a unique name for your role, such as eksClusterRole, then choose Create role.

[ To create your Amazon EKS cluster role with AWS CloudFormation ]

1. Save the following AWS CloudFormation template to a text file on your local system.

   ```
   ---
   AWSTemplateFormatVersion: '2010-09-09'
   Description: 'Amazon EKS Cluster Role'
  
   Resources:

   eksClusterRole:
       Type: AWS::IAM::Role
       Properties:
         AssumeRolePolicyDocument:
           Version: '2012-10-17'
           Statement:
             - Effect: Allow
               Principal:
                 Service:
                   - eks.amazonaws.com
               Action:
                 - sts:AssumeRole
         ManagedPolicyArns:
           - arn:aws:iam::aws:policy/AmazonEKSClusterPolicy
   Outputs:

   RoleArn:
       Description: The role that Amazon EKS will use to create AWS resources for Kubernetes clusters
       Value: !GetAtt eksClusterRole.Arn
       Export:
         Name: !Sub "#{AWS::StackName}-RoleArn"
   ```

   Note
   Prior to April 16, 2020, ManagedPolicyArns had an entry for
   arn:aws:iam::aws:policy/AmazonEKSServicePolicy. With the
   AWSServiceRoleForAmazonEKS service-linked role, that policy is no longer required.

3. Choose Create stack.
4. For Specify template, select Upload a template file, and then choose Choose file.
5. Choose the file you created earlier, and then choose Next.
6. For Stack name, enter a name for your role, such as eksClusterRole, and then choose Next.
7. On the Configure stack options page, choose Next.
8. On the Review page, review your information, acknowledge that the stack might create IAM resources, and then choose Create stack.

Create your Amazon EKS cluster VPC

This section guides you through creating a VPC with either:

- Two public subnets and two private subnets (p. 22)
- Three public subnets (p. 23)
- Three private subnets (p. 24)

When you create an Amazon EKS cluster, you specify the VPC subnets for your cluster to use. Amazon EKS requires subnets in at least two Availability Zones. We recommend a VPC with public and private subnets so that Kubernetes can create public load balancers in the public subnets that load balance traffic to pods running on nodes that are in private subnets.

For more information about the VPC types, see Creating a VPC for your Amazon EKS cluster (p. 198).

To create your cluster VPC with public and private subnets

2. From the navigation bar, select a Region that supports Amazon EKS.
3. Choose Create stack, With new resources (standard).
4. For Choose a template, select Specify an Amazon S3 template URL.
5. Paste the URL that corresponds to the Region that your cluster is in into the text area and choose Next:
   - All Regions other than China Regions.
     
   - Beijing and Ningxia China Regions.
     
6. On the Specify Details page, fill out the parameters accordingly, and then choose Next.
   - Stack name: Choose a stack name for your AWS CloudFormation stack. For example, you can call it eks-vpc.
   - VpcBlock: Choose a CIDR range for your VPC. Each worker node, pod, and load balancer that you deploy is assigned an IP address from this block. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it. For more information, see VPC and subnet sizing in the Amazon VPC User Guide. You can also add additional CIDR blocks to the VPC once it's created.
   - PublicSubnet01Block: Specify a CIDR block for public subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it
Prerequisites

- **PublicSubnet02Block**: Specify a CIDR block for public subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
- **PrivateSubnet01Block**: Specify a CIDR block for private subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
- **PrivateSubnet02Block**: Specify a CIDR block for private subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.

7. (Optional) On the **Options** page, tag your stack resources. Choose **Next**.
8. On the **Review** page, choose **Create**.
9. When your stack is created, select it in the console and choose **Outputs**.
10. Record the **SecurityGroups** value for the security group that was created. When you add nodes to your cluster, you must specify the ID of the security group. The security group is applied to the elastic network interfaces that are created by Amazon EKS in your subnets that allows the control plane to communicate with your nodes. These network interfaces have `Amazon EKS <cluster name>` in their description.
11. Record the **VpcId** for the VPC that was created. You need this when you launch your node group template.
12. Record the **SubnetIds** for the subnets that were created and whether you created them as public or private subnets. When you add nodes to your cluster, you must specify the IDs of the subnets that you want to launch the nodes into.

**To create your cluster VPC with only public subnets**

2. From the navigation bar, select a Region that supports Amazon EKS.
3. Choose **Create stack, With new resources (standard)**.
4. For **Choose a template**, select **Specify an Amazon S3 template URL**.
5. Paste the URL that corresponds to the Region that your cluster is in into the text area and choose **Next**:
   - All Regions other than China Regions.

   ```
   ```

   - Beijing and Ningxia China Regions.

   ```
   ```

6. On the **Specify Details** page, fill out the parameters accordingly, and then choose **Next**.

   - **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it `eks-vpc`.
   - **VpcBlock**: Choose a CIDR block for your VPC. Each worker node, pod, and load balancer that you deploy is assigned an IP address from this block. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it. For more information, see VPC and subnet sizing in the Amazon VPC User Guide. You can also add additional CIDR blocks to the VPC once it's created.
   - **Subnet01Block**: Specify a CIDR block for subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
   - **Subnet02Block**: Specify a CIDR block for subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
- **Subnet03Block**: Specify a CIDR block for subnet 3. The default value provides enough IP addresses for most implementations, but if it doesn’t, then you can change it.

7. (Optional) On the **Options** page, tag your stack resources. Choose **Next**.

8. On the **Review** page, choose **Create**.

9. When your stack is created, select it in the console and choose **Outputs**.

10. Record the **SecurityGroups** value for the security group that was created. When you add nodes to your cluster, you must specify the ID of the security group. The security group is applied to the elastic network interfaces that are created by Amazon EKS in your subnets that allows the control plane to communicate with your nodes. These network interfaces have Amazon EKS <cluster name> in their description.

11. Record the **VpcId** for the VPC that was created. You need this when you launch your node group template.

12. Record the **SubnetIds** for the subnets that were created. When you add nodes to your cluster, you must specify the IDs of the subnets that you want to launch the nodes into.

### To create your cluster VPC with only private subnets

2. From the navigation bar, select a Region that supports Amazon EKS.
3. Choose **Create stack**, **With new resources (standard)**.
4. For **Choose a template**, select **Specify an Amazon S3 template URL**.
5. Paste the URL that corresponds to the Region that your cluster is in into the text area and choose **Next**:
   - All Regions other than China Regions.
     ```
     ```
   - Beijing and Ningxia China Regions.
     ```
     ```
6. On the **Specify Details** page, fill out the parameters accordingly, and then choose **Next**.
   - **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it **eks-vpc**.
   - **VpcBlock**: Choose a CIDR block for your VPC. Each worker node, pod, and load balancer that you deploy is assigned an IP address from this block. The default value provides enough IP addresses for most implementations, but if it doesn’t, then you can change it. For more information, see **VPC and subnet sizing** in the Amazon VPC User Guide. You can also add additional CIDR blocks to the VPC once it’s created.
   - **PrivateSubnet01Block**: Specify a CIDR block for subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn’t, then you can change it.
   - **PrivateSubnet02Block**: Specify a CIDR block for subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn’t, then you can change it.
   - **PrivateSubnet03Block**: Specify a CIDR block for subnet 3. The default value provides enough IP addresses for most implementations, but if it doesn’t, then you can change it.

7. (Optional) On the **Options** page, tag your stack resources. Choose **Next**.

8. On the **Review** page, choose **Create**.

9. When your stack is created, select it in the console and choose **Outputs**.
10. Record the **SecurityGroups** value for the security group that was created. When you add nodes to your cluster, you must specify the ID of the security group. The security group is applied to the elastic network interfaces that are created by Amazon EKS in your subnets that allow the control plane to communicate with your nodes. These network interfaces have `Amazon EKS <cluster name>` in their description.

11. Record the **VpcId** for the VPC that was created. You need this when you launch your node group template.

12. Record the **SubnetIds** for the subnets that were created. When you add nodes to your cluster, you must specify the IDs of the subnets that you want to launch the nodes into.

### Step 1: Create your Amazon EKS cluster

This section helps you to create an Amazon EKS cluster. The latest Kubernetes version available in Amazon EKS is installed so that you can take advantage of the latest Kubernetes and Amazon EKS features. Some features are not available on older versions of Kubernetes.

**Important**
When an Amazon EKS cluster is created, the IAM entity (user or role) that creates the cluster is added to the Kubernetes RBAC authorization table as the administrator (with `system:masters` permissions). Initially, only that IAM user can make calls to the Kubernetes API server using `kubectl`. For more information, see [Managing users or IAM roles for your cluster](#). If you use the console to create the cluster, you must ensure that the same IAM user credentials are in the AWS SDK credential chain when you are running `kubectl` commands on your cluster. If you install and configure the AWS CLI, you can configure the IAM credentials for your user. If the AWS CLI version 1.16.156 or later is configured properly for your user, then `eksctl` can find those credentials. For more information, see [Configuring the AWS CLI](#) in the [AWS Command Line Interface User Guide](#). If you can't install the AWS CLI version 1.16.156 or later, then you must install the `aws-iam-authenticator`.

#### To create your cluster with the console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose **Create cluster**.
   
   **Note**
   If your IAM user doesn't have administrative privileges, you must explicitly add permissions for that user to call the Amazon EKS API operations. For more information, see [Amazon EKS identity-based policy examples](#).
3. On the **Configure cluster** page, fill in the following fields:
   
   - **Name** – A unique name for your cluster.
   - **Kubernetes version** – The version of Kubernetes to use for your cluster.
   - **Cluster service role** – Select the IAM role that you created with [Create your Amazon EKS cluster](#) IAM role (p. 21).
   - **Secrets encryption** – (Optional) Choose to enable envelope encryption of Kubernetes secrets using the AWS Key Management Service (AWS KMS). If you enable envelope encryption, the Kubernetes secrets are encrypted using the customer master key (CMK) that you select. The CMK must be symmetric, created in the same region as the cluster, and if the CMK was created in a different account, the user must have access to the CMK. For more information, see [Allowing users in other accounts to use a CMK](#) in the [AWS Key Management Service Developer Guide](#). Kubernetes secrets encryption with an AWS KMS CMK requires Kubernetes version 1.13 or later. If no keys are listed, you must create one first. For more information, see [Creating keys](#).
   - **Tags** – (Optional) Add any tags to your cluster. For more information, see [Tagging your Amazon EKS resources](#).
4. Select Next.
5. On the Specify networking page, select values for the following fields:

- **VPC** – The VPC that you created previously in Create your Amazon EKS cluster VPC (p. 22). You can find the name of your VPC in the drop-down list.

- **Subnets** – By default, the available subnets in the VPC specified in the previous field are preselected. Unselect any subnet that you don't want to host cluster resources, such as worker nodes or load balancers.

  **Important**
  Do not select a subnet in AWS Outposts, AWS Wavelength or an AWS Local Zone when creating your cluster. After cluster creation, you can tag the AWS Outposts AWS Wavelength or AWS Local Zone subnets with the cluster name, which will then enable you to deploy self-managed nodes to the subnet. For more information, see Subnet tagging requirement (p. 205).

- **Security groups** – The SecurityGroups value from the AWS CloudFormation output that you generated with Create your Amazon EKS cluster VPC (p. 22). This security group has ControlPlaneSecurityGroup in the drop-down name.

  **Important**
  The node AWS CloudFormation template modifies the security group that you specify here, so Amazon EKS strongly recommends that you use a dedicated security group for each cluster control plane (one per cluster). If this security group is shared with other resources, you might block or disrupt connections to those resources.

  (Optional) Choose Configure Kubernetes Service IP address range and specify a Service IPv4 range if you want to specify which CIDR block Kubernetes assigns service IP addresses from. The CIDR block must meet the following requirements:
  - Within one of the following ranges: 10.0.0.0/8, 172.16.0.0/12, or 192.168.0.0/16.
  - Between /24 and /12.
  - Doesn't overlap with any CIDR block specified in your VPC.

  We recommend specifying a CIDR block that doesn't overlap with any other networks that are peered or connected to your VPC. If you don't enable this, Kubernetes assigns service IP addresses from either the 10.100.0.0/16 or 172.20.0.0/16 CIDR blocks.

  **Important**
  You can only specify a custom CIDR block when you create a cluster and can't change this value once the cluster is created.

- **For Cluster endpoint access** – Choose one of the following options:
  - **Public** – Enables only public access to your cluster's Kubernetes API server endpoint. Kubernetes API requests that originate from outside of your cluster's VPC use the public endpoint. By default, access is allowed from any source IP address. You can optionally restrict access to one or more CIDR ranges such as 192.168.0.0/16, for example, by selecting Advanced settings and then selecting Add source.
  - **Private** – Enables only private access to your cluster's Kubernetes API server endpoint. Kubernetes API requests that originate from within your cluster's VPC use the private VPC endpoint.

    **Important**
    If you created a VPC without outbound internet access, then you must enable private access.

  - **Public and private** – Enables public and private access.

  For more information about the previous options, see Modifying cluster endpoint access (p. 57).

6. If you selected Kubernetes version 1.17 or earlier on the previous page, skip to the next step. If you selected version 1.18, accept the defaults in the Networking add-ons section to install the latest
In this section, you create a **kubeconfig** file for your cluster with the AWS CLI `update-kubeconfig` command.

### To create your kubeconfig file with the AWS CLI

1. Use the AWS CLI `update-kubeconfig` command to create or update a kubeconfig for your cluster.
   
   ```bash
   aws eks update-kubeconfig
   ```
   
   By default, the resulting configuration file is created at the default kubeconfig path (`.kube/config`) in your home directory or merged with an existing kubeconfig at that location. You can specify another path with the `--kubeconfig` option.

   You can specify an IAM role ARN with the `--role-arn` option to use for authentication when you issue `kubectl` commands. Otherwise, the IAM entity in your default AWS CLI or SDK credential
chain is used. You can view your default AWS CLI or SDK identity by running the `aws sts get-caller-identity` command.

- For more information, see the help page with the `aws eks update-kubeconfig help` command or see `update-kubeconfig` in the AWS CLI Command Reference.

**Note**
To run the following command, you must have permission to use the `eks:DescribeCluster` API action with the cluster that you specify. For more information, see Amazon EKS identity-based policy examples (p. 316).

```
aws eks --region <us-west-2> update-kubeconfig --name <cluster_name>
```

2. Test your configuration.

```
kubectl get svc
```

**Note**
If you receive any authorization or resource type errors, see Unauthorized or access denied (`kubectl`) (p. 367) in the troubleshooting section.

Output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>svc/kubernetes</td>
<td>ClusterIP</td>
<td>10.100.0.1</td>
<td>&lt;none&gt;</td>
<td>443/TCP</td>
<td>1m</td>
</tr>
</tbody>
</table>

**Step 3: Create compute**

Select one of the following compute options. To learn more about each option, see Amazon EKS nodes (p. 96). After your cluster is deployed, you can add other options, if you choose.

- **Fargate – Linux** (p. 28) – Select this option if you want to run Linux applications on AWS Fargate.
- **Managed nodes – Linux** (p. 29) – Select this option if you want to run Amazon Linux or Windows applications on Amazon EC2 instances.

Though not covered in this guide, you can also add Bottlerocket nodes to your cluster. For more information, see Launching self-managed Bottlerocket nodes (p. 122).

**[ Fargate – Linux ]**

**Note**
You can only use AWS Fargate with Amazon EKS in some Regions. Before using Fargate with Amazon EKS, ensure that the Region that you want to use is supported. For more information, see Getting started with AWS Fargate using Amazon EKS (p. 139).

Before creating an AWS Fargate profile, you must create a Fargate pod execution role to use with your profile.

**To create an AWS Fargate pod execution role with the AWS Management Console**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Roles, then Create role.
3. Choose EKS from the list of services, EKS - Fargate pod for your use case, and then Next: Permissions.
4. Choose Next: Tags.
5. (Optional) Add metadata to the role by attaching tags as key-value pairs. For more information about using tags in IAM, see Tagging IAM Entities in the IAM User Guide.
6. Choose Next: Review.
7. For Role name, enter a unique name for your role, such as AmazonEKSFargatePodExecutionRole, then choose Create role.

You can now create the Fargate profile, specifying the IAM role that you created.

**To create a Fargate profile for a cluster with the AWS Management Console**

1. Open the Amazon EKS console at [https://console.aws.amazon.com/eks/home#/clusters](https://console.aws.amazon.com/eks/home#/clusters).
2. Choose the cluster to create a Fargate profile for.
3. Under Fargate profiles, choose Add Fargate profile.
4. On the Configure Fargate profile page, enter the following information and choose Next.
   a. For Name, enter a unique name for your Fargate profile.
   b. For Pod execution role, choose the pod execution role to use with your Fargate profile. Only IAM roles with the eks-fargate-pods.amazonaws.com service principal are shown. If you do not see any roles listed here, you must create one. For more information, see Pod execution role (p. 328).
   c. For Subnets, choose the subnets to use for your pods. By default, all subnets in your cluster's VPC are selected. Only private subnets are supported for pods running on Fargate; you must deselect any public subnets.
   d. For Tags, you can optionally tag your Fargate profile. These tags do not propagate to other resources associated with the profile, such as its pods.
5. On the Configure pods selection page, enter the following information and choose Next.
   a. For Namespace, enter a namespace to match for pods, such as kube-system or default.
   b. (Optional) Add Kubernetes labels to the selector that pods in the specified namespace must have to match the selector. For example, you could add the label infrastructure: fargate to the selector so that only pods in the specified namespace that also have the infrastructure: fargate Kubernetes label match the selector.
6. On the Review and create page, review the information for your Fargate profile and choose Create.

**[ Managed nodes – Linux ]**

The Amazon EKS node kubelet daemon makes calls to AWS APIs on your behalf. Nodes receive permissions for these API calls through an IAM instance profile and associated policies. You must create an IAM role before you can launch the nodes. You can create the role using the AWS Management Console (p. 29) or AWS CloudFormation (p. 30).

**Note**
We recommend that you create a new node IAM role for each cluster. Otherwise, a node from one cluster could authenticate with another cluster that it does not belong to.

**To create your Amazon EKS node role in the IAM console**

2. Choose Roles, then Create role.
3. Choose EC2 from the list of Common use cases under Choose a use case, then choose Next: Permissions.
4. In the Filter policies box, enter AmazonEKSWorkerNodePolicy. Check the box to the left of AmazonEKSWorkerNodePolicy.

5. In the Filter policies box, enter AmazonEC2ContainerRegistryReadOnly. Check the box to the left of AmazonEC2ContainerRegistryReadOnly.

6. The AmazonEKS_CNI_Policy policy must be attached to either this role or to a different role that is mapped to the aws-node Kubernetes service account. We recommend assigning the policy to the role associated to the Kubernetes service account instead of assigning it to this role. For more information, see Configuring the VPC CNI plugin to use IAM roles for service accounts (p. 211).

7. Choose Next: Tags.

8. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM Entities in the IAM User Guide.

9. Choose Next: Review.

10. For Role name, enter a unique name for your role, such as NodeInstanceRole. For Role description, replace the current text with descriptive text such as Amazon EKS - Node Group Role, then choose Create role.

**To create your Amazon EKS node role using AWS CloudFormation**

2. Choose Create stack and then choose With new resources (standard).
3. For Specify template, select Amazon S3 URL.
4. Paste the URL that corresponds to the Region that your cluster is in into the Amazon S3 URL text area and choose Next twice:
   - All Regions other than China Regions.
   ```
   ```
   - Beijing and Ningxia China Regions.
   ```
   ```
5. On the Specify stack details page, for Stack name enter a name such as eks-node-group-instance-role and choose Next.
6. (Optional) On the Configure stack options page, you can choose to tag your stack resources. Choose Next.
7. On the Review page, check the box in the Capabilities section and choose Create stack.
8. When your stack is created, select it in the console and choose Outputs.
9. Record the NodeInstanceRole value for the IAM role that was created. You need this when you create your node group.
10. (Optional, but recommended) One of the IAM policies attached to the role by the AWS CloudFormation template in a previous step is the AmazonEKS_CNI_Policy managed policy. The policy must be attached to this role or to a role associated to the Kubernetes aws-node service account that is used for the Amazon EKS VPC CNI plugin. We recommend assigning the policy to the role associated to the Kubernetes service account. For more information, see Configuring the VPC CNI plugin to use IAM roles for service accounts (p. 211).

You can now create a managed node group.
Important
Amazon EKS nodes are standard Amazon EC2 instances, and you are billed for them based on normal Amazon EC2 instance prices. For more information, see Amazon EC2 pricing.

To create your managed node group using the AWS Management Console

1. Wait for your cluster status to show as ACTIVE. You cannot create a managed node group for a cluster that is not yet ACTIVE.
2. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
3. Choose the name of the cluster that you want to create your managed node group in.
4. Select the Configuration tab.
5. On the Configuration tab, select the Compute tab, and then choose Add Node Group.
6. On the Configure node group page, fill out the parameters accordingly, and then choose Next.
   - Name – Enter a unique name for your managed node group.
   - Node IAM role name – Choose the node instance role to use with your node group. For more information, see Amazon EKS node IAM role (p. 326).
     Important
     We recommend using a role that is not currently in use by any self-managed node group, or that you plan to use with a new self-managed node group. For more information, see Deleting a managed node group (p. 116).
   - Use launch template – (Optional) Choose if you want to use an existing launch template and then select a Launch template version (Optional). If you don’t select a version, then Amazon EKS uses the template’s default version. Launch templates allow for more customization of your node group, including allowing you to deploy a custom AMI. The launch template must meet the requirements in Launch template support (p. 112). If you don’t use your own launch template, the Amazon EKS API creates a default Amazon EC2 launch template in your account and deploys the node group using the default launch template. If you implement IAM roles for service accounts (p. 330), assign necessary permissions directly to all pods that require access to AWS services, and no pods in your cluster require access to IMDS for other reasons, such as retrieving the current Region, then you can also disable access to IMDS for pods that don’t use host networking in a launch template. For more information, see the section called “Restricting access to the instance profile” (p. 349).
   - Kubernetes labels – (Optional) You can choose to apply Kubernetes labels to the nodes in your managed node group.
   - Tags – (Optional) You can choose to tag your Amazon EKS managed node group. These tags do not propagate to other resources in the node group, such as Auto Scaling groups or instances. For more information, see Tagging your Amazon EKS resources (p. 303).
7. On the Set compute and scaling configuration page, fill out the parameters accordingly, and then choose Next.

Node group compute configuration

- AMI type – Choose Amazon Linux 2 (AL2_x86_64) for non-GPU instances, Amazon Linux 2 GPU Enabled (AL2_x86_64_GPU) for GPU instances, or Amazon Linux 2 (AL2_ARM_64) for Arm.

If you are deploying Arm instances, be sure to review the considerations in the section called “Arm” (p. 161) before deploying.

If you specified a launch template on the previous page, and specified an AMI in the launch template, then you cannot select a value. The value from the template is displayed. The AMI specified in the template must meet the requirements in Using a custom AMI (p. 115).
- Capacity type – Select a capacity type. For more information about choosing a capacity type, see the section called “Managed node group capacity types” (p. 102). You cannot mix different
capacity types within the same node group. If you want to use both capacity types, create separate node groups, each with their own capacity and instance types.

- **Instance type** – One or more instance type is specified by default. To remove a default instance type, select the X on the right side of the instance type. Choose the instance types to use in your managed node group. The console displays a set of commonly used instance types. If you need to create a managed node group with an instance type that is not displayed, then use **eksctl**, the AWS CLI, AWS CloudFormation, or an SDK to create the node group. If you specified a launch template on the previous page, then you cannot select a value because it must be specified in the launch template. The value from the launch template is displayed. If you selected **Spot** for **Capacity type**, then we recommend specifying multiple instance types to enhance availability. For more information about selecting instance types, see **Considerations** in the section called “Managed node group capacity types” (p. 102).

Each Amazon EC2 instance type supports a maximum number of elastic network interfaces (ENIs) and each ENI supports a maximum number of IP addresses. Since each worker node and pod is assigned its own IP address it's important to choose an instance type that will support the maximum number of pods that you want to run on each worker node. For a list of the number of ENIs and IP addresses supported by instance types, see IP addresses per network interface per instance type. For example, the **m5.large** instance type supports a maximum of 30 IP addresses for the worker node and pods. Some instance types might not be available in all Regions.

If you plan to use **Security groups for pods** (p. 214), then make sure to specify a supported Amazon EC2 instance type. For more information, see Amazon EC2 supported instances and branch network interfaces (p. 218). If specifying an Arm Amazon EC2 instance type, then review the considerations in Amazon EKS optimized Arm Amazon Linux AMIs (p. 161) before deploying.

- **Disk size** – Enter the disk size (in GiB) to use for your node's root volume.

If you specified a launch template on the previous page, then you cannot select a value because it must be specified in the launch template.

**Node group scaling configuration**

**Note**

Amazon EKS does not automatically scale your node group in or out. However, you can configure the Kubernetes Cluster Autoscaler (p. 61) to do this for you.

- **Minimum size** – Specify the minimum number of nodes that the managed node group can scale in to.
- **Maximum size** – Specify the maximum number of nodes that the managed node group can scale out to.
- **Desired size** – Specify the current number of nodes that the managed node group should maintain at launch.

8. On the **Specify networking** page, fill out the parameters accordingly, and then choose **Next**.

- **Subnets** – Choose the subnets to launch your managed nodes into.

**Important**

If you are running a stateful application across multiple Availability Zones that is backed by Amazon EBS volumes and using the Kubernetes Cluster Autoscaler (p. 61), you should configure multiple node groups, each scoped to a single Availability Zone. In addition, you should enable the --balance-similar-node-groups feature.

**Important**

- If you choose a public subnet, then the subnet must have MapPublicIpOnLaunch set to true for the instances to be able to successfully join a cluster. If the subnet was created using **eksctl** or the Amazon EKS vended AWS CloudFormation templates (p. 198) on or after March 26, 2020, then this setting is already set to true.
If the subnets were created with `eksctl` or the AWS CloudFormation templates before March 26, 2020, then you need to change the setting manually. For more information, see Modifying the public IPv4 addressing attribute for your subnet.

- Do not select a subnet in AWS Outposts, AWS Wavelength, or an AWS Local Zone. You can't deploy managed nodes to a subnet in AWS Outposts, AWS Wavelength, or an AWS Local Zone. You can only deploy self-managed nodes (p. 117) to AWS Outposts, AWS Wavelength, or AWS Local Zone subnets.

- **Allow remote access to nodes** (Optional, but default). Enabling SSH allows you to connect to your instances and gather diagnostic information if there are issues. Complete the following steps to enable remote access. We highly recommend enabling remote access when you create your node group. You cannot enable remote access after the node group is created.

  If you chose to use a launch template, then this option isn't shown. To enable remote access to your nodes, specify a key pair in the launch template and ensure that the proper port is open to the nodes in the security groups that you specify in the launch template. For more information, see Using custom security groups (p. 114).

- For **SSH key pair** (Optional), choose an Amazon EC2 SSH key to use. For more information, see Amazon EC2 key pairs in the Amazon EC2 User Guide for Linux Instances. If you chose to use a launch template, then you can't select one.

- For **Allow remote access from**, if you want to limit access to specific instances, then select the security groups that are associated to those instances. If you don't select specific security groups, then SSH access is allowed from anywhere on the internet (0.0.0.0/0).

9. On the **Review and create** page, review your managed node group configuration and choose **Create**.

   If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 366) in the Troubleshooting guide.

10. Watch the status of your nodes and wait for them to reach the **Ready** status.

    ```
kubectl get nodes --watch
    ```

11. (GPU nodes only) If you chose a GPU instance type and the Amazon EKS optimized accelerated AMI, then you must apply the NVIDIA device plugin for Kubernetes as a DaemonSet on your cluster with the following command.

    ```
kubectl apply -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.6.0/nvidia-device-plugin.yml
    ```

12. (Optional) **Deploy a sample Linux workload** (p. 249) – Deploy a sample application to test your cluster and Linux nodes.

13. (Optional) After you add Linux worker nodes to your cluster, follow the procedures in Windows support (p. 80) to add Windows support to your cluster and to add Windows worker nodes. All Amazon EKS clusters must contain at least one Linux worker node, even if you only want to run Windows workloads in your cluster.

**Next steps**

Now that you have a working Amazon EKS cluster with nodes, you are ready to start installing Kubernetes add-ons and deploying applications to your cluster. The following documentation topics help you to extend the functionality of your cluster.

- **Restrict access to IMDS** (p. 349) – If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current Region, then we recommend blocking pod access to IMDS. For more information,
see the section called “IAM roles for service accounts” (p. 330) and the section called “Restricting access to the instance profile” (p. 349).

- **Cluster Autoscaler (p. 61)** – Configure the Kubernetes Cluster Autoscaler to automatically adjust the number of nodes in your node groups.
- **Deploy a sample Linux workload** (p. 249) – Deploy a sample application to test your cluster and Linux nodes.
- **Deploy a Windows sample application** (p. 85) – Deploy a sample application to test your cluster and Windows nodes.
- **Cluster management (p. 283)** – Learn how to use important tools for managing your cluster.
Amazon EKS clusters

An Amazon EKS cluster consists of two primary components:

- The Amazon EKS control plane
- Amazon EKS nodes that are registered with the control plane

The Amazon EKS control plane consists of control plane nodes that run the Kubernetes software, such as etcd and the Kubernetes API server. The control plane runs in an account managed by AWS, and the Kubernetes API is exposed via the Amazon EKS endpoint associated with your cluster. Each Amazon EKS cluster control plane is single-tenant and unique, and runs on its own set of Amazon EC2 instances.

All of the data stored by the etcd nodes and associated Amazon EBS volumes is encrypted using AWS KMS. The cluster control plane is provisioned across multiple Availability Zones and fronted by an Elastic Load Balancing Network Load Balancer. Amazon EKS also provisions elastic network interfaces in your VPC subnets to provide connectivity from the control plane instances to the nodes (for example, to support `kubectl exec`, `logs`, and `proxy` data flows).

Amazon EKS nodes run in your AWS account and connect to your cluster’s control plane via the API server endpoint and a certificate file that is created for your cluster.

Creating an Amazon EKS cluster

This topic walks you through creating an Amazon EKS cluster. If this is your first time creating an Amazon EKS cluster, then we recommend that you follow one of our Getting started with Amazon EKS (p. 4) guides instead. They provide complete end-to-end walkthroughs for creating an Amazon EKS cluster with nodes.

**Important**

When an Amazon EKS cluster is created, the IAM entity (user or role) that creates the cluster is added to the Kubernetes RBAC authorization table as the administrator (with `system:masters` permissions). Initially, only that IAM user can make calls to the Kubernetes API server using `kubectl`. For more information, see Managing users or IAM roles for your cluster (p. 279). If you use the console to create the cluster, you must ensure that the same IAM user credentials are in the AWS SDK credential chain when you are running `kubectl` commands on your cluster.

If you install and configure the AWS CLI, you can configure the IAM credentials for your user. If the AWS CLI version 1.16.156 or later is configured properly for your user, then `eksctl` can find those credentials. For more information, see Configuring the AWS CLI in the AWS Command Line Interface User Guide. If you can’t install the AWS CLI version 1.16.156 or later, then you must install the `aws-iam-authenticator`.

**Prerequisites**

You must have the AWS CLI version 1.16.156 or later or the `aws-iam-authenticator` installed. For more information, see Install the AWS CLI (p. 16) or Installing `aws-iam-authenticator` (p. 271).

You can create a cluster with `eksctl` (p. 36), the AWS Management Console (p. 37), or the AWS CLI (p. 40).
[Create a cluster with eksctl]

This procedure requires eksctl version 0.35.0 or later. You can check your version with the following command:

```
eksctl version
```

For more information on installing or upgrading eksctl, see Installing or upgrading eksctl (p. 292).

**To create your cluster with eksctl**

1. Create a cluster with the Amazon EKS latest Kubernetes version in your default Region. Replace the `<example-values>` (including `<>` with your own values. You can replace `<1.18>` with any supported version (p. 68).

   ```
   eksctl create cluster \
   --name <my-cluster> \
   --version <1.18> \ 
   --with-oidc \ 
   --without-nodegroup
   ```

**Note**

To see most options that can be specified when creating a cluster with eksctl, use the `eksctl create cluster --help` command. To see all options, you can use a config file. For more information, see Using config files and the config file schema in the eksctl documentation. You can find config file examples on GitHub.

**Important**

Do not use eksctl to create a cluster or nodes in an AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled. Create a cluster and self-managed nodes using the Amazon EC2 API or AWS CloudFormation instead. For more information, see To launch self-managed Linux nodes using the AWS Management Console (p. 119) and To launch self-managed Windows nodes using the AWS Management Console (p. 126).

**Warning**

If you create a cluster using a config file with the `secretsEncryption` option, which requires an existing AWS Key Management Service key, and the key that you use is ever deleted, then there is no path to recovery for the cluster. If you enable envelope encryption, the Kubernetes secrets are encrypted using the customer master key (CMK) that you select. The CMK must be symmetric, created in the same Region as the cluster, and if the CMK was created in a different account, the user must have access to the CMK. For more information, see Allowing users in other accounts to use a CMK in the AWS Key Management Service Developer Guide. Kubernetes secrets encryption with an AWS KMS CMK requires Kubernetes version 1.13 or later.

By default, the `create-key` command creates a symmetric key with a key policy that gives the account's root user admin access on AWS KMS actions and resources. For more information, see Creating keys. If you want to scope down the permissions, make sure that the `kms:DescribeKey` and `kms:CreateGrant` actions are permitted on the key policy for the principal that will be calling the `create-cluster` API. Amazon EKS does not support the key policy condition `kms:GrantIsForAWSResource`. Creating a cluster will not work if this action is in the key policy statement.

Cluster provisioning takes several minutes. During cluster creation, you'll see several lines of output. The last line of output is similar to the following example line.

```
[✓]  EKS cluster "<my-cluster>" in "<region-code>" region is ready
```
2. When your cluster is ready, test that your `kubectl` configuration is correct.

```
kubectl get svc
```

**Note**
If you receive any authorization or resource type errors, see Unauthorized or access denied (`kubectl`) (p. 367) in the troubleshooting section.

Output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>svc/kubernetes</td>
<td>ClusterIP</td>
<td>10.100.0.1</td>
<td>&lt;none&gt;</td>
<td>443/TCP</td>
<td>1m</td>
</tr>
</tbody>
</table>

3. (Optional) If you want to run pods on AWS Fargate in your cluster, then you must Create a Fargate pod execution role (p. 140) and Create a Fargate profile for your cluster (p. 141).
4. Follow the procedures in Launching self-managed Amazon Linux nodes (p. 117) to add Linux nodes to your cluster to support your workloads.
5. (Optional) After you add Linux nodes to your cluster, follow the procedures in Windows support (p. 80) to add Windows support to your cluster and to add Windows nodes. All Amazon EKS clusters must contain at least one Linux node, even if you only want to run Windows workloads in your cluster.

[ Create a cluster with the AWS Management Console ]

**Prerequisites**

- You have created a VPC and a dedicated security group that meet the requirements for an Amazon EKS cluster. For more information, see Cluster VPC considerations (p. 203) and Amazon EKS security group considerations (p. 205). The Getting started with the AWS Management Console (p. 15) guide creates a VPC that meets the requirements, or you can also follow Creating a VPC for your Amazon EKS cluster (p. 198) to create one.
- You have created an Amazon EKS cluster IAM role to apply to your cluster. The Getting started with Amazon EKS (p. 4) guide creates a service role for you, or you can also follow Amazon EKS IAM roles (p. 316) to create one manually.

**To create your cluster with the console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose Create cluster.

   **Note**
   If your IAM user doesn’t have administrative privileges, you must explicitly add permissions for that user to call the Amazon EKS API operations. For more information, see Amazon EKS identity-based policy examples (p. 316).
3. On the Configure cluster page, fill in the following fields:

   - **Name** – A unique name for your cluster.
   - **Kubernetes version** – The version of Kubernetes to use for your cluster.
   - **Cluster service role** – Choose the Amazon EKS cluster role to allow the Kubernetes control plane to manage AWS resources on your behalf. For more information, see Amazon EKS cluster IAM role (p. 324).
• **Secrets encryption** – (Optional) Choose to enable envelope encryption of Kubernetes secrets using the AWS Key Management Service (AWS KMS). If you enable envelope encryption, the Kubernetes secrets are encrypted using the customer master key (CMK) that you select. The CMK must be symmetric, created in the same region as the cluster, and if the CMK was created in a different account, the user must have access to the CMK. For more information, see Allowing users in other accounts to use a CMK in the AWS Key Management Service Developer Guide.

Kubernetes secrets encryption with an AWS KMS CMK requires Kubernetes version 1.13 or later. If no keys are listed, you must create one first. For more information, see Creating keys.

**Note**
By default, the create-key command creates a symmetric key with a key policy that gives the account's root user admin access on AWS KMS actions and resources. If you want to scope down the permissions, make sure that the kms:DescribeKey and kms:CreateGrant actions are permitted on the key policy for the principal that will be calling the create-cluster API.

Amazon EKS does not support the key policy condition kms:GrantIsForAWSResource. Creating a cluster will not work if this action is in the key policy statement.

**Warning**
Deletion of the CMK will permanently put the cluster in a degraded state. If any CMKs used for cluster creation are scheduled for deletion, verify that this is the intended action before deletion. Once the key is deleted, there is no path to recovery for the cluster.

• **Tags** – (Optional) Add any tags to your cluster. For more information, see Tagging your Amazon EKS resources (p. 303).

4. Select Next.

5. On the **Specify networking** page, select values for the following fields:

• **VPC** – Select an existing VPC to use for your cluster. If none are listed, then you need to create one first. For more information, see Creating a VPC for your Amazon EKS cluster (p. 198).

• **Subnets** – By default, the available subnets in the VPC specified in the previous field are preselected. Unselect any subnet that you don't want to host cluster resources, such as worker nodes or load balancers. The subnets must meet the requirements for an Amazon EKS cluster. For more information, see Cluster VPC considerations (p. 203).

**Important**
If you select subnets that were created before March 26, 2020 using one of the Amazon EKS AWS CloudFormation VPC templates, be aware of a default setting change that was introduced on March 26, 2020. For more information, see Creating a VPC for your Amazon EKS cluster (p. 198).

**Important**
Do not select a subnet in AWS Outposts, AWS Wavelength or an AWS Local Zone when creating your cluster. After cluster creation, you can tag the AWS Outposts AWS Wavelength or AWS Local Zone subnets with the cluster name, which will then enable you to deploy self-managed nodes to the subnet. For more information, see Subnet tagging requirement (p. 205).

• **Security groups** – The **SecurityGroups** value from the AWS CloudFormation output that you generated with Create your Amazon EKS cluster VPC (p. 22). This security group has **ControlPlaneSecurityGroup** in the drop-down name.

**Important**
The node AWS CloudFormation template modifies the security group that you specify here, so Amazon EKS strongly recommends that you use a dedicated security group for each cluster control plane (one per cluster). If this security group is shared with other resources, you might block or disrupt connections to those resources.
• (Optional) Choose **Configure Kubernetes Service IP address range** and specify a **Service IPv4 range** if you want to specify which CIDR block Kubernetes assigns service IP addresses from. The CIDR block must meet the following requirements:
  • Within one of the following ranges: 10.0.0.0/8, 172.16.0.0/12, or 192.168.0.0/16.
  • Between /24 and /12.
  • Doesn't overlap with any CIDR block specified in your VPC.

We recommend specifying a CIDR block that doesn't overlap with any other networks that are peered or connected to your VPC. If you don't enable this, Kubernetes assigns service IP addresses from either the 10.100.0.0/16 or 172.20.0.0/16 CIDR blocks.

**Important**  
You can only specify a custom CIDR block when you create a cluster and can't change this value once the cluster is created.

• For **Cluster endpoint access** – Choose one of the following options:
  • **Public** – Enables only public access to your cluster's Kubernetes API server endpoint. Kubernetes API requests that originate from outside of your cluster's VPC use the public endpoint. By default, access is allowed from any source IP address. You can optionally restrict access to one or more CIDR ranges such as 192.168.0.0/16, for example, by selecting **Advanced settings** and then selecting **Add source**.
  • **Private** – Enables only private access to your cluster's Kubernetes API server endpoint. Kubernetes API requests that originate from within your cluster's VPC use the private VPC endpoint.

**Important**  
If you created a VPC without outbound internet access, then you must enable private access.

• **Public and private** – Enables public and private access.

For more information about the previous options, see **Modifying cluster endpoint access** (p. 57).

6. If you selected Kubernetes version 1.17 or earlier on the previous page, skip to the next step. If you selected version 1.18, accept the defaults in the **Networking add-ons** section to install the latest version of the **AWS VPC CNI** (p. 209) Amazon EKS add-on. You can only use Amazon EKS add-ons with 1.18 clusters because Amazon EKS add-ons require the Server-side Apply Kubernetes feature, which wasn't available until Kubernetes 1.18. If you selected a different Kubernetes version for your cluster, then this option isn't shown.

**Important**  
The AWS VPC CNI add-on is configured to use the IAM permissions assigned to the **Amazon EKS node IAM role** (p. 326). After the cluster is created, but before you deploy any Amazon EC2 nodes to your cluster, you must ensure that the **AmazonEKS_CNI_Policy IAM policy** is attached to either the node IAM role, or to a different role associated to the Kubernetes service account that the add-on runs as. We recommend that you assign the policy to a different IAM role than the node IAM role by completing the instructions in **Configuring the VPC CNI plugin to use IAM roles for service accounts** (p. 211). Once your cluster and IAM role are created, you can update the add-on (p. 52) to use the IAM role that you create.

7. Select **Next**.

8. On the **Configure logging** page, you can optionally choose which log types that you want to enable. By default, each log type is **Disabled**. For more information, see **Amazon EKS control plane logging** (p. 66).

9. Select **Next**.

10. On the **Review and create** page, review the information that you entered or selected on the previous pages. Select **Edit** if you need to make changes to any of your selections. Once you're satisfied with your settings, select **Create**. The **Status** field shows **CREATING** until the cluster provisioning process completes.
[ Create a cluster with the AWS CLI ]

This procedure has the following prerequisites:

- You have created a VPC and a dedicated security group that meets the requirements for an Amazon EKS cluster. For more information, see Cluster VPC considerations (p. 203) and Amazon EKS security group considerations (p. 205). The Getting started with the AWS Management Console (p. 15) guide creates a VPC that meets the requirements, or you can also follow Creating a VPC for your Amazon EKS cluster (p. 198) to create one.
- You have created an Amazon EKS cluster IAM role to apply to your cluster. The Getting started with Amazon EKS (p. 4) guide creates a service role for you, or you can also follow Amazon EKS IAM roles (p. 316) to create one manually.

To create your cluster with the AWS CLI

1. Create your cluster with the following command. Replace the Amazon Resource Name (ARN) of your Amazon EKS cluster IAM role that you created in Create your Amazon EKS cluster IAM role (p. 21), and the subnet and security group IDs for the VPC that you created in Create your Amazon EKS cluster VPC (p. 22). Replace <my-cluster> with your cluster name and <region-code> with a supported Region. You can replace <1.18> with any supported version (p. 68).

   
   ```bash
   aws eks create-cluster \
   --region <region-code> \
   --name <my-cluster> \
   ```

Note
You might receive an error that one of the Availability Zones in your request doesn't have sufficient capacity to create an Amazon EKS cluster. If this happens, the error output contains the Availability Zones that can support a new cluster. Retry creating your cluster with at least two subnets that are located in the supported Availability Zones for your account. For more information, see Insufficient capacity (p. 366).

Cluster provisioning usually takes between 10 and 15 minutes.

11. (Optional) To use Amazon EKS add-ons, or to enable individual Kubernetes workloads to have specific IAM permissions, you need to enable an OpenID Connect (OIDC) provider for your cluster. To configure an OIDC provider for your cluster, see the section called “Create OIDC provider” (p. 334). You only need to enable an OIDC provider for your cluster once. To learn more about Amazon EKS add-ons, see Configure an Amazon EKS add-on (p. 52). To learn more about assigning specific IAM permissions to your workloads, see Technical overview (p. 330).

12. Now that you have created your cluster, follow the procedures in Installing aws-iam-authenticator (p. 271) and Create a kubeconfig for Amazon EKS (p. 275) to enable communication with your new cluster.

13. (Optional) If you want to run pods on AWS Fargate in your cluster, see Getting started with AWS Fargate using Amazon EKS (p. 139).

14. After you enable communication, follow the procedures in Launching self-managed Amazon Linux nodes (p. 117) to add Linux worker nodes to your cluster to support your workloads.

15. (Optional) After you add Linux worker nodes to your cluster, follow the procedures in Windows support (p. 80) to add Windows support to your cluster and to add Windows worker nodes. All Amazon EKS clusters must contain at least one Linux worker node, even if you only want to run Windows workloads in your cluster.

Before deploying nodes to your cluster, we recommend configuring the AWS VPC CNI plugin that was deployed with the cluster to use IAM roles for service accounts (p. 330). For more information, see the section called “Configure plugin for IAM account” (p. 211).
--kubernetes-version <1.18> \
--role-arn --arn:aws:iam::111122223333:role/eks-service-role-\nAWSServiceRoleForAmazonEKS-EXAMPLEBKZRQR> \n--resources-vpc-config subnetIds=<subnet-a9189fe2>,<subnet-50432629>,securityGroupIds=<sg-f5c54184>

Important
Do not specify subnets in AWS Outposts, AWS Wavelength, or an AWS Local Zone. Specify only subnets in the Region. After the cluster is deployed, tag the AWS Outposts, AWS Wavelength, or AWS Local Zones, subnets that you want to deploy self-managed nodes to with the cluster name. For more information, see Subnet tagging requirement (p. 205).

Note
If your IAM user doesn’t have administrative privileges, you must explicitly add permissions for that user to call the Amazon EKS API operations. For more information, see Amazon EKS identity-based policy examples (p. 316).

Output:

```json
{
"cluster": {
  "name": "<my-cluster>",
  "createdAt": <1527785885.159>,
  "version": "<1.18>",
  "roleArn": "arn:aws:iam::<111122223333>:role/eks-service-role-\nAWSServiceRoleForAmazonEKS-<AFNL4H8HB71P>",
  "resourcesVpcConfig": {
    "subnetIds": [
      "<subnet-a9189fe2>",
      "<subnet-50432629>"
    ],
    "securityGroupIds": [
      "<sg-f5c54184>"
    ],
    "vpcId": "<vpc-a54041dc>",
    "endpointPublicAccess": true,
    "endpointPrivateAccess": false
  },
  "status": "CREATING",
  "certificateAuthority": {}
}
```

Note
You might receive an error that one of the Availability Zones in your request doesn't have sufficient capacity to create an Amazon EKS cluster. If this happens, the error output contains the Availability Zones that can support a new cluster. Retry creating your cluster with at least two subnets that are located in the supported Availability Zones for your account. For more information, see Insufficient capacity (p. 366).

To encrypt the Kubernetes secrets with a customer master key (CMK) from AWS Key Management Service (AWS KMS), first create a CMK using the create-key operation.

```
MY_KEY_ARN=$(aws kms create-key --query KeyMetadata.Arn --output text)
```

Note
By default, the create-key command creates a symmetric key with a key policy that gives the account’s root user admin access on AWS KMS actions and resources. If you want to scope down the permissions, make sure that the kms:DescribeKey and
kms:CreateGrant actions are permitted on the key policy for the principal that will be calling the create-cluster API.

Amazon EKS does not support the key policy condition `kms:GrantIsForAWSResource`. Creating a cluster will not work if this action is in the key policy statement.

Add the `--encryption-config` parameter to the `aws eks create-cluster` command. Encryption of Kubernetes secrets can only be enabled when the cluster is created.

```bash
--encryption-config '[{"resources": ["secrets"], "provider": {"keyArn": "<$MY_KEY_ARN>"}}]'
```

The `keyArn` member can contain either the alias or ARN of your CMK. The CMK must be symmetric, created in the same Region as the cluster, and if the CMK was created in a different account, the user must have access to the CMK. For more information, see Allowing users in other accounts to use a CMK in the AWS Key Management Service Developer Guide. Kubernetes secrets encryption with an AWS KMS CMK requires Kubernetes version 1.13 or later.

**Warning**
Deletion of the CMK will permanently put the cluster in a degraded state. If any CMKs used for cluster creation are scheduled for deletion, verify that this is the intended action before deletion. Once the key is deleted, there is no path to recovery for the cluster.

2. Cluster provisioning usually takes between 10 and 15 minutes. You can query the status of your cluster with the following command. When your cluster status is `ACTIVE`, you can proceed.

```bash
aws eks --region <region-code> describe-cluster --name <my-cluster> --query "cluster.status"
```

3. When your cluster provisioning is complete, retrieve the `endpoint` and `certificateAuthority.data` values with the following commands. You must add these values to your `kubectl` configuration so that you can communicate with your cluster.

   a. Retrieve the `endpoint`.

   ```bash
   aws eks --region <region-code> describe-cluster --name <my-cluster> --query "cluster.endpoint" --output text
   ```

   b. Retrieve the `certificateAuthority.data`.

   ```bash
   aws eks --region <region-code> describe-cluster --name <my-cluster> --query "cluster.certificateAuthority.data" --output text
   ```

4. Now that you have created your cluster, follow the procedures in Create a kubeconfig for Amazon EKS (p. 275) to enable communication with your new cluster.

5. (Optional) If you want to run pods on AWS Fargate in your cluster, see Getting started with AWS Fargate using Amazon EKS (p. 139).

6. After you enable communication, follow the procedures in Launching self-managed Amazon Linux nodes (p. 117) to add nodes to your cluster to support your workloads.

7. (Optional) After you add Linux nodes to your cluster, follow the procedures in Windows support (p. 80) to add Windows support to your cluster and to add Windows nodes. All Amazon EKS clusters must contain at least one Linux node, even if you only want to run Windows workloads in your cluster.

8. (Optional) If the `AmazonEKS_CNI_Policy` managed IAM policy is attached to your node IAM role, we recommend assigning it to an IAM role that you associate to the Kubernetes `aws-node` service account instead. For more information, see Configuring the VPC CNI plugin to use IAM roles for service accounts (p. 211).
# Updating a Cluster

You can update an existing cluster to a new Kubernetes version or configure managed add-ons for your cluster.

## Updating an Amazon EKS cluster Kubernetes version

When a new Kubernetes version is available in Amazon EKS, you can update your cluster to the latest version.

**Important**

We recommend that before updating to a new Kubernetes version that you review the information in [Amazon EKS Kubernetes versions](#) and in the update steps in this topic.

New Kubernetes versions have introduced significant changes. Therefore, we recommend that you test the behavior of your applications against a new Kubernetes version before you update your production clusters. You can achieve this by building a continuous integration workflow to test your application behavior before moving to a new Kubernetes version.

The update process consists of Amazon EKS launching new API server nodes with the updated Kubernetes version to replace the existing ones. Amazon EKS performs standard infrastructure and readiness health checks for network traffic on these new nodes to verify that they’re working as expected. If any of these checks fail, Amazon EKS reverts the infrastructure deployment, and your cluster remains on the prior Kubernetes version. Running applications aren’t affected, and your cluster is never left in a non-deterministic or unrecoverable state. Amazon EKS regularly backs up all managed clusters, and mechanisms exist to recover clusters if necessary. We're constantly evaluating and improving our Kubernetes infrastructure management processes.

To upgrade the cluster, Amazon EKS requires 2 to 3 free IP addresses from the subnets that were provided when you created the cluster. If these subnets don’t have available IP addresses, then the upgrade can fail. Additionally, if any of the subnets or security groups that were provided during cluster creation have been deleted, the cluster upgrade process can fail.

**Note**

Even though Amazon EKS runs a highly available control plane, you might experience minor service interruptions during an update. For example, if you attempt to connect to an API server just before or just after it’s terminated and replaced by a new API server running the new version of Kubernetes, you might experience API call errors or connectivity issues. If this happens, retry your API operations until they succeed.

Amazon EKS doesn’t modify any of your Kubernetes add-ons when you update a cluster. After updating your cluster, we recommend that you update your add-ons to the versions listed in the following table for the new Kubernetes version that you’re updating to. Steps to accomplish this are included in the update procedures.

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>1.18</th>
<th>1.17</th>
<th>1.16</th>
<th>1.15</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon VPC CNI plug-in</td>
<td>1.7.5</td>
<td>1.7.5</td>
<td>1.7.5</td>
<td>1.7.5</td>
</tr>
<tr>
<td>DNS (CoreDNS)</td>
<td>1.7.0</td>
<td>1.6.6</td>
<td>1.6.6</td>
<td>1.6.6</td>
</tr>
<tr>
<td>KubeProxy</td>
<td>1.18.9</td>
<td>1.17.12</td>
<td>1.16.15</td>
<td>1.15.12</td>
</tr>
</tbody>
</table>

If you’re using additional add-ons for your cluster that aren’t listed in the previous table, update them to the latest compatible versions after updating your cluster.
Update an existing cluster

Update the cluster and Kubernetes add-ons.

To update an existing cluster

1. Compare the Kubernetes version of your cluster control plane to the Kubernetes version of your nodes.
   • Get the Kubernetes version of your cluster control plane with the following command.
     
     ```bash
     kubectl version --short
     ```
   • Get the Kubernetes version of your nodes with the following command.
     
     ```bash
     kubectl get nodes
     ```

   If your nodes are more than one Kubernetes minor version older than your control plane, then you must upgrade your nodes to a newer Kubernetes minor version before you update your cluster's Kubernetes version. For more information, see Kubernetes version and version skew support policy in the Kubernetes documentation.

   We recommend that you update your nodes to your cluster’s current pre-update Kubernetes minor version prior to your cluster update. Your nodes must not run a newer Kubernetes version than your control plane. For example, if your control plane is running version 1.17 and your nodes are running version 1.15, update your nodes to version 1.16 or 1.17 (recommended) before you update your cluster’s Kubernetes version to 1.18. For more information, see Self-managed node updates (p. 129).

2. The pod security policy admission controller is enabled on Amazon EKS clusters running Kubernetes version 1.13 or later. If you’re upgrading your cluster to Kubernetes version 1.13 or later, ensure that the proper pod security policies are in place before you update to avoid any issues. You can check for the default policy with the following command:

   ```bash
   kubectl get psp eks.privileged
   ```

   If you receive the following error, see To install or restore the default pod security policy (p. 355) before proceeding.

   ```Error from server (NotFound): podsecuritypolicies.extensions "eks.privileged" not found```

3. If you originally deployed your cluster on Kubernetes 1.17 or earlier, then you may need to remove a deprecated term from your CoreDNS manifest.
   a. Check to see if your CoreDNS manifest has the line.

   ```bash
   kubectl get configmap coredns -n kube-system -o yaml |grep upstream
   ```

   If no output is returned, your manifest doesn't have the line and you can skip to the next step to update your cluster. If output is returned, then you need to remove the line.

   b. Edit the configmap, removing the line in the file that has the word upstream in it. Don’t change anything else in the file. After the line is removed, save the changes.

   ```bash
   kubectl edit configmap coredns -n kube-system -o yaml
   ```
4. Update your cluster using `eksctl`, the AWS Management Console, or the AWS CLI.

- **`eksctl`** – This procedure requires `eksctl` version 0.35.0 or later. You can check your version with the following command:

  ```bash
  eksctl version
  ```

  For more information about installing or upgrading `eksctl`, see Installing or upgrading `eksctl` (p. 292).

  **Note**
  This procedure only works for clusters that were created with `eksctl`.

  Update your Amazon EKS cluster Kubernetes version one minor version later than its current version with the following command. Replace `<dev>` with your cluster name. Because Amazon EKS runs a highly available control plane, you can update only one minor version at a time. See Kubernetes Version and Version Skew Support Policy for the rationale behind this requirement.

  **Important**
  You may need to update some of your deployed resources before you can update to 1.16. For more information, see Kubernetes 1.16 upgrade prerequisites (p. 50). Upgrading a cluster from 1.16 to 1.17 will fail if any of your AWS Fargate pods have a kubelet minor version earlier than 1.16. Before upgrading your cluster from 1.16 to 1.17, you need to recycle your Fargate pods so that their kubelet is 1.16 before attempting to upgrade the cluster to 1.17.

  ```bash
  eksctl upgrade cluster --name <dev> --approve
  ```

  This process takes several minutes to complete.

- **AWS Management Console**
  a. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
  b. Choose the name of the cluster to update and choose Update cluster version.
  c. For Kubernetes version, select the version to update your cluster to and choose Update.

    **Important**
    Upgrading a cluster from 1.16 to 1.17 will fail if any of your AWS Fargate pods have a kubelet minor version earlier than 1.16. Before upgrading your cluster from 1.16 to 1.17, you need to recycle your Fargate pods so that their kubelet is 1.16 before attempting to upgrade the cluster to 1.17.

    **Important**
    You may need to update some of your deployed resources before you can update to 1.16. For more information, see Kubernetes 1.16 upgrade prerequisites (p. 50).

    Because Amazon EKS runs a highly available control plane, you can update only one minor version at a time. See Kubernetes Version and Version Skew Support Policy for the rationale behind this requirement. Therefore, if your current version is 1.16 and you want to upgrade to 1.18, then you must first upgrade your cluster to 1.17 and then upgrade it from 1.17 to 1.18. If you try to update directly from 1.16 to 1.18, then the update version command throws an error.

  d. For Cluster name, type the name of your cluster and choose Confirm.

    **Note**
    The cluster update should finish in a few minutes.

- **AWS CLI**
  a. Update your cluster with the following AWS CLI command. Substitute your cluster name and desired Kubernetes minor version.
**Important**
You may need to update some of your deployed resources before you can update to 1.16. For more information, see Kubernetes 1.16 upgrade prerequisites (p. 50).

Upgrading a cluster from 1.16 to 1.17 will fail if any of your AWS Fargate pods have a kubelet minor version earlier than 1.16. Before upgrading your cluster from 1.16 to 1.17, you need to recycle your Fargate pods so that their kubelet is 1.16 before attempting to upgrade the cluster to 1.17.

**Important**
Because Amazon EKS runs a highly available control plane, you can update only one minor version at a time. See Kubernetes Version and Version Skew Support Policy for the rationale behind this requirement. Therefore, if your current version is 1.16 and you want to upgrade to 1.18, then you must first upgrade your cluster to 1.17 and then upgrade it from 1.17 to 1.18. If you try to update directly from 1.16 to 1.18, then the update version command throws an error.

```
aws eks --region <region-code> update-cluster-version --name <my-cluster> --kubernetes-version <1.18>
```

The output is as follows:

```
{
  "update": {
    "id": "b5f0ba18-9a87-4450-b5a0-825e6e84496f",
    "status": "InProgress",
    "type": "VersionUpdate",
    "params": [
      {
        "type": "Version",
        "value": "1.18"
      },
      {
        "type": "PlatformVersion",
        "value": "eks.1"
      }
    ],
    "errors": []
  }
}
```

b. Monitor the status of your cluster update with the following command. Use the cluster name and update ID that the previous command returned. Your update is complete when the status appears as `Successful`.

**Note**
The cluster update should finish in a few minutes.

```
aws eks --region <region-code> describe-update --name <my-cluster> --update-id <b5f0ba18-9a87-4450-b5a0-825e6e84496f>
```

Output:

```
{
  "update": {
    "id": "b5f0ba18-9a87-4450-b5a0-825e6e84496f",
    "status": "<Successful>",
    "type": "VersionUpdate",
    "params": [
```

5. Patch the kube-proxy daemonset to use the image that corresponds to your cluster's Region and current Kubernetes version (in this example, 1.18.9).

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>1.18</th>
<th>1.17</th>
<th>1.16</th>
<th>1.15</th>
</tr>
</thead>
<tbody>
<tr>
<td>KubeProxy</td>
<td>1.18.9</td>
<td>1.17.12</td>
<td>1.16.15</td>
<td>1.15.12</td>
</tr>
</tbody>
</table>

a. First, retrieve your current kube-proxy image:

```
kubectl get daemonset kube-proxy --namespace kube-system -o=jsonpath='{$.spec.template.spec.containers[:1].image}'
```

b. Update kube-proxy to the recommended version by taking the output from the previous step and replacing the version tag with your cluster's recommended kube-proxy version:

```
kubectl set image daemonset.apps/kube-proxy -n kube-system kube-proxy=<602401143452.dkr.ecr.us-west-2.amazonaws.com>/eks/kube-proxy:v<1.18.9>-eksbuild.1
```

Your account ID and Region may differ from the example above.

c. (Optional) If you're using x86 and Arm nodes in the same cluster and your cluster was deployed before August 17, 2020. Then, edit your kube-proxy manifest to include a node selector for multiple hardware architectures with the following command. This is a one-time operation. After you've added the selector to your manifest, you don't need to do it each time you upgrade. If your cluster was deployed on or after August 17, 2020, then kube-proxy is already multi-architecture capable.

```
kubectl edit -n kube-system daemonset/kube-proxy
```

Add the following node selector to the file in the editor and then save the file. For an example of where to include this text in the editor, see the CNI manifest file on GitHub. This enables Kubernetes to pull the correct hardware image based on the node's hardware architecture.

```
- key: "beta.kubernetes.io/arch"
  operator: In
  values:
  - amd64
  - arm64
```

6. Check your cluster's DNS provider. Clusters that were created with Kubernetes version 1.10 shipped with kube-dns as the default DNS and service discovery provider. If you have updated a 1.10 cluster
to a newer version and you want to use CoreDNS for DNS and service discovery, then you must install CoreDNS and remove kube-dns.

To check if your cluster is already running CoreDNS, use the following command.

```
kubectl get pod -n kube-system -l k8s-app=kube-dns
```

If the output shows `coredns` in the pod names, you’re already running CoreDNS in your cluster. If not, see Installing or upgrading CoreDNS (p. 237) to install CoreDNS on your cluster, update it to the recommended version, return here, and skip steps 7-8.

7. Check the current version of your cluster’s `coredns` deployment.

```
kubectl describe deployment coredns --namespace kube-system | grep Image | cut -d "/" -f 3
```

Output:

```
coredns:v<1.1.3>
```

The recommended `coredns` versions for the corresponding Kubernetes versions are as follows:

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>1.18</th>
<th>1.17</th>
<th>1.16</th>
<th>1.15</th>
</tr>
</thead>
<tbody>
<tr>
<td>CoreDNS</td>
<td>1.7.0</td>
<td>1.6.6</td>
<td>1.6.6</td>
<td>1.6.6</td>
</tr>
</tbody>
</table>

8. If your current `coredns` version is 1.5.0 or later, but earlier than the recommended version, then skip this step. If your current version is earlier than 1.5.0, then you need to modify the config map for `coredns` to use the forward plug-in, rather than the proxy plug-in.

   a. Open the configmap with the following command.

```
kubectl edit configmap coredns -n kube-system
```

   b. Replace `proxy` in the following line with `forward`. Save the file and exit the editor.

```
proxy . /etc/resolv.conf
```

9. Retrieve your current `coredns` image:

```
kubectl get deployment coredns --namespace kube-system -o=jsonpath='{.spec.template.spec.containers[:1].image}'
```

10. Update `coredns` to the recommended version by taking the output from the previous step and replacing `<1.7.0>` (including `<`) with your cluster’s recommended `coredns` version:

```
kubectl set image --namespace kube-system deployment.apps/coredns \    coredns=<602401143452.dkr.ecr.us-west-2.amazonaws.com>/eks/ \    coredns:v<1.7.0>-eksbuild.1
```

11. (Optional) If you’re using x86 and Arm nodes in the same cluster and your cluster was deployed before August 17, 2020, then edit your `coredns` manifest to include a node selector for multiple hardware architectures with the following command. This is a one-time operation. After you’ve added the selector to your manifest, you don’t need to do it each time you upgrade. If you cluster was deployed on or after August 17, 2020, then `coredns` is already multi-architecture capable.
Add the following node selector to the file in the editor and then save the file. For an example of where to include this text in the editor, see the CNI manifest file on GitHub.

```
- key: "beta.kubernetes.io/arch"
  operator: In
  values:
    - amd64
    - arm64
```

12. Check the version of your cluster’s Amazon VPC CNI Plugin for Kubernetes. Use the following command to print your cluster’s CNI version.

```
kubectl describe daemonset aws-node --namespace kube-system | grep Image | cut -d "/" -f 2
```

The output is as follows:

```
amazon-k8s-cni:<1.6.3>
```

If your CNI version is earlier than 1.7.5, then use the appropriate command below to update your CNI version to the latest recommended version:

- **US West (Oregon) (us-west-2)**

  ```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.7.5/config/v1.7/aws-k8s-cni.yaml
```

- **China (Beijing) (cn-north-1) or China (Ningxia) (cn-northwest-1)**

  ```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.7.5/config/v1.7/aws-k8s-cni-cn.yaml
```

- **AWS GovCloud (US-East) (us-gov-east-1)**

  ```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.7.5/config/v1.7/aws-k8s-cni-us-gov-east-1.yaml
```

- **AWS GovCloud (US-West) (us-gov-west-1)**

  ```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.7.5/config/v1.7/aws-k8s-cni-us-gov-west-1.yaml
```

- **For all other Regions**
  - **Download the manifest file.**
    ```
curl -o aws-k8s-cni.yaml https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.7.5/config/v1.7/aws-k8s-cni.yaml
```
  - **Replace <region-code>** in the following command with the Region that your cluster is in. Then, run the modified command to replace the Region code in the file (currently us-west-2).
    ```
sed -i -e 's/us-west-2/<region-code>/' aws-k8s-cni.yaml
```
• Apply the modified manifest file to your cluster.

```
kubectl apply -f aws-k8s-cni.yaml
```

13. (Optional) If you deployed the Kubernetes Cluster Autoscaler to your cluster before upgrading the cluster, update the Cluster Autoscaler to the latest version that matches the Kubernetes major and minor version that you upgraded to.

**Important**
You can’t use the Kubernetes Cluster Autoscaler with Arm.

a. Open the Cluster Autoscaler releases page in a web browser and find the latest Cluster Autoscaler version that matches your cluster’s Kubernetes major and minor version. For example, if your cluster’s Kubernetes version is 1.18 find the latest Cluster Autoscaler release that begins with 1.18. Record the semantic version number (<1.18.n>) for that release to use in the next step.

b. Set the Cluster Autoscaler image tag to the version that you recorded in the previous step with the following command. Replace <1.18.n> with your own value. You can replace us with <asia> or <eu>.

```
kubectl -n kube-system set image deployment.apps/cluster-autoscaler cluster-autoscaler=us.gcr.io/k8s-artifacts-prod/autoscaling/cluster-autoscaler:v<1.18.n>
```

**Note**
Depending on the version that you need, you may need to change the previous address to gcr.io/google-containers/cluster-autoscaler:v1.<n.n>. The image address is listed on the releases page.

14. (Clusters with GPU nodes only) If your cluster has node groups with GPU support (for example, p3.2xlarge), you must update the NVIDIA device plugin for Kubernetes DaemonSet on your cluster with the following command.

```
kubectl apply -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.6.0/nvidia-device-plugin.yml
```

15. After your cluster update is complete, update your nodes to the same Kubernetes version of your updated cluster. For more information, see Self-managed node updates (p. 129) or Updating a managed node group (p. 109). Any new pods launched on Fargate will have a kubelet version that matches your cluster version. Existing Fargate pods won’t be changed.

**Kubernetes 1.16 upgrade prerequisites**

As noted in the Kubernetes 1.15 changelog and Deprecated APIs Removed In 1.16: Here’s What You Need To Know documents, if you have an existing cluster, API changes are required for the following deployed resources before upgrading a cluster to 1.16.

**Warning**
If you don’t change these APIs before upgrading to 1.16, workloads fail after the upgrade is complete.

- NetworkPolicy resources will no longer be served from extensions/v1beta1 in v1.16. Migrate use to the networking.k8s.io/v1 API, available since v1.8. Existing persisted data can be retrieved through the networking.k8s.io/v1 API.

- PodSecurityPolicy resources will no longer be served from extensions/v1beta1 in v1.16. Migrate to the policy/v1beta1 API, available since v1.10. Existing persisted data can be retrieved through the policy/v1beta1 API.
• DaemonSet, Deployment, StatefulSet, and ReplicaSet resources will no longer be served from extensions/v1beta1, apps/v1beta1, or apps/v1beta2 in v1.16. Migrate to the apps/v1 API, available since v1.9. Existing persisted data can be retrieved through the apps/v1 API. For example, to convert a Deployment that currently uses apps/v1beta1, enter the following command.

```bash
kubectl convert -f ./<my-deployment.yaml> --output-version apps/v1
```

**Note**
The previous command may use different default values from what is set in your current manifest file. To learn more about a specific resource, see the Kubernetes API reference.

If you originally created an Amazon EKS cluster with Kubernetes version 1.11 or earlier and haven't removed the `--resource-container` flag from the kube-proxy DaemonSet, then updating to Kubernetes 1.16 will cause kube-proxy failures. This flag is deprecated in Kubernetes 1.16. For more information, see kube-proxy in Kubernetes 1.16 Deprecations and removals. You must remove this flag before updating to Kubernetes 1.16.

**What you need to do before upgrading to 1.16**

• Change your YAML files to reference the new APIs.
• Update custom integrations and controllers to call the new APIs.
• Ensure that you use an updated version of any third party tools, such as ingress controllers, continuous delivery systems, and other tools that call the new APIs.

To easily check for deprecated API usage in your cluster, make sure that the audit control plane log (p. 66) is enabled, and specify v1beta as a filter for the events. All of the replacement APIs are in Kubernetes versions later than 1.10. Applications on any supported version of Amazon EKS can begin using the updated APIs now.

• Remove the `--resource-container=""` flag from your kube-proxy DaemonSet, if your cluster was originally deployed with Kubernetes 1.11 or earlier or use a kube-proxy configuration file (recommended). To determine whether your current version of kube-proxy has the flag, enter the following command.

```bash
kubectl get daemonset kube-proxy --namespace kube-system -o yaml | grep 'resource-container=""
```

If you receive no output, then you don't need to remove anything. If you receive output similar to `--resource-container=""`, then you need to remove the flag. Enter the following command to edit your current kube-proxy config.

```bash
kubectl edit daemonset kube-proxy --namespace kube-system
```

With the editor open, remove the `--resource-container=""` line, and save the file. We recommend that you instead, start using a kube-proxy configuration file. To do so, download the following manifest.

```bash
curl -o kube-proxy-daemonset.yaml https://amazon-eks.s3-us-west-2.amazonaws.com/cloudf ormation/2020-06-10/kube-proxy-daemonset.yaml
```

Determine your cluster's endpoint with the following command.

```bash
aws eks describe-cluster \   --name <cluster-name> \   --region <region-code>
```
---query 'cluster.endpoint' \\ 
---output text

The output is as follows:

https://<A89DBB2140C8AC0C2F920A36CCC6E18C>.sk1.<region-code>.eks.amazonaws.com

Edit the `kube-proxy-daemonset.yaml` file that you downloaded. In your editor, replace `<MASTER_ENDPOINT>` (including <> with the output from the previous command. Replace <REGION> with your cluster's Region. On the same line, replace the version with the version of your cluster if necessary. Apply the file with the following command.

```
kubectl apply -f kube-proxy-daemonset.yaml
```

Configure an Amazon EKS add-on

An add-on is Kubernetes operational software that provides capabilities like observability, scaling, networking, and AWS cloud resource integrations for your Amazon EKS cluster. You can manage add-ons yourself, or let Amazon EKS control the launch and version of the add-on through the Amazon EKS API for clusters running Kubernetes version 1.18 with platform version eks.3 or later. Amazon EKS add-ons use the Kubernetes Server-Side Apply feature, which is only available with Kubernetes version 1.18 or later. For more information, see Server-Side Apply in the Kubernetes documentation.

**To configure an Amazon EKS add-on using the AWS Management Console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation, select **Clusters**, and then select the name of the cluster that you want to configure an Amazon EKS add-on for.
3. Choose the **Configuration** tab and then choose the **Add-ons** tab.
4. Configure the add-on. To add a new Amazon EKS add-on, select **Add new**. To change an existing Amazon EKS add-on, select the add-on and choose **Edit**. To remove an add-on, select the add-on and select **Remove**. Removing the add-on also removes it from your cluster. You can always manually add the add-on back to your cluster, but be aware that its removal and addition could cause service disruption to your cluster.
   a. Select the **Name** of the Amazon EKS add-on that you want to add or edit.
   b. Select the **Version** of the Amazon EKS add-on that you want to use.
   c. Select the **Service account role** that you want the add-on to run as. If you don’t select an existing IAM role, then the **section called “Node IAM role” (p. 326)** is used. However, we recommend specifying your own role so that the node IAM role isn’t assigned more than the minimum permissions that it requires.

   Whichever role you choose must be assigned the permissions required by the add-on. For example, the role that you specify for the vpc-cni add-on must have the AmazonEKS_CNI_Policy IAM policy assigned to it, and the role must have unique settings in its trust relationship. For more information, see To create your CNI plugin IAM role with the AWS Management Console (p. 212). If the Kubernetes service account used by the add-on isn’t currently annotated with the IAM role that you specify, then the API will annotate the service account with the IAM role for you.

   **Important**
   To specify an IAM role, you must have an IAM OpenID Connect (OIDC) provider for your cluster. To create an OIDC provider, see the section called “Create OIDC provider” (p. 334).
To configure an Amazon EKS add-on using `eksctl`

Replace the `<example values>` (including `<>`) with your own values.

1. **Add an Amazon EKS add-on to your cluster.**
   
   a. Determine which Amazon EKS add-ons are available for your cluster.

   ```bash
   eksctl utils describe-addon-versions --cluster <name-of-your-cluster>
   ```

   b. Add an Amazon EKS add-on to your cluster. When specifying `<name-of-addon>`, specify a name returned from the previous command. The `--force` option overwrites any existing configuration if the add-on is already installed on your cluster, but you're managing it yourself. You can specify the ARN of an IAM role, policy, or both. The add-on's Kubernetes service account is then annotated with the role. If you don't specify an existing role or policy, `eksctl` creates a default role and attaches the necessary policy to it for you.

   ```bash
   eksctl create addon --name <name-of-addon-from-previous-command> --cluster <name-of-your-cluster> --force
   ```

2. **You can update an add-on to a newer version.** See other update options with `eksctl update addon -h`.
   
   a. Determine which versions are available for an add-on.

   ```bash
   eksctl utils describe-addon-versions --name <name-of-addon> --cluster <name-of-your-cluster>
   ```

   b. Update the add-on to a newer version.

   ```bash
   eksctl update addon --name <name-from-previous-command> --version <version-from-previous-command> --cluster <name-of-your-cluster>
   ```

3. **Delete an Amazon EKS add-on from your cluster.**
   
   a. See which add-ons are currently enabled for your cluster.

   ```bash
   eksctl get addons --cluster <name-of-your-cluster>
   ```

   b. Delete an Amazon EKS add-on from your cluster. Deleting the add-on also deletes any IAM roles associated to it.

   ```bash
   eksctl delete addon --cluster <name-of-your-cluster> --name <addon-name-from-previous-command>
   ```
Deleting a cluster

When you're done using an Amazon EKS cluster, you should delete the resources associated with it so that you don't incur any unnecessary costs.

**Important**

If you have active services in your cluster that are associated with a load balancer, you must delete those services before deleting the cluster so that the load balancers are deleted properly. Otherwise, you can have orphaned resources in your VPC that prevent you from being able to delete the VPC.

You can delete a cluster with `eksctl (p. 54)`, the AWS Management Console (p. 54), or the AWS CLI (p. 55).

[To delete an Amazon EKS cluster and nodes with `eksctl`]

This procedure requires `eksctl` version 0.35.0 or later. You can check your version with the following command:

```bash
eksctl version
```

For more information on installing or upgrading `eksctl`, see Installing or upgrading `eksctl` (p. 292).

**Note**

This procedure only works for clusters that were created with `eksctl`.

1. List all services running in your cluster.

   ```bash
   kubectl get svc --all-namespaces
   ```

2. Delete any services that have an associated `EXTERNAL-IP` value. These services are fronted by an Elastic Load Balancing load balancer, and you must delete them in Kubernetes to allow the load balancer and associated resources to be properly released.

   ```bash
   kubectl delete svc <service-name>
   ```

3. Delete the cluster and its associated nodes with the following command, replacing `<prod>` with your cluster name.

   ```bash
   eksctl delete cluster --name <prod>
   ```

   Output:

   ```
   [✓]  using region <region-code>
   [✓]  deleting EKS cluster "prod"
   [✓]  will delete stack "eksctl-prod-nodegroup-standard-nodes"
   [✓]  waiting for stack "eksctl-prod-nodegroup-standard-nodes" to get deleted
   [✓]  will delete stack "eksctl-prod-cluster"
   [✓]  the following EKS cluster resource(s) for "prod" will be deleted: cluster. If in doubt, check CloudFormation console
   ```

[To delete an Amazon EKS cluster with the AWS Management Console]

1. List all services running in your cluster.

   ```bash
   kubectl get svc --all-namespaces
   ```
2. Delete any services that have an associated `EXTERNAL-IP` value. These services are fronted by an Elastic Load Balancing load balancer, and you must delete them in Kubernetes to allow the load balancer and associated resources to be properly released.

   ```
kubectl delete svc <service-name>
   ```

3. Delete all node groups and Fargate profiles.
   a. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
   b. In the left navigation, select **Clusters**, and then in the tabbed list of clusters, select the name of the cluster that you want to delete.
   c. Select the **Configuration** tab. On the **Compute** tab, select a node group to delete, select **Delete**, enter the name of the node group, and then select **Delete**. Delete all node groups in the cluster.

   **Note**
   The node groups listed are managed node groups (p. 101) only.
   d. Select a **Fargate Profile** to delete, select **Delete**, enter the name of the profile, and then select **Delete**. Delete all Fargate profiles in the cluster.

4. Delete all self-managed node AWS CloudFormation stacks.
   b. Select the node stack to delete and then choose **Actions**, **Delete Stack**.
   c. On the **Delete Stack** confirmation screen, choose **Yes, Delete**. Delete all self-managed node stacks in the cluster.

5. Delete the cluster.
   a. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
   b. Select the cluster to delete and choose **Delete**.
   c. On the delete cluster confirmation screen, choose **Delete**.

6. (Optional) Delete the VPC AWS CloudFormation stack.
   a. Select the VPC stack to delete and choose **Actions** and then **Delete Stack**.
   b. On the **Delete Stack** confirmation screen, choose **Yes, Delete**.

[ To delete an Amazon EKS cluster with the AWS CLI ]

1. List all services running in your cluster.

   ```
kubectl get svc --all-namespaces
   ```

2. Delete any services that have an associated `EXTERNAL-IP` value. These services are fronted by an Elastic Load Balancing load balancer, and you must delete them in Kubernetes to allow the load balancer and associated resources to be properly released.

   ```
kubectl delete svc <service-name>
   ```

3. Delete all node groups and Fargate profiles.
   a. List the node groups in your cluster with the following command.

   ```
aws eks list-nodegroups --cluster-name <my-cluster>
   ```

   **Note**
   The node groups listed are managed node groups (p. 101) only.
b. Delete each node group with the following command. Delete all node groups in the cluster.

```
aws eks delete-nodegroup --nodegroup-name <my-nodegroup> --cluster-name <my-cluster>
```

c. List the Fargate profiles in your cluster with the following command.

