What Is Amazon Fraud Detector?

Amazon Fraud Detector is a fully managed service that makes it easy to identify potentially fraudulent online activities such as online payment fraud and the creation of fake accounts. Amazon Fraud Detector uses your data, machine learning (ML), and more than 20 years of fraud detection expertise from Amazon to automatically identify potentially fraudulent online activity so you can catch more fraud faster.

Amazon Fraud Detector enables you to build fraud-detection models. You don't need ML experience to start using Amazon Fraud Detector, you only need to provide your company's historical fraud data. Amazon Fraud Detector uses this data to automatically train, test, and deploy a customized fraud detection model. During this process, a series of models that have learned patterns of fraud from AWS and Amazon's own fraud expertise are used to boost your model's performance. To use the model, call the Amazon Fraud Detector GetEventPrediction API with meta data about an online event and synchronously receive a fraud prediction score and an outcome based on your configuration.

Amazon Fraud Detector Overview

You don't need ML experience to use Amazon Fraud Detector. Simply upload your data to train, test, and deploy a fraud-detection model. Deployed models are imported to detectors, where you can configure decision logic (for example rules) to interpret the model's score and assign outcomes such as pass or send transaction to a human investigator for review.

To use the model, call the Amazon Fraud Detector GetEventPrediction API with meta data about an online event. Amazon Fraud Detector synchronously returns a fraud prediction score and an outcome based on your detector configuration. For example, you can send Amazon Fraud Detector metadata for an online transaction event, such as price, product name, and shipping address of the purchasing entity, and determine the appropriate action for the transaction based on your deployed model and detector configuration.

Note
Amazon Fraud Detector is available in the US East (N. Virginia), US East (Ohio), US West (Oregon), Europe (Ireland), Asia Pacific (Singapore) and Asia Pacific (Sydney) AWS regions.

How to Use this Guide

If you are a new user of Amazon Fraud Detector, read the following sections to get started:

1. How Amazon Fraud Detector works (p. 2) – Introduction to Amazon Fraud Detector concepts that you use to create fraud detection models and fraud evaluations.
2. Set up Amazon Fraud Detector (p. 4) – Prerequisite steps to get started with Amazon Fraud Detector.
3. Get started (console) (p. 6) – Tutorial that walks you through how to use Amazon Fraud Detector.

For information about Amazon Fraud Detector the API operations, see the Amazon Fraud Detector API Reference.
How Amazon Fraud Detector works

To generate fraud predictions, Amazon Fraud Detector uses machine learning models that are trained with your historical fraud data. Each model is trained using a model type, which is a specialized recipe to build a fraud detection model for a specific fraud use case. Deployed models are imported to detectors, where you can configure decision logic (for example, rules) to interpret the model's score and assign outcomes such as pass or send transaction to a human investigator for review.

You can use the AWS Console to create and manage models and detector versions. Alternatively, you can use the AWS Command Line Interface (AWS CLI) or one of the Amazon Fraud Detector SDKs.

Amazon Fraud Detector components include events, entities, labels, models, rules, variables, outcomes, and detectors. Using these components, you can build an evaluation that contains your fraud detection logic.

For additional information about Amazon Fraud Detector concepts and how they operate, see Amazon Fraud Detector concepts (p. 2).

Amazon Fraud Detector workflow

The steps for creating a model, building a detector, and getting fraud predictions include:

1. Define the event you want to evaluate for fraud.
2. Gather historical event data (training data).
3. Create a model version (trained model) using a model type.
4. Create a detector that includes the model version and decision rules.
5. Send events to Amazon Fraud Detector and get a fraud prediction.

Amazon Fraud Detector concepts

Key concepts for understanding Amazon Fraud Detector include:

Events and Event Types

An event is a business activity that is evaluated for fraud risk. With Amazon Fraud Detector, you generate fraud predictions for events.

An event type defines the structure for an event sent to Amazon Fraud Detector. This includes the variables sent as part of the event, the entity performing the event (such as a customer), and the labels that classify the event. Example event types include online payment transactions, account registrations, and authentication.

Entity and Entity Type

An entity represents who is performing the event. As part of a fraud prediction, you can pass the entity ID to indicate the specific entity who performed the event.

An entity type classifies the entity. Example classifications include customer, merchant, or account.

Label

A label classifies an event as fraudulent or legitimate. Labels are used to train supervised machine learning models in Amazon Fraud Detector.
Model type

The model type defines the algorithms, enrichments, and feature transformations used during model training as well as the data requirements to train the model.

Model training and Model Versions

Model training is the process of using a provided dataset to create a model that can predict fraudulent events. All steps in the model training process are fully automated including data validation, data transformation, feature engineering, algorithm selection, training, and model optimization. In Amazon Fraud Detector, the output from training is called a model version.

Model deployment

When you deploy a model, you make a trained model version available for real-time fraud predictions. Only deployed model versions can be imported to detectors.

Amazon SageMaker model endpoint

In addition to building models using Amazon Fraud Detector, you can optionally use SageMaker-hosted model endpoints in Amazon Fraud Detector evaluations.

For more information about building a model in SageMaker, see Train a Model with Amazon SageMaker.

Detector

A detector contains the detection logic (such as the models and rules) for a particular event that you want to evaluate for fraud. A detector can have multiple versions, with each version having a status of Draft, Active, or Inactive. Only one detector version can be in Active status at a time.

Variable

A variable represents a data element associated with an event that you want to use in a fraud prediction. Variables can either be sent with an event as part of a fraud prediction or derived, such as the output of an Amazon Fraud Detector model or Amazon SageMaker model.

Rule

A rule is a condition that tells Amazon Fraud Detector how to interpret variable values during a fraud prediction. A rule consists of one or more variables, a logic expression, and one or more outcomes. The variables used in the rule must be part of the event evaluated by the detector. A detector must have at least one associated rule.

Outcome

This is the result, or output, from a fraud prediction. Each rule used in a fraud prediction must specify one or more outcomes.

Prediction

After you create a detector, you can generate fraud predictions by calling the GetEventPrediction API with your event variables and specifying which detector you want to use. The API always returns an outcome. If a model is used in the detector, Amazon Fraud Detector also returns the corresponding fraud prediction score.
Set up Amazon Fraud Detector

Before using Amazon Fraud Detector, you must have an Amazon Web Service (AWS) account. After you have an AWS account, you can access Amazon Fraud Detector console, the AWS Command Line Interface (AWS CLI), or the AWS SDKs.

After you complete these steps, see Get started (console) (p. 6) to continue getting started with Amazon Fraud Detector.

Sign up for AWS

When you sign up for Amazon Web Services (AWS), your AWS account is automatically signed up for all services in AWS, including Amazon Fraud Detector. You are charged only for the services that you use. If you have an AWS account already, skip to the next task. If you don’t have an AWS account, use the following procedure to create one.

To create an AWS account

1. Open https://aws.amazon.com and then choose Create an AWS Account.
2. Follow the on-screen instructions to complete the account creation. Note your 12-digit AWS account number.

Setting up permissions

To use Amazon Fraud Detector, you have to set up permissions that allow access to the Amazon Fraud Detector console and API operations. You also have to allow Amazon Fraud Detector to perform tasks on your behalf and to access resources that you own.

We recommend creating an AWS Identity and Access Management (IAM) user with access restricted to Amazon Fraud Detector operations and required permissions. You can add other permissions as needed.

The following policies provide the required permission to use Amazon Fraud Detector:

- AmazonFraudDetectorFullAccessPolicy
  Allows you to perform the following actions:
  - Access all Amazon Fraud Detector resources
  - List and describe all model endpoints in SageMaker
  - List all IAM roles in the account
  - List all Amazon S3 buckets
  - Allow IAM Pass Role to pass a role to Amazon Fraud Detector

- AmazonS3FullAccess
  Allows full access to Amazon S3. This is required if you need to upload training datasets to S3.

Create an IAM user and assign required permissions

The following describes how to create an IAM user and assign the needed permissions.
To create an IAM user and assign required permissions

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Users and then choose Add user.
3. For User name, enter AmazonFraudDetectorUser.
4. Select the AWS Management Console access check box, and then configure the user's password.
5. (Optional) By default, AWS requires the new user to create a new password when first signing in. You can clear the check box next to User must create a new password at next sign-in to allow the new user to reset their password after they sign in.
6. Choose Next: Permissions.
7. Choose Create group.
8. For Group name enter AmazonFraudDetectorGroup.
9. In the policy list, select the check box for AmazonFraudDetectorFullAccessPolicy and AmazonS3FullAccess. Choose Create group.
10. In the list of groups, select the check box for your new group. Choose Refresh if necessary to see the group in the list.
11. Choose Next: Tags.
12. (Optional) Add metadata to the user by attaching tags as key-value pairs. For more information about using tags in IAM, see Tagging IAM Users and Roles.
13. Choose Next: Review to see the User details and Permissions summary for the new user. When you are ready to proceed, choose Create user.
Get started (console)

Before you start this exercise, you must complete the steps in Set up Amazon Fraud Detector (p. 4).

This exercise consists of the following parts:

- In Part A: Build an Amazon Fraud Detector model (p. 6), you create a registration event and train a model by associating training data with the Amazon Fraud Detector Online Fraud Insights model type. Then, you train and deploy the model.
- In Part B: Generate real-time fraud predictions (p. 8), you create a detector to evaluate registrations events. You will add your deployed model, write rules to interpret the model output, and generate a fraud prediction.

Part A: Build an Amazon Fraud Detector model

The procedures in this section provide the steps for you to successfully train and deploy a fraud-detection model.

Topics
- Get and upload example training data (p. 6)
- Step 1: Create event to evaluate for fraud (p. 7)
- Step 2: Define model details (p. 7)
- Step 3: Configure training and train model (p. 7)
- Step 4: Review the trained model's performance (p. 8)
- Step 5: Deploy the model (p. 8)

Get and upload example training data

1. Download the following file, unzip and use one of the sample CSV files that contain fictitious, synthetically generated training data.
   