```
aws eks list-fargate-profiles --cluster-name <my-cluster>
```

d. Delete each Fargate profile with the following command. Delete all Fargate profiles in the cluster.

```
aws eks delete-fargate-profile --fargate-profile-name <my-fargate-profile> --cluster-name <my-cluster>
```

4. Delete all self-managed node AWS CloudFormation stacks.
   a. List your available AWS CloudFormation stacks with the following command. Find the node template name in the resulting output.

```
aws cloudformation list-stacks --query "StackSummaries[].StackName"
```
   b. Delete each node stack with the following command, replacing <node-stack> with your node stack name. Delete all self-managed node stacks in the cluster.

```
aws cloudformation delete-stack --stack-name <node-stack>
```

5. Delete the cluster with the following command, replacing <my-cluster> with your cluster name.

```
aws eks delete-cluster --name <my-cluster>
```

6. (Optional) Delete the VPC AWS CloudFormation stack.
   a. List your available AWS CloudFormation stacks with the following command. Find the VPC template name in the resulting output.

```
aws cloudformation list-stacks --query "StackSummaries[].StackName"
```
   b. Delete the VPC stack with the following command, replacing <my-vpc-stack> with your VPC stack name.

```
aws cloudformation delete-stack --stack-name <my-vpc-stack>
```

### Amazon EKS cluster endpoint access control

This topic helps you to enable private access for your Amazon EKS cluster’s Kubernetes API server endpoint and limit, or completely disable, public access from the internet.

When you create a new cluster, Amazon EKS creates an endpoint for the managed Kubernetes API server that you use to communicate with your cluster (using Kubernetes management tools such as `kubectl`). By default, this API server endpoint is public to the internet, and access to the API server is secured using a combination of AWS Identity and Access Management (IAM) and native Kubernetes Role Based Access Control (RBAC).
You can enable private access to the Kubernetes API server so that all communication between your nodes and the API server stays within your VPC. You can limit the IP addresses that can access your API server from the internet, or completely disable internet access to the API server.

**Note**

Because this endpoint is for the Kubernetes API server and not a traditional AWS PrivateLink endpoint for communicating with an AWS API, it doesn't appear as an endpoint in the Amazon VPC console.

When you enable endpoint private access for your cluster, Amazon EKS creates a Route 53 private hosted zone on your behalf and associates it with your cluster's VPC. This private hosted zone is managed by Amazon EKS, and it doesn't appear in your account's Route 53 resources. In order for the private hosted zone to properly route traffic to your API server, your VPC must have `enableDnsHostnames` and `enableDnsSupport` set to `true`, and the DHCP options set for your VPC must include `AmazonProvidedDNS` in its domain name servers list. For more information, see Updating DNS support for your VPC in the Amazon VPC User Guide.

You can define your API server endpoint access requirements when you create a new cluster, and you can update the API server endpoint access for a cluster at any time.

### Modifying cluster endpoint access

Use the procedures in this section to modify the endpoint access for an existing cluster. The following table shows the supported API server endpoint access combinations and their associated behavior.

#### API server endpoint access options

<table>
<thead>
<tr>
<th>Endpoint public access</th>
<th>Endpoint private access</th>
<th>Behavior</th>
</tr>
</thead>
</table>
| Enabled                | Disabled                | • This is the default behavior for new Amazon EKS clusters.  
                          |             | • Kubernetes API requests that originate from within your cluster's VPC (such as node to control plane communication) leave the VPC but not Amazon's network.  
<pre><code>                      |             | • Your cluster API server is accessible from the internet. You can, optionally, limit the CIDR blocks that can access the public endpoint. If you limit access to specific CIDR blocks, then it is recommended that you also enable the private endpoint, or ensure that the CIDR blocks that you specify include the addresses that nodes and Fargate pods (if you use them) access the public endpoint from. |
</code></pre>
<p>| Enabled                | Enabled                 | • Kubernetes API requests within your cluster's VPC (such as node to control plane communication) use the private VPC endpoint. |</p>
<table>
<thead>
<tr>
<th>Endpoint public access</th>
<th>Endpoint private access</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disabled</td>
<td>Enabled</td>
<td>- Your cluster API server is accessible from the internet. You can, optionally, limit the CIDR blocks that can access the public endpoint.</td>
</tr>
</tbody>
</table>

| Disabled | Enabled | - All traffic to your cluster API server must come from within your cluster’s VPC or a connected network. |
|          |        | - There is no public access to your API server from the internet. Any `kubectl` commands must come from within the VPC or a connected network. For connectivity options, see [Accessing a private only API server](p. 60). |
|          |        | - The cluster’s API server endpoint is resolved by public DNS servers to a private IP address from the VPC. In the past, the endpoint could only be resolved from within the VPC. |

If your endpoint does not resolve to a private IP address within the VPC for an existing cluster, you can:

- Enable public access and then disable it again. You only need to do so once for a cluster and the endpoint will resolve to a private IP address from that point forward.
- [Update](p. 43) your cluster.

You can modify your cluster API server endpoint access using the AWS Management Console (p. 58) or AWS CLI (p. 59).

**[To modify your cluster API server endpoint access using the AWS Management Console]**

1. Open the Amazon EKS console at [https://console.aws.amazon.com/eks/home#/clusters](https://console.aws.amazon.com/eks/home#/clusters).
2. Choose the name of the cluster to display your cluster information.
3. Choose the **Configuration** tab. On the **Networking** tab, choose **Update**.
4. For **Private access**, choose whether to enable or disable private access for your cluster’s Kubernetes API server endpoint. If you enable private access, Kubernetes API requests that originate from within your cluster’s VPC use the private VPC endpoint. You must enable private access to disable public access.
5. For **Public access**, choose whether to enable or disable public access for your cluster’s Kubernetes API server endpoint. If you disable public access, your cluster’s Kubernetes API server can only receive requests from within the cluster VPC.

6. (Optional) If you’ve enabled **Public access**, you can specify which addresses from the Internet can communicate to the public endpoint. Select **Advanced Settings**. Enter a CIDR block, such as <203.0.113.5/32>. The block cannot include reserved addresses. You can enter additional blocks by selecting **Add Source**. There is a maximum number of CIDR blocks that you can specify. For more information, see Amazon EKS service quotas (p. 306). If you specify no blocks, then the public API server endpoint receives requests from all (0.0.0.0/0) IP addresses. If you restrict access to your public endpoint using CIDR blocks, it is recommended that you also enable private endpoint access so that nodes and Fargate pods (if you use them) can communicate with the cluster. Without the private endpoint enabled, your public access endpoint CIDR sources must include the egress sources from your VPC. For example, if you have a node in a private subnet that communicates to the internet through a NAT Gateway, you will need to add the outbound IP address of the NAT gateway as part of your allowed CIDR block on your public endpoint.

7. Choose **Update** to finish.

**[To modify your cluster API server endpoint access using the AWS CLI]**

Complete the following steps using the AWS CLI version 1.18.190 or later. You can check your current version with `aws --version`. To install or upgrade the AWS CLI, see Installing the AWS CLI.

1. Update your cluster API server endpoint access with the following AWS CLI command. Substitute your cluster name and desired endpoint access values. If you set `endpointPublicAccess=true`, then you can (optionally) enter single CIDR block, or a comma-separated list of CIDR blocks for `publicAccessCidrs`. The blocks cannot include reserved addresses. If you specify CIDR blocks, then the public API server endpoint will only receive requests from the listed blocks. There is a maximum number of CIDR blocks that you can specify. For more information, see Amazon EKS service quotas (p. 306). If you restrict access to your public endpoint using CIDR blocks, it is recommended that you also enable private endpoint access so that nodes and Fargate pods (if you use them) can communicate with the cluster. Without the private endpoint enabled, your public access endpoint CIDR sources must include the egress sources from your VPC. For example, if you have a node in a private subnet that communicates to the internet through a NAT Gateway, you will need to add the outbound IP address of the NAT gateway as part of an allowed CIDR block on your public endpoint. If you specify no CIDR blocks, then the public API server endpoint receives requests from all (0.0.0.0/0) IP addresses.

   **Note**
   The following command enables private access and public access from a single IP address for the API server endpoint. Replace <203.0.113.5/32> with a single CIDR block, or a comma-separated list of CIDR blocks that you want to restrict network access to.

   ```bash
   aws eks update-cluster-config \
   --region <region-code> \
   --name <my-cluster> \
   --resources-vpc-config \
   endpointPublicAccess=<true>,publicAccessCidrs="<203.0.113.5/32>",endpointPrivateAccess=<true>
   ```

   **Output:**

   ```json
   {"update": {
   "id": "<e6f0905f-a5d4-4a2a-8c49-EXAMPLE00000>",
   "status": "InProgress",
   "type": "EndpointAccessUpdate",
   "params": [
   
   ]
   }
   ```
Accessing a private only API server

If you have disabled public access for your cluster's Kubernetes API server endpoint, you can only access the API server from within your VPC or a connected network. Here are a few possible ways to access the Kubernetes API server endpoint:

- **Connected network** – Connect your network to the VPC with an AWS transit gateway or other connectivity option and then use a computer in the connected network. You must ensure that your
Amazon EKS User Guide
Cluster Autoscaler

Amazon EKS control plane security group contains rules to allow ingress traffic on port 443 from your connected network.

- **Amazon EC2 bastion host** – You can launch an Amazon EC2 instance into a public subnet in your cluster's VPC and then log in via SSH into that instance to run `kubectl` commands. For more information, see [Linux bastion hosts on AWS](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/lb-bastion-hosts.html). You must ensure that your Amazon EKS control plane security group contains rules to allow ingress traffic on port 443 from your bastion host. For more information, see [Amazon EKS security group considerations](https://docs.aws.amazon.com/eks/latest/userguide/security-group-eip.html) (p. 205).

When you configure `kubectl` for your bastion host, be sure to use AWS credentials that are already mapped to your cluster's RBAC configuration, or add the IAM user or role that your bastion will use to the RBAC configuration before you remove endpoint public access. For more information, see [Managing users or IAM roles for your cluster](https://docs.aws.amazon.com/eks/latest/userguide/cluster-security-group.html) (p. 279) and [Unauthorized or access denied](https://docs.aws.amazon.com/eks/latest/userguide/access-denied.html) (p. 367).

- **AWS Cloud9 IDE** – AWS Cloud9 is a cloud-based integrated development environment (IDE) that lets you write, run, and debug your code with just a browser. You can create an AWS Cloud9 IDE in your cluster's VPC and use the IDE to communicate with your cluster. For more information, see [Creating an environment in AWS Cloud9](https://docs.aws.amazon.com/cloud9/latest/userguide/creating-environment.html). You must ensure that your Amazon EKS control plane security group contains rules to allow ingress traffic on port 443 from your IDE security group. For more information, see [Amazon EKS security group considerations](https://docs.aws.amazon.com/eks/latest/userguide/security-group-eip.html) (p. 205).

When you configure `kubectl` for your AWS Cloud9 IDE, be sure to use AWS credentials that are already mapped to your cluster's RBAC configuration, or add the IAM user or role that your IDE will use to the RBAC configuration before you remove endpoint public access. For more information, see [Managing users or IAM roles for your cluster](https://docs.aws.amazon.com/eks/latest/userguide/cluster-security-group.html) (p. 279) and [Unauthorized or access denied](https://docs.aws.amazon.com/eks/latest/userguide/access-denied.html) (p. 367).

## Cluster Autoscaler

The Kubernetes Cluster Autoscaler automatically adjusts the number of nodes in your cluster when pods fail to launch due to lack of resources or when nodes in the cluster are underutilized and their pods can be rescheduled onto other nodes in the cluster.

This topic shows you how to deploy the Cluster Autoscaler to your Amazon EKS cluster and how to configure it to modify your Amazon EC2 Auto Scaling groups. The Cluster Autoscaler modifies your node groups so that they scale out when you need more resources and scale in when you have underutilized resources.

### Create an Amazon EKS cluster

This section helps you to create a cluster and node group or groups. If you already have a cluster, you can skip ahead to [Cluster Autoscaler node group considerations](https://docs.aws.amazon.com/eks/latest/userguide/autoscaler-nodegroups.html) (p. 63).

If you are running a stateful application across multiple Availability Zones that is backed by Amazon EBS volumes and using the Kubernetes Cluster Autoscaler (p. 61), you should configure multiple node groups, each scoped to a single Availability Zone. In addition, you should enable the `--balance-similar-node-groups` feature. Otherwise, you can create a single node group that spans multiple Availability Zones.

Complete the steps in one of the following cluster creation procedures.

[To create a cluster with a single managed group that spans multiple Availability Zones](https://docs.aws.amazon.com/eks/latest/userguide/cluster-creation.html)

- Create an Amazon EKS cluster with a single managed node group with the following `eksctl` command. For more information, see [Creating an Amazon EKS cluster](https://docs.aws.amazon.com/eks/latest/userguide/cluster-creation.html) (p. 35). Substitute the `<variable text>` with your own values.
eksctl create cluster --name <my-cluster> --version <1.18> --managed --asg-access

Portions of the output showing the Availability Zones:

...  
[✓]  using region <region-code>  
[✓]  setting availability zones to [<region-code>a <region-code>c <region-code>b]  
[✓]  subnets for <region-code>a = public:192.168.0.0/19 private:192.168.96.0/19  
[✓]  subnets for <region-code>c = public:192.168.32.0/19 private:192.168.128.0/19  
[✓]  subnets for <region-code>b = public:192.168.64.0/19 private:192.168.160.0/19  
...  
[✓]  nodegroup "ng-6bcca56a" has 2 node(s)  
[✓]  node "ip-192-168-28-68.<region-code>.compute.internal" is ready  
[✓]  node "ip-192-168-61-153.<region-code>.compute.internal" is ready  
[✓]  waiting for at least 2 node(s) to become ready in "ng-6bcca56a"  
[✓]  nodegroup "ng-6bcca56a" has 2 node(s)  
[✓]  node "ip-192-168-28-68.<region-code>.compute.internal" is ready  
[✓]  node "ip-192-168-61-153.<region-code>.compute.internal" is ready  
...  
[✓]  EKS cluster "my-cluster" in "<region-code>" region-code is ready

[ To create a cluster with a dedicated managed node group for each Availability Zone ]

1. Create an Amazon EKS cluster with no node groups with the following eksctl command. For more information, see Creating an Amazon EKS cluster (p. 35). Note the Availability Zones that the cluster is created in. You will use these Availability Zones when you create your node groups. Substitute the red variable text with your own values.

eksctl create cluster --name <my-cluster> --version <1.18> --without-nodegroup

Portions of the output showing the Availability Zones:

...  
[✓]  using region <region-code>  
[✓]  setting availability zones to [<region-code>a <region-code>c <region-code>b]  
[✓]  subnets for <region-code>a = public:192.168.0.0/19 private:192.168.96.0/19  
[✓]  subnets for <region-code>c = public:192.168.32.0/19 private:192.168.128.0/19  
[✓]  subnets for <region-code>b = public:192.168.64.0/19 private:192.168.160.0/19  
...  
[✓]  EKS cluster "my-cluster" in "<region-code>" region-code is ready

This cluster was created in the following Availability Zones: <region-code>a, <region-code>c, and <region-code>b.

2. For each Availability Zone in your cluster, use the following eksctl command to create a node group. Substitute the <variable text> with your own values. This command creates an Auto Scaling group with a minimum count of one and a maximum count of ten.

eksctl create nodegroup --cluster <my-cluster> --node-zones <<region-code>a> --name <<region-code>a> --asg-access --nodes-min <1> --nodes <5> --nodes-max <10> --managed
Cluster Autoscaler node group considerations

The Cluster Autoscaler requires additional IAM and resource tagging considerations that are explained in this section.

Node group IAM policy

The Cluster Autoscaler requires the following IAM permissions to make calls to AWS APIs on your behalf.

If you used the previous eksctl commands to create your node groups, these permissions are automatically provided and attached to your node IAM roles. If you did not use eksctl, you must create an IAM policy with the following document and attach it to your node IAM roles. For more information, see Modifying a role in the IAM User Guide.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "autoscaling:DescribeAutoScalingGroups",
                "autoscaling:DescribeAutoScalingInstances",
                "autoscaling:DescribeLaunchConfigurations",
                "autoscaling:DescribeTags",
                "autoscaling:SetDesiredCapacity",
                "autoscaling:TerminateInstanceInAutoScalingGroup",
                "ec2:DescribeLaunchTemplateVersions"
            ],
            "Resource": "*",
            "Effect": "Allow"
        }
    ]
}
```

Auto Scaling group tags

The Cluster Autoscaler requires the following tags on your node group Auto Scaling groups so that they can be auto-discovered.

If you used the previous eksctl commands to create your node groups, these tags are automatically applied. If not, you must manually tag your Auto Scaling groups with the following tags. For more information, see Tagging your Amazon EC2 resources in the Amazon EC2 User Guide for Linux Instances.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>k8s.io/cluster-autoscaler/&lt;cluster-name&gt;</td>
<td>owned</td>
</tr>
<tr>
<td>k8s.io/cluster-autoscaler/enabled</td>
<td>true</td>
</tr>
</tbody>
</table>

Deploy the Cluster Autoscaler

To deploy the Cluster Autoscaler

1. Apply the manifest to your cluster by completing the option that corresponds to the region that your cluster is in.
   - All regions other than China (Ningxia) or China (Beijing)
Deploy the Cluster Autoscaler

kubectl apply -f https://raw.githubusercontent.com/kubernetes/autoscaler/master/cluster-autoscaler/cloudprovider/aws/examples/cluster-autoscaler-autodiscover.yaml

• China (Ningxia) or China (Beijing)
  1. Download the manifest with the following command.

```bash
curl -o cluster-autoscaler-autodiscover.yaml https://raw.githubusercontent.com/kubernetes/autoscaler/master/cluster-autoscaler/cloudprovider/aws/examples/cluster-autoscaler-autodiscover.yaml
```

2. Modify the manifest.
   a. View the manifest file or files that you downloaded and note the name of the image.
      Download the image locally with the following command.

```bash
docker pull image:<tag>
```

b. Tag the image to be pushed to an Amazon Elastic Container Registry repository in China with the following command.

```bash
docker tag image:<tag> <aws_account_id>.dkr.ecr.<cn-north-1>.amazonaws.com/image:<tag>
```

c. Push the image to a China Amazon ECR repository with the following command.

```bash
docker push image:<tag> <aws_account_id>.dkr.ecr.<cn-north-1>.amazonaws.com/image:<tag>
```

d. Update the Kubernetes manifest file or files to reference the Amazon ECR image URL in your region.

3. Apply the manifest.

```bash
kubectl apply -f cluster-autoscaler-autodiscover.yaml
```

2. Add the `cluster-autoscaler.kubernetes.io/safe-to-evict` annotation to the deployment with the following command.

```bash
kubectl -n kube-system annotate deployment.apps/cluster-autoscaler cluster-autoscaler.kubernetes.io/safe-to-evict="false"
```

3. Edit the Cluster Autoscaler deployment with the following command.

```bash
kubectl -n kube-system edit deployment.apps/cluster-autoscaler
```

Edit the `cluster-autoscaler` container command to replace `<YOUR CLUSTER NAME>` with your cluster's name, and add the following options.

- `--balance-similar-node-groups`
- `--skip-nodes-with-system-pods=false`

```yaml
spec:
  containers:
  - command:
    - ./cluster-autoscaler
    - --v=4
    - --stderrthreshold=info
```

64
View your Cluster Autoscaler logs

After you have deployed the Cluster Autoscaler, you can view the logs and verify that it is monitoring your cluster load.

View your Cluster Autoscaler logs with the following command.

kubectl -n kube-system logs -f deployment.apps/cluster-autoscaler

Output:

```
I0926 23:15:55.165842       1 static_autoscaler.go:138] Starting main loop
I0926 23:15:55.166279       1 utils.go:595] No pod using affinity / antiaffinity found in cluster, disabling affinity predicate for this loop
I0926 23:15:55.166293       1 static_autoscaler.go:294] Filtering out schedulables
I0926 23:15:55.166330       1 static_autoscaler.go:311] No schedulable pods
I0926 23:15:55.166338       1 static_autoscaler.go:319] No unschedulable pods
I0926 23:15:55.166345       1 static_autoscaler.go:366] Calculating unneeded nodes
I0926 23:15:55.166357       1 utils.go:552] Skipping ip-192-168-3-111.<region-code>.compute.internal - node group min size reached
I0926 23:15:55.166365       1 utils.go:552] Skipping ip-192-168-71-83.<region-code>.compute.internal - node group min size reached
I0926 23:15:55.166435       1 static_autoscaler.go:393] Scale down status: unneededOnly=false lastScaleUpTime=2019-09-26 21:42:40.908059094 ...
I0926 23:15:55.166458       1 static_autoscaler.go:403] Starting scale down
I0926 23:15:55.166488       1 scale_down.go:706] No candidates for scale down
```
Amazon EKS control plane logging

Amazon EKS control plane logging provides audit and diagnostic logs directly from the Amazon EKS control plane to CloudWatch Logs in your account. These logs make it easy for you to secure and run your clusters. You can select the exact log types you need, and logs are sent as log streams to a group for each Amazon EKS cluster in CloudWatch.

You can start using Amazon EKS control plane logging by choosing which log types you want to enable for each new or existing Amazon EKS cluster. You can enable or disable each log type on a per-cluster basis using the AWS Management Console, AWS CLI (version 1.16.139 or higher), or through the Amazon EKS API. When enabled, logs are automatically sent from the Amazon EKS cluster to CloudWatch Logs in the same account.

When you use Amazon EKS control plane logging, you're charged standard Amazon EKS pricing for each cluster that you run. You are charged the standard CloudWatch Logs data ingestion and storage costs for any logs sent to CloudWatch Logs from your clusters. You are also charged for any AWS resources, such as Amazon EC2 instances or Amazon EBS volumes, that you provision as part of your cluster.

The following cluster control plane log types are available. Each log type corresponds to a component of the Kubernetes control plane. To learn more about these components, see Kubernetes Components in the Kubernetes documentation.

- **Kubernetes API server component logs (api)** – Your cluster's API server is the control plane component that exposes the Kubernetes API. For more information, see kube-apiserver in the Kubernetes documentation.
- **Audit (audit)** – Kubernetes audit logs provide a record of the individual users, administrators, or system components that have affected your cluster. For more information, see Auditing in the Kubernetes documentation.
- **Authenticator (authenticator)** – Authenticator logs are unique to Amazon EKS. These logs represent the control plane component that Amazon EKS uses for Kubernetes Role Based Access Control (RBAC) authentication using IAM credentials. For more information, see Cluster authentication (p. 271).
- **Controller manager (controllerManager)** – The controller manager manages the core control loops that are shipped with Kubernetes. For more information, see kube-controller-manager in the Kubernetes documentation.
- **Scheduler (scheduler)** – The scheduler component manages when and where to run pods in your cluster. For more information, see kube-scheduler in the Kubernetes documentation.

**Enabling and disabling control plane logs**

By default, cluster control plane logs aren't sent to CloudWatch Logs. You must enable each log type individually to send logs for your cluster. CloudWatch Logs ingestion, archive storage, and data scanning rates apply to enabled control plane logs. For more information, see CloudWatch pricing.

When you enable a log type, the logs are sent with a log verbosity level of 2.

**To enable or disable control plane logs with the console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the name of the cluster to display your cluster information.
3. Select the Configuration tab.
4. Under Logging, choose Update.
5. For each individual log type, choose whether the log type should be **Enabled** or **Disabled**. By default, each log type is **Disabled**.

6. Choose **Update** to finish.

**To enable or disable control plane logs with the AWS CLI**

1. Check your AWS CLI version with the following command.

   ```bash
   aws --version
   ```

   If your AWS CLI version is below 1.16.139, you must first update to the latest version. To install or upgrade the AWS CLI, see Installing the AWS command line interface in the AWS Command Line Interface User Guide.

2. Update your cluster's control plane log export configuration with the following AWS CLI command. Substitute your cluster name and desired endpoint access values.

   Note
   The following command sends all available log types to CloudWatch Logs.

   ```bash
   aws eks --region <region-code> update-cluster-config --name <prod> \
   --logging '{"clusterLogging": [{"types": ["api","audit","authenticator","controllerManager","scheduler"],"enabled":true}]}'
   ```

   Output:

   ```
   {
   "update": {
   "id": "<883405c8-65c6-4758-8cee-2a7c1340a6d9>",
   "status": "InProgress",
   "type": "LoggingUpdate",
   "params": [
   {
   "type": "ClusterLogging",
   "value": ","clusterLogging": [{"types": ["api","audit","authenticator","controllerManager","scheduler"],"enabled":true}]
   }
   ,
   "createdAt": 1553271814.684,
   "errors": []
   }
   }
   ```

3. Monitor the status of your log configuration update with the following command, using the cluster name and the update ID that were returned by the previous command. Your update is complete when the status appears as **Successful**.

   ```bash
   aws eks --region <region-code> describe-update --name <prod> --update-id <883405c8-65c6-4758-8cee-2a7c1340a6d9>
   ```

   Output:

   ```
   {
   "update": {
   "id": "<883405c8-65c6-4758-8cee-2a7c1340a6d9>",
   "status": "Successful",
   "type": "LoggingUpdate",
   "params": ["api","audit","authenticator","controllerManager","scheduler"],"enabled":true}]
   ```
Viewing cluster control plane logs

After you have enabled any of the control plane log types for your Amazon EKS cluster, you can view them on the CloudWatch console.

To learn more about viewing, analyzing, and managing logs in CloudWatch, see the Amazon CloudWatch Logs User Guide.

To view your cluster control plane logs on the CloudWatch console

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/home#logs:prefix=/aws/eks. This URL displays your current available log groups and filters them with the /aws/eks prefix.
2. Choose the cluster that you want to view logs for. The log group name format is /aws/eks/<cluster-name>/cluster.
3. Choose the log stream to view. The following list describes the log stream name format for each log type.

   Note
   As log stream data grows, the log stream names are rotated. When multiple log streams exist for a particular log type, you can view the latest log stream by looking for the log stream name with the latest Last Event Time.

   - Kubernetes API server component logs (api) – kube-apiserver-<nnn...>
   - Audit (audit) – kube-apiserver-audit-<nnn...>
   - Authenticator (authenticator) – authenticator-<nnn...>
   - Controller manager (controllerManager) – kube-controller-manager-<nnn...>
   - Scheduler (scheduler) – kube-scheduler-<nnn...>

Amazon EKS Kubernetes versions

The Kubernetes project is rapidly evolving with new features, design updates, and bug fixes. The community releases new Kubernetes minor versions, such as 1.18, as generally available approximately every three months, and each minor version is supported for approximately twelve months after it is first released.

Available Amazon EKS Kubernetes versions

The following Kubernetes versions are currently available for new clusters in Amazon EKS:

- 1.18.9
- 1.17.12
Unless your application requires a specific version of Kubernetes, we recommend that you choose the latest available Kubernetes version supported by Amazon EKS for your clusters. As new Kubernetes versions become available in Amazon EKS, we recommend that you proactively update your clusters to use the latest available version. For more information, see Updating a Cluster (p. 43). For more information, see Amazon EKS Kubernetes release calendar (p. 72) and Amazon EKS version support and FAQ (p. 72).

Kubernetes 1.18

Kubernetes 1.18 is now available in Amazon EKS. For more information about Kubernetes 1.18, see the official release announcement.

The following Kubernetes features are now supported in Kubernetes 1.18 Amazon EKS clusters:

- Topology Manager has reached beta status. This feature allows the CPU and Device Manager to coordinate resource allocation decisions, optimizing for low latency with machine learning and analytics workloads. For more information, see Control Topology Management Policies on a node in the Kubernetes documentation.
- Server-side Apply is updated with a new beta version. This feature tracks and manages changes to fields of all new Kubernetes objects, allowing you to know what changed your resources and when. For more information, see What is Server-side Apply? in the Kubernetes documentation.
- A new `pathType` field and a new `IngressClass` resource has been added to the Ingress specification. These features make it simpler to customize Ingress configuration, and are supported by the AWS Load Balancer Controller (p. 265) (formerly called the ALB Ingress Controller). For more information, see Improvements to the Ingress API in Kubernetes 1.18 in the Kubernetes documentation.
- Configurable horizontal pod autoscaling behavior. For more information, see Support for configurable scaling behavior in the Kubernetes documentation.
- In 1.18 clusters, you no longer need to include the `AWS_DEFAULT_REGION=<region-code>` environment variable to pods when using IAM roles for service accounts in China regions, whether you use the mutating web hook or configure the environment variables manually. You still need to include the variable for all pods in earlier versions.

For the complete Kubernetes 1.18 changelog, see https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.18.md.

Kubernetes 1.17

Kubernetes 1.17 is now available in Amazon EKS. For more information about Kubernetes 1.17, see the official release announcement.

Important

- EKS has not enabled the `CSIMigrationAWS` feature flag. This will be enabled in a future release, along with detailed migration instructions. For more info on CSI migration, see the Kubernetes blog.
- Upgrading a cluster from 1.16 to 1.17 will fail if any of your AWS Fargate pods have a kubelet minor version earlier than 1.16. Before upgrading your cluster from 1.16 to 1.17, you need to recycle your Fargate pods so that their kubelet is 1.16 before attempting to upgrade the cluster to 1.17. To recycle a Kubernetes deployment on a 1.15 or later cluster, use the following command.
kubectl rollout restart deployment <deployment-name>

The following Kubernetes features are now supported in Kubernetes 1.17 Amazon EKS clusters:

- **Cloud Provider Labels** have reached general availability. If you are using the beta labels in your pod specs for features such as node affinity, or in any custom controllers, then we recommend that you start migrating them to the new GA labels. For information about the new labels, see the following Kubernetes documentation:
  - `node.kubernetes.io/instance-type`
  - `topology.kubernetes.io/region`
  - `topology.kubernetes.io/zone`
- The **ResourceQuotaScopeSelectors** feature has graduated to generally available. This feature allows you to limit the number of resources a quota supports to only those that pertain to the scope.
- The **TaintNodesByCondition** feature has graduated to generally available. This feature allows you to taint nodes that have conditions such as high disk or memory pressure.
- The **CSI Topology** feature has graduated to generally available, and is fully supported by the EBS CSI driver. You can use topology to restrict the Availability Zone where a volume is provisioned.
- **Finalizer protection** for services of type `LoadBalancer` has graduated to generally available. This feature ensures that a service resource is not fully deleted until the correlating load balancer is also deleted.
- Custom resources now support **default values**. You specify values in an OpenAPI v3 validation schema.
- The **Windows containers RunAs_username** feature is now in beta, allowing you to run Windows applications in a container as a different username than the default.

For the complete Kubernetes 1.17 changelog, see [https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.17.md](https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.17.md).

**Kubernetes 1.16**

Kubernetes 1.16 is now available in Amazon EKS. For more information about Kubernetes 1.16, see the [official release announcement](https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.16.md).

**Important**

- Kubernetes 1.16 removes a number of deprecated APIs. Changes to your applications may be required before upgrading your cluster to 1.16. Carefully follow the [1.16 upgrade prerequisites](https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.16.md) before upgrading.
- Starting with 1.16, the Amazon EKS certificate authority will honor certificate signing requests with SAN X.509 extensions, which resolves the [EKS CA should honor SAN x509 extension](https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.16.md) feature request from GitHub.

The following Kubernetes features are now supported in Kubernetes 1.16 Amazon EKS clusters:

- Volume expansion in the CSI specification has moved to beta, which allows for any CSI spec volume plugin to be resizeable. For more information, see [Volume Expansion](https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.16.md) in the Kubernetes CSI documentation. The latest version of the EBS CSI driver supports volume expansion when running on an Amazon EKS 1.16 cluster.
- Windows GMSA support has graduated from alpha to beta, and is now supported by Amazon EKS. For more information, see [Configure GMSA for Windows Pods and containers](https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.16.md) in the Kubernetes documentation.
• A new annotation: `service.beta.kubernetes.io/aws-load-balancer-eip-allocations` is available on service type `LoadBalancer` to assign an elastic IP address to Network Load Balancers. For more information, see the Support EIP Allocations with AWS NLB GitHub issue.

• Finalizer protection for service load balancers is now in beta and enabled by default. Service load balancer finalizer protection ensures that any load balancer resources allocated for a Kubernetes Service object, such as the AWS Network Load Balancer, will be destroyed or released when the service is deleted. For more information, see Garbage Collecting Load Balancers in the Kubernetes documentation.

• The Kubernetes custom resource definitions and admission webhooks extensibility mechanisms have both reached general availability. For more information, see Custom Resources and Dynamic Admission Control in the Kubernetes documentation.

• The server-side apply feature has reached beta status and is enabled by default. For more information, see Server Side Apply in the Kubernetes documentation.

• The `CustomResourceDefaulting` feature is promoted to beta and enabled by default. Defaults may be specified in structural schemas through the `apiextensions.k8s.io/v1` API. For more information, see Specifying a structural schema in the Kubernetes documentation.

For the complete Kubernetes 1.16 changelog, see https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.16.md.

Kubernetes 1.15

Kubernetes 1.15 is now available in Amazon EKS. For more information about Kubernetes 1.15, see the official release announcement.

**Important**
Starting with 1.15, Amazon EKS no longer tags the VPC containing your cluster.

• Subnets within the VPC of your cluster are still tagged.

• VPC tags will not be modified on existing cluster upgrades to 1.15.

• For more information about VPC tagging, see VPC tagging requirement (p. 204).

**Important**
Amazon EKS has set the re-invocation policy for the Pod Identity Webhook to `IfNeeded`. This allows the webhook to be re-invoked if objects are changed by other mutating admission webhooks like the App Mesh sidecar injector. For more information about the App Mesh sidecar injector, see Install the sidecar injector.

The following features are now supported in Kubernetes 1.15 Amazon EKS clusters:

• EKS now supports configuring transport layer security (TLS) termination, access logs, and source ranges for network load balancers. For more information, see Network Load Balancer support on AWS on GitHub.

• Improved flexibility of Custom Resource Definitions (CRD), including the ability to convert between versions on the fly. For more information, see Extend the Kubernetes API with CustomResourceDefinitions on GitHub.

• NodeLocal DNSCache is in beta for Kubernetes version 1.15 clusters. This feature can help improve cluster DNS performance by running a DNS caching agent on cluster nodes as a DaemonSet. For more information, see Using NodeLocal DNSCache in Kubernetes clusters on GitHub.

**Note**
When running CoreDNS on Amazon EC2, we recommend not using `force_tcp` in the configuration and ensuring that `options use-vc` is not set in `/etc/resolv.conf`. 
For the complete Kubernetes 1.15 changelog, see https://github.com/kubernetes/kubernetes/blob/master/CHANGELOG/CHANGELOG-1.15.md.

### Amazon EKS Kubernetes release calendar

**Note**
Dates with only a month and a year are approximate and are updated with an exact date when it is known.

### Amazon EKS version support and FAQ

In line with the Kubernetes community support for Kubernetes versions, Amazon EKS is committed to supporting at least four production-ready versions of Kubernetes at any given time. We will announce the end of support date of a given Kubernetes minor version at least 60 days before the end of support date. Because of the Amazon EKS qualification and release process for new Kubernetes versions, the end of support date of a Kubernetes version on Amazon EKS will be on or after the date that the Kubernetes project stops supporting the version upstream.

Kubernetes supports compatibility between the control plane and nodes for up to two minor versions. For example, 1.16 nodes will continue to operate when orchestrated by a 1.18 control plane. For more information, see Kubernetes version and version skew support policy in the Kubernetes documentation.

### Frequently asked questions

**Q: How long is a Kubernetes version supported by Amazon EKS?**

A: A Kubernetes version is fully supported for 14 months after first being available on Amazon EKS. This is true even if upstream Kubernetes is no longer supporting a version available on Amazon EKS. We backport security patches that are applicable to the Kubernetes versions supported on Amazon EKS.

**Q: When does support end for a Kubernetes version on Amazon EKS?**

A: Approximately 12 months after a version is released on Amazon EKS (usually with the release of a new version) Amazon EKS will send out a notice through the AWS Personal Health Dashboard if any clusters in your account are running the version nearing end of support. The notice will include the end of support date, which will be at least 60 days from the date of the notice.

**Q: What happens on the end of support date?**

A: On the end of support date, you will no longer be able to create new Amazon EKS clusters with the unsupported version. Existing clusters will be automatically upgraded to the oldest supported version through a gradual deployment process after the end of support date.

**Q: When exactly will my cluster be automatically upgraded after the end of support date?**
A: Amazon EKS is unable to provide specific timeframes. Automatic upgrades can happen at any time after the end of support date. We recommend that you take proactive action and upgrade your clusters without relying on the Amazon EKS automatic upgrade process.

Q: Can I leave my cluster on a Kubernetes version indefinitely?
A: No. In the interest of security, Amazon EKS does not allow clusters to stay on a version that has reached end of support.

Q: Are EKS managed node groups automatically upgraded along with the cluster control plane version?
A: No. An Amazon EKS managed node group creates Amazon EC2 instances in your account. These instances are not automatically upgraded. A managed node group will have a health issue if it contains instances that are running a version of Kubernetes more than one version behind the control plane.

Amazon EKS platform versions

Amazon EKS platform versions represent the capabilities of the cluster control plane, such as which Kubernetes API server flags are enabled, as well as the current Kubernetes patch version. Each Kubernetes minor version has one or more associated Amazon EKS platform versions. The platform versions for different Kubernetes minor versions are independent.

When a new Kubernetes minor version is available in Amazon EKS, such as 1.18, the initial Amazon EKS platform version for that Kubernetes minor version starts at eks.1. However, Amazon EKS releases new platform versions periodically to enable new Kubernetes control plane settings and to provide security fixes.

When new Amazon EKS platform versions become available for a minor version:

• The Amazon EKS platform version number is incremented (eks.<n+1>).
• Amazon EKS automatically upgrades all existing clusters to the latest Amazon EKS platform version for their corresponding Kubernetes minor version.
• Amazon EKS might publish a new node AMI with a corresponding patch version. However, all patch versions are compatible between the EKS control plane and node AMIs for a given Kubernetes minor version.

New Amazon EKS platform versions don't introduce breaking changes or cause service interruptions.

Note
Automatic upgrades of existing Amazon EKS platform versions are rolled out incrementally. The roll-out process might take some time. If you need the latest Amazon EKS platform version features immediately, you should create a new Amazon EKS cluster.

Clusters are always created with the latest available Amazon EKS platform version (eks.<n>) for the specified Kubernetes version. If you update your cluster to a new Kubernetes minor version, your cluster receives the current Amazon EKS platform version for the Kubernetes minor version that you updated to.

The current and recent Amazon EKS platform versions are described in the following tables.

Kubernetes version 1.18

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>Amazon EKS platform version</th>
<th>Enabled admission controllers</th>
<th>Release notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.18.9</td>
<td>eks.3</td>

<td>New platform version with bug fixes and enhancements, including an update to the server side AWS IAM Authenticator, with IAM role traceability improvements.</td>
</tr>
</tbody>
</table>
Windows support

This topic describes how to add Windows support to Amazon EKS clusters.

Considerations

Before deploying Windows nodes, be aware of the following considerations.

- Amazon EC2 instance types C3, C4, D2, I2, M4 (excluding m4.16xlarge), and R3 instances are not supported for Windows workloads.
- Host networking mode is not supported for Windows workloads.
- Amazon EKS clusters must contain one or more Linux nodes to run core system pods that only run on Linux, such as coredns and the VPC resource controller.
- The kubelet and kube-proxy event logs are redirected to the EKS Windows Event Log and are set to a 200 MB limit.
- You cannot use Security groups for pods (p. 214) with pods running on Windows nodes.
- Windows nodes support one elastic network interface per node. The number of pods that you can run per Windows node is equal to the number of IP addresses available per elastic network interface for the node's instance type, minus one. For more information, see IP addresses per network interface per instance type in the Amazon EC2 User Guide for Linux Instances.
- Group Managed Service Accounts (GMSA) for Windows pods and containers is not supported by Amazon EKS versions earlier than 1.16. You can follow the instructions in the Kubernetes documentation to enable and test this alpha feature on clusters that are earlier than 1.16.

Enabling Windows support

The following steps help you to enable Windows support for your Amazon EKS cluster. You can use eksctl (p. 80), a Windows client (p. 81), or a macOS or Linux client (p. 83) to enable Windows support for your cluster.

To enable Windows support for your cluster with eksctl

This procedure only works for clusters that were created with eksctl and assumes that your eksctl version is 0.35.0 or later. You can check your version with the following command.
For more information about installing or upgrading `eksctl`, see Installing or upgrading `eksctl` (p. 292).

1. Enable Windows support for your Amazon EKS cluster with the following `eksctl` command. This command deploys the VPC resource controller and VPC admission controller webhook that are required on Amazon EKS clusters to run Windows workloads.

   ```bash
   eksctl utils install-vpc-controllers --cluster <cluster_name> --approve
   ```

2. After you have enabled Windows support, you can launch a Windows node group into your cluster. For more information, see Launching self-managed Windows nodes (p. 125).

After you add Windows support to your cluster, you must specify node selectors on your applications so that the pods land on a node with the appropriate operating system. For Linux pods, use the following node selector text in your manifests.

```yaml
nodeSelector:
  kubernetes.io/os: linux
  kubernetes.io/arch: amd64
```

For Windows pods, use the following node selector text in your manifests.

```yaml
nodeSelector:
  kubernetes.io/os: windows
  kubernetes.io/arch: amd64
```

### To enable Windows support for your cluster with a Windows client

In the following steps, replace the `<region-code>` with the Region that your cluster resides in.

1. Deploy the VPC resource controller to your cluster using the command that corresponds to the Region that your cluster is in.
   - All Regions other than China (Beijing) and China (Ningxia)

   ```bash
   ```

   - China (Beijing) and China (Ningxia)

   ```bash
   ```

2. Deploy the VPC admission controller webhook to your cluster.

   a. Download the required scripts and deployment files that correspond to the Region that your cluster is in.

   - All Regions other than China (Beijing) and China (Ningxia)

   ```bash
   ```
Enabling Windows support

- China (Beijing) and China (Ningxia)

b. Install OpenSSL and jq.

c. Set up and deploy the VPC admission webhook.

`./Setup-VPCAdmissionWebhook.ps1 -DeploymentTemplate "/vpc-admission-webhook-deployment.yaml"

3. Determine if your cluster has the required cluster role binding.

`kubectl get clusterrolebinding eks:kube-proxy-windows`

If output similar to the following example output is returned, then the cluster has the necessary role binding.

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>eks:kube-proxy-windows</td>
<td>10d</td>
</tr>
</tbody>
</table>

If the output includes Error from server (NotFound), then the cluster does not have the necessary cluster role binding. Add the binding by creating a file named eks-kube-proxy-windows-crb.yaml with the following content.

```
kind: ClusterRoleBinding
apiVersion: rbac.authorization.k8s.io/v1beta1
metadata:
  name: eks:kube-proxy-windows
labels:
  k8s-app: kube-proxy
  eks.amazonaws.com/component: kube-proxy
subjects:
- kind: Group
  name: "eks:kube-proxy-windows"
roleRef:
  kind: ClusterRole
  name: system:node-proxier
  apiGroup: rbac.authorization.k8s.io
```
Apply the configuration to the cluster.

```bash
kubectl apply -f eks-kube-proxy-windows-crb.yaml
```

4. After you have enabled Windows support, you can launch a Windows node group into your cluster. For more information, see Launching self-managed Windows nodes (p. 125).

After you add Windows support to your cluster, you must specify node selectors on your applications so that the pods land on a node with the appropriate operating system. For Linux pods, use the following node selector text in your manifests.

```yaml
nodeSelector:
  kubernetes.io/os: linux
  kubernetes.io/arch: amd64
```

For Windows pods, use the following node selector text in your manifests.

```yaml
nodeSelector:
  kubernetes.io/os: windows
  kubernetes.io/arch: amd64
```

To enable Windows support for your cluster with a macOS or Linux client

This procedure requires that the `openssl` library and `jq` JSON processor are installed on your client system.

In the following steps, replace `<region-code>` with the Region that your cluster resides in.

1. Deploy the VPC resource controller to your cluster using the command that corresponds to the Region that your cluster is in.

   - All Regions other than China (Beijing) and China (Ningxia)
     ```bash
     ```

   - China (Beijing) and China (Ningxia)
     ```bash
     ```

2. Create the VPC admission controller webhook manifest for your cluster.

   a. Download the required scripts and deployment files for the Region that your cluster is in.

      - All Regions other than China (Beijing) and China (Ningxia)
        ```bash
        ```

      - China (Beijing) and China (Ningxia)
        ```bash
        ```
Enabling Windows support

b. Add permissions to the shell scripts so that they can be executed.

```bash
chmod +x webhook-create-signed-cert.sh webhook-patch-ca-bundle.sh
```

c. Create a secret for secure communication.

```bash
./webhook-create-signed-cert.sh
```

d. Verify the secret.

```bash
c kubectl get secret -n kube-system vpc-admission-webhook-certs
```

e. Configure the webhook and create a deployment file.

```bash
cat ./vpc-admission-webhook-deployment.yaml | ./webhook-patch-ca-bundle.sh > vpc-admission-webhook.yaml
```

3. Deploy the VPC admission webhook.

```bash
c kubectl apply -f vpc-admission-webhook.yaml
```

4. Determine if your cluster has the required cluster role binding.

```bash
c kubectl get clusterrolebinding eks:kube-proxy-windows
```

If output similar to the following example output is returned, then the cluster has the necessary role binding.

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>eks:kube-proxy-windows</td>
<td>10d</td>
</tr>
</tbody>
</table>

If the output includes `Error from server (NotFound)`, then the cluster does not have the necessary cluster role binding. Add the binding by creating a file named `eks-kube-proxy-windows-crb.yaml` with the following content.

```yaml
kind: ClusterRoleBinding
apiVersion: rbac.authorization.k8s.io/v1beta1
metadata:
  name: eks:kube-proxy-windows
  labels:
    k8s-app: kube-proxy
    eks.amazonaws.com/component: kube-proxy
subjects:
  - kind: Group
    name: "eks:kube-proxy-windows"
roleRef:
  kind: ClusterRole
```
Apply the configuration to the cluster.

```
kubectl apply -f eks-kube-proxy-windows-crb.yaml
```

5. After you have enabled Windows support, you can launch a Windows node group into your cluster. For more information, see Launching self-managed Windows nodes (p. 125).

After you add Windows support to your cluster, you must specify node selectors on your applications so that the pods land on a node with the appropriate operating system. For Linux pods, use the following node selector text in your manifests.

```
nodeSelector:
  kubernetes.io/os: linux
  kubernetes.io/arch: amd64
```

For Windows pods, use the following node selector text in your manifests.

```
nodeSelector:
  kubernetes.io/os: windows
  kubernetes.io/arch: amd64
```

### Deploy a Windows sample application

**To deploy a Windows sample application**

1. Create a file named `windows-server-iis.yaml` with the following content.

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: windows-server-iis
spec:
  selector:
    matchLabels:
      app: windows-server-iis
      tier: backend
      track: stable
  replicas: 1
  template:
    metadata:
      labels:
        app: windows-server-iis
        tier: backend
        track: stable
    spec:
      containers:
        - name: windows-server-iis
          image: mcr.microsoft.com/windows/servercore:1809
          ports:
            - name: http
              containerPort: 80
          imagePullPolicy: IfNotPresent
          command:
            - powershell.exe
            - "command
```
Inferentia support

This topic describes how to create an Amazon EKS cluster with nodes running Amazon EC2 Inf1 instances and (optionally) deploy a sample application. Amazon EC2 Inf1 instances are powered by AWS Inferentia chips, which are custom built by AWS to provide high performance and lowest cost inference in the cloud. Machine learning models are deployed to containers using AWS Neuron, a specialized software development kit (SDK) consisting of a compiler, run-time, and profiling tools that optimize the machine learning inference performance of Inferentia chips. AWS Neuron supports popular machine learning frameworks such as TensorFlow, PyTorch, and MXNet.
Considerations

- Neuron device logical IDs must be contiguous. If a pod requesting multiple Neuron devices is
  scheduled on an inf1.6xlarge or inf1.24xlarge instance type (which have more than one Neuron
device), that pod will fail to start if the Kubernetes scheduler selects non-contiguous device IDs. For
more information, see Device logical IDs must be contiguous on GitHub.
- Amazon EC2 Inf1 instances are not currently supported with managed node groups.

Prerequisites

- Have eksctl installed on your computer. If you don't have it installed, see Install eksctl (p. 6) for
installation instructions.
- Have kubectl installed on your computer. For more information, see Installing kubectl (p. 283).
- (Optional) Have python3 installed on your computer. If you don't have it installed, then see Python
downloads for installation instructions.

Create a cluster

To create a cluster with Inf1 Amazon EC2 instance nodes

1. Create a cluster with Inf1 Amazon EC2 instance nodes. You can replace <inf1.2xlarge> with any Inf1
instance type. eksctl detects that you are launching a node group with an Inf1 instance type and
will start your nodes using the EKS-optimized accelerated AMI (p. 164).

   Note
   You can't use IAM roles for service accounts (p. 330) with TensorFlow Serving.

   eksctl create cluster \
   --name <inferentia> \ 
   --version <1.16> \ 
   --region <region-code> \ 
   --nodegroup-name <ng-inf1> \ 
   --node-type <inf1.2xlarge> \ 
   --nodes <2> \ 
   --nodes-min <1> \ 
   --nodes-max <4>

   Note
   Note the value of the following line of the output. It's used in a later (optional) step.

   [#] adding identity "arn:aws:iam::<111122223333>:role/eksctl-<inferentia>-<nodegroup-ng-in>-NodeInstanceRole-<FI7HIYS3BS09>" to auth ConfigMap

   When launching a node group with Inf1 instances, eksctl automatically installs the AWS Neuron
Kubernetes device plugin. This plugin advertises Neuron devices as a system resource to the
Kubernetes scheduler, which can be requested by a container. In addition to the default Amazon EKS
node IAM policies, the Amazon S3 read only access policy is added so that the sample application,
covered in a later step, can load a trained model from Amazon S3.

2. Make sure that all pods have started correctly.

   kubectl get pods -n kube-system
**Output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws-node-kx2m8</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>5m</td>
</tr>
<tr>
<td>aws-node-q57pf</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>5m</td>
</tr>
<tr>
<td>coredns-86d5cbb4bd-56dz2</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>5m</td>
</tr>
<tr>
<td>kubeproxy-75zx6</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>5m</td>

</tr>
<tr>
<td>neuron-device-plugin-daemonset-hwjsj</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>5m</td>
</tr>
</tbody>
</table>

**(Optional) Create a Neuron TensorFlow Serving application image**

**Note**

Neuron will soon be available pre-installed in AWS Deep Learning Containers. For updates, check AWS Neuron.

1. Create an Amazon ECR repository to store your application image.

   ```bash
   aws ecr create-repository --repository-name tensorflow-model-server-neuron
   ```

   **Note** the `repositoryUri` returned in the output for use in a later step.

2. Create a Dockerfile named `Dockerfile.tf-serving` with the following contents. The Dockerfile contains the commands to build a Neuron optimized TensorFlow Serving application image. Neuron TensorFlow Serving uses the same API as normal TensorFlow Serving. The only differences are that the saved model must be compiled for Inferentia and the entry point is a different binary.

   ```bash
   FROM amazonlinux:2
   RUN yum install -y awscli
   RUN echo $'[
   
   name=Neuron YUM Repository
   baseurl=https://yum.repos.neuron.amazonaws.com
   enabled=1'] > /etc/yum.repos.d/neuron.repo
   RUN rpm --import https://yum.repos.neuron.amazonaws.com/GPG-PUB-KEY-AMAZON-AWS-NEURON.PUB
   RUN yum install -y tensorflow-model-server-neuron
   ```

3. Log your Docker client into your ECR repository.

   ```bash
   aws ecr get-login-password
   --region <region-code>
   | docker login
   --username AWS
   --password-stdin <111122223333>.dkr.ecr.<region-code>.amazonaws.com
   ```

4. Build the Docker image and upload it to the Amazon ECR repository created in a previous step.

   ```bash
   docker build . -f Dockerfile.tf-serving -t tensorflow-model-server-neuron
   docker tag tensorflow-model-server-neuron:latest <111122223333>.dkr.ecr.<region-code>.amazonaws.com/tensorflow-model-server-neuron:1.15.0
   ```
(Optional) Deploy a TensorFlow Serving application image

A trained model must be compiled to an Inferentia target before it can be deployed on Inferentia instances. To continue, you will need a Neuron optimized TensorFlow model saved in Amazon S3. If you don't already have a saved model, then you can follow the tutorial in the AWS Neuron documentation to create a Neuron compatible BERT-Large model and upload it to S3. BERT is a popular machine learning technique used for understanding natural language tasks. For more information about compiling Neuron models, see The AWS Inferentia Chip With DLAMI in the AWS Deep Learning AMI Developer Guide.

The sample deployment manifest manages two containers: The Neuron runtime container image and the TensorFlow Serving application. For more information about the Neuron container image, see Tutorial: Neuron container tools on GitHub. The Neuron runtime runs as a sidecar container image and is used to interact with the Inferentia chips on your nodes. The two containers communicate over a Unix domain socket placed in a shared mounted volume. At start-up, the application image will fetch your model from Amazon S3, launch Neuron TensorFlow Serving with the saved model, and wait for prediction requests.

The number of Inferentia devices can be adjusted using the `aws.amazon.com/neuron` resource in the Neuron runtime container specification. The runtime expects 128 2-MB pages per Inferentia device, therefore, `hugepages-2Mi` has to be set to `256 x the number of Inferentia devices`. In order to access Inferentia devices, the Neuron runtime requires `SYS_ADMIN` and `IPC_LOCK` capabilities, however, the runtime drops these capabilities at initialization, before opening a gRPC socket.

1. Add the `AmazonS3ReadOnlyAccess` IAM policy to the node instance role that was created in step 1 of Create a cluster (p. 87). This is necessary so that the sample application can load a trained model from Amazon S3.

   ```bash
   aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonS3ReadOnlyAccess
   --role-name eksctl-<inferentia>-<nodegroup-ng-in>-NodeInstanceRole-<FI7HIYS3BS09>
   ```

2. Create a file named `bert_deployment.yaml` with the contents below. Update `<111122223333>`, `<region-code>`, and `<bert/saved_model>` with your account ID, Region code, and saved model name and location. The model name is for identification purposes when a client makes a request to the TensorFlow server. This example uses a model name to match a sample BERT client script that will be used in a later step for sending prediction requests. You can also replace `<1.0.7865.0>` with a later version. For the latest version, see Neuron Runtime Release Notes on GitHub or enter the following command.

   ```bash
   aws ecr list-images --repository-name neuron-rtd --registry-id 790709498068 --region us-west-2
   ```

   ```yaml
   kind: Deployment
   apiVersion: apps/v1
   metadata:
     name: <eks-neuron-test>
   ```
app: <eks-neuron-test>
  role: master
spec:
  replicas: <2>
  selector:
    matchLabels:
      app: <eks-neuron-test>
      role: master
template:
  metadata:
    labels:
      app: <eks-neuron-test>
      role: master
  spec:
    volumes:
    - name: sock
      emptyDir: {}
    containers:
    - name: <eks-neuron-test>
      image: <111122223333>.dkr.ecr.<region-code>.amazonaws.com/tensorflow-model-server-neuron:1.15.0
      command:
        - /usr/local/bin/tensorflow_model_server_neuron
      args:
        - --port=9000
        - --rest_api_port=8500
        - --model_name=bert_mrpc_hc_gelus_b4_l24_0926_02
        - --model_base_path=s3://<bert/saved_model>
      ports:
        - containerPort: 8500
        - containerPort: 9000
      imagePullPolicy: IfNotPresent
      env:
      - name: AWS_REGION
        value: "<region-code>"
      - name: S3_USE_HTTPS
        value: "1"
      - name: S3_VERIFY_SSL
        value: "0"
      - name: AWS_LOG_LEVEL
        value: "3"
      - name: NEURON_RTD_ADDRESS
        value: unix:/sock/neuron.sock
      resources:
        limits:
          cpu: 4
          memory: 4Gi
        requests:
          cpu: "1"
          memory: 1Gi
      volumeMounts:
      - name: sock
        mountPath: /sock
      - name: neuron-rtd
        image: 790709498068.dkr.ecr.<region-code>.amazonaws.com/neuron-rtd:<1.0.7865.0>
        securityContext:
          capabilities:
            add:
              - SYS_ADMIN
              - IPC_LOCK
        volumeMounts:
        - name: sock
          mountPath: /sock
        resources:
        limits:
3. Deploy the model.

```bash
kubectl apply -f bert_deployment.yaml
```

4. Create a file named `bert_service.yaml` with the following contents. The HTTP and gRPC ports are opened for accepting prediction requests.

```yaml
kind: Service
apiVersion: v1
metadata:
  name: <eks-neuron-test>
  labels:
    app: <eks-neuron-test>
spec:
  type: ClusterIP
  ports:
    - name: http-tf-serving
      port: 8500
      targetPort: 8500
    - name: grpc-tf-serving
      port: 9000
      targetPort: 9000
  selector:
    app: <eks-neuron-test>
    role: master
```

5. Create a Kubernetes service for your TensorFlow model Serving application.

```bash
ekubectl apply -f bert_service.yaml
```

(Optional) Make predictions against your TensorFlow Serving service

1. To test locally, forward the gRPC port to the `eks-neuron-test` service.

```bash
ekubectl port-forward svc/eks-neuron-test 9000:9000 &
```

2. Download the sample BERT client from the Neuron GitHub repository.

```bash
curl https://raw.githubusercontent.com/aws/aws-neuron-sdk/master/src/examples/tensorflow/k8s_bert_demo/bert_client.py > bert_client.py
```

3. Run the script to submit predictions to your service.

```bash
python3 bert_client.py
```

Output

```bash
...  
Inference successful: 0  
Inference successful: 1
```
Viewing API server flags

You can use the control plane logging feature for Amazon EKS clusters to view the API server flags that were enabled when a cluster was created. For more information, see Amazon EKS control plane logging (p. 66). This topic shows you how to view the API server flags for an Amazon EKS cluster in the Amazon CloudWatch console.

When a cluster is first created, the initial API server logs include the flags that were used to start the API server. If you enable API server logs when you launch the cluster, or shortly thereafter, these logs are sent to CloudWatch Logs and you can view them there.

To view API server flags for a cluster

1. If you have not already done so, enable API server logs for your Amazon EKS cluster.
   a. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
   b. Choose the name of the cluster to display your cluster information.
   c. Select the Configuration tab. On the Logging tab, choose Update.
   d. For API server, make sure that the log type is Enabled.
   e. Choose Update to finish.

2. In the Amazon EKS console, scroll down to the Logging section of the cluster detail page. Choose the link under CloudWatch to open the CloudWatch console page for your cluster's logs.

3. In the list of log streams, find the earliest version of the kube-apiserver-<example-ID-288ec988b77a59d70ec77> log stream. Use the Last Event Time column to determine the log stream ages.

4. Scroll up to the earliest events (the beginning of the log stream). You should see the initial API server flags for the cluster.

   **Note**
   If you don't see the API server logs at the beginning of the log stream, then it is likely that the API server log file was rotated on the server before you enabled API server logging on the server. Any log files that are rotated before API server logging is enabled cannot be exported to CloudWatch.
   However, you can create a new cluster with the same Kubernetes version and enable the API server logging when you create the cluster. Clusters with the same platform version have the same flags enabled, so your flags should match the new cluster's flags. When you finish viewing the flags for the new cluster in CloudWatch, you can delete the new cluster.
### Private clusters

This topic describes how to deploy a private cluster without outbound internet access. If you're not familiar with Amazon EKS networking, see [De-mystifying cluster networking for Amazon EKS worker nodes](#).

### Requirements

The following requirements must be met to run Amazon EKS in a private cluster without outbound internet access.

- A container image must be in or copied to Amazon Elastic Container Registry (Amazon ECR) or to a registry inside the VPC to be pulled. For more information, see [Creating local copies of container images](#).
- Endpoint private access is required for nodes to register with the cluster endpoint. Endpoint public access is optional. For more information, see [Amazon EKS cluster endpoint access control](#).
- You may need to include the VPC endpoints found at [VPC endpoints for private clusters](#).
- You must include the following text to the bootstrap arguments when launching self-managed nodes. This text bypasses the Amazon EKS introspection and does not require access to the Amazon EKS API from within the VPC. Replace `<cluster-endpoint>` and `<cluster-certificate-authority>` with the values from your Amazon EKS cluster.
  
  ```
  --apiserver-endpoint <cluster-endpoint> --b64-cluster-ca <cluster-certificate-authority>
  ```

- The `aws-auth` ConfigMap must be created from within the VPC. For more information about create the `aws-auth` ConfigMap, see [Managing users or IAM roles for your cluster](#).

### Considerations

Here are some things to consider when running Amazon EKS in a private cluster without outbound internet access.

- AWS X-Ray is not supported with private clusters.
- Amazon CloudWatch Logs is supported with private clusters, but you must use an Amazon CloudWatch Logs VPC endpoint. For more information, see [VPC endpoints for private clusters](#).
- Self-managed and managed nodes (p. 117) are supported. The instances for nodes must have access to the VPC endpoints. If you create a managed node group, the VPC endpoint security group must allow the CIDR for the subnets, or you must add the created node security group to the VPC endpoint security group.
- [IAM roles for service accounts](#) is supported. You must include the STS VPC endpoint. For more information, see [VPC endpoints for private clusters](#).
- The [Amazon EBS CSI driver](#) is supported. Before deploying, the `kustomization.yaml` file must be changed to set the container images to use the same Region as the Amazon EKS cluster.
- The [Amazon EFS CSI driver](#) is supported. Before deploying, the `kustomization.yaml` file must be changed to set the container images to use the same Region as the Amazon EKS cluster.
- The [Amazon FSx for Lustre CSI driver](#) is not supported.
- [AWS Fargate](#) is supported with private clusters. You must include the STS VPC endpoint. For more information, see [VPC endpoints for private clusters](#). You can use the AWS load balancer controller to deploy AWS Application Load Balancers and Network Load Balancers with. The controller supports network load balancers with IP targets, which are required for use with Fargate. For more information, see the section called ”Application load balancing” (p. 265) and the section called ”Load balancer – IP targets” (p. 263).
Creating local copies of container images

Because a private cluster has no outbound internet access, container images cannot be pulled from external sources such as Docker Hub. Instead, container images must be copied locally to Amazon ECR or an alternative registry accessible in the VPC. A container image can be copied to Amazon ECR from outside the private VPC. The private cluster accesses the Amazon ECR repository using the Amazon ECR VPC endpoints. You must have Docker and the AWS CLI installed on the workstation that you use to create the local copy.

To create a local copy of a container image

1. Create an Amazon ECR repository. For more information, see Creating a repository.
2. Pull the container image from the external registry using `docker pull`.
3. Tag your image with the Amazon ECR registry, repository, and optional image tag name combination using `docker tag`.
4. Authenticate to the registry. For more information, see Registry authentication.
5. Push the image to Amazon ECR using `docker push`.

   **Note**

   Be sure to update your resource configuration to use the new image location.

The following example pulls the `amazon/aws-node-termination-handler` image, using tag `v1.3.1-linux-amd64`, from Docker Hub and creates a local copy in Amazon ECR.

```
aws ecr create-repository --repository-name amazon/aws-node-termination-handler
docker pull amazon/aws-node-termination-handler:v1.3.1-linux-amd64
docker tag amazon/aws-node-termination-handler <111122223333>.dkr.ecr.<region-code>.amazonaws.com/amazon/aws-node-termination-handler:v1.3.1-linux-amd64
aws ecr get-login-password --region <region-code> | docker login --username AWS --password-stdin <111122223333>.dkr.ecr.<region-code>.amazonaws.com
docker push <111122223333>.dkr.ecr.<region-code>.amazonaws.com/amazon/aws-node-termination-handler:v1.3.1-linux-amd64
```

VPC endpoints for private clusters

The following VPC endpoints may be required.

- `com.amazonaws.<region>.ec2`
- `com.amazonaws.<region>.ecr.api`
- `com.amazonaws.<region>.ecr.dkr`
- `com.amazonaws.<region>.s3` – For pulling container images
- `com.amazonaws.<region>.logs` – For CloudWatch Logs
- `com.amazonaws.<region>.sts` – If using AWS Fargate or IAM roles for service accounts
- `com.amazonaws.<region>.elasticloadbalancing` – If using Application Load Balancers
- `com.amazonaws.<region>.autoscaling` – If using Cluster Autoscaler
• `com.amazonaws.<region>.appmesh-envoy-management` – If using App Mesh
Amazon EKS nodes

Your Amazon EKS cluster can schedule pods on any combination of [Self-managed nodes](p. 117), Amazon EKS [Managed node groups](p. 101), and [AWS Fargate](p. 137). The following table provides several criteria to evaluate when deciding which options best meets your requirements. We recommend reviewing this page often because the data in this table changes frequently as new capabilities are introduced to Amazon EKS. To view details about any existing nodes deployed in your cluster, see [View nodes](p. 99).

<table>
<thead>
<tr>
<th>Criteria</th>
<th>EKS managed node groups</th>
<th>Self-managed nodes</th>
<th>AWS Fargate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Can be deployed to [AWS Outposts](p. 362)</td>
<td>No</td>
<td>Yes – For more information, see Amazon EKS on AWS Outposts (p. 362).</td>
<td>No</td>
</tr>
<tr>
<td>Can be deployed to [AWS Local Zones](p. 364)</td>
<td>No</td>
<td>Yes – For more information, see Amazon EKS on AWS Local Zones (p. 364).</td>
<td>No</td>
</tr>
<tr>
<td>Can run containers that require Windows</td>
<td>No</td>
<td>Yes (p. 80) – Your cluster still requires at least one (two recommended for availability) Linux node though.</td>
<td>No</td>
</tr>
<tr>
<td>Can run containers that require Linux</td>
<td>Yes</td>

View nodes

The Amazon EKS console shows information about all of your cluster’s nodes, including Amazon EKS managed nodes, self-managed nodes, and Fargate. Nodes represent the compute resources provisioned for your cluster from the perspective of the Kubernetes API. For more information, see Nodes in the Kubernetes documentation. To learn more about the different types of Amazon EKS nodes that you can deploy your workloads (p. 247) to, see Nodes (p. 96).

Prerequisites

The IAM user or IAM role that you sign into the AWS Management Console with must meet the following requirements.

- Have the eks:AccessKubernetesApi and other necessary IAM permissions to view nodes attached to it. For an example IAM policy, see the section called “View nodes and workloads for all clusters in the AWS Management Console” (p. 318).
- Is mapped to Kubernetes user or group in the aws-auth configmap. For more information, see the section called “Managing users or IAM roles for your cluster” (p. 279).
- The Kubernetes user or group that the IAM user or role is mapped to in the configmap must be bound to a Kubernetes role or clusterrole that has permissions to view the resources in the namespaces that you want to view. For more information, see Using RBAC Authorization in the Kubernetes documentation. You can download the following example manifests that create a clusterrole and clusterrolebinding or a role and rolebinding:

• **View Kubernetes resources in all namespaces** – The group name in the file is `eks-console-dashboard-full-access-group`, which is the group that your IAM user or role needs to be mapped to in the `aws-auth` configmap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the configmap. To download the file, select the appropriate link for the Region that your cluster is in.

  • **All Regions other than Beijing and Ningxia China**
  • **Beijing and Ningxia China Regions**

• **View Kubernetes resources in a specific namespace** – The namespace in this file is `default`, so if you want to specify a different namespace, edit the file before applying it to your cluster. The group name in the file is `eks-console-dashboard-restricted-access-group`, which is the group that your IAM user or role needs to be mapped to in the `aws-auth` configmap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the configmap. To download the file, select the appropriate link for the Region that your cluster is in.

  • **All Regions other than Beijing and Ningxia China**
  • **Beijing and Ningxia China Regions**

**To view nodes using the AWS Management Console**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the left navigation panel, select **Clusters**, and then in the **Clusters** list, select the cluster that you want to view compute resources for.
3. On the **Overview** tab, you see a list of all compute **Nodes** for your cluster and the nodes' status.

   **Important**
   If you can’t see any **Nodes** on the **Overview** tab, or you see a **Your current user or role does not have access to Kubernetes objects on this EKS cluster** error, see the prerequisites for this topic. If you don’t resolve the issue, you can still view and manage your Amazon EKS cluster on the **Configuration** tab, but you won’t see self-managed nodes or some of the information that you see for managed nodes and Fargate under **Nodes**.

   **Note**
   Each pod that runs on Fargate is registered as a separate Kubernetes node within the cluster. This is because Fargate runs each pod in an isolated compute environment and independently connects to the cluster control plane. For more information, see the section called “AWS Fargate” (p. 137).

4. In the **Nodes** list, you see a list of all of the managed, self-managed, and Fargate nodes for your cluster. Selecting the link for one of the nodes provides the following information about the node:

   • The Amazon EC2 **Instance type**, **Kernel version**, **Kubelet version**, **Container runtime**, **OS** and **OS image** for managed and self-managed nodes.
   • Deep links to the Amazon EC2 console and the Amazon EKS managed node group (if applicable) for the node.
   • The **Resource allocation**, which shows baseline and allocatable capacity for the node.
   • **Conditions** describe the current operational status of the node. This is useful information for troubleshooting issues on the node.

   Conditions are reported back to the Kubernetes control plane by the Kubernetes agent **kubelet** that runs locally on each node. For more information, see **kubelet** in the Kubernetes documentation. Conditions on the node are always reported as part of the node detail and the **Status** of each condition along with its **Message** indicates the health of the node for that condition. The following common conditions are reported for a node:

   • **Ready** – This condition is **TRUE** if the node is healthy and can accept pods. The condition is **FALSE** if the node is not ready and will not accept pods. **UNKNOWN** indicates that the
Kubernetes control plane has not recently received a heartbeat signal from the node. The heartbeat timeout period is set to the Kubernetes default of 40 seconds for Amazon EKS clusters.

- **Memory pressure** – This condition is **FALSE** under normal operation and **TRUE** if node memory is low.
- **Disk pressure** – This condition is **FALSE** under normal operation and **TRUE** if disk capacity for the node is low.
- **PID pressure** – This condition is **FALSE** under normal operation and **TRUE** if there are too many processes running on the node. On the node, each container runs as a process with a unique Process ID, or PID.
- **NetworkUnavailable** – This condition is **FALSE**, or not present, under normal operation. If **TRUE**, the network for the node is not properly configured.

- The Kubernetes **Labels** and **Annotations** assigned to the node. These could have been assigned by you, by Kubernetes, or by the Amazon EKS API when the node was created. These values can be used by your workloads for scheduling pods.

### Managed node groups

Amazon EKS managed node groups automate the provisioning and lifecycle management of nodes (Amazon EC2 instances) for Amazon EKS Kubernetes clusters.

With Amazon EKS managed node groups, you don’t need to separately provision or register the Amazon EC2 instances that provide compute capacity to run your Kubernetes applications. You can create, update, or terminate nodes for your cluster with a single operation. Nodes run using the latest Amazon EKS optimized AMIs in your AWS account. Node updates and terminations gracefully drain nodes to ensure that your applications stay available.

All managed nodes are provisioned as part of an Amazon EC2 Auto Scaling group that’s managed for you by Amazon EKS. All resources including the instances and Auto Scaling groups run within your AWS account. Each node group uses the Amazon EKS optimized Amazon Linux 2 AMI and can run across multiple Availability Zones that you define.

You can add a managed node group to new or existing clusters using the Amazon EKS console, eksctl, AWS CLI, AWS API, or infrastructure as code tools including AWS CloudFormation. Nodes launched as part of a managed node group are automatically tagged for auto-discovery by the Kubernetes cluster autoscaler. You can use the node group to apply Kubernetes labels to nodes and update them at any time.

There are no additional costs to use Amazon EKS managed node groups, you only pay for the AWS resources you provision. These include Amazon EC2 instances, Amazon EBS volumes, Amazon EKS cluster hours, and any other AWS infrastructure. There are no minimum fees and no upfront commitments.

To get started with a new Amazon EKS cluster and managed node group, see [Getting started with the AWS Management Console](#). To add a managed node group to an existing cluster, see [Creating a managed node group](#).

### Managed node groups concepts

- Amazon EKS managed node groups create and manage Amazon EC2 instances for you.
- All managed nodes are provisioned as part of an Amazon EC2 Auto Scaling group that’s managed for you by Amazon EKS. Moreover, all resources including Amazon EC2 instances and Auto Scaling groups run within your AWS account.
A managed node group's Auto Scaling group spans all of the subnets that you specify when you create the group.

Amazon EKS tags managed node group resources so that they are configured to use the Kubernetes Cluster Autoscaler (p. 61).

**Important**

If you are running a stateful application across multiple Availability Zones that is backed by Amazon EBS volumes and using the Kubernetes Cluster Autoscaler (p. 61), you should configure multiple node groups, each scoped to a single Availability Zone. In addition, you should enable the --balance-similar-node-groups feature.

By default, instances in a managed node group use the latest version of the Amazon EKS optimized Amazon Linux 2 AMI for its cluster's Kubernetes version. You can choose between standard and GPU variants of the Amazon EKS optimized Amazon Linux 2 AMI. If you deploy using a launch template, you can also use a custom AMI. For more information, see Launch template support (p. 112).

Amazon EKS follows the shared responsibility model for CVEs and security patches on managed node groups. When managed nodes run an Amazon EKS optimized AMI, Amazon EKS is responsible for building patched versions of the AMI when bugs or issues are reported. We can publish a fix. However, you're responsible for deploying these patched AMI versions to your managed node groups. When managed nodes run a custom AMI, you're responsible for building patched versions of the AMI when bugs or issues are reported and then deploying the AMI. For more information, see Updating a managed node group (p. 109).

Amazon EKS managed node groups can be launched in both public and private subnets. If you launch a managed node group in a public subnet on or after April 22, 2020, the subnet must have MapPublicIpOnLaunch set to true for the instances to successfully join a cluster. If the public subnet was created using eksctl or the Amazon EKS vended AWS CloudFormation templates (p. 198) on or after March 26, 2020, then this setting is already set to true. If the public subnets were created before March 26, 2020, then you need to change the setting manually. For more information, see Modifying the public IPv4 addressing attribute for your subnet.

When using VPC endpoints in private subnets, you must create endpoints for com.amazonaws.region.ecr.api, com.amazonaws.region.ecr.dkr, and a gateway endpoint for Amazon S3. For more information, see Amazon ECR interface VPC endpoints (AWS PrivateLink).

Managed node groups can't be deployed to nodes on AWS Outposts (p. 362) or to nodes deployed in AWS Wavelength or AWS Local Zones.

You can create multiple managed node groups within a single cluster. For example, you can create one node group with the standard Amazon EKS optimized Amazon Linux 2 AMI for some workloads and another with the GPU variant for workloads that require GPU support.

If your managed node group encounters a health issue, Amazon EKS returns an error message to help you to diagnose the issue. For more information, see Managed node group errors (p. 368).

Amazon EKS adds Kubernetes labels to managed node group instances. These Amazon EKS provided labels are prefixed with eks.amazonaws.com.

Amazon EKS automatically drains nodes using the Kubernetes API during terminations or updates. Updates respect the pod disruption budgets that you set for your pods.

There are no additional costs to use Amazon EKS managed node groups. You only pay for the AWS resources that you provision.

### Managed node group capacity types

When creating a managed node group, you can choose either the On-Demand or Spot capacity type. Amazon EKS deploys a managed node group with an Amazon EC2 Auto Scaling Group that either contains only On-Demand or only Amazon EC2 Spot Instances. You can schedule pods for fault tolerant applications to Spot managed node groups, and fault intolerant applications to On-Demand node groups within a single Kubernetes cluster. By default, a managed node group deploys On-Demand Amazon EC2 instances.
On-Demand

With On-Demand Instances, you pay for compute capacity by the second, with no long-term commitments.

How it works

By default, if you don’t specify a **Capacity Type**, the managed node group is provisioned with On-Demand Instances. A managed node group configures an Amazon EC2 Auto Scaling group on your behalf with the following settings applied:

- The allocation strategy to provision On-Demand capacity is set to **prioritized**. Managed node groups use the order of instance types passed in the API to determine which instance type to use first when fulfilling On-Demand capacity. For example, you might specify three instance types in the following order: `c5.large`, `c4.large`, and `c3.large`. When your On-Demand Instances are launched, the managed node group fulfills On-Demand capacity by starting with `c5.large`, then `c4.large`, and then `c3.large`. For more information, see Amazon EC2 Auto Scaling group in the Amazon EC2 Auto Scaling User Guide.
- Amazon EKS adds the following Kubernetes label to all nodes in your managed node group that specifies the capacity type: `eks.amazonaws.com/capacityType: ON_DEMAND`. You can use this label to schedule stateful or fault intolerant applications on On-Demand nodes.

Spot

Amazon EC2 Spot Instances are spare Amazon EC2 capacity that offers steep discounts off of On-Demand prices. Amazon EC2 Spot Instances can be interrupted with a two-minute interruption notice when EC2 needs the capacity back. For more information, see Spot Instances in the Amazon EC2 User Guide for Linux Instances. You can configure a managed node group with Amazon EC2 Spot Instances to optimize costs for the compute nodes running in your Amazon EKS cluster.

How it works

To use Spot Instances inside a managed node group, you need to create a managed node group by setting the capacity type as **spot**. A managed node group configures an Amazon EC2 Auto Scaling group on your behalf with the following Spot best practices applied:

- The allocation strategy to provision Spot capacity is set to **capacity-optimized** to ensure that your Spot nodes are provisioned in the optimal Spot capacity pools. To increase the number of Spot capacity pools available for allocating capacity from, we recommend that you configure a managed node group to use multiple instance types.
- Amazon EC2 Spot Capacity Rebalancing is enabled so that Amazon EKS can gracefully drain and rebalance your Spot nodes to minimize application disruption when a Spot node is at elevated risk of interruption. For more information, see Amazon EC2 Auto Scaling Capacity Rebalancing in the Amazon EC2 Auto Scaling User Guide.
- When a Spot node receives a rebalance recommendation, Amazon EKS automatically attempts to launch a new replacement Spot node and waits until it successfully joins the cluster.
- When a replacement Spot node is bootstrapped and in the **Ready** state on Kubernetes, Amazon EKS cordon and drains the Spot node that received the rebalance recommendation. Cordon the Spot node ensures that the service controller doesn’t send any new requests to this Spot node. It also removes it from its list of healthy, active Spot nodes. Draining the Spot node ensures that running pods are evicted gracefully.
- If a Spot two-minute interruption notice arrives before the replacement Spot node is in a Ready state, Amazon EKS starts draining the Spot node that received the rebalance recommendation.
- Amazon EKS adds the following Kubernetes label to all nodes in your managed node group that specifies the capacity type: `eks.amazonaws.com/capacityType: SPOT`. You can use this label to schedule fault tolerant applications on Spot nodes.
Considerations for selecting a capacity type

When deciding whether to deploy a node group with On-Demand or Spot capacity, you should consider the following conditions:

- Spot Instances are a good fit for stateless, fault-tolerant, flexible applications such as batch and machine learning training workloads, big data ETLs such as Apache Spark, queue processing applications, and stateless API endpoints. Because Spot is spare Amazon EC2 capacity, which can change over time, we recommend that you use Spot capacity for interruption-tolerant workloads that can tolerate periods where the required capacity is not available.

- We recommend that you use On-Demand for applications that are fault intolerant, including cluster management tools such as monitoring and operational tools, deployments that require StatefulSets, and stateful applications, such as databases.

- To maximize the availability of your applications while using Spot Instances, we recommend that you configure a Spot managed node group to use multiple instance types. We recommend applying the following rules when using multiple instance types:

  - Within a managed node group, if you're using the section called “Cluster Autoscaler” (p. 61), we recommend using a flexible set of instance types with the same amount of vCPU and memory resources to ensure that the nodes in your cluster scale as expected. For example, if you need four vCPUs and eight GiB memory, we recommend that you use c3.xlarge, c4.xlarge, c5.xlarge, c5d.xlarge, c5a.xlarge, c5n.xlarge, or other similar instance types.

  - To enhance application availability, we recommend deploying multiple Spot managed node groups, each using a flexible set of instance types that have the same vCPU and memory resources. For example, if you need 4 vCPUs and 8 GiB memory, we recommend that you create one managed node group with c3.xlarge, c4.xlarge, c5.xlarge, c5d.xlarge, c5a.xlarge, c5n.xlarge, or other similar instance types, and a second managed node group with m3.xlarge, m4.xlarge, m5.xlarge, m5d.xlarge, m5a.xlarge, m5n.xlarge, or other similar instance types.

  - When deploying your node group with the Spot capacity type that's using a custom launch template, use the API to pass multiple instance types instead of passing a single instance type through the launch template. For more information about deploying a node group using a launch template, see the section called “Launch template support” (p. 112).

Creating a managed node group

This topic describes how you can launch an Amazon EKS managed node group of Linux nodes that register with your Amazon EKS cluster. After the nodes join the cluster, you can deploy Kubernetes applications to them.

If this is your first time launching an Amazon EKS managed node group, we recommend that you follow one of our Getting started with Amazon EKS (p. 4) guides instead. The guides provide walkthroughs for creating an Amazon EKS cluster with nodes.

Important

Amazon EKS nodes are standard Amazon EC2 instances. You're billed based on the normal Amazon EC2 prices. For more information, see Amazon EC2 Pricing.

You can create a managed node group with eksctl (p. 104) or the AWS Management Console (p. 106).

To create a managed node group with eksctl

This procedure requires eksctl version 0.35.0 or later. You can check your version with the following command:

```
eksctl version
```
For more information on installing or upgrading eksctl, see Installing or upgrading eksctl (p. 292).

Do not use eksctl to create a cluster or nodes in an AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled. Create a cluster and self-managed nodes using the Amazon EC2 API or AWS CloudFormation instead. For more information, see To launch self-managed Linux nodes using the AWS Management Console (p. 119) and To launch self-managed Windows nodes using the AWS Management Console (p. 126).

You can create your node group with or without a launch template. A launch template allows for greater customization of a node group, to include deploying a custom AMI. Complete one of the following steps.

1. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy is attached to your the section called “Node IAM role” (p. 326), we recommend assigning it to an IAM role that you associate to the Kubernetes aws-node service account instead. For more information, see Configuring the VPC CNI plugin to use IAM roles for service accounts (p. 211).

2. Create your managed node group without a launch template with the following eksctl command, replacing the <example values> (including the <> with your own values. When you don't specify your own launch template, eksctl creates a default Amazon EC2 launch template in your account and deploys the node group using a launch template that it creates based on options you specify.

   If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current Region, then we recommend blocking pod access to IMDS. For more information, see the section called “IAM roles for service accounts” (p. 330) and the section called “Restricting access to the instance profile” (p. 349). If you want to block pod access to IMDS, then add the --disable-pod-imds option to the following command.

   ```
   eksctl create nodegroup \
   --cluster <my-cluster> \
   --region <us-west-2> \
   --name <my-mng> \
   --node-type <m5.large> \
   --nodes <3> \
   --nodes-min <2> \
   --nodes-max <4> \
   --ssh-access \
   --ssh-public-key <my-public-key.pub> \
   --managed
   ```

3. Create your managed node group with a launch template. The launch template must already exist and must meet the requirements specified in Launch template configuration basics (p. 113). If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current Region, then we recommend blocking pod access to IMDS. For more information, see the section called “IAM roles for service accounts” (p. 330) and the section called “Restricting access to the instance profile” (p. 349). If you want to block pod access to IMDS, then specify the necessary settings in the launch template.

   a. Create a file with the following contents, replacing the <example values> (including <> with your own values. Several settings that you specify when deploying without a launch template are moved into the launch template. If you don't specify a version, the template's default version is used.
Creating a managed node group

```
apiVersion: eksctl.io/v1alpha5
type: ClusterConfig
metadata:
  name: <my-cluster>
  region: <region-code>
managedNodeGroups:
  - name: <node-group-name>
    launchTemplate:
      id: lt-<id>
      version: "<1>"
```

b. Deploy the nodegroup with the following command.