   Download: Training Data.zip.

   This zip file contains two files of synthetic registrations that you can use to train a model. The dataset registration_data_20K_minimum contains only two variables: ip_address and email_address. The dataset registration_data_20K_full contains additional variables for each event such as billing_address, phone_number, and user_agent. Both datasets also contains two mandatory fields:
   - EVENT_TIMESTAMP – Defines when the event occurred
   - EVENT_LABEL – Classifies the event as fraudulent or legitimate

2. Create an Amazon S3 bucket:
   
   a. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
   b. Choose Create bucket, and perform the steps to create your bucket. You must choose an AWS region where Amazon Fraud Detector is currently available: US East (N. Virginia), US East (Ohio), US West (Oregon), Europe (Ireland), Asia Pacific (Singapore) or Asia Pacific (Sydney).

   For this exercise, the generic name bucket-name is used. You must rename your bucket because Amazon S3 bucket names must be globally unique.
3. Upload a training data file (that is, one of the .csv files listed previously) to your Amazon S3 bucket.

Note the Amazon S3 location of your training file (for example, `s3://bucketname/path/to/some/object.csv`) and your role name. For details about formatting your dataset file, see Preparing training data (p. 17).

**Step 1: Create event to evaluate for fraud**

1. Open the AWS Console and sign in to your account. Navigate to Amazon Fraud Detector.
2. In the left navigation pane, choose **Events**.
3. On the **Events type** page, choose **Create**.
4. Enter `sample_registration` as the event type name.
5. In the Entity drop-down, select **Create entity**.
6. In **Create entity type**, enter `sample_customer` as the entity type name and, optionally, enter a description of the entity type.
7. Choose **Create entity**.
8. For **Event variables**, choose **Select variables from a training dataset**.
9. In **IAM role**, select **Create IAM role**. On the **Create IAM role** page, enter the specific bucket name where you uploaded your training data. Choose **Create role**.
10. In **Data location**, enter the path to your training data. Then choose **upload**. Amazon Fraud Detector will extract the headers from your training dataset.
11. To allow Amazon Fraud Detector to interpret your variables, you must map them to variable types. Map `ip_address` to “IP Address” and `email_address`, to “Email Address”.
12. For **Labels**, choose **Create new labels**.
13. In **Create label**, enter `fraud` as the label name as this label corresponds to the value that represents fraudulent events in the synthetic dataset.
14. Choose **Create label**.
15. Create a second label by following the same steps, this time entering `legit` as the label name as this corresponds to the value that represents legitimate events in the synthetic dataset.
16. Choose **Create event type**.

**Step 2: Define model details**

1. On the **Models** page, choose **Add model** and then choose **Create model**.
2. On **Step 1 – Define model details**, enter `sample_fraud_detection_model` as the model name and, optionally, enter a description of the model.
3. For **Model Type**, choose the **Online Fraud Insights** model.
4. For **Event type**, choose `sample_registration` (the event type you created in Step 1).
5. In **Historical event data**, for **IAM role**, select the role you created in Step 1.
6. In **Training data location**, enter the path to your training data.
7. Choose **Next**.

**Step 3: Configure training and train model**

1. In **Model inputs**, leave all checkboxes checked. By default, Amazon Fraud Detector will use all variables from your historical event dataset as model inputs.
Step 4: Review the trained model’s performance

An important step in using Amazon Fraud Detector is to assess the accuracy of your model using model scores and performance metrics.

After model training is complete, Amazon Fraud Detector validates model performance using 15% of your data that was not used to train the model. You can expect your trained Amazon Fraud Detector model to have real-world fraud detection performance that is similar to the validation performance metrics.

To learn more about model scores and model performance metrics, see Model scores (p. 21) and Model performance metrics (p. 22).

Step 5: Deploy the model

After you’ve validated your trained model and are ready to use it in real-time fraud predictions, you can deploy the model.

1. In the Amazon Fraud Detector console’s left navigation pane, choose Models.
2. In the Models page, choose sample_fraud_detection_model, and then choose the specific model version that you want to deploy (for example, version 1.0).
3. On the Model version page, choose Actions and then choose Deploy model version. The model version is now available to add to detectors, which is covered in Part B: Generate real-time fraud predictions (p. 8).

Part B: Generate real-time fraud predictions

In Amazon Fraud Detector, you create and configure detector versions to hold your fraud prediction logic. Fraud prediction logic consists of your deployed model and rules that tell Amazon Fraud Detector how to interpret the data associated with the model. In Part A, you created, trained, and deployed your model. In Part B, you will create a detector version.

To get a fraud prediction for an event, you send metadata about an online event using the GetEventPrediction API and then synchronously receive a fraud prediction outcome and model score. In Amazon Fraud Detector, you configure fraud prediction logic using these components: event types, models, variables, rules, outcomes, and detectors.

To create your fraud prediction logic in Amazon Fraud Detector, follow the steps in this section.
Step 1: Create a detector

You use a detector to house your fraud prediction configurations.

1. In the Amazon Fraud Detector console’s left navigation pane, choose Detectors.
2. Choose Create detector.
3. On Step 1 – Define detector details, enter sample_detector, and optionally enter a description for the detector, such as my sample fraud detector.
4. For Event Type, select sample_registration (the event you created in Part A of this exercise).
5. Choose Next.

Step 2: (Optional) Add a model to a detector

If you completed Part A of the Get Started exercise, you should already have an Amazon Fraud Detector model available to add to your detector. If you haven’t created a model yet, go to the model library, configure and train a new model, and then deploy it.

1. On Step 2 – Add model, choose Add Model, choose the Amazon Fraud Detector model name and version you created and deployed in Part A of the Get Started exercise from the list, and then choose Add model.
2. Choose Next.

Step 3: Add rules to a detector

After you have named your detector and added a model, you can create rules to interpret your Amazon Fraud Detector model’s score. For this exercise, you create three rules: high_fraud_risk, medium_fraud_risk, and low_fraud_risk.

1. On Step 3 – Add rules, enter high_fraud_risk for the rule name under Define a rule, and enter This rule captures events with a high ML model score as the description for the rule.
2. In Expression, enter the following rule expression using the Amazon Fraud Detector simplified rule expression language:

   $sample_fraud_detection_model_insightscore > 900

3. In Outcomes, choose Create a new outcome. An outcome is the result from a fraud prediction and is returned if the rule matches during an evaluation.
4. In Create a new outcome, enter verify_customer as the outcome name. Optionally, enter a description.
5. Choose Save outcome. For details, see Create an outcome (p. 37).
6. Choose Add rule to run the rule validation checker and save the rule. After it’s created, Amazon Fraud Detector makes the rule available for use in your detector.
7. Choose Add another rule, and then choose the Create rule tab.
Step 4: Configure rule execution and define rule order

8. Repeat this process twice more to create your medium_fraud_risk and low_fraud_risk rules using the following rule details:

   • medium_fraud_risk
     
     Rule name: medium_fraud_risk
     
     Outcome: review
     
     Expression:
     
     $sample_fraud_detection_model_insightscore <= 900 and $sample_fraud_detection_model_insightscore > 700

   • low_fraud_risk
     
     Rule name: low_fraud_risk
     
     Outcome: approve
     
     Expression:
     
     $sample_fraud_detection_model_insightscore <= 700

   These values are examples only. When creating rules for your own detector, you should use values that are appropriate based on your model, data and business.

9. After you have created all three rules, choose Next.

   For more information about creating and writing rules, see Create a rule (p. 28) and Rule language reference (p. 30).

Step 4: Configure rule execution and define rule order

The rule execution mode for the rules included in the detector version determines if all the rules you define are evaluated, or if rule evaluation stops at the first matched rule. You can define and edit the rule execution mode at the detector version level, when the detector version is in draft status.

The default rule execution mode is FIRST_MATCHED.

First matched

First matched rule execution mode returns the outcomes for the first matching rule based on defined rule order. If you specify FIRST_MATCHED, Amazon Fraud Detector evaluates rules sequentially, first to last, stopping at the first matched rule. Amazon Fraud Detector then provides the outcomes for that single rule.

The order in which you execute rules can affect the resulting fraud prediction outcome. After you have created your rules, re-order the rules to execute them in the desired order by following these steps:

   If your high_fraud_risk rule is not already on the top of your rule list, choose Order, and then choose 1. This moves high_fraud_risk to the first position.

   Repeat this process so that your medium_fraud_risk rule is in the second position and your low_fraud_risk rule is in the third position.
All matched

All matched rule execution mode returns outcomes for all matched rules, regardless of rule order. If you specify ALL_MATCHED, Amazon Fraud Detector evaluates all rules and returns the outcomes for all matched rules.

Select FIRST_MATCHED and then choose Next.

Step 5: Review and create detector version

Next, review your detection logic and create the first version of your detector.

1. Review the detector details, models, and rules you have configured. If you need to make any changes, choose Edit next to the corresponding section.
2. Choose Create detector. After it’s created, the first version of your detector appears in the Detector versions table with Draft status.

Step 6: Test and get predictions

In the Amazon Fraud Detector console, you can test your detector’s logic using mock event data with the Run test feature.

1. Scroll to Run test at the bottom of the Detector version details page.
2. For Event metadata, enter a timestamp of when the event occurred, as well as a unique identifier for the entity performing the event. For this exercise, select a date from the date picker for timestamp, and enter “1234” for the Entity ID.
3. For Event variable, enter the variable values that you would like to test. For this exercise, you only need two input fields (that is, ip_address and email_address) because these are the inputs used to train your Amazon Fraud Detector model. You can use the following example values (assuming you used the suggested variable names):
   - ip_address: 205.251.233.178
   - email_address: johndoe@exampledomain.com
4. Choose Run test.
5. Amazon Fraud Detector returns the fraud prediction outcome based on the rule execution mode. If the rule execution mode is FIRST_MATCHED, then the returned outcome corresponds to the first rule (the highest priority) that matched (evaluated to true). If the rule execution mode is ALL_MATCHED, then the returned outcome corresponds to all rules that matched (evaluated to be true). Amazon Fraud Detector also returns the model score for any models added to your detector.
6. When you are satisfied that the detector is working as expected, you can promote it from Draft to Active, which makes the detector available for use in real-time fraud detection.

On the Detector version details page, choose Actions, Publish, Publish version. This changes the detector’s status from Draft to Active.

At this point, your model and associated detector logic are ready to evaluate online activities for fraud in real-time using the Amazon Fraud Detector GetEventPrediction API. Alternatively, you can evaluate events offline, using a CSV input file and the CreateBatchPredictionJob API. For a code sample, see Get fraud predictions (p. 49).
Get started (AWS SDK for Python)

This topic explains how to get started programming Amazon Fraud Detector with the AWS SDK for Python (Boto3). For instruction on completing this exercise using the AWS Console, see Get started (console) (p. 6).

Prerequisites

The following are prerequisite steps for using the Python examples in this guide. Ensure you are using the Boto3 SDK version 1.14.29 or higher.

- Complete Set up Amazon Fraud Detector (p. 4).
- Complete Get and upload example training data (p. 6) to upload the training data required for this exercise.

Step 1: Setup and verify your Python environment

Boto is the Amazon Web Services (AWS) SDK for Python. It enables Python developers to create, configure, and manage AWS services. For details on how to install Boto3, refer to the AWS SDK for Python (Boto3).

After installing, run the following Python example to confirm that your environment is configured correctly. If your environment is configured correctly, the response will contain a list of detectors. If no detectors have been created, the list will be empty.

```python
import boto3
fraudDetector = boto3.client('frauddetector')
response = fraudDetector.get_detectors()
print(response)
```

Step 2: Create variables, entity type, and labels

After you verify that your Python environment is configured correctly, create the component resources that will be used in your events, models, and rules.

1. Create variables. A variable is a data element that can be used in models and rules. For a code sample, see Create a variable (p. 34).
2. Create an entity type. An entity type classifies who is performing the event, such as a customer or a merchant. For a code sample, see Create an entity type (p. 38).
3. Create labels. Labels are used to classify events as either fraudulent or legitimate. For a code sample, see Create a label (p. 39).

Step 3: Create event type

After you have created your component resources, you can create an event type. With Amazon Fraud Detector, you generate fraud predictions for events. An event type defines the structure for an individual
Step 4: Create and train a model

Amazon Fraud Detector models learn to detect fraud for a specific event type. In Amazon Fraud Detector, you first create a model, which acts as a container for your model versions. Each time you train a model, a new version is created. For a code sample, see Building a model (p. 20).

The example code trains an Online Fraud Insights model using data stored in Amazon S3. Online Fraud Insights is a supervised machine learning model that can be adapted to detect a variety of online fraud and abuse risks such as new account fraud, online transaction fraud, and fraudulent reviews.

Once model training is complete, you can review model performance in the AWS Console or programmatically by calling the DescribeModelVersions API. To learn more, refer to Model performance metrics (p. 22).

After reviewing the model performance, activate the model to make it available for use by detectors in real-time fraud predictions. For a code sample, see Building a model (p. 20).

Step 5: Create a detector, outcome, rules, and detector version

A detector contains the detection logic, such as the models and rules, for a particular event that you want to evaluate for fraud. During a fraud prediction, you will specify the detector that you want to use to evaluate your event. To create a detector, complete the following steps.

1. Create a detector. A detector acts as a container for your detector versions. For a code sample, Create a detector (p. 27).
2. Create outcomes. An outcome is the result of a fraud prediction. For example, you may want outcomes to represent risk levels (high_risk, medium_risk, and low_risk). For a code sample, see Create an outcome (p. 37).
3. Create rules. A rule is a condition that tells Amazon Fraud Detector how to interpret variable values during a fraud prediction. A rule consists of one or more variables, a logic expression, and one or more outcomes. For a code sample, see Create a rule (p. 28).
4. Create a detector version. A detector version defines the specific models and rules that will be run as part of a fraud prediction. For a code sample, see Create a detector version (p. 27).

Step 6: Generate fraud predictions

To get fraud predictions, call the GetEventPrediction API or the CreateBatchPredictionJob API. Supply information about the event you want to evaluate and synchronously receive a model score and outcome based on the designated detector. For a code sample, see Get fraud predictions (p. 49).

(Optional) Explore the Amazon Fraud Detector APIs with a Jupyter (iPython) Notebook

For additional examples on how to use the Amazon Fraud Detector APIs, refer to the aws-fraud-detector-samples GitHub repository. Topics covered by the notebooks include building models and
detectors using the Amazon Fraud Detector APIs and making batch fraud prediction requests using the `GetEventPrediction` API.
Create event types

With Amazon Fraud Detector, you generate fraud predictions for events. An event type defines the structure for an individual event sent to Amazon Fraud Detector. Once defined, you can build models and detectors that evaluate the risk for specific event types.

The structure of an event includes the following:

- **Entity Type**: Classifies who is performing the event. During prediction, specify the entity type and entity id to define who performed the event.
- **Variables**: Defines what variables can be sent as part of the event. Variables are used by models and rules to evaluate fraud risk. Once added, variables cannot be removed from an event type.
- **Labels**: Classifies an event as fraudulent or legitimate. Used during model training. Once added, labels cannot be removed from an event type.

For details on how to create an event type using the AWS Console see Step 1: Create event to evaluate for fraud (p. 7).

Create an event type using the AWS SDK for Python (Boto3)

The following example shows a sample request for the `PutEventType` API. The example assumes you have created the variables `ip_address` and `email_address`, the labels `legit` and `fraud`, and the entity type `sample_customer`. For information about how to create these resources, see Create resources (p. 34).

**Note**
You must first create variables, entity types, and labels prior to adding them to the event type.

```python
import boto3
fraudDetector = boto3.client('frauddetector')

fraudDetector.put_event_type (
    name = 'sample_registration',
    eventVariables = ['ip_address', 'email_address'],
    labels = ['legit', 'fraud'],
    entityTypes = ['sample_customer'])
```
Create model

A model version is the term Amazon Fraud Detector uses for a trained fraud detection machine learning model. All steps in the model training process are fully automated including data validation, data transformation, feature engineering, algorithm selection, training, and model optimization. Creating a model requires selecting the model type and specifying the model version configuration. The model type specifies the algorithms and transformations used to build the model.

Topics
- Online fraud insights (p. 16)
- Uploading to an Amazon S3 bucket (p. 19)
- Building a model (p. 20)
- Model scores (p. 21)
- Model performance metrics (p. 22)
- Model variable importance (p. 23)
- Import a SageMaker model (p. 25)

Online fraud insights

Amazon Fraud Detector Online Fraud Insights is a supervised machine learning model designed to detect a variety of online fraud and risks. Because the model is supervised, it requires historical examples of fraudulent and legitimate events to train the model.

The Online Fraud Insights model uses an ensemble of machine-learning algorithms for data enrichment, transformation, and fraud classification. As part of the model training process, Online Fraud Insights enriches raw data elements like IP address and BIN number with 3rd party data such as the geo-location of the IP address or the issuing bank for a credit card. In addition to 3rd party data, Online Fraud Insights uses deep learning algorithms leveraging fraud patterns seen at Amazon and AWS. These fraud patterns become input features to your model using a gradient tree boosting algorithm.

To increase performance, Online Fraud Insights optimizes the hyper parameters of the gradient tree boosting algorithm via a Bayesian optimization process, sequentially training dozens of different models with varying model parameters (such as number of trees, depth of trees, number of samples per leaf) as well as different optimization strategies like upweighting the minority fraud population to take care of very low fraud rates.

By adapting the variables included in the model, Online Fraud Insights can be used to detect a variety of online fraud including:

- New account fraud: Accurately distinguish between legitimate and high-risk customer account registrations so you can selectively introduce additional steps or checks based on risk.
- Online payment fraud: Reduce online payment fraud by flagging suspicious online payment transactions before processing payments and fulfilling orders.
- Guest checkout fraud: Spot potential fraudsters among customers without transaction histories. You can send as little as two pieces of data from a guest checkout order (for example, email, IP address) to assess its potential fraud risk.
• Fake reviews abuse: Detect potentially fraudulent or fake reviews so that you can review prior to posting.

Preparing training data

Amazon Fraud Detector imports data only from files that are in the comma-separated values (CSV) format. Amazon Fraud Detector requires that the first row of your CSV file to contain column headers. The column headers in your CSV file need to map to the variables defined in the event type. For an example dataset, see Get and upload example training data (p. 6).

The Online Fraud Insights model requires a training dataset that has at least two variables, 10K total examples, and 400 examples of fraud to train a model. Amazon Fraud Detector will automatically re-balance your dataset if the percentage of events associated to fraud is less than 5%. This improves model performance and results in faster and more stable model tuning.

In addition to the event variables, the training dataset must contain the following headers:

• **EVENT_TIMESTAMP**: Defines when the event occurred. For more information, see Event Timestamps Format.
• **EVENT_LABEL**: Classifies the event as fraudulent or legitimate. The values in the column must correspond to the values defined in the event type.