```
eksctl create nodegroup --config-file <filename-you-used-in-previous-step>
```

To create your managed node group using the AWS Management Console

1. Wait for your cluster status to show as ACTIVE. You cannot create a managed node group for a cluster that is not yet ACTIVE.
2. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
3. Choose the name of the cluster that you want to create your managed node group in.
4. Select the Configuration tab.
5. On the Configuration tab, select the Compute tab, and then choose Add Node Group.
6. On the Configure node group page, fill out the parameters accordingly, and then choose Next.
   - **Name** – Enter a unique name for your managed node group.
   - **Node IAM role name** – Choose the node instance role to use with your node group. For more information, see Amazon EKS node IAM role (p. 326).

   **Important**
   We recommend using a role that is not currently in use by any self-managed node group, or that you plan to use with a new self-managed node group. For more information, see Deleting a managed node group (p. 116).

   - **Use launch template** – (Optional) Choose if you want to use an existing launch template and then select a Launch template version (Optional). If you don't select a version, then Amazon EKS uses the template's default version. Launch templates allow for more customization of your node group, including allowing you to deploy a custom AMI. The launch template must meet the requirements in Launch template support (p. 112). If you don't use your own launch template, the Amazon EKS API creates a default Amazon EC2 launch template in your account and deploys the node group using the default launch template. If you implement IAM roles for service accounts (p. 330), assign necessary permissions directly to all pods that require access to AWS services, and no pods in your cluster require access to IMDS for other reasons, such as retrieving the current Region, then you can also disable access to IMDS for pods that don't use host networking in a launch template. For more information, see the section called “Restricting access to the instance profile” (p. 349).

   - **Kubernetes labels** – (Optional) You can choose to apply Kubernetes labels to the nodes in your managed node group.

   - **Tags** – (Optional) You can choose to tag your Amazon EKS managed node group. These tags do not propagate to other resources in the node group, such as Auto Scaling groups or instances. For more information, see Tagging your Amazon EKS resources (p. 303).
7. On the Set compute and scaling configuration page, fill out the parameters accordingly, and then choose Next.
Node group compute configuration

- **AMI type** – Choose Amazon Linux 2 (AL2_x86_64) for non-GPU instances, Amazon Linux 2 GPU Enabled (AL2_x86_64_GPU) for GPU instances, or Amazon Linux 2 (AL2_ARM_64) for Arm.

  If you are deploying Arm instances, be sure to review the considerations in the section called "Arm" (p. 161) before deploying.

  If you specified a launch template on the previous page, and specified an AMI in the launch template, then you cannot select a value. The value from the template is displayed. The AMI specified in the template must meet the requirements in Using a custom AMI (p. 115).

- **Capacity type** – Select a capacity type. For more information about choosing a capacity type, see the section called "Managed node group capacity types" (p. 102). You cannot mix different capacity types within the same node group. If you want to use both capacity types, create separate node groups, each with their own capacity and instance types.

- **Instance type** – One or more instance type is specified by default. To remove a default instance type, select the X on the right side of the instance type. Choose the instance types to use in your managed node group. The console displays a set of commonly used instance types. If you need to create a managed node group with an instance type that is not displayed, then use eksctl, the AWS CLI, AWS CloudFormation, or an SDK to create the node group. If you specified a launch template on the previous page, then you cannot select a value because it must be specified in the launch template. The value from the launch template is displayed. If you selected Spot for **Capacity type**, then we recommend specifying multiple instance types to enhance availability. For more information about selecting instance types, see Considerations in the section called “Managed node group capacity types” (p. 102).

  Each Amazon EC2 instance type supports a maximum number of elastic network interfaces (ENIs) and each ENI supports a maximum number of IP addresses. Since each worker node and pod is assigned its own IP address it's important to choose an instance type that will support the maximum number of pods that you want to run on each worker node. For a list of the number of ENIs and IP addresses supported by instance types, see IP addresses per network interface per instance type. For example, the m5.large instance type supports a maximum of 30 IP addresses for the worker node and pods. Some instance types might not be available in all Regions.

  If you plan to use Security groups for pods (p. 214), then make sure to specify a supported Amazon EC2 instance type. For more information, see Amazon EC2 supported instances and branch network interfaces (p. 218). If specifying an Arm Amazon EC2 instance type, then review the considerations in Amazon EKS optimized Arm Amazon Linux AMIs (p. 161) before deploying.

- **Disk size** – Enter the disk size (in GiB) to use for your node's root volume.

  If you specified a launch template on the previous page, then you cannot select a value because it must be specified in the launch template.

Node group scaling configuration

- **Note**

  Amazon EKS does not automatically scale your node group in or out. However, you can configure the Kubernetes Cluster Autoscaler (p. 61) to do this for you.

- **Minimum size** – Specify the minimum number of nodes that the managed node group can scale in to.

- **Maximum size** – Specify the maximum number of nodes that the managed node group can scale out to.

- **Desired size** – Specify the current number of nodes that the managed node group should maintain at launch.
8. On the **Specify networking** page, fill out the parameters accordingly, and then choose **Next**.

- **Subnets** – Choose the subnets to launch your managed nodes into.
  
  **Important**
  
  If you are running a stateful application across multiple Availability Zones that is backed by Amazon EBS volumes and using the Kubernetes Cluster Autoscaler (p. 61), you should configure multiple node groups, each scoped to a single Availability Zone. In addition, you should enable the `--balance-similar-node-groups` feature.
  
  **Important**
  
  - If you choose a public subnet, then the subnet must have `MapPublicIpOnLaunch` set to true for the instances to be able to successfully join a cluster. If the subnet was created using `eksctl` or the Amazon EKS vended AWS CloudFormation templates (p. 198) on or after March 26, 2020, then this setting is already set to true. If the subnets were created with `eksctl` or the AWS CloudFormation templates before March 26, 2020, then you need to change the setting manually. For more information, see [Modifying the public IPv4 addressing attribute for your subnet](#).

- **Allow remote access to nodes** (Optional, but default). Enabling SSH allows you to connect to your instances and gather diagnostic information if there are issues. Complete the following steps to enable remote access. We highly recommend enabling remote access when you create your node group. You cannot enable remote access after the node group is created.

  If you chose to use a launch template, then this option isn’t shown. To enable remote access to your nodes, specify a key pair in the launch template and ensure that the proper port is open to the nodes in the security groups that you specify in the launch template. For more information, see [Using custom security groups](#).

- For **SSH key pair** (Optional), choose an Amazon EC2 SSH key to use. For more information, see [Amazon EC2 key pairs](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/EC2-ControlPlane.html) in the Amazon EC2 User Guide for Linux Instances. If you chose to use a launch template, then you can’t select one.

- For **Allow remote access from**, if you want to limit access to specific instances, then select the security groups that are associated to those instances. If you don’t select specific security groups, then SSH access is allowed from anywhere on the internet (0.0.0.0/0).

9. On the **Review and create** page, review your managed node group configuration and choose **Create**.

   If nodes fail to join the cluster, then see [Nodes fail to join cluster](#) in the Troubleshooting guide.

10. Watch the status of your nodes and wait for them to reach the **Ready** status.

```
kubectl get nodes --watch
```

11. (GPU nodes only) If you chose a GPU instance type and the Amazon EKS optimized accelerated AMI, then you must apply the [NVIDIA device plugin for Kubernetes](https://github.com/NVIDIA/k8s-device-plugin/releases) as a DaemonSet on your cluster with the following command.

```
kubectl apply -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.6.0/nvidia-device-plugin.yml
```

12. (Optional) **Deploy a sample Linux workload** (p. 249) – Deploy a sample application to test your cluster and Linux nodes.

13. (Optional) After you add Linux worker nodes to your cluster, follow the procedures in [Windows support](#) to add Windows support to your cluster and to add Windows worker nodes. All
Amazon EKS User Guide

Updating a managed node group

Amazon EKS clusters must contain at least one Linux worker node, even if you only want to run Windows workloads in your cluster.

Now that you have a working Amazon EKS cluster with nodes, you're ready to start installing Kubernetes add-ons and deploying applications to your cluster. The following documentation topics help you to extend the functionality of your cluster.

- **Restrict access to IMDS (p. 349)** – If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current Region, then we recommend blocking pod access to IMDS. For more information, see the section called “IAM roles for service accounts” (p. 330) and the section called “Restricting access to the instance profile” (p. 349).
- **Cluster Autoscaler (p. 61)** – Configure the Kubernetes Cluster Autoscaler to automatically adjust the number of nodes in your node groups.
- **Deploy a sample Linux workload (p. 249)** – Deploy a sample application to test your cluster and Linux nodes.
- **Deploy a Windows sample application (p. 85)** – Deploy a sample application to test your cluster and Windows nodes.
- **Cluster management (p. 283)** – Learn how to use important tools for managing your cluster.

**Updating a managed node group**

There are several scenarios where it's useful to update your Amazon EKS managed node group's version or configuration:

- You have updated the Kubernetes version for your Amazon EKS cluster and want to update your nodes to use the same Kubernetes version.
- A new AMI release version is available for your managed node group. For more information about AMI versions, see Amazon EKS optimized Amazon Linux AMI versions (p. 161).
- You want to adjust the minimum, maximum, or desired count of the instances in your managed node group.
- You want to add or remove Kubernetes labels from the instances in your managed node group.
- You want to add or remove AWS tags from your managed node group.
- You need to deploy a new version of a launch template with configuration changes, such as an updated custom AMI.

If there's a newer AMI release version for your managed node group's Kubernetes version, you can update your node group's version to use the newer AMI version. Similarly, if your cluster is running a Kubernetes version that's newer than your node group, you can update the node group to use the latest AMI release version to match your cluster's Kubernetes version.

**Note**

You can't roll back a node group to an earlier Kubernetes version or AMI version.

When a node in a managed node group is terminated due to a scaling action or update, the pods in that node are drained first. For more information, see Managed node update behavior (p. 112).

**Update a node group version**

You can update a node group version with the AWS Management Console (p. 110) or eksctl (p. 110).
To update a node group version with the AWS Management Console

1. (Optional) If you’re using the Kubernetes Cluster Autoscaler, scale the deployment down to zero replicas to avoid conflicting scaling actions.

   ```bash
   kubectl scale deployments/cluster-autoscaler --replicas=0 -n kube-system
   ```

2. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.

3. Choose the cluster that contains the node group to update.

4. If at least one of your node groups that was deployed with an Amazon EKS optimized AMI has an update available, you’ll see a notification under the cluster name. The notification lets you know how many of your node groups have an update available. In the Node Groups table on the Compute tab of the Configuration tab, you will see Update now to the right of these values:

   - The value in the AMI release version column for each node group that has an Amazon EKS optimized AMI update available. If a node group is deployed with a custom AMI, this option won’t appear. If your nodes are deployed with a custom AMI, you should follow these steps to deploy a new updated custom AMI. First, create a new version of your AMI, then create a new launch template version with the new AMI ID, and last upgrade the nodes to the new version of the launch template. To do this, select Update now for a node group that you want to update.
   - The value in the Launch template column for each node group that’s deployed with a launch template. Select Update now for a node group that you want to update the launch template version for.

   If you select a node group from the table and an update is available for it, you’ll receive a notification on the Node Group configuration page. On this page, you can choose Update now.

5. On the Update Node Group version page, select:

   - **Update Node Group version** – This option is unavailable if you deployed a custom AMI or your EKS optimized AMI is already currently on the latest version for your cluster.
   - **Launch template version** – This option is unavailable if the node group is deployed without a custom launch template. You can only update the launch template version for a node group that has been deployed with a custom launch template. Select the version that you want to update the node group to. If your node group is configured with a custom AMI, then the version that you select must also specify an AMI. When you upgrade to a newer version of your launch template, all of your nodes are recycled to match the new configuration of the launch template version specified.

6. For **Update strategy**, select one of the following options and then choose Update.

   - **Rolling update** – This option respects the pod disruption budgets for your cluster. Updates fail if there is a pod disruption budget issue that causes Amazon EKS to be unable to gracefully drain the pods that are running on this node group.
   - **Force update** – This option doesn’t respect pod disruption budgets. Updates occur regardless of pod disruption budget issues by forcing node restarts to occur.

7. (Optional) If you use the Kubernetes Cluster Autoscaler, scale the deployment back to your desired number of replicas.

   ```bash
   kubectl scale deployments/cluster-autoscaler --replicas=<1> -n kube-system
   ```

To update a node group version with `eksctl`

1. (Optional) If you’re using the Kubernetes Cluster Autoscaler, scale the deployment down to zero replicas to avoid conflicting scaling actions.
Updating a managed node group

kubectl scale deployments/cluster-autoscaler --replicas=0 -n kube-system

2. Upgrade a managed node group to the latest AMI release of the same Kubernetes version that's currently deployed on the nodes with the following command.

```bash
eksctl upgrade nodegroup --name=<node-group-name> --cluster=<cluster-name>
```

**Note**
If you're upgrading a node group that's deployed with a launch template to a new launch template version, add `--launch-template=<version>` to the preceding command. The launch template must meet the requirements described in Launch template support (p. 112). If the launch template includes a custom AMI, the AMI must meet the requirements in Using a custom AMI (p. 115). When you upgrade your node group to a newer version of your launch template, all of your nodes are recycled to match the new configuration of the launch template version that's specified.

You can't directly upgrade a node group that's deployed without a launch template to a new launch template version. Instead, you must deploy a new node group using the launch template to update the node group to a new launch template version.

You can upgrade a node group to a version that's one minor release later than the node group's current Kubernetes version, but the version can't be later than the cluster's Kubernetes version. For example, if you have a cluster running Kubernetes 1.18, you can upgrade nodes currently running Kubernetes 1.17 to version 1.18 with the following command.

```bash
eksctl upgrade nodegroup --name=<node-group-name> --cluster=<cluster-name> --kubernetes-version=1.18
```

3. (Optional) If you use the Kubernetes Cluster Autoscaler, scale the deployment back to your desired number of replicas.

```bash
kubectl scale deployments/cluster-autoscaler --replicas=1 -n kube-system
```

---

**Edit a node group configuration**

You can modify some of the configurations of a managed node group.

**To edit a node group configuration**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster that contains the node group to edit.
3. Select the **Configuration** tab. On the **Compute** tab, select the node group to edit, and choose **Edit**.
4. (Optional) On the **Edit node group** page, edit the **Group configuration**.
   - **Tags** – Add tags to or remove tags from your node group resource. These tags are only applied to the Amazon EKS node group. They do not propagate to other resources, such as subnets or Amazon EC2 instances in the node group.
   - **Kubernetes labels** – Add or remove Kubernetes labels to the nodes in your node group. The labels shown here are only the labels that you have applied with Amazon EKS. Other labels may exist on your nodes that aren't shown here.
5. (Optional) On the **Edit node group** page, edit the **Group size**.
   - **Minimum size** – Specify the minimum number of nodes that the managed node group can scale in to.
• **Maximum size** – Specify the maximum number of nodes that the managed node group can scale out to. Managed node groups can support up to 100 nodes by default.

• **Desired size** – Specify the current number of nodes that the managed node group should maintain.

6. When you're finished editing, choose **Save changes**.

**Managed node update behavior**

When you update a managed node group version to the latest AMI release version for your node group's Kubernetes version or to a newer Kubernetes version to match your cluster, Amazon EKS triggers the following logic:

1. Amazon EKS creates a new Amazon EC2 launch template version for the Auto Scaling group associated with your node group. The new template uses the target AMI for the update.
2. The Auto Scaling group is updated to use the latest launch template with the new AMI.
3. The Auto Scaling group maximum size and desired size are incremented by one up to twice the number of Availability Zones in the Region that the Auto Scaling group is deployed in. This is to ensure that at least one new instance comes up in every Availability Zone in the Region that your node group is deployed in.
4. Amazon EKS checks the nodes in the node group for the `eks.amazonaws.com/nodegroup-image` label, and applies a `eks.amazonaws.com/nodegroup=unschedulable:NoSchedule` taint on all of the nodes in the node group that aren't labeled with the latest AMI ID. This prevents nodes that have already been updated from a previous failed update from being tainted.
5. Amazon EKS randomly selects a node in the node group and evicts all pods from it.
6. After all of the pods are evicted, Amazon EKS cordons the node. This is done so that the service controller doesn’t send any new request to this node and removes this node from its list of healthy, active nodes.
7. Amazon EKS sends a termination request to the Auto Scaling group for the cordoned node.
8. Steps 5-7 are repeated until there are no nodes in the node group that are deployed with the earlier version of the launch template.
9. The Auto Scaling group maximum size and desired size are decremented by 1 to return to your pre-update values.

**Launch template support**

Managed node groups are always deployed with an Amazon EC2 Auto Scaling Group launch template. If you don't specify your own launch template to use when creating a managed node group, the Amazon EKS API creates a launch template with default values in your account. Creating your own launch template and a managed node group from that template has the benefit of providing you with a greater level of flexibility and customization when deploying managed nodes than is provided by the default launch template. For the highest level of customization, you can deploy managed nodes using your own launch template and a custom AMI.

After you've deployed a managed node group with your own launch template, you can then update it with a different version of the same launch template. When you update your node group to a different version of your launch template, all of the nodes in the group are recycled to match the new configuration of the specified launch template version. Existing node groups that do not use a custom launch template can't be updated directly. Rather, you must create a new node group with a custom launch template to do so.
Launch template configuration basics

You can create an Amazon EC2 Auto Scaling launch template with the AWS Management Console, AWS CLI, or an AWS SDK. For more information, see Creating a Launch Template for an Auto Scaling Group in the Amazon EC2 User Guide. Some of the settings in a launch template are similar to the settings used for managed node configuration. When deploying or updating a node group with a launch template, some settings must be specified in the node group configuration or the launch template, but not both. If a setting exists where it shouldn't, then operations such as creating or updating a node group fail.

The following table lists the settings that are prohibited in a launch template and which similar settings (if any) are required in the managed node group configuration. The listed settings are the settings that appear in the console. They might have similar but different names in the AWS CLI and SDK.

<table>
<thead>
<tr>
<th>Launch template – Prohibited</th>
<th>Amazon EKS node group configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAM instance profile under Advanced details</td>
<td>Node IAM Role under Node Group configuration on the Configure Node Group page</td>
</tr>
<tr>
<td>Subnet under Network interfaces (Add network interface)</td>
<td>Subnets under Node Group network configuration on the Specify networking page</td>
</tr>
<tr>
<td>Shutdown behavior and Stop - Hibernate behavior under Advanced details. Retain default Don't include in launch template setting in launch template for both settings.</td>
<td>No equivalent. Amazon EKS must control the instance lifecycle, not the Auto Scaling group.</td>
</tr>
</tbody>
</table>

The following table lists the settings that are prohibited in a managed node group configuration and which similar settings (if any) are required in a launch template. The listed settings are the settings that appear in the console. They might have similar names in the AWS CLI and SDK.

<table>
<thead>
<tr>
<th>Amazon EKS node group configuration – Prohibited</th>
<th>Launch template</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Only if you specified a custom AMI in a launch template) AMI type under Node Group compute configuration on Set compute and scaling configuration page – Console displays Specified in launch template and the AMI ID that was specified.</td>
<td>AMI under Launch template contents – You must specify if you're using a custom AMI. If you specify an AMI that doesn't meet the requirements listed in Using a custom AMI (p. 115), the node group deployment will fail.</td>
</tr>
<tr>
<td>If an AMI type was not specified in the launch template, then you can select an AMI in the node group configuration.</td>
<td></td>
</tr>
<tr>
<td>Disk size under Node Group compute configuration on Set compute and scaling configuration page – Console displays Specified in launch template.</td>
<td>Size under Storage (Volumes) (Add new volume). You must specify this in the launch template.</td>
</tr>
<tr>
<td>SSH key pair under Node Group configuration on the Specify Networking page – The console displays the key that was specified in the launch template or displays Not specified in launch template.</td>
<td>Key pair name under Key pair (login).</td>
</tr>
</tbody>
</table>
### Amazon EKS node group configuration – Prohibited

You can’t specify source security groups that are allowed remote access when using a launch template.

<table>
<thead>
<tr>
<th>Amazon EKS node group configuration – Prohibited</th>
<th>Launch template</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security groups under <strong>Network settings</strong> for the instance or <strong>Security groups</strong> under <strong>Network interfaces</strong> (<strong>Add network interface</strong>), but not both. For more information, see Using custom security groups (p. 114).</td>
<td></td>
</tr>
</tbody>
</table>

**Note**

- If you deploy a node group using a launch template, then you can specify zero or one **Instance type** under **Launch template contents** in a launch template or you can specify 0-20 instance types for **Instance types** on the **Set compute and scaling configuration** page in the console, or using other tools that use the Amazon EKS API. If you specify an instance type in a launch template, and use that launch template to deploy your node group, then you can’t specify any instance types in the console or using other tools that use the Amazon EKS API. If you don’t specify an instance type in a launch template, in the console, or using other tools that use the Amazon EKS API, then the `t3.medium` instance type is used, by default. If your node group is using the Spot capacity type, then we recommend specifying multiple instance types using the console. For more information, see the section called “Managed node group capacity types” (p. 102).

- If any containers that you deploy to the node group use the Instance Metadata Service Version 2, then make sure to set the **Metadata response hop limit** to 2 in your launch template. For more information, see Instance metadata and user data in the Amazon EC2 User Guide. If you deploy a managed node group without using a custom launch template, this value is automatically set for the node group in the default launch template.

### Tagging Amazon EC2 instances

You can use the `TagSpecification` parameter of a launch template to specify which tags to apply to Amazon EC2 instances in your node group. The IAM entity calling the `CreateNodegroup` or `UpdateNodegroupVersion` APIs must have permissions for `ec2:RunInstances` and `ec2:CreateTags`, and the tags must be added to the launch template.

### Using custom security groups

You can use a launch template to specify custom Amazon EC2 **security groups** to apply to instances in your node group. This can be either in the instance level security groups parameter or as part of the network interface configuration parameters. However, you can’t create a launch template that specifies both instance level and network interface security groups. Consider the following conditions that apply to using custom security groups with managed node groups:

- Amazon EKS only allows launch templates with a single network interface specification.
- By default, Amazon EKS applies the **cluster security group** to the instances in your node group to facilitate communication between nodes and the control plane. If you specify custom security groups in the launch template using either option mentioned earlier, Amazon EKS doesn’t add the cluster security group. Therefore, you must ensure that the inbound and outbound rules of your security groups enable communication with your cluster’s endpoint. Incorrect security group rules result in worker nodes being unable to join the cluster. To learn about the security group rules that you should need to apply, see Amazon EKS security group considerations (p. 205).
- If you need SSH access to the instances in your node group, be sure to include a security group that allows that access.
Amazon EC2 user data

You can supply Amazon EC2 user data in your launch template using cloud-init when launching your instances. For more information, see the cloud-init documentation. Your user data can be used to perform common configuration operations. This includes the following operations:

- Including users or groups
- Installing packages

Amazon EC2 user data in launch templates that are used with managed node groups must be in the MIME multi-part archive format. This is because your user data is merged with Amazon EKS user data required for nodes to join the cluster. Do not specify any commands in your user data that starts or modifies kubelet, as this will be performed as part of the user data merged by Amazon EKS. Certain kubelet parameters, such as setting labels on nodes, can be configured directly through the managed node groups API.

**Note**

If you have a need for advanced kubelet customization, including manually starting it or passing in custom configuration parameters, see Using a custom AMI (p. 115) for more information. Amazon EKS doesn't merge user data when a custom AMI ID is specified in a launch template.

You can combine multiple user data blocks together into a single MIME multi-part file. For example, you can combine a cloud boothook that configures the Docker daemon with a user data shell script that installs a custom package. A MIME multi-part file consists of the following components:

- The content type and part boundary declaration - `Content-Type: multipart/mixed; boundary="==BOUNDARY=="`
- The MIME version declaration - `MIME-Version: 1.0`
- One or more user data blocks, which contain the following components:
  - The opening boundary, which signals the beginning of a user data block - `--==BOUNDARY==--`
  - The content type declaration for the block: `Content-Type: text/cloud-config; charset="us-ascii"`. For more information about content types, see the cloud-init documentation.
  - The content of the user data, for example, a list of shell commands or cloud-init directives.
  - The closing boundary, which signals the end of the MIME multi-part file: `--==BOUNDARY==--`

The following is an example of a MIME multi-part file that you can use to create your own.

```
MIME-Version: 1.0
Content-Type: multipart/mixed; boundary="==MYBOUNDARY=="

--==MYBOUNDARY==
Content-Type: text/x-shellscript; charset="us-ascii"

#!/bin/bash
echo "Running custom user data script"

--==MYBOUNDARY==--
```

Using a custom AMI

If your organization needs to run a custom AMI due to specific security, compliance, or internal policy requirements, you can deploy such AMIs to managed node groups by using a launch template. For more
Deleting a managed node group

This topic describes how you can delete an Amazon EKS managed node group.

When you delete a managed node group, Amazon EKS will first set the minimum, maximum, and desired size of your Auto Scaling group to zero, which will trigger a scale down of your node group. Before each instance is terminated, Amazon EKS will send a signal to drain the pods from that node and wait a few minutes. If the pods haven’t drained after a few minutes, Amazon EKS will let Auto Scaling continue the termination of the instance. Once all instances are terminated, the Auto Scaling group is deleted.

Important
If you delete a managed node group that uses a node IAM role that isn’t used by any other managed node group in the cluster, the role is removed from the `aws-auth ConfigMap` (p. 279). If any self-managed node groups in the cluster are using the same node IAM role, the self-managed nodes move to the `NotReady` status, and the cluster operation are also disrupted. You can add the mapping back to the ConfigMap to minimize disruption.

To delete a managed node group

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster that contains the node group to delete.
3. Select the Configuration tab. On the Compute tab, select the node group to delete, and choose Delete.
4. On the Delete Node group: `<node group name>` page, type the name of the node group in the text field and choose Delete.
Self-managed nodes

A cluster contains one or more Amazon EC2 nodes that pods are scheduled on. Amazon EKS nodes run in your AWS account and connect to your cluster's control plane via the cluster API server endpoint. You deploy one or more nodes into a node group. A node group is one or more Amazon EC2 instances that are deployed in an Amazon EC2 Auto Scaling group. All instances in a node group must:

- Be the same instance type
- Be running the same Amazon Machine Image (AMI)
- Use the same Amazon EKS node IAM role (p. 326)

A cluster can contain several node groups. As long as each node group meets the previous requirements, the cluster can contain node groups that contain different instance types and host operating systems. Each node group can contain several nodes.

Amazon EKS nodes are standard Amazon EC2 instances, and you are billed for them based on normal EC2 prices. For more information, see Amazon EC2 pricing.

Amazon EKS provides specialized Amazon Machine Images (AMI) called Amazon EKS optimized AMIs. The AMIs are configured to work with Amazon EKS and include Docker, kubelet, and the AWS IAM Authenticator. The AMIs also contain a specialized bootstrap script that allows it to discover and connect to your cluster's control plane automatically.

If you restrict access to your cluster's public endpoint using CIDR blocks, it is recommended that you also enable private endpoint access so that nodes can communicate with the cluster. Without the private endpoint enabled, the CIDR blocks that you specify for public access must include the egress sources from your VPC. For more information, see Amazon EKS cluster endpoint access control (p. 56).

To add self-managed nodes to your Amazon EKS cluster, see the topics that follow. If you launch self-managed nodes manually, then you must add the following tag to each node. For more information, see Adding and deleting tags on an individual resource. If you follow the steps in the guides that follow, then the required tag is automatically added to nodes for you.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/cluster/&lt;cluster-name&gt;</td>
<td>owned</td>
</tr>
</tbody>
</table>

For more information about nodes from a general Kubernetes perspective, see Nodes in the Kubernetes documentation.

Topics

- Launching self-managed Amazon Linux nodes (p. 117)
- Launching self-managed Bottlerocket nodes (p. 122)
- Launching self-managed Windows nodes (p. 125)
- Self-managed node updates (p. 129)

Launching self-managed Amazon Linux nodes

This topic helps you to launch an Auto Scaling group of Linux nodes that register with your Amazon EKS cluster. After the nodes join the cluster, you can deploy Kubernetes applications to them. You can launch self-managed Amazon Linux 2 nodes with eksctl (p. 118) or the AWS Management Console (p. 119).
To launch self-managed Linux nodes using `eksctl`

This procedure only works for clusters that were created with `eksctl`.

**Note**
This procedure requires `eksctl` version 0.35.0 or later. You can check your version with the following command:

```
eksctl version
```

For more information on installing or upgrading `eksctl`, see [Installing or upgrading `eksctl`](p. 292).

**Important**
Do not use `eksctl` to create a cluster or nodes in an AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled. Create a cluster and self-managed nodes using the Amazon EC2 API or AWS CloudFormation instead. For more information, see [To launch self-managed Linux nodes using the AWS Management Console](p. 119) and [To launch self-managed Windows nodes using the AWS Management Console](p. 126).

1. (Optional) If the `AmazonEKS_CNI_Policy` managed IAM policy is attached to your the section called “Node IAM role” (p. 326), we recommend assigning it to an IAM role that you associate to the Kubernetes `aws-node` service account instead. For more information, see [Configuring the VPC CNI plugin to use IAM roles for service accounts](p. 211).

2. The following command assumes that you have an existing cluster named `my-cluster` in the `us-west-2` Region. For a different existing cluster, change the values. If you don't have an existing cluster then you must first [create a cluster](p. 35). If you want to deploy on Amazon EC2 Arm instances, then replace `t3.medium` with an Arm instance type. If specifying an Arm Amazon EC2 instance type, then review the considerations in [Amazon EKS optimized Arm Amazon Linux AMIs](p. 161) before deploying.

Create your node group with the following command. Replace the `<example values>` with your own values.

```
eksctl create nodegroup \
  --cluster <my-cluster> \
  --version auto \
  --name <al-nodes> \
  --node-type <t3.medium> \
  --node-ami auto \
  --nodes <3> \
  --nodes-min <1> \
  --nodes-max <4>
```

If nodes fail to join the cluster, then see [Nodes fail to join cluster](p. 366) in the Troubleshooting guide.

Output:

You'll see several lines of output as the nodes are created. One of the last lines of output is the following example line.

```
[✓] created 1 nodegroup(s) in cluster "<my-cluster>"
```

3. (Optional) Deploy a [sample application](p. 249) to test your cluster and Linux nodes.

4. (Optional) If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current Region, then we recommend blocking pod access to IMDS. For more information, see [the section](p. 126)
called “IAM roles for service accounts” (p. 330) and the section called “Restricting access to the instance profile” (p. 349).

To launch self-managed Linux nodes using the AWS Management Console

This procedure has the following prerequisites:

• An existing VPC and security group that meet the requirements for an Amazon EKS cluster. For more information, see Cluster VPC considerations (p. 203) and Amazon EKS security group considerations (p. 205). The Getting started with Amazon EKS (p. 4) guide creates a VPC that meets the requirements, or you can also follow Creating a VPC for your Amazon EKS cluster (p. 198) to create one manually.

• An existing Amazon EKS cluster that uses a VPC and security group that meet the requirements of an Amazon EKS cluster. For more information, see Creating an Amazon EKS cluster (p. 35).

1. Wait for your cluster status to show as ACTIVE. If you launch your nodes before the cluster is active, the nodes will fail to register with the cluster and you will have to relaunch them.

3. Choose Create stack.

4. For Specify template, select Amazon S3 URL, copy the URL that corresponds to the Region that your cluster is in, paste it into Amazon S3 URL, and then select Next twice.

   • All Regions other than China (Beijing) and China (Ningxia)

   • China (Beijing) and China (Ningxia)

5. On the Quick create stack page, fill out the following parameters accordingly:

   • Stack name: Choose a stack name for your AWS CloudFormation stack. For example, you can call it cluster-name-nodes.

   • ClusterName: Enter the name that you used when you created your Amazon EKS cluster.

     Important
     This name must exactly match the name you used in Step 1: Create your Amazon EKS cluster (p. 25); otherwise, your nodes cannot join the cluster.

   • ClusterControlPlaneSecurityGroup: Choose the SecurityGroups value from the AWS CloudFormation output that you generated with Create your Amazon EKS cluster VPC (p. 22).

   • NodeGroupName: Enter a name for your node group. This name can be used later to identify the Auto Scaling node group that is created for your nodes.

   • NodeAutoScalingGroupMinSize: Enter the minimum number of nodes that your node Auto Scaling group can scale in to.

   • NodeAutoScalingGroupDesiredCapacity: Enter the desired number of nodes to scale to when your stack is created.

   • NodeAutoScalingGroupMaxSize: Enter the maximum number of nodes that your node Auto Scaling group can scale out to.

   • NodeInstanceType: Choose an instance type for your nodes. Before choosing an Arm instance type, make sure to review the considerations in Amazon EKS optimized Arm Amazon Linux AMIs (p. 161).
Note
The supported instance types for the latest version of the Amazon VPC CNI plugin for Kubernetes are shown here. You may need to update your CNI version to take advantage of the latest supported instance types. For more information, see Amazon VPC CNI plugin for Kubernetes upgrades (p. 230).

Important
Some instance types might not be available in all Regions.

- **NodeImageIdSSMParam**: Pre-populated with the Amazon EC2 Systems Manager parameter of the current recommended Amazon EKS optimized Amazon Linux AMI ID for a Kubernetes version. If you want to use the Amazon EKS optimized accelerated AMI, then replace `amazon-linux-2` with `amazon-linux-2-gpu`. If you want to use the Amazon EKS optimized Arm AMI, then replace `amazon-linux-2` with `amazon-linux-2-arm64`. If you want to use a different Kubernetes minor version supported with Amazon EKS, then you can replace `1.x` with a different supported version (p. 68). We recommend specifying the same Kubernetes version as your cluster.

Note
The Amazon EKS node AMI is based on Amazon Linux 2. You can track security or privacy events for Amazon Linux 2 at the Amazon Linux Security Center or subscribe to the associated RSS feed. Security and privacy events include an overview of the issue, what packages are affected, and how to update your instances to correct the issue.

- **NodeImageId**: (Optional) If you are using your own custom AMI (instead of the Amazon EKS optimized AMI), enter a node AMI ID for your Region. If you specify a value here, it overrides any values in the **NodeImageIdSSMParam** field.

- **NodeVolumeSize**: Specify a root volume size for your nodes, in GiB.

- **KeyName**: Enter the name of an Amazon EC2 SSH key pair that you can use to connect using SSH into your nodes with after they launch. If you don't already have an Amazon EC2 keypair, you can create one in the AWS Management Console. For more information, see Amazon EC2 key pairs in the Amazon EC2 User Guide for Linux Instances.

Note
If you do not provide a keypair here, the AWS CloudFormation stack creation fails.

- **BootstrapArguments**: Specify any optional arguments to pass to the node bootstrap script, such as extra kubelet arguments. For more information, view the bootstrap script usage information on GitHub.

Note
- If you are launching nodes into a private VPC without outbound internet access, then you need to include the following arguments.

```
--apiserver-endpoint <cluster-endpoint> --b64-cluster-ca <cluster-certificate-authority>
```

- If you want to assign IP addresses to pods that are from a different CIDR block than the block that includes the IP address for the node, then you may need to add a CIDR block to your VPC and specify an argument to support the capability. For more information, see CNI custom networking (p. 224).

- **DisableIMDSv1**: Each node supports the Instance Metadata Service Version 1 (IMDSv1) and IMDSv2 by default, but you can disable IMDSv1. Select `true` if you don't want any nodes in the node group, or any pods scheduled on the nodes in the node group to use IMDSv1. For more information about IMDS, see Configuring the instance metadata service. For more information about restricting access to it on your nodes, see the section called “Restricting access to the instance profile” (p. 349).

- **VpcId**: Enter the ID for the VPC that you created in Create your Amazon EKS cluster VPC (p. 22).

- **Subnets**: Choose the subnets that you created in Create your Amazon EKS cluster VPC (p. 22). If you created your VPC using the steps described at Creating a VPC for your Amazon EKS
cluster (p. 198), then specify only the private subnets within the VPC for your nodes to launch into.

**Important**
If any of the subnets are public subnets, then they must have the automatic public IP address assignment setting enabled. If the setting is not enabled for the public subnet, then any nodes that you deploy to that public subnet will not be assigned a public IP address and will not be able to communicate with the cluster or other AWS services. If the subnet was deployed before March 26, 2020 using either of the Amazon EKS AWS CloudFormation VPC templates (p. 198), or by using eksctl, then automatic public IP address assignment is disabled for public subnets. For information about how to enable public IP address assignment for a subnet, see Modifying the Public IPv4 Addressing Attribute for Your Subnet. If the node is deployed to a private subnet, then it is able to communicate with the cluster and other AWS services through a NAT gateway.

**Important**
- If the subnets do not have internet access, then make sure that you're aware of the considerations and extra steps in Private clusters (p. 93).
- Ensure that the subnets you select are tagged with the cluster name. For more information, see Subnet tagging requirement (p. 205). If you have subnets in AWS Outposts, AWS Wavelength, or an AWS Local Zone, they likely are not currently tagged.

6. Acknowledge that the stack might create IAM resources, and then choose Create stack.
7. When your stack has finished creating, select it in the console and choose Outputs.
8. Record the NodeInstanceRole for the node group that was created. You need this when you configure your Amazon EKS nodes.

**To enable nodes to join your cluster**

**Note**
If you launched nodes inside a private VPC without outbound internet access, then you must enable nodes to join your cluster from within the VPC.

1. Download, edit, and apply the AWS IAM Authenticator configuration map.
   a. Use the command that corresponds to the Region that your cluster is in to download the configuration map:
      - All Regions other than China (Beijing) and China (Ningxia)
        ```bash
        curl -o aws-auth-cm.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/cloudformation/2020-10-29/aws-auth-cm.yaml
        ```
      - China (Beijing) and China (Ningxia)
        ```bash
        curl -o aws-auth-cm.yaml https://s3.cn-north-1.amazonaws.com.cn/amazon-eks/cloudformation/2020-10-29/aws-auth-cm.yaml
        ```
   b. Open the file with your text editor. Replace the `<ARN of instance role (not instance profile)>` snippet with the NodeInstanceRole value that you recorded in the previous procedure, and save the file.

**Important**
Do not modify any other lines in this file.

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: aws-auth
```
namespace: kube-system
data:
  mapRoles: |
    - rolearn: <ARN of instance role (not instance profile)>
      username: system:node:{{EC2PrivateDNSName}}
    groups:
      - system:bootstrappers
      - system:nodes

c. Apply the configuration. This command may take a few minutes to finish.

    kubectl apply -f aws-auth-cm.yaml

**Note**
If you receive any authorization or resource type errors, see Unauthorized or access denied (*kubectl*) (p. 367) in the troubleshooting section.

If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 366) in the Troubleshooting guide.

2. Watch the status of your nodes and wait for them to reach the Ready status.

    kubectl get nodes --watch

3. (GPU nodes only) If you chose a GPU instance type and the Amazon EKS optimized accelerated AMI, you must apply the NVIDIA device plugin for Kubernetes as a DaemonSet on your cluster with the following command.

    kubectl apply -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.6.0/nvidia-device-plugin.yml

4. (Optional) Deploy a sample application (p. 249) to test your cluster and Linux nodes.

5. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy is attached to your the section called “Node IAM role” (p. 326), we recommend assigning it to an IAM role that you associate to the Kubernetes aws-node service account instead. For more information, see Configuring the VPC CNI plugin to use IAM roles for service accounts (p. 211).

6. (Optional) If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current Region, then we recommend blocking pod access to IMDS. For more information, see the section called “IAM roles for service accounts” (p. 330) and the section called “Restricting access to the instance profile” (p. 349).

## Launching self-managed Bottlerocket nodes

This topic helps you to launch an Auto Scaling group of Bottlerocket nodes that register with your Amazon EKS cluster. Bottlerocket is a Linux-based open-source operating system that is purpose-built by AWS for running containers on virtual machines or bare metal hosts. After the nodes join the cluster, you can deploy Kubernetes applications to them. For more information about Bottlerocket, see the documentation on GitHub.

**Important**
Amazon EKS nodes are standard Amazon EC2 instances, and you are billed for them based on normal Amazon EC2 instance prices. For more information, see Amazon EC2 pricing.

**Important**
Considerations
• You can deploy to Amazon EC2 instances with x86 or Arm processors, but not to instances that have GPUs or Inferentia chips.
• You cannot deploy to the following regions: China (Beijing) (cn-north-1), China (Ningxia) (cn-northwest-1), AWS GovCloud (US-East) (us-gov-east-1), or AWS GovCloud (US-West) (us-gov-west-1).
• There is no AWS CloudFormation template to deploy nodes with.

**Important**
Do not use eksctl to create a cluster or nodes in an AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled. Create a cluster and self-managed nodes using the Amazon EC2 API or AWS CloudFormation instead. For more information, see To launch self-managed Linux nodes using the AWS Management Console (p. 119) and To launch self-managed Windows nodes using the AWS Management Console (p. 126).

To launch Bottlerocket nodes using eksctl

This procedure requires eksctl version 0.35.0 or later. You can check your version with the following command:

```
eksctl version
```

For more information on installing or upgrading eksctl, see Installing or upgrading eksctl (p. 292).

**Note**
This procedure only works for clusters that were created with eksctl.

1. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy is attached to your the section called “Node IAM role” (p. 326), we recommend assigning it to an IAM role that you associate to the Kubernetes aws-node service account instead. For more information, see Configuring the VPC CNI plugin to use IAM roles for service accounts (p. 211).

2. This procedure assumes that you have an existing cluster named my-cluster in the us-west-2 Region. For a different existing cluster, change the values. If you don't have an existing cluster then you must first create a cluster (p. 35).

Create a file with the following contents. Replace the `<example values>` (including `< >`) with your own values. If you change 1.18, then it can only be changed to 1.15 or later. If you want to deploy on Arm instances, then replace m5.large with an Arm instance type. If specifying an Arm Amazon EC2 instance type, then review the considerations in Amazon EKS optimized Arm Amazon Linux AMIs (p. 161) before deploying. If you want to deploy using a custom AMI, then see Building Bottlerocket on GitHub and Custom AMI support in the eksctl documentation. If you want to deploy a managed node group then you must deploy a custom AMI using a launch template. For more information, see the section called “Launch template support” (p. 112).

For more information about using a config file with eksctl, the config file schema, and config file samples, see the eksctl documentation.

```yaml
---
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig

metadata:
  name: <my-cluster>
  region: <us-west-2>
  version: `<1.18'

nodeGroups:
  - name: <ng-bottlerocket>
    instanceType: <m5.large>
```
desiredCapacity: <3>
amiFamily: <Bottlerocket>
iam:
  attachPolicyARNs:
    - arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy
    - arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy
    - arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly
    - arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
ssh:
  allow: true
  publicKeyName: <YOUR_EC2_KEYPAIR_NAME>

3. Deploy your nodes with the following command.

```bash
eksctl create nodegroup --config-file=<filename-you-used-in-previous-step.yaml>
```

If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 366) in the Troubleshooting guide.

Output:

You'll see several lines of output as the nodes are created. One of the last lines of output is the following example line.

```
[✓]  created 1 nodegroup(s) in cluster "<my-cluster>"
```

4. (Optional) Create a Kubernetes persistent volume on a Bottlerocket node using the Amazon EBS CSI Plugin. The default Amazon EBS driver relies on file system tools that are not included with Bottlerocket. For more information about creating a storage class using the driver, see Amazon EBS CSI driver (p. 182).

5. (Optional) By default kube-proxy will set the `nf_conntrack_max` kernel parameter to a default value that may differ from what Bottlerocket originally sets at boot. If you prefer to keep Bottlerocket's default setting, then edit the kube-proxy configuration with the following command.

```bash
kubectl edit -n kube-system daemonset kube-proxy
```

Add `--conntrack-max-per-core` and `--conntrack-min` to the kube-proxy arguments as shown in the following example. A setting of 0 implies no change.

```
containers:
  command:
    - kube-proxy
    - --v=2
    - --config=/var/lib/kube-proxy-config/config
    - --conntrack-max-per-core=0
    - --conntrack-min=0
```

6. (Optional) Deploy a sample application (p. 249) to test your Bottlerocket nodes.

7. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy is attached to your the section called "Node IAM role" (p. 326), we recommend assigning it to an IAM role that you associate to the Kubernetes aws-node service account instead. For more information, see Configuring the VPC CNI plugin to use IAM roles for service accounts (p. 211).

8. (Optional) If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current Region, then we recommend blocking pod access to IMDS. For more information, see the section called “IAM roles for service accounts” (p. 330) and the section called “Restricting access to the instance profile” (p. 349).
Launching self-managed Windows nodes

This topic helps you to launch an Auto Scaling group of Windows nodes that register with your Amazon EKS cluster. After the nodes join the cluster, you can deploy Kubernetes applications to them.

**Important**
Amazon EKS nodes are standard Amazon EC2 instances, and you are billed for them based on normal Amazon EC2 instance prices. For more information, see Amazon EC2 pricing.

**Important**
Do not use eksctl to create a cluster or nodes in an AWS Region where you have AWS Outposts, AWS Wavelength, or AWS Local Zones enabled. Create a cluster and self-managed nodes using the Amazon EC2 API or AWS CloudFormation instead. For more information, see To launch self-managed Linux nodes using the AWS Management Console (p. 119) and To launch self-managed Windows nodes using the AWS Management Console (p. 126).

You must enable Windows support for your cluster and we recommend that you review important considerations before you launch a Windows node group. For more information, see Enabling Windows support (p. 80).

You can launch self-managed Windows nodes with eksctl (p. 125) or the AWS Management Console (p. 126).

**To launch self-managed Windows nodes using eksctl**

This procedure assumes that you have installed eksctl, and that your eksctl version is at least 0.35.0. You can check your version with the following command:

```
eksctl version
```

For more information on installing or upgrading eksctl, see Installing or upgrading eksctl (p. 292).

**Note**
This procedure only works for clusters that were created with eksctl.

1. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy is attached to your the section called "Node IAM role" (p. 326), we recommend assigning it to an IAM role that you associate to the Kubernetes aws-node service account instead. For more information, see Configuring the VPC CNI plugin to use IAM roles for service accounts (p. 211).

2. This procedure assumes that you have an existing cluster named my-cluster in the us-west-2 Region. For a different existing cluster, change the values. If you don't already have an Amazon EKS cluster and an Amazon Linux 2 node group to add a Windows node group to, then we recommend that you follow the Getting started with eksctl (p. 4) guide instead. The guide provides a complete end-to-end walkthrough for creating an Amazon EKS cluster with Amazon Linux and Windows nodes.

Create your node group with the following command. Replace the <example values> with your own values.

```
eksctl create nodegroup \
  --region <us-west-2> \
  --cluster <my-cluster> \
  --name <ng-windows> \
  --node-type <t2.large> \
  --nodes <3> \
  --nodes-min <1> \
  --nodes-max <4>
```
--node-ami-family <WindowsServer2019FullContainer>

Note

- If nodes fail to join the cluster, see Nodes fail to join cluster (p. 366) in the Troubleshooting guide.
- For more information on the available options for eksctl commands, enter the following command.

```
eksctl <command> -help
```

Output:

You'll see several lines of output as the nodes are created. One of the last lines of output is the following example line.

```
[✓] created 1 nodegroup(s) in cluster "<my-cluster>"
```

3. (Optional) Deploy a sample application (p. 85) to test your cluster and Windows nodes.

4. (Optional) If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current Region, then we recommend blocking pod access to IMDS. For more information, see the section called “IAM roles for service accounts” (p. 330) and the section called “Restricting access to the instance profile” (p. 349).

To launch self-managed Windows nodes using the AWS Management Console

These procedures have the following prerequisites:

- You have an existing Amazon EKS cluster and a Linux node group. If you don't have these resources, we recommend that you follow one of our Getting started with Amazon EKS (p. 4) guides to create them. The guides provide a complete end-to-end walkthrough for creating an Amazon EKS cluster with Linux nodes.
- You have created a VPC and security group that meet the requirements for an Amazon EKS cluster. For more information, see Cluster VPC considerations (p. 203) and Amazon EKS security group considerations (p. 205). The Getting started with Amazon EKS (p. 4) guide creates a VPC that meets the requirements, or you can also follow Creating a VPC for your Amazon EKS cluster (p. 198) to create one manually.

1. Wait for your cluster status to show as ACTIVE. If you launch your nodes before the cluster is active, the nodes will fail to register with the cluster and you will have to relaunch them.

2. Open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation

3. Choose Create stack.

4. For Specify template, select Amazon S3 URL, copy the URL that corresponds to the Region that your cluster is in, paste it into Amazon S3 URL, and select Next twice.

- All Regions other than China (Beijing) and China (Ningxia)

- China (Beijing) and China (Ningxia)
5. On the Quick create stack page, fill out the following parameters accordingly:

- **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it `<cluster-name>-nodes`.

- **ClusterName**: Enter the name that you used when you created your Amazon EKS cluster.

  **Important**
  This name must exactly match the name you used in **Step 1: Create your Amazon EKS cluster (p. 25)**; otherwise, your nodes cannot join the cluster.

- **ClusterControlPlaneSecurityGroup**: Choose the **SecurityGroups** value from the AWS CloudFormation output that you generated with Create your Amazon EKS cluster VPC (p. 22).

- **NodeGroupName**: Enter a name for your node group. This name can be used later to identify the Auto Scaling node group that is created for your nodes.

- **NodeAutoScalingGroupMinSize**: Enter the minimum number of nodes that your node Auto Scaling group can scale in to.

- **NodeAutoScalingGroupDesiredCapacity**: Enter the desired number of nodes to scale to when your stack is created.

- **NodeAutoScalingGroupMaxSize**: Enter the maximum number of nodes that your node Auto Scaling group can scale out to.

- **NodeInstanceType**: Choose an instance type for your nodes.

  **Note**
  The supported instance types for the latest version of the Amazon VPC CNI plugin for Kubernetes are shown here. You may need to update your CNI version to take advantage of the latest supported instance types. For more information, see Amazon VPC CNI plugin for Kubernetes upgrades (p. 230).

- **NodeImageIdSSMParm**: Pre-populated with the Amazon EC2 Systems Manager parameter of the current recommended Amazon EKS optimized Windows Core AMI ID. If you want to use the full version of Windows, then replace `<Core>` with `Full`.

- **NodeImageId**: (Optional) If you are using your own custom AMI (instead of the Amazon EKS optimized AMI), enter a node AMI ID for your Region. If you specify a value here, it overrides any values in the **NodeImageIdSSMParm** field.

- **NodeVolumeSize**: Specify a root volume size for your nodes, in GiB.

- **KeyName**: Enter the name of an Amazon EC2 SSH key pair that you can use to connect using SSH into your nodes with after they launch. If you don't already have an Amazon EC2 keypair, you can create one in the AWS Management Console. For more information, see Amazon EC2 key pairs in the Amazon EC2 User Guide for Windows Instances.

  **Note**
  If you do not provide a keypair here, the AWS CloudFormation stack creation fails.

- **BootstrapArguments**: Specify any optional arguments to pass to the node bootstrap script, such as extra kubelet arguments using `-KubeletExtraArgs`.

- **DisableIMDSv1**: Each node supports the Instance Metadata Service Version 1 (IMDSv1) and IMDSv2 by default, but you can disable IMDSv1. Select **true** if you don't want any nodes in the node group, or any pods scheduled on the nodes in the node group to use IMDSv1. For more information about IMDS, see Configuring the instance metadata service.

- **VpcId**: Select the ID for the VPC that you created in Create your Amazon EKS cluster VPC (p. 22).

- **NodeSecurityGroups**: Select the security group that was created for your Linux node group in Create your Amazon EKS cluster VPC (p. 22). If your Linux nodes have more than one security group attached to them (for example, if the Linux node group was created with `eksctl`), specify all of them here.
• **Subnets**: Choose the subnets that you created in Create your Amazon EKS cluster VPC (p. 22). If you created your VPC using the steps described at Creating a VPC for your Amazon EKS cluster (p. 198), then specify only the private subnets within the VPC for your nodes to launch into.

**Important**
If any of the subnets are public subnets, then they must have the automatic public IP address assignment setting enabled. If the setting is not enabled for the public subnet, then any nodes that you deploy to that public subnet will not be assigned a public IP address and will not be able to communicate with the cluster or other AWS services. If the subnet was deployed before March 26, 2020 using either of the Amazon EKS AWS CloudFormation VPC templates (p. 198), or by using eksctl, then automatic public IP address assignment is disabled for public subnets. For information about how to enable public IP address assignment for a subnet, see Modifying the Public IPv4 Addressing Attribute for Your Subnet. If the node is deployed to a private subnet, then it is able to communicate with the cluster and other AWS services through a NAT gateway.

**Important**
Ensure that the subnets you select are tagged with the cluster name. For more information, see Subnet tagging requirement (p. 205). If you have subnets in AWS Outposts, AWS Wavelength, or an AWS Local Zone, they likely are not currently tagged.

6. Acknowledge that the stack might create IAM resources, and then choose Create stack.
7. When your stack has finished creating, select it in the console and choose Outputs.
8. Record the **NodeInstanceRole** for the node group that was created. You need this when you configure your Amazon EKS Windows nodes.

**To enable nodes to join your cluster**

1. Download, edit, and apply the AWS IAM Authenticator configuration map.

   a. Use the command that corresponds to the Region that your cluster is deployed in to download the configuration map:

   - All Regions other than China (Beijing) and China (Ningxia)

   ```bash
   curl -o aws-auth-cm-windows.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/cloudformation/2020-10-29/aws-auth-cm-windows.yaml
   ```

   - China (Beijing) and China (Ningxia)

   ```bash
   ```

   b. Open the file with your favorite text editor. Replace the `<ARN of instance role (not instance profile) of **Linux** node> and <ARN of instance role (not instance profile) of **Windows** node>` snippets with the **NodeInstanceRole** values that you recorded for your Linux and Windows nodes, and save the file.

   **Important**
   Do not modify any other lines in this file.

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
   name: aws-auth
   namespace: kube-system
data:
   mapRoles: |
   ```
c. Apply the configuration. This command may take a few minutes to finish.

```
kubectl apply -f aws-auth-cm-windows.yaml
```

**Note**
If you receive any authorization or resource type errors, see Unauthorized or access denied (kubectl) (p. 367) in the troubleshooting section.

If nodes fail to join the cluster, then see Nodes fail to join cluster (p. 366) in the Troubleshooting guide.

2. Watch the status of your nodes and wait for them to reach the **Ready** status.

```
kubectl get nodes --watch
```

3. (Optional) Deploy a sample application (p. 85) to test your cluster and Windows nodes.

4. (Optional) If the AmazonEKS_CNI_Policy managed IAM policy is attached to your **Node IAM role** (p. 326), we recommend assigning it to an IAM role that you associate to the Kubernetes aws-node service account instead. For more information, see Configuring the VPC CNI plugin to use IAM roles for service accounts (p. 211).

5. (Optional) If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current Region, then we recommend blocking pod access to IMDS. For more information, see the section called “IAM roles for service accounts” (p. 330) and the section called “Restricting access to the instance profile” (p. 349).

---

**Self-managed node updates**

When a new Amazon EKS optimized AMI is released, you should consider replacing the nodes in your self-managed node group with the new AMI. Likewise, if you have updated the Kubernetes version for your Amazon EKS cluster, you should also update the nodes to use nodes with the same Kubernetes version.

**Important**
This topic covers node updates for self-managed nodes. If you are using Managed node groups (p. 101), see Updating a managed node group (p. 109).

There are two basic ways to update self-managed node groups in your clusters to use a new AMI:

- **Migrating to a new node group** (p. 130) – Create a new node group and migrate your pods to that group. Migrating to a new node group is more graceful than simply updating the AMI ID in an existing AWS CloudFormation stack, because the migration process taints the old node group as NoSchedule and drains the nodes after a new stack is ready to accept the existing pod workload.
• Updating an existing self-managed node group (p. 134) – Update the AWS CloudFormation stack for an existing node group to use the new AMI. This method is not supported for node groups that were created with eksctl.

Migrating to a new node group

This topic helps you to create a new node group, gracefully migrate your existing applications to the new group, and then remove the old node group from your cluster. You can migrate to a new node group using eksctl (p. 130) or the AWS Management Console (p. 131).

To migrate your applications to a new node group with eksctl

This procedure requires eksctl version 0.35.0 or later. You can check your version with the following command:

```bash
eksctl version
```

For more information on installing or upgrading eksctl, see Installing or upgrading eksctl (p. 292).

**Note**

This procedure only works for clusters and node groups that were created with eksctl.

1. Retrieve the name of your existing node groups, replacing `<my-cluster>` (including `<`) with your cluster name.

   ```bash
   eksctl get nodegroups --cluster=<my-cluster>
   ```

   Output:

<table>
<thead>
<tr>
<th>CLUSTER</th>
<th>NODEGROUP</th>
<th>CREATED</th>
<th>MIN SIZE</th>
<th>MAX SIZE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>t3.medium</td>
<td>ami-05a71d094119f2f012</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2. Launch a new node group with eksctl with the following command, substituting the `<example values>` (including `<`) with your own values. If you plan to assign IAM roles to all of your Kubernetes service accounts so that pods only have the minimum permissions that they need, and no pods in the cluster require access to the Amazon EC2 instance metadata service (IMDS) for other reasons, such as retrieving the current Region, then we recommend blocking pod access to IMDS. For more information, see the section called “IAM roles for service accounts” (p. 330) and the section called “Restricting access to the instance profile” (p. 349). If you want to block pod access to IMDS, then add the `--disable-pod-imds` option to the following command.

   **Note**
   For more available flags and their descriptions, see https://eksctl.io/.

   ```bash
   eksctl create nodegroup \ 
   --cluster <my-cluster> \ 
   --version <1.18> \ 
   --name <standard-nodes-new> \ 
   --node-type <t3.medium> \ 
   --nodes <3> \ 
   --nodes-min <1> \ 
   --nodes-max <4> \ 
   --node-ami auto
   ```

3. When the previous command completes, verify that all of your nodes have reached the **Ready** state with the following command:
4. Delete the original node group with the following command, replacing the `<example values>` (including <> ) with your cluster and node group names:

```bash
eksctl delete nodegroup --cluster <my-cluster> --name <standard-nodes>
```

To migrate your applications to a new node group with the AWS Management Console

1. Launch a new node group by following the steps outlined in Launching self-managed Amazon Linux nodes (p. 117).
2. When your stack has finished creating, select it in the console and choose Outputs.
3. Record the NodeInstanceRole for the node group that was created. You need this to add the new Amazon EKS nodes to your cluster.

**Note**
If you have attached any additional IAM policies to your old node group IAM role, such as adding permissions for the Kubernetes Cluster Autoscaler, you should attach those same policies to your new node group IAM role to maintain that functionality on the new group.

4. Update the security groups for both node groups so that they can communicate with each other. For more information, see Amazon EKS security group considerations (p. 205).

   a. Record the security group IDs for both node groups. This is shown as the NodeSecurityGroup value in the AWS CloudFormation stack outputs.

   You can use the following AWS CLI commands to get the security group IDs from the stack names. In these commands, oldNodes is the AWS CloudFormation stack name for your older node stack, and newNodes is the name of the stack that you are migrating to.

```bash
oldNodes="<old_node_CFN_stack_name>"
newNodes="<new_node_CFN_stack_name>"

oldSecGroup=$(aws cloudformation describe-stack-resources --stack-name $oldNodes 
   --query 'StackResources[? ResourceType==`AWS::EC2::SecurityGroup`].PhysicalResourceId' 
   --output text)
newSecGroup=$(aws cloudformation describe-stack-resources --stack-name $newNodes 
   --query 'StackResources[? ResourceType==`AWS::EC2::SecurityGroup`].PhysicalResourceId' 
   --output text)
```

   b. Add ingress rules to each node security group so that they accept traffic from each other.

   The following AWS CLI commands add ingress rules to each security group that allow all traffic on all protocols from the other security group. This configuration allows pods in each node group to communicate with each other while you are migrating your workload to the new group.

```bash
aws ec2 authorize-security-group-ingress --group-id $oldSecGroup 
   --source-group $newSecGroup --protocol -1
aws ec2 authorize-security-group-ingress --group-id $newSecGroup 
   --source-group $oldSecGroup --protocol -1
```

5. Edit the `aws-auth` configmap to map the new node instance role in RBAC.

```bash
kubectl edit configmap -n kube-system aws-auth
```
Add a new `mapRoles` entry for the new node group.

```yaml
apiVersion: v1
data:
  mapRoles: |
    - rolearn: <ARN of instance role (not instance profile)>
      username: system:node:{{EC2PrivateDNSName}}
      groups:
        - system:bootstrappers
        - system:nodes
    - rolearn: arn:aws:iam::111122223333:role/nodes-1-16-NodeInstanceRole-U11V27W93CX5
      username: system:node:{{EC2PrivateDNSName}}
      groups:
        - system:bootstrappers
        - system:nodes
```

Replace the `<ARN of instance role (not instance profile)>` snippet with the `NodeInstanceRole` value that you recorded in a previous step (p. 131), then save and close the file to apply the updated configmap.

6. Watch the status of your nodes and wait for your new nodes to join your cluster and reach the `Ready` status.

```bash
kubectl get nodes --watch
```

7. (Optional) If you are using the Kubernetes Cluster Autoscaler, scale the deployment down to 0 replicas to avoid conflicting scaling actions.

```bash
kubectl scale deployments/cluster-autoscaler --replicas=0 -n kube-system
```

8. Use the following command to taint each of the nodes that you want to remove with `NoSchedule` so that new pods are not scheduled or rescheduled on the nodes you are replacing:

```bash
kubectl taint nodes <node_name> key=value:NoSchedule
```

If you are upgrading your nodes to a new Kubernetes version, you can identify and taint all of the nodes of a particular Kubernetes version (in this case, 1.16) with the following code snippet.

```bash
K8S_VERSION=1.16
nodes=$(kubectl get nodes -o jsonpath="{.items[?(@.status.nodeInfo.kubeletVersion=="v
$K8S_VERSION")].metadata.name}")
for node in ${nodes[@]}
do
  echo "Tainting $node"
  kubectl taint nodes $node key=value:NoSchedule
done
```

9. Determine your cluster's DNS provider.

```bash
kubectl get deployments -l k8s-app=kube-dns -n kube-system
```

Output (this cluster is using `kube-dns` for DNS resolution, but your cluster may return `coredns` instead):

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESIRED</th>
<th>CURRENT</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;kube-dns&gt;</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>31m</td>
</tr>
</tbody>
</table>
10. If your current deployment is running fewer than two replicas, scale out the deployment to two replicas. Replace `<kube-dns>` with `coredns` if your previous command output returned that instead.

```
kubectl scale deployments/<kube-dns> --replicas=2 -n kube-system
```

11. Drain each of the nodes that you want to remove from your cluster with the following command:

```
kubectl drain <node_name> --ignore-daemonsets --delete-local-data
```

If you are upgrading your nodes to a new Kubernetes version, you can identify and drain all of the nodes of a particular Kubernetes version (in this case, 1.16) with the following code snippet.

```
K8S_VERSION=<1.16>
nodes=$(kubectl get nodes -o jsonpath="{.items[?(@.status.nodeInfo.kubeletVersion=="v$K8S_VERSION")].metadata.name}")
for node in ${nodes[@]}
do
echo "Draining $node"
kubectl drain $node --ignore-daemonsets --delete-local-data
done
```

12. After your old nodes have finished draining, revoke the security group ingress rules you authorized earlier, and then delete the AWS CloudFormation stack to terminate the instances.

**Note**
If you have attached any additional IAM policies to your old node group IAM role, such as adding permissions for the Kubernetes Cluster Autoscaler), you must detach those additional policies from the role before you can delete your AWS CloudFormation stack.

a. Revoke the ingress rules that you created for your node security groups earlier. In these commands, `oldNodes` is the AWS CloudFormation stack name for your older node stack, and `newNodes` is the name of the stack that you are migrating to.

```
oldNodes="<old_node_CFN_stack_name>"
newNodes="<new_node_CFN_stack_name>"

oldSecGroup=$(aws cloudformation describe-stack-resources --stack-name $oldNodes --query 'StackResources[?ResourceType==`AWS::EC2::SecurityGroup`].PhysicalResourceId' --output text)
newSecGroup=$(aws cloudformation describe-stack-resources --stack-name $newNodes --query 'StackResources[?ResourceType==`AWS::EC2::SecurityGroup`].PhysicalResourceId' --output text)
aws ec2 revoke-security-group-ingress --group-id $oldSecGroup --protocol -1
aws ec2 revoke-security-group-ingress --group-id $newSecGroup --protocol -1
```

c. Select your old node stack.
d. Choose Actions, then Delete stack.

13. Edit the `aws-auth` configmap to remove the old node instance role from RBAC.

```
kubectl edit configmap -n kube-system aws-auth
```

Delete the `mapRoles` entry for the old node group.
apiVersion: v1
data:
  mapRoles: |
  - rolearn: arn:aws:iam::111122223333:role/nodes-1-16-NodeInstanceRole-W70725MZQFF8
    username: system:node:{{EC2PrivateDNSName}}
    groups: 
      - system:bootstrappers
      - system:nodes
    username: system:node:{{EC2PrivateDNSName}}
    groups:
      - system:bootstrappers
      - system:nodes>

Save and close the file to apply the updated configmap.

14. (Optional) If you are using the Kubernetes Cluster Autoscaler, scale the deployment back to one replica.

   Note
   You must also tag your new Auto Scaling group appropriately (for example, k8s.io/cluster-autoscaler/enabled,k8s.io/cluster-autoscaler/<YOUR CLUSTER NAME>) and update your Cluster Autoscaler deployment's command to point to the newly tagged Auto Scaling group. For more information, see Cluster Autoscaler on AWS.

```
kubectl scale deployments/cluster-autoscaler --replicas=1 -n kube-system
```

15. (Optional) Verify that you are using the latest version of the Amazon VPC CNI plugin for Kubernetes. You may need to update your CNI version to take advantage of the latest supported instance types. For more information, see Amazon VPC CNI plugin for Kubernetes upgrades (p. 230).

16. If your cluster is using kube-dns for DNS resolution (see previous step (p. 132)), scale in the kube-dns deployment to one replica.

```
kubectl scale deployments/kube-dns --replicas=1 -n kube-system
```

### Updating an existing self-managed node group

This topic helps you to update an existing AWS CloudFormation self-managed node stack with a new AMI. You can use this procedure to update your nodes to a new version of Kubernetes following a cluster update, or you can update to the latest Amazon EKS optimized AMI for an existing Kubernetes version.

**Important**
This topic covers node updates for self-managed nodes. If you are using Managed node groups (p. 101), see Updating a managed node group (p. 109).

The latest default Amazon EKS node AWS CloudFormation template is configured to launch an instance with the new AMI into your cluster before removing an old one, one at a time. This configuration ensures that you always have your Auto Scaling group's desired count of active instances in your cluster during the rolling update.

**Note**
This method is not supported for node groups that were created with eksctl. If you created your cluster or node group with eksctl, see Migrating to a new node group (p. 130).

**To update an existing node group**

1. Determine your cluster's DNS provider.
Output (this cluster is using `kube-dns` for DNS resolution, but your cluster may return `coredns` instead):

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESIRED</th>
<th>CURRENT</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;kube-dns&gt;</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>31m</td>
</tr>
</tbody>
</table>

2. If your current deployment is running fewer than two replicas, scale out the deployment to two replicas. Substitute `coredns` for `kube-dns` if your previous command output returned that instead.

   kubectl scale deployments/<kube-dns> --replicas=2 -n kube-system

3. (Optional) If you are using the Kubernetes `Cluster Autoscaler`, scale the deployment down to zero replicas to avoid conflicting scaling actions.

   kubectl scale deployments/cluster-autoscaler --replicas=0 -n kube-system

4. Determine the instance type and desired instance count of your current node group. You will enter these values later when you update the AWS CloudFormation template for the group.

   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. Choose `Launch Configurations` in the left navigation, and note the instance type for your existing node launch configuration.
   c. Choose `Auto Scaling Groups` in the left navigation and note the `Desired` instance count for your existing node Auto Scaling group.

6. Select your node group stack, and then choose `Update`.
7. Select `Replace current template` and select `Amazon S3 URL`.
8. For `Amazon S3 URL`, paste the URL that corresponds to the Region that your cluster is in into the text area to ensure that you are using the latest version of the node AWS CloudFormation template, and then choose `Next`:

   - All Regions other than China (Beijing) and China (Ningxia)

   - China (Beijing) and China (Ningxia)

9. On the `Specify stack details` page, fill out the following parameters, and choose `Next`:

   - `NodeAutoScalingGroupDesiredCapacity` – Enter the desired instance count that you recorded in a previous step (p. 135), or enter a new desired number of nodes to scale to when your stack is updated.
   - `NodeAutoScalingGroupMaxSize` – Enter the maximum number of nodes to which your node Auto Scaling group can scale out. This value must be at least one node greater than your desired capacity so that you can perform a rolling update of your nodes without reducing your node count during the update.
   - `NodeInstanceType` – Choose the instance type you recorded in a previous step (p. 135), or choose a different instance type for your nodes. Each Amazon EC2 instance type supports a
maximum number of elastic network interfaces (ENIs) and each ENI supports a maximum number of IP addresses. Since each worker node and pod is assigned its own IP address it’s important to choose an instance type that will support the maximum number of pods that you want to run on each worker node. For a list of the number of ENIs and IP addresses supported by instance types, see IP addresses per network interface per instance type. For example, the m5.large instance type supports a maximum of 30 IP addresses for the worker node and pods. Some instance types might not be available in all Regions.

**Note**
The supported instance types for the latest version of the Amazon VPC CNI plugin for Kubernetes are shown here. You may need to update your CNI version to take advantage of the latest supported instance types. For more information, see Amazon VPC CNI plugin for Kubernetes upgrades (p. 230).

**Important**
Some instance types might not be available in all Regions.

- **NodeImageIdSSMParam** – The Amazon EC2 Systems Manager parameter of the AMI ID that you want to update to. The following value uses the latest Amazon EKS optimized AMI for Kubernetes version 1.18.

```
/aws/service/eks/optimized-ami/<1.18>/<amazon-linux-2>/recommended/image_id
```

You can replace 1.18 with any supported Kubernetes version (p. 73). If you want to use the Amazon EKS optimized accelerated AMI, then replace `<amazon-linux-2>` with `<amazon-linux-2-gpu>`.

**Note**
Using the Amazon EC2 Systems Manager parameter enables you to update your nodes in the future without having to lookup and specify an AMI ID. If your AWS CloudFormation stack is using this value, any stack update will always launch the latest recommended Amazon EKS optimized AMI for your specified Kubernetes version, even if you don't change any values in the template.

- **NodeImageId** – To use your own custom AMI, enter the ID for the AMI to use.

  **Important**
  This value overrides any value specified for NodeImageIdSSMParam. If you want to use the NodeImageIdSSMParam value, ensure that the value for NodeImageId is blank.

- **DisableIMDSv1** – Each node supports the Instance Metadata Service Version 1 (IMDSv1) and IMDSv2 by default, but you can disable IMDSv1. Select true if you don't want any nodes in the node group, or any pods scheduled on the nodes in the node group to use IMDSv1. For more information about IMDS, see Configuring the instance metadata service. If you've implemented IAM roles for service accounts, have assigned necessary permissions directly to all pods that require access to AWS services, and no pods in your cluster require access to IMDS for other reasons, such as retrieving the current Region, then you can also disable access to IMDSv2 for pods that don't use host networking. For more information, see the section called “Restricting access to the instance profile” (p. 349).

10. (Optional) On the Options page, tag your stack resources. Choose Next.
11. On the Review page, review your information, acknowledge that the stack might create IAM resources, and then choose Update stack.

  **Note**
The update of each node in the cluster takes several minutes. Wait for the update of all nodes to complete before performing the next steps.

12. If your cluster's DNS provider is kube-dns, scale in the kube-dns deployment to one replica.

```
kubectl scale deployments/kube-dns --replicas=1 -n kube-system
```
13. (Optional) If you are using the Kubernetes Cluster Autoscaler, scale the deployment back to your desired amount of replicas.