For example, the following sample CSV data maps to the event type shown in Create event types (p. 15). This data represents historical registration events from an online merchant:

<table>
<thead>
<tr>
<th>EVENT_TIMESTAMP</th>
<th>EVENT_LABEL</th>
<th>ip_address</th>
<th>email_address</th>
</tr>
</thead>
<tbody>
<tr>
<td>4/10/2019 11:05</td>
<td>fraud</td>
<td>209.146.137.48</td>
<td><a href="mailto:fake_burtonlinda@example.net">fake_burtonlinda@example.net</a></td>
</tr>
<tr>
<td>12/20/2018 20:04</td>
<td>legit</td>
<td>203.0.112.189</td>
<td><a href="mailto:fake_davidbutler@example.org">fake_davidbutler@example.org</a></td>
</tr>
<tr>
<td>3/14/2019 10:56</td>
<td>legit</td>
<td>169.255.33.54</td>
<td><a href="mailto:fake_shelby76@example.net">fake_shelby76@example.net</a></td>
</tr>
<tr>
<td>1/3/2019 8:38</td>
<td>legit</td>
<td>192.119.44.26</td>
<td><a href="mailto:fake_curtis40@example.com">fake_curtis40@example.com</a></td>
</tr>
<tr>
<td>9/25/2019 3:12</td>
<td>legit</td>
<td>192.169.85.29</td>
<td><a href="mailto:fake_rmiranda@example.org">fake_rmiranda@example.org</a></td>
</tr>
</tbody>
</table>

A simplified version of the corresponding event type is represented below. The event variables correspond to the headers in the CSV file and the values in EVENT_LABEL correspond to the values in the labels list.

```python
{
    name = 'sample_registration',
    eventVariables = ['ip_address', 'email_address'],
    labels = ['legit', 'fraud'],
    entityTypes = ['sample_customer']
}
```

Data set guidance

The following guidance for training data will help you get the most out of your Online Fraud Insights model.

Gathering data

We recommend that you collect a minimum of six weeks of historic data, though three - six months of data is preferable. There is a maximum file size of 5GB. If the recommended six weeks of historic data exceeds this threshold, shorten the time range of your extraction.
Model variables

The Online Fraud Insights model requires at least two variables for model training. Generally, the more variables you provide the better the model can differentiate between fraud and legitimate events.

**EVENT_TIMESTAMP**

You must include the header **EVENT_TIMESTAMP**. Ensure your event timestamp is in the required format. For more information, see Timestamp formats (p. 18). As part of the model build process, the Online Fraud Insights model type orders your data based on the event timestamp, and splits your data for training and testing purposes. To get a fair estimate of performance, the model first trains on the training dataset, then tests this model on the test dataset.

**EVENT_LABEL**

You must include the header **EVENT_LABEL**. The Online Fraud Insights model requires a minimum of 400 observations are identified and labeled as “fraud”.

Data and label maturity

Ensure that records used to train the model have had sufficient time to “mature”, that is, enough time has passed to ensure “legitimate” and “fraud” records have been correctly identified. The maturity period is dependent on your business, and can take anywhere from two weeks to 90 days. For example, for chargeback fraud, it often takes 30 - 60 days (or more) to correctly identify fraudulent events. For the best model performance, ensure that all records in your training dataset are mature. For example, if your maturity is 30 days, ensure that the latest records in your dataset are at least 30 days old.

Sampling

The Online Fraud Insights training process will sample and partition historic data based on **EVENT_TIMESTAMP**. There is no need to manually sample the data and doing so may negatively impact your model results.

Nulls and missing values

Online Fraud Insights handles null and missing values. However, the percentage of nulls for variables should be limited. **EVENT_TIMESTAMP** and **EVENT_LABEL** columns should not contain any missing values.

Timestamp formats

Amazon Fraud Detector supports the following date/timestamp formats for the values in **EVENT_TIMESTAMP** during model training:

- %yyyyMMdd-mm-ddT%hh:%mm:%ssZ (ISO 8601 standard in UTC only with no milliseconds)
  
  Example: 2019-11-30T13:01:01Z

- %yyyy/mm/dd %hh:mm:ss (AM/PM)
  
  Examples: 2019/11/30 1:01:01 PM, or 2019/11/30 13:01:01

- %mm/dd/yyyy %hh:mm:ss
  
  Examples: 11/30/2019 1:01:01 PM, 11/30/2019 13:01:01

- %mm/dd/yyyy %hh:mm:ss
  
  Examples: 11/30/19 1:01:01 PM, 11/30/19 13:01:01
Amazon Fraud Detector makes the following assumptions when parsing date/timestamp formats for event timestamps:

- If you are using the ISO 8601 standard, it must be an exact match of the above specification
- If you are using one of the other formats, there is additional flexibility:
  - For months and days, you can provide single or double digits. For example, 1/12/2019 is a valid date.
  - You do not need to include hh:mm:ss if you do not have them (e.g. you can simply provide a date). You can also provide a subset of just the hour and minutes (e.g. hh:mm). Just providing hour is not supported. Milliseconds are also not supported.
  - If you provide AM/PM labels, a 12-hour clock is assumed. If there is no AM/PM information, a 24-hour clock is assumed.
  - You can use “/” or “-” as delimiters for the date elements. “:” is assumed for the timestamp elements.

Training data validations

As part of the training process, Online Fraud Insights will validate the training dataset for data quality issues that may impact model training. After validating the data, Amazon Fraud Detector will take appropriate action to build the best possible model. This includes issuing warnings for potential data quality issues, automatically removing variables that have data quality issues, or issuing an error and stopping the model training process.

Amazon Fraud Detector will fail to train a model if any of the following conditions are triggered:

- If the CSV is unable to be parsed
- If the datatype for a column is incorrect
- If the number of rows is < 10k
- If the number of rows identified as fraud or legitimate are < 400
- If more than 0.1% of values in EVENT_TIMESTAMP contains nulls or values other than the supported date/timestamp formats
- If more than 1% of the values in EVENT_LABEL contains nulls or values other than those defined in the event type
- If less than two variables are available for model training

Uploading to an Amazon S3 bucket

After you create a CSV file with your data, upload the file to your Amazon Simple Storage Service (Amazon S3) bucket.

To upload to an Amazon S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Choose Create bucket.
   - The Create bucket wizard opens.
3. In Bucket name, enter a DNS-compliant name for your bucket.
   - The bucket name must:
     - Be unique across all of Amazon S3.
Building a model

Amazon Fraud Detector models learn to detect fraud for a specific event type. In Amazon Fraud Detector, you first create a model, which acts as a container for your model versions. Each time you train a model, a new version is created. For details on how to create and train a model using the AWS Console see Step 2: Define model details (p. 7).

Each model has a corresponding model score variable. Amazon Fraud Detector creates this variable on your behalf when you create a model. You can use this variable in your rule expressions to interpret your model scores during a fraud evaluation.

Train and deploy a model using the AWS SDK for Python (Boto3)

A model version is created by calling the CreateModel and CreateModelVersion operations. CreateModel initiates the model, which acts as a container for your model versions. CreateModelVersion starts the training process, which results in a specific version of the model. A new version of the solution is created each time you call CreateModelVersion.

The following example shows a sample request for the CreateModel API. This example assumes you have created an event type sample_registration. For additional details about creating an event type, see Create event types (p. 15).

```python
import boto3
fraudDetector = boto3.client('frauddetector')

fraudDetector.create_model (
    modelId = 'sample_fraud_detection_model',
    eventType = 'sample_registration',
)  
```
Train your first version using the `CreateModelVersion` API. `TrainingDataSource` and `ExternalEventsDetail` specify the source and Amazon S3 location of the training data set. `TrainingDataSchema` specifies how Amazon Fraud Detector should interpret the training data, specifically which event variables to include and how to classify the event labels.

```python
import boto3
fraudDetector = boto3.client('frauddetector')

fraudDetector.create_model_version(
    modelId = 'sample_fraud_detection_model',
    modelType = 'ONLINE_FRAUD_INSIGHTS',
    trainingDataSource = 'EXTERNAL_EVENTS',
    trainingDataSchema = {
        'modelVariables': ['ip_address', 'email_address'],
        'labelSchema': {
            'labelMapper': {
                'FRAUD': ['fraud'],
                'LEGIT': ['legit']
            }
        }
    },
    externalEventsDetail = {
        'dataLocation': 's3://bucket/file.csv',
        'dataAccessRoleArn': 'role_arn'
    }
)
```

A successful request will result in a new model version with status `TRAINING_IN_PROGRESS`. At any point during the training, you can cancel the training by calling `UpdateModelVersionStatus` and updating the status to `TRAINING_CANCELLED`. Once training is complete, the model version status will update to `TRAINING_COMPLETE`. You can review model performance using the Amazon Fraud Detector console or by calling `DescribeModelVersions`. For more information on how to interpret model scores and performance, see Model scores (p. 21) and Model performance metrics (p. 22).

After reviewing the model performance, activate the model to make it available to use by Detectors in real-time fraud predictions. Amazon Fraud Detector will deploy the model in multiple availability zones for redundancy with auto-scaling turned on to ensure the model scales with the number of fraud predictions you are making. To activate the model, call the `UpdateModelVersionStatus` API and update the status to `ACTIVE`.

```python
import boto3
fraudDetector = boto3.client('frauddetector')

fraudDetector.update_model_version_status(
    modelId = 'sample_fraud_detection_model',
    modelType = 'ONLINE_FRAUD_INSIGHTS',
    modelVersionNumber = '1.00',
    status = 'ACTIVE'
)
```

### Model scores

Amazon Fraud Detector generates model scores between 0 and 1000, where 0 is low fraud risk and 1000 is high fraud risk. Model scores are directly related to the false positive rate (FPR). For example, a score of 600 corresponds to an estimated 10% false positive rate whereas a score of 900 corresponds...
to an estimated 2% false positive rate. The following table provides details of how certain model scores correlate to estimated false positive rates.

<table>
<thead>
<tr>
<th>Model score</th>
<th>Estimated FPR</th>
</tr>
</thead>
<tbody>
<tr>
<td>975</td>
<td>0.50%</td>
</tr>
<tr>
<td>950</td>
<td>1%</td>
</tr>
<tr>
<td>900</td>
<td>2%</td>
</tr>
<tr>
<td>860</td>
<td>3%</td>
</tr>
<tr>
<td>775</td>
<td>5%</td>
</tr>
<tr>
<td>700</td>
<td>7%</td>
</tr>
<tr>
<td>600</td>
<td>10%</td>
</tr>
</tbody>
</table>

Model performance metrics

After model training is complete, Amazon Fraud Detector validates model performance using 15% of your data that was not used to train the model. You can expect your trained Amazon Fraud Detector model to have real-world fraud detection performance that is similar to the validation performance metrics.

As a business, you must balance between detecting more fraud, and adding more friction to legitimate customers. To assist in choosing the right balance, Amazon Fraud Detector provides the following tools to assess model performance:

- **Score distribution chart** – A histogram of model score distributions assumes an example population of 100,000 events. The left Y axis represents the legitimate events and the right Y axis represents the fraud events. You can select a specific model threshold by clicking on the chart area. This will update the corresponding views in the confusion matrix and ROC chart.
- **Confusion matrix** – Summarizes the model accuracy for a given score threshold by comparing model predictions versus actual results. Amazon Fraud Detector assumes an example population of 100,000 events. The distribution of fraud and legitimate events simulates the fraud rate in your businesses.
  - **True positives** – The model predicts fraud and the event is actually fraud.
  - **False positives** – The model predicts fraud but the event is actually legitimate.
  - **True negatives** – The model predicts legitimate and the event is actually legitimate.
  - **False negatives** – The model predicts legitimate but the event is actually fraud.
  - **True positive rate (TPR)** – Percentage of total fraud the model detects. Also known as capture rate.
  - **False positive rate (FPR)** – Percentage of total legitimate events that are incorrectly predicted as fraud.
- **Receiver Operator Curve (ROC)** – Plots the true positive rate as a function of false positive rate over all possible model score thresholds. View this chart by choosing Advanced Metrics.
- **Area under the curve (AUC)** – Summarizes TPR and FPR across all possible model score thresholds. A model with no predictive power has an AUC of 0.5, whereas a perfect model has a score of 1.0.

**To use the model performance metrics**

1. Start with the Score distribution chart to review the distribution of model scores for your fraud and legitimate events. Ideally, you will have a clear separation between the fraud and legitimate
events. This indicates the model can accurately identify which events are fraudulent and which are legitimate. Select a model threshold by clicking on the chart area. You can see how adjusting the model score threshold impacts your true positive and false positive rates.

**Note**
The score distribution chart plots the fraud and legitimate events on two different Y axis. The left Y axis represents the legitimate events and the right Y axis represents the fraud events.

2. Review the **Confusion matrix**. Depending on your selected model score threshold, you can see the simulated impact based on a sample of 100,000 events. The distribution of fraud and legitimate events simulates the fraud rate in your businesses. Use this information to find the right balance between true positive rate and false positive rate.

3. For additional details, choose **Advanced Metrics**. Use the ROC chart to understand the relationship between true positive rate and false positive rate for any model score threshold. The ROC curve can help you fine-tune the tradeoff between true positive rate and false positive rate.

**Note**
You can also review metrics in table form by choosing **Table**. The table view also shows the metric **Precision**. Precision is the percentage of fraud events correctly predicted as fraudulent as compared to all events predicted as fraudulent.

4. Use the performance metrics to determine the optimal model thresholds for your businesses based on your goals and fraud-detection use case. For example, if you plan to use the model to classify new account registrations as either high, medium, or low risk, you need to identify two threshold scores so you can draft three rule conditions as follows:

- Scores > X are high risk
- Scores < X but > Y are medium risk
- Scores < Y are low risk

### Model variable importance

**Model variable importance** is a feature of Amazon Fraud Detector that ranks model variables within a model version. Each model variable is provided a value based on its relative importance to the overall performance of your model. The model variable with the highest value is more important to the model than the other model variables in the dataset for that model version, and is listed at the top by default. Likewise, the model variable with the lowest value is listed at the bottom by default and is least important compared to the other model variables. Using model variable importance values, you can gain insight into what inputs are driving your model's performance.

You can view model variable importance values for your trained model version in the Amazon Fraud Detector console or by using the **DescribeModelVersion** API.

Model variable importance provides the following set of values for each **Variable** used to train the **Model Version**.

- **Variable Name**: Name of the model variable that was used to train the model version (for example, `ip_address` or `email_address`)
- **Variable Type**: Type of variable (for example, IP address or Email)
- **Variable Importance Value**: A number that represents the relative importance of the variable to the model's performance. Typical range: 0–10

In the Amazon Fraud Detector console, the model variable importance values are displayed as follows. The visual chart makes it easy to see the relative importance between variables with the vertical dotted line providing reference to the importance value of the highest ranked variable.
Amazon Fraud Detector User Guide

Using model variable importance values

Amazon Fraud Detector generates variable importance values for every Fraud Detector model version at no additional cost.

Important

Model versions that were created before July 9, 2021 do not have variable importance values.

You must train a new version of your model to generate the model variable importance values.

Using model variable importance values

You can use model variable importance values to gain insight into what is driving performance of your model up or down and which of variables contribute the most. And then tweak your model to improve overall performance.

More specifically, to improve your model performance, examine the variable importance values against your domain knowledge and debug issues in the training data. For example, if Account Id was used as an input to the model and it is listed at the top, take a look at its variable importance value. If the variable importance value is significantly higher than the rest of the values, then your model might be overfitting on a specific fraud pattern (for example, all the fraud events are from the same Account Id). However, it might also be the case that there is a label leakage if the variable depends on the fraud labels. Depending on the outcome of your analysis based on your domain knowledge, you might want to remove the variable and train with a more diverse dataset, or keep the model as it is.

Similarly, take a look at the variables ranked last. If the variable importance value is significantly lower than the rest of the values, then this model variable might not have any importance in training your model. You could consider removing the variable to train a simpler model version. If your model has few variables, such as only two variables, Amazon Fraud Detector still provides the variable importance values and rank the variables. However, the insights in this case will be limited.

Important

1. If you notice variables missing in the Model variable importance chart, it might be due to one of the following reasons. Consider modifying the variable in your dataset and retrain your model.
   • The count of unique values for the variable in the training dataset is lower than 100.
   • Greater than 0.9 of values for the variable are missing from the training data-set.

2. You need to train a new model version every time that you want to adjust your model's input variables.

Evaluating model variable importance values

We recommend that you consider the following when you evaluate model variable importance values:

• Variable importance values must always be evaluated in combination with the domain knowledge.

• Examine variable importance value of a variable relative to the variable importance value of the other variables within the model version. Do not consider variable importance value for a single variable independently.
• Compare variable importance values of the variables within the same model version. Do not compare variable importance values of the same variables across model versions because the variable importance value of a variable in a model version might differ from the value of the same variable in a different model version. If you use the same variables and dataset to train different model versions, this does not necessarily generate the same variable importance values.

Viewing model variable importance ranking

After model training is complete, you can view model variable importance ranking of your trained model version in the Amazon Fraud Detector console or by using the DescribeModelVersion API.

To view the model variable importance ranking using console,

1. Open the AWS Console and sign in to your account. Navigate to Amazon Fraud Detector.
2. In the left navigation pane, choose **Models**.
3. Choose your model and then your model version.
4. Make sure that the **Overview** tab is selected.
5. Scroll down to view the **Model variable importance** pane.

Understanding how the model variable importance value is calculated

Upon completion of each model version training, Amazon Fraud Detector automatically generates model variable importance values and model's performance metrics. For this, Amazon Fraud Detector uses Shapley Additive exPlanations (SHAP). SHAP is essentially the average expected contribution of a model variable after all possible combinations of all model variables have been considered.

SHAP first assigns contribution of each model variable for prediction of an event. Then, it aggregates these predictions to create a ranking of the variables at the model level. To assign contributions of each model variable for a prediction, SHAP considers differences in model outputs among all possible variable combinations. By including all possibilities of including or removing specific set of variables to generate a model output, SHAP can accurately access the importance of each model variable. This is particularly important when the model variables are highly correlated with one another.

ML models, in most cases, do not allow you to remove variables. You can instead replace a removed or missing variable in the model with the corresponding variable values from one or more baselines (for example, non-fraud events). Choosing proper baseline instances can be difficult, but Amazon Fraud Detector makes this easy by setting this baseline as the population average for you.

Import a SageMaker model

You can optionally import SageMaker-hosted models to Amazon Fraud Detector. Similar to models, SageMaker models can be added to detectors and generate fraud predictions using the GetEventPrediction API. As part of the GetEventPrediction request, Amazon Fraud Detector will invoke your SageMaker endpoint and pass the results to your rules.

You can configure Amazon Fraud Detector to use the event variables sent as part of the GetEventPrediction request. If you choose to use event variables, you must provide an input template. Amazon Fraud Detector will use this template to transform your event variables into the required input payload to invoke the SageMaker endpoint. Alternatively, you can configure your SageMaker model to use a byteBuffer that is sent as part of the GetEventPrediction request.
Amazon Fraud Detector supports importing SageMaker algorithms that use JSON or CSV input formats and JSON or CSV output formats. Examples of supported SageMaker algorithms include XGBoost, Linear Learner, and Random Cut Forest.

**Import a SageMaker model using the AWS SDK for Python (Boto3)**

To import a SageMaker model, use the `PutExternalModel` API. The following example assumes the SageMaker endpoint `sagemaker-transaction-model` has been deployed, is `InService` status, and uses the XGBoost algorithm.

The input configuration specifies that will use the event variables to construct the model input (`useEventVariables` is set to `TRUE`). The input format is `TEXT_CSV`, given XGBoost requires a CSV input. The `csvInputTemplate` specifies how to construct the CSV input from the variables sent as part of the `GetEventPrediction` request. This example assumes you have created the variables `order_amt`, `prev_amt`, `hist_amt` and `payment_type`.

The output configuration specifies the response format of the SageMaker model, and maps the appropriate CSV index to the Amazon Fraud Detector variable `sagemaker_output_score`. Once configured, you can use the output variable in rules.