```
kubectl scale deployments/cluster-autoscaler --replicas=<1> -n kube-system
```

14. (Optional) Verify that you are using the latest version of the Amazon VPC CNI plugin for Kubernetes. You may need to update your CNI version to take advantage of the latest supported instance types. For more information, see Amazon VPC CNI plugin for Kubernetes upgrades (p. 230).

AWS Fargate

This topic discusses using Amazon EKS to run Kubernetes pods on AWS Fargate.

AWS Fargate is a technology that provides on-demand, right-sized compute capacity for containers. With AWS Fargate, you no longer have to provision, configure, or scale groups of virtual machines to run containers. This removes the need to choose server types, decide when to scale your node groups, or optimize cluster packing.

You can control which pods start on Fargate and how they run with Fargate profiles (p. 143), which are defined as part of your Amazon EKS cluster.

Amazon EKS integrates Kubernetes with AWS Fargate by using controllers that are built by AWS using the upstream, extensible model provided by Kubernetes. These controllers run as part of the Amazon EKS managed Kubernetes control plane and are responsible for scheduling native Kubernetes pods onto Fargate. The Fargate controllers include a new scheduler that runs alongside the default Kubernetes scheduler in addition to several mutating and validating admission controllers. When you start a pod that meets the criteria for running on Fargate, the Fargate controllers running in the cluster recognize, update, and schedule the pod onto Fargate.

Each pod running on Fargate has its own isolation boundary and does not share the underlying kernel, CPU resources, memory resources, or elastic network interface with another pod.

This topic describes the different components of pods running on Fargate, and calls out special considerations for using Fargate with Amazon EKS.

AWS Fargate with Amazon EKS is currently available in the following Regions:

<table>
<thead>
<tr>
<th>Region name</th>
<th>Region (Availability Zone constraint)</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>us-west-1</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
</tr>
<tr>
<td>Asia Pacific (Hong Kong)</td>
<td>ap-east-1</td>
</tr>
<tr>
<td>Asia Pacific (Mumbai)</td>
<td>ap-south-1</td>
</tr>
<tr>
<td>Asia Pacific (Seoul)</td>
<td>ap-northeast-2</td>
</tr>
<tr>
<td>Asia Pacific (Singapore)</td>
<td>ap-southeast-1</td>
</tr>
<tr>
<td>Asia Pacific (Sydney)</td>
<td>ap-southeast-2</td>
</tr>
<tr>
<td>Asia Pacific (Tokyo)</td>
<td>ap-northeast-1 (apne1-az1, apne1-az2, and apne1-az4 only)</td>
</tr>
</tbody>
</table>
AWS Fargate considerations

Here’s some things to consider about using Fargate on Amazon EKS.

- Classic Load Balancers and Network Load Balancers can be used with IP targets only. You can also use AWS Application Load Balancers with Fargate. For more information, see the section called “Load balancer – IP targets” (p. 263) and the section called “Application load balancing” (p. 265).
- Pods must match a Fargate profile at the time that they are scheduled in order to run on Fargate. Pods which do not match a Fargate profile may be stuck as Pending. If a matching Fargate profile exists, you can delete pending pods that you have created to reschedule them onto Fargate.
- Daemonsets are not supported on Fargate. If your application requires a daemon, you should reconfigure that daemon to run as a sidecar container in your pods.
- Privileged containers are not supported on Fargate.
- Pods running on Fargate cannot specify HostPort or HostNetwork in the pod manifest.
- GPUs are currently not available on Fargate.
- You cannot use Security groups for pods (p. 214) with pods running on Fargate.
- Pods running on Fargate are only supported on private subnets (with NAT gateway access to AWS services, but not a direct route to an Internet Gateway), so your cluster’s VPC must have private subnets available. For clusters without outbound internet access, see Private clusters (p. 93).
- You can use the Vertical Pod Autoscaler (p. 253) to initially right size the CPU and memory for your Fargate pods, and then use the Horizontal Pod Autoscaler (p. 258) to scale those pods. If you want the Vertical Pod Autoscaler to automatically re-deploy pods to Fargate with larger CPU and memory combinations, then set the Vertical Pod Autoscaler’s mode to either Auto or Recreate to ensure correct functionality. For more information, see the Vertical Pod Autoscaler documentation on GitHub.
- DNS resolution and DNS hostnames must be enabled for your VPC. For more information, see Viewing and updating DNS support for your VPC.
- Fargate runs each pod in a VM-isolated environment without sharing resources with other pods. However, because Kubernetes is a single-tenant orchestrator, Fargate cannot guarantee pod-level security isolation. You should run sensitive workloads or untrusted workloads that need complete security isolation using separate Amazon EKS clusters.
- Fargate profiles support specifying subnets from VPC secondary CIDR blocks. You may want to specify a secondary CIDR block because there are a limited number of IP addresses available in a subnet. As a result, there are a limited number of pods that can be created in the cluster. Using different subnets for pods allows you to increase the number of available IP addresses. For more information, see Adding IPv4 CIDR blocks to a VPC.

### Region name | Region (Availability Zone constraint)
--- | ---
Canada (Central) | ca-central-1 (cac1-az1 and cac1-az2 only)
Europe (Frankfurt) | eu-central-1
Europe (Ireland) | eu-west-1
Europe (London) | eu-west-2
Europe (Paris) | eu-west-3
Europe (Stockholm) | eu-north-1
South America (São Paulo) | sa-east-1
Middle East (Bahrain) | me-south-1
Getting started with AWS Fargate using Amazon EKS

This topic helps you to get started running pods on AWS Fargate with your Amazon EKS cluster.

**Note**

AWS Fargate with Amazon EKS is currently only available in the following Regions:

<table>
<thead>
<tr>
<th>Region name</th>
<th>Region (Availability Zone constraint)</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>us-west-1</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
</tr>
<tr>
<td>Asia Pacific (Hong Kong)</td>
<td>ap-east-1</td>
</tr>
<tr>
<td>Asia Pacific (Mumbai)</td>
<td>ap-south-1</td>
</tr>
<tr>
<td>Asia Pacific (Seoul)</td>
<td>ap-northeast-2</td>
</tr>
<tr>
<td>Asia Pacific (Singapore)</td>
<td>ap-southeast-1</td>
</tr>
<tr>
<td>Asia Pacific (Sydney)</td>
<td>ap-southeast-2</td>
</tr>
<tr>
<td>Asia Pacific (Tokyo)</td>
<td>ap-northeast-1 (apne1-az1, apne1-az2, and apne1-az4 only)</td>
</tr>
<tr>
<td>Canada (Central)</td>
<td>ca-central-1 (cac1-az1 and cac1-az2 only)</td>
</tr>
<tr>
<td>Europe (Frankfurt)</td>
<td>eu-central-1</td>
</tr>
<tr>
<td>Europe (Ireland)</td>
<td>eu-west-1</td>
</tr>
<tr>
<td>Europe (London)</td>
<td>eu-west-2</td>
</tr>
<tr>
<td>Europe (Paris)</td>
<td>eu-west-3</td>
</tr>
<tr>
<td>Europe (Stockholm)</td>
<td>eu-north-1</td>
</tr>
<tr>
<td>South America (São Paulo)</td>
<td>sa-east-1</td>
</tr>
<tr>
<td>Middle East (Bahrain)</td>
<td>me-south-1</td>
</tr>
</tbody>
</table>

If you restrict access to your cluster's public endpoint using CIDR blocks, it is recommended that you also enable private endpoint access so that Fargate pods can communicate with the cluster. Without the private endpoint enabled, the CIDR blocks that you specify for public access must include the egress sources from your VPC. For more information, see Amazon EKS cluster endpoint access control (p. 56).

(Optional) Create a cluster

**Prerequisite**

An existing cluster in a supported Region (p. 139). If you do not already have an Amazon EKS cluster, you can create one with the following `eksctl` command.

**Note**

This procedure requires `eksctl` version 0.35.0 or later. You can check your version with the following command:
For more information on installing or upgrading eksctl, see Installing or upgrading eksctl (p. 292).

Adding the --fargate option in the command above creates a cluster without a node group. However, eksctl creates a pod execution role, a Fargate profile for the default and kube-system namespaces, and it patches the coredns deployment so that it can run on Fargate.

Ensure that existing nodes can communicate with Fargate pods

If you are working with a new cluster with no nodes, or a cluster with only managed node groups (p. 101), you can skip to Create a Fargate pod execution role (p. 140).

If you are working with an existing cluster that already has nodes associated with it, you need to make sure that pods on these nodes can communicate freely with pods running on Fargate. Pods running on Fargate are automatically configured to use the cluster security group for the cluster that they are associated with. You must ensure that any existing nodes in your cluster can send and receive traffic to and from the cluster security group. Managed node groups (p. 101) are automatically configured to use the cluster security group as well, so you do not need to modify or check them for this compatibility.

For existing node groups that were created with eksctl or the Amazon EKS managed AWS CloudFormation templates, you can add the cluster security group to the nodes manually, or you can modify the node group's Auto Scaling group launch template to attach the cluster security group to the instances. For more information, see Changing an instance's security groups in the Amazon VPC User Guide.

You can check for a cluster security group for your cluster in the AWS Management Console under the cluster's Networking section, or with the following AWS CLI command:

```
aws eks describe-cluster --name <cluster_name> --query 
cluster.resourcesVpcConfig.clusterSecurityGroupId
```

Create a Fargate pod execution role

When your cluster creates pods on AWS Fargate, the components running on the Fargate infrastructure need to make calls to AWS APIs on your behalf to do things like pull container images from Amazon ECR or route logs to other AWS services. The Amazon EKS pod execution role provides the IAM permissions to do this.

**Note**

If you created your cluster with eksctl using the --fargate option, then your cluster already has a pod execution role and you can skip ahead to Create a Fargate profile for your cluster (p. 141). Similarly, if you use eksctl to create your Fargate profiles, eksctl will create your pod execution role if one does not already exist.

When you create a Fargate profile, you must specify a pod execution role to use with your pods. This role is added to the cluster's Kubernetes Role based access control (RBAC) for authorization. This allows the kubelet that is running on the Fargate infrastructure to register with your Amazon EKS cluster so that it can appear in your cluster as a node. For more information, see Pod execution role (p. 328).

**Important**

The containers running in the Fargate pod can't assume the IAM permissions associated with a pod execution role. To give the containers in your Fargate pod permissions to access other AWS services, you must use IAM roles for service accounts (p. 330).
To create an AWS Fargate pod execution role with the AWS Management Console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Roles, then Create role.
3. Choose EKS from the list of services, EKS - Fargate pod for your use case, and then Next: Permissions.
4. Choose Next: Tags.
5. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM Entities in the IAM User Guide.
6. Choose Next: Review.
7. For Role name, enter a unique name for your role, such as AmazonEKSFargatePodExecutionRole, then choose Create role.

Create a Fargate profile for your cluster

Before you can schedule pods running on Fargate in your cluster, you must define a Fargate profile that specifies which pods should use Fargate when they are launched. For more information, see AWS Fargate profile (p. 143).

Note
If you created your cluster with eksctl using the --fargate option, then a Fargate profile has already been created for your cluster with selectors for all pods in the kube-system and default namespaces. Use the following procedure to create Fargate profiles for any other namespaces you would like to use with Fargate.

You can create a Fargate profile using eksctl (p. 141) or the AWS Management Console (p. 141).

To create a Fargate profile for a cluster with eksctl

This procedure requires eksctl version 0.35.0 or later. You can check your version with the following command:

```
eksctl version
```

For more information on installing or upgrading eksctl, see Installing or upgrading eksctl (p. 292).

- Create your Fargate profile with the following eksctl command, replacing the <variable text> with your own values. You must specify a namespace, but the labels option is not required.

```
eksctl create fargateprofile --cluster <cluster_name> --name <fargate_profile_name> --namespace <kubernetes_namespace> --labels <key=value>
```

To create a Fargate profile for a cluster with the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster to create a Fargate profile for.
3. Under Fargate profiles, choose Add Fargate profile.
4. On the Configure Fargate profile page, enter the following information and choose Next.
   a. For Name, enter a unique name for your Fargate profile.
   b. For Pod execution role, choose the pod execution role to use with your Fargate profile. Only IAM roles with the eks-fargate-pods.amazonaws.com service principal are shown. If you
do not see any roles listed here, you must create one. For more information, see Pod execution role (p. 328).

c. For **Subnets**, choose the subnets to use for your pods. By default, all subnets in your cluster's VPC are selected. Only private subnets are supported for pods running on Fargate; you must deselect any public subnets.

d. For **Tags**, you can optionally tag your Fargate profile. These tags do not propagate to other resources associated with the profile, such as its pods.

5. On the **Configure pods selection** page, enter the following information and choose **Next**.
   
a. For **Namespace**, enter a namespace to match for pods, such as `kube-system` or `default`.

b. (Optional) Add Kubernetes labels to the selector that pods in the specified namespace must have to match the selector. For example, you could add the label `infrastructure: fargate` to the selector so that only pods in the specified namespace that also have the `infrastructure: fargate` Kubernetes label match the selector.

6. On the **Review and create** page, review the information for your Fargate profile and choose **Create**.

**Optional** Update CoreDNS

By default, CoreDNS is configured to run on Amazon EC2 infrastructure on Amazon EKS clusters. If you want to **only** run your pods on Fargate in your cluster, you need to modify the CoreDNS deployment to remove the `eks.amazonaws.com/compute-type : ec2` annotation. You would also need to create a Fargate profile to target the CoreDNS pods. The following Fargate profile JSON file does this.

**Note**
If you created your cluster with `eksctl` using the `--fargate` option, then `coredns` has already been patched to run on Fargate and you can skip ahead to Next steps (p. 143).

```json
{
    "fargateProfileName": "coredns",
    "clusterName": "<dev>",
    "podExecutionRoleArn": "<arn:aws:iam::111122223333:role/AmazonEKSFargatePodExecutionRole>",
    "subnets": ["subnet-<0b6dd02d0c43864>", "subnet-<0b03756df55e2b87>", "subnet-<0418fcb68ed294abf>"],
    "selectors": [
        {
            "namespace": "kube-system",
            "labels": {
                "k8s-app": "kube-dns"
            }
        }
    ]
}
```

You could apply this Fargate profile to your cluster with the following AWS CLI command. First, create a file called `coredns.json` and paste the JSON file from the previous step into it, replacing the `<variable text>` with your own cluster values.

```
aws eks create-fargate-profile --cli-input-json file://coredns.json
```

Then, use the following `kubectl` command to remove the `eks.amazonaws.com/compute-type : ec2` annotation from the CoreDNS pods.

```
kubectl patch deployment coredns -n kube-system --type json \\`

142
Next steps

- You can start migrating your existing applications to run on Fargate with the following workflow.
  1. Create a Fargate profile (p. 144) that matches your application's Kubernetes namespace and
     Kubernetes labels.
  2. Delete and re-create any existing pods so that they are scheduled on Fargate. For example, the
     following command triggers a rollout of the coredns Deployment. You can modify the namespace
     and deployment type to update your specific pods.

     
     kubectl rollout restart -n <kube-system> <deployment coredns>

- Deploy the Application load balancing on Amazon EKS (p. 265) to allow Ingress objects for your pods
  running on Fargate.

- You can use the Vertical Pod Autoscaler (p. 253) to initially right size the CPU and memory for your
  Fargate pods, and then use the Horizontal Pod Autoscaler (p. 258) to scale those pods. If you want
  the Vertical Pod Autoscaler to automatically re-deploy pods to Fargate with larger CPU and memory
  combinations, then set the Vertical Pod Autoscaler's mode to either Auto or Recreate to ensure
  correct functionality. For more information, see the Vertical Pod Autoscaler documentation on GitHub.

AWS Fargate profile

Before you can schedule pods on Fargate in your cluster, you must define at least one Fargate profile that
specifies which pods should use Fargate when they are launched.

The Fargate profile allows an administrator to declare which pods run on Fargate. This declaration is
done through the profile's selectors. Each profile can have up to five selectors that contain a namespace
and optional labels. You must define a namespace for every selector. The label field consists of multiple
optional key-value pairs. Pods that match a selector (by matching a namespace for the selector and all of
the labels specified in the selector) are scheduled on Fargate. If a namespace selector is defined without
any labels, Amazon EKS will attempt to schedule all pods that run in that namespace onto Fargate using
the profile. If a to-be-scheduled pod matches any of the selectors in the Fargate profile, then that pod is
scheduled on Fargate.

If a pod matches multiple Fargate profiles, Amazon EKS picks one of the matches at random. In this
case, you can specify which profile a pod should use by adding the following Kubernetes label to the pod
specification: eks.amazonaws.com/fargate-profile: <profile_name>. However, the pod must
still match a selector in that profile in order to be scheduled onto Fargate.

When you create a Fargate profile, you must specify a pod execution role for the Amazon EKS
components that run on the Fargate infrastructure using the profile. This role is added to the cluster's
Kubernetes Role Based Access Control (RBAC) for authorization so that the kubelet that is running on
the Fargate infrastructure can register with your Amazon EKS cluster and appear in your cluster as a
node. The pod execution role also provides IAM permissions to the Fargate infrastructure to allow read
access to Amazon ECR image repositories. For more information, see Pod execution role (p. 328).

Fargate profiles are immutable. However, you can create a new updated profile to replace an existing
profile and then delete the original after the updated profile has finished creating.

Note
  Any pods that are running using a Fargate profile will be stopped and put into pending when
  the profile is deleted.

If any Fargate profiles in a cluster are in the DELETING status, you must wait for that Fargate profile to
finish deleting before you can create any other profiles in that cluster.
Fargate profile components

The following components are contained in a Fargate profile.

```json
{
  "fargateProfileName": "",
  "clusterName": "",
  "podExecutionRoleArn": "",
  "subnets": [""],
  "selectors": [
    {
      "namespace": "",
      "labels": {
        "KeyName": ""
      }
    }
  ],
  "clientRequestToken": "",
  "tags": {
    "KeyName": ""
  }
}
```

Pod execution role

When your cluster creates pods on AWS Fargate, the kubelet that is running on the Fargate infrastructure needs to make calls to AWS APIs on your behalf, for example, to pull container images from Amazon ECR. The Amazon EKS pod execution role provides the IAM permissions to do this.

When you create a Fargate profile, you must specify a pod execution role to use with your pods. This role is added to the cluster's Kubernetes Role Based Access Control (RBAC) for authorization, so that the kubelet that is running on the Fargate infrastructure can register with your Amazon EKS cluster and appear in your cluster as a node. For more information, see Pod execution role (p. 328).

Subnets

The IDs of subnets to launch pods into that use this profile. At this time, pods running on Fargate are not assigned public IP addresses, so only private subnets (with no direct route to an Internet Gateway) are accepted for this parameter.

Selectors

The selectors to match for pods to use this Fargate profile. Each selector must have an associated namespace. Optionally, you can also specify labels for a namespace. You may specify up to five selectors in a Fargate profile. A pod only needs to match one selector to run using the Fargate profile.

Namespace

You must specify a namespace for a selector. The selector only matches pods that are created in this namespace, but you can create multiple selectors to target multiple namespaces.

Labels

You can optionally specify Kubernetes labels to match for the selector. The selector only matches pods that have all of the labels that are specified in the selector.

Creating a Fargate profile

This topic helps you to create a Fargate profile. Your cluster must be in a supported Region (p. 137). You also must have created a pod execution role to use for your Fargate profile. For more information,
see Pod execution role (p. 328). Pods running on Fargate are only supported on private subnets (with
NAT gateway access to AWS services, but not a direct route to an Internet Gateway), so your cluster's
VPC must have private subnets available. You can create a profile with eksctl (p. 145) or the AWS
Management Console (p. 145).

To create a Fargate profile for a cluster with eksctl

This procedure requires eksctl version 0.35.0 or later. You can check your version with the following
command:

```
eksctl version
```

For more information on installing or upgrading eksctl, see Installing or upgrading eksctl (p. 292).

- Create your Fargate profile with the following eksctl command, replacing the <variable text> with
  your own values. You must specify a namespace, but the labels option is not required.

```
eksctl create fargateprofile --cluster <cluster_name> --name <fargate_profile_name> --namespace <kubernetes_namespace> --labels <key=value>
```

To create a Fargate profile for a cluster with the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster to create a Fargate profile for.
3. Under Fargate profiles, choose Add Fargate profile.
4. On the Configure Fargate profile page, enter the following information and choose Next.
   a. For Name, enter a unique name for your Fargate profile.
   b. For Pod execution role, choose the pod execution role to use with your Fargate profile. Only
      IAM roles with the eks-fargate-pods.amazonaws.com service principal are shown. If you
donot see any roles listed here, you must create one. For more information, see Pod execution
      role (p. 328).
   c. For Subnets, choose the subnets to use for your pods. By default, all subnets in your cluster's
      VPC are selected. Only private subnets are supported for pods running on Fargate; you must
deselect any public subnets.
   d. For Tags, you can optionally tag your Fargate profile. These tags do not propagate to other
      resources associated with the profile, such as its pods.
5. On the Configure pods selection page, enter the following information and choose Next.
   a. For Namespace, enter a namespace to match for pods, such as kube-system or default.
   b. (Optional) Add Kubernetes labels to the selector that pods in the specified namespace
      must have to match the selector. For example, you could add the label infrastructure:
      fargate to the selector so that only pods in the specified namespace that also have the
      infrastructure: fargate Kubernetes label match the selector.
6. On the Review and create page, review the information for your Fargate profile and choose Create.

Deleting a Fargate profile

This topic helps you to delete a Fargate profile.

When you delete a Fargate profile, any pods that were scheduled onto Fargate with the profile are
deleted. If those pods match another Fargate profile, then they are scheduled on Fargate with that
profile. If they no longer match any Fargate profiles, then they are not scheduled onto Fargate and may remain as pending.

Only one Fargate profile in a cluster can be in the DELETING status at a time. You must wait for a Fargate profile to finish deleting before you can delete any other profiles in that cluster.

To delete a Fargate profile from a cluster

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose the cluster that you want to delete the Fargate profile from.
3. Choose the Fargate profile to delete and then Delete.
4. On the Delete <cluster_name> page, type the name of the cluster and choose Confirm to delete.

Fargate pod configuration

This section describes some of the unique pod configuration details for running Kubernetes pods on AWS Fargate.

Pod CPU and memory

Kubernetes allows you to define requests, a minimum amount of vCPU and memory resources that are allocated to each container in a pod. Pods are scheduled by Kubernetes to ensure that at least the requested resources for each pod are available on the compute resource. For more information, see Managing compute resources for containers in the Kubernetes documentation.

When pods are scheduled on Fargate, the vCPU and memory reservations within the pod specification determine how much CPU and memory to provision for the pod.

- The maximum request out of any Init containers is used to determine the Init request vCPU and memory requirements.
- Requests for all long-running containers are added up to determine the long-running request vCPU and memory requirements.
- The larger of the above two values is chosen for the vCPU and memory request to use for your pod.
- Fargate adds 256 MB to each pod's memory reservation for the required Kubernetes components (kubelet, kube-proxy, and containerd).

Fargate rounds up to the compute configuration shown below that most closely matches the sum of vCPU and memory requests in order to ensure pods always have the resources that they need to run.

If you do not specify a vCPU and memory combination, then the smallest available combination is used (.25 vCPU and 0.5 GB memory).

The table below shows the vCPU and memory combinations that are available for pods running on Fargate.

<table>
<thead>
<tr>
<th>vCPU value</th>
<th>Memory value</th>
</tr>
</thead>
<tbody>
<tr>
<td>.25 vCPU</td>
<td>0.5 GB, 1 GB, 2 GB</td>
</tr>
<tr>
<td>.5 vCPU</td>
<td>1 GB, 2 GB, 3 GB, 4 GB</td>
</tr>
<tr>
<td>1 vCPU</td>
<td>2 GB, 3 GB, 4 GB, 5 GB, 6 GB, 7 GB, 8 GB</td>
</tr>
<tr>
<td>vCPU value</td>
<td>Memory value</td>
</tr>
<tr>
<td>------------</td>
<td>------------------------------------------</td>
</tr>
<tr>
<td>2 vCPU</td>
<td>Between 4 GB and 16 GB in 1-GB increments</td>
</tr>
<tr>
<td>4 vCPU</td>
<td>Between 8 GB and 30 GB in 1-GB increments</td>
</tr>
</tbody>
</table>

For pricing information on these compute configurations, see [AWS Fargate pricing](https://aws.amazon.com/fargate/pricing/).

### Fargate storage

When provisioned, each pod running on Fargate receives 20 GB of container image layer storage. Pod storage is ephemeral. After a pod stops, the storage is deleted. New pods launched onto Fargate on or after 5/28/2020, have encryption of the ephemeral storage volume enabled by default. The ephemeral pod storage is encrypted with an AES-256 encryption algorithm using AWS Fargate managed keys.

**Note**
The usable storage for Amazon EKS pods running on Fargate is less than 20GB because some space is used by the `kubelet` and other Kubernetes modules that are loaded inside the pod.

### AWS Fargate usage metrics

You can use CloudWatch usage metrics to provide visibility into your accounts usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

AWS Fargate usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about Fargate service quotas, see [Amazon EKS service quotas (p. 306)](https://docs.aws.amazon.com/eks/latest/userguide/service-quotas.html).

AWS Fargate publishes the following metrics in the `AWS/Usage` namespace.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourceCount</td>
<td>The total number of the specified resource running on your account. The resource is defined by the dimensions associated with the metric.</td>
</tr>
</tbody>
</table>

The following dimensions are used to refine the usage metrics that are published by AWS Fargate.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service</td>
<td>The name of the AWS service containing the resource. For AWS Fargate usage metrics, the value for this dimension is <code>Fargate</code>.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of entity that is being reported. Currently, the only valid value for AWS Fargate usage metrics is <code>Resource</code>.</td>
</tr>
<tr>
<td>Resource</td>
<td>The type of resource that is running.</td>
</tr>
</tbody>
</table>

Currently, AWS Fargate returns information on your Fargate On-Demand usage. The resource value for Fargate On-Demand usage is `OnDemand`.

**Note**
Fargate On-Demand usage combines Amazon EKS pods using Fargate, Amazon ECS tasks using the Fargate launch.
Creating a CloudWatch alarm to monitor Fargate resource usage metrics

AWS Fargate provides CloudWatch usage metrics that correspond to the AWS service quotas for Fargate On-Demand resource usage. In the Service Quotas console, you can visualize your usage on a graph and configure alarms that alert you when your usage approaches a service quota. For more information, see AWS Fargate usage metrics (p. 147).

Use the following steps to create a CloudWatch alarm based on the Fargate resource usage metrics.

To create an alarm based on your Fargate usage quotas (AWS Management Console)

2. In the navigation pane, choose AWS services.
3. From the AWS services list, search for and select AWS Fargate.
4. In the Service quotas list, select the Fargate usage quota you want to create an alarm for.
5. In the Amazon CloudWatch Events alarms section, choose Create.
6. For Alarm threshold, choose the percentage of your applied quota value that you want to set as the alarm value.
7. For Alarm name, enter a name for the alarm and then choose Create.

Fargate logging

Amazon EKS with Fargate supports a built-in log router, which means there are no sidecar containers to install or maintain. The log router allows you to use the breadth of services at AWS for log analytics and storage. You can stream logs from Fargate directly to Amazon CloudWatch, Amazon Elasticsearch Service, and Amazon Kinesis Data Firehose destinations such as Amazon S3, Amazon Kinesis Data Streams, and partner tools. Fargate uses a version of AWS for Fluent Bit, an upstream compliant distribution of Fluent Bit managed by AWS. For more information, see AWS for Fluent Bit on GitHub.

Prerequisites

- An existing Amazon EKS cluster. The cluster must be running one of the following (or later) platform versions.
Fargate logging

If you don't have an existing cluster at one of these platform versions, or later, see Getting started with Amazon EKS (p. 4) to deploy a cluster.

- An existing Fargate profile that specifies an existing Kubernetes namespace that you deploy Fargate pods to. For more information, see the section called "Create a Fargate profile for your cluster" (p. 141).

To send logs to a destination of your choice

Apply a ConfigMap to your Amazon EKS cluster with a Fluent Conf data value that defines where container logs are shipped to. Fluent Conf is Fluent Bit, which is a fast and lightweight log processor configuration language that is used to route container logs to a log destination of your choice. For more information, see Configuration File in the Fluent Bit documentation.

1. Create a Kubernetes namespace.
   a. Save the following contents to a yaml file on your computer.

```
kind: Namespace
apiVersion: v1
metadata:
  name: aws-observability
  labels:
    aws-observability: enabled
```
   b. Create the namespace. Replace the <example values> (including <> with your own values.

```
kubectl apply -f <name-of-file-from-previous-step>.yaml
```

2. Configure Kubernetes to send Fargate logs to one of the following destinations.
   a. (Optional) Send logs to CloudWatch. You have two output options when using CloudWatch:
      - `cloudwatch_logs` - An output plugin written in C.
      - `cloudwatch` - An output plugin written in Golang.

      The following example shows you how to use the `cloudwatch_logs` plugin to send logs to CloudWatch.
      i. Create a yaml file with the following contents.

```
kind: ConfigMap
apiVersion: v1
metadata:
  name: aws-logging
  namespace: aws-observability
  labels:
    data:
      output.conf: |
      [OUTPUT]
      Name cloudwatch_logs
      Match *
      region <us-east-1>
      log_group_name fluent-bit-cloudwatch
      log_stream_prefix from-fluent-bit
      auto_create_group On
```
   ii. Apply the manifest to your cluster.
iii. Download the CloudWatch IAM policy to your computer. You can also view the policy on GitHub.

curl -o permissions.json https://raw.githubusercontent.com/aws-samples/amazon-eks-fluent-logging-examples/mainline/examples/fargate/cloudwatchlogs/permissions.json

b. (Optional) Send logs to Amazon Elasticsearch Service. You can use es output, which is a plugin written in C. The following example shows you how to use the plugin to send logs to Elasticsearch.

i. Create a yaml file with the following contents.

```yaml
kind: ConfigMap
apiVersion: v1
metadata:
  name: aws-logging
  namespace: aws-observability
  labels:
  data:
    output.conf: |
      [OUTPUT]
      Name  es
      Match *
      Host  192.168.2.3
      Port  9200
      Index my_index
      Type  my_type
      AWS_Auth On
      AWS_Region <us-east-1>
```

ii. Apply the manifest to your cluster.

kubectl apply -f <filename-you-created>.yaml

iii. Download the Elasticsearch IAM policy to your computer. You can also view the policy on GitHub.

curl -o permissions.json https://raw.githubusercontent.com/aws-samples/amazon-eks-fluent-logging-examples/mainline/examples/fargate/amazon-elasticsearch/permissions.json

c. (Optional) Send logs to Kinesis Data Firehose. You have two output options when using Kinesis Data Firehose:

- kinesis_firehose – An output plugin written in C.
- firehose – An output plugin written in Golang.

The following example shows you how to use the kinesis_firehose plugin to send logs to Kinesis Data Firehose.

i. Create a yaml file with the following contents.

```yaml
kind: ConfigMap
apiVersion: v1
metadata:
  name: aws-logging
  namespace: aws-observability
  labels:
  data:
    output.conf: |
      [OUTPUT]
      Name  kinesis_firehose
      Match *
      Host  192.168.2.3
      Port  9200
      Index my_index
      Type  my_type
      AWS_Auth On
      AWS_Region <us-east-1>
```

```bash
kubectl apply -f <filename-you-created>.yaml
```
name: aws-logging
namespace: aws-observability
labels:
data:
output.conf: |
[OUTPUT]
Name kinesis_firehose
Match *
region <us-east-1>
delivery_stream my-stream-firehose

ii. Apply the manifest to your cluster.

```bash
kubectl apply -f <filename-you-created>.yaml
```

iii. Download the Kinesis Data Firehose IAM policy to your computer. You can also view the policy on GitHub.

```bash
```

3. Create an IAM policy.

```bash
aws iam create-policy --policy-name <eks-fargate-logging-policy> --policy-document file://permissions.json
```

4. Attach the IAM policy to the pod execution role specified for your Fargate profile. Replace `<111122223333>` with your account ID.

```bash
aws iam attach-role-policy --policy-arn arn:aws:iam::<111122223333>:policy/<eks-fargate-logging-policy> --role-name <your-pod-execution-role>
```

5. Deploy a sample pod.

   a. Save the following contents to a `yaml` file on your computer.

   ```yaml
   apiVersion: apps/v1
   kind: Deployment
   metadata:
     name: sample-app
     namespace: <same-namespace-as-your-fargate-profile>
   spec:
     replicas: 3
     selector:
       matchLabels:
         app: nginx
     template:
       metadata:
         labels:
           app: nginx
       spec:
         containers:
           - name: nginx
             image: nginx:latest
             ports:
               - name: http
                 containerPort: 80
   ```

   b. Apply the manifest to the cluster.
6. View your logs using the tool that you sent your logs to.

**Size considerations**

We suggest that you plan for up to 50 MB of memory for your logs. If you expect your application to generate logs at very high throughput then you should plan for up to 100 MB.

**Troubleshooting**

To confirm whether the logging feature is enabled or disabled for some reason, such as an invalid ConfigMap, and why it is invalid, check your pod events with `kubectl describe pod <pod_name>`. The output might include pod events that clarify whether logging is enabled or not, such as the following example output.

```
... Annotations:          CapacityProvisioned: 0.25vCPU 0.5GB
                     Logging: LoggingDisabled: LOGGING_CONFIGMAP_NOT_FOUND
                     kubernetes.io/psp: eks.privileged
... Events:
  Type     Reason           Age        From
  Message
  ----     ------           ----       ----
  Warning  LoggingDisabled <unknown> fargate-scheduler
           Disabled logging because aws-logging configmap was not found. configmap "aws-logging" not found
```

The pod events are ephemeral with a time period depending on the settings. You can also view a pod's annotations using `kubectl describe pod <pod-name>`. In the pod annotation, there is information about whether the logging feature is enabled or disabled and the reason.

**Validation strategy**

The main sections included in a typical Fluent Conf are Service, Input, Filter, and Output. Filter, Output, and Parser. Service and Input are generated by Fargate. Fargate only validates the Filter, Output, and Parser specified in the Fluent Conf. Any sections provided other than Filter, Output, and Parser are ignored. The following rules are used to validate the Filter, Output, and Parser fields.

1. [FILTER], [OUTPUT], and [PARSER] are supposed to be specified under each corresponding key: `filters.conf`, `output.conf`, and `parsers.conf`. For example, [FILTER] must be under `filters.conf`. You can have many [FILTER]s under `filters.conf`. The same is true for [OUTPUT] and [PARSER].
2. Fargate validates the required keys for each section. Name and match are required for each [FILTER] and [OUTPUT]. Name and format are required for each [PARSER]. The keys are case-insensitive.
3. Environment variables such as `${ENV_VAR}` are not allowed in the configmap.
4. The indentation has to be the same for either directive or key-value pair within each `filters.conf`, `output.conf`, and `parsers.conf`. Key-value pairs have to be indented more than directives.
5. Fargate validates against the following supported filters: `grep`, `kubernetes`, `parser`, `record_modifier`, `rewrite_tag`, `throttle`, `nest`, and `modify`.
6. Fargate validates against the following supported output: `es`, `firehose`, `kinesis_firehose`, `cloudwatch`, `cloudwatch_logs`, and `kinesis`.
7. At least one supported Output plugin has to be provided in the ConfigMap to enable logging. Filter and Parser are not required to enable logging.
For more information about Fluent Conf see Configuration File in the Fluent Bit documentation. You can also run Fluent Bit on Amazon EC2 using the desired configuration to troubleshoot any issues that arise from validation.

Amazon EKS optimized AMIs

You can deploy nodes with pre-built Amazon EKS optimized Amazon Machine Images (AMI), or your own custom AMIs. For more information about each type of Amazon EKS optimized AMI, see one of the following topics. For more information about creating your own custom AMI, see Amazon EKS optimized Amazon Linux AMI build script (p. 166).

Topics

• Amazon EKS optimized Amazon Linux AMIs (p. 153)

Amazon EKS optimized Amazon Linux AMIs

The Amazon EKS optimized Amazon Linux AMI is built on top of Amazon Linux 2, and is configured to serve as the base image for Amazon EKS nodes. The AMI is configured to work with Amazon EKS and it includes Docker, kubelet, and the AWS IAM Authenticator.

Note

• You can track security or privacy events for Amazon Linux 2 at the Amazon Linux security center or subscribe to the associated RSS feed. Security and privacy events include an overview of the issue, what packages are affected, and how to update your instances to correct the issue.
• Before deploying an accelerated or Arm AMI, review the information in Amazon EKS optimized accelerated Amazon Linux AMIs (p. 159) and Amazon EKS optimized Arm Amazon Linux AMIs (p. 161).

Select a link in one of the following tables to view the latest Amazon EKS optimized Amazon Linux AMI ID for a region and Kubernetes version. You can also retrieve the IDs with an AWS Systems Manager parameter using different tools. For more information, see Retrieving Amazon EKS optimized Amazon Linux AMI IDs (p. 166).

Kubernetes version 1.18.9

Important
These AMIs require the latest AWS CloudFormation node template. You can't use these AMIs with a previous version of the node template; they will fail to join your cluster. Be sure to upgrade any existing AWS CloudFormation node stacks with the latest template (URL shown below) before you attempt to use these AMIs. Use the URL that corresponds to the Region that your cluster is in.

• All Regions other than China (Beijing) and China (Ningxia)

• China (Beijing) and China (Ningxia)

The AWS CloudFormation node template launches your nodes with Amazon EC2 user data that triggers a specialized bootstrap script. This script allows your nodes to discover and connect to your cluster's control plane automatically. For more information, see Launching self-managed Amazon Linux nodes (p. 117).

Amazon EKS optimized accelerated Amazon Linux AMIs

The Amazon EKS optimized accelerated Amazon Linux AMI is built on top of the standard Amazon EKS optimized Amazon Linux AMI, and is configured to serve as an optional image for Amazon EKS nodes to support GPU and Inferentia based workloads.

In addition to the standard Amazon EKS optimized AMI configuration, the accelerated AMI includes the following:

• NVIDIA drivers
• The nvidia-container-runtime (as the default runtime)
• AWS Neuron container runtime

Note

• The Amazon EKS optimized accelerated AMI only supports GPU and Inferentia based instance types. Be sure to specify these instance types in your node AWS CloudFormation template. By using the Amazon EKS optimized accelerated AMI, you agree to NVIDIA's end user license agreement (EULA).
• The Amazon EKS optimized accelerated AMI was previously referred to as the Amazon EKS optimized AMI with GPU support.
Previous versions of the Amazon EKS optimized accelerated AMI installed the nvidia-docker repository. The repository is no longer included in Amazon EKS AMI version v20200529 and later.

To enable GPU based workloads

The following procedure describes how to run a workload on a GPU based instance with the Amazon EKS optimized accelerated AMI. For more information about using Inferentia based workloads, see Inferentia support (p. 86).

1. After your GPU nodes join your cluster, you must apply the NVIDIA device plugin for Kubernetes as a DaemonSet on your cluster with the following command.

   ```bash
   kubectl apply -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.6.0/nvidia-device-plugin.yml
   ```

2. You can verify that your nodes have allocatable GPUs with the following command:

   ```bash
   kubectl get nodes -o=custom-columns=NAME:.metadata.name,GPU:.status.allocatable.nvidia\.com/gpu
   ```

To deploy a pod to test that your GPU nodes are configured properly

1. Create a file named `nvidia-smi.yaml` with the following contents. This manifest launches a Cuda container that runs `nvidia-smi` on a node.

   ```yaml
   apiVersion: v1
   kind: Pod
   metadata:
     name: nvidia-smi
   spec:
     restartPolicy: OnFailure
     containers:
     - name: nvidia-smi
       image: nvidia/cuda:9.2-devel
       args:
       - "nvidia-smi"
       resources:
         limits:
           nvidia.com/gpu: 1
   ```

2. Apply the manifest with the following command:

   ```bash
   kubectl apply -f nvidia-smi.yaml
   ```

3. After the pod has finished running, view its logs with the following command:

   ```bash
   kubectl logs nvidia-smi
   ```

Output:

```
Mon Aug  6 20:23:31 2018
+-----------------------------------------------------------------------------+
| NVIDIA-SMI 396.26 | Driver Version: 396.26 |
|-------------------------------+----------------------+----------------------+
| GPU  Name        Persistence-M| Bus-Id        Disp.A | Volatile Uncorr. ECC |
| Fan  Temp  Perf  Pwr:Usage/Cap| Memory-Usage | GPU-Util  Compute M. |
|-------------------------------+----------------------+----------------------|
```

160
Amazon EKS optimized Arm Amazon Linux AMIs

Arm instances deliver significant cost savings for scale-out and Arm-based applications such as web servers, containerized microservices, caching fleets, and distributed data stores. When adding Arm nodes to your cluster, review the following considerations.

**Considerations**

- You can only deploy Arm AMIs in 1.15 or later clusters.
- If your cluster was deployed before August 17, 2020, then you must do a one-time upgrade of critical cluster add-on manifests so that Kubernetes can pull the correct image for each hardware architecture in use in your cluster. For more information about updating cluster add-ons, see Update an existing cluster (p. 44). If you deployed your cluster on or after August 17, 2020, then your **coredns**, **kube-proxy**, and Amazon VPC CNI Plugin for Kubernetes add-ons are already multi-architecture capable.
- Applications deployed to Arm nodes must be compiled for Arm.
- You can’t use the Amazon FSx for Lustre CSI driver (p. 191) with Arm.
- If you have any DaemonSets deployed in an existing cluster, or you want to deploy them to a new cluster that you also want to deploy Arm nodes in, then ensure that your DaemonSet can run on all hardware architectures in your cluster.
- You can run Arm node groups and x86 node groups in the same cluster. If you do, consider deploying multi-architecture container images to a container repository such as Amazon Elastic Container Registry and then adding node selectors to your manifests so that Kubernetes knows what hardware architecture a pod can be deployed to. For more information, see Pushing a multi-architecture image in the Amazon ECR User Guide and the Introducing multi-architecture container images for Amazon ECR blog post.

Amazon EKS optimized Amazon Linux AMI versions

This topic lists versions of the Amazon EKS optimized Amazon Linux AMIs and their corresponding versions of **kubelet**, Docker, the Linux kernel, and the **Packer build script** (p. 166) configuration.

The Amazon EKS optimized AMI metadata, including the AMI ID, for each variant can be retrieved programmatically. For more information, see Retrieving Amazon EKS optimized Amazon Linux AMI IDs (p. 166).

AMIs are versioned by Kubernetes version and the release date of the AMI in the following format:

```
<k8s_major_version>.<k8s_minor_version>.<k8s_patch_version>-<release_date>
```

### Retrieving Amazon EKS optimized Amazon Linux AMI IDs

You can programmatically retrieve the Amazon Machine Image (AMI) ID for Amazon EKS optimized AMIs by querying the AWS Systems Manager Parameter Store API. This parameter eliminates the need for you to manually look up Amazon EKS optimized AMI IDs. For more information about the Systems Manager Parameter Store API, see [GetParameter](#). Your user account must have the `ssm:GetParameter` IAM permission to retrieve the Amazon EKS optimized AMI metadata.

You can retrieve the AMI ID with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon EKS optimized Amazon Linux AMI with the following command by using the sub-parameter `image_id`. Replace `<1.18>` with a supported version (p. 73) and `<region-code>` with an Amazon EKS supported Region for which you want the AMI ID. Replace `<amazon-linux-2>` with `amazon-linux-2-gpu` to see the accelerated AMI ID and `amazon-linux-2-arm64` to see the Arm ID.

  ```bash
  aws ssm get-parameter --name /aws/service/eks/optimized-ami/<1.18>/<amazon-linux-2>/recommended/image_id --region <region-code> --query "Parameter.Value" --output text
  ```

  Example output:

  ```
  ami-<abcd1234efgh5678i>
  ```

- **AWS Management Console** – You can query for the recommended Amazon EKS optimized AMI ID using a URL. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, replace `<1.18>` with a supported version (p. 73) and `<region-code>` with an Amazon EKS supported Region for which you want the AMI ID. Replace `<amazon-linux-2>` with `amazon-linux-2-gpu` to see the accelerated AMI ID and `amazon-linux-2-arm64` to see the Arm ID.

  ```url
  https://console.aws.amazon.com/systems-manager/parameters/%252Faws%252Fs3%252Fservice%252Feks%252Foptimized-ami%252F<1.18>%252Famazon-linux-2%252Frecommended%252Fimage_id/?region=<region-code>
  ```

### Amazon EKS optimized Amazon Linux AMI build script

Amazon Elastic Kubernetes Service (Amazon EKS) has open-sourced the build scripts that are used to build the Amazon EKS optimized AMI. These build scripts are now available on [GitHub](#).
The Amazon EKS optimized Amazon Linux AMI is built on top of Amazon Linux 2, specifically for use as a node in Amazon EKS clusters. You can use this repository to view the specifics of how the Amazon EKS team configures kubectl, Docker, the AWS IAM Authenticator for Kubernetes, and more.

The build scripts repository includes a HashiCorp packer template and build scripts to generate an AMI. These scripts are the source of truth for Amazon EKS optimized AMI builds, so you can follow the GitHub repository to monitor changes to our AMIs. For example, perhaps you want your own AMI to use the same version of Docker that the EKS team uses for the official AMI.

The GitHub repository also contains the specialized bootstrap script that runs at boot time to configure your instance's certificate data, control plane endpoint, cluster name, and more.

Additionally, the GitHub repository contains our Amazon EKS node AWS CloudFormation templates. These templates make it easier to spin up an instance running the Amazon EKS optimized AMI and register it with a cluster.

For more information, see the repositories on GitHub at https://github.com/awslabs/amazon-eks-ami.

Amazon EKS optimized Ubuntu Linux AMIs

Canonical has partnered with Amazon EKS to create node AMIs that you can use in your clusters.

Canonical delivers a built-for-purpose Kubernetes Node OS image. This minimized Ubuntu image is optimized for Amazon EKS and includes the custom AWS kernel that is jointly developed with AWS. For more information, see Ubuntu and Amazon Elastic Kubernetes Service and Optimized support for Amazon EKS on Ubuntu 18.04.

Amazon EKS optimized Bottlerocket AMIs

The Amazon EKS optimized Bottlerocket AMI is built on top of Bottlerocket. The AMI is configured to work with Amazon EKS and it includes containerd and kubectl.

Select a link in one of the following tables to view the latest Amazon EKS optimized Bottlerocket AMI ID for a region and Kubernetes version. You can also retrieve the IDs with an AWS Systems Manager parameter using different tools. For more information, see Retrieving Amazon EKS optimized Bottlerocket AMI IDs (p. 170).

Retrieving Amazon EKS optimized Bottlerocket AMI IDs

You can programmatically retrieve the Amazon Machine Image (AMI) ID for Amazon EKS optimized AMIs by querying the AWS Systems Manager Parameter Store API. This parameter eliminates the need for you to manually look up Amazon EKS optimized AMI IDs. For more information about the Systems Manager Parameter Store API, see GetParameter. Your user account must have the ssm:GetParameter IAM permission to retrieve the Amazon EKS optimized AMI metadata.

You can retrieve the AMI ID with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon EKS optimized Bottlerocket AMI with the following AWS CLI command by using the sub-parameter `image_id`. Replace `<1.18>` with a supported version (p. 73) and `<region-code>` with an Amazon EKS supported Region for which you want the AMI ID.

  ```bash
  aws ssm get-parameter --name /aws/service/bottlerocket/aws-k8s-<1.18>/x86_64/latest/image_id --region <region-code> --query "Parameter.Value" --output text
  ```

  Example output:

  ```
  
  ```

<table>
<thead>
<tr>
<th>Region</th>
<th>x86</th>
<th>Arm</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asia Pacific (Tokyo) (ap-northeast-1)</td>
<td>View AMI ID</td>
<td>View AMI ID</td>
</tr>
<tr>
<td>Asia Pacific (Seoul) (ap-northeast-2)</td>
<td>View AMI ID</td>
<td>View AMI ID</td>
</tr>
<tr>
<td>Asia Pacific (Singapore) (ap-southeast-1)</td>
<td>View AMI ID</td>
<td>View AMI ID</td>
</tr>
<tr>
<td>Asia Pacific (Sydney) (ap-southeast-2)</td>
<td>View AMI ID</td>
<td>View AMI ID</td>
</tr>
<tr>
<td>Canada (Central) (ca-central-1)</td>
<td>View AMI ID</td>
<td>View AMI ID</td>

<td>View AMI ID</td>
<td>View AMI ID</td>
</tr>
<tr>
<td>Europe (Paris) (eu-west-3)</td>
<td>View AMI ID</td>
<td>View AMI ID</td>
</tr>
<tr>
<td>Europe (Stockholm) (eu-north-1)</td>
<td>View AMI ID</td>
<td>View AMI ID</td>
</tr>
<tr>
<td>Middle East (Bahrain) (me-south-1)</td>
<td>View AMI ID</td>
<td>View AMI ID</td>
</tr>
<tr>
<td>South America (São Paulo) (sa-east-1)</td>
<td>View AMI ID</td>
<td>View AMI ID</td>
</tr>
</tbody>
</table>
AWS Management Console – You can query for the recommended Amazon EKS optimized AMI ID using a URL in the AWS Management Console. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, replace `<1.18>` with a supported version (p. 73) and `<region-code>` with an Amazon EKS supported Region for which you want the AMI ID.

https://console.aws.amazon.com/systems-manager/parameters/aws/service/bottlerocket/aws-k8s-<1.18>/x86_64/latest/image_id/description?region=<region-code>

Amazon EKS optimized Windows AMIs

The Amazon EKS optimized AMI is built on top of Windows Server 2019, and is configured to serve as the base image for Amazon EKS nodes. The AMI is configured to work with Amazon EKS out of the box, and it includes Docker, kubectl, and the AWS IAM Authenticator.

Note
You can track security or privacy events for Windows Server with the Microsoft security update guide.

The AMI IDs for the latest Amazon EKS optimized AMI are shown in the following tables. Windows Server 2019 is a Long-Term Servicing Channel (LTSC) release and Windows Server, version 2004 is a Semi-Annual Channel (SAC) release. For more information, see Windows Server servicing channels: LTSC and SAC in the Microsoft documentation. You can also retrieve the IDs with an AWS Systems Manager parameter using different tools. For more information, see Retrieving Amazon EKS optimized Windows AMI IDs (p. 179).

Amazon EKS optimized Windows AMI versions

This topic lists versions of the Amazon EKS optimized Windows AMIs and their corresponding versions of kubelet and Docker.

The Amazon EKS optimized AMI metadata, including the AMI ID, for each variant can be retrieved programmatically. For more information, see Retrieving Amazon EKS optimized Windows AMI IDs (p. 179).

AMIs are versioned by Kubernetes version and the release date of the AMI in the following format:

<k8s_major_version>.<k8s_minor_version>--<release_date>

Retrieving Amazon EKS optimized Windows AMI IDs

You can programmatically retrieve the Amazon Machine Image (AMI) ID for Amazon EKS optimized AMIs by querying the AWS Systems Manager Parameter Store API. This parameter eliminates the need for you to manually look up Amazon EKS optimized AMI IDs. For more information about the Systems Manager Parameter Store API, see GetParameter. Your user account must have the ssm:GetParameter IAM permission to retrieve the Amazon EKS optimized AMI metadata.

You can retrieve the AMI ID with the AWS CLI or the AWS Management Console.
• **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon EKS optimized Windows AMI with the following command by using the sub-parameter `image_id`. You can replace `<1.18>` (including `<>`) with any supported Amazon EKS version and can replace `<region-code>` with an Amazon EKS supported Region for which you want the AMI ID. Replace `<Core>` with Full to see the Windows Server full AMI ID. You can also replace `<2019>` with `2004` for the Core version only.

```bash
```

Example output:

`ami-<ami-00a053f1635f65ea0>`

• **AWS Management Console** – You can query for the recommended Amazon EKS optimized AMI ID using a URL. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, you can replace `<1.18>` (including `<>`) with any supported Amazon EKS version and can replace `<region-code>` with an Amazon EKS supported Region for which you want the AMI ID. Replace `<Core>` with Full to see the Windows Server full AMI ID. You can also replace `<2019>` with `2004` for the Core version only.

```
```
Storage

This chapter covers storage options for Amazon EKS clusters.

The Storage classes (p. 181) topic uses the in-tree Amazon EBS storage provisioner.

Note
The existing in-tree Amazon EBS plugin is still supported, but by using a CSI driver, you benefit from the decoupling of Kubernetes upstream release cycle and CSI driver release cycle. Eventually, the in-tree plugin will be deprecated in favor of the CSI driver.

Topics
- Storage classes (p. 181)
- Amazon EBS CSI driver (p. 182)
- Amazon EFS CSI driver (p. 186)
- Amazon FSx for Lustre CSI driver (p. 191)

Storage classes

Amazon EKS clusters that were created prior to Kubernetes version 1.11 were not created with any storage classes. You must define storage classes for your cluster to use and you should define a default storage class for your persistent volume claims. For more information, see Storage classes in the Kubernetes documentation.

Note
This topic uses the in-tree Amazon EBS storage provisioner. The existing in-tree Amazon EBS plugin is still supported, but by using a CSI driver, you benefit from the decoupling of Kubernetes upstream release cycle and CSI driver release cycle. Eventually, the in-tree plugin will be deprecated in favor of the CSI driver.

To create an AWS storage class for your Amazon EKS cluster

1. Create an AWS storage class manifest file for your storage class. The gp2-storage-class.yaml example below defines a storage class called gp2 that uses the Amazon EBS gp2 volume type.

   For more information about the options available for AWS storage classes, see AWS EBS in the Kubernetes documentation.

   ```yaml
   kind: StorageClass
   apiVersion: storage.k8s.io/v1
   metadata:
     name: gp2
   annotations:
     storageclass.kubernetes.io/is-default-class: "true"
   provisioner: kubernetes.io/aws-ebs
   parameters:
     type: gp2
     fsType: ext4
   ```

   2. Use kubectl to create the storage class from the manifest file.

   ```shell
   kubectl create -f gp2-storage-class.yaml
   ```
Output:

```
storageclass "gp2" created
```

**To define a default storage class**

1. List the existing storage classes for your cluster. A storage class must be defined before you can set it as a default.

```
kubectl get storageclass
```

Output:

```
NAME   PROVISIONER             AGE
gp2    kubernetes.io/aws-ebs   8m
```

2. Choose a storage class and set it as your default by setting the `storageclass.kubernetes.io/is-default-class=true` annotation.

```
kubectl patch storageclass <gp2> -p '{"metadata": {"annotations": {"storageclass.kubernetes.io/is-default-class":"true"}}}'
```

Output:

```
storageclass "gp2" patched
```

3. Verify that the storage class is now set as default.

```
kubectl get storageclass
```

Output:

```
 gp2 (default) kubernetes.io/aws-ebs 12m
```

---

**Amazon EBS CSI driver**

The Amazon EBS Container Storage Interface (CSI) driver provides a CSI interface that allows Amazon EKS clusters to manage the lifecycle of Amazon EBS volumes for persistent volumes.

This topic shows you how to deploy the Amazon EBS CSI Driver to your Amazon EKS cluster and verify that it works. We recommend using version v0.8.0 of the driver.

**Note**

The driver is not supported on Fargate. Alpha features of the Amazon EBS CSI Driver are not supported on Amazon EKS clusters. The driver is in Beta release. It is well tested and supported by Amazon EKS for production use. Support for the driver will not be dropped, though details may change. If the schema or schematics of the driver changes, instructions for migrating to the next version will be provided.

For detailed descriptions of the available parameters and complete examples that demonstrate the driver's features, see the Amazon EBS Container Storage Interface (CSI) driver project on GitHub.
To deploy the Amazon EBS CSI driver to an Amazon EKS cluster

1. Create an IAM policy called `Amazon_EBS_CSI_Driver` for your node instance profile that allows the Amazon EBS CSI Driver to make calls to AWS APIs on your behalf. Use the following AWS CLI commands to create the IAM policy in your AWS account. You can view the policy document on GitHub.

   a. Download the policy document from GitHub.

      ```bash
      curl -O https://raw.githubusercontent.com/kubernetes-sigs/aws-ebs-csi-driver/v0.8.0/docs/example-iam-policy.json
      ```

   b. Create the policy.

      ```bash
      aws iam create-policy --policy-name Amazon_EBS_CSI_Driver --policy-document file://example-iam-policy.json
      ```

      Take note of the policy ARN that is returned.

2. Get the IAM role name for your nodes. Use the following command to print the `aws-auth` configmap.

   ```bash
   kubectl -n kube-system describe configmap aws-auth
   ```

   Output:

   ```
   Name:         aws-auth
   Namespace:    kube-system
   Labels:       <none>
   Annotations:  <none>
   
   Data
   ====
   mapRoles:
   ----
   - groups:
     - system:bootstrappers
     - system:nodes
     username: system:node:{{EC2PrivateDNSName}}
   ```

   Record the role name for any `rolearn` values that have the `system:nodes` group assigned to them. In the previous example output, the role name is `eksctl-my-cluster-my-nodegroup-NodeInstanceRole-XXXXXXXXXXXX`. You should have one value for each node group in your cluster.

3. Attach the new `Amazon_EBS_CSI_Driver` IAM policy to each of the node IAM roles you identified earlier with the following command, substituting the red text with your own AWS account number and node IAM role name.

   ```bash
   aws iam attach-role-policy
   --policy-arn arn:aws:iam::<111122223333>:policy/Amazon_EBS_CSI_Driver
   --role-name <eksctl-my-cluster-my-nodegroup-NodeInstanceRole-XXXXXXXXXXXX>
   ```

4. If you want the driver to tag all Amazon EBS volumes that the Amazon EBS CSI driver creates with the same tag, complete the following steps. If you don't want the driver to tag the volumes that it creates, skip to step 5.
a. Clone the Amazon EBS Container Storage Interface (CSI) driver GitHub repository to your computer.

```bash
git clone https://github.com/kubernetes-sigs/aws-ebs-csi-driver.git
```

b. Navigate to the base example folder.

```bash
cd aws-ebs-csi-driver/deploy/kubernetes/base/
```

c. Edit the `controller.yaml` file. Find the section of the file with the following text and add `--extra-tags` to it. The following text shows the section of the file with the existing and added text. This example will cause the controller to add `department` and `environment` tags to all volumes it creates.

```yaml
... containers:
  - name: ebs-plugin
    image: amazon/aws-ebs-csi-driver:latest
    imagePullPolicy: IfNotPresent
    args:
      # - {all,controller,node} # specify the driver mode
      - --endpoint=$(CSI_ENDPOINT)
      - --logtostderr
      - --v=5
      - --extra-tags=department=accounting,environment=dev
...
```

d. Apply the modified manifest to your cluster.

```bash
kubectl apply -k ../base
```

5. Skip this step if you completed step 4. Deploy the Amazon EBS CSI Driver with the command that corresponds to the Region that your cluster is in.

**Note**

This commands require version 1.14 or later of `kubectl`. You can see your `kubectl` version with the following command. To install or upgrade your `kubectl` version, see Installing `kubectl` (p. 283).

```bash
kubectl version --client --short
```

- All Regions other than China Regions.

```bash
kubectl apply -k "github.com/kubernetes-sigs/aws-ebs-csi-driver/deploy/kubernetes/overlays/stable/?ref=master"
```

- Beijing and Ningxia China Regions.

```bash
kubectl apply -k "github.com/kubernetes-sigs/aws-ebs-csi-driver/deploy/kubernetes/overlays/stable-cn/?ref=master"
```

**To deploy a sample application and verify that the CSI driver is working**

This procedure uses the Dynamic volume provisioning example from the Amazon EBS Container Storage Interface (CSI) driver GitHub repository to consume a dynamically-provisioned Amazon EBS volume.
1. Clone the Amazon EBS Container Storage Interface (CSI) driver GitHub repository to your local system.

   ```
   git clone https://github.com/kubernetes-sigs/aws-ebs-csi-driver.git
   ```

2. Navigate to the dynamic-provisioning example directory.

   ```
   cd aws-ebs-csi-driver/examples/kubernetes/dynamic-provisioning/
   ```

3. Deploy the ebs-sc storage class, ebs-claim persistent volume claim, and app sample application from the specs directory.

   ```
   kubectl apply -f specs/
   ```

4. Describe the ebs-sc storage class.

   ```
   kubectl describe storageclass ebs-sc
   ```

   Output:

   ```
   Name:            ebs-sc
   IsDefaultClass:  No
   Annotations:     kubectl.kubernetes.io/last-applied-
   configuration={"apiVersion":"storage.k8s.io/v1","kind":"StorageClass","metadata":
   {"annotations":{},"name":"ebs-
   sc"},"provisioner":"ebs.csi.aws.com","volumeBindingMode":"WaitForFirstConsumer"}
   Provisioner:           ebs.csi.aws.com
   Parameters:            <none>
   AllowVolumeExpansion:  <unset>
   MountOptions:          <none>
   ReclaimPolicy:         Delete
   VolumeBindingMode:     WaitForFirstConsumer
   Events:                <none>
   ```

   Note that the storage class uses the WaitForFirstConsumer volume binding mode. This means that volumes are not dynamically provisioned until a pod makes a persistent volume claim. For more information, see Volume Binding Mode in the Kubernetes documentation.

5. Watch the pods in the default namespace and wait for the app pod to become ready.

   ```
   kubectl get pods --watch
   ```

6. List the persistent volumes in the default namespace. Look for a persistent volume with the default/ebs-claim claim.

   ```
   kubectl get pv
   ```

   Output:

   ```
   NAME                                       CAPACITY   ACCESS MODES   RECLAIM POLICY
   STATUS   CLAIM               STORAGECLASS   REASON   AGE
   pvc-37717cd6-d0dc-11e9-b17f-06fa4858a5a   4Gi        RWO            Delete
   Bound    default/ebs-claim   ebs-sc                  30s
   ```

7. Describe the persistent volume.
kubectl describe pv <pvc-37717cd6-d0dc-11e9-b17f-06fad4858a5a>

Output:

<table>
<thead>
<tr>
<th>Name:</th>
<th>pvc-37717cd6-d0dc-11e9-b17f-06fad4858a5a</th>
</tr>
</thead>
<tbody>
<tr>
<td>Labels:</td>
<td>&lt;none&gt;</td>
</tr>
<tr>
<td>Annotations:</td>
<td>pv.kubernetes.io/provisioned-by: ebs.csi.aws.com</td>
</tr>
<tr>
<td>Finalizers:</td>
<td>[kubernetes.io/pv-protection external-attacher/ebs-csi-aws-com]</td>
</tr>
<tr>

</tr>
<tr>
<td>Term 0:</td>
<td>topology.ebs.csi.aws.com(zone in [&lt;regiona&gt;])</td>
</tr>
<tr>
<td>Message:</td>
<td>Source: CSI (a Container Storage Interface (CSI) volume source)</td>
</tr>
<tr>
<td></td>
<td>Driver: ebs.csi.aws.com</td>
</tr>
<tr>
<td></td>
<td>VolumeHandle: &lt;vol-0d651e157c6d93445&gt;</td>
</tr>
<tr>
<td></td>
<td>ReadOnly: false</td>
</tr>
<tr>
<td></td>
<td>VolumeAttributes: storage.kubernetes.io/csiProvisionerIdentity=1567792483192-8081-ebs.csi.aws.com</td>
</tr>
<tr>
<td>Events:</td>
<td>&lt;none&gt;</td>
</tr>
</tbody>
</table>

The Amazon EBS volume ID is listed as the VolumeHandle.

8. Verify that the pod is successfully writing data to the volume.

    kubectl exec -it app cat /data/out.txt

Output:

```
Wed Jul 8 13:52:09 UTC 2020
Wed Jul 8 13:52:14 UTC 2020
Wed Jul 8 13:52:19 UTC 2020
Wed Jul 8 13:52:24 UTC 2020
Wed Jul 8 13:52:29 UTC 2020
Wed Jul 8 13:52:34 UTC 2020
```

9. When you finish experimenting, delete the resources for this sample application to clean up.

    kubectl delete -f specs/

---

Amazon EFS CSI driver

The Amazon EFS Container Storage Interface (CSI) driver provides a CSI interface that allows Kubernetes clusters running on AWS to manage the lifecycle of Amazon EFS file systems.

This topic shows you how to deploy the Amazon EFS CSI Driver to your Amazon EKS cluster and verify that it works.

**Note**

Alpha features of the Amazon EFS CSI Driver are not supported on Amazon EKS clusters.
For detailed descriptions of the available parameters and complete examples that demonstrate the driver's features, see the Amazon EFS Container Storage Interface (CSI) driver project on GitHub.

To deploy the Amazon EFS CSI driver to an Amazon EKS cluster

- Deploy the Amazon EFS CSI driver using the command that corresponds with the Region that your cluster is in. If your cluster contains nodes (it can also include AWS Fargate pods), then deploy the driver with the following command.

  ```
  kubectl apply -k "github.com/kubernetes-sigs/aws-efs-csi-driver/deploy/kubernetes/overlays/stable/ecr/?ref=release-1.0"
  ```

- All Regions other than China Regions.

  ```
  kubectl apply -k "github.com/kubernetes-sigs/aws-efs-csi-driver/deploy/kubernetes/overlays/stable/?ref=release-1.0"
  ```

- Beijing and Ningxia China Regions.

  ```
  kubectl apply -k "github.com/kubernetes-sigs/aws-efs-csi-driver/deploy/kubernetes/overlays/stable/?ref=release-1.0"
  ```

If your cluster contains only Fargate pods (no nodes), then deploy the driver with the following command.

  ```
  ```

**Note**

- Starting with the 1.0.0 release, encryption of data in transit using TLS is enabled by default. Using encryption in transit, data will be encrypted during its transition over the network to the Amazon EFS service. To disable it and mount volumes using NFSv4, set the `volumeAttributes` field `encryptInTransit` to "false" in your persistent volume manifest. For an example manifest, see Encryption in Transit example on GitHub.

- Only static volume provisioning is supported. This means that an Amazon EFS file system needs to be created outside of Amazon EKS before being used by pods in your cluster.

Amazon EFS access points

The Amazon EFS CSI driver supports Amazon EFS access points, which are application-specific entry points into an Amazon EFS file system that make it easier to share a file system between multiple pods. Access points can enforce a user identity for all file system requests that are made through the access point, and enforce a root directory for each pod. For more information, see Amazon EFS access points on GitHub.

To create an Amazon EFS file system for your Amazon EKS cluster

1. Locate the VPC ID for your Amazon EKS cluster. You can find this ID in the Amazon EKS console, or you can use the following AWS CLI command.

   ```
   aws eks describe-cluster --name <cluster_name> --query "cluster.resourcesVpcConfig.vpcId" --output text
   ```

   Output:

   ```
   vpc=<exampledb76d3e813>
   ```
2. Locate the CIDR range for your cluster’s VPC. You can find this in the Amazon VPC console, or you can use the following AWS CLI command.

```bash
aws ec2 describe-vpcs --vpc-ids vpc-<exampledb76d3e813> --query "Vpcs[].CidrBlock" --output text
```

Output:

```
192.168.0.0/16
```

3. Create a security group that allows inbound NFS traffic for your Amazon EFS mount points.
   a. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
   b. Choose Security Groups in the left navigation panel, and then choose Create security group.
   c. Enter a name and description for your security group, and choose the VPC that your Amazon EKS cluster is using.
   d. Under Inbound rules, select Add rule.
   e. Under Type, select NFS.
   f. Under Source, select Custom, and paste the VPC CIDR range that you obtained in the previous step.
   g. Choose Create security group.

4. Create the Amazon EFS file system for your Amazon EKS cluster.
   b. Choose File systems in the left navigation pane, and then choose Create file system.
   c. On the Create file system page, choose Customize.
   d. On the File system settings page, you don't need to enter or select any information, but can if desired, and then select Next.
   e. On the Network access page, for Virtual Private Cloud (VPC), choose your VPC.

   **Note**
   If you don't see your VPC, at the top right of the console, make sure that the region that your VPC is in is selected.

   f. Under Mount targets, if a default security group is already listed, select the X in the top right corner of the box with the default security group name to remove it from each mount point, select the security group that you created in a previous step for each mount target, and then select Next.
   g. On the File system policy page, select Next.
   h. On the Review and create page, select Create.

   **Important**
   By default, new Amazon EFS file systems are owned by root:root, and only the root user (UID 0) has read-write-execute permissions. If your containers are not running as root, you must change the Amazon EFS file system permissions to allow other users to modify the file system. For more information, see Working with users, groups, and permissions at the Network File System (NFS) level in the Amazon Elastic File System User Guide.

---

**To deploy a sample application and verify that the CSI driver is working**

This procedure uses the Multiple Pods Read Write Many example from the Amazon EFS Container Storage Interface (CSI) driver GitHub repository to consume a statically provisioned Amazon EFS persistent volume and access it from multiple pods with the ReadWriteMany access mode.
1. Clone the Amazon EFS Container Storage Interface (CSI) driver GitHub repository to your local system.

   
   ```
   git clone https://github.com/kubernetes-sigs/aws-efs-csi-driver.git
   ```

2. Navigate to the `multiple_pods` example directory.

   ```
   cd aws-efs-csi-driver/examples/kubernetes/multiple_pods/
   ```

3. Retrieve your Amazon EFS file system ID. You can find this in the Amazon EFS console, or use the following AWS CLI command.

   ```
   aws efs describe-file-systems --query "FileSystems[*].FileSystemId" --output text
   ```

   Output:

   ```
   fs-<582a03f3>
   ```

4. Edit the `specs/pv.yaml` file and replace the `volumeHandle` value with your Amazon EFS file system ID.

   ```
   apiVersion: v1
   kind: PersistentVolume
   metadata:
     name: efs-pv
   spec:
     capacity:
       storage: <5Gi>
     volumeMode: Filesystem
     accessModes:
       - ReadWriteMany
     persistentVolumeReclaimPolicy: Retain
     storageClassName: efs-sc
     csi:
       driver: efs.csi.aws.com
       volumeHandle: fs-<582a03f3>
   ```

   **Note**

   Because Amazon EFS is an elastic file system, it does not enforce any file system capacity limits. The actual storage capacity value in persistent volumes and persistent volume claims is not used when creating the file system. However, since storage capacity is a required field in Kubernetes, you must specify a valid value, such as, `<5Gi>` in this example. This value does not limit the size of your Amazon EFS file system.

5. Deploy the `efs-sc` storage class, `efs-claim` persistent volume claim, `efs-pv` persistent volume, and `app1` and `app2` sample applications from the `specs` directory.

   ```
   kubectl apply -f specs/
   ```

6. Watch the pods in the default namespace and wait for the `app1` and `app2` pods’ STATUS become Running.

   ```
   kubectl get pods --watch
   ```

   **Note**

   It may take a few minutes for the pods to reach the Running status.
7. List the persistent volumes in the default namespace. Look for a persistent volume with the default/efs-claim claim.

```bash
kubectl get pv
```

Output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>CAPACITY</th>
<th>ACCESS MODES</th>
<th>RECLAIM POLICY</th>
<th>STATUS</th>
<th>CLAIM</th>
</tr>
</thead>
<tbody>
<tr>
<td>efs-pv</td>
<td>5Gi</td>
<td>RWX</td>
<td>Retain</td>
<td>Bound</td>
<td>default/efs-claim</td>
</tr>
</tbody>
</table>

8. Describe the persistent volume.

```bash
kubectl describe pv efs-pv
```

Output:

```
Name:            efs-pv
Labels:          <none>
Annotations:     kubectl.kubernetes.io/last-applied-configuration:
"apiVersion": "v1", "kind": "PersistentVolume", "metadata":
{"annotations": {}}, "name": "efs-pv"}, "spec": {"accessModes": ["ReadWriteMany"], "capacity": 5Gi, "volumeMode": "Filesystem", "volumeHandle": "fs-<582a03f3>", "readOnly": false}
Finalizers:      [kubernetes.io/pv-protection]
StorageClass:    efs-sc
Status:          Bound
Claim:           default/efs-claim
Reclaim Policy:  Retain
Access Modes:    RWX
VolumeMode:      Filesystem
Capacity:        5Gi
Node Affinity:   <none>
Message:         <none>
Source:          CSI (a Container Storage Interface (CSI) volume source)
Driver:          efs.csi.aws.com
VolumeHandle:    fs-<582a03f3>
ReadOnly:        false
VolumeAttributes: <none>
Events:          <none>
```

The Amazon EFS file system ID is listed as the VolumeHandle.

9. Verify that the app1 pod is successfully writing data to the volume.

```bash
kubectl exec -ti app1 -- tail /data/out1.txt
```

Output:

```
Thu Jul 23 21:44:02 UTC 2020
Thu Jul 23 21:44:07 UTC 2020
Thu Jul 23 21:44:12 UTC 2020
Thu Jul 23 21:44:17 UTC 2020
Thu Jul 23 21:44:22 UTC 2020
Thu Jul 23 21:44:27 UTC 2020
```

10. Verify that the app2 pod is shows the same data in the volume.
kubectl exec -ti app2 -- tail /data/out1.txt

Output:

Thu Jul 23 21:44:47 UTC 2020
Thu Jul 23 21:44:52 UTC 2020
Thu Jul 23 21:44:57 UTC 2020
Thu Jul 23 21:45:02 UTC 2020
Thu Jul 23 21:45:07 UTC 2020
Thu Jul 23 21:45:12 UTC 2020

11. When you finish experimenting, delete the resources for this sample application to clean up.

kubectl delete -f specs/

Amazon FSx for Lustre CSI driver

Important
This capability is not available in China Regions.

The Amazon FSx for Lustre Container Storage Interface (CSI) driver provides a CSI interface that allows Amazon EKS clusters to manage the lifecycle of Amazon FSx for Lustre file systems.

This topic shows you how to deploy the Amazon FSx for Lustre CSI Driver to your Amazon EKS cluster and verify that it works. We recommend using version 0.4.0 of the driver.

Note
This driver is supported on Kubernetes version 1.18 and later Amazon EKS clusters and nodes. The driver is not supported on Fargate or Arm nodes. Alpha features of the Amazon FSx for Lustre CSI Driver are not supported on Amazon EKS clusters. The driver is in Beta release. It is well tested and supported by Amazon EKS for production use. Support for the driver will not be dropped, though details may change. If the schema or schematics of the driver changes, instructions for migrating to the next version will be provided.

For detailed descriptions of the available parameters and complete examples that demonstrate the driver's features, see the Amazon FSx for Lustre Container Storage Interface (CSI) driver project on GitHub.

Prerequisites

You must have:

- Version 1.18.190 or later of the AWS CLI installed. You can check your currently-installed version with the aws --version command. To install or upgrade the AWS CLI, see Installing the AWS CLI.
- An existing Amazon EKS cluster. If you don't currently have a cluster, see Getting started with Amazon EKS (p. 4) to create one.
- Version 0.35.0 or later of eksctl installed. You can check your currently-installed version with the eksctl version command. To install or upgrade eksctl, see Installing or upgrading eksctl (p. 292).
- The latest version of kubectl installed that aligns to your cluster version. You can check your currently-installed version with the kubectl version --short --client command. For more information, see Installing kubectl (p. 283).
To deploy the Amazon FSx for Lustre CSI driver to an Amazon EKS cluster

1. Create an AWS Identity and Access Management OIDC provider and associate it with your cluster.

```bash
eksctl utils associate-iam-oidc-provider \
    --region <region-code> \
    --cluster <prod> \
    --approve
```

2. Create an IAM policy and service account that allows the driver to make calls to AWS APIs on your behalf.

   a. Copy the following text and save it to a file named `fsx-csi-driver.json`.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "iam:CreateServiceLinkedRole",
                "iam:AttachRolePolicy",
                "iam:PutRolePolicy"
            ],
            "Resource": "arn:aws:iam::*:role/aws-service-role/s3.data-source.lustre.fsx.amazonaws.com/*",
        },
        {
            "Action": "iam:CreateServiceLinkedRole",
            "Effect": "Allow",
            "Resource": "*",
            "Condition": {
                "StringLike": {
                    "iam:AWSServiceName": [
                        "fsx.amazonaws.com"
                    ]
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "fsx:CreateFileSystem",
                "fsx:DeleteFileSystem",
                "fsx:DescribeFileSystems"
            ],
            "Resource": [
                "*"
            ]
        }
    ]
}
```

   b. Create the policy.

```bash
aws iam create-policy \
    --policy-name <Amazon_FSx_Lustre_CSI_Driver> \
    --policy-document file://fsx-csi-driver.json
```

Take note of the policy Amazon Resource Name (ARN) that is returned.
3. Create a Kubernetes service account for the driver and attach the policy to the service account. Replacing the ARN of the policy with the ARN returned in the previous step.

```bash
eksctl create iamserviceaccount \
  --region <region-code> \
  --name fsx-csi-controller-sa \
  --namespace kube-system \
  --cluster <prod> \
  --attach-policy-arn arn:aws:iam::<111122223333:policy/Amazon_FSx_Lustre_CSI_Driver> \
  --approve
```

Output:

You'll see several lines of output as the service account is created. The last line of output is similar to the following example line.

```
[✓]  created serviceaccount "kube-system/fsx-csi-controller-sa"
```

Note the name of the AWS CloudFormation stack that was deployed. In the example output above, the stack is named eksctl-prod-addon-iamserviceaccount-kube-system-fsx-csi-controller-sa.

4. Note the Role ARN for the role that was created.

4b. Ensure that the console is set to the Region that you created your IAM role in and then select Stacks.
4d. Select the Outputs tab. The Role ARN is listed on the Output(1) page.

5. Deploy the driver with the following command.

```bash
kubectl apply -f "github.com/kubernetes-sigs/aws-fsx-csi-driver/deploy/kubernetes/overlays/stable/?ref=master"
```

Output

Warning: kubectl apply should be used on resource created by either kubectl create --save-config or kubectl apply
serviceaccount/fsx-csi-controller-sa configured
clusterrole.rbac.authorization.k8s.io/fsx-csi-external-provisioner-role created
clusterrolebinding.rbac.authorization.k8s.io/fsx-csi-external-provisioner-binding created
deployment.apps/fsx-csi-controller created
daemonset.apps/fsx-csi-node created
csidriver.storage.k8s.io/fsx.csi.aws.com created

6. Patch the driver deployment to add the service account that you created in step 3, replacing the ARN with the ARN that you noted in step 4.

```bash
kubectl annotate serviceaccount -n kube-system <fsx-csi-controller-sa> \
  eks.amazonaws.com/role-arn=<arn:aws:iam::111122223333:role/eksctl-prod-addon-iamserviceaccount-kube-sys-Role1-NPFTLHJ5PJF5> --overwrite=true
```
To deploy a Kubernetes storage class, persistent volume claim, and sample application to verify that the CSI driver is working

This procedure uses the Dynamic volume provisioning for Amazon S3 from the Amazon FSx for Lustre Container Storage Interface (CSI) driver GitHub repository to consume a dynamically-provisioned Amazon FSx for Lustre volume.

1. Create an Amazon S3 bucket and a folder within it named export by creating and copying a file to the bucket.

   ```bash
   aws s3 mb s3://<fsx-csi>
   echo test-file >> testfile
   aws s3 cp testfile s3://<fsx-csi>/export/testfile
   ```

2. Download the storageclass manifest with the following command.

   ```bash
   curl -o storageclass.yaml https://raw.githubusercontent.com/kubernetes-sigs/aws-fsx-csi-driver/master/examples/kubernetes/dynamic_provisioning_s3/specs/storageclass.yaml
   ```

3. Edit the file and replace the existing, `<example values>` with your own.

   ```yaml
   parameters:
     subnetId: <subnet-056da83524edbe641>
     securityGroupIds: <sg-086f61ea73388f6b6>
     s3ImportPath: s3://<ml-training-data-000>
     s3ExportPath: s3://<fsx-csi>/export/testfile
     deploymentType: <SCRATCH_2>
   ```

   - **subnetId** – The subnet ID that the Amazon FSx for Lustre file system should be created in. Amazon FSx for Lustre is not supported in all Availability Zones. Open the Amazon FSx for Lustre console at [https://console.aws.amazon.com/fsx/](https://console.aws.amazon.com/fsx/) to confirm that the subnet that you want to use is in a supported Availability Zone. The subnet can include your nodes, or can be a different subnet or VPC. If the subnet that you specify is not the same subnet that you have nodes in, then your VPCs must be connected, and you must ensure that you have the necessary ports open in your security groups.

   - **securityGroupIds** – The security group ID for your nodes.

   - **s3ImportPath** – The Amazon Simple Storage Service data repository that you want to copy data from to the persistent volume. Specify the `fsx-csi` bucket that you created in step 1.

   - **s3ExportPath** – The Amazon S3 data repository that you want to export new or modified files to. Specify the `fsx-csi/export` folder that you created in step 1.

   - **deploymentType** – The file system deployment type. Valid values are `SCRATCH_1`, `SCRATCH_2`, and `PERSISTENT_1`. For more information about deployment types, see Create your Amazon FSx for Lustre file system.

   **Note**
   
   The Amazon S3 bucket for `s3ImportPath` and `s3ExportPath` must be the same, otherwise the driver cannot create the Amazon FSx for Lustre file system. The `s3ImportPath` can stand alone. A random path will be created automatically like `s3://ml-training-data-000/FSxLustre20190308T012310Z`. The `s3ExportPath` cannot be used without specifying a value for `s3ImportPath`.

4. Create the storageclass.

   ```bash
   kubectl apply -f storageclass.yaml
   ```

5. Download the persistent volume claim manifest.
6. (Optional) Edit the `claim.yaml` file. Change the following `<value>` to one of the increment values listed below, based on your storage requirements and the deploymentType that you selected in a previous step.

   ```yaml
   storage: <1200Gi>
   ```

   - SCRATCH_2 and PERSISTENT – 1.2 TiB, 2.4 TiB, or increments of 2.4 TiB over 2.4 TiB.
   - SCRATCH_1 – 1.2 TiB, 2.4 TiB, 3.6 TiB, or increments of 3.6 TiB over 3.6 TiB.

7. Create the persistent volume claim.

   ```bash
   kubectl apply -f claim.yaml
   ```

8. Confirm that the file system is provisioned.

   ```bash
   kubectl get pvc
   ```

   **Output.**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>VOLUME</th>
<th>CAPACITY</th>
<th>ACCESS MODES</th>
</tr>
</thead>
<tbody>
<tr>
<td>fsx-claim</td>
<td>Bound</td>
<td>pvc-15dad3c1-2365-11ea-a836-02468c18769e</td>
<td>1200Gi</td>
<td>RWX</td>
</tr>
<tr>
<td>fsx-sc</td>
<td>7m37s</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   **Note**

   The STATUS may show as Pending for 5-10 minutes, before changing to Bound. Don't continue with the next step until the STATUS is Bound.

9. Deploy the sample application.

   ```bash
   ```

10. Verify that the sample application is running.

    ```bash
    kubectl get pods
    ```

    **Output**

    | NAME | READY | STATUS  | RESTARTS | AGE |
    |------|-------|---------|----------|-----|
    | fsx-app | 1/1   | Running | 0        | 8s  |

**Access Amazon S3 files from the Amazon FSx for Lustre file system**

If you only want to import data and read it without any modification and creation, then you don't need a value for `s3ExportPath` in your `storageclass.yaml` file. Verify that data was written to the Amazon FSx for Lustre file system by the sample app.