**Note**
The output from a SageMaker model must be mapped to a variable with source `EXTERNAL_MODEL_SCORE`. You cannot create these variables in the console using Variables. You must instead create them when you configure your model import.

```python
import boto3
fraudDetector = boto3.client('frauddetector')

fraudDetector.put_external_model(
    modelSource = 'SAGEMAKER',
    modelEndpoint = 'sagemaker-transaction-model',
    invokeModelEndpointRoleArn = 'your_SagemakerExecutionRole_arn',
    inputConfiguration = {
        'useEventVariables' : True,
        'eventTypeName' : 'sample_transaction',
        'format' : 'TEXT_CSV',
        'csvInputTemplate' : '\{order_amt\}, \{prev_amt\}, \{hist_amt\}, \{payment_type\}'
    },
    outputConfiguration = {
        'format' : 'TEXT_CSV',
        'csvIndexToVariableMap' : {
            '0' : 'sagemaker_output_score'
        }
    },
    modelEndpointStatus = 'ASSOCIATED'
)
```
Create a detector

A detector contains the detection logic, such as the models and rules, for a particular event that you want to evaluate for fraud. Each detector can evaluate one event type.

A detector can have multiple versions, with each version having a status of DRAFT, ACTIVE, or INACTIVE. Only one detector version can be in ACTIVE status at a time.

To create a detector using the AWS Console, see Step 1: Create a detector (p. 9).

Create a detector using the AWS SDK for Python (Boto3)

The following example shows a sample request for the PutDetector API. A detector acts as a container for your detector versions. The PutDetector API specifies what event type the detector will evaluate. The following example assumes you have created an event type sample_registration.

```python
import boto3
fraudDetector = boto3.client('frauddetector')

fraudDetector.put_detector (
    detectorId = 'sample_detector',
    eventTypeName = 'sample_registration'
)
```

After you create a detector, you can Create a rule (p. 28).

Create a detector version

A detector version defines the specific models and rules that will be run as part of the GetEventPrediction request. You can add any of the rules defined within a detector to the detector version. You can also add any model trained on the evaluated event type.

Each detector version has a status of DRAFT, ACTIVE, or INACTIVE. Only one detector version can be in ACTIVE status at a time. During the GetEventPrediction request, Amazon Fraud Detector will use the ACTIVE detector if no DetectorVersion is specified.

To create a detector using the AWS Console, see Step 1: Create a detector (p. 9).

Rule execution mode

Amazon Fraud Detector supports two different rule execution modes: FIRST_MATCHED and ALL_MATCHED.

- If the rule execution mode is FIRST_MATCHED, Amazon Fraud Detector evaluates rules sequentially, first to last, stopping at the first matched rule. Amazon Fraud Detector then provides the outcomes for that single rule. If a rule evaluates to false (not matched), the next rule in the list is evaluated.
- If the rule execution mode is ALL_MATCHED, then all rules in an evaluation are executed in parallel, regardless of their order. Amazon Fraud Detector executes all rules and returns the defined outcomes for every matched rule.
Create a detector version using the AWS SDK for Python (Boto3)

The following example shows a sample request for the CreateDetectorVersion API. The example assumes you have created the rules described in Create a rule (p. 28) and the model sample_fraud_detection_model as described in Building a model (p. 20). The rule execution mode is set to FIRST_MATCHED, therefore Amazon Fraud Detector will evaluate rules sequentially, first to last, stopping at the first matched rule. Amazon Fraud Detector then provides the outcomes for that single rule during the GetEventPrediction response.

```python
import boto3

fraudDetector = boto3.client('frauddetector')

def create_detector_version():
    detectorId = 'sample_detector'
    rules = [(
        {'detectorId': 'sample_detector',
         'ruleId': 'high_fraud_risk',
         'ruleVersion': '1'},
        {'detectorId': 'sample_detector',
         'ruleId': 'medium_fraud_risk',
         'ruleVersion': '1'},
        {'detectorId': 'sample_detector',
         'ruleId': 'low_fraud_risk',
         'ruleVersion': '1'}),
    modelVersions = [
        {'modelId': 'sample_fraud_detection_model',
         'modelType': 'ONLINE_FRAUD_INSIGHTS',
         'modelVersionNumber': '1.00'}],
    ruleExecutionMode = 'FIRST_MATCHED'
    fraudDetector.create_detector_version(
        detectorId = detectorId,
        rules = rules,
        modelVersions = modelVersions,
        ruleExecutionMode = ruleExecutionMode)

create_detector_version()
```

To update the status of a detector version, use the UpdateDetectorVersionStatus API. The following example updates the detector version status from DRAFT to ACTIVE. During a GetEventPrediction request, if a detector ID is not specified, Amazon Fraud Detector will use the ACTIVE version of the detector.

```python
import boto3

fraudDetector = boto3.client('frauddetector')

def update_detector_version_status():
    detectorId = 'sample_detector'
    detectorVersionId = '1'
    status = 'ACTIVE'
    fraudDetector.update_detector_version_status(
        detectorId = detectorId,
        detectorVersionId = detectorVersionId,
        status = status)

update_detector_version_status()
```

Create a rule

A rule is a condition that tells Amazon Fraud Detector how to interpret variable values during a fraud prediction. A rule consists of one or more variables, a logic expression, and one or more outcomes. A
Expressions

Each rule must contain a single expression that captures your business logic. All expressions must evaluate to a Boolean value (true or false) and be less than 4,000 characters in length. If-else type conditions are not supported. All variables used in the expression must be predefined in the evaluated event type.

To create a rule using the AWS Console, see Step 3: Add rules to a detector (p. 9).

Create a rule using the AWS SDK for Python (Boto3)

The following example creates three different rules (high_fraud_risk, medium_fraud_risk, and low_fraud_risk). The example assumes you have completed the steps outlined in Building a model (p. 20) and created the model sample_fraud_detection_model. The example also assumes you have created the outcomes verify_customer, review, and approve (see Create an outcome (p. 37) for details on how to create an outcome). The expressions compare the model score output variable sample_fraud_detection_model_insightscore against various thresholds to determine the level of risk for an event.

```python
import boto3

fraudDetector = boto3.client('frauddetector')

fraudDetector.create_rule(
    ruleId = 'high_fraud_risk',
    detectorId = 'sample_detector',
    expression = '$sample_fraud_detection_model_insightscore > 900',
    language = 'DETECTORPL',
    outcomes = ['verify_customer'])

fraudDetector.create_rule(
    ruleId = 'medium_fraud_risk',
    detectorId = 'sample_detector',
    expression = '$sample_fraud_detection_model_insightscore <= 900 and $sample_fraud_detection_model_insightscore > 700',
    language = 'DETECTORPL',
    outcomes = ['review'])

fraudDetector.create_rule(
    ruleId = 'low_fraud_risk',
    detectorId = 'sample_detector',
    expression = '$sample_fraud_detection_model_insightscore <= 700',
    language = 'DETECTORPL',
    outcomes = ['approve'])
```

After you create the rules, you can Create a detector version (p. 27).

You can update a rule by calling the UpdateRuleVersion API. The following example updates the model score thresholds for the rules high_fraud_risk and medium_fraud_risk from 900 to 950.

```python
fraudDetector.update_rule_version(
    rule = {
        'detectorId' : 'sample_detector',
        'ruleId' : 'high_fraud_risk',
```
Rule language reference

The following section outlines the expression (that is, rule writing) capabilities in Amazon Fraud Detector.

Using variables

You can use any variable defined in the evaluated event type as part of your expression. Use the dollar sign to indicate a variable:

```plaintext
#example_variable < 100
```

Comparison, membership, and identity operators

Amazon Fraud Detector includes the following comparison operators: >, >=, <, <=, !=, ==, in, not in

The following are examples:

**Example:** `<`

```plaintext
#variable < 100
```

**Example:** `in, not in`

```plaintext
#variable in [5, 10, 25, 100]
```

**Example:** `!=`

```plaintext
#variable != "US"
```

**Example:** `==`

```plaintext
#variable == 1000
```

Operator Tables
### Operator

<table>
<thead>
<tr>
<th>Operator</th>
<th>Amazon Fraud Detector Operator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equal to</td>
<td>==</td>

</tr>
<tr>
<td>And</td>
<td>and</td>
</tr>
<tr>
<td>Or</td>
<td>or</td>
</tr>
<tr>
<td>Not</td>
<td>!</td>
</tr>
</tbody>
</table>

### Basic math

You can use basic math operators in your expression (for example, +, -, *, /). A typical use case is when you need to combine variables during your evaluation.

In the rule below, we are adding the variable \$variable_1 with \$variable_2, and checking whether the total is less than 10.

\$variable_1 + \$variable_2 < 10

### Basic Math Table Data

</tr>
<tr>
<td>Modulo</td>
<td>%</td>
</tr>
</tbody>
</table>

### Regular Expression (regex)

You can use regex to search for specific patterns as part of your expression. This is particularly useful if you are looking to match a specific string or numerical value for one of your variables. Amazon Fraud Detector only supports match when working with regular expressions (for example, it returns True/False depending on whether the provided string is matched by the regular expression). Amazon Fraud Detector's regular expression support is based on .matches() in java (using the RE2J Regular Expression library). There are several helpful websites on the internet that are useful for testing different regular expression patterns.
In the first example below, we first transform the variable email to lowercase. We then check whether the pattern @gmail.com is in the email variable. Notice the second period is escaped so that we can explicitly check for the string .com.

```javascript
regex_match(".*@gmail\.com", lowercase($email))
```

In the second example, we check whether the variable phone_number contains the country code +1 to determine if the phone number is from the US. The plus symbol is escaped so that we can explicitly check for the string +1.

```javascript
regex_match(".*\+1", $phone_number)
```

### Regex Table

<table>
<thead>
<tr>
<th>Operator</th>
<th>Amazon Fraud Detector Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Match any string that starts with</td>
<td><code>regex_match(&quot;^mystring&quot;, $variable)</code></td>
</tr>
<tr>
<td>Match entire string exactly</td>
<td><code>regex_match(&quot;mystring&quot;, $variable)</code></td>
</tr>
<tr>
<td>Match any character except new line</td>
<td><code>regex_match(&quot;.&quot;, $variable)</code></td>
</tr>
<tr>
<td>Match any number of characters except new line prior ‘mystring’</td>
<td><code>regex_match(&quot;.*mystring&quot;, $variable)</code></td>
</tr>
<tr>
<td>Escape special characters</td>
<td>\</td>
</tr>
</tbody>
</table>

### Checking for missing values

Sometimes it is beneficial to check whether the value is missing. In Amazon Fraud Detector this is represented by null. You can do this by using the following syntax:

```javascript
$variable != null
```

Similarly, if you wanted to check whether a value is not present, you could do the following:

```javascript
$variable == null
```

### Multiple conditions

You can combine multiple expressions together using **and** and **or**. Amazon Fraud Detector stops in an **OR** expression when a single true value is found, and it stops in an **AND** when a single false value is found.