```bash
kubectl exec -it fsx-app ls /data
```

**Output.**
export out.txt

The sample app wrote the out.txt file to the file system.

**Archive files to the s3ExportPath**

For new files and modified files, you can use the Lustre user space tool to archive the data back to Amazon S3 using the value that you specified for s3ExportPath.

1. Export the file back to Amazon S3.

```bash
kubectl exec -ti fsx-app -- lfs hsm_archive /data/out.txt
```

**Note**

- New files aren't synced back to Amazon S3 automatically. In order to sync files to the s3ExportPath, you need to install the Lustre client in your container image and manually run the `lfs hsm_archive` command. The container should run in privileged mode with the `CAP_SYS_ADMIN` capability.
- This example uses a lifecycle hook to install the Lustre client for demonstration purpose. A normal approach is building a container image with the Lustre client.

2. Confirm that the out.txt file was written to the s3ExportPath folder in Amazon S3.

```bash
aws s3 ls fsx-csi/export/
```

**Output**

```
2019-12-23 12:11:35       4553 out.txt
2019-12-23 11:41:21         10 testfile
```
Amazon EKS networking

This chapter provides an overview of Amazon EKS networking. The following diagram shows key components of an Amazon EKS cluster, and the relationship of these components to a VPC.

The following explanations help you understand how components of the diagram relate to each other and which topics in this guide and other AWS guides that you can reference for more information.

- **Amazon VPC and subnets** – All Amazon EKS resources are deployed to one Region in an existing subnet in an existing VPC. For more information, see VPCs and subnets in the Amazon VPC User Guide. Each subnet exists in one Availability Zone. The VPC and subnets must meet requirements such as the following:

  - VPCs and subnets must be tagged appropriately, so that Kubernetes knows that it can use them for deploying resources, such as load balancers. For more information, see VPC tagging requirement (p. 204) and Subnet tagging requirement (p. 205). If you deploy the VPC using an Amazon EKS provided AWS CloudFormation template (p. 200) or using eksctl, then the VPC and subnets are tagged appropriately for you.
  
  - A subnet may or may not have internet access. If a subnet does not have internet access, the pods deployed within it must be able to access other AWS services, such as Amazon ECR, to pull container images. For more information about using subnets that don’t have internet access, see Private clusters (p. 93).
  
  - Any public subnets that you use must be configured to auto-assign public IP addresses for Amazon EC2 instances launched within them. For more information, see VPC IP addressing (p. 203).
  
  - The nodes and control plane must be able to communicate over all ports through appropriately tagged security groups. For more information, see Amazon EKS security group considerations (p. 205).
  
  - You can implement a network segmentation and tenant isolation network policy. Network policies are similar to AWS security groups in that you can create network ingress and egress rules. Instead of assigning instances to a security group, you assign network policies to pods using pod selectors and labels. For more information, see the section called “Installing Calico on Amazon EKS” (p. 240).
You can deploy a VPC and subnets that meet the Amazon EKS requirements through manual configuration, or by deploying the VPC and subnets using `eksctl` (p. 292), or an Amazon EKS provided AWS CloudFormation template. Both `eksctl` and the AWS CloudFormation template create the VPC and subnets with the required configuration. For more information, see Creating a VPC for your Amazon EKS cluster (p. 200).

- **Amazon EKS control plane** – Deployed and managed by Amazon EKS in an Amazon EKS managed VPC. When you create the cluster, Amazon EKS creates and manages network interfaces in your account that have Amazon EKS `<cluster name>` in their description. These network interfaces allow AWS Fargate and Amazon EC2 instances to communicate with the control plane.

  By default, the control plane exposes a public endpoint so that clients and nodes can communicate with the cluster. You can limit the internet client source IP addresses that can communicate with the public endpoint. Alternatively, you can enable a private endpoint and disable the public endpoint or enable both the public and private endpoints. To learn more about cluster endpoints, see Amazon EKS cluster endpoint access control (p. 56).

  Clients in your on-premises network or other VPCs can communicate with the public or private-only endpoint, if you've configured connectivity between the VPC that the cluster is deployed to and the other networks. For more information about connecting your VPC to other networks, see the AWS Network-to-Amazon VPC connectivity options and Amazon VPC-to-Amazon VPC connectivity options technical papers.

- **Amazon EC2 instances** – Each Amazon EC2 node is deployed to one subnet. Each node is assigned a **private IP address** from a CIDR block assigned to the subnet. If the subnets were created using one of the Amazon EKS provided AWS CloudFormation templates (p. 200), then nodes deployed to public subnets are automatically assigned a **public IP address** by the subnet. Each node is deployed with the Pod networking (CNI) (p. 209) which, by default, assigns each pod a private IP address from the CIDR block assigned to the subnet that the node is in and adds the IP address as a secondary IP address to one of the network interfaces attached to the instance. This AWS resource is referred to as a **network interface** in the AWS Management Console and the Amazon EC2 API. Therefore, we use "network interface" in this documentation instead of "elastic network interface". The term "network interface" in this documentation always means "elastic network interface".

  You can change this behavior by assigning additional CIDR blocks to your VPC and enabling **CNI custom networking** (p. 224), which assigns IP addresses to pods from different subnets than the node is deployed to. To use custom networking, you must enable it when you launch your nodes. You can also associate unique security groups with some of the pods running on many Amazon EC2 instance types. For more information, see Security groups for pods (p. 214).

  By default, the source IP address of each pod that communicates with resources outside of the VPC is translated through network address translation (NAT) to the primary IP address of the primary network interface attached to the node. You can change this behavior to instead have a NAT device in a private subnet translate each pod's IP address to the NAT device's IP address. For more information, see External source network address translation (SNAT) (p. 210).

- **Fargate pods** – Deployed to private subnets only. Each pod is assigned a private IP address from the CIDR block assigned to the subnet. Fargate does not support all pod networking options. For more information, see AWS Fargate considerations (p. 138).

### Creating a VPC for your Amazon EKS cluster

Amazon Virtual Private Cloud (Amazon VPC) enables you to launch AWS resources into a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS. For more information, see the Amazon VPC User Guide and De-mystifying cluster networking for Amazon EKS nodes.
If you want to use an existing VPC, then it must meet specific requirements for use with Amazon EKS. For more information, see Cluster VPC considerations (p. 203). This topic guides you through creating a VPC for your cluster using one of the following configurations:

- **Public and private subnets** – This VPC has two public and two private subnets. One public and one private subnet are deployed to the same Availability Zone. The other public and private subnets are deployed to a second Availability Zone in the same Region. We recommend this option for all production deployments. This option allows you to deploy your nodes to private subnets and allows Kubernetes to deploy load balancers to the public subnets that can load balance traffic to pods running on nodes in the private subnets.

  Public IP addresses are automatically assigned to resources deployed to one of the public subnets, but public IP addresses are not assigned to any resources deployed to the private subnets. The nodes in private subnets can communicate with the cluster and other AWS services, and pods can communicate outbound to the internet through a NAT gateway that is deployed in each Availability Zone. A security group is deployed that denies all inbound traffic and allows all outbound traffic. The subnets are tagged so that Kubernetes is able to deploy load balancers to them. For more information about subnet tagging, see Subnet tagging requirement (p. 205). For more information about this type of VPC, see VPC with public and private subnets (NAT).

- **Only public subnets** – This VPC has three public subnets that are deployed into different Availability Zones in the region. All nodes are automatically assigned public IP addresses and can send and receive internet traffic through an internet gateway. A security group is deployed that denies all inbound traffic and allows all outbound traffic. The subnets are tagged so that Kubernetes can deploy load balancers to them. For more information about subnet tagging, see Subnet tagging requirement (p. 205). For more information about this type of VPC, see VPC with a single public subnet.

- **Only private subnets** – This VPC has three private subnets that are deployed into different Availability Zones in the Region. All nodes can optionally send and receive internet traffic through a NAT instance or NAT gateway. A security group is deployed that denies all inbound traffic and allows all outbound traffic. The subnets are tagged so that Kubernetes can deploy internal load balancers to them. For more information about subnet tagging, see Subnet tagging requirement (p. 205). For more information about this type of VPC, see VPC with a private subnet only and AWS Site-to-Site VPN access.

  **Important**
  There are additional requirements if the VPC does not have outbound internet access, such as via a NAT Instance, NAT Gateway, VPN, or Direct Connect. You must bypass the EKS cluster introspection by providing the cluster certificate authority and cluster API endpoint to the nodes. You also may need to configure VPC endpoints listed in Modifying cluster endpoint access (p. 57).

**Important**
If you deployed a VPC using eksctl or by using either of the Amazon EKS AWS CloudFormation VPC templates:

- On or after March 26, 2020 – Public IPv4 addresses are automatically assigned by public subnets to new nodes deployed to public subnets.
- Before March 26, 2020 – Public IPv4 addresses are not automatically assigned by public subnets to new nodes deployed to public subnets.

This change impacts new node groups deployed to public subnets in the following ways:

- **Managed node groups (p. 104)** – If the node group is deployed to a public subnet on or after April 22, 2020, the public subnet must have automatic assignment of public IP addresses enabled. For more information, see Modifying the public IPv4 addressing attribute for your subnet.
Creating a VPC for your Amazon EKS cluster

You can create a VPC with public and private subnets (p. 200), only public subnets (p. 201), or only private subnets (p. 202).

To create your cluster VPC with public and private subnets

2. From the navigation bar, select a Region that supports Amazon EKS.
3. Choose Create stack, With new resources (standard).
4. For Choose a template, select Specify an Amazon S3 template URL.
5. Paste the URL that corresponds to the Region that your cluster is in into the text area and choose Next:
   - All Regions other than China Regions.
   - Beijing and Ningxia China Regions.
6. On the Specify Details page, fill out the parameters accordingly, and then choose Next.
   - Stack name: Choose a stack name for your AWS CloudFormation stack. For example, you can call it eks-vpc.
   - VpcBlock: Choose a CIDR range for your VPC. Each worker node, pod, and load balancer that you deploy is assigned an IP address from this block. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it. For more information, see VPC and subnet sizing in the Amazon VPC User Guide. You can also add additional CIDR blocks to the VPC once it's created.
   - PublicSubnet01Block: Specify a CIDR block for public subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it
   - PublicSubnet02Block: Specify a CIDR block for public subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it
   - PrivateSubnet01Block: Specify a CIDR block for private subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it
   - PrivateSubnet02Block: Specify a CIDR block for private subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it
7. (Optional) On the Options page, tag your stack resources. Choose Next.
9. When your stack is created, select it in the console and choose Outputs.
10. Record the SecurityGroups value for the security group that was created. When you add nodes to your cluster, you must specify the ID of the security group. The security group is applied to the
elastic network interfaces that are created by Amazon EKS in your subnets that allows the control plane to communicate with your nodes. These network interfaces have Amazon EKS <cluster name> in their description.

11. Record the `VpcId` for the VPC that was created. You need this when you launch your node group template.

12. Record the `SubnetIds` for the subnets that were created and whether you created them as public or private subnets. When you add nodes to your cluster, you must specify the IDs of the subnets that you want to launch the nodes into.

To create your cluster VPC with only public subnets

2. From the navigation bar, select a Region that supports Amazon EKS.
3. Choose Create stack, With new resources (standard).
4. For Choose a template, select Specify an Amazon S3 template URL.
5. Paste the URL that corresponds to the Region that your cluster is in into the text area and choose Next:
   - All Regions other than China Regions.
   
   ```
   ```
   - Beijing and Ningxia China Regions.
   
   ```
   ```
6. On the Specify Details page, fill out the parameters accordingly, and then choose Next.
   - **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it `eks-vpc`.
   - **VpcBlock**: Choose a CIDR block for your VPC. Each worker node, pod, and load balancer that you deploy is assigned an IP address from this block. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it. For more information, see VPC and subnet sizing in the Amazon VPC User Guide. You can also add additional CIDR blocks to the VPC once it's created.
   - **Subnet01Block**: Specify a CIDR block for subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
   - **Subnet02Block**: Specify a CIDR block for subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
   - **Subnet03Block**: Specify a CIDR block for subnet 3. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it.
7. (Optional) On the Options page, tag your stack resources. Choose Next.
9. When your stack is created, select it in the console and choose Outputs.
10. Record the **SecurityGroups** value for the security group that was created. When you add nodes to your cluster, you must specify the ID of the security group. The security group is applied to the elastic network interfaces that are created by Amazon EKS in your subnets that allows the control plane to communicate with your nodes. These network interfaces have Amazon EKS <cluster name> in their description.
11. Record the `VpcId` for the VPC that was created. You need this when you launch your node group template.
12. Record the **SubnetIds** for the subnets that were created. When you add nodes to your cluster, you must specify the IDs of the subnets that you want to launch the nodes into.

**To create your cluster VPC with only private subnets**

2. From the navigation bar, select a Region that supports Amazon EKS.
3. Choose **Create stack, With new resources (standard)**.
4. For **Choose a template**, select **Specify an Amazon S3 template URL**.
5. Paste the URL that corresponds to the Region that your cluster is in into the text area and choose **Next**:  
   - All Regions other than China Regions.
     
   - Beijing and Ningxia China Regions.
     

6. On the **Specify Details** page, fill out the parameters accordingly, and then choose **Next**.
   - **Stack name**: Choose a stack name for your AWS CloudFormation stack. For example, you can call it **eks-vpc**.
   - **VpcBlock**: Choose a CIDR block for your VPC. Each worker node, pod, and load balancer that you deploy is assigned an IP address from this block. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it. For more information, see **VPC and subnet sizing** in the Amazon VPC User Guide. You can also add additional CIDR blocks to the VPC once it's created.
   - **PrivateSubnet01Block**: Specify a CIDR block for subnet 1. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it
   - **PrivateSubnet02Block**: Specify a CIDR block for subnet 2. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it
   - **PrivateSubnet03Block**: Specify a CIDR block for subnet 3. The default value provides enough IP addresses for most implementations, but if it doesn't, then you can change it

7. (Optional) On the **Options** page, tag your stack resources. Choose **Next**.
8. On the **Review** page, choose **Create**.
9. When your stack is created, select it in the console and choose **Outputs**.
10. Record the **SecurityGroups** value for the security group that was created. When you add nodes to your cluster, you must specify the ID of the security group. The security group is applied to the elastic network interfaces that Amazon EKS creates in your subnets to allow the control plane to communicate with your nodes. These network interfaces have Amazon EKS <cluster name> in their description.
11. Record the **VpcId** for the VPC that was created. You need this when you launch your node group template.
12. Record the **SubnetIds** for the subnets that were created. When you add nodes to your cluster, you must specify the IDs of the subnets that you want to launch the nodes into.
Next steps

After you have created your VPC, you can try the Getting started with Amazon EKS (p. 4) walkthrough, but you can skip the Create your Amazon EKS cluster VPC (p. 22) section and use these subnets and security groups for your cluster.

Cluster VPC considerations

When you create an Amazon EKS cluster, you specify the VPC subnets for your cluster to use. Amazon EKS requires subnets in at least two Availability Zones. We recommend a VPC with public and private subnets so that Kubernetes can create public load balancers in the public subnets that load balance traffic to pods running on nodes that are in private subnets.

When you create your cluster, you also specify all of the subnets that host resources for your cluster, such as nodes and load balancers.

**Note**

Internet-facing load balancers require a public subnet in your cluster. By default, nodes also require outbound internet access to the Amazon EKS APIs for cluster introspection and node registration at launch time. For clusters without outbound internet access, see Private clusters (p. 93).

To pull container images, they require access to the Amazon S3 and Amazon ECR APIs (and any other container registries, such as DockerHub). For more information, see Amazon EKS security group considerations (p. 205) and AWS IP Address Ranges in the AWS General Reference.

The subnets that you pass when you create the cluster influence where Amazon EKS places network interfaces that are used for the control plane to node communication.

It is possible to specify only public or private subnets when you create your cluster, but there are some limitations associated with these configurations:

- **Private-only**: Everything runs in a private subnet and Kubernetes cannot create internet-facing load balancers for your pods.
- **Public-only**: Everything runs in a public subnet, including your nodes.

Amazon EKS creates a network interface in your private subnets to facilitate communication to your nodes. This communication channel supports Kubernetes functionality such as `kubectl exec` and `kubectl logs`. The security group that you specify when you create your cluster is applied to the network interfaces that are created for your cluster control plane.

Your VPC must have DNS hostname and DNS resolution support. Otherwise, your nodes cannot register with your cluster. For more information, see Using DNS with Your VPC in the Amazon VPC User Guide.

VPC IP addressing

Nodes must be able to communicate with the control plane and other AWS services. If your nodes are deployed in a private subnet, then you must have either:

- Set up a default route for the subnet to a NAT gateway. The NAT gateway must be assigned a public IP address to provide internet access for the nodes.
- Configured several necessary settings for the subnet and taken the necessary actions listed in Private clusters (p. 93).

If self-managed nodes are deployed to a public subnet, the subnet must be configured to auto-assign public IP addresses. Otherwise, your node instances must be assigned a public IP address when they're
launched. If managed nodes are deployed to a public subnet, the subnet must be configured to auto-assign public IP addresses. This is because, if they are not, then the nodes aren't assigned a public IP address. Determine whether your public subnets are configured to auto-assign public IP addresses with the following command.

```bash
aws ec2 describe-subnets \
   --filters "Name=vpc-id,Values=<VPC-ID>" | grep 'SubnetId\|MapPublicIpOnLaunch'
```

The output is as follows.

```
"MapPublicIpOnLaunch": <false>,
"SubnetId": "<subnet-aaaaaaaaaaaaaaaaa>",
"MapPublicIpOnLaunch": <false>,
"SubnetId": "<subnet-bbbbbbbbbbbbbbbb>",
```

For any subnets that have `MapPublicIpOnLaunch` set to false, change the setting to true.

```bash
aws ec2 modify-subnet-attribute --map-public-ip-on-launch --subnet-id <subnet-aaaaaaaaaaaaaaaaa>
```

**Important**

If you used an Amazon EKS AWS CloudFormation template (p. 198) to deploy your VPC before March 26, 2020, then you need to change the setting for your public subnets.

You can define both private (RFC 1918), and public (non-RFC 1918) CIDR ranges within the VPC used for your Amazon EKS cluster. For more information, see Adding IPv4 CIDR blocks to a VPC in the Amazon VPC User Guide. When choosing the classless inter-domain routing (CIDR) blocks for your VPC and subnets, make sure that the blocks contain enough IP addresses for all of the Amazon EC2 nodes and pods that you plan to deploy. There should be at least one IP address for each of your pods. You can conserve IP address use by implementing a transit gateway with a shared services VPC. For more information, see Isolated VPCs with shared services and EKS VPC routable IP address conservation patterns in a hybrid network.

The Amazon EKS control plane creates up to 4 network interfaces in your VPC for each cluster. These network interfaces have Amazon EKS `<cluster name>` in their description. Be sure that the subnets that you specify have enough available IP addresses for the network interfaces and your pods.

**VPC tagging requirement**

When you create an Amazon EKS cluster that is earlier than version 1.15, Amazon EKS tags the VPC containing the subnets you specify in the following way so that Kubernetes can discover it:

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/cluster/&lt;cluster-name&gt;</td>
<td>shared</td>
</tr>
</tbody>
</table>

- **Key**: The `<cluster-name>` value matches your Amazon EKS cluster’s name.
- **Value**: The shared value allows more than one cluster to use this VPC.

This tag is not required or created by Amazon EKS for 1.15 or later clusters. If you deploy a 1.15 or later cluster to a VPC that already has this tag, the tag is not removed.
Subnet tagging requirement

When you create your Amazon EKS cluster, Amazon EKS tags the subnets you specify in the following way so that Kubernetes can discover them:

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/cluster/&lt;cluster-name&gt;</td>
<td>shared</td>
</tr>
</tbody>
</table>

- **Key:** The `<cluster-name>` value matches your Amazon EKS cluster.
- **Value:** The `shared` value allows more than one cluster to use this subnet.

Private subnet tagging requirement for internal load balancers

Private subnets must be tagged as follows so that Kubernetes knows it can use the subnets for internal load balancers. If you use `eksctl` or an Amazon EKS AWS CloudFormation template to create your VPC after March 26, 2020, then the subnets are tagged appropriately when they're created. For more information about the Amazon EKS AWS CloudFormation VPC templates, see Creating a VPC for your Amazon EKS cluster (p. 198).

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/role/internal-elb</td>
<td>1</td>
</tr>
</tbody>
</table>

Public subnet tagging option for external load balancers

Public subnets must be tagged as follows so that Kubernetes knows to use only those subnets for external load balancers instead of choosing a public subnet in each Availability Zone (in lexicographical order by subnet ID). If you use `eksctl` or an Amazon EKS AWS CloudFormation template to create your VPC after March 26, 2020, then the subnets are tagged appropriately when they're created. For more information about the Amazon EKS AWS CloudFormation VPC templates, see Creating a VPC for your Amazon EKS cluster (p. 198).

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/role/elb</td>
<td>1</td>
</tr>
</tbody>
</table>

Amazon EKS security group considerations

The following sections describe the recommended or minimum required security group settings for the cluster, control plane, and node security groups of your cluster. These considerations are dependent on which Kubernetes version and Amazon EKS platform version you use.

Cluster security group

Amazon EKS clusters, starting with Kubernetes version 1.14 and platform version (p. 73) eks. 3, create a cluster security group when they are created. This also happens when a cluster of an earlier version is upgraded to this Kubernetes version and platform version. A cluster security group is designed to allow all traffic from the control plane and managed node groups (p. 101) to flow freely between each other.
By assigning the cluster security group to the elastic network interfaces created by Amazon EKS that allow the control plane to communicate with the managed node group instances, you don't need to configure complex security group rules to allow this communication. Any instance or network interface that is assigned this security group can freely communicate with other resources with this security group.

You can check for a cluster security group for your cluster in the AWS Management Console under the cluster's **Networking** section, or with the following AWS CLI command:

```
aws eks describe-cluster --name <cluster_name> --query cluster.resourcesVpcConfig.clusterSecurityGroupId
```

We recommend that you add the cluster security group to all existing and future node groups. For more information, see Security Groups for Your VPC in the Amazon VPC User Guide. Amazon EKS managed node groups (p. 101) are automatically configured to use the cluster security group.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Ports</th>
<th>Source</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recommended inbound traffic</td>
<td>All</td>
<td>All</td>
<td>Self</td>
</tr>
<tr>
<td>Recommended outbound traffic</td>
<td>All</td>
<td>All</td>
<td>0.0.0.0/0</td>
</tr>
</tbody>
</table>

**Restricting cluster traffic**

If you need to limit the open ports between the control plane and nodes, the default cluster security group can be modified to allow only the following required minimum ports. The required minimum ports are the same as they were in previous Amazon EKS versions.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Source</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum inbound traffic</td>
<td>TCP</td>
<td>443</td>
<td>Cluster security group</td>
</tr>
<tr>
<td>Minimum inbound traffic*</td>
<td>TCP</td>
<td>10250</td>
<td>Cluster security group</td>
</tr>
<tr>
<td>Minimum outbound traffic</td>
<td>TCP</td>
<td>443</td>
<td>Cluster security group</td>
</tr>
<tr>
<td>Minimum outbound traffic*</td>
<td>TCP</td>
<td>10250</td>
<td>Cluster security group</td>
</tr>
</tbody>
</table>

*Any protocol and ports that you expect your nodes to use for inter-node communication should be included, if required. Nodes also require outbound internet access to the Amazon EKS APIs for cluster introspection and node registration at launch time, or that you’ve implemented the required necessary settings in Private clusters (p. 93). To pull container images, they require access to Amazon S3, Amazon ECR APIs, and any other container registries that they need to pull images from, such as DockerHub. For more information, see AWS IP address ranges in the AWS General Reference.

**Control plane and node security groups**

For Amazon EKS clusters created earlier than Kubernetes version 1.14 and platform version (p. 73) eks.3, control plane to node communication was configured by manually creating a control plane security group and specifying that security group when you created the cluster. At cluster creation,
this security group was then attached to the network interfaces created by Amazon EKS that allow communication between the control plane and the nodes. These network interfaces have Amazon EKS <cluster name> in their description.

**Note**

If you used the API directly, or a tool such as AWS CloudFormation to create your cluster and didn't specify a security group, then the default security group for the VPC was applied to the control plane cross-account network interfaces.

You can check the control plane security group for your cluster in the AWS Management Console under the cluster’s Networking section (listed as Additional security groups), or with the following AWS CLI command:

```
aws eks describe-cluster --name <cluster_name> --query cluster.resourcesVpcConfig.securityGroupIds
```

If you launch nodes with the AWS CloudFormation template in the Getting started with Amazon EKS (p. 4) walkthrough, AWS CloudFormation modifies the control plane security group to allow communication with the nodes. **Amazon EKS strongly recommends that you use a dedicated security group for each control plane (one for each cluster).** If you share a control plane security group with other Amazon EKS clusters or resources, you may block or disrupt connections to those resources.

The security group for the nodes and the security group for the control plane communication to the nodes have been set up to prevent communication to privileged ports in the nodes. If your applications require added inbound or outbound access from the control plane or nodes, you must add these rules to the security groups associated with your cluster. For more information, see Security Groups for Your VPC in the Amazon VPC User Guide.

**Note**

To allow proxy functionality on privileged ports or to run the CNCF conformance tests yourself, you must edit the security groups for your control plane and the nodes. The security group on the nodes' side needs to allow inbound access for ports 0-65535 from the control plane, and the control plane side needs to allow outbound access to the nodes on ports 0-65535.

### Control Plane Security Group

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port range</th>
<th>Source</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum inbound traffic</td>
<td>TCP</td>
<td>443</td>
<td>All node security groups</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>When cluster endpoint private access (p. 56) is enabled:</strong> Any security groups that generate API server client traffic (such as <code>kubectl</code> commands on a bastion host within your cluster’s VPC)</td>
</tr>
<tr>
<td>Recommended inbound traffic</td>
<td>TCP</td>
<td>443</td>
<td>All node security groups</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>When cluster endpoint private</strong></td>
</tr>
</tbody>
</table>
### Control plane and node security groups

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port range</th>
<th>Source</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum outbound traffic</td>
<td>TCP</td>
<td>10250</td>
<td>All node security groups</td>
</tr>
<tr>
<td>Recommended outbound traffic</td>
<td>TCP</td>
<td>1025-65535</td>
<td>All node security groups</td>
</tr>
</tbody>
</table>

**Node security group**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port range</th>
<th>Source</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum inbound traffic (from other nodes)</td>
<td>Any protocol that you expect your nodes to use for inter-node communication</td>
<td>Any ports that you expect your nodes to use for inter-node communication</td>
<td>All node security groups</td>
</tr>
<tr>
<td>Minimum inbound traffic (from control plane)</td>
<td>TCP</td>
<td>10250</td>
<td>Control plane security group</td>
</tr>
<tr>
<td>Recommended inbound traffic</td>
<td>All</td>
<td>All 443, 1025-65535</td>
<td>All node security groups</td>
</tr>
<tr>
<td></td>
<td>TCP</td>
<td></td>
<td>Control plane security group</td>
</tr>
<tr>
<td>Minimum outbound traffic*</td>
<td>TCP</td>
<td>443</td>
<td>Control plane security group</td>
</tr>
<tr>
<td>Recommended outbound traffic</td>
<td>All</td>
<td>All</td>
<td>0.0.0.0/0</td>
</tr>
</tbody>
</table>

*Nodes also require access to the Amazon EKS APIs for cluster introspection and node registration at launch time either through the internet or VPC endpoints. To pull container images, they require access to the Amazon S3 and Amazon ECR APIs (and any other container registries, such as DockerHub). For more information, see AWS IP address ranges in the AWS General Reference and Private clusters (p. 93).

One, and only one, of the security groups associated to your nodes should have the following tag applied: For more information about tagging, see Working with tags using the console (p. 304).

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/cluster/cluster-name</td>
<td>owned</td>
</tr>
</tbody>
</table>
Pod networking (CNI)

Amazon EKS supports native VPC networking with the Amazon VPC Container Network Interface (CNI) plugin for Kubernetes. Using this plugin allows Kubernetes pods to have the same IP address inside the pod as they do on the VPC network. The plugin is an open-source project that is maintained on GitHub. For more information, see amazon-vpc-cni-k8s and Proposal: CNI plugin for Kubernetes networking over AWS VPC on GitHub. The Amazon VPC CNI plugin is fully supported for use on Amazon EKS and self-managed Kubernetes clusters on AWS.

Note

Kubernetes can use the Container Networking Interface (CNI) for configurable networking setups. The Amazon VPC CNI plugin might not meet requirements for all use cases. Amazon EKS maintains a network of partners that offer alternative CNI solutions with commercial support options. For more information, see Alternate compatible CNI plugins (p. 232).

When you create an Amazon EKS node, it has one network interface. All Amazon EC2 instance types support more than one network interface. The network interface attached to the instance when the instance is created is called the primary network interface. Any additional network interface attached to the instance is called a secondary network interface. Each network interface can be assigned multiple private IP addresses. One of the private IP addresses is the primary IP address, whereas all other addresses assigned to the network interface are secondary IP addresses. For more information about network interfaces, see Elastic network interfaces in the Amazon EC2 User Guide for Linux Instances. For more information about how many network interfaces and private IP addresses are supported for each network interface, see IP addresses per network interface per instance type in the Amazon EC2 User Guide for Linux Instances. For example, an m5.large instance type supports three network interfaces and ten private IP addresses for each network interface.

The Amazon VPC Container Network Interface (CNI) plugin for Kubernetes is deployed with each of your Amazon EC2 nodes in a Daemonset with the name aws-node. The plugin consists of two primary components:

- L-IPAM daemon – Responsible for creating network interfaces and attaching the network interfaces to Amazon EC2 instances, assigning secondary IP addresses to network interfaces, and maintaining a warm pool of IP addresses on each node for assignment to Kubernetes pods when they are scheduled. When the number of pods running on the node exceeds the number of addresses that can be assigned to a single network interface, the plugin starts allocating a new network interface, as long as the maximum number of network interfaces for the instance aren't already attached. There are configuration variables that allow you to change the default value for when the plugin creates new network interfaces. For more information, see WARM_ENI_TARGET, WARM_IP_TARGET and MINIMUM_IP_TARGET on GitHub.

Each pod that you deploy is assigned one secondary private IP address from one of the network interfaces attached to the instance. Previously, it was mentioned that an m5.large instance supports three network interfaces and ten private IP addresses for each network interface. Even though an m5.large instance supports 30 private IP addresses, you can't deploy 30 pods to that node. To determine how many pods you can deploy to a node, use the following formula:

\[(\text{Number of network interfaces for the instance type} \times (\text{the number of IP addresses per network interface} - 1)) + 2\]

Using this formula, an m5.large instance type can support a maximum of 29 pods. For a list of the maximum number of pods supported by each instance type, see eni-max-pods.txt on GitHub. System pods count towards the maximum pods. For example, the CNI plugin and kube-proxy pods run on every node in a cluster, so you're only able to deploy 27 additional pods to an m5.large instance, not 29. Further, CoreDNS runs on some of the nodes in the cluster, which decrements the maximum pods by another one for the nodes it runs on.
By default, all pods deployed to a node are assigned the same security groups and are assigned private IP addresses from a CIDR block that is assigned to the subnet that one of the instance's network interfaces is connected to. You can assign IP addresses from a different CIDR block than the subnet that the primary network interface is connected to by configuring CNI custom networking (p. 224). You can also use CNI custom networking to assign all pods on a node the same security groups. The security groups assigned to all pods can be different than the security groups assigned to the primary network interface. You can assign unique security groups to pods deployed to many Amazon EC2 instance types using security groups for pods. For more information, see Security groups for pods (p. 214).

- **CNI plugin** – Responsible for wiring the host network (for example, configuring the network interfaces and virtual Ethernet pairs) and adding the correct network interface to the pod namespace.

**Important**

If you are using version 1.7.0 or later of the CNI plugin and you assign a custom pod security policy to the `aws-node` Kubernetes service account used for the `aws-node` pods deployed by the Daemonset, then the policy must have `NET_ADMIN` in its `allowedCapabilities` section along with `hostNetwork: true` and `privileged: true` in the policy's `spec`. For more information, see the section called “Pod security policy” (p. 353).

### External source network address translation (SNAT)

Communication within a VPC (such as pod to pod) is direct between private IP addresses and requires no source network address translation (SNAT). When traffic is destined for an address outside of the VPC, the Amazon VPC CNI plugin for Kubernetes translates the private IP address of each pod to the primary private IP address assigned to the primary network interface (network interface) of the Amazon EC2 node that the pod is running on, by default. SNAT:

- Enables pods to communicate bi-directionally with the internet. The node must be in a public subnet and have a public or elastic IP address assigned to the primary private IP address of its primary network interface. The traffic is translated to and from the public or elastic IP address and routed to and from the internet by an internet gateway, as shown in the following picture.
SNAT is necessary because the internet gateway can only translate between the primary private and public or elastic IP address assigned to the primary network interface of the Amazon EC2 instance node that pods are running on.

- Prevents a device in other private IP address spaces (for example, VPC peering, Transit VPC, or Direct Connect) from communicating directly to a pod that is not assigned the primary private IP address of the primary network interface of the Amazon EC2 instance node.

If the internet or devices in other private IP address spaces need to communicate with a pod that isn't assigned the primary private IP address assigned to the primary network interface of the Amazon EC2 instance node that the pod is running on, then:

- The node must be deployed in a private subnet that has a route to a NAT device in a public subnet.
- You need to enable external SNAT in the CNI plugin `aws-node` DaemonSet with the following command:

  

  ```bash
  kubectl set env daemonset -n kube-system aws-node AWS_VPC_K8S_CNI_EXTERNALSNAT=true
  ```

After external SNAT is enabled, the CNI plugin doesn't translate a pod's private IP address to the primary private IP address assigned to the primary network interface of the Amazon EC2 instance node that the pod is running on when traffic is destined for an address outside of the VPC. Traffic from the pod to the internet is externally translated to and from the public IP address of the NAT device and routed to and from the internet by an internet gateway, as shown in the following picture.

**Configuring the VPC CNI plugin to use IAM roles for service accounts**

The Amazon VPC CNI plugin for Kubernetes is the networking plugin for pod networking in Amazon EKS clusters. The CNI plugin is responsible for allocating VPC IP addresses to Kubernetes nodes and configuring the necessary networking for pods on each node. The plugin:

- Requires IAM permissions, provided by the AWS managed policy `AmazonEKS_CNI_Policy`, to make calls to AWS APIs on your behalf.
Configure plugin for IAM account

- Creates and is configured to use a service account named `aws-node` when it's deployed. The service account is bound to a Kubernetes `clusterrole` named `aws-node`, which is assigned the required Kubernetes permissions.

**Note**
Regardless of whether you configure the VPC CNI plugin to use IAM roles for service accounts, the pods also have access to the permissions assigned to the the section called “Node IAM role” (p. 326), unless you block access to IMDS. For more information, see the section called “Restricting access to the instance profile” (p. 349).

**[eksctl]**
1. Create an IAM role and attach the AmazonEKS_CNI_Policy managed IAM policy with the following command. Replace `<cluster_name>` with your own value. This command creates an IAM OIDC provider for your cluster if it doesn’t already exist. It then deploys an AWS CloudFormation stack that creates an IAM role, attaches the AmazonEKS_CNI_Policy AWS managed policy to it, and annotates the existing `aws-node` service account with the ARN of the IAM role.

   ```bash
   eksctl create iamserviceaccount \
   --name aws-node \
   --namespace kube-system \
   --cluster <cluster_name> \
   --attach-policy-arn arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy \
   --approve \
   --override-existing-serviceaccounts
   ```

2. Describe one of the pods and verify that the `AWS_WEB_IDENTITY_TOKEN_FILE` and `AWS_ROLE_ARN` environment variables exist.

   ```bash
   kubectl exec -n kube-system aws-node-<9rgzw> env | grep AWS
   ```

   Output:

   ```
   AWS_VPC_K8S_CNI_LOGLEVEL=DEBUG
   AWS_ROLE_ARN=arn:aws:iam::<11122222333>:role/eksctl-prod-addon-iamserviceaccount-kube-sys-Role1-<V66K516JLDGK>
   AWS_WEB_IDENTITY_TOKEN_FILE=/var/run/secrets/eks.amazonaws.com/serviceaccount/token
   ```

**[AWS Management Console]**

**Prerequisite**

You must have an existing IAM OIDC provider for your cluster. To determine whether you already do or to create one, see Create an IAM OIDC provider for your cluster (p. 334).

To create your CNI plugin IAM role with the AWS Management Console

1. In the navigation panel, choose **Roles, Create Role**.
2. In the **Select type of trusted entity** section, choose **Web identity**.
3. In the **Choose a web identity provider** section:
   1. For **Identity provider**, choose the URL for your cluster.
   2. For **Audience**, choose `sts.amazonaws.com`.
4. Choose **Next: Permissions**.
5. In the **Attach Policy** section, select the AmazonEKS_CNI_Policy policy to use for your service account.

6. Choose **Next: Tags**.

7. On the **Add tags (optional)** screen, you can add tags for the account. Choose **Next: Review**.

8. For **Role Name**, enter a name for your role, such as AmazonEKSCNIRole, and then choose **Create Role**.

9. After the role is created, choose the role in the console to open it for editing.

10. Choose the **Trust relationships** tab, and then choose **Edit trust relationship**.

11. Change the line that looks similar to the following:

   ```
   "oidc.eks.us-west-2.amazonaws.com/id/EXAMPLED539D4633E53DE1B716D3041E:aud": 
   "sts.amazonaws.com"
   ```

   To look like the following, changing the `<example values>` (including `<>`) to your own:

   ```
   "oidc.eks.<region-code>.amazonaws.com/id/<EXAMPLED539D4633E53DE1B716D3041E>:sub": 
   "system:serviceaccount:kube-system:aws-node"
   ```

12. Choose **Update Trust Policy** to finish.

**To annotate the aws-node Kubernetes service account with the IAM role**

1. If you're using the Amazon EKS add-on with a 1.18 or later Amazon EKS cluster with platform version eks.3 or later, see the section called “Configure an Amazon EKS add-on” (p. 52), instead of completing this procedure. If you're not using the Amazon VPC CNI Amazon EKS add-on, then use the following command to annotate the aws-node service account with the ARN of the IAM role that you created previously. Be sure to substitute your own values for the `<example values>` to use with your pods.

   ```
   kubectl annotate serviceaccount \
   -n kube-system aws-node \
   eks.amazonaws.com/role-arn=arn:aws:iam::<AWS_ACCOUNT_ID>:role/<AmazonEKSCNIRole>
   ```

2. Delete and re-create any existing pods that are associated with the service account to apply the credential environment variables. The mutating web hook does not apply them to pods that are already running. The following command deletes the existing the aws-node DaemonSet pods and deploys them with the service account annotation.

   ```
   kubectl delete pods -n kube-system -l k8s-app=aws-node
   ```

3. Confirm that the pods all restarted.

   ```
   kubectl get pods -n kube-system -l k8s-app=aws-node
   ```

4. Describe one of the pods and verify that the AWS_WEB_IDENTITY_TOKEN_FILE and AWS_ROLE_ARN environment variables exist.

   ```
   kubectl exec -n kube-system aws-node-<9rgzw> env | grep AWS
   ```

   **Output:**

   ```
   AWS_VPC_K8S_CNI_LOGLEVEL=DEBUG
   AWS_ROLE_ARN=arn:aws:iam::<AWS_ACCOUNT_ID>:role/<IAM_ROLE_NAME>
   AWS_WEB_IDENTITY_TOKEN_FILE=/var/run/secrets/eks.amazonaws.com/serviceaccount/token
   ```
Remove the CNI policy from the node IAM role

If your [Node IAM role](p. 326) currently has the AmazonEKS_CNI_Policy IAM policy attached to it, and you’ve created a separate IAM role, attached the policy to it instead, and assigned it to the `aws-node` Kubernetes service account, then we recommend that you remove the policy from your node role.

2. In the left navigation, choose Roles, and then search for your node instance role.
3. Choose the Permissions tab for your node instance role and then choose the X to the right of the AmazonEKS_CNI_Policy.
4. Choose Detach to finish.

Security groups for pods

Security groups for pods integrate Amazon EC2 security groups with Kubernetes pods. You can use Amazon EC2 security groups to define rules that allow inbound and outbound network traffic to and from pods that you deploy to nodes running on many Amazon EC2 instance types. For a detailed explanation of this capability, see the [Introducing security groups for pods](blog post).

Considerations

Before deploying security groups for pods, consider the following limits and conditions:

- Your Amazon EKS cluster must be running Kubernetes version 1.17 and Amazon EKS platform version eks.3 or later. You can’t use security groups for pods on Kubernetes clusters that you deployed to Amazon EC2.
- Traffic flow to and from pods with associated security groups are not subjected to Calico network policy (p. 240) enforcement and are limited to Amazon EC2 security group enforcement only. Community effort is underway to remove this limitation.
- Security groups for pods can’t be used with pods deployed to Fargate.
- Security groups for pods can’t be used with Windows nodes.
- Security groups for pods are supported by most Nitro-based Amazon EC2 instance families, including the m5, c5, r5, p3, m6g, c6g, and r6g instance families. The t3 instance family is not supported. For a complete list of supported instances, see the [section called “Supported instances”](p. 218). Your nodes must be one of the supported instance types.
- Source NAT is disabled for outbound traffic from pods with assigned security groups so that outbound security group rules are applied. To access the internet, pods with assigned security groups must be launched on nodes that are deployed in a private subnet configured with a NAT gateway or instance. Pods with assigned security groups deployed to public subnets are not able to access the internet.
- Kubernetes services of type NodePort and LoadBalancer using instance targets with an externalTrafficPolicy set to Local are not supported with pods that you assign security groups to. For more information about using a load balancer with instance targets, see the [section called “Load balancer – Instance targets”](p. 263).
- If you’re also using pod security policies to restrict access to pod mutation, then the eks-vpc-resource-controller and vpc-resource-controller Kubernetes service accounts must be specified in the Kubernetes ClusterRoleBinding for the the Role that your psp is assigned to. If you’re using the [default Amazon EKS psp](psp), Role, and [ClusterRoleBinding](p. 353), this is the eks:podsecuritypolicy:authenticated ClusterRoleBinding. For example, you would add the service accounts to the subjects section, as shown in the following example:

```yaml
...
subjects:
```
Security groups for pods

- kind: Group
  apiGroup: rbac.authorization.k8s.io
  name: system:authenticated
- kind: ServiceAccount
  name: vpc-resource-controller
- kind: ServiceAccount
  name: eks-vpc-resource-controller

- If you're using custom networking (p. 224) and security groups for pods together, the security group specified by security groups for pods is used instead of the security group specified in the ENI config.

Deploy security groups for pods

To deploy security groups for pods

1. Check your current CNI plugin version with the following command.

   kubectl describe daemonset aws-node --namespace kube-system | grep Image | cut -d "/" -f 2

   The output is similar to the following output.

   amazon-k8s-cni:<1.7.7>

   If your CNI plugin version is earlier than 1.7.7, then upgrade your CNI plugin to version 1.7.7 or later. For more information, see Amazon VPC CNI plugin for Kubernetes upgrades (p. 230).

2. Add the AmazonEKSVPCResourceController managed policy to the cluster role (p. 325) that is associated with your Amazon EKS cluster. The policy allows the role to manage network interfaces, their private IP addresses, and their attachment and detachment to and from instances. The following command adds the policy to a cluster role named <eksClusterRole>.

   aws iam attach-role-policy
   --policy-arn arn:aws:iam::aws:policy/AmazonEKSVPCResourceController
   --role-name <eksClusterRole>

3. Enable the CNI plugin to manage network interfaces for pods by setting the ENABLE_POD_ENI variable to true in the aws-node DaemonSet. Once this setting is set to true, for each node in the cluster the plugin adds a label with the value vpc.amazonaws.com/has-trunk-attached=true. The VPC resource controller creates and attaches one special network interface called a trunk network interface with the description aws-k8s-trunk-eni.

   kubectl set env daemonset aws-node -n kube-system ENABLE_POD_ENI=true

   **Note**

   The trunk network interface is included in the maximum number of network interfaces supported by the instance type. For a list of the maximum number of interfaces supported by each instance type, see IP addresses per network interface per instance type in the Amazon EC2 User Guide for Linux Instances. If your node already has the maximum number of standard network interfaces attached to it then the VPC resource controller will reserve a space. You will have to scale down your running pods enough for the controller to detach and delete a standard network interface, create the trunk network interface, and attach it to the instance.

   You can see which of your nodes have aws-k8s-trunk-eni set to true with the following command.
Once the trunk network interface is created, pods can be assigned secondary IP addresses from the
trunk or standard network interfaces. The trunk interface is automatically deleted if the node is
deleted.

When you deploy a security group for a pod in a later step, the VPC resource controller creates a
special network interface called a **branch network interface** with a description of aws-k8s-branch-
eni and associates the security groups to it. Branch network interfaces are created in addition to the
standard and trunk network interfaces attached to the node. If are you using liveness or readiness
probes, you also need to disable TCP early demux, so that the kubelet can connect to pods on
branch network interfaces via TCP. To disable TCP early demux, run the following command:

```
kubectl patch daemonset aws-node \
  -n kube-system \
  -p '{"spec": {"template": {"initContainers": [{"env": [
  {"name":"DISABLE_TCP_EARLY_DEMUX","value":"true"},
  {"name":"aws-vpc-cni-init"]}}]}}}'
```

4. Create a namespace to deploy resources to.

```
kubectl create namespace <my-namespace>
```

5. Deploy an Amazon EKS SecurityGroupPolicy to your cluster.

a. Save the following example security policy to a file named <my-security-group-policy.yaml>. You
can replace podSelector with serviceAccountSelector if you'd rather select
pods based on service account labels. You must specify one selector or the other. An empty
podSelector (example: podSelector: {}) selects all pods in the namespace. An empty
serviceAccountSelector selects all service accounts in the namespace. You must specify
1-5 security group IDs for groupIds. If you specify more than one ID, then the combination of
all the rules in all the security groups are effective for the selected pods.

```yaml
apiVersion: vpcresources.k8s.aws/v1beta1
kind: SecurityGroupPolicy
metadata:
  name: <my-security-group-policy>
  namespace: <my-namespace>
spec:
  podSelector:
    matchLabels:
      <role>: <my-role>
    securityGroups:
    groupIds:
      - <sg-abc123>
```

**Important**

- The security groups that you specify in the policy must exist. If they don't exist, then,
  when you deploy a pod that matches the selector, your pod remains stuck in the
  creation process. If you describe the pod, you'll see an error message similar to the
  following one: An error occurred (InvalidSecurityGroupId.NotFound)
  when calling the CreateNetworkInterface operation: The
  securityGroupId '<sg-abc123>' does not exist.

- The security group must allow inbound communication from the cluster security
  group (for kubelet) over any ports you've configured probes for.
• The security group must allow outbound communication to the cluster security group (for CoreDNS) over TCP and UDP port 53. The cluster security group must also allow inbound TCP and UDP port 53 communication from all security groups associated to pods.

b. Deploy the policy.

```bash
kubectl apply -f <my-security-group-policy.yaml>
```

6. Deploy a sample application with a label that matches the `<my-role>` value for `<podSelector>` that you specified in the previous step.

a. Save the following contents to a file.

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: <my-deployment>
  namespace: <my-namespace>
  labels:
    app: <my-app>
spec:
  replicas: <1>
  selector:
    matchLabels:
      app: <my-app>
  template:
    metadata:
      labels:
        app: <my-app>
        role: <my-role>
    spec:
      containers:
        - name: <my-container>
          image: <my-image>
          ports:
            - containerPort: <80>
```

b. Deploy the application with the following command. When you deploy the application, the CNI plugin matches the `role` label and the security groups that you specified in the previous step are applied to the pod.

```bash
kubectl apply -f <file-name-you-used-in-previous-step.yaml>
```

**Note**

- If your pod is stuck in the *Waiting* state and you see *Insufficient permissions: Unable to create Elastic Network Interface*. when you describe the pod, confirm that you added the IAM policy to the IAM cluster role in a previous step.

- If your pod is stuck in the *Pending* state, confirm that your node instance type is listed in the section called "Supported instances" (p. 218) and that that the maximum number of branch network interfaces supported by the instance type multiplied times the number of nodes in your node group hasn't already been met. For example, an *m5.large* instance supports nine branch network interfaces. If your node group has five nodes, then a maximum of 45 branch network interfaces can be created for the node group. The 46th pod that you attempt to deploy will sit in *Pending* state until another pod that has associated security groups is deleted.
If you run `kubectl describe pod <my-deployment-xxxxxxxxx-xxxxx> -n <my-namespace>` and see a message similar to the following message, then it can be safely ignored. This message might appear when the CNI plugin tries to set up host networking and fails while the network interface is being created. The CNI plugin logs this event until the network interface is created.

```
Failed to create pod sandbox: rpc error: code = Unknown desc = failed to set up sandbox container 
"<e24268322e55c8185721f52df6493684f6c2c3bf4fd59c9c121fd4c894579f>" network for 
pod "<my-deployment-59f5f68b58-c89wx>": networkPlugin 
cni failed to set up pod "<my-deployment-59f5f68b58-c89wx_my-namespace>" network: 
add cmd: failed to assign an IP address to container
```

You cannot exceed the maximum number of pods that can be run on the instance type. For a list of the maximum number of pods that you can run on each instance type, see `eni-max-pods.txt` on GitHub. When you delete a pod that has associated security groups, or delete the node that the pod is running on, the VPC resource controller deletes the branch network interface. If you delete a cluster with pods using pods for security groups, then the controller does not delete the branch network interfaces, so you'll need to delete them yourself.

### Amazon EC2 supported instances and branch network interfaces

The following table lists the number of branch network interfaces that you can use with each supported Amazon EC2 instance type.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Branch network interfaces</th>

**CNI custom networking**

By default, when new network interfaces are allocated for pods, `ipamD` uses the node's primary network interface's security groups and subnet. You might want your pods to use a different security group or subnet, within the same VPC as your control plane security group. For example:

- There are a limited number of IP addresses available in a subnet. This might limit the number of pods that can be created in the cluster. Using different subnets for pods allows you to increase the number of available IP addresses.
• For security reasons, your pods must use different security groups or subnets than the node's primary network interface.
• The nodes are configured in public subnets and you want the pods to be placed in private subnets using a NAT Gateway. For more information, see External source network address translation (SNAT) (p. 210).

Note
• You can configure custom networking for self-managed node groups or for managed node groups that were created with a launch template that uses a custom AMI (p. 115). The procedures in this topic require the Amazon VPC CNI plugin for Kubernetes version 1.4.0 or later. To check your CNI version, and upgrade if necessary, see Amazon VPC CNI plugin for Kubernetes upgrades (p. 230).
• Enabling a custom network effectively removes an available network interface (and all of its available IP addresses for pods) from each node that uses it. The primary network interface for the node is not used for pod placement when a custom network is enabled.
• The procedure in this topic instructs the CNI plugin to associate different security groups to secondary network interfaces than are associated to the primary network interface in the instance. All pods using the secondary network interfaces will still share use of the secondary network interfaces and will all use the same security groups. If you want to assign different security groups to individual pods, then you can use Security groups for pods (p. 214).
Security groups for pods create additional network interfaces that can each be assigned a unique security group. security groups for pods can be used with or without custom networking.

To configure CNI custom networking

1. Associate a secondary CIDR block to your cluster's VPC. For more information, see Associating a Secondary IPv4 CIDR Block with Your VPC in the Amazon VPC User Guide.
2. Create a subnet in your VPC for each Availability Zone, using your secondary CIDR block. Your custom subnets must be from a different VPC CIDR block than the subnet that your nodes were launched into. For more information, see Creating a subnet in your VPC in the Amazon VPC User Guide.
3. Set the AWS_VPC_K8S_CNI_CUSTOM_NETWORK_CFG environment variable to true in the aws-node DaemonSet:

   kubectl set env daemonset aws-node -n kube-system AWS_VPC_K8S_CNI_CUSTOM_NETWORK_CFG=true

4. View the currently-installed CNI version.

   kubectl describe daemonset aws-node --namespace kube-system | grep Image | cut -d "/" -f 2

   Output:

   amazon-k8s-cni:1.7.5

5. If you have version 1.3 or later of the CNI installed, you can skip to step 6. Define a new ENIConfig custom resource for your cluster.

   a. Create a file called ENIConfig.yaml and paste the following content into it:

      apiVersion: apiextensions.k8s.io/v1beta1
kind: CustomResourceDefinition
metadata:
  name: eniconfigs.crd.k8s.amazonaws.com
spec:
  scope: Cluster
  group: crd.k8s.amazonaws.com
  version: v1alpha1
  names:
    plural: eniconfigs
    singular: eniconfig
    kind: ENIConfig

b. Apply the file to your cluster with the following command:

```bash
kubectl apply -f ENIConfig.yaml
```

6. Create an ENIConfig custom resource for each subnet that you want to schedule pods in.

a. Create a unique file for each network interface configuration. Each file must include the following contents with a unique value for name. We highly recommend using a value for name that matches the Availability Zone of the subnet because this makes deployment of multi-AZ Auto Scaling groups simpler (see step 6c below).

In this example, a file named `us-west-2a.yaml` is created. Replace the `<example values>` for name, subnet, and securityGroups with your own values. In this example, we follow best practices and set the value for name to the Availability Zone that the subnet is in. If you don’t have a specific security group that you want to attach for your pods, you can leave that value empty for now. Later, you will specify the node security group in the ENIConfig.

```yaml
apiVersion: crd.k8s.amazonaws.com/v1alpha1
kind: ENIConfig
metadata:
  name: <us-west-2a>
spec:
  securityGroups:
  - <sg-0dff111a11t1t11c11>
  subnet: <subnet-011b111c1f11fdf11>
```

**Note**

Each subnet and security group combination requires its own custom resource. If you have multiple subnets in the same Availability Zone, use the following command to annotate the nodes in each subnet with the matching config name.

```bash
kubectl annotate node <node-name>.<region>.compute.internal k8s.amazonaws.com/eniConfig=<subnet1ConfigName>
```

b. Apply each custom resource file that you created to your cluster with the following command:

```bash
kubectl apply -f <us-west-2a>.yaml
```

c. (Optional, but recommended for multi-Availability Zone node groups) By default, Kubernetes applies the Availability Zone of a node to the `failure-domain.beta.kubernetes.io/zone` label. If you named your ENIConfig custom resources after each Availability Zone in your VPC, as recommended in step 6a, then you can enable Kubernetes to automatically apply the corresponding ENIConfig for the node's Availability Zone with the following command.

```bash
kubectl set env daemonset aws-node -n kube-system ENI_CONFIG_LABEL_DEF=failure-domain.beta.kubernetes.io/zone
```
### Note

Ensure that an annotation with the key `k8s.amazonaws.com/eniConfig` for the `ENI_CONFIG_ANNOTATION_DEF` environment variable doesn't exist in the container spec for the `aws-node` daemonset. If it exists, it overrides the `ENI_CONFIG_LABEL_DEF` value, and should be removed. You can check to see if the variable is set with the `kubectl describe daemonset aws-node -n kube-system | grep ENI_CONFIG_ANNOTATION_DEF` command. If no output is returned, then the variable is not set.

7. Create a new self-managed node group. For managed node groups, use a custom AMI with a launch template (p. 115).

   a. Determine the maximum number of pods that can be scheduled on each node using the following formula.

   $maxPods = (\text{number of interfaces} - 1) \times (\text{max IPv4 addresses per interface} - 1) + 2$

   For example, the `m5.large` instance type supports three network interfaces and ten IPv4 addresses for each interface. Inserting the values into the formula, the instance can support up to 20 pods, as shown in the following calculation.

   $maxPods = (3 - 1) \times (10 - 1) + 2 = 20$

   For more information about the maximum number of network interfaces for each instance type, see IP addresses per network interface per instance type in the Amazon EC2 User Guide for Linux Instances.

   b. Follow the steps for Self-managed nodes in Launching self-managed Amazon Linux nodes (p. 117) to create a new self-managed node group. After you've opened the AWS CloudFormation template, enter values as described in the instructions. Specify the subnets that you specified in the `ENIConfig` resources that you deployed. For the `BootstrapArguments` field, enter the following value.

   `--use-max-pods false --kubelet-extra-args '--max-pods=20'`

8. After your node group is created, record the security group that was created for subnet and apply the security group to the associated ENIConfig. Edit each ENIConfig with the following command, replacing `<eniconfig-name>` with your value:

   `kubectl edit eniconfig.crd.k8s.amazonaws.com/<eniconfig-name>`

   If you followed best practices from steps 6a and 6c, the `eniconfig-name` corresponds to the Availability Zone name.

   The `spec` section should look like this:

   ```yaml
   spec:
     securityGroups:
     - <sg-0dff222a2d22c2c22>
     subnet: <subnet-022b222c2f22f22>
   ```

9. If you have any nodes in your cluster that had pods placed on them before you completed this procedure, you should terminate them. Only new nodes that are registered with the `k8s.amazonaws.com/eniConfig` label use the new custom networking feature.
CNI metrics helper

The CNI metrics helper is a tool that you can use to scrape network interface and IP address information, aggregate metrics at the cluster level, and publish the metrics to Amazon CloudWatch.

When managing an Amazon EKS cluster, you may want to know how many IP addresses have been assigned and how many are available. The CNI metrics helper helps you to:

- Track these metrics over time
- Troubleshoot and diagnose issues related to IP assignment and reclamation
- Provide insights for capacity planning

When a node is provisioned, the CNI plugin automatically allocates a pool of secondary IP addresses from the node's subnet to the primary network interface (eth0). This pool of IP addresses is known as the warm pool, and its size is determined by the node's instance type. For example, a c4.large instance can support three network interfaces and nine IP addresses per interface. The number of IP addresses available for a given pod is one less than the maximum (of ten) because one of the IP addresses is reserved for the elastic network interface itself. For more information, see IP Addresses Per Network Interface Per Instance Type in the Amazon EC2 User Guide for Linux Instances.

As the pool of IP addresses is depleted, the plugin automatically attaches another elastic network interface to the instance and allocates another set of secondary IP addresses to that interface. This process continues until the node can no longer support additional elastic network interfaces.

The following metrics are collected for your cluster and exported to CloudWatch:

- The maximum number of network interfaces that the cluster can support
- The number of network interfaces have been allocated to pods
- The number of IP addresses currently assigned to pods
- The total and maximum numbers of IP addresses available
- The number of ipamD errors

Deploying the CNI metrics helper

The CNI metrics helper requires cloudwatch:PutMetricData permissions to send metric data to CloudWatch. This section helps you to create an IAM policy with those permissions, apply it to your node instance role, and then deploy the CNI metrics helper.

To create an IAM policy for the CNI metrics helper

1. Create a file called allow_put_metrics_data.json and populate it with the following policy document.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "cloudwatch:PutMetricData",
      "Resource": "*"
    }
  ]
}
```
2. Create an IAM policy called `CNIMetricsHelperPolicy` for your node instance profile that allows the CNI metrics helper to make calls to AWS APIs on your behalf. Use the following AWS CLI command to create the IAM policy in your AWS account.

```
aws iam create-policy --policy-name CNIMetricsHelperPolicy \ 
--description "Grants permission to write metrics to CloudWatch" \ 
--policy-document file://allow_put_metrics_data.json
```

Take note of the policy ARN that is returned.

3. Get the IAM role name for your nodes. Use the following command to print the `aws-auth` configmap.

```
kubectl -n kube-system describe configmap aws-auth
```

Output:

```
Name:         aws-auth
Namespace:    kube-system
Labels:       <none>
Annotations:  <none>

Data
====
mapRoles:
  - groups:
    - system:bootstrappers
    - system:nodes
    rolearn: arn:aws:iam::<111122223333>:role/<eksctl-prod-nodegroup-standard-wo-
    NodeInstanceRole-GKNS581EASPU>
    username: system:node:{{EC2PrivateDNSName}}

Events:  <none>
```

Record the role name for any `rolearn` values that have the `system:nodes` group assigned to them. In the above example output, the role name is `<eksctl-prod-nodegroup-standard-wo-
NodeInstanceRole-GKNS581EASPU>`. You should have one value for each node group in your cluster.

4. Attach the new `CNIMetricsHelperPolicy` IAM policy to each of the node IAM roles you identified earlier with the following command, substituting the red text with your own AWS account number and node IAM role name.

```
aws iam attach-role-policy \
--policy-arn arn:aws:iam::<111122223333>:policy/CNIMetricsHelperPolicy \
--role-name <eksctl-prod-nodegroup-standard-wo-NodeInstanceRole-GKNS581EASPU>
```

**To deploy the CNI metrics helper**

- Apply the CNI metrics helper manifest with the command that corresponds to the Region that your cluster is in.
  - All regions other than China Regions.
    ```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/release-1.7/config/v1.7/cni-metrics-helper.yaml
```
  - Beijing and Ningxia China Regions.
Creating a metrics dashboard

After you have deployed the CNI metrics helper, you can view the CNI metrics in the CloudWatch console. This topic helps you to create a dashboard for viewing your cluster's CNI metrics.

To create a CNI metrics dashboard

2. In the left navigation, choose Metrics.
4. Choose CLUSTER_ID.
5. On the All metrics tab, select the metrics you want to add to the dashboard.
6. Choose Actions, and then Add to dashboard.
7. In the Select a dashboard section, choose Create new and enter a name for your dashboard, such as "EKS-CNI-metrics".
8. In the Select a widget type section, choose Number.
9. In the Customize the widget title section, enter a logical name for your dashboard title, such as "EKS CNI metrics".
10. Choose Add to dashboard to finish. Now your CNI metrics are added to a dashboard that you can monitor, as shown below.

Amazon VPC CNI plugin for Kubernetes upgrades

When you launch an Amazon EKS cluster, a recent version of the Amazon VPC CNI plugin for Kubernetes is deployed to your cluster. The absolute latest version of the plugin is available on GitHub for a short grace period before new clusters are switched over to use it. Amazon EKS does not automatically upgrade the CNI plugin on your cluster when new versions are released. To get a newer version of the CNI plugin on existing clusters, you must manually upgrade the plugin.

The latest version that we recommend is version 1.7.5. You can view the different releases available for the plugin, and read the release notes for each version on GitHub. With version 1.7.0 and later, the privileged container capability was removed from the CNI pod (aws-node). The pod has the NET_ADMIN capability in its securityContext capabilities, which is required for the aws-node container to add iptables, routes, and rules to setup pod networking. An init container was also added to the aws-node pod, which has the privileged capability, so that it can setup reverse path filters and copy loopback plugins during aws-node pod start up.
Important
If you have assigned a custom pod security policy to the `aws-node` Kubernetes service account used for the `aws-node` pod, then the policy must have `NET_ADMIN` in its `allowedCapabilities` section along with `hostNetwork: true` and `privileged: true` in the policy's `spec`. For more information, see the section called “Pod security policy” (p. 353).

Use the following procedures to check your CNI plugin version and upgrade to the latest recommended version.

### To check your Amazon VPC CNI plugin for Kubernetes version

- Use the following command to print your cluster’s CNI version:

  ```bash
  kubectl describe daemonset aws-node --namespace kube-system | grep Image | cut -d "/" -f 2
  ```

  Output:

  ```bash
  amazon-k8s-cni:1.6.3
  ```

  In this example output, the CNI version is 1.6.3, which is earlier than the current recommended version, 1.7.5. Use the following procedure to upgrade the CNI.

### To upgrade the Amazon VPC CNI plugin for Kubernetes

- If your CNI version is earlier than 1.7.5, and you are managing the plugin yourself, then use the appropriate command below to update your CNI version to the latest recommended version. If your cluster is running Kubernetes 1.18 or later with `eks.3` platform version or later, and the plugin is managed by Amazon EKS, then to update the plugin, see the section called “Configure an Amazon EKS add-on” (p. 52).

  - **US West (Oregon) (us-west-2)**
    
    ```bash
    kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.7.5/config/v1.7/aws-k8s-cni-us-gov-east-1.yaml
    ```

  - **China (Beijing) (cn-north-1) or China (Ningxia) (cn-northwest-1)**
    
    ```bash
    kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.7.5/config/v1.7/aws-k8s-cni-cn.yaml
    ```

  - **AWS GovCloud (US-East) (us-gov-east-1)**
    
    ```bash
    kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.7.5/config/v1.7/aws-k8s-cni-us-gov-east-1.yaml
    ```

  - **AWS GovCloud (US-West) (us-gov-west-1)**
    
    ```bash
    kubectl apply -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.7.5/config/v1.7/aws-k8s-cni-us-gov-west-1.yaml
    ```

  - **For all other Regions**
    
    Download the manifest file.
    
    ```bash
    curl -o aws-k8s-cni.yaml https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.7.5/config/v1.7/aws-k8s-cni.yaml
    ```
Alternate compatible CNI plugins

Amazon EKS only officially supports the Amazon VPC CNI plugin (p. 209). Amazon EKS runs upstream Kubernetes and is certified Kubernetes conformant however, so alternate CNI plugins will work with Amazon EKS clusters. If you plan to use an alternate CNI plugin in production, then we strongly recommend that you either obtain commercial support, or have the in-house expertise to troubleshoot and contribute fixes to the open source CNI plugin project.

Amazon EKS maintains relationships with a network of partners that offer support for alternate compatible CNI plugins. Refer to the following partners' documentation for details on supported Kubernetes versions and qualifications and testing performed.

<table>
<thead>
<tr>
<th>Partner</th>
<th>Product</th>
<th>Documentation</th>

Amazon EKS aims to give you a wide selection of options to cover all use cases. If you develop a commercially supported Kubernetes CNI plugin that is not listed here, then please contact our partner team at aws-container-partners@amazon.com for more information.

AWS Load Balancer Controller

The AWS Load Balancer Controller manages AWS Elastic Load Balancers for a Kubernetes cluster. The controller provisions:

- An AWS Application Load Balancer (ALB) when you create a Kubernetes Ingress.
- An AWS Network Load Balancer (NLB) when you create a Kubernetes Service of type LoadBalancer using IP targets on 1.18 or later Amazon EKS clusters. If you're load balancing network traffic to instance targets, then you use the in-tree Kubernetes load balancer controller and don't need to install this controller. For more information about NLB target types, see Target type in the User Guide for Network Load Balancers.

The controller was formerly named the AWS ALB Ingress Controller. It is an open source project managed on GitHub. This topic helps you install the controller using default options. You can view the full documentation for the controller on GitHub. Before deploying the controller we recommend that you review the prequisites and considerations in the section called "Application load balancing" (p. 265)
and the section called "Network load balancing" (p. 261). Those topics also include steps to deploy a sample application that require the controller to provision AWS resources.

**Prerequisite**

An existing cluster. If you don’t have an existing cluster, see *Getting started with Amazon EKS* (p. 4).

**To deploy the AWS Load Balancer Controller to an Amazon EKS cluster**

In the following steps, replace the `<example values>` (including `<`) with your own values.

1. Determine whether you have an existing IAM OIDC provider for your cluster.

   View your cluster's OIDC provider URL.

   ```bash
   aws eks describe-cluster --name <cluster_name> --query "cluster.identity.oidc.issuer" --output text
   ```

   Example output:

   ```text
   https://oidc.eks.us-west-2.amazonaws.com/id/EXAMPLED539D4633E53DE1B716D3041E
   ```

   List the IAM OIDC providers in your account. Replace `<EXAMPLED539D4633E53DE1B716D3041E>` (including `<`) with the value returned from the previous command.

   ```bash
   aws iam list-open-id-connect-providers | grep <EXAMPLED539D4633E53DE1B716D3041E>
   ```

   Example output:

   ```text
   ```

   If output is returned from the previous command, then you already have a provider for your cluster. If no output is returned, then you must create an IAM OIDC provider.

   To create an IAM OIDC provider, see *Create an IAM OIDC provider for your cluster* (p. 334).

2. Download an IAM policy for the AWS Load Balancer Controller that allows it to make calls to AWS APIs on your behalf. You can view the policy document on GitHub. Use the command that corresponds to the Region that your cluster is in.

   - All Regions other than China Regions.

     ```bash
     curl -o iam_policy.json https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.1.0/docs/install/iam_policy.json
     ```

   - Beijing and Ningxia China Regions.

     ```bash
     curl -o iam_policy_cn.json https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.1.0/docs/install/iam_policy_cn.json
     ```

3. Create an IAM policy using the policy downloaded in the previous step. Change `iam_policy.json` to `iam_policy_cn.json` in the following command, if you downloaded that file instead.

   ```bash
   aws iam create-policy \
   --policy-name <AWSLoadBalancerControllerIAMPolicy> \
   --policy-document file://iam_policy.json
   ```
Take note of the policy ARN that is returned.

4. Create an IAM role and annotate the Kubernetes service account named `aws-load-balancer-controller` in the `kube-system` namespace for the AWS Load Balancer Controller using one of the following options.

**Using eksctl**

Use the following command:

```bash
eksctl create iamserviceaccount \
--cluster=<my-cluster> \
--namespace=kube-system \
--name=aws-load-balancer-controller \
--attach-policy-arn=arn:aws:iam::<AWS_ACCOUNT_ID>:policy/\nAWSLoadBalancerControllerIAMPolicy> \
--override-existing-serviceaccounts \
--approve
```

**Using the AWS Management Console and kubectl**

b. In the navigation panel, choose Roles, Create Role.
c. In the Select type of trusted entity section, choose Web identity.
d. In the Choose a web identity provider section:
   i. For Identity provider, choose the URL for your cluster.
   ii. For Audience, choose sts.amazonaws.com.
e. Choose Next: Permissions.
f. In the Attach Policy section, select the AWSLoadBalancerControllerIAMPolicy policy that you created in step 3 to use for your service account.
g. Choose Next: Tags.
h. On the Add tags (optional) screen, you can add tags for the account. Choose Next: Review.
   i. For Role Name, enter a name for your role, such as AmazonEKSLoadBalancerControllerRole, and then choose Create Role.
j. After the role is created, choose the role in the console to open it for editing.
k. Choose the Trust relationships tab, and then choose Edit trust relationship.
l. Change the line that looks similar to the following:

```
"oidc.eks.us-west-2.amazonaws.com/id/EXAMPLED539D4633E53DE1B716D3041E:aud": "sts.amazonaws.com"
```

To look like the following, changing the `<example values>` (including `<>) to your own:

```
"oidc.eks.<region-code>.amazonaws.com/id/<EXAMPLED539D4633E53DE1B716D3041E>:sub": "system:serviceaccount:kube-system:aws-load-balancer-controller"
```
m. Choose Update Trust Policy to finish.

n. Note the ARN of the role for use in a later step.
o. Save the following contents to a file named `aws-load-balancer-controller-service-account.yaml`

```yaml
apiVersion: v1
kind: ServiceAccount
```
p. Create the service account on your cluster.

```bash
kubectl apply -f aws-load-balancer-controller-service-account.yaml
```

5. If you currently have the AWS ALB Ingress Controller for Kubernetes installed, uninstall it. The AWS Load Balancer Controller replaces the functionality of the AWS ALB Ingress Controller for Kubernetes.

a. Check to see if the controller is currently installed.

```bash
kubectl get deployment -n kube-system alb-ingress-controller
```

Output (if it is installed). Skip to step 5b.

```
NAME                   READY UP-TO-DATE AVAILABLE AGE
alb-ingress-controller 1/1   1          1         122d
```

Output (if it isn't installed). If it isn't installed, skip to step 6.

Error from server (NotFound): deployments.apps "alb-ingress-controller" not found

b. If the controller is installed, enter the following commands to remove it.

```bash
kubectl delete -f https://raw.githubusercontent.com/kubernetes-sigs/aws-alb-ingress-controller/v1.1.8/docs/examples/rbac-role.yaml
```

c. If you removed the AWS ALB Ingress Controller for Kubernetes, add the following IAM policy to the IAM role created in step 4. The policy allows the AWS Load Balancer Controller access to the resources that were created by the ALB Ingress Controller for Kubernetes.

1. Download the IAM policy. You can also view the policy.

```bash
curl -o iam_policy_v1_to_v2_additional.json https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.1.0/docs/install/iam_policy_v1_to_v2_additional.json
```

2. Create the IAM policy and note the ARN returned.

```bash
aws iam create-policy \
--policy-name <AWSLoadBalancerControllerAdditionalIAMPolicy> \
--policy-document file://iam_policy_v1_to_v2_additional.json
```

3. Attach the IAM policy to the IAM role that you created in step 4. Replace `<your-role-name>` (including <> with the name of the role. If you created the role using `eksctl`, then to find the role name that was created, open the AWS CloudFormation console and select the `eksctl-<your-cluster-name>-addon-iamserviceaccount-kube-system-aws-load-balancer-235`
controller stack. Select the Resources tab. The role name is in the Physical ID column. If you used the AWS Management Console to create the role, then the role name is whatever you named it, such as AmazonEKSLoadBalancerControllerRole.

```
aws iam attach-role-policy
  --role-name eksctl-<your-role name>
  --policy-arn arn:aws:iam::111122223333:policy/AWSLoadBalancerControllerAdditionalIAMPolicy
```

6. Install the AWS Load Balancer Controller using one of the following methods:

- With Helm
  a. Install the TargetGroupBinding custom resource definitions.

```
```

b. Add the eks-charts repository.

```
helm repo add eks https://aws.github.io/eks-charts
```

c. Install the AWS Load Balancer Controller using the command that corresponds to the Region that your cluster is in.

**Important**
If you are deploying the controller to Amazon EC2 nodes that you have restricted access to the Amazon EC2 instance metadata service (IMDS) (p. 349) from, or if you are deploying to Fargate, then you need to add the following flags to the command that you run:

- `--set region=<region-code>`
- `--set vpcId=<vpc-xxxxxxxx>`

- All Regions other than China Regions.

```
helm upgrade -i aws-load-balancer-controller eks/aws-load-balancer-controller
  --set clusterName=<cluster-name>
  --set serviceAccount.create=false
  --set serviceAccount.name=aws-load-balancer-controller
  -n kube-system
```

- Beijing and Ningxia China Regions.

```
helm upgrade -i aws-load-balancer-controller eks/aws-load-balancer-controller
  --set clusterName=<cluster-name>
  --set serviceAccount.create=false
  --set serviceAccount.name=aws-load-balancer-controller
  --set image.repository=918309763551.dkr.ecr.cn-north-1.amazonaws.com.cn/amazon/aws-load-balancer-controller
  -n kube-system
```

**Important**
The deployed chart does not receive security updates automatically. You need to manually upgrade to a newer chart when it becomes available.

- With a Kubernetes manifest
  a. Install `cert-manager` to inject certificate configuration into the webhooks.

```
- Install on Kubernetes 1.16 or later.
```
Installing or upgrading CoreDNS

CoreDNS is supported on Amazon EKS clusters with Kubernetes version 1.15 or later. Clusters that were created with Kubernetes version 1.10 shipped with kube-dns as the default DNS and service discovery provider. If you have updated from a 1.10 cluster and you want to use CoreDNS for DNS and service discovery, then you must install CoreDNS and remove kube-dns.

To check if your cluster is already running CoreDNS, use the following command.

```
kubectl get pod -n kube-system -l k8s-app=kube-dns
```

If the output shows coredns in the pod names, then you’re already running CoreDNS in your cluster. If not, use the following procedure to update your DNS and service discovery provider to CoreDNS.

**Note**
The service for CoreDNS is still called kube-dns for backward compatibility.
Amazon EKS User Guide
Installing or upgrading CoreDNS

To install CoreDNS on an updated Amazon EKS cluster with kubectl
1.

Add the {"eks.amazonaws.com/component": "kube-dns"} selector to the kube-dns
deployment for your cluster. This prevents the two DNS deployments from competing for control of
the same set of labels.
kubectl patch -n kube-system deployment/kube-dns --patch \
'{"spec":{"selector":{"matchLabels":{"eks.amazonaws.com/component":"kube-dns"}}}}'

2.

Deploy CoreDNS to your cluster.
a.

Set your cluster's DNS IP address to the DNS_CLUSTER_IP environment variable.
export DNS_CLUSTER_IP=$(kubectl get svc -n kube-system kube-dns -o
jsonpath='{.spec.clusterIP}')

b.

Replace <region-code> (including <>) with the Region code that your cluster is in.
export REGION="<region-code>"

c.

Download the CoreDNS manifest from the Amazon EKS resource bucket that corresponds to the
Region that your cluster is in.
• All regions other than China Regions.
curl -o dns.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/
cloudformation/2020-10-29/dns.yaml

• Beijing and Ningxia China Regions.
curl -o dns.yaml https://s3.cn-north-1.amazonaws.com.cn/amazon-eks//
cloudformation/2020-10-29/dns.yaml

d.

Replace the variable placeholders in the dns.yaml ﬁle with your environment variable values
and apply the updated manifest to your cluster. The following command completes this in one
step.
cat dns.yaml | sed -e "s/REGION/$REGION/g" | sed -e "s/DNS_CLUSTER_IP/
$DNS_CLUSTER_IP/g" | kubectl apply -f -

e.

Fetch the coredns pod name from your cluster.
COREDNS_POD=$(kubectl get pod -n kube-system -l eks.amazonaws.com/component=coredns
\
-o jsonpath='{.items[0].metadata.name}')

f.