In the example below, we are checking for two conditions using the **and** condition. In the first statement, we are checking whether variable 1 is less than 100. In the second we check whether variable 2 is not the US.

Given the rule uses an **and**, both must be **TRUE** for the entire condition to evaluate to **TRUE**.

```javascript
$variable_1 < 100 and $variable_2 != "US"
```

You can use parenthesis to group Boolean operations, as shown following:
Other expression types

Create resources

Models, rules, and detectors use resources to evaluate events for fraud risk. This chapter provides information about creating resources.

Topics
- Create a variable (p. 34)
- Create an outcome (p. 37)
- Create an entity type (p. 38)
- Create a label (p. 39)

Create a variable

Variables represent data elements that you want to use in a fraud prediction, such as data from the event that is being evaluated or risk score outputs from Amazon Fraud Detector models or Amazon SageMaker models.

To create a variable using the AWS Console, navigate to Amazon Fraud Detector, choose Variables in the left navigation, then choose Create.

You can optionally assign variables a variable type. Variable types represent common data elements used during fraud predictions. Only variables with an associated variable type can be used for model training. Select from a number of pre-defined variable types or one of three custom variable types FREE_FORM_TEXT, CATEGORICAL, or NUMERIC.

Variables must have a data type for the data element that the variable represents. For variables that are mapped to a variable type, the data type is pre-selected. Possible data types include:

<table>
<thead>
<tr>
<th>Data type</th>
<th>Description</th>
<th>Default value</th>
<th>Example values</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Any combination of letters and/or whole numbers</td>
<td>&lt;empty&gt;</td>
<td>abc, 123, 1D3B</td>
</tr>
<tr>
<td>Integer</td>
<td>Positive or negative whole numbers</td>
<td>0</td>
<td>1, -1</td>
</tr>
<tr>
<td>Boolean</td>
<td>True or False</td>
<td>False</td>
<td>True, False</td>
</tr>
<tr>
<td>Float</td>
<td>Numbers with decimal points</td>
<td>0.0</td>
<td>4.01, 0.10</td>
</tr>
</tbody>
</table>

Variables must have a default value. During a GetEventPrediction API call, this value will be used to run a rule or model if Amazon Fraud Detector does not receive a value for a variable. Default values must match the selected data type. In the AWS Console, Amazon Fraud Detector will automatically assign the default value of 0 for integers, false for Booleans, 0.0 for floats, and (empty) for strings. You can optionally set a custom default value.

Variable types

Amazon Fraud Detector supports the following variable types:
<table>
<thead>
<tr>
<th>Category</th>
<th>Variable Type</th>
<th>Description</th>
<th>Data Type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>EMAIL_ADDRESS</td>
<td>Email address collected during the event</td>
<td>String</td>
<td><a href="mailto:abc@domain.com">abc@domain.com</a></td>
</tr>
<tr>
<td>IP address</td>
<td>IP_ADDRESS</td>
<td>IP address collected during the event</td>
<td>String</td>
<td>1.1.1.1</td>
</tr>
<tr>
<td>Phone number</td>
<td>PHONE_NUMBER</td>
<td>Phone number collected during the event</td>
<td>String</td>
<td>1-123-456-7891</td>
</tr>
<tr>
<td>Browser Device</td>
<td>USERAGENT</td>
<td>User agent collected during the event</td>
<td>String</td>
<td>Mozilla/5.0 (Windows NT 10.0; Win64; x64; rv:68.0) Gecko/20100101</td>
</tr>
<tr>

<td>String</td>
<td>Large</td>
</tr>
</tbody>
</table>
Create a variable using the AWS SDK for Python (Boto3)

The following example shows requests for the CreateVariable API. The example creates two variables, `email_address` and `ip_address`, and assigns them to the corresponding variable types (`EMAIL_ADDRESS` and `IP_ADDRESS`). Specifying the variable type allows Amazon Fraud Detector to interpret the variable during model training and `GetEventPrediction` requests. Only variables with an associated variable type can be used for model training.

You must specify a variable source, which identifies where the variable value will be derived. If the variable source is `EVENT`, the variable value will be sent as part of the `GetEventPrediction` request. If the variable value is `MODEL_SCORE`, it will be populated by an Amazon Fraud Detector model. If `EXTERNAL_MODEL_SCORE`, the variable value will be populated by an imported SageMaker model.

```python
import boto3
fraudDetector = boto3.client('frauddetector')

#Create variable email_address
fraudDetector.create_variable(
    name = 'email_address',
    variableType = 'EMAIL_ADDRESS',
    dataSource = 'EVENT',
    dataType = 'STRING',
    defaultValue = '<unknown>'
)

#Create variable ip_address
fraudDetector.create_variable(
    name = 'ip_address',
    variableType = 'IP_ADDRESS',
    dataSource = 'EVENT',
    dataType = 'STRING',
    defaultValue = '<unknown>'
)
```

Create an outcome

An outcome is the result of a fraud prediction. Create an outcome for each possible fraud prediction result. For example, you may want outcomes to represent risk levels (high_risk, medium_risk, and low_risk) or actions (approve, review). Once created, you can add one or more outcomes to a rule. As part of the `GetEventPrediction` response, Amazon Fraud Detector will return the defined outcomes for any matched rule.
To create a outcome using the AWS Console, open the AWS Console and sign in to your account. Navigate to Amazon Fraud Detector and in the left navigation pane, choose Outcomes, then choose Create.

Create an outcome using the AWS SDK for Python (Boto3)

The following example shows requests for the CreateOutcome API. The example creates three outcomes, verify_customer, review, and approve. You can then assign these outcomes to rules.

```python
import boto3
fraudDetector = boto3.client('frauddetector')

fraudDetector.put_outcome(
    name = 'verify_customer',
    description = 'this outcome initiates a verification workflow'
)

fraudDetector.put_outcome(
    name = 'review',
    description = 'this outcome sidelines event for review'
)

fraudDetector.put_outcome(
    name = 'approve',
    description = 'this outcome approves the event'
)
```

Create an entity type

An entity represents who is performing the event. As part of a fraud prediction, you can pass the entity ID to indicate the specific entity who performed the event.

An entity type classifies the entity. Example classifications include customer, merchant, or account.

To create a entity type using the AWS Console, open the AWS Console and sign in to your account. Navigate to Amazon Fraud Detector and in the left navigation pane, choose Entities, then choose Create.

Create an entity type using the AWS SDK for Python (Boto3)

The following example shows a request for the PutEntityType API. The example creates the entity type sample_customer. You can then associate this entity with an event type to describe who is performing the event.

```python
import boto3
fraudDetector = boto3.client('frauddetector')

fraudDetector.put_entity_type(
    name = 'sample_customer',
    description = 'sample customer entity type'
)
```
Create a label

A label classifies an event as fraudulent or legitimate. Once you have created a label, add the label to the event type by calling the PutEventType API.

Use labels to train supervised machine learning models in Amazon Fraud Detector. As part of model version configuration, you classify the event labels as either fraudulent or legitimate. The supervised model will then learn to classify events using the variable values.

To create a label using the AWS Console, open the AWS Console and sign in to your account. Navigate to Amazon Fraud Detector and in the left navigation pane, choose Labels, then choose Create.

Create a label using the AWS SDK for Python (Boto3)

The following example shows requests for the PutLabel API. The example creates two labels (fraud, legit). You can add these labels to an event type to classify specific events.

```python
import boto3
fraudDetector = boto3.client('frauddetector')

fraudDetector.put_label(
    name = 'fraud',
    description = 'label for fraud events'
)

fraudDetector.put_label(
    name = 'legit',
    description = 'label for legitimate events'
)
```
Delete resources

This section provides information about deleting resources.

When you delete a resource, Amazon Fraud Detector permanently deletes that resource and the data is no longer stored in Amazon Fraud Detector.

Some delete operations require you to first delete associated resources. For example, prior to deleting a model, you must first delete the model versions. See the following table for additional details.

<table>
<thead>
<tr>
<th>If you want to delete this resource</th>
<th>You must delete this first</th>

Delete a detector, detector version, or rule version

Before deleting a detector in Amazon Fraud Detector, you must first delete all detector versions and rule versions that are associated with the detector.

When you delete a detector, detector version, or rule version, Amazon Fraud Detector permanently deletes that resource and the data is no longer stored in Amazon Fraud Detector.

To delete a detector version

You can only delete detector versions that are in DRAFT or INACTIVE status.

1. Sign in to the AWS Management Console and open the Amazon Fraud Detector console at https://console.aws.amazon.com/frauddetector.
2. In the left navigation pane of the Amazon Fraud Detector console, choose Detectors.
3. Choose the detector that contains the detector version you want to delete.
4. Choose the detector version that you want to delete.
5. Choose Actions, and then choose Delete.
6. Enter delete, and then choose Delete detector.

To delete a rule version

You can delete a rule version only if it is not used by any ACTIVE or INACTIVE detector versions. If necessary, before deleting a rule version, first move the ACTIVE detector version to INACTIVE, then delete the INACTIVE detector version.

1. In the left navigation pane of the Amazon Fraud Detector console, choose Detectors.
2. Choose the detector that contains the rule version you want to delete.
3. Choose the Associated rules tab, and choose the rule that you want to delete.
4. Choose the rule version that you want to delete.
5. Choose Actions, and then choose Delete rule version.
6. Enter delete, and then choose Delete version.
To delete a detector
Before deleting a detector, you must first delete all detector versions and rule versions that are associated with the detector.