Query the coredns pod to ensure that it's receiving requests.
kubectl get --raw /api/v1/namespaces/kube-system/pods/$COREDNS_POD:9153/proxy/
metrics \
| grep 'coredns_dns_request_count_total'

Note

It might take several minutes for the expected output to return properly, depending on
the rate of DNS requests in your cluster.
In the following expected output, the number 23 is the DNS request count total.
238


Upgrading CoreDNS

1. Check the current version of your cluster's coredns deployment.

```bash
kubectl describe deployment coredns --namespace kube-system | grep Image | cut -d "/" -f 3
```

**Output:**

```
coredns:v<1.1.3>
```

The recommended coredns versions for the corresponding Kubernetes versions are as follows:

<table>
<thead>
<tr>
<th>Kubernetes version</th>
<th>1.18</th>
<th>1.17</th>
<th>1.16</th>
<th>1.15</th>
</tr>
</thead>
<tbody>
<tr>
<td>CoreDNS</td>
<td>1.7.0</td>
<td>1.6.6</td>
<td>1.6.6</td>
<td>1.6.6</td>
</tr>
</tbody>
</table>

2. If your current coredns version is 1.5.0 or later, but earlier than the recommended version, then skip this step. If your current version is earlier than 1.5.0, then you need to modify the config map for coredns to use the forward plug-in, rather than the proxy plug-in.

   a. Open the configmap with the following command.

   ```bash
   kubectl edit configmap coredns -n kube-system
   ```

   b. Replace `proxy` in the following line with `forward`. Save the file and exit the editor.

   ```bash
   proxy . /etc/resolv.conf
   ```

3. If you originally deployed your cluster on Kubernetes 1.17 or earlier, then you may need to remove a deprecated term from your CoreDNS manifest.

   **Important**
   You must complete this before upgrading to CoreDNS version 1.7.0, but it's recommended that you complete this step even if you're upgrading to an earlier version.

---

```
HELP coredns_dns_request_count_total Counter of DNS requests made per zone, protocol and family.
TYPE coredns_dns_request_count_total counter
coredns_dns_request_count_total{family="1",proto="udp",server="dns://:53",zone="."} 23
```
Installing Calico on Amazon EKS

Project Calico is a network policy engine for Kubernetes. With Calico network policy enforcement, you can implement network segmentation and tenant isolation. This is useful in multi-tenant environments where you must isolate tenants from each other or when you want to create separate environments for development, staging, and production. Network policies are similar to AWS security groups in that you can create network ingress and egress rules. Instead of assigning instances to a security group, you assign network policies to pods using pod selectors and labels. The following procedure shows you how to install Calico on Linux nodes in your Amazon EKS cluster. To install Calico on Windows nodes, see Using Calico on Amazon EKS Windows Containers.

Note

- Calico is not supported when using Fargate with Amazon EKS.
- Calico adds rules to iptables on the node that may be higher priority than existing rules that you've already implemented outside of Calico. Consider adding existing iptables rules to your Calico policies to avoid having rules outside of Calico policy overridden by Calico.
- If you're using security groups for pods (p. 214), traffic flow to pods on branch network interfaces is not subjected to Calico network policy enforcement and is limited to Amazon EC2 security group enforcement only. Community effort is underway to remove this limitation.

To install Calico on your Amazon EKS Linux nodes

1. Apply the Calico manifest to your cluster by completing the option that corresponds to the Region that your cluster is in.
   - All regions other than China (Ningxia) or China (Beijing) – Apply the Calico manifest from the aws/amazon-vpc-cni-k8s GitHub project. This manifest creates DaemonSets in the kube-system namespace.
Installing Calico on Amazon EKS

1. Download the Calico manifest with the following command.

   ```bash
curl -o calico.yaml https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.7.5/config/v1.7/calico.yaml
   ```

2. Modify the manifest.
   a. View the manifest file or files that you downloaded and note the name of the image.
      Download the image locally with the following command.

      ```bash
docker pull image:<tag>
      ```

   b. Tag the image to be pushed to an Amazon Elastic Container Registry repository in China with
      the following command.

      ```bash
docker tag image:<tag> <aws_account_id>.dkr.ecr.<cn-north-1>.amazonaws.com/image:<tag>
      ```

   c. Push the image to a China Amazon ECR repository with the following command.

      ```bash
docker push image:<tag> <aws_account_id>.dkr.ecr.<cn-north-1>.amazonaws.com/image:<tag>
      ```

   d. Update the Kubernetes manifest file or files to reference the Amazon ECR image URL in your
      region.

3. Apply the Calico manifest. This manifest creates DaemonSets in the `kube-system` namespace.

   ```bash
cubectl apply -f calico.yaml
   ```

2. Watch the `kube-system` DaemonSets and wait for the `calico-node` DaemonSet to have the
   DESIRED number of pods in the READY state. When this happens, Calico is working.

   ```bash
cubectl get daemonset calico-node --namespace kube-system
   ```

   Output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESIRED</th>
<th>CURRENT</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>NODE SELECTOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>calico-node</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>&lt;none&gt;</td>
</tr>
<tr>
<td></td>
<td>38s</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

To delete Calico from your Amazon EKS cluster

- If you are done using Calico in your Amazon EKS cluster, you can delete the DaemonSet with the
  following command:

   ```bash
cubectl delete -f https://raw.githubusercontent.com/aws/amazon-vpc-cni-k8s/v1.7.5/config/v1.7/calico.yaml
   ```
Stars policy demo

This section walks through the Stars policy demo provided by the Project Calico documentation. The demo creates a frontend, backend, and client service on your Amazon EKS cluster. The demo also creates a management GUI that shows the available ingress and egress paths between each service.

Before you create any network policies, all services can communicate bidirectionally. After you apply the network policies, you can see that the client can only communicate with the frontend service, and the backend only accepts traffic from the frontend.

To run the Stars policy demo

1. Apply the frontend, backend, client, and management UI services:

   ```
kubectl apply -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/manifests/00-namespace.yaml
kubectl apply -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/manifests/01-management-ui.yaml
kubectl apply -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/manifests/02-backend.yaml
kubectl apply -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/manifests/03-frontend.yaml
kubectl apply -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/manifests/04-client.yaml
   ```

2. Wait for all of the pods to reach the Running status:

   ```
kubectl get pods --all-namespaces --watch
   ```

3. To connect to the management UI, forward your local port 9001 to the management-ui service running on your cluster:

   ```
kubectl port-forward service/management-ui -n management-ui 9001
   ```

4. Open a browser on your local system and point it to http://localhost:9001/. You should see the management UI. The C node is the client service, the F node is the frontend service, and the B node is the backend service. Each node has full communication access to all other nodes (as indicated by the bold, colored lines).
5. Apply the following network policies to isolate the services from each other:

```bash
kubectl apply -n stars -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/policies/default-deny.yaml
kubectl apply -n client -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/policies/default-deny.yaml
```

6. Refresh your browser. You see that the management UI can no longer reach any of the nodes, so they don't show up in the UI.

7. Apply the following network policies to allow the management UI to access the services:

```bash
kubectl apply -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/policies/allow-ui.yaml
kubectl apply -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/policies/allow-ui-client.yaml
```

8. Refresh your browser. You see that the management UI can reach the nodes again, but the nodes cannot communicate with each other.
9. Apply the following network policy to allow traffic from the frontend service to the backend service:

```
kubectl apply -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/policies/backend-policy.yaml
```

10. Apply the following network policy to allow traffic from the client namespace to the frontend service:

```
kubectl apply -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/policies/frontend-policy.yaml
```
11. (Optional) When you are done with the demo, you can delete its resources with the following commands:

```
kubectl delete -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/manifests/04-client.yaml
kubectl delete -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/manifests/03-frontend.yaml
kubectl delete -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/manifests/02-backend.yaml
kubectl delete -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/manifests/01-management-ui.yaml
kubectl delete -f https://docs.projectcalico.org/v3.3/getting-started/kubernetes/tutorials/stars-policy/manifests/00-namespace.yaml
```

Even after deleting the resources, there can still be iptables rules on the nodes that might interfere in unexpected ways with networking in your cluster. The only sure way to remove Calico is to terminate all of the nodes and recycle them. To terminate all nodes, either set the Auto Scaling Group desired count to 0, then back up to the desired number, or just terminate the nodes. If you
are unable to recycle the nodes, then see Disabling and removing Calico Policy in the Calico GitHub repository for a last resort procedure.
Workloads

Your workloads are deployed in containers, which are deployed in pods in Kubernetes. A pod includes one or more containers. Typically, one or more pods that provide the same service are deployed in a Kubernetes service. Once you've deployed multiple pods that provide the same service, you can:

- View information about the workloads (p. 247) running on each of your clusters using the AWS Management Console.
- Vertically scale pods up or down with the Kubernetes Vertical Pod Autoscaler (p. 253).
- Horizontally scale the number of pods needed to meet demand up or down with the Kubernetes Horizontal Pod Autoscaler (p. 258).
- Create an external (for internet-accessible pods) or an internal (for private pods) load balancer (p. 261) to balance network traffic across pods. The load balancer routes traffic at Layer 4 of the OSI model.
- Create an Application load balancing on Amazon EKS (p. 265) to balance application traffic across pods. The application load balancer routes traffic at Layer 7 of the OSI model.
- If you're new to Kubernetes, this topic helps you Deploy a sample Linux workload (p. 249).
- You can restrict IP addresses that can be assigned to a service (p. 268) with `externalIPs`.

View workloads

Workloads define applications running on a Kubernetes cluster. Every workload controls pods. Pods are the fundamental unit of computing within a Kubernetes cluster and represent one or more containers that run together.

You can use the Amazon EKS console to view information about the Kubernetes workloads and pods running on your cluster.

Prerequisites

The IAM user or IAM role that you sign into the AWS Management Console with must meet the following requirements.

- Has the `eks:AccessKubernetesApi` and other necessary IAM permissions to view workloads attached to it. For an example IAM policy, see the section called “View nodes and workloads for all clusters in the AWS Management Console” (p. 318).
- Is mapped to Kubernetes user or group in the `aws-auth` configmap. For more information, see the section called “Managing users or IAM roles for your cluster” (p. 279).
- The Kubernetes user or group that the IAM user or role is mapped to in the configmap must be bound to a Kubernetes role or clusterrole that has permissions to view the resources in the namespaces that you want to view. For more information, see Using RBAC Authorization in the Kubernetes documentation. You can download the following example manifests that create a clusterrole and clusterrolebinding or a role and rolebinding:
  - View Kubernetes resources in all namespaces – The group name in the file is `eks-console-dashboard-full-access-group`, which is the group that your IAM user or role needs to be mapped to in the `aws-auth` configmap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the configmap. To download the file, select the appropriate link for the Region that your cluster is in.
To view workloads using the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. In the Clusters list, select the cluster that you want to view workloads for.
3. On the Workloads tab, you see a list of Names of all the Kubernetes workloads that are currently deployed to your cluster, the Pod count, and Status for each workload.

   Important
   If you can't see any workloads, or you see a Your current user or role does not have access to Kubernetes objects on this EKS cluster, you may need to select a different namespace from the All Namespaces drop-down list. If you're still having problems, see the prerequisites for this topic. If you don't resolve the issue, you can still view and manage your Amazon EKS cluster on the Configuration tab, but you won't be able to see information about your workloads.

You can deploy the following types of workloads on a cluster.

- **Deployment** – Ensures that a specific number of pods run and includes logic to deploy changes.
- **ReplicaSet** – Ensures that a specific number of pods run. Can be controlled by deployments.
- **StatefulSet** – Manages the deployment of stateful applications.
- **DaemonSet** – Ensures that a copy of a pod runs on all (or some) nodes in the cluster.
- **Job** – Creates one or more pods and ensures that a specified number of them run to completion.

For more information, see Workloads in the Kubernetes documentation.

By default, all Amazon EKS clusters have the following workloads:

- **coredns** – A Deployment that deploys two replicas of the coredns pods. The pods provide name resolution for all pods in the cluster. Two pods are deployed by default for high availability, regardless of the number of nodes deployed in your cluster. For more information, see the section called "Installing or upgrading CoreDNS" (p. 237). The pods can be deployed to any node type. However, they can be deployed to Fargate nodes only if your cluster includes a Fargate profile with a namespace that matches the namespace for the workload.

- **aws-node** – A DaemonSet that deploys one pod to each Amazon EC2 node in your cluster. The pod runs the Amazon Virtual Private Cloud (Amazon VPC) CNI controller, which provides VPC networking functionality to the pods and nodes in your cluster. For more information, see the section called "Pod networking (CNI)" (p. 209). This workload isn't deployed to Fargate nodes because Fargate already contains the Amazon VPC CNI controller.

- **kube-proxy** – A DaemonSet that deploys one pod to each Amazon EC2 node in your cluster. The pods maintain network rules on nodes that enable networking communication to your pods. For more information, see kube-proxy in the Kubernetes documentation. This workload isn't deployed to Fargate nodes.
View workload details

Selecting the link in the **Name** column for one of the **Workloads** shows you the following information:

- The **Status**, **Namespace**, and **Selectors** (if any) assigned to the workload.
- The list of **Pods** managed by the workload, their **Status** and **Created** date and time.
- The Kubernetes **Labels** and **Annotations** assigned to the workload. These could have been assigned by you, by Kubernetes, or by the Amazon EKS API when the workload was created.

Some of the detailed information that you see when inspecting a workload might be different depending on the type of workload. To learn more about the unique properties of each workload type, see **Workloads** in the Kubernetes documentation.

View pod details

Pods are the fundamental unit of computing within a Kubernetes cluster and represent one or more containers that run together. Each workload controls one of more pods running on the cluster. Pods are designed as relatively ephemeral and immutable objects. Over time it’s normal to have pods start and stop while your cluster is running. Pods starting or stopping reflect changes in your workloads as well as changes in the scale of your cluster. For more information, see **Pods** in the Kubernetes documentation.

When viewing a workload, select a link in the **Name** column for one of the **Pods** to see the following information about the pod:

- The Kubernetes **Namespace** that the pod is in and the pod’s **Status**.
- The node on which the pod is running. The node might be an Amazon EC2 instance or a Fargate pod. For more information about viewing nodes, see the section called “View nodes” (p. 99).
- The **Containers** in the pod. Selecting the name of a container provides the **Image**, **Ports**, **Mounts**, and **Arguments** provided when the pod was started. Pods can define two types of containers. The first is **application** containers, which run as long as the pod is running. The second is **init** containers, which serve as processes that run during pod startup. You can see both types of containers on the pod detail page.
- The Kubernetes **Labels** and **Annotations** assigned to the pod.

Deploy a sample Linux workload

In this topic, you create a Kubernetes manifest and deploy it to your cluster.

**Prerequisites**

- You must have an existing Kubernetes cluster to deploy a sample application. If you don't have an existing cluster, you can deploy an Amazon EKS cluster using one of the Getting started with Amazon EKS (p. 4) guides.
- You must have **kubectl** installed on your computer. For more information, see Installing **kubectl** (p. 283).
- **kubectl** must be configured to communicate with your cluster. For more information, see Create a kubeconfig for Amazon EKS (p. 275).
To deploy a sample application

1. Create a Kubernetes namespace for the sample app.

   ```bash
kubectl create namespace <my-namespace>
```

2. Create a Kubernetes service and deployment.

   a. Save the following contents to a file named `sample-service.yaml` on your computer. If you're deploying to AWS Fargate (p. 137) pods, then make sure that the value for `namespace` matches the namespace that you defined in your AWS Fargate profile (p. 143). This sample deployment will pull a container image from a public repository, deploy three replicas of it to your cluster, and create a Kubernetes service with its own IP address that can be accessed from within the cluster only. To access the service from outside the cluster, you need to deploy a load balancer (p. 261) or ALB Ingress Controller (p. 265).

   The image is a multi-architecture image, so if your cluster includes both x86 and Arm nodes, then the pod can be scheduled on either type of hardware architecture. Kubernetes will deploy the appropriate hardware image based on the hardware type of the node it schedules the pod on. Alternatively, if you only want the deployment to run on nodes with a specific hardware architecture, or your cluster only contains one hardware architecture, then remove either `amd64` or `arm64` from the example that follows.

```
apiVersion: v1
kind: Service
metadata:
  name: my-service
  namespace: my-namespace
  labels:
    app: my-app
spec:
  selector:
    app: my-app
  ports:
  - protocol: TCP
    port: 80
    targetPort: 80
---
apiVersion: apps/v1
kind: Deployment
metadata:
  name: my-deployment
  namespace: my-namespace
  labels:
    app: my-app
spec:
  replicas: 3
  selector:
    matchLabels:
      app: my-app
  template:
    metadata:
      labels:
        app: my-app
    spec:
      affinity:
        nodeAffinity:
          requiredDuringSchedulingIgnoredDuringExecution:
            nodeSelectorTerms:
              - matchExpressions:
                - key: beta.kubernetes.io/arch
                  operator: In
```
values:
  - amd64
  - arm64

containers:
  - name: nginx
    image: public.ecr.aws/z9d2n7e1/nginx:1.19.5
    ports:
      - containerPort: 80

To learn more about Kubernetes services and deployments, see the Kubernetes documentation. The containers in the sample manifest do not use network storage, but they may be able to. For more information, see Storage (p. 181). Though not implemented in this example, we recommend that you create Kubernetes service accounts for your pods, and associate them to AWS IAM accounts. Specifying service accounts enables your pods to have the minimum permissions that they require to interact with other services. For more information, see IAM roles for service accounts (p. 330)

b. Deploy the application.

```
kubectl apply -f <sample-service.yaml>
```

3. View all resources that exist in the my-namespace namespace.

```
kubectl get all -n my-namespace
```

**Output**

```
NAME                                 READY   STATUS    RESTARTS   AGE
pod/my-deployment-776d8f8fd8-78w66   1/1     Running   0          27m
pod/my-deployment-776d8f8fd8-dkjfr   1/1     Running   0          27m
pod/my-deployment-776d8f8fd8-wmqj6   1/1     Running   0          27m

NAME                 TYPE        CLUSTER-IP      EXTERNAL-IP   PORT(S)   AGE
service/my-service   ClusterIP   10.100.190.12   <none>        80/TCP    32m

NAME                            READY   UP-TO-DATE   AVAILABLE   AGE
deployment.apps/my-deployment   3/3     3            3           27m

NAME                                       DESIRED   CURRENT   READY   AGE
replicaset.apps/my-deployment-776d8f8fd8   3         3         3       27m
```

In the output, you see the service and deployment that are specified in the sample manifest deployed in the previous step. You also see three pods, which are due to specifying 3 for replicas in the sample manifest. For more information about pods, see Pods in the Kubernetes documentation. Kubernetes automatically created the replicaset resource, even though it wasn’t specified in the sample manifest. For more information about ReplicaSets, see ReplicaSet in the Kubernetes documentation.

**Note**

Kubernetes will maintain the number of replicas specified in the manifest. If this were a production deployment and you wanted Kubernetes to horizontally scale the number of replicas or vertically scale the compute resources for the pods, you’d need to use the Horizontal Pod Autoscaler (p. 258) and the Vertical Pod Autoscaler (p. 253).

4. View the details of the deployed service.

```
kubectl -n <my-namespace> describe service <my-service>
```

Abbreviated output

```
NAME                            READY   UP-TO-DATE   AVAILABLE   AGE
deployment.apps/my-deployment   3/3     3            3           27m
```
Sample workload deployment

### Abbreviated output

<table>
<thead>
<tr>
<th>Name:</th>
<th>my-deployment-776d8f8fd8-78w66</th>
</tr>
</thead>
<tbody>
<tr>
<td>Namespace:</td>
<td>my-namespace</td>
</tr>
<tr>
<td>Priority:</td>
<td>0</td>
</tr>
<tr>
<td>IP:</td>
<td>192.168.16.57</td>
</tr>
<tr>
<td>Controlled By:</td>
<td>ReplicaSet/my-deployment-776d8f8fd8</td>
</tr>
<tr>
<td>Conditions:</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Status</td>
</tr>
<tr>
<td>Initialized</td>
<td>True</td>
</tr>
<tr>
<td>Ready</td>
<td>True</td>
</tr>
<tr>
<td>ContainersReady</td>
<td>True</td>
</tr>
<tr>
<td>PodScheduled</td>
<td>True</td>
</tr>
<tr>
<td>Events:</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Reason</td>
</tr>
<tr>
<td>Message</td>
<td>Age</td>
</tr>
<tr>
<td></td>
<td>From</td>
</tr>
<tr>
<td>Normal</td>
<td>Scheduled 3m20s</td>
</tr>
<tr>
<td></td>
<td>Successfully assigned</td>
</tr>
<tr>
<td></td>
<td>my-namespace/my-deployment-776d8f8fd8-78w66 to</td>
</tr>
<tr>
<td></td>
<td>ip-192-168-9-36.us-west-2.compute.internal</td>
</tr>
</tbody>
</table>

In the output, the value for **IP:** is a unique IP that is assigned to the pod from the CIDR block assigned to the subnet that the node is in, by default. If you'd prefer that pods be assigned IP addresses from different CIDR blocks than the subnet that the node is in, you can change the default behavior. For more information, see CNI custom networking (p. 224). You can also see that the Kubernetes scheduler scheduled the pod on the node with the IP address 192.168.9.36.

### Execute a shell on one of the pods by replacing the **<value>** below with a value returned for one of your pods in step 3.

**kubectl exec -it <my-deployment-776d8f8fd8-78w66> -n <my-namespace> -- /bin/bash**
7. View the DNS resolver configuration file.

```bash
cat /etc/resolv.conf
```

Output

```
nameserver 10.100.0.10
search my-namespace.svc.cluster.local svc.cluster.local cluster.local us-west-2.compute.internal
options ndots:5
```

In the previous output, the value for `nameserver` is the cluster's nameserver and is automatically assigned as the name server for any pod deployed to the cluster.

8. Disconnect from the pod by typing `exit`.

9. Remove the sample service, deployment, pods, and namespace.

```bash
kubectl delete namespace <my-namespace>
```

---

**Vertical Pod Autoscaler**

The Kubernetes Vertical Pod Autoscaler automatically adjusts the CPU and memory reservations for your pods to help "right size" your applications. This adjustment can improve cluster resource utilization and free up CPU and memory for other pods. This topic helps you to deploy the Vertical Pod Autoscaler to your cluster and verify that it is working.

**Install the metrics server**

The Kubernetes metrics server is an aggregator of resource usage data in your cluster. It is not deployed by default in Amazon EKS clusters, but it provides metrics that are required by the Vertical Pod Autoscaler. This topic explains how to deploy the Kubernetes metrics server on your Amazon EKS cluster.

**Note**

You can also use Prometheus to provide metrics for the Vertical Pod Autoscaler. For more information, see Control plane metrics with Prometheus (p. 299).

If you have already deployed the metrics server to your cluster, you can move on to the next section. You can check for the metrics server with the following command.

```bash
kubectl -n kube-system get deployment/metrics-server
```

If this command returns a `NotFound` error, then you must deploy the metrics server to your Amazon EKS cluster.

**To deploy the Metrics Server**

1. Deploy the Metrics Server with the following command:

```bash
kubectl apply -f https://github.com/kubernetes-sigs/metrics-server/releases/download/v0.3.7/components.yaml
```

2. Verify that the `metrics-server` deployment is running the desired number of pods with the following command.
Deploy the Vertical Pod Autoscaler

In this section, you deploy the Vertical Pod Autoscaler to your cluster.

To deploy the Vertical Pod Autoscaler

1. Open a terminal window and navigate to a directory where you would like to download the Vertical Pod Autoscaler source code.
2. Clone the kubernetes/autoscaler GitHub repository.

   ```bash
git clone https://github.com/kubernetes/autoscaler.git
```
3. Change to the `vertical-pod-autoscaler` directory.

   ```bash
cd autoscaler/vertical-pod-autoscaler/
```
4. (Optional) If you have already deployed another version of the Vertical Pod Autoscaler, remove it with the following command.

   ```bash
./hack/vpa-down.sh
```
5. If your cluster isn't in the China (Beijing) or China (Ningxia) Region, skip to step 6. Edit the manifest files in ./vertical-pod-autoscaler/deploy using the following steps.

   1. View the manifest file or files that you downloaded and note the name of the image. Download the image locally with the following command.

   ```bash
docker pull image:<tag>
```
   2. Tag the image to be pushed to an Amazon Elastic Container Registry repository in China with the following command.

   ```bash
docker tag image:<tag> <aws_account_id>.dkr.ecr.<cn-north-1>.amazonaws.com/image:<tag>
```
   3. Push the image to a China Amazon ECR repository with the following command.

   ```bash
docker push image:<tag> <aws_account_id>.dkr.ecr.<cn-north-1>.amazonaws.com/image:<tag>
```
   4. Update the Kubernetes manifest file or files to reference the Amazon ECR image URL in your region.
6. Deploy the Vertical Pod Autoscaler to your cluster with the following command.

   ```bash
./hack/vpa-up.sh
```
7. Verify that the Vertical Pod Autoscaler pods have been created successfully.

```
kubectl get pods -n kube-system
```

Output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws-node-949vx</td>
<td>1/1</td>

---

**Test your Vertical Pod Autoscaler installation**

In this section, you deploy a sample application to verify that the Vertical Pod Autoscaler is working.

**To test your Vertical Pod Autoscaler installation**

1. Deploy the `hamster.yaml` Vertical Pod Autoscaler example with the following command.

```
kubectl apply -f examples/hamster.yaml
```

2. Get the pods from the `hamster` example application.

```
kubectl get pods -l app=hamster
```

Output:

| hamster-c7d89d6db-rglf5          | 1/1   | Running   | 0        | 48s  |
| hamster-c7d89d6db-znvz5         | 1/1   | Running   | 0        | 48s  |

3. Describe one of the pods to view its CPU and memory reservation.

```
kubectl describe pod hamster-<c7d89d6db-rglf5>
```

Output:

<table>
<thead>
<tr>
<th>Name:</th>
<th>hamster-c7d89d6db-rglf5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Namespace:</td>
<td>default</td>
</tr>
<tr>
<td>Priority:</td>
<td>0</td>
</tr>
<tr>
<td>Node:</td>
<td>ip-192-168-9-44.&lt;region-code&gt;.compute.internal/192.168.9.44</td>
</tr>
<tr>
<td>Start Time:</td>
<td>Fri, 27 Sep 2019 10:35:15 -0700</td>
</tr>
<tr>
<td>Labels:</td>
<td>app=hamster</td>
</tr>
<tr>
<td>pod-template-hash:</td>
<td>c7d89d6db</td>
</tr>
<tr>
<td>Annotations:</td>
<td>kubernetes.io/psp: eks.privileged</td>
</tr>
<tr>
<td></td>
<td>vpaUpdates: Pod resources updated by hamster-vpa: container 0:</td>
</tr>
<tr>
<td>Status:</td>
<td>Running</td>
</tr>
<tr>
<td>IP:</td>
<td>192.168.23.42</td>
</tr>
<tr>
<td>IPs:</td>
<td>&lt;none&gt;</td>
</tr>
<tr>
<td>Controlled By:</td>
<td>ReplicaSet/hamster-c7d89d6db</td>
</tr>
</tbody>
</table>
You can see that the original pod reserves 100 milliCPU of CPU and 50 mebibytes of memory. For this example application, 100 milliCPU is less than the pod needs to run, so it is CPU-constrained. It also reserves much less memory than it needs. The Vertical Pod Autoscaler \texttt{vpa-recommender} deployment analyzes the \texttt{hamster} pods to see if the CPU and memory requirements are appropriate. If adjustments are needed, the \texttt{vpa-updater} relaunches the pods with updated values.

4. Wait for the \texttt{vpa-updater} to launch a new \texttt{hamster} pod. This should take a minute or two. You can monitor the pods with the following command.

    \texttt{kubectl get \--watch pods \-l app=hamster}

5. When a new \texttt{hamster} pod is started, describe it and view the updated CPU and memory reservations.

    \texttt{kubectl describe pod hamster-\<c7d89d6db\>-\<jxgfv\>}

Output:

<table>
<thead>
<tr>
<th>Name:</th>
<th>hamster-c7d89d6db-jxgfv</th>
</tr>
</thead>
<tbody>
<tr>
<td>Namespace:</td>
<td>default</td>
</tr>
<tr>
<td>Priority:</td>
<td>0</td>
</tr>
<tr>
<td>Node:</td>
<td>ip-192-168-9-44.&lt;region-code&gt;.compute.internal/192.168.9.44</td>
</tr>
<tr>
<td>Start Time:</td>
<td>Fri, 27 Sep 2019 10:37:08 -0700</td>
</tr>
<tr>
<td>Labels:</td>
<td>app=hamster</td>
</tr>
<tr>
<td>Annotations:</td>
<td>pod-template-hash=c7d89d6db</td>
</tr>
<tr>
<td></td>
<td>kubernetes.io/psp: eks.privileged</td>
</tr>
<tr>
<td></td>
<td>vpaUpdates: Pod resources updated by hamster-vpa: container 0: cpu request, memory request</td>
</tr>
<tr>
<td>Status:</td>
<td>Running</td>
</tr>
<tr>
<td>IP:</td>
<td>192.168.3.140</td>
</tr>
<tr>
<td>IFS:</td>
<td>&lt;none&gt;</td>
</tr>
<tr>
<td>Controlled By:</td>
<td>ReplicaSet/hamster-c7d89d6db</td>
</tr>
<tr>
<td>Containers:</td>
<td>hamster:</td>
</tr>
</tbody>
</table>
Here you can see that the CPU reservation has increased to 587 millicpu, which is over five times the original value. The memory has increased to 262,144 Kilobytes, which is around 250 mebibytes, or five times the original value. This pod was under-resourced, and the Vertical Pod Autoscaler corrected our estimate with a much more appropriate value.

6. Describe the `hamster-vpa` resource to view the new recommendation.

```
kubectl describe vpa/hamster-vpa
```

Output:

```
Name:         hamster-vpa
Namespace:    default
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:
              {"apiVersion":"autoscaling.k8s.io/v1beta2","kind":"VerticalPodAutoscaler","metadata":{"annotations":{},"name":"hamster-vpa","namespace":"d...  
API Version:  autoscaling.k8s.io/v1beta2
Kind:         VerticalPodAutoscaler
Metadata:
Generation:          23
Resource Version:    14411
Self Link:           /apis/autoscaling.k8s.io/v1beta2/namespaces/default/verticalpodautoscalers/hamster-vpa
UID:                 d0d85fb9-e153-11e9-ae53-0205785d75b0
Spec:
  Target Ref:
    API Version:  apps/v1
    Kind:         Deployment
    Name:         hamster
Status:
Conditions:
  Status:                True

Recommendation:
  Container Recommendations:
    Container Name:  hamster
    Lower Bound:
      Cpu:      550m
```
When you finish experimenting with the example application, you can delete it with the following command.

```
kubectl delete -f examples/hamster.yaml
```

## Horizontal Pod Autoscaler

The Kubernetes Horizontal Pod Autoscaler automatically scales the number of pods in a deployment, replication controller, or replica set based on that resource's CPU utilization. This can help your applications scale out to meet increased demand or scale in when resources are not needed, thus freeing up your nodes for other applications. When you set a target CPU utilization percentage, the Horizontal Pod Autoscaler scales your application in or out to try to meet that target.

The Horizontal Pod Autoscaler is a standard API resource in Kubernetes that simply requires that a metrics source (such as the Kubernetes metrics server) is installed on your Amazon EKS cluster to work. You do not need to deploy or install the Horizontal Pod Autoscaler on your cluster to begin scaling your applications. For more information, see Horizontal Pod Autoscaler in the Kubernetes documentation.

Use this topic to prepare the Horizontal Pod Autoscaler for your Amazon EKS cluster and to verify that it is working with a sample application.

**Note**

This topic is based on the Horizontal pod autoscaler walkthrough in the Kubernetes documentation.

### Install the metrics server

The Kubernetes metrics server is an aggregator of resource usage data in your cluster. The metrics server is not deployed by default in Amazon EKS clusters, but it provides metrics that are required by the Horizontal Pod Autoscaler. This topic explains how to deploy the Kubernetes metrics server on your Amazon EKS cluster.

If you have already deployed the metrics server to your cluster, you can move on to the next section. You can check for the metrics server with the following command.

```
kubectl -n kube-system get deployment/metrics-server
```

If this command returns a `NotFound` error, then you must deploy the metrics server to your Amazon EKS cluster.

**To deploy the Metrics Server**

1. Deploy the Metrics Server with the following command:
Run a Horizontal Pod Autoscaler test application

In this section, you deploy a sample application to verify that the Horizontal Pod Autoscaler is working.

**Note**
This example is based on the Horizontal pod autoscaler walkthrough in the Kubernetes documentation.

**To test your Horizontal Pod Autoscaler installation**

1. Deploy a simple Apache web server application with the following command.

   ```bash
kubectl apply -f https://k8s.io/examples/application/php-apache.yaml
   ```

   This Apache web server pod is given a 500 millicpu CPU limit and it is serving on port 80.

2. Create a Horizontal Pod Autoscaler resource for the `php-apache` deployment.

   ```bash
   kubectl autoscale deployment php-apache --cpu-percent=50 --min=1 --max=10
   ```

   This command creates an autoscaler that targets 50 percent CPU utilization for the deployment, with a minimum of one pod and a maximum of ten pods. When the average CPU load is below 50 percent, the autoscaler tries to reduce the number of pods in the deployment, to a minimum of one. When the load is greater than 50 percent, the autoscaler tries to increase the number of pods in the deployment, up to a maximum of ten. For more information, see How does the Horizontal Pod Autoscaler work? in the Kubernetes documentation.

3. Describe the autoscaler with the following command to view its details.

   ```bash
   kubectl describe hpa
   ```

   **Output:**

<table>
<thead>
<tr>
<th>Name: php-apache</th>
<th>Namespace: default</th>
<th>Labels: &lt;none&gt;</th>
<th>Annotations: &lt;none&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metrics:</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>resource cpu on pods (as a percentage of request):</td>
<td>&lt;unknown&gt; / 50%</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Min replicas:</td>
<td></td>
<td></td>
<td>1</td>
</tr>
</tbody>
</table>
As you can see, the current CPU load is <unknown>, because there's no load on the server yet. The pod count is already at its lowest boundary (one), so it cannot scale in.

4. Create a load for the web server by running a container.

```bash
kubectl run -it --rm load-generator --image=busybox /bin/sh --generator=run-pod/v1
```

If you don't receive a command prompt after several seconds, you may need to press Enter. From the command prompt, enter the following command to generate load and cause the autoscaler to scale out the deployment.

```bash
while true; do wget -q -O- http://php-apache; done
```

5. To watch the deployment scale out, periodically run the following command in a separate terminal from the terminal that you ran the previous step in.

```bash
kubectl get hpa
```

Output:

```
NAME       REFERENCE             TARGETS         MINPODS  MAXPODS  REPLICAS  AGE
php-apache Deployment/php-apache 250%/50%   1        10        5          4m44s
```

As long as actual CPU percentage is higher than the target percentage, then the replica count increases, up to 10. In this case, it's 250%, so the number of REPLICAS continues to increase.

**Note**

It may take a few minutes before you see the replica count reach its maximum. If only 6 replicas, for example, are necessary for the CPU load to remain at or under 50%, then the load won’t scale beyond 6 replicas.

6. Stop the load. In the terminal window you're generating the load in (from step 4), stop the load by holding down the Ctrl+C keys. You can watch the replicas scale back to 1 by running the following command again.
kubectl get hpa

Output

<table>
<thead>
<tr>
<th>NAME</th>
<th>REFERENCE</th>
<th>TARGETS</th>
<th>MINPODS</th>
<th>MAXPODS</th>
<th>REPLICAS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>php-apache</td>
<td>Deployment/php-apache</td>
<td>0%/50%</td>
<td>1</td>
<td>10</td>
<td>1</td>
<td>25m</td>
</tr>
</tbody>
</table>

**Note**
The default timeframe for scaling back down is five minutes, so it will take some time before you see the replica count reach 1 again, even when the current CPU percentage is 0 percent. The timeframe is modifiable. For more information, see Horizontal Pod Autoscaler in the Kubernetes documentation.

7. When you are done experimenting with your sample application, delete the php-apache resources.

kubectl delete deployment.apps/php-apache service/php-apache horizontalpodautoscaler.autoscaling/php-apache

---

**Network load balancing on Amazon EKS**

When you create a Kubernetes Service of type LoadBalancer, an AWS Network Load Balancer (NLB) or Classic Load Balancer (CLB) is provisioned that load balances network traffic. To learn more about the differences between the two types of load balancers, see Elastic Load Balancing features on the AWS web site. For more information about a Kubernetes Service, see Service in the Kubernetes documentation. NLBs can be used with pods deployed to nodes or to AWS Fargate IP targets. You can deploy an AWS load balancer to a public or private subnet.

Network traffic is load balanced at L4 of the OSI model. To load balance application traffic at L7, you deploy a Kubernetes Ingress, which provisions an AWS Application Load Balancer. For more information, see the section called “Application load balancing” (p. 265). To learn more about the differences between the two types of load balancing, see Elastic Load Balancing features on the AWS web site.

In Amazon EKS, you can load balance network traffic to an NLB (instance or IP target) or a CLB (instance target only). For more information about NLB target types, see Target type in the User Guide for Network Load Balancers. When you load balance network traffic to instance targets, the Kubernetes in-tree controller creates the NLB or CLB. To load balance network traffic to IP target types, the AWS Load Balancer Controller creates an NLB. For more information, see AWS load balancer controller on GitHub.

**Prerequisites**

Before you can load balance network traffic to an application, you must meet the following requirements.

- Have an existing cluster. If you don't have an existing cluster, see Getting started with Amazon EKS (p. 4). If you're load balancing to IP targets, the cluster must be 1.18 or later. To update an existing cluster, see the section called “Updating a cluster” (p. 43).
- If you're load balancing to IP targets, you must have the AWS Load Balancer Controller provisioned on your cluster. For more information, see the section called “AWS Load Balancer Controller” (p. 232).
- Public subnets must be tagged as follows so that Kubernetes knows to use only those subnets for external load balancers instead of choosing a public subnet in each Availability Zone (in lexicographical order by subnet ID). If you use eksctl or an Amazon EKS AWS CloudFormation template to create your VPC after March 26, 2020, then the subnets are tagged appropriately when they're created. For
more information about the Amazon EKS AWS CloudFormation VPC templates, see Creating a VPC for your Amazon EKS cluster (p. 198).

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/role/elb</td>
<td>1</td>
</tr>
</tbody>
</table>

- Private subnets must be tagged as follows so that Kubernetes knows it can use the subnets for internal load balancers. If you use `eksctl` or an Amazon EKS AWS CloudFormation template to create your VPC after March 26, 2020, then the subnets are tagged appropriately when they’re created. For more information about the Amazon EKS AWS CloudFormation VPC templates, see Creating a VPC for your Amazon EKS cluster (p. 198).

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/role/internal-elb</td>
<td>1</td>
</tr>
</tbody>
</table>

**Considerations**

- Use of the UDP protocol is supported with the load balancer on Amazon EKS clusters with the following platform versions. For more information, see the section called "Platform versions" (p. 73).

<table>
<thead>
<tr>
<th>Amazon EKS version</th>
<th>Platform version</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.18</td>
<td>1.1</td>
</tr>
<tr>
<td>1.17</td>
<td>1.2</td>
</tr>
<tr>
<td>1.16</td>
<td>1.3</td>
</tr>
<tr>
<td>1.15</td>
<td>1.4</td>
</tr>
</tbody>
</table>

- You can only use NLB IP targets with the Amazon EKS VPC CNI plugin (p. 209). You can use NLB instance targets with the Amazon EKS VPC CNI plugin or alternate compatible CNI plugins (p. 232).
- You can only use IP targets with NLB. You can’t use IP targets with CLBs.
- The configuration of your load balancer is controlled by annotations that are added to the manifest for your service. If you want to add tags to the load balancer when (or after) it’s created, add the following annotation in your service specification. For more information, see Other ELB annotations in the Kubernetes documentation.

```
service.beta.kubernetes.io/aws-load-balancer-additional-resource-tags
```

- If you’re using Amazon EKS 1.16 or later, you can assign elastic IP addresses to the Network Load Balancer by adding the following annotation. Replace the `<example-values>` (including <> with the Allocation IDs of your elastic IP addresses. The number of Allocation IDs must match the number of subnets used for the load balancer.

```
service.beta.kubernetes.io/aws-load-balancer-eip-allocations: eipalloc-<xxxxxxxxxxxxxxxxxxxxxx>,eipalloc-<yyyyyyyyyyyyyyyyyyy>
```

- For each NLB that you create on 1.16 or later clusters, Amazon EKS adds one inbound rule to the node’s security group for client traffic and one rule for each load balancer subnet in the VPC for health checks. On 1.15 clusters, one rule is added for each CIDR block assigned to the VPC. Deployment of a service of type `LoadBalancer` can fail if Amazon EKS attempts to create rules that exceed the quota for the maximum number of rules allowed for a security group. For more information, see Security
groups in Amazon VPC quotas in the Amazon VPC User Guide. Consider the following options to minimize the chances of exceeding the maximum number of rules for a security group.

- Request an increase in your rules per security group quota. For more information, see Requesting a quota increase in the Service Quotas User Guide.
- Use the section called “Load balancer – IP targets” (p. 263), rather than instance targets. With IP targets, rules can potentially be shared for the same target ports. Load balancer subnets can be manually specified with an annotation. For more information, see Annotations on GitHub.
- Use an Ingress, instead of a Service of type LoadBalancer to send traffic to your service. The AWS Application Load Balancer (ALB) requires fewer rules than NLBs. An ALB can also be shared across multiple Ingresses. For more information, see the section called “Application load balancing” (p. 265).
- Deploy your clusters to multiple accounts.

## Load balancer – Instance targets

NLB or CLBs with instance targets are created by the Kubernetes in-tree load balancing controller. The in-tree controller is included with Kubernetes, so you don't need to deploy it to your cluster. You can use NLB instance targets with pods deployed to nodes, but not to Fargate. To load balance network traffic across pods deployed to Fargate, you must use IP targets (p. 263). By default, external (public) Classic Load Balancers are created when you deploy a Kubernetes service of type LoadBalancer. To deploy a Network Load Balancer instead, apply the following annotation to your service:

```
service.beta.kubernetes.io/aws-load-balancer-type: nlb
```

**Important**

Do not edit this annotation after creating your service. If you need to modify it, delete the service object and create it again with the desired value for this annotation.

To deploy a load balancer to a private subnet, your service specification must have the following annotation:

```
service.beta.kubernetes.io/aws-load-balancer-internal: "true"
```

For internal load balancers, your Amazon EKS cluster must be configured to use at least one private subnet in your VPC. Kubernetes examines the route table for your subnets to identify whether they are public or private. Public subnets have a route directly to the internet using an internet gateway, but private subnets do not.

For an example service manifest that specifies a load balancer, see Type LoadBalancer in the Kubernetes documentation. For more information about using Network Load Balancer with Kubernetes, see Network Load Balancer support on AWS in the Kubernetes documentation.

## Load balancer – IP targets

NLBs with IP targets are created by the AWS Load Balancer Controller (you cannot use CLBs with IP targets). You can use NLB IP targets with pods deployed to Amazon EC2 nodes or Fargate. Your Kubernetes service must be created as type LoadBalancer. For more information, see Type LoadBalancer in the Kubernetes documentation.

To create a load balancer that uses IP targets, add the following annotation to a service manifest and deploy your service.

```
service.beta.kubernetes.io/aws-load-balancer-type: nlb-ip
```
Important
Do not edit this annotation after creating your service. If you need to modify it, delete the service object and create it again with the desired value for this annotation. You can only use NLB IP targets with clusters running at least Amazon EKS version 1.18. To upgrade your current version, see the section called “Updating a cluster” (p. 43).

To deploy a sample application
1. Deploy a sample application.
   a. Save the following contents to a yam1 file on your computer.

   ```yaml
   apiVersion: apps/v1
   kind: Deployment
   metadata:
     name: sample-app
   spec:
     replicas: 3
     selector:
       matchLabels:
         app: nginx
   template:
     metadata:
       labels:
         app: nginx
     spec:
       containers:
       - name: nginx
         image: public.ecr.aws/z9d2n7e1/nginx:1.19.5
         ports:
           - name: http
             containerPort: 80
   
   b. Apply the manifest to the cluster.

   ```

   kubectl apply -f <file-name-you-specified>.yaml

2. Create a service of type LoadBalancer with an annotation to create an NLB with IP targets.
   a. Save the following contents to a yam1 file on your computer.

   ```yaml
   apiVersion: v1
   kind: Service
   metadata:
     name: sample-service
   annotations:
     service.beta.kubernetes.io/aws-load-balancer-type: nlb-ip
   spec:
     ports:
     - port: 80
       targetPort: 80
       protocol: TCP
     type: LoadBalancer
     selector:
       app: nginx
   
   b. Apply the manifest to the cluster.

   ```

   kubectl apply -f <file-name-you-specified>.yaml

3. Verify that the service was deployed.
kubectl get svc sample-service

```
NAME            TYPE           CLUSTER-IP       EXTERNAL-IP
sample-service  LoadBalancer   10.100.240.137   k8s-default-sample-service-xxxxxxxxxx-xxxxxxxxxxxxxxxxelb.us-west-2.amazonaws.com 80:32400/TCP 16h
```

4. Open the Amazon EC2 AWS Management Console. Select **Target Groups** (under **Load Balancing**) in the left panel. In the **Name** column, select the target group's name that matches the name in the **EXTERNAL-IP** column of the output in the previous step. For example, you'd select the target group named `k8s-default-sample-service-xxxxxxxxxx` if your output were the same as the output above. The **Target type** is IP because that was specified in the sample service deployment manifest.

5. Select the **Target group** and then select the **Targets** tab. Under **Registered targets**, you should see three IP addresses of the three replicas deployed in a previous step. Wait until the status of all targets is **healthy** before continuing. It may take several minutes before all targets are healthy. The targets may have an unhealthy state before changing to healthy.

6. Send traffic to the service replacing the example value with the value returned in a previous step for the **EXTERNAL-IP**.

```
curl <k8s-default-sample-service-xxxxxxxxxx-xxxxxxxxxxxxxxxxelb.us-west-2.amazonaws.com>
```

Output

```
<!DOCTYPE html>
<html>
<head>
<title>Welcome to nginx!</title>
...
```

7. When you’re finished with the sample deployment and service, remove them.

```
kubectl delete service sample-service
kubectl delete deployment sample-app
```

---

**Application load balancing on Amazon EKS**

When you create a Kubernetes Ingress, an AWS Application Load Balancer is provisioned that load balances application traffic. To learn more, see **What is an Application Load Balancer?** in the **Application Load Balancers User Guide** and **Ingress** in the Kubernetes documentation. ALBs can be used with pods deployed to nodes or to AWS Fargate. You can deploy an ALB to public or private subnets.

Application traffic is balanced at L7 of the OSI model. To load balance network traffic at L4, you deploy a Kubernetes **Service** of type **LoadBalancer**, which provisions an AWS Network Load Balancer. For more information, see the section called “**Network load balancing**” (p. 261). To learn more about the differences between the two types of load balancing, see **Elastic Load Balancing features** on the AWS web site.

**Prerequisites**

Before you can load balance application traffic to an application, you must meet the following requirements.
- Have an existing cluster. If you don't have an existing cluster, see *Getting started with Amazon EKS* (p. 4). If you need to update the version of an existing cluster, see the section called “Updating a cluster” (p. 43).

- The AWS Load Balancer Controller provisioned on your cluster. For more information, see the section called “AWS Load Balancer Controller” (p. 232).

- Public subnets must be tagged as follows so that Kubernetes knows to use only those subnets for external load balancers instead of choosing a public subnet in each Availability Zone (in lexicographical order by subnet ID). If you use *eksctl* or an Amazon EKS AWS CloudFormation template to create your VPC after March 26, 2020, then the subnets are tagged appropriately when they're created. For more information about the Amazon EKS AWS CloudFormation VPC templates, see *Creating a VPC for your Amazon EKS cluster* (p. 198).

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/role/elb</td>
<td>1</td>
</tr>
</tbody>
</table>

- Private subnets must be tagged as follows so that Kubernetes knows it can use the subnets for internal load balancers. If you use *eksctl* or an Amazon EKS AWS CloudFormation template to create your VPC after March 26, 2020, then the subnets are tagged appropriately when they're created. For more information about the Amazon EKS AWS CloudFormation VPC templates, see *Creating a VPC for your Amazon EKS cluster* (p. 198).

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/role/internal-elb</td>
<td>1</td>
</tr>
</tbody>
</table>

**Considerations**

- The AWS Load Balancer Controller creates ALBs and the necessary supporting AWS resources whenever a Kubernetes Ingress resource is created on the cluster with the `kubernetes.io/ingress.class: alb` annotation. The Ingress resource configures the ALB to route HTTP or HTTPS traffic to different pods within the cluster. To ensure that your Ingress objects use the AWS Load Balancer Controller, add the following annotation to your Kubernetes Ingress specification. For more information, see *Ingress specification* on GitHub.

```yaml
annotations:
  kubernetes.io/ingress.class: alb
```

- The AWS Load Balancer Controller supports the following traffic modes:
  - **Instance** – Registers nodes within your cluster as targets for the ALB. Traffic reaching the ALB is routed to NodePort for your service and then proxied to your pods. This is the default traffic mode. You can also explicitly specify it with the `alb.ingress.kubernetes.io/target-type: instance` annotation.

    **Note**
    
    Your Kubernetes service must specify the `NodePort` type to use this traffic mode.

  - **IP** – Registers pods as targets for the ALB. Traffic reaching the ALB is directly routed to pods for your service. You must specify the `alb.ingress.kubernetes.io/target-type: ip` annotation to use this traffic mode. The IP target type is required when target pods are running on Fargate.

  - To tag ALBs created by the controller, add the following annotation to the controller: `alb.ingress.kubernetes.io/tags`. For a list of all available annotations supported by the AWS Load Balancer Controller, see *Ingress annotations* on GitHub.

**To share an application load balancer across multiple ingress resources using IngressGroups**
To join an Ingress to an Ingress group, add the following annotation to a Kubernetes Ingress resource specification.

```
alb.ingress.kubernetes.io/group.name: <my-group>
```

The group name must be:
- 63 characters or less in length.
- Consist of lower case alphanumeric characters, -, and ., and must start and end with an alphanumeric character.

The controller will automatically merge ingress rules for all Ingresses in the same Ingress group and support them with a single ALB. Most annotations defined on an Ingress only apply to the paths defined by that Ingress. By default, Ingress resources don’t belong to any Ingress group.

**Warning**

*Potential security risk:* You should only specify an Ingress group for an Ingress when all Kubernetes users with RBAC permission to create or modify Ingress resources are within the same trust boundary. If you add the annotation with a group name, other Kubernetes users may create or modify their Ingresses to belong to the same Ingress group. Doing so can cause undesirable behavior, such as overwriting existing rules with higher priority rules.

You can add an order number of your Ingress resource.

```
alb.ingress.kubernetes.io/group.order: <'10'>
```

The number can be between 1-1000. The lowest number for all Ingresses in the same Ingress group is evaluated first. All Ingresses without this annotation are evaluated with a value of zero. Duplicate rules with a higher number can overwrite rules with a lower number. By default, the rule order between Ingresses within the same Ingress group are determined by the lexical order of an Ingress’ namespace and name.

**Important**

Ensure that each Ingress in the same Ingress group has a unique priority number. You can’t have duplicate order numbers across Ingresses.

**To deploy a sample application**

You can run the sample application on a cluster that has Amazon EC2 nodes only, Fargate pods, or both.

1. If you're deploying to Fargate, create a Fargate profile. If you're not deploying to Fargate skip this step. The command that follows only works for clusters that were created with eksctl. If you didn’t create your cluster with eksctl, then you can create the profile with the the AWS Management Console (p. 144), using the same values for name and namespace that are in the command below.

   ```bash
   eksctl create fargateprofile --cluster <my-cluster> --region <region-code> --name <alb-sample-app> --namespace game-2048
   ```

2. Deploy the game 2048 as a sample application to verify that the AWS Load Balancer Controller creates an AWS ALB as a result of the Ingress object.

   ```bash
   kubectl apply -f https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.1.0/doc/examples/2048/2048_full.yaml
   ```

3. After a few minutes, verify that the Ingress resource was created with the following command.

   ```bash
   kubectl get ingress/ingress-2048 -n game-2048
   ```
Restricting external IP addresses that can be assigned to services

Kubernetes services can be reached from inside of a cluster through:

- A cluster IP address that is assigned automatically by Kubernetes
- Any IP address that you specify for the `externalIPs` property in a service spec. External IP addresses are not managed by Kubernetes and are the responsibility of the cluster administrator. External IP addresses specified with `externalIPs` are different than the external IP address assigned to a service of type `LoadBalancer` by a cloud provider.

To learn more about Kubernetes services, see Service in the Kubernetes documentation. You can restrict the IP addresses that can be specified for `externalIPs` in a service spec.

To restrict the IP addresses that can be specified for externalIPs in a service spec

1. Deploy cert-manager to manage webhook certificates. For more information, see the cert-manager documentation.
   
   ```
   kubectl apply -f https://github.com/jetstack/cert-manager/releases/download/v1.1.0/cert-manager.yaml
   ```

2. Verify that the cert-manager pods are running.

   ```
   kubectl get pods -n cert-manager
   ```

   Output

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
</table>

   Note

   If your Ingress has not been created after several minutes, run the following command to view the Load Balancer Controller logs. These logs may contain error messages that can help you diagnose any issues with your deployment.

   ```
   kubectl logs -n kube-system deployment.apps/aws-load-balancer-controller
   ```

   4. Open a browser and navigate to the ADDRESS URL from the previous command output to see the sample application. If you don't see anything, wait a few minutes and refresh your browser.

   5. When you finish experimenting with your sample application, delete it with the following commands.

   ```
   kubectl delete -f https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.1.0/docs/examples/2048/2048_full.yaml
   ```
3. Review your existing services to ensure that none of them have external IP addresses assigned to them that aren't contained within the CIDR block you want to limit addresses to.

```
kubectl get services --all-namespaces
```

**Output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLUSTER-IP</td>
<td>EXTERNAL-IP</td>
<td>PORT(S)</td>
</tr>
<tr>
<td>cert-manager</td>
<td>cert-manager</td>
<td>9402/TCP</td>
</tr>
<tr>
<td>cert-manager</td>
<td>cert-manager-webhook</td>
<td>443/TCP</td>
</tr>
<tr>
<td>default</td>
<td>kubernetes</td>
<td>53/UDP,53/TCP</td>
</tr>
<tr>
<td>externalip-validation-system</td>
<td>externalip-validation-webhook-service</td>
<td>443/TCP</td>
</tr>
<tr>
<td>kube-system</td>
<td>kube-dns</td>
<td>53/UDP,53/TCP</td>
</tr>
<tr>
<td>my-namespace</td>
<td>my-service</td>
<td>80/TCP</td>
</tr>
</tbody>
</table>

If any of the values are IP addresses that are not within the block you want to restrict access to, you'll need to change the addresses to be within the block, and redeploy the services. For example, the `my-service` service in the previous output has an external IP address assigned to it that isn't within the CIDR block example in step 5.

4. Download the external IP webhook manifest for the Region that your cluster is in. You can also view the source code for the webhook on GitHub.

- All Regions except Beijing and Ningxia China Regions

```
curl -o externalip-webhook.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/docs/externalip-webhook.yaml
```

- Beijing and Ningxia China Regions

```
curl -o externalip-webhook.yaml https://s3.cn-north-1.amazonaws.com.cn/amazon-eks/docs/externalip-webhook.yaml
```

5. Open the downloaded file in your editor and remove the `#` at the start of the following lines.

```yaml
#args:
#- --allowed-external-ip-cidrs=10.0.0.0/8
```

Replace `10.0.0.0/8` with your own CIDR block. You can specify as many blocks as you like. If specifying multiple blocks, add a comma between blocks.

6. If necessary, change the following address to a different address from the following table, depending on the Region your cluster is in, and then save the file.

```
image: 602401143452.dkr.ecr.us-west-2.amazonaws.com/externalip-webhook:v1.0.0
```
7. Apply the manifest to your cluster.

```
kubectl apply -f externalip-webhook.yaml
```

An attempt to deploy a service to your cluster with an IP address specified for `externalIPs` that is not contained in the blocks that you specified in step 5 will fail.
Amazon EKS uses IAM to provide authentication to your Kubernetes cluster (through the `aws eks get-token` command, available in version 1.16.156 or later of the AWS CLI, or the AWS IAM Authenticator for Kubernetes), but it still relies on native Kubernetes Role Based Access Control (RBAC) for authorization. This means that IAM is only used for authentication of valid IAM entities. All permissions for interacting with your Amazon EKS cluster's Kubernetes API is managed through the native Kubernetes RBAC system.

### Topics
- Installing `aws-iam-authenticator` (p. 271)
- Create a `kubeconfig` for Amazon EKS (p. 275)
- Managing users or IAM roles for your cluster (p. 279)

## Installing `aws-iam-authenticator`

Amazon EKS uses IAM to provide authentication to your Kubernetes cluster through the AWS IAM authenticator for Kubernetes. You can configure the stock `kubectl` client to work with Amazon EKS by installing the AWS IAM authenticator for Kubernetes and modifying your `kubectl` configuration file to use it for authentication.

**Note**

If you're running the AWS CLI version 1.16.156 or later, then you don't need to install the authenticator. Instead, you can use the `aws eks get-token` command. For more information, see Create `kubeconfig` manually (p. 277).

If you're unable to use the AWS CLI version 1.16.156 or later to create the `kubeconfig` file, then you can install the AWS IAM authenticator for Kubernetes on macOS (p. 272), Linux (p. 273), or Windows (p. 274).
To install aws-iam-authenticator with Homebrew

The easiest way to install the aws-iam-authenticator is with Homebrew.

1. If you do not already have Homebrew installed on your Mac, install it with the following command.

   ```bash
   /bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/master/install.sh)"
   ```

2. Install the aws-iam-authenticator with the following command.

   ```bash
   brew install aws-iam-authenticator
   ```

3. Test that the aws-iam-authenticator binary works.

   ```bash
   aws-iam-authenticator help
   ```

To install aws-iam-authenticator on macOS

You can also install the AWS-vended version of the aws-iam-authenticator by following these steps.

1. Download the Amazon EKS vended aws-iam-authenticator binary from Amazon S3 using the command that corresponds to the Region that your cluster is in.

   - All Regions other than China Regions.
     ```bash
     curl -o aws-iam-authenticator https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/darwin/amd64/aws-iam-authenticator
     ```

   - Beijing and Ningxia China Regions.
     ```bash
     curl -o aws-iam-authenticator https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/darwin/amd64/aws-iam-authenticator
     ```

2. (Optional) Verify the downloaded binary with the SHA-256 sum provided in the same bucket prefix.

   a. Download the SHA-256 sum for your system using the command that corresponds to the Region that your cluster is in.

      - All Regions other than China Regions.
        ```bash
        curl -o aws-iam-authenticator.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/darwin/amd64/aws-iam-authenticator.sha256
        ```

      - Beijing and Ningxia China Regions.
        ```bash
        ```

   b. Check the SHA-256 sum for your downloaded binary.

      ```bash
      openssl sha1 -sha256 aws-iam-authenticator
      ```

   c. Compare the generated SHA-256 sum in the command output against your downloaded aws-iam-authenticator.sha256 file. The two should match.
3. Apply execute permissions to the binary.

```bash
chmod +x ./aws-iam-authenticator
```

4. Copy the binary to a folder in your $PATH. We recommend creating a $HOME/bin/aws-iam-authenticator and ensuring that $HOME/bin comes first in your $PATH.

```bash
mkdir -p $HOME/bin && cp ./aws-iam-authenticator $HOME/bin/aws-iam-authenticator && export PATH=$PATH:$HOME/bin
```

5. Add $HOME/bin to your PATH environment variable.

```bash
echo 'export PATH=$PATH:$HOME/bin' >> ~/.bash_profile
```

6. Test that the aws-iam-authenticator binary works.

```bash
aws-iam-authenticator help
```

**To install aws-iam-authenticator on Linux**

1. Download the Amazon EKS vended aws-iam-authenticator binary from Amazon S3 using the command that corresponds to the Region that your cluster is in. To download the Arm version, change amd64 to arm64 before running the command.

   - All Regions other than China Regions.

   ```bash
curl -o aws-iam-authenticator https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/linux/amd64/aws-iam-authenticator
```

   - Beijing and Ningxia China Regions.

   ```bash
curl -o aws-iam-authenticator https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/linux/amd64/aws-iam-authenticator
```

2. (Optional) Verify the downloaded binary with the SHA-256 sum provided in the same bucket prefix.

   a. Download the SHA-256 sum for your system using the command that corresponds to the Region that your cluster is in. To download the Arm version, change <amd64> to arm64 before running the command.

      - All Regions other than China Regions.

      ```bash
curl -o aws-iam-authenticator.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/linux/amd64/aws-iam-authenticator.sha256
```

      - Beijing and Ningxia China Regions.

      ```bash
```

   b. Check the SHA-256 sum for your downloaded binary.

   ```bash
openssl sha1 -sha256 aws-iam-authenticator
```
c. Compare the generated SHA-256 sum in the command output against your downloaded `aws-iam-authenticator.sha256` file. The two should match.

3. Apply execute permissions to the binary.

```bash
chmod +x ./aws-iam-authenticator
```

4. Copy the binary to a folder in your `$PATH`. We recommend creating a `$HOME/bin/aws-iam-authenticator` and ensuring that `$HOME/bin` comes first in your `$PATH`.

```bash
mkdir -p $HOME/bin && cp ./aws-iam-authenticator $HOME/bin/aws-iam-authenticator && export PATH=$PATH:$HOME/bin
```

5. Add `$HOME/bin` to your `PATH` environment variable.

```bash
echo 'export PATH=PATH:$HOME/bin' >> ~/.bashrc
```

6. Test that the `aws-iam-authenticator` binary works.

```bash
aws-iam-authenticator help
```

**To install `aws-iam-authenticator` on Windows with Chocolatey**

1. If you do not already have Chocolatey installed on your Windows system, see Installing chocolatey.
2. Open a PowerShell terminal window and install the `aws-iam-authenticator` package with the following command:

```bash
choco install -y aws-iam-authenticator
```

3. Test that the `aws-iam-authenticator` binary works.

```bash
aws-iam-authenticator help
```

**To install `aws-iam-authenticator` on Windows**

1. Open a PowerShell terminal window and download the Amazon EKS vended `aws-iam-authenticator` binary from Amazon S3 using the command that corresponds to the Region that your cluster is in.
   - All Regions other than China Regions.
     ```bash
curl -o aws-iam-authenticator.exe https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/windows/amd64/aws-iam-authenticator.exe
```
   - Beijing and Ningxia China Regions.
     ```bash
```
2. (Optional) Verify the downloaded binary with the SHA-256 sum provided in the same bucket prefix.
   a. Download the SHA-256 sum for your system using the command that corresponds to the Region that your cluster is in.
Create a kubeconfig for Amazon EKS

In this section, you create a kubeconfig file for your cluster (or update an existing one).

This section offers two procedures to create or update your kubeconfig. You can quickly create or update a kubeconfig with the AWS CLI `update-kubeconfig` command automatically by using the AWS CLI, or you can create a kubeconfig manually using the AWS CLI or the `aws-iam-authenticator`.

Amazon EKS uses the `aws eks get-token` command, available in version 1.16.156 or later of the AWS CLI or the AWS IAM Authenticator for Kubernetes with `kubectl` for cluster authentication. If you have installed the AWS CLI on your system, then by default the AWS IAM Authenticator for Kubernetes will use the same credentials that are returned with the following command:

```
aws sts get-caller-identity
```

For more information, see Configuring the AWS CLI in the AWS Command Line Interface User Guide.
Create kubeconfig automatically

To create your kubeconfig file with the AWS CLI

1. Ensure that you have version 1.16.156 or later of the AWS CLI installed. To install or upgrade the AWS CLI, see Installing the AWS Command Line Interface in the AWS Command Line Interface User Guide.

   **Note**
   
   Your system’s Python version must be 2.7.9 or later. Otherwise, you receive hostname doesn’t match errors with AWS CLI calls to Amazon EKS.
   
   You can check your AWS CLI version with the following command:
   ```
   aws --version
   ```

   **Important**
   
   Package managers such as yum, apt-get, or Homebrew for macOS are often behind several versions of the AWS CLI. To ensure that you have the latest version, see Installing the AWS Command Line Interface in the AWS Command Line Interface User Guide.

2. Use the AWS CLI update-kubeconfig command to create or update your kubeconfig for your cluster.

   • By default, the resulting configuration file is created at the default kubeconfig path (`.kube/config`) in your home directory or merged with an existing kubeconfig at that location. You can specify another path with the `--kubeconfig` option.
   
   • You can specify an IAM role ARN with the `--role-arn` option to use for authentication when you issue kubectl commands. Otherwise, the IAM entity in your default AWS CLI or SDK credential chain is used. You can view your default AWS CLI or SDK identity by running the `aws sts get-caller-identity` command.
   
   • For more information, see the help page with the `aws eks update-kubeconfig help` command or see update-kubeconfig in the AWS CLI Command Reference.

   **Note**
   
   To run the following command, you must have permission to the use the eks:DescribeCluster API action with the cluster that you specify. For more information, see Amazon EKS identity-based policy examples (p. 316).
   ```
   aws eks --region <region-code> update-kubeconfig --name <cluster_name>
   ```

3. Test your configuration.
```
kubectl get svc
```  

   **Note**
   
   If you receive any authorization or resource type errors, see Unauthorized or access denied (kubectl) (p. 367) in the troubleshooting section.

Output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>svc/kubernetes</td>
<td>ClusterIP</td>
<td>10.100.0.1</td>
<td>&lt;none&gt;</td>
<td>443/TCP</td>
<td>1m</td>
</tr>
</tbody>
</table>

276
Create kubeconfig manually

To create your kubeconfig file manually

1. Create the default ~/.kube directory if it does not already exist.

   ```bash
   mkdir -p ~/.kube
   ```

2. Open your favorite text editor and copy one of the kubeconfig code blocks below into it, depending on your preferred client token method.

   - To use the AWS CLI `aws eks get-token` command (requires version 1.16.156 or later of the AWS CLI):

     ```yaml
     apiVersion: v1
     clusters:
     - cluster:
       server: <endpoint-url>
       certificate-authority-data: <base64-encoded-ca-cert>
       name: kubernetes
       contexts:
       - context:
         cluster: kubernetes
         user: aws
       current-context: aws
       kind: Config
       preferences: {}
       users:
       - name: aws
         user:
         exec:
         apiVersion: client.authentication.k8s.io/v1alpha1
         command: aws
         args:
         - "eks"
         - "get-token"
         - "--cluster-name"<cluster-name>
         - "--role"<role-arn>
         env:
         - name: AWS_PROFILE
         value: "<aws-profile>"
     ```

   - To use the AWS IAM authenticator for Kubernetes:

     ```yaml
     apiVersion: v1
     clusters:
     - cluster:
       server: <endpoint-url>
       certificate-authority-data: <base64-encoded-ca-cert>
       name: kubernetes
       contexts:
       - context:
         cluster: kubernetes
         user: aws
       current-context: aws
       kind: Config
       preferences: {}
       users:
     ```
3. Replace the `<endpoint-url>` with the endpoint URL that was created for your cluster.
4. Replace the `<base64-encoded-ca-cert>` with the `certificateAuthority.data` that was created for your cluster.
5. Replace the `<cluster-name>` with your cluster name.
6. (Optional) To assume an IAM role to perform cluster operations instead of the default AWS credential provider chain, uncomment the `-r` or `--role` and `<role-arn>` lines and substitute an IAM role ARN to use with your user.
7. (Optional) To always use a specific named AWS credential profile (instead of the default AWS credential provider chain), uncomment the `env` lines and substitute `<aws-profile>` with the profile name to use.
8. Save the file to the default `kubectl` folder, with your cluster name in the file name. For example, if your cluster name is `<devel>`, save the file to `~/.kube/config-<devel>`.
9. Add that file path to your `KUBECONFIG` environment variable so that `kubectl` knows where to look for your cluster configuration.
   - For Bash shells on macOS or Linux:
     ```bash
echo 'export KUBECONFIG=$KUBECONFIG:~/.kube/config-<devel>' >> ~/.bash_profile
```
   - For PowerShell on Windows:
     ```powershell
$ENV:KUBECONFIG="{0};{1}" -f $ENV:KUBECONFIG, "$ENV:userprofile\.kube\config-<devel>"
```
10. (Optional) Add the configuration to your shell initialization file so that it is configured when you open a shell.
    - For Bash shells on macOS:
      ```bash
echo 'export KUBECONFIG=$KUBECONFIG:~/.kube/config-<devel>' >> ~/.bash_profile
```
    - For Bash shells on Linux:
      ```bash
echo 'export KUBECONFIG=$KUBECONFIG:~/.kube/config-<devel>' >> ~/.bashrc
```
    - For PowerShell on Windows:
      ```powershell
[System.Environment]::SetEnvironmentVariable('KUBECONFIG', $ENV:KUBECONFIG, 'Machine')
```
11. Test your configuration.
Managing users or IAM roles for your cluster

When you create an Amazon EKS cluster, the IAM entity user or role, such as a federated user that creates the cluster, is automatically granted system:masters permissions in the cluster's RBAC configuration in the control plane. This IAM entity does not appear in the ConfigMap, or any other visible configuration, so make sure to keep track of which IAM entity originally created the cluster. To grant additional AWS users or roles the ability to interact with your cluster, you must edit the `aws-auth` ConfigMap within Kubernetes.

Note
For more information about different IAM identities, see Identities (Users, Groups, and Roles) in the IAM User Guide. For more information on Kubernetes RBAC configuration, see Using RBAC Authorization. For all ConfigMap settings, see Full Configuration Format on GitHub.

The `aws-auth` ConfigMap is applied as part of the Getting started with Amazon EKS (p. 4) guide which provides a complete end-to-end walkthrough from creating an Amazon EKS cluster to deploying a sample Kubernetes application. It is initially created to allow your nodes to join your cluster, but you also use this ConfigMap to add RBAC access to IAM users and roles. If you have not launched nodes and applied the `aws-auth` ConfigMap, you can do so with the following procedure.

To apply the `aws-auth` ConfigMap to your cluster

1. Check to see if you have already applied the `aws-auth` ConfigMap.

```bash
cubectl describe configmap -n kube-system aws-auth
```

If you receive an error stating "Error from server (NotFound): configmaps "aws-auth" not found", then proceed with the following steps to apply the stock ConfigMap.

2. Download, edit, and apply the AWS authenticator configuration map.

   a. Download the configuration map using the command that corresponds to the Region that your cluster is in.

      • All Regions other than China Regions.

      ```bash
curl -o aws-auth-cm.yaml https://s3.us-west-2.amazonaws.com/amazon-eks/cloudformation/2020-10-29/aws-auth-cm.yaml
```

      • Beijing and Ningxia China Regions.

      ```bash
curl -o aws-auth-cm.yaml https://s3.cn-north-1.amazonaws.com.cn/amazon-eks/cloudformation/2020-10-29/aws-auth-cm.yaml
```
Managing users or IAM roles for your cluster

b. Open the file with your favorite text editor. Replace `<ARN of instance role (not instance profile)>` with the Amazon Resource Name (ARN) of the IAM role associated with your nodes, and save the file. Do not modify any other lines in this file.

**Important**
The role ARN cannot include a path. The format of the role ARN must be `arn:aws:iam::<123456789012>:role/<role-name>`. For more information, see `aws-auth ConfigMap does not grant access to the cluster (p. 374).

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: aws-auth
  namespace: kube-system
data:
  mapRoles: |
    - rolearn: <ARN of instance role (not instance profile)>
      username: system:node:{{EC2PrivateDNSName}}
      groups:
        - system:bootstrappers
        - system:nodes
```

You can inspect the AWS CloudFormation stack outputs for your worker node groups and look for the following values:

- **InstanceRoleARN** (for node groups that were created with `eksctl`)
- **NodeInstanceRole** (for node groups that were created with Amazon EKS vended AWS CloudFormation templates in the AWS Management Console)

c. Apply the configuration. This command may take a few minutes to finish.

```
kubectl apply -f aws-auth-cm.yaml
```

**Note**
If you receive any authorization or resource type errors, see `Unauthorized or access denied (kubectl)` (p. 367) in the troubleshooting section.

3. Watch the status of your nodes and wait for them to reach the `Ready` status.

```
kubectl get nodes --watch
```

**To add an IAM user or role to an Amazon EKS cluster**

1. Ensure that the AWS credentials that `kubectl` is using are already authorized for your cluster. The IAM user that created the cluster has these permissions by default.

2. Open the `aws-auth` ConfigMap.

```
kubectl edit -n kube-system configmap/aws-auth
```

**Note**
If you receive an error stating "Error from server (NotFound): configmaps "aws-auth" not found", then use the previous procedure to apply the stock ConfigMap.

**Example ConfigMap:**

```
apiversion: v1
data:
```

280
mapRoles: |
  - groups:
    - system:bootstrappers
    - system:nodes
    rolearn: arn:aws:iam::111122223333:role/eksctl-my-cluster-nodegroup-standard-wo-
      NodeInstanceRole-1WP3NUE30GUCF
    username: system:node:{{EC2PrivateDNSName}}
kind: ConfigMap
metadata:
  creationTimestamp: "2020-09-30T21:09:18Z"
  name: aws-auth
  namespace: kube-system
  resourceVersion: "1021"
  selfLink: /api/v1/namespaces/kube-system/configmaps/aws-auth
  uid: dcc31de5-3838-11e8-af26-02e00430057c

3. Add your IAM users, roles, or AWS accounts to the configMap. You cannot add IAM groups to the
configMap.

- To add an IAM role (for example, for federated users): add the role details to the mapRoles
  section of the ConfigMap, under data. Add this section if it does not already exist in the file. Each
  entry supports the following parameters:
    - rolearn: The ARN of the IAM role to add.
    - username: The user name within Kubernetes to map to the IAM role.
    - groups: A list of groups within Kubernetes to which the role is mapped. For more information,
      see Default Roles and Role Bindings in the Kubernetes documentation.
  
- To add an IAM user: add the user details to the mapUsers section of the ConfigMap, under
data. Add this section if it does not already exist in the file. Each entry supports the following
parameters:
    - userarn: The ARN of the IAM user to add.
    - username: The user name within Kubernetes to map to the IAM user.
    - groups: A list of groups within Kubernetes to which the user is mapped to. For more
      information, see Default Roles and Role Bindings in the Kubernetes documentation.

For example, the block below contains:

- A mapRoles section that adds the node instance role so that nodes can register themselves with
  the cluster.
- A mapUsers section with the AWS users admin from the default AWS account, and ops-user
  from another AWS account. Both users are added to the system:masters group.

Replace all <example-values> (including <>) with your own values.

```yaml
# Please edit the object below. Lines beginning with a '#' will be ignored,
# and an empty file will abort the edit. If an error occurs while saving this file will
# reopened with the relevant failures.
#
apiVersion: v1
data:
  mapRoles: |
    - rolearn: <arn:aws:iam::111122223333:role/eksctl-my-cluster-nodegroup-standard-wo-
      NodeInstanceRole-1WP3NUE30GUCF>
      username: <system:node>{{EC2PrivateDNSName}}>
    groups:
      - <system:bootstrappers>
      - <system:nodes>
  mapUsers: |
```
Managing users or IAM roles for your cluster

4. Save the file and exit your text editor.

5. Ensure that the Kubernetes user or group that you mapped the IAM user or role to is bound to a Kubernetes role with a RoleBinding or ClusterRoleBinding. For more information, see Using RBAC Authorization in the Kubernetes documentation. You can download the following example manifests that create a clusterrole and clusterrolebinding or a role and rolebinding:

- **View Kubernetes resources in all namespaces** – The group name in the file is eks-console-dashboard-full-access-group, which is the group that your IAM user or role needs to be mapped to in the aws-auth configmap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the configmap. To download the file, select the appropriate link for the Region that your cluster is in.
  - All Regions other than Beijing and Ningxia China
  - Beijing and Ningxia China Regions

- **View Kubernetes resources in a specific namespace** – The namespace in this file is default, so if you want to specify a different namespace, edit the file before applying it to your cluster. The group name in the file is eks-console-dashboard-restricted-access-group, which is the group that your IAM user or role needs to be mapped to in the aws-auth configmap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the configmap. To download the file, select the appropriate link for the Region that your cluster is in.
  - All Regions other than Beijing and Ningxia China
  - Beijing and Ningxia China Regions

6. (Optional) If you want the users you’ve added to the configmap to be able to the section called “View nodes” (p. 99) or the section called “View workloads” (p. 247) in the AWS Management Console, then the user or role must have the appropriate permissions to view the resources in Kubernetes, but also need to have the appropriate IAM permissions to view those resources in the AWS Management Console. For more information, see the section called “View nodes and workloads for all clusters in the AWS Management Console” (p. 318).
Cluster management

This chapter includes the following topics to help you manage your cluster. You can also view information about your nodes (p. 99) and workloads (p. 247) using the AWS Management Console.

- **Installing kubectl** (p. 283) – Learn how to install kubectl; a command line tool for managing Kubernetes.
- **The eksctl command line utility** (p. 292) – Learn how to install a simple command line utility for creating and managing Kubernetes clusters on Amazon EKS.
- **Tutorial: Deploy the Kubernetes Dashboard (web UI)** (p. 293) – Learn how to install the dashboard, a web-based user interface for your Kubernetes cluster and applications.
- **Installing the Kubernetes Metrics Server** (p. 298) – The Kubernetes Metrics Server is an aggregator of resource usage data in your cluster. It is not deployed by default in your cluster, but is used by Kubernetes add-ons, such as the Kubernetes Dashboard and Horizontal Pod Autoscaler (p. 258). In this topic you learn how to install the Metrics Server.
- **Control plane metrics with Prometheus** (p. 299) – The Kubernetes API server exposes a number of metrics that are useful for monitoring and analysis. This topic explains how to deploy Prometheus and some of the ways that you can use it to view and analyze what your cluster is doing.
- **Using Helm with Amazon EKS** (p. 302) – The Helm package manager for Kubernetes helps you install and manage applications on your Kubernetes cluster. This topic helps you install and run the Helm binaries so that you can install and manage charts using the Helm CLI on your local computer.
- **Tagging your Amazon EKS resources** (p. 303) – To help you manage your Amazon EKS resources, you can assign your own metadata to each resource in the form of tags. This topic describes tags and shows you how to create them.
- **Amazon EKS service quotas** (p. 306) – Your AWS account has default quotas, formerly referred to as limits, for each AWS service. Learn about the quotas for Amazon EKS and how to increase them.

**Installing kubectl**

Kubernetes uses a command line utility called kubectl for communicating with the cluster API server. The kubectl binary is available in many operating system package managers, and this option is often much easier than a manual download and install process. You can follow the instructions for your specific operating system or package manager in the Kubernetes documentation to install.

This topic helps you to download and install the Amazon EKS vended kubectl binaries for macOS (p. 283), Linux (p. 285), and Windows (p. 286) operating systems. These binaries are identical to the upstream community versions, and are not unique to Amazon EKS or AWS.

**Note**

You must use a kubectl version that is within one minor version difference of your Amazon EKS cluster control plane. For example, a 1.17 kubectl client should work with Kubernetes 1.16, 1.17 and 1.18 clusters.

**All Regions except China (Ningxia) and China (Beijing)**

To install kubectl if you're in a China Region, see the section called “China Regions” (p. 287).

[To install kubectl on macOS]

1. Download the Amazon EKS vended kubectl binary for your cluster’s Kubernetes version from Amazon S3:
• Kubernetes 1.18:

```
curl -o kubectl https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/darwin/amd64/kubectl
```

• Kubernetes 1.17:

```
curl -o kubectl https://amazon-eks.s3.us-west-2.amazonaws.com/1.17.12/2020-11-02/bin/darwin/amd64/kubectl
```

• Kubernetes 1.16:

```
curl -o kubectl https://amazon-eks.s3.us-west-2.amazonaws.com/1.16.15/2020-11-02/bin/darwin/amd64/kubectl
```

• Kubernetes 1.15:

```
curl -o kubectl https://amazon-eks.s3.us-west-2.amazonaws.com/1.15.12/2020-11-02/bin/darwin/amd64/kubectl
```

2. (Optional) Verify the downloaded binary with the SHA-256 sum for your binary.

a. Download the SHA-256 sum for your cluster’s Kubernetes version for macOS:

• Kubernetes 1.18:

```
curl -o kubectl.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/darwin/amd64/kubectl.sha256
```

• Kubernetes 1.17:

```
```

• Kubernetes 1.16:

```
curl -o kubectl.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.16.15/2020-11-02/bin/darwin/amd64/kubectl.sha256
```

• Kubernetes 1.15:

```
curl -o kubectl.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.15.12/2020-11-02/bin/darwin/amd64/kubectl.sha256
```

b. Check the SHA-256 sum for your downloaded binary.

```
openssl sha1 -sha256 kubectl
```

c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match.

3. Apply execute permissions to the binary.

```
chmod +x ./kubectl
```

4. Copy the binary to a folder in your PATH. If you have already installed a version of kubectl, then we recommend creating a $HOME/bin/kubectl and ensuring that $HOME/bin comes first in your $PATH.
mkdir -p $HOME/bin && cp ./kubectl $HOME/bin/kubectl && export PATH=$PATH:$HOME/bin

5. (Optional) Add the $HOME/bin path to your shell initialization file so that it is configured when you open a shell.

```bash
echo 'export PATH=$PATH:$HOME/bin' >> ~/.bash_profile
```

6. After you install kubectl, you can verify its version with the following command:

```bash
kubectl version --short --client
```

[To install kubectl on Linux]

1. Download the Amazon EKS vended kubectl binary for your cluster's Kubernetes version from Amazon S3. To download the Arm version, change amd64 to arm64 before running the command.

   - Kubernetes 1.18:

     ```bash
curl -o kubectl https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/linux/amd64/kubectl
     ```

   - Kubernetes 1.17:

     ```bash
curl -o kubectl https://amazon-eks.s3.us-west-2.amazonaws.com/1.17.12/2020-11-02/bin/linux/amd64/kubectl
     ```

   - Kubernetes 1.16:

     ```bash
curl -o kubectl https://amazon-eks.s3.us-west-2.amazonaws.com/1.16.15/2020-11-02/bin/linux/amd64/kubectl
     ```

   - Kubernetes 1.15:

     ```bash
curl -o kubectl https://amazon-eks.s3.us-west-2.amazonaws.com/1.15.12/2020-11-02/bin/linux/amd64/kubectl
     ```

2. (Optional) Verify the downloaded binary with the SHA-256 sum for your binary.

   a. Download the SHA-256 sum for your cluster's Kubernetes version for Linux. To download the Arm version, change <amd64> to <arm64> before running the command.

      - Kubernetes 1.18:

        ```bash
curl -o kubectl.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/linux/amd64/kubectl.sha256
        ```

      - Kubernetes 1.17:

        ```bash
        ```

      - Kubernetes 1.16:

        ```bash
curl -o kubectl.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.16.15/2020-11-02/bin/linux/amd64/kubectl.sha256
        ```
• **Kubernetes 1.15:**

```bash
curl -o kubectl.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.15.12/2020-11-02/bin/linux/amd64/kubectl.sha256
```

b. Check the SHA-256 sum for your downloaded binary.

```bash
openssl sha1 -sha256 kubectl
```

c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match.

3. Apply execute permissions to the binary.

```bash
chmod +x ./kubectl
```

4. Copy the binary to a folder in your PATH. If you have already installed a version of kubectl, then we recommend creating a `$HOME/bin/kubectl` and ensuring that `$HOME/bin` comes first in your `$PATH`.

```bash
mkdir -p $HOME/bin && cp ./kubectl $HOME/bin/kubectl && export PATH=$PATH:$HOME/bin
```

5. (Optional) Add the `$HOME/bin` path to your shell initialization file so that it is configured when you open a shell.

**Note**

This step assumes you are using the Bash shell; if you are using another shell, change the command to use your specific shell initialization file.

```bash
echo 'export PATH=$PATH:$HOME/bin' >> ~/.bashrc
```

6. After you install kubectl, you can verify its version with the following command:

```bash
kubectl version --short --client
```

[To install kubectl on Windows]

1. Open a PowerShell terminal.

2. Download the Amazon EKS vended kubectl binary for your cluster's Kubernetes version from Amazon S3:

   • **Kubernetes 1.18:**

   ```bash
curl -o kubectl.exe https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/windows/amd64/kubectl.exe
```

   • **Kubernetes 1.17:**

   ```bash
curl -o kubectl.exe https://amazon-eks.s3.us-west-2.amazonaws.com/1.17.12/2020-11-02/bin/windows/amd64/kubectl.exe
```

   • **Kubernetes 1.16:**

   ```bash
curl -o kubectl.exe https://amazon-eks.s3.us-west-2.amazonaws.com/1.16.15/2020-11-02/bin/windows/amd64/kubectl.exe
```

   • **Kubernetes 1.15:**
3. (Optional) Verify the downloaded binary with the SHA-256 sum for your binary.
   a. Download the SHA-256 sum for your cluster's Kubernetes version for Windows:
      
      **Kubernetes 1.18:**
      
      ```shell
      curl -o kubectl.exe.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.18.9/2020-11-02/bin/windows/amd64/kubectl.exe.sha256
      ```
      
      **Kubernetes 1.17:**
      
      ```shell
      ```
      
      **Kubernetes 1.16:**
      
      ```shell
      curl -o kubectl.exe.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.16.15/2020-11-02/bin/windows/amd64/kubectl.exe.sha256
      ```
      
      **Kubernetes 1.15:**
      
      ```shell
      curl -o kubectl.exe.sha256 https://amazon-eks.s3.us-west-2.amazonaws.com/1.15.12/2020-11-02/bin/windows/amd64/kubectl.exe.sha256
      ```
      
      b. Check the SHA-256 sum for your downloaded binary.
      
      ```powershell
      Get-FileHash kubectl.exe
      ```
      
      c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match, although the PowerShell output will be uppercase.

4. Copy the binary to a folder in your `PATH`. If you have an existing directory in your PATH that you use for command line utilities, copy the binary to that directory. Otherwise, complete the following steps.
   a. Create a new directory for your command line binaries, such as `C:\bin`.
   b. Copy the `kubectl.exe` binary to your new directory.
   c. Edit your user or system PATH environment variable to add the new directory to your PATH.
   d. Close your PowerShell terminal and open a new one to pick up the new PATH variable.

5. After you install `kubectl`, you can verify its version with the following command:
   
   ```shell
   kubectl version --short --client
   ```

---

**China Regions**

Complete these instructions if you're in the China (Beijing) or China (Ningxia) Region. To install `kubectl` if you're any any other Region, see the section called "All Regions except China (Ningxia) and China (Beijing)" (p. 283).
[To install kubectl on macOS]

1. Download the Amazon EKS vended kubectl binary for your cluster’s Kubernetes version from Amazon S3:

   - Kubernetes 1.18:
     
     ```bash
curl -o kubectl https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/darwin/amd64/kubectl
     ```

   - Kubernetes 1.17:
     
     ```bash
curl -o kubectl https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.17.12/2020-11-02/bin/darwin/amd64/kubectl
     ```

   - Kubernetes 1.16:
     
     ```bash
curl -o kubectl https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.16.15/2020-11-02/bin/darwin/amd64/kubectl
     ```

   - Kubernetes 1.15:
     
     ```bash
curl -o kubectl https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.15.12/2020-11-02/bin/darwin/amd64/kubectl
     ```

2. (Optional) Verify the downloaded binary with the SHA-256 sum for your binary.

   a. Download the SHA-256 sum for your cluster’s Kubernetes version for macOS:

      - Kubernetes 1.18:
        
        ```bash
curl -o kubectl.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/darwin/amd64/kubectl.sha256
        ```

      - Kubernetes 1.17:
        
        ```bash
        ```

      - Kubernetes 1.16:
        
        ```bash
curl -o kubectl.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.16.15/2020-11-02/bin/darwin/amd64/kubectl.sha256
        ```

      - Kubernetes 1.15:
        
        ```bash
curl -o kubectl.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.15.12/2020-11-02/bin/darwin/amd64/kubectl.sha256
        ```

   b. Check the SHA-256 sum for your downloaded binary.

      ```bash
      openssl sha1 -sha256 kubectl
      ```

   c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match.

3. Apply execute permissions to the binary.
4. Copy the binary to a folder in your PATH. If you have already installed a version of kubectl, then we recommend creating a $HOME/bin/kubectl and ensuring that $HOME/bin comes first in your $PATH.

    chmod +x ./kubectl
    mkdir -p $HOME/bin && cp ./kubectl $HOME/bin/kubectl && export PATH=$PATH:$HOME/bin

5. (Optional) Add the $HOME/bin path to your shell initialization file so that it is configured when you open a shell.

    echo 'export PATH=$PATH:$HOME/bin' >> ~/.bash_profile

6. After you install kubectl, you can verify its version with the following command:

    kubectl version --short --client

[ To install kubectl on Linux ]

1. Download the Amazon EKS vended kubectl binary for your cluster's Kubernetes version from Amazon S3. To download the Arm version, change amd64 to arm64 before running the command.

   • Kubernetes 1.18:

     curl -o kubectl https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/linux/amd64/kubectl

   • Kubernetes 1.17:

     curl -o kubectl https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.17.12/2020-11-02/bin/linux/amd64/kubectl

   • Kubernetes 1.16:

     curl -o kubectl https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.16.15/2020-11-02/bin/linux/amd64/kubectl

   • Kubernetes 1.15:

     curl -o kubectl https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.15.12/2020-11-02/bin/linux/amd64/kubectl

2. (Optional) Verify the downloaded binary with the SHA-256 sum for your binary.

   a. Download the SHA-256 sum for your cluster's Kubernetes version for Linux. To download the Arm version, change <amd64> to arm64 before running the command.

      • Kubernetes 1.18:

        curl -o kubectl.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/linux/amd64/kubectl.sha256

      • Kubernetes 1.17:

- **Kubernetes 1.16:**

  curl -o kubectl.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.16.15/2020-11-02/bin/linux/amd64/kubectl.sha256

- **Kubernetes 1.15:**

  curl -o kubectl.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.15.12/2020-11-02/bin/linux/amd64/kubectl.sha256

b. Check the SHA-256 sum for your downloaded binary.

  openssl sha256 kubectl

c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match.

3. Apply execute permissions to the binary.

  chmod +x ./kubectl

4. Copy the binary to a folder in your PATH. If you have already installed a version of kubectl, then we recommend creating a $HOME/bin/kubectl and ensuring that $HOME/bin comes first in your $PATH.

  mkdir -p $HOME/bin && cp ./kubectl $HOME/bin/kubectl && export PATH=$PATH:$HOME/bin

5. (Optional) Add the $HOME/bin path to your shell initialization file so that it is configured when you open a shell.

  **Note**

  This step assumes you are using the Bash shell; if you are using another shell, change the command to use your specific shell initialization file.

  echo 'export PATH=$PATH:$HOME/bin' >> ~/.bashrc

6. After you install kubectl, you can verify its version with the following command:

  kubectl version --short --client

[To install kubectl on Windows]

1. Open a PowerShell terminal.

2. Download the Amazon EKS vended kubectl binary for your cluster’s Kubernetes version from Amazon S3:

   - **Kubernetes 1.18:**

     curl -o kubectl.exe https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/windows/amd64/kubectl.exe

   - **Kubernetes 1.17:**
3. (Optional) Verify the downloaded binary with the SHA-256 sum for your binary.
   a. Download the SHA-256 sum for your cluster's Kubernetes version for Windows:
      • Kubernetes 1.18:
        curl -o kubectl.exe.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.18.9/2020-11-02/bin/windows/amd64/kubectl.exe.sha256
      • Kubernetes 1.17:
      • Kubernetes 1.16:
        curl -o kubectl.exe.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.16.15/2020-11-02/bin/windows/amd64/kubectl.exe.sha256
      • Kubernetes 1.15:
        curl -o kubectl.exe.sha256 https://amazon-eks.s3.cn-north-1.amazonaws.com.cn/1.15.12/2020-11-02/bin/windows/amd64/kubectl.exe.sha256
   b. Check the SHA-256 sum for your downloaded binary.
      Get-FileHash kubectl.exe
      c. Compare the generated SHA-256 sum in the command output against your downloaded SHA-256 file. The two should match, although the PowerShell output will be uppercase.

4. Copy the binary to a folder in your PATH. If you have an existing directory in your PATH that you use for command line utilities, copy the binary to that directory. Otherwise, complete the following steps.
   a. Create a new directory for your command line binaries, such as C:\bin.
   b. Copy the kubectl.exe binary to your new directory.
   c. Edit your user or system PATH environment variable to add the new directory to your PATH.
   d. Close your PowerShell terminal and open a new one to pick up the new PATH variable.

5. After you install kubectl, you can verify its version with the following command:

```bash
kubectl version --short --client
```
The `eksctl` command line utility

This topic covers `eksctl`, a simple command line utility for creating and managing Kubernetes clusters on Amazon EKS. The `eksctl` command line utility provides the fastest and easiest way to create a new cluster with nodes for Amazon EKS.

For more information and to see the official documentation, visit [https://eksctl.io/](https://eksctl.io/).

Installing or upgrading `eksctl`

This section helps you to install or upgrade the latest version of the `eksctl` command line utility.

You can install `eksctl` on macOS (p. 292), Linux (p. 292), or Windows (p. 293).

[To install or upgrade `eksctl` on macOS using Homebrew]

The easiest way to get started with Amazon EKS and macOS is by installing `eksctl` with Homebrew. The `eksctl` Homebrew recipe installs `eksctl` and any other dependencies that are required for Amazon EKS, such as `kubectl`. The recipe also installs the `aws-iam-authenticator` (p. 271), which is required if you don't have the AWS CLI version 1.16.156 or higher installed.

1. If you do not already have Homebrew installed on macOS, install it with the following command.

   ```bash
   /bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/master/install.sh)"
   ```

2. Install the Weaveworks Homebrew tap.

   ```bash
   brew tap weaveworks/tap
   ```

3. Install or upgrade `eksctl`.

   - Install `eksctl` with the following command:

     ```bash
     brew install weaveworks/tap/eksctl
     ```

   - If `eksctl` is already installed, run the following command to upgrade:

     ```bash
     brew upgrade eksctl && brew link --overwrite eksctl
     ```

4. Test that your installation was successful with the following command.

   ```bash
   eksctl version
   ```

   **Note**
   The GitTag version should be at least 0.35.0. If not, check your terminal output for any installation or upgrade errors, or manually download an archive of the release from [https://github.com/weaveworks/eksctl/releases/download/0.35.0/eksctl_Darwin_amd64.tar.gz](https://github.com/weaveworks/eksctl/releases/download/0.35.0/eksctl_Darwin_amd64.tar.gz), extract `eksctl`, and then execute it.

[To install or upgrade `eksctl` on Linux using `curl`]

1. Download and extract the latest release of `eksctl` with the following command.
curl --silent --location "https://github.com/weaveworks/eksctl/releases/latest/download/eksctl_$(uname -s)_amd64.tar.gz" | tar xz -C /tmp

2. Move the extracted binary to /usr/local/bin.

    sudo mv /tmp/eksctl /usr/local/bin

3. Test that your installation was successful with the following command.

    eksctl version

Note
The GitTag version should be at least 0.35.0. If not, check your terminal output for any installation or upgrade errors, or replace the address in step 1 with https://github.com/weaveworks/eksctl/releases/download/0.35.0/eksctl_Linux_amd64.tar.gz and complete steps 1-3 again.

[ To install or upgrade eksctl on Windows using Chocolatey ]

1. If you do not already have Chocolatey installed on your Windows system, see Installing Chocolatey.
2. Install or upgrade eksctl.
   • Install the binaries with the following command:

        choco install -y eksctl

   • If they are already installed, run the following command to upgrade:

        choco upgrade -y eksctl

3. Test that your installation was successful with the following command.

    eksctl version

Note
The GitTag version should be at least 0.35.0. If not, check your terminal output for any installation or upgrade errors, or manually download an archive of the release from https://github.com/weaveworks/eksctl/releases/download/0.35.0/eksctl_Windows_amd64.zip, extract eksctl, and then execute it.

Tutorial: Deploy the Kubernetes Dashboard (web UI)

This tutorial guides you through deploying the Kubernetes Dashboard to your Amazon EKS cluster, complete with CPU and memory metrics. It also helps you to create an Amazon EKS administrator service account that you can use to securely connect to the dashboard to view and control your cluster.
Prerequisites

This tutorial assumes the following:

- You have created an Amazon EKS cluster by following the steps in Getting started with Amazon EKS (p. 4).
- The security groups for your control plane elastic network interfaces and nodes follow the recommended settings in Amazon EKS security group considerations (p. 205).
- You are using a kubectl client that is configured to communicate with your Amazon EKS cluster (p. 27).

Step 1: Deploy the Kubernetes Metrics Server

The Kubernetes Metrics Server is an aggregator of resource usage data in your cluster, and it is not deployed by default in Amazon EKS clusters. The Kubernetes Dashboard uses the metrics server to gather metrics for your cluster, such as CPU and memory usage over time.

To deploy the Metrics Server

1. Deploy the Metrics Server with the following command:

```
kubectl apply -f https://github.com/kubernetes-sigs/metrics-server/releases/download/v0.3.7/components.yaml
```

2. Verify that the metrics-server deployment is running the desired number of pods with the following command.

```
kubectl get deployment metrics-server -n kube-system
```

Output
Step 2: Deploy the Kubernetes dashboard

Complete the instructions for the option that corresponds to the Region that your cluster is in.

- All Regions other than Beijing and Ningxia China

  kubectl apply -f https://raw.githubusercontent.com/kubernetes/dashboard/v2.0.5/aio/deploy/recommended.yaml

- Beijing and Ningxia China
  1. Download the Kubernetes Dashboard manifest with the following command.

     curl -o recommended.yaml https://raw.githubusercontent.com/kubernetes/dashboard/v2.0.5/aio/deploy/recommended.yaml

  2. Edit the manifest files using the following steps.

     a. View the manifest file or files that you downloaded and note the name of the image. Download the image locally with the following command.

        docker pull image:<tag>

     b. Tag the image to be pushed to an Amazon Elastic Container Registry repository in China with the following command.

        docker tag image:<tag> <aws_account_id>.dkr.ecr.<cn-north-1>.amazonaws.com/image:<tag>

     c. Push the image to a China Amazon ECR repository with the following command.

        docker push image:<tag> <aws_account_id>.dkr.ecr.<cn-north-1>.amazonaws.com/image:<tag>

     d. Update the Kubernetes manifest file or files to reference the Amazon ECR image URL in your region.

  3. Apply the manifest to your cluster with the following command.

     kubectl apply -f recommended.yaml

Output:

namespace/kubernetes-dashboard created
serviceaccount/kubernetes-dashboard created
service/kubernetes-dashboard created
secret/kubernetes-dashboard-certs created
secret/kubernetes-dashboard-csrf created
secret/kubernetes-dashboard-key-holder created
cfgmap/kubernetes-dashboard-settings created
role.rbac.authorization.k8s.io/kubernetes-dashboard created
clusterrole.rbac.authorization.k8s.io/kubernetes-dashboard created
rolebinding.rbac.authorization.k8s.io/kubernetes-dashboard created
clusterrolebinding.rbac.authorization.k8s.io/kubernetes-dashboard created
Step 3: Create an eks-admin service account and cluster role binding

By default, the Kubernetes Dashboard user has limited permissions. In this section, you create an eks-admin service account and cluster role binding that you can use to securely connect to the dashboard with admin-level permissions. For more information, see Managing Service Accounts in the Kubernetes documentation.

To create the eks-admin service account and cluster role binding

Important
The example service account created with this procedure has full cluster-admin (superuser) privileges on the cluster. For more information, see Using RBAC authorization in the Kubernetes documentation.

1. Create a file called eks-admin-service-account.yaml with the text below. This manifest defines a service account and cluster role binding called eks-admin.

   ```yaml
   apiVersion: v1
   kind: ServiceAccount
   metadata:
     name: eks-admin
     namespace: kube-system
   ---
   apiVersion: rbac.authorization.k8s.io/v1beta1
   kind: ClusterRoleBinding
   metadata:
     name: eks-admin
   roleRef:
     apiGroup: rbac.authorization.k8s.io
     kind: ClusterRole
     name: cluster-admin
   subjects:
     - kind: ServiceAccount
       name: eks-admin
       namespace: kube-system
   ```

2. Apply the service account and cluster role binding to your cluster.

   ```bash
   kubectl apply -f eks-admin-service-account.yaml
   ```

   Output:

   ```
   serviceaccount "eks-admin" created
   clusterrolebinding.rbac.authorization.k8s.io "eks-admin" created
   ```

Step 4: Connect to the dashboard

Now that the Kubernetes Dashboard is deployed to your cluster, and you have an administrator service account that you can use to view and control your cluster, you can connect to the dashboard with that service account.
To connect to the Kubernetes dashboard

1. Retrieve an authentication token for the eks-admin service account. Copy the
<authentication_token> value from the output. You use this token to connect to the dashboard.

   kubectl -n kube-system describe secret $(kubectl -n kube-system get secret | grep eks-admin | awk '{print $1}')

   Output:

   Name:         eks-admin-token-b52v4
   Namespace:    kube-system
   Labels:       <none>
   Annotations:  kubernetes.io/service-account.name=eks-admin
                 kubernetes.io/service-account.uid=bcfe66ac-39be-11e8-97e8-026dce96b6e8
   Type:  kubernetes.io/service-account-token
   Data
   ====
   ca.crt:     1025 bytes
   namespace:  11 bytes
   token:      <authentication_token>

2. Start the kubectl proxy.

   kubectl proxy

3. To access the dashboard endpoint, open the following link with a web browser: http://localhost:8001/api/v1/namespaces/kubernetes-dashboard/services/https:kubernetes-dashboard:/proxy#!/login.

4. Choose Token, paste the <authentication_token> output from the previous command into the
Token field, and choose SIGN IN.
Installing the Kubernetes Metrics Server

The Kubernetes Metrics Server is an aggregator of resource usage data in your cluster, and it is not deployed by default in Amazon EKS clusters. The Metrics Server is commonly used by other Kubernetes add-ons, such as the Horizontal Pod Autoscaler (p. 258) or the Kubernetes Dashboard (p. 293). For more information, see Resource metrics pipeline in the Kubernetes documentation. This topic explains how to deploy the Kubernetes Metrics Server on your Amazon EKS cluster.

To deploy the Metrics Server

1. Deploy the Metrics Server with the following command:

```
kubectl apply -f https://github.com/kubernetes-sigs/metrics-server/releases/download/v0.3.7/components.yaml
```

2. Verify that the metrics-server deployment is running the desired number of pods with the following command.
Control plane metrics with Prometheus

The Kubernetes API server exposes a number of metrics that are useful for monitoring and analysis. These metrics are exposed internally through a metrics endpoint that refers to the `/metrics` HTTP API. Like other endpoints, this endpoint is exposed on the Amazon EKS control plane. This topic explains some of the ways you can use this endpoint to view and analyze what your cluster is doing.

Viewing the raw metrics

To view the raw metrics output, use `kubectl` with the `--raw` flag. This command allows you to pass any HTTP path and returns the raw response.

```
kubectl get --raw /metrics
```

Example output:

```
...  
# HELP rest_client_requests_total Number of HTTP requests, partitioned by status code, method, and host.  
# TYPE rest_client_requests_total counter  
rest_client_requests_total{code="200",host="127.0.0.1:21362",method="POST"} 4994  
rest_client_requests_total{code="200",host="127.0.0.1:443",method="DELETE"} 1  
rest_client_requests_total{code="200",host="127.0.0.1:443",method="GET"} 1.326086e+06  
rest_client_requests_total{code="200",host="127.0.0.1:443",method="PUT"} 862173  
rest_client_requests_total{code="404",host="127.0.0.1:443",method="GET"} 2  
rest_client_requests_total{code="409",host="127.0.0.1:443",method="POST"} 3  
rest_client_requests_total{code="409",host="127.0.0.1:443",method="PUT"} 8  
# HELP ssh_tunnel_open_count Counter of ssh tunnel total open attempts  
# TYPE ssh_tunnel_open_count counter  
ssh_tunnel_open_count 0  
# HELP ssh_tunnel_open_fail_count Counter of ssh tunnel failed open attempts  
# TYPE ssh_tunnel_open_fail_count counter  
ssh_tunnel_open_fail_count 0
```

This raw output returns verbatim what the API server exposes. These metrics are represented in a Prometheus format. This format allows the API server to expose different metrics broken down by line. Each line includes a metric name, tags, and a value.

```
<metric_name>{"<tag>"="<value>"[<,...>]"} <value>
```

While this endpoint is useful if you are looking for a specific metric, you typically want to analyze these metrics over time. To do this, you can deploy Prometheus into your cluster. Prometheus is a monitoring and time series database that scrapes exposed endpoints and aggregates data, allowing you to filter, graph, and query the results.
Deploying Prometheus

This topic helps you deploy Prometheus into your cluster with Helm V3. If you already have Helm installed, you can check your version with the `helm version` command. Helm is a package manager for Kubernetes clusters. For more information about Helm and how to install it, see Using Helm with Amazon EKS (p. 302).

After you configure Helm for your Amazon EKS cluster, you can use it to deploy Prometheus with the following steps.

**To deploy Prometheus using Helm**

1. Create a Prometheus namespace.

   ```
   kubectl create namespace prometheus
   ```

2. Deploy Prometheus.

   ```
   helm install prometheus prometheus-community/prometheus 
   --namespace prometheus 
   --set alertmanager.persistentVolume.storageClass="gp2",server.persistentVolume.storageClass="gp2"
   ```

   **Note**
   
   If you get the error `Error: failed to download "stable/prometheus" (hint: running `helm repo update` may help)` when executing this command, run `helm repo update`, and then try running the Step 2 command again.

   If you get the error `rendered manifests contain a resource that already exists`, run `helm uninstall your-release-name -n namespace`, then try running the Step 2 command again.

3. Verify that all of the pods in the `prometheus` namespace are in the `READY` state.

   ```
   kubectl get pods -n prometheus
   ```

   Output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>prometheus-alertmanager-59b4c8c744-r7bgs</td>
<td>1/2</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-kube-state-metrics-7cf787cf99-jkz2f</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-node-exporter-7c7j</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-node-exporter-jxvz2h</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-node-exporter-vbdks</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-pushgateway-76c44b68c-82tnw</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
<tr>
<td>prometheus-server-775957f748-mmht9</td>
<td>1/2</td>
<td>Running</td>
<td>0</td>
<td>48s</td>
</tr>
</tbody>
</table>

4. Use `kubectl` to port forward the Prometheus console to your local machine.

   ```
   kubectl --namespace=prometheus port-forward deploy/prometheus-server 9090
   ```

5. Point a web browser to localhost:9090 to view the Prometheus console.

6. Choose a metric from the `- insert metric at cursor` menu, then choose **Execute**. Choose the **Graph** tab to show the metric over time. The following image shows `container_memory_usage_bytes` over time.
7. From the top navigation bar, choose **Status**, then **Targets**.
All of the Kubernetes endpoints that are connected to Prometheus using service discovery are displayed.

## Using Helm with Amazon EKS

The Helm package manager for Kubernetes helps you install and manage applications on your Kubernetes cluster. For more information, see the [Helm documentation](#). This topic helps you install and run the Helm binaries so that you can install and manage charts using the Helm CLI on your local system.

**Important**

Before you can install Helm charts on your Amazon EKS cluster, you must configure `kubectl` to work for Amazon EKS. If you have not already done this, see [Create a kubeconfig for Amazon EKS](p. 275) before proceeding. If the following command succeeds for your cluster, you're properly configured.

```bash
kubectl get svc
```

### To install the Helm binaries on your local system

1. Run the appropriate command for your client operating system.
   - If you're using macOS with Homebrew, install the binaries with the following command.
   ```bash
   brew install helm
   ```
   - If you're using Windows with Chocolatey, install the binaries with the following command.
   ```bash
   choco install kubernetes-helm
   ```
   - If you're using Linux, install the binaries with the following commands.
   ```bash
   chmod 700 get_helm.sh
   ./get_helm.sh
   ```

2. To pick up the new binary in your `PATH`, Close your current terminal window and open a new one.

3. Confirm that Helm is running with the following command.
   ```bash
   helm help
   ```

4. At this point, you can run any Helm commands (such as `helm install <chart_name>`) to install, modify, delete, or query Helm charts in your cluster. If you're new to Helm and don't have a specific chart to install, you can:
   - Experiment by installing an example chart. See [Install an example chart](#) in the Helm Quickstart guide.
   - Create an example chart and push it to Amazon ECR. For more information, see [Pushing a Helm chart](#) in the [Amazon Elastic Container Registry User Guide](#).
   - Install an Amazon EKS chart from the `eks-charts` GitHub repo or from [ArtifactHub](#).
Tagging your Amazon EKS resources

To help you manage your Amazon EKS resources, you can assign your own metadata to each resource using tags. This topic provides an overview of the tags function and shows how you can create tags.

Contents
- Tag basics (p. 303)
- Tagging your resources (p. 303)
- Tag restrictions (p. 304)
- Working with tags using the console (p. 304)
- Working with tags using the CLI, API, or eksctl (p. 305)

Tag basics

A tag is a label that you assign to an AWS resource. Each tag consists of a key and an optional value, both of which you define.

Tags enable you to categorize your AWS resources by, for example, purpose, owner, or environment. When you have many resources of the same type, you can quickly identify a specific resource based on the tags you've assigned to it. For example, you can define a set of tags for your Amazon EKS clusters to help you track each cluster's owner and stack level. We recommend that you devise a consistent set of tag keys for each resource type. You can then search and filter the resources based on the tags that you add.

Tags are not automatically assigned to your resources. After you add a tag, you can edit tag keys and values or remove tags from a resource at any time. If you delete a resource, any tags for the resource are also deleted.

Tags don't have any semantic meaning to Amazon EKS and are interpreted strictly as a string of characters. You can set the value of a tag to an empty string, but you can't set the value of a tag to null. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the earlier value.

You can tag new or existing cluster resources using the AWS Management Console, the AWS CLI, or the Amazon EKS API. You can tag only new cluster resources using eksctl.

If you use AWS Identity and Access Management (IAM), you can control which users in your AWS account have permission to manage tags.

Tagging your resources

You can tag new or existing Amazon EKS clusters and managed node groups.

If you're using the Amazon EKS console, then you can apply tags to new or existing resources at any time. You can do this by using the Tags tab on the relevant resource page. If you're using eksctl, then you can apply tags to resources when they are created using the --tags option.

If you're using the Amazon EKS API, the AWS CLI, or an AWS SDK, you can apply tags to new resources using the tags parameter on the relevant API action. You can apply tags to existing resources using the TagResource API action. For more information, see TagResource.

Some resource-creating actions enable you to specify tags for a resource when the resource is created. If tags cannot be applied while a resource is being created, the resource fails to be created. This mechanism
Tag restrictions

The following basic restrictions apply to tags:

- Maximum number of tags per resource – 50
- For each resource, each tag key must be unique, and each tag key can have only one value.
- Maximum key length – 128 Unicode characters in UTF-8
- Maximum value length – 256 Unicode characters in UTF-8
- If your tagging schema is used across multiple AWS services and resources, remember that other services may have restrictions on allowed characters. Generally allowed characters are letters, numbers, spaces representable in UTF-8, and the following characters: + - = . _ : / @.
- Tag keys and values are case sensitive.
- Don't use `aws:`, `AWS:`, or any upper or lowercase combination of such as a prefix for either keys or values. These are reserved only for AWS use. You can't edit or delete tag keys or values with this prefix. Tags with this prefix do not count against your tags-per-resource limit.

Working with tags using the console

Using the Amazon EKS console, you can manage the tags associated with new or existing clusters and managed node groups.
When you select a resource-specific page in the Amazon EKS console, it displays a list of those resources. For example, if you select Clusters from the navigation panel, the console displays a list of Amazon EKS clusters. When you select a resource from one of these lists (for example, a specific cluster) that supports tags, you can view and manage its tags on the Tags tab.

Adding tags on an individual resource on creation

You can add tags to Amazon EKS clusters, managed node groups, and Fargate profiles when you create them. For more information, see Creating an Amazon EKS cluster (p. 35).

Adding and deleting tags on an individual resource

Amazon EKS allows you to add or delete tags associated with your clusters directly from the resource's page.

To add or delete a tag on an individual resource

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. From the navigation bar, select the Region to use.
3. In the navigation panel, choose Clusters.
5. On the Update tags page, add or delete your tags as necessary.
   - To add a tag — choose Add tag and then specify the key and value for each tag.
   - To delete a tag — choose Remove tag.
6. Repeat this process for each tag you want to add or delete, and then choose Update to finish.

Working with tags using the CLI, API, or eksctl

Use the following AWS CLI commands or Amazon EKS API operations to add, update, list, and delete the tags for your resources. You can only use eksctl to add tags to new resources.

Tagging support for Amazon EKS resources

<table>
<thead>
<tr>
<th>Task</th>
<th>AWS CLI</th>
<th>AWS Tools for Windows PowerShell</th>
<th>API action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add or overwrite one or more tags.</td>
<td>tag-resource</td>
<td>Add-EKSResourceTag</td>
<td>TagResource</td>
</tr>
<tr>
<td>Delete one or more tags.</td>
<td>untag-resource</td>
<td>Remove-EKSResourceTag</td>
<td>UntagResource</td>
</tr>
</tbody>
</table>

The following examples show how to tag or untag resources using the AWS CLI.

Example 1: Tag an existing cluster

The following command tags an existing cluster.

```sh
aws eks tag-resource --resource-arn <resource_ARN> --tags <team>=<devs>
```

Example 2: Untag an existing cluster
The following command deletes a tag from an existing cluster.

```bash
aws eks untag-resource --resource-arn <resource_ARN> --tag-keys <tag_key>
```

**Example 3: List tags for a resource**

The following command lists the tags associated with an existing resource.

```bash
aws eks list-tags-for-resource --resource-arn <resource_ARN>
```

Some resource-creating actions enable you to specify tags when you create the resource. The following actions support tagging when creating a resource.

<table>
<thead>
<tr>
<th>Task</th>
<th>AWS CLI</th>
<th>AWS Tools for Windows PowerShell</th>
<th>API action</th>
<th>eksctl</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a cluster</td>
<td>create-cluster</td>
<td>New-EKSCluster</td>
<td>CreateCluster</td>
<td>create-cluster</td>
</tr>
<tr>
<td>Create a managed node group*</td>
<td>create-nodegroup</td>
<td>New-EKSNodegroup</td>
<td>CreateNodegroup</td>
<td>create-nodegroup</td>
</tr>
<tr>
<td>Create a Fargate profile</td>
<td>create-fargate-profile</td>
<td>New-EKSFargateProfile</td>
<td>CreateFargate</td>
<td>create-profile</td>
</tr>
</tbody>
</table>

*If you want to also tag the Amazon EC2 instances when creating a managed node group, create the managed node group using a launch template. For more information, see the section called “Tagging Amazon EC2 instances” (p. 114). If your instances already exist, you can manually tag the instances. For more information, see Tagging your resources in the Amazon EC2 User Guide for Linux Instances.

## Amazon EKS service quotas

Amazon EKS has integrated with Service Quotas, an AWS service that enables you to view and manage your quotas from a central location. For more information, see What Is Service Quotas? in the Service Quotas User Guide. Service Quotas makes it easy to look up the value of your Amazon EKS and AWS Fargate service quotas using the AWS Management Console and AWS CLI.

### To view Amazon EKS and Fargate service quotas using the AWS Management Console

2. In the navigation panel, choose AWS services.
3. From the AWS services list, search for and select Amazon Elastic Kubernetes Service (Amazon EKS) or AWS Fargate.
   
   In the Service quotas list, you can see the service quota name, applied value (if it is available), AWS default quota, and whether the quota value is adjustable.
4. To view additional information about a service quota, such as the description, choose the quota name.
5. (Optional) To request a quota increase, select the quota that you want to increase, select Request quota increase, enter or select the required information, and select Request.
To work more with service quotas using the AWS Management Console see the Service Quotas User Guide. To request a quota increase, see Requesting a Quota Increase in the Service Quotas User Guide.

To view Amazon EKS and Fargate service quotas using the AWS CLI

Run the following command to view your Amazon EKS quotas.

```
aws service-quotas list-aws-default-service-quotas
   --query 'Quotas[*].{Adjustable:Adjustable,Name:QuotaName,Value:Value,Code:QuotaCode}'
   --service-code eks
   --output table
```

Run the following command to view your Fargate quotas.

```
aws service-quotas list-aws-default-service-quotas
   --query 'Quotas[*].{Adjustable:Adjustable,Name:QuotaName,Value:Value,Code:QuotaCode}'
   --service-code fargate
   --output table
```

**Note**
The quota returned is the maximum number of Amazon ECS tasks or Amazon EKS pods running concurrently on Fargate in this account in the current Region.

To work more with service quotas using the AWS CLI, see the Service Quotas AWS CLI Command Reference. To request a quota increase, see the `request-service-quota-increase` command in the AWS CLI Command Reference.

The following tables provide the default quotas (also referred to as limits) for Amazon EKS and AWS Fargate for an AWS account.

**Amazon EKS service quotas**

The following quotas are Amazon EKS service quotas. Most of these service quotas are listed under the Amazon Elastic Kubernetes Service (Amazon EKS) namespace in the Service Quotas console. To request a quota increase, see Requesting a quota increase in the Service Quotas User Guide.

<table>
<thead>
<tr>
<th>Service quota</th>
<th>Description</th>
<th>Default quota value</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clusters</td>
<td>The maximum number of EKS clusters in this account in the current Region.</td>
<td>100</td>
<td>Yes</td>
</tr>
<tr>
<td>Control plane security groups per cluster</td>
<td>The maximum number of control plane security groups per cluster (these are specified when you create the cluster).</td>
<td>4</td>
<td>No</td>
</tr>
<tr>
<td>Managed node groups per cluster</td>
<td>The maximum number of managed node groups per cluster.</td>
<td>30</td>
<td>Yes</td>
</tr>
<tr>
<td>Nodes per managed node group</td>
<td>The maximum number of nodes per managed node group.</td>
<td>450</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Service quotas

<table>
<thead>
<tr>
<th>Service quota</th>
<th>Description</th>
<th>Default quota value</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Public endpoint access CIDR ranges per cluster</td>
<td>The maximum number of public endpoint access CIDR ranges per cluster (these are specified when you create or update the cluster).</td>
<td>40</td>
<td>No</td>
</tr>
<tr>
<td>Fargate profiles per cluster</td>
<td>The maximum number Fargate profiles per cluster.</td>
<td>10</td>
<td>Yes</td>
</tr>
<tr>
<td>Selectors per Fargate profile</td>
<td>The maximum number selectors per Fargate profile</td>
<td>5</td>
<td>Yes</td>
</tr>
<tr>
<td>Label pairs per Fargate profile selector</td>
<td>The maximum number of label pairs per Fargate profile selector</td>
<td>5</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**AWS Fargate service quotas**

The following quota is an Amazon EKS on AWS Fargate service quota. The service quota is listed under the AWS Fargate namespace in the Service Quotas console. To request a quota increase, see [Requesting a quota increase](https://docs.aws.amazon.com/service-quotas/latest/APIReference/API_AcceptServiceQuotaIncreaseRequest.html) in the [Service Quotas User Guide](https://docs.aws.amazon.com/service-quotas/latest/APIReference/API_AcceptServiceQuotaIncreaseRequest.html).

<table>
<thead>
<tr>
<th>Service quota</th>
<th>Description</th>
<th>Default quota value</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fargate On-Demand resource count</td>
<td>The maximum number of Amazon ECS tasks and Amazon EKS pods running concurrently on Fargate in this account in the current Region.</td>
<td>500</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Security in Amazon EKS

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. For Amazon EKS, AWS is responsible for the Kubernetes control plane, which includes the control plane nodes and etcd database. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon EKS, see AWS Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility includes the following areas.
  - The security configuration of the data plane, including the configuration of the security groups that allow traffic to pass from the Amazon EKS control plane into the customer VPC
  - The configuration of the nodes and the containers themselves
  - The node's operating system (including updates and security patches)
  - Other associated application software:
    - Setting up and managing network controls, such as firewall rules
    - Managing platform-level identity and access management, either with or in addition to IAM
    - The sensitivity of your data, your company’s requirements, and applicable laws and regulations

This documentation helps you understand how to apply the shared responsibility model when using Amazon EKS. The following topics show you how to configure Amazon EKS to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Amazon EKS resources.

**Note**

Linux containers are made up of control groups (cgroups) and namespaces that help limit what a container can access, but all containers share the same Linux kernel as the host Amazon EC2 instance. Running a container as the root user (UID 0) or granting a container access to host resources or namespaces such as the host network or host PID namespace are strongly discouraged, because doing so reduces the effectiveness of the isolation that containers provide.

**Topics**

- Identity and access management for Amazon EKS (p. 309)
- Logging and monitoring in Amazon EKS (p. 346)
- Compliance validation for Amazon EKS (p. 346)
- Resilience in Amazon EKS (p. 347)
- Infrastructure security in Amazon EKS (p. 347)
- Configuration and vulnerability analysis in Amazon EKS (p. 348)
- Amazon EKS security best practices (p. 349)
- Pod security policy (p. 353)
authorized (have permissions) to use Amazon EKS resources. IAM is an AWS service that you can use with no additional charge.

**Audience**

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in Amazon EKS.

**Service user** – If you use the Amazon EKS service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Amazon EKS features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon EKS, see Troubleshooting Amazon EKS identity and access (p. 346).

**Service administrator** – If you're in charge of Amazon EKS resources at your company, you probably have full access to Amazon EKS. It's your job to determine which Amazon EKS features and resources your employees should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Amazon EKS, see How Amazon EKS works with IAM (p. 313).

**IAM administrator** – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to Amazon EKS. To view example Amazon EKS identity-based policies that you can use in IAM, see Amazon EKS identity-based policy examples (p. 316).

**Authenticating with identities**

Authentication is how you sign in to AWS using your identity credentials. For more information about signing in using the AWS Management Console, see Signing in to the AWS Management Console as an IAM user or root user in the IAM User Guide.

You must be authenticated (signed in to AWS) as the AWS account root user, an IAM user, or by assuming an IAM role. You can also use your company's single sign-on authentication or even sign in using Google or Facebook. In these cases, your administrator previously set up identity federation using IAM roles. When you access AWS using credentials from another company, you are assuming a role indirectly.

To sign in directly to the AWS Management Console, use your password with your root user email address or your IAM user name. You can access AWS programmatically using your root user or IAM users access keys. AWS provides SDK and command line tools to cryptographically sign your request using your credentials. If you don't use AWS tools, you must sign the request yourself. Do this using Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 signing process in the AWS General Reference.

Regardless of the authentication method that you use, you might also be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

**AWS account root user**

When you first create an AWS account, you begin with a single sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you do not use the root user for your everyday tasks, even the administrative ones. Instead, adhere to the best practice of using the root user only to create your first IAM user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks.
IAM users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. An IAM user can have long-term credentials such as a user name and password or a set of access keys. To learn how to generate access keys, see Managing access keys for IAM users in the IAM User Guide. When you generate access keys for an IAM user, make sure you view and securely save the key pair. You cannot recover the secret access key in the future. Instead, you must generate a new access key pair.

An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary IAM user permissions** – An IAM user can assume an IAM role to temporarily take on different permissions for a specific task.
- **Federated user access** – Instead of creating an IAM user, you can use existing identities from AWS Directory Service, your enterprise user directory, or a web identity provider. These are known as federated users. AWS assigns a role to a federated user when access is requested through an identity provider. For more information about federated users, see Federated users and roles in the IAM User Guide.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.
- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
- **Principal permissions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see Actions, Resources, and Condition Keys for Amazon Elastic Kubernetes Service in the Service Authorization Reference.
- **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. Service roles provide access only within your account and cannot be used to grant access to services in other accounts. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.
• **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

• **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the [IAM User Guide](https://docs.aws.amazon.com/IAM/latest/UserGuide/).

To learn whether to use IAM roles or IAM users, see When to create an IAM role (instead of a user) in the [IAM User Guide](https://docs.aws.amazon.com/IAM/latest/UserGuide/).

### Managing access using policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. You can sign in as the root user or an IAM user, or you can assume an IAM role. When you then make a request, AWS evaluates the related identity-based or resource-based policies. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the [IAM User Guide](https://docs.aws.amazon.com/IAM/latest/UserGuide/).

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on **what resources**, and under what **conditions**.

Every IAM entity (user or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

#### Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the [IAM User Guide](https://docs.aws.amazon.com/IAM/latest/UserGuide/).

Identity-based policies can be further categorized as **inline policies** or **managed policies**. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the [IAM User Guide](https://docs.aws.amazon.com/IAM/latest/UserGuide/).

#### Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM **role trust policies** and Amazon S3 **bucket policies**. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the
resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

**Access control lists (ACLs)**

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the *Amazon Simple Storage Service Developer Guide*.

**Other policy types**

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the *IAM User Guide*.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the *AWS Organizations User Guide*.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the *IAM User Guide*.

**Multiple policy types**

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

**How Amazon EKS works with IAM**

Before you use IAM to manage access to Amazon EKS, you should understand what IAM features are available to use with Amazon EKS. To get a high-level view of how Amazon EKS and other AWS services work with IAM, see AWS services that work with IAM in the *IAM User Guide*.

**Topics**

- Amazon EKS identity-based policies (p. 314)
Amazon EKS identity-based policies

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. Amazon EKS supports specific actions, resources, and condition keys. To learn about all of the elements that you use in a JSON policy, see IAM JSON policy elements reference in the IAM User Guide.

Actions

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as permission-only actions that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called dependent actions.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Amazon EKS use the following prefix before the action: eks:. For example, to grant someone permission to get descriptive information about an Amazon EKS cluster, you include the DescribeCluster action in their policy. Policy statements must include either an Action or NotAction element.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": ["eks:<action1>", "eks:<action2>"
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action:

```
"Action": "eks:Describe*"
```

To see a list of Amazon EKS actions, see Actions Defined by Amazon Elastic Kubernetes Service in the IAM User Guide.

Resources

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as resource-level permissions.

For actions that don’t support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*
```
The Amazon EKS cluster resource has the following ARN:

`arn:${Partition}:eks:${Region}:${Account}:cluster/${ClusterName}`

For more information about the format of ARNs, see Amazon resource names (ARNs) and AWS service namespaces.

For example, to specify the dev cluster in your statement, use the following ARN:

"Resource": "arn:aws:eks:<region-code>:123456789012:cluster/dev"

To specify all clusters that belong to a specific account and Region, use the wildcard (*):

Some Amazon EKS actions, such as those for creating resources, cannot be performed on a specific resource. In those cases, you must use the wildcard (*).

"Resource": "*

To see a list of Amazon EKS resource types and their ARNs, see Resources Defined by Amazon Elastic Kubernetes Service in the IAM User Guide. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon Elastic Kubernetes Service.

**Condition keys**

Amazon EKS does not provide any service-specific condition keys, but it does support using some global condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

**Examples**

To view examples of Amazon EKS identity-based policies, see Amazon EKS identity-based policy examples (p. 316).

When you create an Amazon EKS cluster, the IAM entity user or role, such as a federated user that creates the cluster, is automatically granted system:masters permissions in the cluster's RBAC configuration in the control plane. This IAM entity does not appear in the ConfigMap, or any other visible configuration, so make sure to keep track of which IAM entity originally created the cluster. To grant additional AWS users or roles the ability to interact with your cluster, you must edit the `aws-auth` ConfigMap within Kubernetes.

For additional information about working with the ConfigMap, see Managing users or IAM roles for your cluster (p. 279).

**Amazon EKS resource-based policies**

Amazon EKS does not support resource-based policies.

**Authorization based on Amazon EKS tags**

You can attach tags to Amazon EKS resources or pass tags in a request to Amazon EKS. To control access based on tags, you provide tag information in the condition element of a policy using the `eks:ResourceTag/<key-name>`, `aws:RequestTag/<key-name>`, or `aws:TagKeys` condition.
keys. For more information about tagging Amazon EKS resources, see Tagging your Amazon EKS resources (p. 303).

Amazon EKS IAM roles

An IAM role is an entity within your AWS account that has specific permissions.

Using temporary credentials with Amazon EKS

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling AWS STS API operations such as AssumeRole or GetFederationToken.

Amazon EKS supports using temporary credentials.

Service-linked roles

Service-linked roles allow AWS services to access resources in other services to complete an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view but not edit the permissions for service-linked roles.

Amazon EKS supports service-linked roles. For details about creating or managing Amazon EKS service-linked roles, see Using Service-Linked Roles for Amazon EKS (p. 320).

Service roles

This feature allows a service to assume a service role on your behalf. This role allows the service to access resources in other services to complete an action on your behalf. Service roles appear in your IAM account and are owned by the account. This means that an IAM administrator can change the permissions for this role. However, doing so might break the functionality of the service.

Amazon EKS supports service roles. For more information, see Amazon EKS cluster IAM role (p. 324) and Amazon EKS node IAM role (p. 326).

Choosing an IAM role in Amazon EKS

When you create a cluster resource in Amazon EKS, you must choose a role to allow Amazon EKS to access several other AWS resources on your behalf. If you have previously created a service role, then Amazon EKS provides you with a list of roles to choose from. It's important to choose a role that has the Amazon EKS managed policies attached to it. For more information, see Check for an existing cluster role (p. 324) and Check for an existing node role (p. 326).

Amazon EKS identity-based policy examples

By default, IAM users and roles don't have permission to create or modify Amazon EKS resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating policies on the JSON tab in the IAM User Guide.

When you create an Amazon EKS cluster, the IAM entity user or role, such as a federated user that creates the cluster, is automatically granted system:masters permissions in the cluster's RBAC configuration in the control plane. This IAM entity does not appear in the ConfigMap, or any other visible configuration, so make sure to keep track of which IAM entity originally created the cluster. To grant additional AWS users or roles the ability to interact with your cluster, you must edit the aws-auth ConfigMap within Kubernetes.
For additional information about working with the ConfigMap, see Managing users or IAM roles for your cluster (p. 279).

**Topics**
- Policy best practices (p. 317)
- Using the Amazon EKS console (p. 317)
- View nodes and workloads for all clusters in the AWS Management Console (p. 318)
- Allow users to view their own permissions (p. 319)
- Update a Kubernetes cluster (p. 320)
- List or describe all clusters (p. 320)

**Policy best practices**

Identity-based policies are very powerful. They determine whether someone can create, access, or delete Amazon EKS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started using AWS managed policies** – To start using Amazon EKS quickly, use AWS managed policies to give your employees the permissions they need. These policies are already available in your account and are maintained and updated by AWS. For more information, see Get started using permissions with AWS managed policies in the IAM User Guide.

- **Grant least privilege** – When you create custom policies, grant only the permissions required to perform a task. Start with a minimum set of permissions and grant additional permissions as necessary. Doing so is more secure than starting with permissions that are too lenient and then trying to tighten them later. For more information, see Grant least privilege in the IAM User Guide.

- **Enable MFA for sensitive operations** – For extra security, require IAM users to use multi-factor authentication (MFA) to access sensitive resources or API operations. For more information, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

- **Use policy conditions for extra security** – To the extent that it's practical, define the conditions under which your identity-based policies allow access to a resource. For example, you can write conditions to specify a range of allowable IP addresses that a request must come from. You can also write conditions to allow requests only within a specified date or time range, or to require the use of SSL or MFA. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

**Using the Amazon EKS console**

To access the Amazon EKS console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon EKS resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (IAM users or roles) with that policy.

**Important**

If you see an **Error loading Namespaces** error in the console, or don't see anything on the Overview or Workloads tabs, see Can't see workloads or nodes and receive an error in the AWS Management Console (p. 373) to resolve the issue. If you don't resolve the issue, you can still view and manage aspects of your Amazon EKS cluster on the **Configuration** tab.

To ensure that those entities can still use the Amazon EKS console, create a policy with your own unique name, such as AmazonEKSAdminPolicy. Attach the policy to the entities. For more information, see Adding permissions to a user in the IAM User Guide.

**Important**

The following example policy will allow you to view information on the **Configuration** tab in the console. To view information on the **Nodes** and **Workloads** in the AWS Management Console, you need additional IAM permissions, as well as Kubernetes permissions. For more information,
Identity-based policy examples

see the the section called “View nodes and workloads for all clusters in the AWS Management Console” (p. 318) example policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

View nodes and workloads for all clusters in the AWS Management Console

This example shows how you can create a policy that allows a user to the section called “View nodes” (p. 99) and the section called “View workloads” (p. 247) for all clusters.

Important
The policy must be attached to a user or role that is mapped to a Kubernetes user or group in the aws-auth configmap. The user or group must be a subject in a rolebinding or clusterrolebinding that is bound to a Kubernetes role or clusterrole that has the necessary permissions to view the Kubernetes resources. For more information about adding
IAM users or roles to the `aws-auth` configmap, see the section called "Managing users or IAM roles for your cluster" (p. 279). To create roles and role bindings, see Using RBAC Authorization in the Kubernetes documentation. You can download the following example manifests that create a clusterrole and clusterrolebinding or a role and rolebinding:

- **View Kubernetes resources in all namespaces** – The group name in the file is `eks-console-dashboard-full-access-group`, which is the group that your IAM user or role needs to be mapped to in the `aws-auth` configmap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the configmap. To download the file, select the appropriate link for the Region that your cluster is in.
  - All Regions other than Beijing and Ningxia China
  - Beijing and Ningxia China Regions

- **View Kubernetes resources in a specific namespace** – The namespace in this file is `default`, so if you want to specify a different namespace, edit the file before applying it to your cluster. The group name in the file is `eks-console-dashboard-restricted-access-group`, which is the group that your IAM user or role needs to be mapped to in the `aws-auth` configmap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the configmap. To download the file, select the appropriate link for the Region that your cluster is in.
  - All Regions other than Beijing and Ningxia China
  - Beijing and Ningxia China Regions

### Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"],
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies",
                "iam:ListUsers"
            ],
            "Resource": "*
        }
    ]
}
```
Update a Kubernetes cluster

This example shows how you can create a policy that allows a user to update the Kubernetes version of any dev cluster for an account, in any region.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "eks:UpdateClusterVersion",
            "Resource": "arn:aws:eks:<111122223333>:cluster/<dev>"
        }
    ]
}
```

List or describe all clusters

This example shows how you can create a policy that allows a user read-only access to list or describe all clusters. An account must be able to list and describe clusters to use the `update-kubeconfig` AWS CLI command.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "eks:DescribeCluster",
                "eks:ListClusters"
            ],
            "Resource": "*"
        }
    ]
}
```

Using Service-Linked Roles for Amazon EKS

Amazon Elastic Kubernetes Service uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.

Topics
- Using Roles for Amazon EKS (p. 320)
- Using Roles for Amazon EKS node groups (p. 322)

Using Roles for Amazon EKS

Amazon Elastic Kubernetes Service uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.
A service-linked role makes setting up Amazon EKS easier because you don't have to manually add the necessary permissions. Amazon EKS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon EKS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Amazon EKS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have Yes in the Service-Linked Role column. Choose a Yes with a link to view the service-linked role documentation for that service.

**Service-Linked Role Permissions for Amazon EKS**

Amazon EKS uses the service-linked role named **AWSServiceRoleForAmazonEKS** – These permissions are required for Amazon EKS to manage clusters in your account. These policies are related to management of the following resources: network interfaces, security groups, logs, and VPCs.

**Note**

The **AWSServiceRoleForAmazonEKS** service-linked role is distinct from the role required for cluster creation. For more information, see Amazon EKS cluster IAM role (p. 324).

The **AWSServiceRoleForAmazonEKS** service-linked role trusts the following services to assume the role:

- eks.amazonaws.com

The role permissions policy allows Amazon EKS to complete the following actions on the specified resources:

- AmazonEKSServiceRolePolicy

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the IAM User Guide.

**Creating a Service-Linked Role for Amazon EKS**

You don't need to manually create a service-linked role. When you create a cluster in the AWS Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a cluster, Amazon EKS creates the service-linked role for you again.

**Editing a Service-Linked Role for Amazon EKS**

Amazon EKS does not allow you to edit the **AWSServiceRoleForAmazonEKS** service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the IAM User Guide.

**Deleting a Service-Linked Role for Amazon EKS**

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can manually delete it.
Cleaning Up a Service-Linked Role

Before you can use IAM to delete a service-linked role, you must first delete any resources used by the role.

**Note**

If the Amazon EKS service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

**To delete Amazon EKS resources used by the AWSServiceRoleForAmazonEKS**

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose a cluster.
3. On the cluster page, if there are any managed node groups in the **Node Groups** section, select each one individually, and then choose **Delete**.
4. Type the name of the node group in the deletion confirmation window, and then choose **Confirm** to delete.
5. Repeat this procedure for any other node groups in the cluster. Wait for all of the delete operations to finish.
6. On the cluster page choose **Delete**.
7. Repeat this procedure for any other clusters in your account.

**Manually Delete the Service-Linked Role**

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForAmazonEKS service-linked role. For more information, see Deleting a Service-Linked Role in the **IAM User Guide**.

**Supported Regions for Amazon EKS Service-Linked Roles**

Amazon EKS supports using service-linked roles in all of the regions where the service is available. For more information, see Amazon EKS Service Endpoints and Quotas.

**Using Roles for Amazon EKS node groups**

Amazon EKS uses AWS Identity and Access Management (IAM) **service-linked roles**. A service-linked role is a unique type of IAM role that is linked directly to Amazon EKS. Service-linked roles are predefined by Amazon EKS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon EKS easier because you don't have to manually add the necessary permissions. Amazon EKS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon EKS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Amazon EKS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see AWS Services That Work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

**Service-Linked Role Permissions for Amazon EKS**

Amazon EKS uses the service-linked role named **AWSServiceRoleForAmazonEKSNodegroup** – These permissions are required for managing nodegroups in your account. These policies are related to
management of the following resources: Auto Scaling groups, security groups, launch templates and IAM instance profiles.

The AWSServiceRoleForAmazonEKSNodegroup service-linked role trusts the following services to assume the role:

- eks-nodegroup.amazonaws.com

The role permissions policy allows Amazon EKS to complete the following actions on the specified resources:

- AWSServiceRoleForAmazonEKSNodegroup

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the IAM User Guide.

Creating a Service-Linked Role for Amazon EKS

You don't need to manually create a service-linked role. When you CreateNodegroup in the AWS Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.

**Important**

This service-linked role can appear in your account if you completed an action in another service that uses the features supported by this role. If you were using the Amazon EKS service before January 1, 2017, when it began supporting service-linked roles, then Amazon EKS created the AWSServiceRoleForAmazonEKSNodegroup role in your account. To learn more, see A New Role Appeared in My IAM Account.

Creating a Service-Linked Role in Amazon EKS (AWS API)

You don't need to manually create a service-linked role. When you create a managed node group in the AWS Management Console, the AWS CLI, or the AWS API, Amazon EKS creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create another managed node group, Amazon EKS creates the service-linked role for you again.

Editing a Service-Linked Role for Amazon EKS

Amazon EKS does not allow you to edit the AWSServiceRoleForAmazonEKSNodegroup service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the IAM User Guide.

Deleting a Service-Linked Role for Amazon EKS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can manually delete it.

Cleaning Up a Service-Linked Role

Before you can use IAM to delete a service-linked role, you must first delete any resources used by the role.

**Note**

If the Amazon EKS service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.
To delete Amazon EKS resources used by the AWSServiceRoleForAmazonEKSNodegroup

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Choose a cluster.
3. On the cluster page, if there are any managed node groups in the Node Groups section, select each one individually, and then choose Delete.
4. Type the name of the cluster in the deletion confirmation window, and then choose Confirm to delete.
5. Repeat this procedure for any other node groups in the cluster and for any other clusters in your account.

Manually Delete the Service-Linked Role

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForAmazonEKSNodegroup service-linked role. For more information, see Deleting a Service-Linked Role in the IAM User Guide.

Supported Regions for Amazon EKS Service-Linked Roles

Amazon EKS supports using service-linked roles in all of the regions where the service is available. For more information, see Amazon EKS Service Endpoints and Quotas.

Amazon EKS cluster IAM role

Kubernetes clusters managed by Amazon EKS make calls to other AWS services on your behalf to manage the resources that you use with the service. Before you can create Amazon EKS clusters, you must create an IAM role with the following IAM policies:

- AmazonEKSClusterPolicy

Note

Prior to April 16, 2020, AmazonEKSServicePolicy was also required and the suggested name was eksServiceRole. With the AWSServiceRoleForAmazonEKS service-linked role, that policy is no longer required for clusters created on or after April 16, 2020.

Check for an existing cluster role

You can use the following procedure to check and see if your account already has the Amazon EKS cluster role.

To check for the eksClusterRole in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation panel, choose Roles.
3. Search the list of roles for eksClusterRole. If a role that includes eksClusterRole does not exist, then see Creating the Amazon EKS cluster role (p. 325) to create the role. If a role that includes eksClusterRole does exist, then select the role to view the attached policies.
4. Choose Permissions.
5. Ensure that the AmazonEKSClusterPolicy managed policy is attached to the role. If the policy is attached, your Amazon EKS cluster role is properly configured.
7. Verify that the trust relationship contains the following policy. If the trust relationship matches the policy below, choose Cancel. If the trust relationship does not match, copy the policy into the Policy Document window and choose Update Trust Policy.
Creating the Amazon EKS cluster role

You can use the AWS Management Console (p. 325) or AWS CloudFormation (p. 325) to create the cluster role if you do not already have one for your account.

To create your Amazon EKS cluster role in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Roles, then Create role.
3. Choose EKS from the list of services, then EKS - Cluster for your use case, and then Next: Permissions.
4. Choose Next: Tags.
5. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM Entities in the IAM User Guide.
6. Choose Next: Review.
7. For Role name, enter a unique name for your role, such as eksClusterRole, then choose Create role.

To create your Amazon EKS cluster role with AWS CloudFormation

1. Save the following AWS CloudFormation template to a text file on your local system.

```yaml
---
AWSTemplateFormatVersion: '2010-09-09'
Description: 'Amazon EKS Cluster Role'

Resources:

  eksClusterRole:
    Type: AWS::IAM::Role
    Properties:
      AssumeRolePolicyDocument:
        Version: '2012-10-17'
        Statement:
          - Effect: Allow
            Principal:
              Service:
                - eks.amazonaws.com
            Action:
              - sts:AssumeRole
            ManagedPolicyArns:
              - arn:aws:iam::aws:policy/AmazonEKSClusterPolicy
```

325
Amazon EKS node IAM role

The Amazon EKS node `kubelet` daemon makes calls to AWS APIs on your behalf. Nodes receive permissions for these API calls through an IAM instance profile and associated policies. Before you can launch nodes and register them into a cluster, you must create an IAM role for those nodes to use when they are launched. This requirement applies to nodes launched with the Amazon EKS optimized AMI provided by Amazon, or with any other node AMIs that you intend to use. Before you create nodes, you must create an IAM role with the following IAM policies:

- `AmazonEKSWorkerNodePolicy`
- `AmazonEC2ContainerRegistryReadOnly`

Check for an existing node role

You can use the following procedure to check and see if your account already has the Amazon EKS node role.

**To check for the `NodeInstanceRole` in the IAM console**

2. In the navigation panel, choose Roles.
3. Search the list of roles for `NodeInstanceRole`. If a role that contains `NodeInstanceRole` does not exist, then see Creating the Amazon EKS node IAM role (p. 327) to create the role. If a role that contains `NodeInstanceRole` does exist, then select the role to view the attached policies.
4. Choose Permissions.
5. Ensure that the `AmazonEKSWorkerNodePolicy` and `AmazonEC2ContainerRegistryReadOnly` managed policies are attached to the role. If the policies are attached, your Amazon EKS node role is properly configured.

### Amazon EKS User Guide

**Node IAM role**

Outputs:

<table>
<thead>
<tr>
<th>RoleArn:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description: The role that Amazon EKS will use to create AWS resources for Kubernetes clusters</td>
</tr>
<tr>
<td>Value: !GetAtt eksClusterRole.Arn</td>
</tr>
<tr>
<td>Export:</td>
</tr>
<tr>
<td>Name: !Sub &quot;#{AWS::StackName}-RoleArn&quot;</td>
</tr>
</tbody>
</table>

**Note**

Prior to April 16, 2020, `ManagedPolicyArns` had an entry for `arn:aws:iam::aws:policy/AmazonEKSServicePolicy`. With the `AWSServiceRoleForAmazonEKS` service-linked role, that policy is no longer required.

3. Choose **Create stack**.
4. For **Specify template**, select **Upload a template file**, and then choose **Choose file**.
5. Choose the file you created earlier, and then choose **Next**.
6. For **Stack name**, enter a name for your role, such as `eksClusterRole`, and then choose **Next**.
7. On the **Configure stack options** page, choose **Next**.
8. On the **Review** page, review your information, acknowledge that the stack might create IAM resources, and then choose **Create stack**.
Node IAM role

**Note**

If the AmazonEKS_CNI_Policy policy is attached to the role, we recommend removing it and attaching it to an IAM role that is mapped to the aws-node Kubernetes service account instead. For more information, see the section called “Configure plugin for IAM account” (p. 211).

7. Verify that the trust relationship contains the following policy. If the trust relationship matches the policy below, choose Cancel. If the trust relationship does not match, copy the policy into the Policy Document window and choose Update Trust Policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "ec2.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Creating the Amazon EKS node IAM role

If you created your nodes by following the steps in the Getting started with the AWS Management Console (p. 15) or Getting started with eksctl (p. 4) topics, then the node role already exists and you don't need to manually create it. You can use the AWS Management Console or AWS CloudFormation to create the Amazon EKS node role if you do not already have one for your account. You can create the node role with the AWS Management Console (p. 327) or AWS CloudFormation (p. 328).

To create your Amazon EKS node role in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Roles, then Create role.
3. Choose EC2 from the list of Common use cases under Choose a use case, then choose Next: Permissions.
4. In the Filter policies box, enter AmazonEKSWorkerNodePolicy. Check the box to the left of AmazonEKSWorkerNodePolicy.
5. In the Filter policies box, enter AmazonEC2ContainerRegistryReadOnly. Check the box to the left of AmazonEC2ContainerRegistryReadOnly.
6. The AmazonEKS_CNI_Policy policy must be attached to either this role or to a different role that is mapped to the aws-node Kubernetes service account. We recommend assigning the policy to the role associated to the Kubernetes service account instead of assigning it to this role. For more information, see Configuring the VPC CNI plugin to use IAM roles for service accounts (p. 211).
7. Choose Next: Tags.
8. (Optional) Add metadata to the role by attaching tags as key-value pairs. For more information about using tags in IAM, see Tagging IAM Entities in the IAM User Guide.
9. Choose Next: Review.
10. For Role name, enter a unique name for your role, such as NodeInstanceRole. For Role description, replace the current text with descriptive text such as Amazon EKS - Node Group Role, then choose Create role.
To create your Amazon EKS node role using AWS CloudFormation

2. Choose Create stack and then choose With new resources (standard).
3. For Specify template, select Amazon S3 URL.
4. Paste the URL that corresponds to the Region that your cluster is in into the Amazon S3 URL text area and choose Next twice:
   - All Regions other than China Regions.
   - Beijing and Ningxia China Regions.

5. On the Specify stack details page, for Stack name enter a name such as eks-node-group-instance-role and choose Next.
6. (Optional) On the Configure stack options page, you can choose to tag your stack resources. Choose Next.
7. On the Review page, check the box in the Capabilities section and choose Create stack.
8. When your stack is created, select it in the console and choose Outputs.
9. Record the NodeInstanceRole value for the IAM role that was created. You need this when you create your node group.
10. (Optional, but recommended) One of the IAM policies attached to the role by the AWS CloudFormation template in a previous step is the AmazonEKS_CNI_Policy managed policy. The policy must be attached to this role or to a role associated to the Kubernetes aws-node service account that is used for the Amazon EKS VPC CNI plugin. We recommend assigning the policy to the role associated to the Kubernetes service account. For more information, see Configuring the VPC CNI plugin to use IAM roles for service accounts (p. 211).

Pod execution role

The Amazon EKS pod execution role is required to run pods on AWS Fargate infrastructure.

When your cluster creates pods on AWS Fargate infrastructure, the components running on the Fargate infrastructure need to make calls to AWS APIs on your behalf to do things like pull container images from Amazon ECR or route logs to other AWS services. The Amazon EKS pod execution role provides the IAM permissions to do this.

When you create a Fargate profile, you must specify a pod execution role for the Amazon EKS components that run on the Fargate infrastructure using the profile. This role is added to the cluster's Kubernetes Role based access control (RBAC) for authorization, so that the kubelet that is running on the Fargate infrastructure can register with your Amazon EKS cluster. This is what allows Fargate infrastructure to appear in your cluster as nodes.

The containers running in the Fargate pod cannot assume the IAM permissions associated with the pod execution role. To give the containers in your Fargate pod permissions to access other AWS services, you must use the section called “IAM roles for service accounts” (p. 330).

Before you create a Fargate profile, you must create an IAM role with the following IAM policy:
• AmazonEKSFargatePodExecutionRolePolicy

Check for an existing pod execution role

You can use the following procedure to check and see if your account already has the Amazon EKS pod execution role.

To check for the AmazonEKSFargatePodExecutionRole in the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation panel, choose Roles.
3. Search the list of roles for AmazonEKSFargatePodExecutionRole. If the role does not exist, see Creating the Amazon EKS pod execution role (p. 329) to create the role. If the role does exist, select the role to view the attached policies.
4. Choose Permissions.
5. Ensure that the AmazonEKSFargatePodExecutionRolePolicy Amazon managed policy is attached to the role. If the policy is attached, then your Amazon EKS pod execution role is properly configured.
7. Verify that the trust relationship contains the following policy. If the trust relationship matches the policy below, choose Cancel. If the trust relationship does not match, copy the policy into the Policy Document window and choose Update Trust Policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "eks-fargate-pods.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Creating the Amazon EKS pod execution role

You can use the following procedure to create the Amazon EKS pod execution role if you do not already have one for your account.

To create an AWS Fargate pod execution role with the AWS Management Console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Roles, then Create role.
3. Choose EKS from the list of services, EKS - Fargate pod for your use case, and then Next: Permissions.
4. Choose Next: Tags.
5. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM Entities in the IAM User Guide.
6. Choose Next: Review.
7. For Role name, enter a unique name for your role, such as AmazonEKSFargatePodExecutionRole, then choose Create role.
IAM roles for service accounts

You can associate an IAM role with a Kubernetes service account. This service account can then provide AWS permissions to the containers in any pod that uses that service account. With this feature, you no longer need to provide extended permissions to the pods on that node can call AWS APIs.

Applications must sign their AWS API requests with AWS credentials. This feature provides a strategy for managing credentials for your applications, similar to the way that Amazon EC2 instance profiles provide credentials to Amazon EC2 instances. Instead of creating and distributing your AWS credentials to the containers or using the Amazon EC2 instance's role, you can associate an IAM role with a Kubernetes service account. The applications in the pod's containers can then use an AWS SDK or the AWS CLI to make API requests to authorized AWS services.

**Important**
Even if you assign an IAM role to a Kubernetes service account, the pod still also has the permissions assigned to the node IAM role (p. 326), unless you block pod access to the IMDS. For more information, see the section called “Restricting access to the instance profile” (p. 349).

The IAM roles for service accounts feature provides the following benefits:

- **Least privilege** — By using the IAM roles for service accounts feature, you no longer need to provide extended permissions to the node IAM role so that pods on that node can call AWS APIs. You can scope IAM permissions to a service account, and only pods that use that service account have access to those permissions. This feature also eliminates the need for third-party solutions such as kiam or kube2iam.

- **Credential isolation** — A container can only retrieve credentials for the IAM role that is associated with the service account to which it belongs. A container never has access to credentials that are intended for another container that belongs to another pod.

- **Auditability** — Access and event logging is available through CloudTrail to help ensure retrospective auditing.

Enable service accounts to access AWS resources in three steps

1. **Create an IAM OIDC provider for your cluster (p. 334)** – You only need to do this once for a cluster.
2. **Create an IAM role and attach an IAM policy to it with the permissions that your service accounts need (p. 335)** – We recommend creating separate roles for each unique collection of permissions that pods need.
3. **Associate an IAM role with a service account (p. 339)** – Complete this task for each Kubernetes service account that needs access to AWS resources.

Technical overview

In 2014, AWS Identity and Access Management added support for federated identities using OpenID Connect (OIDC). This feature allows you to authenticate AWS API calls with supported identity providers and receive a valid OIDC JSON web token (JWT). You can pass this token to the AWS STS AssumeRoleWithWebIdentity API operation and receive IAM temporary role credentials. You can use these credentials to interact with any AWS service, like Amazon S3 and DynamoDB.

Kubernetes has long used service accounts as its own internal identity system. Pods can authenticate with the Kubernetes API server using an auto-mounted token (which was a non-OIDC JWT) that only the Kubernetes API server could validate. These legacy service account tokens do not expire, and rotating the signing key is a difficult process. In Kubernetes version 1.12, support was added for a newProjectedServiceAccountToken feature, which is an OIDC JSON web token that also contains the service account identity, and supports a configurable audience.
Amazon EKS now hosts a public OIDC discovery endpoint per cluster containing the signing keys for the ProjectedServiceAccountToken JSON web tokens so external systems, like IAM, can validate and accept the OIDC tokens issued by Kubernetes.

IAM role configuration

In IAM, you create an IAM role with a trust relationship that is scoped to your cluster's OIDC provider, the service account namespace, and (optionally) the service account name, and then attach the IAM policy that you want to associate with the service account. You can add multiple entries in the StringEquals and StringLike conditions below to use multiple service accounts or namespaces with the role.

- To scope a role to a specific service account:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Federated": "arn:aws:iam::<AWS_ACCOUNT_ID>:oidc-provider/<OIDC_PROVIDER>",
            "Action": "sts:AssumeRoleWithWebIdentity",
            "Condition": {
               "StringEquals": {
                  "<OIDC_PROVIDER>:sub": "system:serviceaccount:<SERVICE_ACCOUNT_NAMESPACE>:<SERVICE_ACCOUNT_NAME>
               }
            }
         }
      }
   ]
}
```

- To scope a role to an entire namespace (to use the namespace as a boundary):

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Federated": "arn:aws:iam::<AWS_ACCOUNT_ID>:oidc-provider/<OIDC_PROVIDER>",
            "Action": "sts:AssumeRoleWithWebIdentity",
            "Condition": {
               "StringLike": {
                  "<OIDC_PROVIDER>:sub": "system:serviceaccount:<SERVICE_ACCOUNT_NAMESPACE>:*
               }
            }
         }
      }
   ]
}
```

Service account configuration

In Kubernetes, you define the IAM role to associate with a service account in your cluster by adding the eks.amazonaws.com/role-arn annotation to the service account.

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  annotations:
```

331
Pod configuration

The Amazon EKS Pod Identity Webhook on the cluster watches for pods that are associated with service accounts with this annotation and applies the following environment variables to them.

AWS_ROLE_ARN=arn:aws:iam::<AWS_ACCOUNT_ID>:role/<IAM_ROLE_NAME>
AWS_WEB_IDENTITY_TOKEN_FILE=/var/run/secrets/eks.amazonaws.com/serviceaccount/token

Note
Your cluster does not need to use the mutating web hook to configure the environment variables and token file mounts; you can choose to configure pods to add these environment variables manually.

Important
If your Amazon EKS cluster is running Kubernetes version 1.17 or earlier, you need to add the following environment variable to all pods that use IAM roles for service accounts in China Regions, whether you use the mutating web hook or configure the environment variables manually.

AWS_DEFAULT_REGION=<region-code>

Supported versions of the AWS SDK (p. 340) look for these environment variables first in the credential chain provider. The role credentials are used for pods that meet this criteria.

Note
When a pod uses AWS credentials from an IAM role associated with a service account, the AWS CLI or other SDKs in the containers for that pod use the credentials provided by that role. The pod still has access to the credentials provided to the the section called "Node IAM role" (p. 326) too, unless you restrict access to those credentials. For more information, see the section called "Restricting access to the instance profile" (p. 349).

By default, only containers that run as root have the proper file system permissions to read the web identity token file. You can provide these permissions by having your containers run as root, or by providing the following security context for the containers in your manifest. The fsGroup ID is arbitrary, and you can choose any valid group ID. For more information about the implications of setting a security context for your pods, see Configure a Security Context for a Pod or Container in the Kubernetes documentation.

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: <my-app>
spec:
template:
  metadata:
    labels:
      app: <my-app>
spec:
  serviceAccountName: <my-app>
containers:
  - name: <my-app>
    image: <my-app>:latest
    securityContext:
      fsGroup: <1337>
...
```

The kubelet requests and stores the token on behalf of the pod. By default, the kubelet refreshes the token if it is older than 80 percent of its total TTL, or if the token is older than 24 hours. You can
modify the expiration duration for any account, except the default service account, with settings in your pod spec. For more information, see Service Account Token Volume Projection in the Kubernetes documentation.

**Cross-account IAM permissions**

You can configure cross-account IAM permissions either by creating an identity provider from another account's cluster or by using chained AssumeRole operations. In the following examples, Account A owns an Amazon EKS cluster that supports IAM roles for service accounts. Pods running on that cluster need to assume IAM permissions from Account B.

**Example : Create an identity provider from another account's cluster**

**Example**

In this example, Account A would provide Account B with the OIDC issuer URL from their cluster. Account B follows the instructions in Create an IAM OIDC provider for your cluster (p. 334) and Creating an IAM role and policy for your service account (p. 335) using the OIDC issuer URL from Account A's cluster. Then a cluster administrator annotates the service account in Account A's cluster to use the role from Account B.

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  annotations:
    eks.amazonaws.com/role-arn: arn:aws:iam::<ACCOUNT_B_AWS_ACCOUNT_ID>:role/<IAM_ROLE_NAME>
```

**Example : Use chained AssumeRole operations**

**Example**

In this example, Account B creates an IAM policy with the permissions to give to pods in Account A's cluster. Account B attaches that policy to an IAM role with a trust relationship that allows AssumeRole permissions to Account A (111111111111), as shown below.

```json
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::111111111111:root"
        },
        "Action": "sts:AssumeRole",
        "Condition": {}
    }
    ]
}
```

Account A creates a role with a trust policy that gets credentials from the identity provider created with the cluster's OIDC issuer URL, as shown below.

```json
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "Federated": "arn:aws:iam::111111111111:oidc-provider/oidc.eks.<region-code>.amazonaws.com/id/EXAMPLEEC061A78C479E31025A21AC4CDE191335D05820BE5CE"
        }
    }
    ]
}
```
Account A attaches a policy to that role with the following permissions to assume the role that Account B created.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Resource": "arn:aws:iam::222222222222:role/account-b-role"
    }
  ]
}
```

The application code for pods to assume Account B's role uses two profiles: `account_b_role` and `account_a_role`. The `account_b_role` profile uses the `account_a_role` profile as its source. For the AWS CLI, the `~/.aws/config` file would look like the following example.

```
[profile account_b_role]
source_profile = account_a_role
role_arn=arn:aws:iam::222222222222:role/account-b-role

[profile account_a_role]
web_identity_token_file = /var/run/secrets/eks.amazonaws.com/serviceaccount/token
role_arn=arn:aws:iam::111111111111:role/account-a-role
```

To specify chained profiles for other AWS SDKs, consult their documentation.

## Create an IAM OIDC provider for your cluster

Your cluster has an OpenID Connect issuer URL associated with it. To use IAM roles for service accounts, an IAM OIDC provider must exist for your cluster.

### Prerequisites

An existing cluster. If you don’t have one, you can create one using one of the Getting started with Amazon EKS (p. 4) guides.

### To create an IAM OIDC identity provider for your cluster with `eksctl`

1. Determine whether you have an existing IAM OIDC provider for your cluster.

   View your cluster’s OIDC provider URL.

   ```
   aws eks describe-cluster --name <cluster_name> --query "cluster.identity.oidc.issuer" --output text
   ```

   Example output:

   ```
   https://oidc.eks.us-west-2.amazonaws.com/id/EXAMPLED539D4633E53DE1B716D3041E
   ```

   List the IAM OIDC providers in your account. Replace `<EXAMPLED539D4633E53DE1B716D3041E>` (including `< >`) with the value returned from the previous command.
aws iam list-open-id-connect-providers | grep <EXAMPLED539D4633E53DE1B716D3041E>

Example output

If output is returned from the previous command, then you already have a provider for your cluster. If no output is returned, then you must create an IAM OIDC provider.

2. Create an IAM OIDC identity provider for your cluster with the following command. Replace `<cluster_name>` (including `<`) with your own value.

    eksctl utils associate-iam-oidc-provider --cluster <cluster_name> --approve

To create an IAM OIDC identity provider for your cluster with the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Select the name of your cluster and then select the Configuration tab.
3. In the Details section, note the value of the OpenID Connect provider URL.
5. In the navigation panel, choose Identity Providers. If a Provider is listed that matches the URL for your cluster, then you already have a provider for your cluster. If a provider isn't listed that matches the URL for your cluster, then you must create one.
6. To create a provider, choose Add Provider.
7. For Provider Type, choose OpenID Connect.
8. For Provider URL, paste the OIDC issuer URL for your cluster, and then choose Get thumbprint.
9. For Audience, enter sts.amazonaws.com and choose Add provider.

Creating an IAM role and policy for your service account

You must create an IAM policy that specifies the permissions that you would like the containers in your pods to have. You have several ways to create a new IAM permission policy. One way is to copy a complete AWS managed policy that already does some of what you're looking for and then customize it to your specific requirements. For more information, see Creating a New Policy in the IAM User Guide.

You must also create an IAM role for your Kubernetes service accounts to use before you associate it with a service account. The trust relationship is scoped to your cluster and service account so that each cluster and service account combination requires its own role. You can then attach a specific IAM policy to the role that gives the containers in your pods the permissions you desire. The following procedures describe how to do this.

Create an IAM policy

In this procedure, we offer two example policies that you can use for your application:

- A policy to allow read-only access to an Amazon S3 bucket. You could store configuration information or a bootstrap script in this bucket, and the containers in your pod can read the file from the bucket and load it into your application.
- A policy to allow paid container images from AWS Marketplace.
1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation panel, choose Policies and then choose Create policy.
3. Choose the JSON tab.
4. In the Policy Document field, paste one of the following policies to apply to your service accounts, or paste your own policy document into the field. You can also use the visual editor to construct your own policy.

The example below allows permission to the <my-pod-secrets-bucket> Amazon S3 bucket. You can modify the policy document to suit your specific needs.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": [
        "arn:aws:s3:::<my-pod-secrets-bucket>/*"
      ]
    }
  ]
}
```

The example below gives the required permissions to use a paid container image from AWS Marketplace.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "aws-marketplace:RegisterUsage"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

5. Choose Review policy.
6. Enter a name and description for your policy and then choose Create policy.
7. Record the Amazon Resource Name (ARN) of the policy to use later when you create your role.

Create an IAM role for a service account

Create an IAM role for your service account. You can use eksctl (p. 337), the AWS Management Console (p. 337), or the AWS CLI (p. 338) to create the role.

Prerequisites

- An existing cluster. If you don’t have one, you can create one using one of the Getting started with Amazon EKS (p. 4) guides.
- If using the AWS Management Console or AWS CLI to create the role, then you must have an existing IAM OIDC provider for your cluster. For more information, see Create an IAM OIDC provider for your cluster (p. 334).
IAM roles for service accounts

- An existing IAM policy that includes the permissions for the AWS resources that your service account needs access to. For more information, see Create an IAM policy (p. 335).

To create your IAM role with eksctl

Create the service account and IAM role with the following command. Replace the <example values> (including <> ) with your own values.

**Note**
This command only works for clusters that were created with eksctl. If you didn’t create your cluster with eksctl, then use the instructions on the AWS Management Console or AWS CLI tabs.

```
eksctl create iamserviceaccount \
  --name <service_account_name> \
  --namespace <service_account_namespace> \
  --cluster <cluster_name> \
  --attach-policy-arn <IAM_policy_ARN> \
  --approve \
  --override-existing-serviceaccounts
```

An AWS CloudFormation template is deployed that creates an IAM role and attaches the IAM policy to it. The role is associated with a Kubernetes service account. If your cluster didn’t have an existing IAM OIDC provider, one was created. If the service account doesn’t exist, it is created in the namespace that you provided. If the service account does exist, then it is annotated with eks.amazonaws.com/role-arn:
arn:aws:iam::<your-account-id>:role/<iam-role-name-that-was-created>.

To create your IAM role with the AWS Management Console

1. Open the Amazon EKS console at https://console.aws.amazon.com/eks/home#/clusters.
2. Select the name of your cluster and then select the Configuration tab.
3. In the Details section, note the value of the OpenID Connect provider URL.
5. In the navigation panel, choose Roles, Create Role.
6. In the Select type of trusted entity section, choose Web identity.
7. In the Choose a web identity provider section:
   1. For Identity provider, choose the URL for your cluster.
   2. For Audience, choose sts.amazonaws.com.
8. Choose Next: Permissions.
9. In the Attach Policy section, select the IAM policy that has the permissions that you want your service account to use.
10. Choose Next: Tags.
11. On the Add tags (optional) screen, you can add tags for the account. Choose Next: Review.
12. For Role Name, enter a name for your role and then choose Create Role.
13. After the role is created, choose the role in the console to open it for editing.
14. Choose the Trust relationships tab, and then choose Edit trust relationship.
15. Change the line that looks similar to the following:

   "oidc.eks.us-west-2.amazonaws.com/id/EXAMPLED539D4633E53DE1B716D3041E:aud": "sts.amazonaws.com"
To look like the following, changing the `<example values>` (including `<>`) to your own:

```
"oidc.eks.<region-code>.amazonaws.com/id/<EXAMPLED539D4633E53DE1B716D3041E>:sub": "system:serviceaccount:<SERVICE_ACCOUNT_NAMESPACE>:<SERVICE_ACCOUNT_NAME>"
```

**Note**
If you don’t have an existing service account, then you need to create one. For more information, see Configure Service Accounts for Pods in the Kubernetes documentation. For the service account to be able to use Kubernetes permissions, you must create a Role, or ClusterRole and then bind the role to the service account. For more information, see Using RBAC Authorization in the Kubernetes documentation. When the AWS VPC CNI plugin (p. 209) is deployed, for example, the deployment manifest creates a service account, cluster role, and cluster role binding. You can view the manifest on GitHub.

16. Choose **Update Trust Policy** to finish.

**To create your IAM role with the AWS CLI**

1. Set your AWS account ID to an environment variable with the following command.

   ```bash
   AWS_ACCOUNT_ID=$(aws sts get-caller-identity --query "Account" --output text)
   ```

2. Set your OIDC identity provider to an environment variable with the following command. Replace the `<example values>` (including `<>`) with your own values.

   **Important**
   You must use at least version 1.18.190 or 2.1.7 of the AWS CLI to receive the proper output from this command. For more information, see Installing the AWS CLI in the AWS Command Line Interface User Guide.

   ```bash
   OIDC_PROVIDER=$(aws eks describe-cluster --name <cluster-name> --query "cluster.identity.oidc.issuer" --output text | sed -e "s/^https:////")
   ```

3. Copy the following code block to your computer and replace the `<example values>` with your own values.

   ```bash
   read -r -d '' TRUST_RELATIONSHIP <<EOF
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Principal": {
   "Federated": "arn:aws:iam::${AWS_ACCOUNT_ID}:oidc-provider/${OIDC_PROVIDER}"
   },
   "Action": "sts:AssumeRoleWithWebIdentity",
   "Condition": {
   "StringEquals": {
   "${OIDC_PROVIDER}:sub": "system:serviceaccount:<my-namespace>:<my-service-account>"
   }
   }
   }
   ]
   }
   EOF
   echo "${TRUST_RELATIONSHIP}" > trust.json
   ```

4. Run the modified code block from the previous step to create a file named `trust.json`.

   ```bash
   338
   ```
5. Run the following AWS CLI command to create the role.

```
aws iam create-role --role-name <IAM_ROLE_NAME> --assume-role-policy-document file://trust.json --description "<IAM_ROLE_DESCRIPTION>"
```

6. Run the following command to attach your IAM policy to your role.

```
aws iam attach-role-policy --role-name <IAM_ROLE_NAME> --policy-arn=<IAM_POLICY_ARN>
```

### Associate an IAM role to a service account

In Kubernetes, you define the IAM role to associate with a service account in your cluster by adding the following annotation to the service account.

**Note**
If you created an IAM role to use with your service account using eksctl, this has already been done for you with the service account that you specified when creating the role.

```yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  annotations:
    eks.amazonaws.com/role-arn: arn:aws:iam::<AWS_ACCOUNT_ID>:role/<IAM_ROLE_NAME>
```

### Prerequisites

- An existing cluster. If you don't have one, you can create one using one of the Getting started with Amazon EKS (p. 4) guides.
- An existing IAM OIDC provider for your cluster. For more information, see Create an IAM OIDC provider for your cluster (p. 334).
- An existing service account. If you don't have one, see Configure Service Accounts for Pods in the Kubernetes documentation.
- An existing IAM role with an attached IAM policy. If you don't have one, see Creating an IAM role and policy for your service account (p. 335).

### To annotate a service account with an IAM role

1. Use the following command to annotate your service account with the ARN of the IAM role that you want to use with your service account. Be sure to replace the `<example values>` (including `<>`) with your own.

```
kubectl annotate serviceaccount -n <SERVICE_ACCOUNT_NAMESPACE> <SERVICE_ACCOUNT_NAME> \
ekms.amazonaws.com/role-arn=arn:aws:iam::<AWS_ACCOUNT_ID>:role/<IAM_ROLE_NAME>
```

**Note**
If you don't have an existing service account, then you need to create one. For more information, see Configure Service Accounts for Pods in the Kubernetes documentation. For the service account to be able to use Kubernetes permissions, you must create a Role, or ClusterRole and then bind the role to the service account. For more information, see Using RBAC Authorization in the Kubernetes documentation. When the AWS VPC CNI plugin (p. 209) is deployed, for example, the deployment manifest creates a service account, cluster role, and cluster role binding. You can view the manifest on GitHub to use as an example.
2. Delete and re-create any existing pods that are associated with the service account to apply the credential environment variables. The mutating web hook does not apply them to pods that are already running. The following command deletes the existing the `aws-node` DaemonSet pods and deploys them with the service account annotation. You can modify the namespace, deployment type, and label to update your specific pods.

```
kubectl delete pods -n <kube-system> -l <k8s-app=aws-node>
```

3. Confirm that the pods all restarted.

```
kubectl get pods -n <kube-system> -l <k8s-app=aws-node>
```

4. Describe one of the pods and verify that the `AWS_WEB_IDENTITY_TOKEN_FILE` and `AWS_ROLE_ARN` environment variables exist.

```
kubectl exec -n kube-system aws-node-<9rgzw> env | grep AWS
```

Output:

```
AWS_VPC_K8S_CNI_LOGLEVEL=DEBUG
AWS_ROLE_ARN=arn:aws:iam::<AWS_ACCOUNT_ID>:role/<IAM_ROLE_NAME>
AWS_WEB_IDENTITY_TOKEN_FILE=/var/run/secrets/eks.amazonaws.com/serviceaccount/token
```

### Using a supported AWS SDK

The containers in your pods must use an AWS SDK version that supports assuming an IAM role via an OIDC web identity token file. AWS SDKs that are included in Linux distribution package managers may not be new enough to support this feature. Be sure to use at least the minimum SDK versions listed below:

- Java (Version 2) — 2.10.11
- Java — 1.11.704
- Go — 1.23.13
- Python (Boto3) — 1.23.13
- Python (botocore) — 1.22.200
- AWS CLI — 1.16.232
- Node — 2.521.0
- Ruby — 2.11.345
- C++ — 1.7.174
- .NET — 3.3.659.1
- PHP — 3.110.7

Many popular Kubernetes add-ons, such as the Cluster Autoscaler and the

The AWS Load Balancer Controller manages AWS Elastic Load Balancers for a Kubernetes cluster. The controller provisions:

- An AWS Application Load Balancer (ALB) when you create a Kubernetes Ingress.
- An AWS Network Load Balancer (NLB) when you create a Kubernetes Service of type `LoadBalancer` using IP targets on 1.18 or later Amazon EKS clusters. If you’re load balancing network traffic to instance targets, then you use the in-tree Kubernetes load balancer.
balancer controller and don’t need to install this controller. For more information about NLB target types, see Target type in the User Guide for Network Load Balancers.

The controller was formerly named the AWS ALB Ingress Controller. It is an open source project managed on GitHub. This topic helps you install the controller using default options. You can view the full documentation for the controller on GitHub. Before deploying the controller we recommend that you review the prequisites and considerations in the section called “Application load balancing” (p. 265) and the section called “Network load balancing” (p. 261). Those topics also include steps to deploy a sample application that require the controller to provision AWS resources.

Prerequisite

An existing cluster. If you don’t have an existing cluster, see Getting started with Amazon EKS (p. 4).

To deploy the AWS Load Balancer Controller to an Amazon EKS cluster

In the following steps, replace the <example values> (including <> ) with your own values.

1. Determine whether you have an existing IAM OIDC provider for your cluster. View your cluster’s OIDC provider URL.

   ```bash
   aws eks describe-cluster --name <cluster_name> --query "cluster.identity.oidc.issuer" --output text
   ```

   Example output:
   ```
   https://oidc.eks.us-west-2.amazonaws.com/id/EXAMPLED539D4633E53DE1B716D3041E
   ```

   List the IAM OIDC providers in your account. Replace <EXAMPLED539D4633E53DE1B716D3041E> (including <> ) with the value returned from the previous command.

   ```bash
   aws iam list-open-id-connect-providers | grep <EXAMPLED539D4633E53DE1B716D3041E>
   ```

   Example output
   ```
   ```

   If output is returned from the previous command, then you already have a provider for your cluster. If no output is returned, then you must create an IAM OIDC provider. To create an IAM OIDC provider, see Create an IAM OIDC provider for your cluster (p. 334).

2. Download an IAM policy for the AWS Load Balancer Controller that allows it to make calls to AWS APIs on your behalf. You can view the policy document on GitHub. Use the command that corresponds to the Region that your cluster is in.

   - All Regions other than China Regions.
3. Create an IAM policy using the policy downloaded in the previous step. Change `iam_policy.json` to `iam_policy_cn.json` in the following command, if you downloaded that file instead.

```bash
aws iam create-policy \
  --policy-name <AWSLoadBalancerControllerIAMPolicy> \
  --policy-document file://iam_policy.json
```

Take note of the policy ARN that is returned.

4. Create an IAM role and annotate the Kubernetes service account named `aws-load-balancer-controller` in the `kube-system` namespace for the AWS Load Balancer Controller using one of the following options.

**Using eksctl**

Use the following command:

```bash
eksctl create iamserviceaccount \
  --cluster=<my-cluster> \
  --namespace=kube-system \
  --name=aws-load-balancer-controller \
  --attach-policy-arn=arn:aws:iam::<AWS_ACCOUNT_ID>:policy/<AWSLoadBalancerControllerIAMPolicy> \
  --override-existing-serviceaccounts \
  --approve
```

**Using the AWS Management Console and kubectl**

b. In the navigation panel, choose Roles, Create Role.
c. In the Select type of trusted entity section, choose Web identity.
d. In the Choose a web identity provider section:
   i. For Identity provider, choose the URL for your cluster.
   ii. For Audience, choose sts.amazonaws.com.
e. Choose Next: Permissions.
f. In the Attach Policy section, select the AWSLoadBalancerControllerIAMPolicy policy that you created in step 3 to use for your service account.
g. Choose Next: Tags.
h. On the Add tags (optional) screen, you can add tags for the account. Choose Next: Review.
   i. For Role Name, enter a name for your role, such as AmazonEKSLoadBalancerControllerRole, and then choose Create Role.
   j. After the role is created, choose the role in the console to open it for editing.
   k. Choose the Trust relationships tab, and then choose Edit trust relationship.
l. Change the line that looks similar to the following:
IAM roles for service accounts

To look like the following, changing the <example values> (including <> to your own:

```
"oidc.eks.<region-code>.amazonaws.com/id/<EXAMPLED539D4633E53DE1B716D3041E>:sub": "system:serviceaccount:kube-system:aws-load-balancer-controller"
```

m. Choose Update Trust Policy to finish.

n. Note the ARN of the role for use in a later step.

o. Save the following contents to a file named `aws-load-balancer-controller-service-account.yaml`

```
apiVersion: v1
kind: ServiceAccount
metadata:
  labels:
    app.kubernetes.io/component: controller
    app.kubernetes.io/name: aws-load-balancer-controller
  annotations:
    eks.amazonaws.com/role-arn: arn:aws:iam::<AWS_ACCOUNT_ID>:role/<AWSLOADBALANCECONTROLLERROLE>
```

p. Create the service account on your cluster.

```
kubectl apply -f aws-load-balancer-controller-service-account.yaml
```

5. If you currently have the AWS ALB Ingress Controller for Kubernetes installed, uninstall it. The AWS Load Balancer Controller replaces the functionality of the AWS ALB Ingress Controller for Kubernetes.

a. Check to see if the controller is currently installed.

```
kubectl get deployment -n kube-system alb-ingress-controller
```

**Output (if it is installed). Skip to step 5b.**

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>alb-ingress-controller</td>
<td>1/1</td>
<td>1</td>
<td>122d</td>
</tr>
</tbody>
</table>

**Output (if it isn't installed). If it isn't installed, skip to step 6.**

Error from server (NotFound): deployments.apps "alb-ingress-controller" not found

b. If the controller is installed, enter the following commands to remove it.

```
kubectl delete -f https://raw.githubusercontent.com/kubernetes-sigs/aws-alb-ingress-controller/v1.1.8/docs/examples/rbac-role.yaml
```
c. If you removed the AWS ALB Ingress Controller for Kubernetes, add the following IAM policy to the IAM role created in step 4. The policy allows the AWS Load Balancer Controller access to the resources that were created by the ALB Ingress Controller for Kubernetes.

1. Download the IAM policy. You can also view the policy.

```
curl -o iam_policy_v1_to_v2_additional.json https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.1.0/docs/install/iam_policy_v1_to_v2_additional.json
```

2. Create the IAM policy and note the ARN returned.

```
aws iam create-policy
   --policy-name <AWSLoadBalancerControllerAdditionalIAMPolicy>
   --policy-document file://iam_policy_v1_to_v2_additional.json
```

3. Attach the IAM policy to the IAM role that you created in step 4. Replace `<your-role-name>` (including <> with the name of the role. If you created the role using eksctl, then to find the role name that was created, open the AWS CloudFormation console and select the eksctl-<your-cluster-name>-addon-iamserviceaccount-kube-system-aws-load-balancer-controller stack. Select the Resources tab. The role name is in the Physical ID column. If you used the AWS Management Console to create the role, then the role name is whatever you named it, such as AmazonEKSLoadBalancerControllerRole.

```
aws iam attach-role-policy
   --role-name eksctl-<your-role-name>
   --policy-arn arn:aws:iam::111122223333:policy/AWSLoadBalancerControllerAdditionalIAMPolicy
```

6. Install the AWS Load Balancer Controller using one of the following methods:
   - With Helm
     a. Install the TargetGroupBinding custom resource definitions.

```
```

b. Add the eks-charts repository.

```
helm repo add eks https://aws.github.io/eks-charts
```

c. Install the AWS Load Balancer Controller using the command that corresponds to the Region that your cluster is in.

**Important**

If you are deploying the controller to Amazon EC2 nodes that you have restricted access to the Amazon EC2 instance metadata service (IMDS) (p. 349) from, or if you are deploying to Fargate, then you need to add the following flags to the command that you run:

- `--set region=<region-code>`
- `--set vpcId=<vpc-xxxxxxx>
```
- All Regions other than China Regions.

```
helm upgrade -i aws-load-balancer-controller eks/aws-load-balancer-controller "
```
Beijing and Ningxia China Regions.

```
helm upgrade -i aws-load-balancer-controller eks/aws-load-balancer-controller \
    --set clusterName=<cluster-name> \
    --set serviceAccount.create=false \
    --set serviceAccount.name=aws-load-balancer-controller \
    --set image.repository=918309763551.dkr.ecr.cn-north-1.amazonaws.com.cn/amazon/aws-load-balancer-controller \
    -n kube-system
```

**Important**
The deployed chart does not receive security updates automatically. You need to manually upgrade to a newer chart when it becomes available.

With a Kubernetes manifest

a. Install cert-manager to inject certificate configuration into the webhooks.

   - Install on Kubernetes 1.16 or later.
     ```
kubectl apply --validate=false -f https://github.com/jetstack/cert-manager/releases/download/v1.0.2/cert-manager.yaml
```

   - Install on Kubernetes 1.15.
     ```
kubectl apply --validate=false -f https://github.com/jetstack/cert-manager/releases/download/v1.0.2/cert-manager-legacy.yaml
```

b. Install the controller.

   1. Download the controller specification. For more information about the controller, see the documentation on GitHub.

     ```
curl -o v2_1_0_full.yaml https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/v2.1.0/docs/install/v2_1_0_full.yaml
```

   2. Edit the saved yaml file. It is recommended that you delete the ServiceAccount section from the yaml specification. Doing so will preserve the service account that you created in step 4 if you delete the controller. In the Deployment spec section set the `--cluster-name` value to your Amazon EKS cluster name.

   3. Apply the file.
     ```
kubectl apply -f v2_1_0_full.yaml
```

7. Verify that the controller is installed.

```
kubectl get deployment -n kube-system aws-load-balancer-controller
```

**Output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws-load-balancer-controller</td>
<td>1/1</td>
<td>1</td>
<td>1</td>
<td>84s</td>
</tr>
</tbody>
</table>
8. Before using the controller to provision AWS resources, your cluster must meet specific requirements. For more information, see the section called "Application load balancing" (p. 265) and the section called "Network load balancing" (p. 261).

(p. 232) support IAM roles for service accounts. The Amazon VPC CNI plugin for Kubernetes also supports IAM roles for service accounts.

To ensure that you are using a supported SDK, follow the installation instructions for your preferred SDK at Tools for Amazon Web Services when you build your containers.

Troubleshooting Amazon EKS identity and access

To diagnose and fix common issues that you might encounter when working with Amazon EKS and IAM see Troubleshooting IAM (p. 373).

Logging and monitoring in Amazon EKS

Amazon EKS control plane logging provides audit and diagnostic logs directly from the Amazon EKS control plane to CloudWatch Logs in your account. These logs make it easy for you to secure and run your clusters. You can select the exact log types you need, and logs are sent as log streams to a group for each Amazon EKS cluster in CloudWatch. For more information, see Amazon EKS Control Plane Logging (p. 66).

Note
When you check the Amazon EKS authenticator logs in Amazon CloudWatch, you'll see entries that contain text similar to the following example text.

```
level=info msg="mapping IAM role" groups="[]"
role="arn:aws:iam::<111122223333:>role/<XXXXXXXXXXXXXXXXXX>-NodeManagerRole-
<XXXXXXXXX>" username="eks:node-manager"
```

Entries that contain this text are expected. The username is an Amazon EKS internal service role that performs specific operations for managed node groups and Fargate.

Amazon EKS is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Amazon EKS. CloudTrail captures all API calls for Amazon EKS as events. The calls captured include calls from the Amazon EKS console and code calls to the Amazon EKS API operations. For more information, see Logging Amazon EKS API calls with AWS CloudTrail (p. 359).

The Kubernetes API server exposes a number of metrics that are useful for monitoring and analysis. For more information, see Control plane metrics with Prometheus (p. 299).

Compliance validation for Amazon EKS

Third-party auditors assess the security and compliance of Amazon EKS as part of multiple AWS compliance programs. These include SOC, PCI, ISO, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS services in scope by compliance program. For general information, see AWS compliance programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading reports in AWS Artifact.
Your compliance responsibility when using Amazon EKS is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and compliance quick start guides** – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- **Architecting for HIPAA security and compliance paper** – This paper describes how companies can use AWS to create HIPAA-compliant applications.
- **AWS compliance resources** – This collection of workbooks and guides might apply to your industry and location.
- **AWS Config** – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.

**Resilience in Amazon EKS**

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

Amazon EKS runs Kubernetes control plane instances across multiple Availability Zones to ensure high availability. Amazon EKS automatically detects and replaces unhealthy control plane instances, and it provides automated version upgrades and patching for them.

This control plane consists of at least two API server nodes and three **etcd** nodes that run across three Availability Zones within a Region. Amazon EKS automatically detects and replaces unhealthy control plane instances, restarting them across the Availability Zones within the Region as needed. Amazon EKS leverages the architecture of AWS Regions in order to maintain high availability. Because of this, Amazon EKS is able to offer an **SLA for API server endpoint availability**.

For more information about AWS Regions and Availability Zones, see **AWS global infrastructure**.

**Infrastructure security in Amazon EKS**

As a managed service, Amazon EKS is protected by the AWS global network security procedures that are described in the **Amazon Web Services: Overview of security processes paper**.

You use AWS published API calls to access Amazon EKS through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the **AWS Security Token Service** (AWS STS) to generate temporary security credentials to sign requests.

When you create an Amazon EKS cluster, you specify the VPC subnets for your cluster to use. Amazon EKS requires subnets in at least two Availability Zones. We recommend a VPC with public and private subnets so that Kubernetes can create public load balancers in the public subnets that load balance traffic to pods running on nodes that are in private subnets.
For more information about VPC considerations, see Cluster VPC considerations (p. 203).

If you create your VPC and node groups with the AWS CloudFormation templates provided in the Getting started with Amazon EKS (p. 4) walkthrough, then your control plane and node security groups are configured with our recommended settings.

For more information about security group considerations, see Amazon EKS security group considerations (p. 205).

When you create a new cluster, Amazon EKS creates an endpoint for the managed Kubernetes API server that you use to communicate with your cluster (using Kubernetes management tools such as kubectl). By default, this API server endpoint is public to the internet, and access to the API server is secured using a combination of AWS Identity and Access Management (IAM) and native Kubernetes Role Based Access Control (RBAC).

You can enable private access to the Kubernetes API server so that all communication between your nodes and the API server stays within your VPC. You can limit the IP addresses that can access your API server from the internet, or completely disable internet access to the API server.

For more information about modifying cluster endpoint access, see Modifying cluster endpoint access (p. 57).

You can implement network policies with tools such as Project Calico (p. 240). Project Calico is a third party open source project. For more information, see the Project Calico documentation.

Configuration and vulnerability analysis in Amazon EKS

Security is a critical consideration for configuring and maintaining Kubernetes clusters and applications. The Center for Internet Security (CIS) Kubernetes Benchmark provides guidance for Amazon EKS node security configurations. The benchmark:

- Is applicable to Amazon EC2 nodes (both managed and self-managed) where you are responsible for security configurations of Kubernetes components.
- Provides a standard, community-approved way to ensure that you have configured your Kubernetes cluster and nodes securely when using Amazon EKS.
- Consists of four sections: control plane logging configuration, node security configurations, policies, and managed services.
- Supports all of the Kubernetes versions currently available in Amazon EKS and can be run using kubectl-bench, a standard open source tool for checking configuration using the CIS benchmark on Kubernetes clusters.

To learn more, see Introducing The CIS Amazon EKS Benchmark.

Amazon EKS platform versions represent the capabilities of the cluster control plane, including which Kubernetes API server flags are enabled and the current Kubernetes patch version. New clusters are deployed with the latest platform version. For details, see Amazon EKS platform versions (p. 73).

You can update an Amazon EKS cluster (p. 43) to newer Kubernetes versions. As new Kubernetes versions become available in Amazon EKS, we recommend that you proactively update your clusters to use the latest available version. For more information about Kubernetes versions in EKS, see Amazon EKS Kubernetes versions (p. 68).

Track security or privacy events for Amazon Linux 2 at the Amazon Linux Security Center or subscribe to the associated RSS feed. Security and privacy events include an overview of the issue affected, packages, and instructions for updating your instances to correct the issue.
You can use Amazon Inspector to check for unintended network accessibility of your nodes and for vulnerabilities on those Amazon EC2 instances.

Amazon EKS security best practices

This topic provides security best practices for your cluster.

Restricting access to the IMDS and Amazon EC2 instance profile credentials

By default, the Amazon EC2 instance metadata service (IMDS) provides the credentials assigned to the node IAM role (p. 326) to the instance, and any container running on the instance. When you use IAM roles for service accounts (p. 330), it updates the credential chain of the pod to use the IAM roles for service accounts token. The pod, however, can still inherit the rights of the instance profile assigned to the node. We recommended that you block pod access to IMDS to minimize the permissions available to your containers if:

- You've implemented IAM roles for service accounts and have assigned necessary permissions directly to all pods that require access to AWS services.
- No pods in your cluster require access to IMDS for other reasons, such as retrieving the current Region.

For more information, see Retrieving Security Credentials from Instance Metadata. You can prevent access to IMDS from your instance and containers using one of the following options.

**Important**

If you use the AWS Load Balancer Controller in your cluster, you may need to change your load balancer configuration. For more information, see To deploy the AWS Load Balancer Controller to an Amazon EKS cluster (p. 233).

- Block access to IMDSv1 from the node and all containers and block access to IMDSv2 for all containers that don't use host networking – Your instance and pods that have hostNetwork: true in their pod spec use host networking. To implement this option, complete the steps in the row and column that apply to your situation.

<table>
<thead>
<tr>
<th>Deployment method</th>
<th>New node group</th>
<th>Existing node group</th>
</tr>
</thead>
<tbody>
<tr>
<td>Managed nodes without a custom launch template</td>
<td>Not possible using any deployment method other than eksctl. If deploying with eksctl, use the --disable-pod-imds option with eksctl create nodegroup. eksctl can be used because it creates a launch template based on options you specify and deploys the node group using that launch template.</td>

- **Block access to IMDSv1 and IMDSv2 for all containers that don't use host networking** – Your instance and pods that have `hostNetwork: true` in their pod spec use host networking, but for legacy reasons still require access to IMDSv1. Run the following `iptables` commands on each of your Amazon Linux nodes (as root) or include them in your instance bootstrap user data script.

```bash
yum install -y iptables-services
iptables --insert FORWARD 1 --in-interface eni+ --destination 169.254.169.254/32 --jump DROP
```
Pod security policy

The Kubernetes pod security policy admission controller validates pod creation and update requests against a set of rules. By default, Amazon EKS clusters ship with a fully permissive security policy with no restrictions. For more information, see Pod Security Policies in the Kubernetes documentation.

Note
The pod security policy admission controller is only enabled on Amazon EKS clusters running Kubernetes version 1.13 or later. You must update your cluster's Kubernetes version to at least 1.13 to use pod security policies. For more information, see Updating a Cluster (p. 43).

Amazon EKS default pod security policy

Amazon EKS clusters with Kubernetes version 1.13 and higher have a default pod security policy named eks.privileged. This policy has no restriction on what kind of pod can be accepted into the system, which is equivalent to running Kubernetes with the PodSecurityPolicy controller disabled.

Note
This policy was created to maintain backwards compatibility with clusters that did not have the PodSecurityPolicy controller enabled. You can create more restrictive policies for your cluster and for individual namespaces and service accounts and then delete the default policy to enable the more restrictive policies.

You can view the default policy with the following command.

```
kubectl get psp eks.privileged
```

Output:

```
NAME       PRIV   CAPS   SELINUX   RUNASUSER   FSGROUP   SUPGROUP   READONLYROOTFS
VOLUMES    eks.privileged   true   *       RunAsAny   RunAsAny   RunAsAny   false

For more details, you can describe the policy with the following command.

```
kubectl describe psp eks.privileged
```
kubectl describe psp eks.privileged

Output:

Name: eks.privileged

Settings:
- Allow Privileged: true
- Allow Privilege Escalation: 0xc0004ce5f8
- Default Add Capabilities: <none>
- Required Drop Capabilities: <none>
- Allowed Capabilities: *
- Allowed Volume Types: *
- Allow Host Network: true
- Allow Host Ports: 0-65535
- Allow Host PID: true
- Allow Host IPC: true
- Read Only Root Filesystem: false
- SELinux Context Strategy: RunAsAny
- User: <none>
- Role: <none>
- Type: <none>
- Level: <none>
- Run As User Strategy: RunAsAny
- Ranges: <none>
- FSGroup Strategy: RunAsAny
- Ranges: <none>
- Supplemental Groups Strategy: RunAsAny
- Ranges: <none>

The following example shows the full YAML file for the eks.privileged pod security policy, its cluster role, and cluster role binding.

```yaml
---
apiVersion: policy/v1beta1
kind: PodSecurityPolicy
metadata:
  name: eks.privileged
  annotations:
    kubernetes.io/description: 'privileged allows full unrestricted access to pod features, as if the PodSecurityPolicy controller was not enabled.'
    seccomp.security.alpha.kubernetes.io/allowedProfileNames: '*'
  labels:
    kubernetes.io/cluster-service: "true"
    eks.amazonaws.com/component: pod-security-policy
spec:
  privileged: true
  allowPrivilegeEscalation: true
  allowedCapabilities:
    - *
  volumes:
    - *
  hostNetwork: true
  hostPorts:
    - min: 0
    - max: 65535
  hostIPC: true
  hostPID: true
  runAsUser:
    rule: 'RunAsAny'
  seLinux:
    rule: 'RunAsAny'
  supplementalGroups:
```
To delete the default pod security policy

After you create custom pod security policies for your cluster, you can delete the default Amazon EKS eks.privileged pod security policy to enable your custom policies.

1. Create a file called privileged-podsecuritypolicy.yaml and paste the full eks.privileged YAML file contents from the preceding example into it (this allows you to delete the pod security policy, the ClusterRole, and the ClusterRoleBinding associated with it).
2. Delete the YAML with the following command.

   kubectl delete -f privileged-podsecuritypolicy.yaml

To install or restore the default pod security policy

If you are upgrading from an earlier version of Kubernetes, or have modified or deleted the default Amazon EKS eks.privileged pod security policy, you can restore it with the following steps.

1. Create a file called privileged-podsecuritypolicy.yaml and paste the YAML file contents below into it.
---
apiVersion: policy/v1beta1
kind: PodSecurityPolicy
metadata:
  name: eks.privileged
  annotations:
    kubernetes.io/description: 'privileged allows full unrestricted access to
    pod features, as if the PodSecurityPolicy controller was not enabled.'
    seccomp.security.alpha.kubernetes.io/allowedProfileNames: '*'
  labels:
    kubernetes.io/cluster-service: "true"
    eks.amazonaws.com/component: pod-security-policy
spec:
  privileged: true
  allowPrivilegeEscalation: true
  allowedCapabilities:
    - '*'
  volumes:
    - '*'
  hostNetwork: true
  hostPorts:
    - min: 0
      max: 65535
  hostIPC: true
  hostPID: true
  runAsUser:
    rule: 'RunAsAny'
  seLinux:
    rule: 'RunAsAny'
  supplementalGroups:
    rule: 'RunAsAny'
  fsGroup:
    rule: 'RunAsAny'
  readOnlyRootFilesystem: false
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: eks:podsecuritypolicy:privileged
  labels:
    kubernetes.io/cluster-service: "true"
    eks.amazonaws.com/component: pod-security-policy
rules:
  - apiGroups:
      - policy
    resourceNames:
    - eks.privileged
    resources:
    - podsecuritypolicies
    verbs:
    - use
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: eks:podsecuritypolicy:authenticated
  annotations:
    kubernetes.io/description: 'Allow all authenticated users to create privileged
    pods.'
  labels:
    kubernetes.io/cluster-service: "true"
    eks.amazonaws.com/component: pod-security-policy
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: eks:podsecuritypolicy:privileged
subjects:
- kind: Group
  apiGroup: rbac.authorization.k8s.io
  name: system:authenticated

2. Apply the YAML with the following command.

```bash
kubectl apply -f privileged-podsecuritypolicy.yaml
```
AWS services integrated with Amazon EKS

Amazon EKS works with other AWS services to provide additional solutions for your business challenges. This topic identifies services that either use Amazon EKS to add functionality, or services that Amazon EKS uses to perform tasks.

Contents
- Creating Amazon EKS resources with AWS CloudFormation (p. 358)
- Logging Amazon EKS API calls with AWS CloudTrail (p. 359)
- Amazon EKS on AWS Outposts (p. 362)
- Use App Mesh with Kubernetes (p. 359)
- Amazon EKS on AWS Local Zones (p. 364)
- Deep Learning Containers (p. 365)

Creating Amazon EKS resources with AWS CloudFormation

Amazon EKS is integrated with AWS CloudFormation, a service that helps you model and set up your AWS resources so that you can spend less time creating and managing your resources and infrastructure. You create a template that describes all the AWS resources that you want, for example an Amazon EKS cluster, and AWS CloudFormation takes care of provisioning and configuring those resources for you.

When you use AWS CloudFormation, you can reuse your template to set up your Amazon EKS resources consistently and repeatedly. Just describe your resources once, and then provision the same resources over and over in multiple AWS accounts and Regions.

Amazon EKS and AWS CloudFormation templates

To provision and configure resources for Amazon EKS and related services, you must understand AWS CloudFormation templates. Templates are formatted text files in JSON or YAML. These templates describe the resources that you want to provision in your AWS CloudFormation stacks. If you're unfamiliar with JSON or YAML, you can use AWS CloudFormation Designer to help you get started with AWS CloudFormation templates. For more information, see What is AWS CloudFormation Designer? in the AWS CloudFormation User Guide.

Amazon EKS supports creating clusters and node groups in AWS CloudFormation. For more information, including examples of JSON and YAML templates for your Amazon EKS resources, see Amazon EKS resource type reference in the AWS CloudFormation User Guide.

Learn more about AWS CloudFormation

To learn more about AWS CloudFormation, see the following resources:
- AWS CloudFormation
Use App Mesh with Kubernetes

App Mesh is a service mesh that makes it easy to monitor and control services. App Mesh standardizes how your services communicate, giving you end-to-end visibility and helping to ensure high availability for your applications. App Mesh gives you consistent visibility and network traffic controls for every service in an application. You can get started using App Mesh with Kubernetes by completing the Getting started with AWS App Mesh and Kubernetes tutorial in the AWS App Mesh User Guide. The tutorial recommends that you have an existing Kubernetes cluster and applications deployed that you want to use App Mesh with.

Logging Amazon EKS API calls with AWS CloudTrail

Amazon EKS is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Amazon EKS. CloudTrail captures all API calls for Amazon EKS as events, including calls from the Amazon EKS console and from code calls to the Amazon EKS API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Amazon EKS. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to Amazon EKS, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Amazon EKS information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Amazon EKS, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see Viewing events with CloudTrail event history.

For an ongoing record of events in your AWS account, including events for Amazon EKS, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- **Overview for creating a trail**
- **CloudTrail supported services and integrations**
- **Configuring Amazon SNS notifications for CloudTrail**
- **Receiving CloudTrail log files from multiple regions** and **Receiving CloudTrail log files from multiple accounts**

All Amazon EKS actions are logged by CloudTrail and are documented in the Amazon EKS API Reference. For example, calls to the CreateCluster, ListClusters and DeleteCluster sections generate entries in the CloudTrail log files.
Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity element.

Understanding Amazon EKS log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the CreateCluster action.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AKIAIOSFODNN7EXAMPLE",
    "arn": "arn:aws:iam::111122223333:user/username",
    "accountId": "111122223333",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "userName": "username"
  },
  "eventSource": "eks.amazonaws.com",
  "eventName": "CreateCluster",
  "awsRegion": "<region-code>",
  "sourceIPAddress": "205.251.233.178",
  "userAgent": "PostmanRuntime/6.4.0",
  "requestParameters": {
    "resourcesVpcConfig": {
      "subnetIds": [
        "subnet-a670c2df",
        "subnet-4f8c5004"
      ]
    },
    "roleArn": "arn:aws:iam::111122223333:role/AWSServiceRoleForAmazonEKS-CAC1G1VH32KZ",
    "clusterName": "test"
  },
  "responseElements": {
    "cluster": {
      "clusterName": "test",
      "status": "CREATING",
      "createdAt": 1527535003.208,
      "certificateAuthority": {},
      "roleArn": "arn:aws:iam::111122223333:role/AWSServiceRoleForAmazonEKS-CAC1G1VH32KZ",
      "version": "1.10",
      "resourcesVpcConfig": {
        "securityGroupIds": [],
        "vpcId": "vpc-21277358",
        "subnetIds": [
          "subnet-a670c2df",
          "subnet-4f8c5004"
        ]
      }
    }
  }
}
```
Log Entries for Amazon EKS Service Linked Roles

The Amazon EKS service linked roles make API calls to AWS resources. You will see CloudTrail log entries with username: AWSServiceRoleForAmazonEKS and username: AWSServiceRoleForAmazonEKSNodegroup for calls made by the Amazon EKS service linked roles.

For more information about Amazon EKS and service linked roles, see Using Service-Linked Roles for Amazon EKS (p. 320).

The following example shows a CloudTrail log entry that demonstrates a DeleteInstanceProfile action made by the AWSServiceRoleForAmazonEKSNodegroup service linked role, noted in the sessionContext.

```json
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "AROA3WHGPEZ7SJ2CW55C5:EKSt",
    "arn": "arn:aws:sts::111122223333:assumed-role/AWSServiceRoleForAmazonEKSNodegroup/EKS",
    "accountId": "111122223333",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "sessionIssuer": {
        "type": "Role",

}
```
Amazon EKS on AWS Outposts

You can create and run Amazon EKS nodes on AWS Outposts. AWS Outposts enables native AWS services, infrastructure, and operating models in on-premises facilities. In AWS Outposts environments, you can use the same AWS APIs, tools, and infrastructure that you use in the AWS Cloud. Amazon EKS nodes on AWS Outposts is ideal for low-latency workloads that need to be run in close proximity to on-premises data and applications. For more information about AWS Outposts, see the AWS Outposts User Guide.

Prerequisites

The following are the prerequisites for using Amazon EKS nodes on AWS Outposts:

- You must have installed and configured an Outpost in your on-premises data center.
- You must have a reliable network connection between your Outpost and its AWS Region.
- The AWS Region for the Outpost must support Amazon EKS. For a list of supported Regions, see Amazon EKS service endpoints in the AWS General Reference.

Considerations

- AWS Identity and Access Management, Application Load Balancer, Network Load Balancer, Classic Load Balancer, and Amazon Route 53 run in the AWS Region, not on Outposts. This will increase latencies between the services and the containers.
- AWS Fargate is not available on AWS Outposts.
- Managed node groups cannot be deployed to nodes on an Outpost.
- You cannot use AWS Outposts in China Regions

Network connectivity considerations

The following are network connectivity considerations for Amazon EKS AWS Outposts:

- If network connectivity between your Outpost and its AWS Region is lost, your nodes will continue to run. However, you cannot create new nodes or take new actions on existing deployments until connectivity is restored. In case of instance failures, the instance will not be automatically replaced. The Kubernetes control plane runs in the Region, and missing heartbeats caused by things like a loss of connectivity to the Availability Zone could lead to failures. The failed heartbeats will lead to pods on the Outposts being marked as unhealthy, and eventually the node status will time out and pods will be marked for eviction. For more information, see Node Controller in the Kubernetes documentation.
- We recommend that you provide reliable, highly available, and low-latency connectivity between your Outpost and its AWS Region.

Creating Amazon EKS nodes on an Outpost

Creating Amazon EKS nodes on an Outpost is similar to creating Amazon EKS nodes in the AWS Cloud. When you create an Amazon EKS node on an Outpost, you must specify a subnet associated with your Outpost.
An Outpost is an extension of an AWS Region, and you can extend a VPC in an account to span multiple Availability Zone and any associated Outpost locations. When you configure your Outpost, you associate a subnet with it to extend your Regional VPC environment to your on-premises facility. Instances on an Outpost appear as part of your Regional VPC, similar to an Availability Zone with associated subnets.

To create Amazon EKS nodes on an Outpost with the AWS CLI, specify a security group and a subnet associated with your Outpost.

**To create an Amazon EKS node group on an Outpost**

1. Create a VPC.
   
   ```bash
   aws ec2 create-vpc --cidr-block <10.0.0.0/16>
   ```

2. Create Outpost subnets. The `--outpost-arn` parameter must be specified for the subnet to be created for the Outpost. (This step is different for AWS Outposts.)
   
   ```bash
   aws ec2 create-subnet --vpc-id <vpc-xxxxxxxx> --cidr-block <10.0.3.0/24> \
   --outpost-arn arn:aws:outposts:<us-west-2>:123456789012:outpost/<op-
   xxxxxxxxx>
   ```

3. Create a cluster, specifying the subnets for the Outpost. (This step is different for AWS Outposts.)
   
   ```bash
   aws eks --region <region-code> create-cluster --name <eks-outpost> --role-arn \ 
   arn:aws:iam::123456789012:role/<eks-service-role-AWSServiceRoleForAmazonEKS-OUTPOST> \ 
   --resources-vpc-config subnetIds=<subnet-xxxxxxxx>,<subnet- 
   yyyyyyyyy>,securityGroupIds=<sg-xxxxxxxx>
   ```

4. Create the node group. Specify an instance type that is available on your Outpost. (This step is different for AWS Outposts.)
Use App Mesh with Kubernetes

App Mesh is a service mesh that makes it easy to monitor and control services. App Mesh standardizes how your services communicate, giving you end-to-end visibility and helping to ensure high availability for your applications. App Mesh gives you consistent visibility and network traffic controls for every service in an application. You can get started using App Mesh with Kubernetes by completing the Getting started with AWS App Mesh and Kubernetes tutorial in the AWS App Mesh User Guide. The tutorial recommends that you have existing services deployed to Kubernetes that you want to use App Mesh with.

Amazon EKS on AWS Local Zones

An AWS Local Zone is an extension of an AWS Region in geographic proximity to your users. Local Zones have their own connections to the internet and support AWS Direct Connect. Resources created in a Local Zone can serve local users with low-latency communications. For more information, see Local Zones.

Amazon EKS supports running certain infrastructure, including Amazon EC2 instances, Amazon EBS volumes, and Application Load Balancers from a Local Zone as part of your cluster. There are several considerations when using Local Zone infrastructure as part of your Amazon EKS cluster.

**Kubernetes versions**

Only Amazon EKS clusters running Kubernetes versions 1.17 and later can use Local Zone compute resources.

**Nodes**

Amazon EKS does not support creating managed node groups in AWS Local Zones. You must create self-managed nodes using the Amazon EC2 API or AWS CloudFormation. **Do not use eksctl to create your cluster or nodes in Local Zones.** For details and options, follow the instructions in Self-managed nodes (p. 117).

**Network architecture**

The Amazon EKS managed Kubernetes control plane always runs in the AWS Region. The Amazon EKS managed Kubernetes control plane cannot run in the Local Zone. Since Local Zones appear as a subnet within your VPC, Kubernetes sees your Local Zone resources as part of that subnet.

The Amazon EKS Kubernetes cluster communicates with the Amazon EC2 instances you run in the AWS Region or Local Zone using Amazon EKS managed **elastic network interfaces**. To learn more about Amazon EKS networking architecture, see Amazon EKS networking (p. 197).
Unlike regional subnets, Amazon EKS cannot place network interfaces into your Local Zone subnets. This means that you must not specify Local Zone subnets when you create your cluster.

After the cluster is created, tag your Local Zone subnets with the Amazon EKS cluster name. For more information, see Subnet tagging requirement (p. 205). You can then deploy self-managed nodes to the Local Zone subnets and the nodes will be able to join your Amazon EKS cluster.

**Deep Learning Containers**

AWS Deep Learning Containers are a set of Docker images for training and serving models in TensorFlow on Amazon EKS and Amazon Elastic Container Service (Amazon ECS). Deep Learning Containers provide optimized environments with TensorFlow, Nvidia CUDA (for GPU instances), and Intel MKL (for CPU instances) libraries and are available in Amazon ECR.

To get started using AWS Deep Learning Containers on Amazon EKS, see AWS Deep Learning Containers on Amazon EKS in the AWS Deep Learning AMI Developer Guide.
Amazon EKS troubleshooting

This chapter covers some common errors that you may see while using Amazon EKS and how to work around them.

Insufficient capacity

If you receive the following error while attempting to create an Amazon EKS cluster, then one of the Availability Zones you specified does not have sufficient capacity to support a cluster.

Cannot create cluster 'example-cluster' because region-1d, the targeted Availability Zone, does not currently have sufficient capacity to support the cluster. Retry and choose from these Availability Zones: region-1a, region-1b, region-1c

Retry creating your cluster with subnets in your cluster VPC that are hosted in the Availability Zones returned by this error message.

Nodes fail to join cluster

There are a few common reasons that prevent nodes from joining the cluster:

- The `aws-auth-cm.yaml` file does not have the correct IAM role ARN for your nodes. Ensure that the node IAM role ARN (not the instance profile ARN) is specified in your `aws-auth-cm.yaml` file. For more information, see Launching self-managed Amazon Linux nodes (p. 117).
- The `ClusterName` in your node AWS CloudFormation template does not exactly match the name of the cluster you want your nodes to join. Passing an incorrect value to this field results in an incorrect configuration of the node's `/var/lib/kubelet/kubeconfig` file, and the nodes will not join the cluster.
- The node is not tagged as being owned by the cluster. Your nodes must have the following tag applied to them, where `<cluster-name>` is replaced with the name of your cluster.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>kubernetes.io/cluster/&lt;cluster-name&gt;</td>
<td>owned</td>
</tr>
</tbody>
</table>

- The nodes may not be able to access the cluster using a public IP address. Ensure that nodes deployed in public subnets are assigned a public IP address. If not, you can associate an elastic IP address to a node after it's launched. For more information, see Associating an elastic IP address with a running instance or network interface. If the public subnet is not set to automatically assign public IP addresses to instances deployed to it, then we recommend enabling that setting. For more information, see Modifying the public IPv4 addressing attribute for your subnet. If the node is deployed to a private subnet, then the subnet must have a route to a NAT gateway that has a public IP address assigned to it.
- The STS endpoint for the Region that you're deploying the nodes to is not enabled for your account. To enable the region, see Activating and deactivating AWS STS in an AWS Region.
Unauthorized or access denied (kubectl)

If you receive one of the following errors while running kubectl commands, then your kubectl is not configured properly for Amazon EKS or the IAM user or role credentials that you are using do not map to a Kubernetes RBAC user with sufficient permissions in your Amazon EKS cluster.

- could not get token: AccessDenied: Access denied
- error: You must be logged in to the server (Unauthorized)
- error: the server doesn't have a resource type "svc"

This could be because the cluster was created with one set of AWS credentials (from an IAM user or role), and `kubectl` is using a different set of credentials.

When an Amazon EKS cluster is created, the IAM entity (user or role) that creates the cluster is added to the Kubernetes RBAC authorization table as the administrator (with system:masters permissions). Initially, only that IAM user can make calls to the Kubernetes API server using `kubectl`. For more information, see Managing users or IAM roles for your cluster (p. 279). If you use the console to create the cluster, you must ensure that the same IAM user credentials are in the AWS SDK credential chain when you are running `kubectl` commands on your cluster.

If you install and configure the AWS CLI, you can configure the IAM credentials for your user. For more information, see Configuring the AWS CLI in the AWS Command Line Interface User Guide.

If you assumed a role to create the Amazon EKS cluster, you must ensure that kubectl is configured to assume the same role. Use the following command to update your kubeconfig file to use an IAM role. For more information, see Create a kubeconfig for Amazon EKS (p. 275).

```bash
aws --region <region-code> eks update-kubeconfig --name <cluster_name> --role-arn arn:aws:iam::<aws_account_id>::role/<role_name>
```

To map an IAM user to a Kubernetes RBAC user, see Managing users or IAM roles for your cluster (p. 279) or watch a video about how to map a user.

aws-iam-authenticator Not found

If you receive the error "aws-iam-authenticator": executable file not found in $PATH, then your kubectl is not configured for Amazon EKS. For more information, see Installing aws-iam-authenticator (p. 271).

**Note**
The `aws-iam-authenticator` is not required if you have the AWS CLI version 1.16.156 or higher installed.

hostname doesn't match

Your system’s Python version must be 2.7.9 or later. Otherwise, you receive hostname doesn’t match errors with AWS CLI calls to Amazon EKS. For more information, see What are "hostname doesn't match" errors? in the Python Requests FAQ.
getsockopt: no route to host

Docker runs in the 172.17.0.0/16 CIDR range in Amazon EKS clusters. We recommend that your cluster's VPC subnets do not overlap this range. Otherwise, you will receive the following error:

```
```

### Managed node group errors

If you receive the error "Instances failed to join the Kubernetes cluster" in the AWS Management Console, ensure that either the cluster's private endpoint access is enabled, or that you have correctly configured CIDR blocks for public endpoint access. For more information, see Amazon EKS cluster endpoint access control (p. 56).

If your managed node group encounters a health issue, Amazon EKS returns an error message to help you to diagnose the issue. The following error messages and their associated descriptions are shown below.

- **AccessDenied**: Amazon EKS or one or more of your managed nodes is failing to authenticate or authorize with your Kubernetes cluster API server. For more information about resolving this error, see Fixing `AccessDenied` errors for managed node groups (p. 369).

- **AutoScalingGroupNotFound**: We couldn't find the Auto Scaling group associated with the managed node group. You may be able to recreate an Auto Scaling group with the same settings to recover.

- **ClusterUnreachable**: Amazon EKS or one or more of your managed nodes is unable to communicate with your Kubernetes cluster API server. This can happen if there are network disruptions or if API servers are timing out processing requests.

- **Ec2SecurityGroupNotFound**: We couldn't find the cluster security group for the cluster. You must recreate your cluster.

- **Ec2SecurityGroupDeletionFailure**: We could not delete the remote access security group for your managed node group. Remove any dependencies from the security group.

- **Ec2LaunchTemplateNotFound**: We couldn't find the Amazon EC2 launch template for your managed node group. You may be able to recreate a launch template with the same settings to recover.

- **Ec2LaunchTemplateVersionMismatch**: The Amazon EC2 launch template version for your managed node group does not match the version that Amazon EKS created. You may be able to revert to the version that Amazon EKS created to recover.

- **IamInstanceProfileNotFound**: We couldn't find the IAM instance profile for your managed node group. You may be able to recreate an instance profile with the same settings to recover.

- **IamNodeRoleNotFound**: We couldn't find the IAM role for your managed node group. You may be able to recreate an IAM role with the same settings to recover.

- **AsgInstanceLaunchFailures**: Your Auto Scaling group is experiencing failures while attempting to launch instances.

- **NodeCreationFailure**: Your launched instances are unable to register with your Amazon EKS cluster. Common causes of this failure are insufficient node IAM role (p. 326) permissions or lack of outbound internet access for the nodes. Your nodes must be able to access the internet using a public IP address to function properly. For more information, see VPC IP addressing (p. 203). Your nodes must also have ports open to the internet. For more information, see Amazon EKS security group considerations (p. 205).

- **InstanceLimitExceeded**: Your AWS account is unable to launch any more instances of the specified instance type. You may be able to request an Amazon EC2 instance limit increase to recover.
- **InsufficientFreeAddresses**: One or more of the subnets associated with your managed node group does not have enough available IP addresses for new nodes.
- **InternalFailure**: These errors are usually caused by an Amazon EKS server-side issue.

## Fixing AccessDenied errors for managed node groups

The most common cause of AccessDenied errors when performing operations on managed node groups is missing the `eks:node-manager` ClusterRole or ClusterRoleBinding. Amazon EKS sets up these resources in your cluster as part of onboarding with managed node groups, and these are required for managing the node groups.

The ClusterRole may change over time, but it should look similar to the following example:

```yaml
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: eks:node-manager
rules:
- apiGroups:
  - ''
  resources:
  - pods
  verbs:
  - get
  - list
  - watch
  - delete
- apiGroups:
  - ''
  resources:
  - nodes
  verbs:
  - get
  - list
  - watch
  - patch
- apiGroups:
  - ''
  resources:
  - pods/eviction
  verbs:
  - create
```

The ClusterRoleBinding may change over time, but it should look similar to the following example:

```yaml
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: eks:node-manager
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: eks:node-manager
subjects:
- apiGroup: rbac.authorization.k8s.io
  kind: User
  name: eks:node-manager
```

Verify that the `eks:node-manager` ClusterRole exists.
kubectl describe clusterrole eks:node-manager

If present, compare the output to the previous ClusterRole example.

Verify that the eks:node-manager ClusterRoleBinding exists.

kubectl describe clusterrolebinding eks:node-manager

If present, compare the output to the previous ClusterRoleBinding example.

If you’ve identified a missing or broken ClusterRole or ClusterRoleBinding as the cause of an AccessDenied error while requesting managed node group operations, you can restore them. Save the following contents to a file named eks-node-manager-role.yaml.

```yaml
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: eks:node-manager
rules:
- apiGroups:
  - ''
  resources:
  - pods
  verbs:
    - get
    - list
    - watch
    - delete
- apiGroups:
  - ''
  resources:
  - nodes
  verbs:
    - get
    - list
    - watch
    - patch
- apiGroups:
  - ''
  resources:
  - pods/eviction
  verbs:
    - create
---
apiversion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: eks:node-manager
roleRef:
  apiGroup: rbac.authorization.k8s.io
  kind: ClusterRole
  name: eks:node-manager
subjects:
- apiGroup: rbac.authorization.k8s.io
  kind: User
  name: eks:node-manager
```

Apply the file.

kubectl apply -f eks-node-manager-role.yaml
Retry the node group operation to see if that resolved your issue.

CNI log collection tool

The Amazon VPC CNI plugin for Kubernetes has its own troubleshooting script (which is available on nodes at /opt/cni/bin/aws-cni-support.sh) that you can use to collect diagnostic logs for support cases and general troubleshooting.

Use the following command to run the script on your node:

```
sudo bash /opt/cni/bin/aws-cni-support.sh
```

Note

If the script is not present at that location, then the CNI container failed to run. You can manually download and run the script with the following command:

```
dsudo bash eks-log-collector.sh
```

The script collects the following diagnostic information. The CNI version that you have deployed can be earlier than the script version.

```
This is version 0.6.1. New versions can be found at https://github.com/awslabs/amazon-eks-ami

Trying to collect common operating system logs...
Trying to collect kernel logs...
Trying to collect mount points and volume information...

```

The diagnostic information is collected and stored at

```
/var/log/eks_i-0717c9d54b6cf6a19_2020-03-24_0103-UTC_0.6.1.tar.gz
```

Container runtime network not ready

You may receive a Container runtime network not ready error and authorization errors similar to the following:
The errors are most likely related to the AWS IAM Authenticator configuration map not being applied to the nodes. The configuration map provides the system:bootstrappers and system:nodes Kubernetes RBAC permissions for nodes to register to the cluster. For more information, see To enable nodes to join your cluster on the Self-managed nodes tab of Launching self-managed Amazon Linux nodes (p. 117). Ensure that you specify the Role ARN of the instance role in the configuration map, not the Instance Profile ARN.

The authenticator does not recognize a Role ARN if it includes a path other than /, such as the following example:

```
arn:aws:iam::<111122223333>:role/<development/apps/prod-iam-role-NodeInstanceRole-621LVEXAMPLE>
```

When specifying a Role ARN in the configuration map that includes a path other than /, you must drop the path. The ARN above would be specified as the following:

```
arn:aws:iam::<111122223333>:role/prod-iam-role-NodeInstanceRole-621LVEXAMPLE
```

**TLS handshake timeout**

When a node is unable to establish a connection to the public API server endpoint, you may an error similar to the following error.

```
server.go:233] failed to run Kubelet: could not init cloud provider "aws": error finding instance i-1111f2222f333e44c: "error listing AWS instances: RequestError: send request failed\ncaused by: Post net/http: TLS handshake timeout"
```

The kubelet process will continually respawn and test the API server endpoint. The error can also occur temporarily during any procedure that performs a rolling update of the cluster in the control plane, such as a configuration change or version update.

To resolve the issue, check the route table and security groups to ensure that traffic from the nodes can reach the public endpoint.

**InvalidClientTokenId**

If you're using IAM roles for service accounts for a pod or daemonset deployed to a cluster in a China Region, and haven't set the AWS_DEFAULT_REGION environment variable in the spec, the pod or daemonset may receive the following error:

```
An error occurred (InvalidClientTokenId) when calling the GetCallerIdentity operation: The security token included in the request is invalid
```
To resolve the issue, you need to add the `AWS_DEFAULT_REGION` environment variable to your pod or daemonset spec, as shown in the following example pod spec.

```yaml
apiVersion: v1
kind: Pod
metadata:
  name: envar-demo
labels:
  purpose: demonstrate-envvars
spec:
  containers:
  - name: envar-demo-container
    image: gcr.io/google-samples/node-hello:1.0
    env:
    - name: AWS_DEFAULT_REGION
      value: "<region-code>"
```

**Troubleshooting IAM**

This topic covers some common errors that you may see while using Amazon EKS with IAM and how to work around them.

**AccessDeniedException**

If you receive an `AccessDeniedException` when calling an AWS API operation, then the AWS Identity and Access Management (IAM) user or role credentials that you are using do not have the required permissions to make that call.

An error occurred (AccessDeniedException) when calling the DescribeCluster operation:  

In the above example message, the user does not have permissions to call the Amazon EKS DescribeCluster API operation. To provide Amazon EKS admin permissions to a user, see Amazon EKS identity-based policy examples (p. 316).

For more general information about IAM, see Controlling access using policies in the IAM User Guide.

**Can't see workloads or nodes and receive an error in the AWS Management Console**

You may see a console error message that says Your current user or role does not have access to Kubernetes objects on this EKS cluster. Make sure that the IAM entity (user or role) that you're signed into the AWS Management Console with meets all of the following requirements:

- Has an IAM policy attached to it that includes the `eks:AccessKubernetesApi` action. For an example IAM policy, see View nodes and workloads for all clusters in the AWS Management Console (p. 318). If you're using the IAM policy visual editor in the AWS Management Console and you don't see the `eks:AccessKubernetesApi` Permission listed, edit the policy's JSON and add `eks:AccessKubernetesApi` to the list of Actions in the JSON.
- Has a mapping to a Kubernetes user or group in the `aws-auth` configmap. For more information about adding IAM users or roles to the `aws-auth` configmap, see Managing users or IAM roles for your
If the user or role isn't mapped, the console error may include **Unauthorized:** Verify you have access to the Kubernetes cluster.

- The Kubernetes user or group that the IAM account or role is mapped to in the configmap must be a subject in a rolebinding or clusterrolebinding that is bound to a Kubernetes role or clusterrole that has the necessary permissions to view the Kubernetes resources. If the user or group doesn't have the necessary permissions, the console error may include **Unauthorized:** Verify you have access to the Kubernetes cluster. To create roles and bindings, see Using RBAC Authorization in the Kubernetes documentation. You can download the following example manifests that create a clusterrole and clusterrolebinding or a role and rolebinding:

  - **View Kubernetes resources in all namespaces** – The group name in the file is eks-console-dashboard-full-access-group, which is the group that your IAM user or role needs to be mapped to in the aws-auth configmap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the configmap. To download the file, select the appropriate link for the Region that your cluster is in.
    - All Regions other than Beijing and Ningxia China
    - Beijing and Ningxia China Regions

  - **View Kubernetes resources in a specific namespace** – The namespace in this file is default, so if you want to specify a different namespace, edit the file before applying it to your cluster. The group name in the file is eks-console-dashboard-restricted-access-group, which is the group that your IAM user or role needs to be mapped to in the aws-auth configmap. You can change the name of the group before applying it to your cluster, if desired, and then map your IAM user or role to that group in the configmap. To download the file, select the appropriate link for the Region that your cluster is in.
    - All Regions other than Beijing and Ningxia China
    - Beijing and Ningxia China Regions

---

**aws-auth ConfigMap does not grant access to the cluster**

*AWS IAM authenticator* does not permit a path in the role ARN used in the configuration map. Therefore, before you specify rolearn, remove the path. For example, change arn:aws:iam::<123456789012>:role/<team>/<developers>/<eks-admin> to arn:aws:iam::<123456789012>:role/<eks-admin>.

**I Am not authorized to perform iam:PassRole**

If you receive an error that you're not authorized to perform the `iam:PassRole` action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password. Ask that person to update your policies to allow you to pass a role to Amazon EKS.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in Amazon EKS. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

User: arn:aws:iam::<123456789012>:user/marmarymajor is not authorized to perform: iam:PassRole

In this case, Mary asks her administrator to update her policies to allow her to perform the `iam:PassRole` action.
I want to view my access keys

After you create your IAM user access keys, you can view your access key ID at any time. However, you can't view your secret access key again. If you lose your secret key, you must create a new access key pair.

Access keys consist of two parts: an access key ID (for example, AKIAIOSFODNN7EXAMPLE) and a secret access key (for example, wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY). Like a user name and password, you must use both the access key ID and secret access key together to authenticate your requests. Manage your access keys as securely as you do your user name and password.

**Important**
Do not provide your access keys to a third party, even to help find your canonical user ID. By doing this, you might give someone permanent access to your account.

When you create an access key pair, you are prompted to save the access key ID and secret access key in a secure location. The secret access key is available only at the time you create it. If you lose your secret access key, you must add new access keys to your IAM user. You can have a maximum of two access keys. If you already have two, you must delete one key pair before creating a new one. To view instructions, see Managing access keys in the *IAM User Guide*.

I'm an administrator and want to allow others to access Amazon EKS

To allow others to access Amazon EKS, you must create an IAM entity (user or role) for the person or application that needs access. They will use the credentials for that entity to access AWS. You must then attach a policy to the entity that grants them the correct permissions in Amazon EKS.

To get started right away, see Creating your first IAM delegated user and group in the *IAM User Guide*.

I want to allow people outside of my AWS account to access my Amazon EKS resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon EKS supports these features, see How Amazon EKS works with IAM (p. 313).
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the *IAM User Guide*.
Amazon EKS Distro

Amazon EKS Distro is a distribution of the same open source Kubernetes software and dependencies deployed by Amazon EKS in the cloud. With Amazon EKS Distro, you can create reliable and secure clusters wherever your applications are deployed. You can rely on the same versions of Kubernetes deployed by Amazon EKS, etcd, CoreDNS, upstream CNI, and CSI sidecars with the latest updates and extended security patching support. Amazon EKS Distro follows the same Kubernetes version release cycle as Amazon EKS and is provided as an open-source project.

Note
The source code for the Amazon EKS Distro is available on GitHub. The latest documentation is available on the Amazon EKS Distro website. If you find any issues, you can report them with Amazon EKS Distro by connecting with us on GitHub. There you can open issues, provide feedback, and report bugs.
Related projects

These open-source projects extend the functionality of Kubernetes clusters running on or outside of AWS, including clusters managed by Amazon EKS.

Management tools

Related management tools for Amazon EKS and Kubernetes clusters.

**eksctl**

Eksctl is a simple CLI tool for creating clusters on Amazon EKS.

- Project URL: https://eksctl.io/
- Project documentation: https://eksctl.io/
- AWS open source blog: eksctl: Amazon EKS cluster with one command

**AWS controllers for Kubernetes**

With AWS Controllers for Kubernetes, you can create and manage AWS resources directly from your Kubernetes cluster.

- Project URL: https://aws.github.io/aws-controllers-k8s/
- AWS open-source blog: AWS service operator for Kubernetes now available

**Flux CD**

Flux is a tool that you can use to manage your cluster configuration using Git. It uses an operator in the cluster to trigger deployments inside of Kubernetes. For more information about operators, see Awesome Operators in the Wild on GitHub.

- Project URL: https://fluxcd.io/
- Project documentation: https://docs.fluxcd.io/

**CDK for Kubernetes**

With the CDK for Kubernetes (cdk8s), you can define Kubernetes apps and components using familiar programming languages. cdk8s apps synthesize into standard Kubernetes manifests, which can be applied to any Kubernetes cluster.

- Project URL: https://cdk8s.io/
- Project documentation: https://github.com/awslabs/cdk8s/tree/master/docs/getting-started
Networking

Related networking projects for Amazon EKS and Kubernetes clusters.

Amazon VPC CNI plugin for Kubernetes

Amazon EKS supports native VPC networking through the Amazon VPC CNI plugin for Kubernetes. Using this CNI plugin allows Kubernetes pods to have the same IP address inside the pod as they do on the VPC network.

- Project URL: https://github.com/aws/amazon-vpc-cni-k8s
- Project documentation: https://github.com/aws/amazon-vpc-cni-k8s/blob/master/README.md

AWS Load Balancer Controller for Kubernetes

The AWS Load Balancer Controller helps manage AWS Elastic Load Balancers for a Kubernetes cluster. It satisfies Kubernetes Ingress resources by provisioning AWS Application Load Balancers. It satisfies Kubernetes Service resources by provisioning AWS Network Load Balancers.

- Project URL: https://github.com/kubernetes-sigs/aws-load-balancer-controller
- Project documentation: https://kubernetes-sigs.github.io/aws-load-balancer-controller/latest/

ExternalDNS

ExternalDNS synchronizes exposed Kubernetes services and ingresses with DNS providers including Amazon Route 53 and AWS Service Discovery.

- Project URL: https://github.com/kubernetes-incubator/external-dns
- Project documentation: https://github.com/kubernetes-incubator/external-dns/blob/master/docs/tutorials/aws.md

App Mesh Controller

The App Mesh Controller for Kubernetes helps to manage App Mesh for your cluster. With the controller, you can manage the service mesh using custom resources within your cluster. The controller manages the injection of networking proxy sidecars to pods to enable the mesh.

- Project URL: https://github.com/aws/aws-app-mesh-controller-for-k8s
- Project documentation: https://docs.aws.amazon.com/app-mesh/latest/userguide/mesh-k8s-integration.html
- AWS blog: Getting started with App Mesh and Amazon EKS

Security

Related security projects for Amazon EKS and Kubernetes clusters.
AWS IAM authenticator

A tool to use AWS IAM credentials to authenticate to a Kubernetes cluster if you’re not using the AWS CLI version 1.16.156 or higher. For more information, see Installing aws-iam-authenticator (p. 271).

- Project URL: https://github.com/kubernetes-sigs/aws-iam-authenticator
- Project documentation: https://github.com/kubernetes-sigs/aws-iam-authenticator/blob/master/README.md
- AWS open source blog: Deploying the AWS IAM authenticator to kops

Machine learning

Related machine learning projects for Amazon EKS and Kubernetes clusters.

Kubeflow

A machine learning toolkit for Kubernetes.

- Project URL: https://www.kubeflow.org/
- Project documentation: https://www.kubeflow.org/docs/
- AWS open source blog: Kubeflow on Amazon EKS

Auto Scaling

Related auto scaling projects for Amazon EKS and Kubernetes clusters.

Cluster autoscaler

Cluster Autoscaler is a tool that automatically adjusts the size of the Kubernetes cluster based on CPU and memory pressure.

- Project URL: https://github.com/kubernetes/autoscaler/tree/master/cluster-autoscaler
- Project documentation: https://github.com/kubernetes/autoscaler/blob/master/cluster-autoscaler/cloudprovider/aws/README.md
- Amazon EKS workshop: https://eksworkshop.com/scaling/deploy_ca/

Escalator

Escalator is a batch or job optimized horizontal autoscaler for Kubernetes.

- Project URL: https://github.com/atlassian/escalator
- Project documentation: https://github.com/atlassian/escalator/blob/master/docs/README.md

Monitoring

Related monitoring projects for Amazon EKS and Kubernetes clusters.
Prometheus

Prometheus is an open-source systems monitoring and alerting toolkit.

- Project URL: https://prometheus.io/
- Project documentation: https://prometheus.io/docs/introduction/overview/
- Amazon EKS workshop: https://eksworkshop.com/intermediate/240_monitoring/

Continuous integration / continuous deployment

Related CI/CD projects for Amazon EKS and Kubernetes clusters.

Jenkins X

CI/CD solution for modern cloud applications on Amazon EKS and Kubernetes clusters.

## Document history for Amazon EKS

The following table describes the major updates and new features for the Amazon EKS User Guide. We also update the documentation frequently to address the feedback that you send us.

<table>
<thead>
<tr>
<th>update-history-change</th>
<th>update-history-description</th>
<th>update-history-date</th>
</tr>
</thead>
<tbody>
<tr>
<td>View node and workload resources in the AWS Management Console</td>
<td>You can now view details about your managed, self-managed, and Fargate nodes and your deployed Kubernetes workloads in the AWS Management Console.</td>
<td>December 1, 2020</td>
</tr>
<tr>
<td>Deploy Spot Instance types in a managed node group</td>
<td>You can now deploy multiple Spot or On-Demand Instance types to a managed node group.</td>
<td>December 1, 2020</td>
</tr>
<tr>
<td>Amazon EKS can now manage specific add-ons for your cluster</td>
<td>You can manage add-ons yourself, or let Amazon EKS control the launch and version of an add-on through the Amazon EKS API for clusters running Kubernetes version 1.18 with platform version eks.3 or later.</td>
<td>December 1, 2020</td>
</tr>
<tr>
<td>Share an ALB across multiple Ingresses</td>
<td>You can now share an AWS Application Load Balancer across multiple Kubernetes Ingresses. In the past, you had to deploy a separate Application Load Balancer for each Ingress.</td>
<td>October 23, 2020</td>
</tr>
<tr>
<td>NLB IP target support</td>
<td>You can now deploy a network load balancer (NLB) with IP targets. This enables you to use an NLB to load balance network traffic to Fargate pods and directly to pods running on Amazon EC2 nodes.</td>
<td>October 23, 2020</td>
</tr>
<tr>
<td>Kubernetes version 1.18</td>
<td>Added Kubernetes version 1.18 support for new clusters and version upgrades.</td>
<td>October 13, 2020</td>
</tr>
<tr>
<td>Specify a custom CIDR block for Kubernetes service IP address assignment.</td>
<td>You can now specify a custom CIDR block that Kubernetes will assign service IP addresses from.</td>
<td>September 29, 2020</td>
</tr>
<tr>
<td>Assign security groups to individual pods</td>
<td>You can now associate different security groups to some of the individual pods running on many Amazon EC2 instance types.</td>
<td>September 9, 2020</td>
</tr>
<tr>
<td>Deploy Bottlerocket on your nodes</td>
<td>You can now deploy nodes running Bottlerocket.</td>
<td>August 31, 2020</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------</td>
</tr>
<tr>
<td>The ability to launch Arm nodes is generally available</td>
<td>You can now launch Arm nodes in managed and self-managed node groups.</td>
<td>August 17, 2020</td>
</tr>
<tr>
<td>Managed node group launch templates and custom AMI</td>
<td>You can now deploy a managed node group using an Amazon EC2 launch template. The launch template can specify a custom AMI, if you choose.</td>
<td>August 17, 2020</td>
</tr>
<tr>
<td>EFS support for AWS Fargate</td>
<td>You can now use Amazon EFS with AWS Fargate.</td>
<td>August 17, 2020</td>
</tr>
<tr>

<tr>
<td>-------</td>
<td>-------------</td>
<td>------</td>
</tr>
<tr>
<td><strong>Amazon EKS platform version update</strong></td>
<td>New platform version for Kubernetes 1.12 clusters to support custom DNS names in the Kubelet certificate and improve etcd performance. This fixes a bug that caused node Kubelet daemons to request a new certificate every few seconds.</td>
<td>May 8, 2019</td>
</tr>
<tr>
<td><strong>Prometheus tutorial</strong></td>
<td>Added topic for deploying Prometheus to your Amazon EKS cluster.</td>
<td>April 5, 2019</td>
</tr>
<tr>
<td><strong>Amazon EKS control plane logging</strong></td>
<td>Amazon EKS control plane logging makes it easy for you to secure and run your clusters by providing audit and diagnostic logs directly from the Amazon EKS control plane to CloudWatch Logs in your account.</td>
<td>April 4, 2019</td>
</tr>
<tr>
<td><strong>Kubernetes version 1.12 (p. 381)</strong></td>
<td>Added Kubernetes version 1.12 support for new clusters and version upgrades.</td>
<td>March 28, 2019</td>
</tr>
<tr>
<td><strong>Added App Mesh getting started guide</strong></td>
<td>Added documentation for getting started with App Mesh and Kubernetes.</td>
<td>March 27, 2019</td>
</tr>
<tr>
<td><strong>Amazon EKS API server endpoint private access</strong></td>
<td>Added documentation for disabling public access for your Amazon EKS cluster's Kubernetes API server endpoint.</td>
<td>March 19, 2019</td>
</tr>
<tr>
<td><strong>Added topic for installing the Kubernetes Metrics Server</strong></td>
<td>The Kubernetes Metrics Server is an aggregator of resource usage data in your cluster.</td>
<td>March 18, 2019</td>
</tr>
<tr>
<td><strong>Added list of related open source projects</strong></td>
<td>These open source projects extend the functionality of Kubernetes clusters running on AWS, including clusters managed by Amazon EKS.</td>
<td>March 15, 2019</td>
</tr>
<tr>
<td><strong>Added topic for installing Helm locally</strong></td>
<td>The helm package manager for Kubernetes helps you install and manage applications on your Kubernetes cluster. This topic helps you install and run the helm and tiller binaries locally so that you can install and manage charts using the helm CLI on your local system.</td>
<td>March 11, 2019</td>