1. In the left navigation pane of the Amazon Fraud Detector console, choose Detectors.
2. Choose the detector that you want to delete.
3. Choose Actions, and then choose Delete detector.
4. Enter delete, and then choose Delete detector.

Delete a model or model version
You can delete models and model versions in Amazon Fraud Detector, provided that they are not associated with a detector version. When you delete a model, Amazon Fraud Detector permanently deletes that model and the data is no longer stored in Amazon Fraud Detector.

You can also remove Amazon SageMaker models if they are not associated with a detector version. Removing a SageMaker model disconnects it from Amazon Fraud Detector, but the model remains available in SageMaker.

To delete a model version
You can only delete model versions that are in the Ready to deploy status. To change a model version from ACTIVE to Ready to deploy status, undeploy the model version.

1. Sign in to the AWS Management Console and open the Amazon Fraud Detector console at https://console.aws.amazon.com/frauddetector.
2. In the left navigation pane of the Amazon Fraud Detector console, choose Models.
3. Choose the model that contains the model version you want to delete.
4. Choose the model version that you want to delete.
5. Choose Actions, and then choose Delete.
6. Enter the model version name, and then choose Delete model version.

To undeploy a model version
You can't undeploy a model version that is in use by any detector version (ACTIVE, INACTIVE, DRAFT). Therefore, to undeploy a model version that is in use by a detector version, first remove the model version from the detector version.

1. In the left navigation pane of the Amazon Fraud Detector console, choose Models.
2. Choose the model that contains the model version you want to undeploy.
3. Choose the model version that you want to delete.
4. Choose Actions, and then choose Undeploy model version.

To delete a model
Before deleting a model, you must first delete all model versions and are associated with the model.

1. In the left navigation pane of the Amazon Fraud Detector console, choose Models.
2. Choose the model that you want to delete.
3. Choose Actions, and then choose Delete.
4. Enter the model name, and then choose Delete model.
To remove an Amazon SageMaker model
1. In the left navigation pane of the Amazon Fraud Detector console, choose Models.
2. Choose the SageMaker model that you want to remove.
3. Choose Actions, and then choose Remove model.
4. Enter the model name and then choose Remove SageMaker model.

Delete an event or event type

When you delete an event, Amazon Fraud Detector permanently deletes that event and the event data is no longer stored in Amazon Fraud Detector.

To delete an event
1. Sign in to the AWS Management Console and open the Amazon Fraud Detector console at https://console.aws.amazon.com/frauddetector.
2. In the left navigation pane of the Amazon Fraud Detector console, choose Search past predictions.
3. Choose the event that you want to delete.
4. Choose Actions, and then choose Delete event.
5. Enter delete, and then choose Delete event.

To delete an event type
You cannot delete an event type that is used in a detector or a model.

When you delete an event type, Amazon Fraud Detector permanently deletes that event type and the data is no longer stored in Amazon Fraud Detector.

1. In the left navigation pane of the Amazon Fraud Detector console, choose Resources, then choose Events.
2. Choose the event type that you want to delete.
3. Choose Actions, and then choose Delete event type.
4. Enter the event type name, and then choose Delete event type.

Delete an entity type

In Amazon Fraud Detector, you cannot delete an entity type that is included in an event type.

When you delete an entity type, Amazon Fraud Detector permanently deletes that entity type and the data is no longer stored in Amazon Fraud Detector.

To delete an entity type
1. Sign in to the AWS Management Console and open the Amazon Fraud Detector console at https://console.aws.amazon.com/frauddetector.
2. In the left navigation pane of the Amazon Fraud Detector console, choose Resources, then choose Entities.
3. Choose the entity type that you want to delete.
4. Choose Actions, and then choose Delete.
5. Enter the entity type name, and then choose Delete entity type.
Delete an outcome

You cannot delete an outcome that is used in a rule version.

When you delete an outcome, Amazon Fraud Detector permanently deletes that outcome and the data is no longer stored in Amazon Fraud Detector.

To delete an outcome

1. Sign in to the AWS Management Console and open the Amazon Fraud Detector console at https://console.aws.amazon.com/frauddetector.
2. In the left navigation pane of the Amazon Fraud Detector console, choose Resources, and then choose Outcomes.
3. Choose the outcome that you want to delete.
4. Choose Actions, and then choose Delete.
5. Enter the outcome name, and then choose Delete outcome.

Delete a label

You cannot delete labels that are included in an event type in Amazon Fraud Detector.

When you delete a label, Amazon Fraud Detector permanently deletes that label and the data is no longer stored in Amazon Fraud Detector.

To delete a label

1. Sign in to the AWS Management Console and open the Amazon Fraud Detector console at https://console.aws.amazon.com/frauddetector.
2. In the left navigation pane of the Amazon Fraud Detector console, choose Resources, then choose Labels.
3. Choose the label that you want to delete.
4. Choose Actions, and then choose Delete.
5. Enter the label name, and then choose Delete label.

Delete a variable

You can't delete variables that are included in an event type in Amazon Fraud Detector.

Amazon Fraud Detector automatically deletes model output variables and SageMaker model output variables when you delete the model. You can't delete these variables manually.

When you delete a variable, Amazon Fraud Detector permanently deletes that variable and the data is no longer stored in Amazon Fraud Detector.

To delete a variable

1. Sign in to the AWS Management Console and open the Amazon Fraud Detector console at https://console.aws.amazon.com/frauddetector.
2. In the left navigation pane of the Amazon Fraud Detector console, choose Resources, then choose Variables.
3. Choose the variable that you want to delete.
4. Choose **Actions**, and then choose **Delete**.
5. Enter the variable name, and then choose **Delete variable**.
Manage Amazon Fraud Detector resources using AWS CloudFormation

Amazon Fraud Detector is integrated with AWS CloudFormation, a service that helps you to model and set up your Amazon Fraud Detector resources so that you can spend less time creating and managing your resources and infrastructure. You create a template that describes all the Amazon Fraud Detector resources that you want (such as Detector, Variables, EntityType, EventType, Outcome, and Label), and AWS CloudFormation provisions and configures those resources for you. You can reuse the template to provision and configure the resources consistently and repeatedly in multiple AWS accounts and Regions.

There is no additional charge for using AWS CloudFormation.

Creating Amazon Fraud Detector templates

To provision and configure resources for Amazon Fraud Detector and related services, you must understand AWS CloudFormation templates. Templates are formatted text files in JSON or YAML. These templates describe the resources that you want to provision in your AWS CloudFormation stacks. If you're unfamiliar with JSON or YAML, you can use AWS CloudFormation Designer to help you get started with AWS CloudFormation templates. For more information, see What is AWS CloudFormation Designer? in the AWS CloudFormation User Guide.

You can also create, update, and delete your Amazon Fraud Detector resources using AWS CloudFormation templates. For more information, including examples of JSON and YAML templates for your resources, see the Amazon Fraud Detector resource type reference in the AWS CloudFormation User Guide.

If you are already using CloudFormation, there is no need to manage additional IAM policies or CloudTrail logging.

Managing Amazon Fraud Detector stacks

You can create, update, and delete your Amazon Fraud Detector stacks through the CloudFormation console or through the AWS CLI.

To create a stack, you must have a template that describes what resources AWS CloudFormation will include in your stack. You can also bring Amazon Fraud Detector resources that you have already created into CloudFormation management by importing them into a new or existing stack.

For detailed instructions for managing your stacks, see the AWS CloudFormation User Guide to learn how to create, update, and delete stacks.

Organizing your Amazon Fraud Detector stacks

The way you organize your AWS CloudFormation stacks is entirely up to you. It is generally a best practice to organize stacks by lifecycle and ownership. This means grouping resources by how frequently they change or by teams that are responsible for updating them.
You can choose to organize your stacks by creating a stack for each detector and its detection logic (for example, rules, variables, etc.). If you are using other services, you should consider whether you want to stack together Amazon Fraud Detector resources with resources from other services. For example, you could create a stack that includes Kinesis resources that help gather data and Amazon Fraud Detector resources that process the data. This can be an effective way to ensure that all of your fraud team’s products are working together.

Understanding Amazon Fraud Detector CloudFormation parameters

In addition to the standard parameters that are available in all CloudFormation templates, Amazon Fraud Detector introduces two additional parameters that will help you manage deployment behavior. If you do not include one or both of these parameters, CloudFormation will use the default value shown below.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Values</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DetectorVersionStatus</td>
<td>ACTIVE: Set the new/updated detector version to Active status</td>
<td>DRAFT</td>
</tr>
<tr>
<td></td>
<td>DRAFT: Set the new/updated detector version to Draft status</td>
<td></td>
</tr>
<tr>
<td>Inline</td>
<td>TRUE: Allow CloudFormation to create/update/delete the resource when creating/updating/deleting the stack.</td>
<td>TRUE</td>
</tr>
<tr>
<td></td>
<td>FALSE: Allow CloudFormation to validate that the object exists but not make any changes to the object.</td>
<td></td>
</tr>
</tbody>
</table>

Sample AWS CloudFormation template for Amazon Fraud Detector resources

The following is a sample AWS CloudFormation YAML template for managing a detector and associated detector versions.

```
# Simple Detector resource containing inline Rule, EventType, Variable, EntityType and Label resource definitions
Resources:
  TestDetectorLogicalId:
    Type: AWS::FraudDetector::Detector
    Properties:
      DetectorId: "sample_cfn_created_detector"
      DetectorVersionStatus: "DRAFT"
      Description: "A detector defined and created in a CloudFormation stack!"
    Rules:
      - RuleId: "over_threshold_investigate"
        Description: "Automatically sends transactions of $10000 or more to an investigation queue"
        DetectorId: "sample_cfn_created_detector"
        Expression: "@amount >= 10000"
```
Language: "DETECTORPL"
Outcomes:
- Name: "investigate"
  Inline: true
- RuleId: "under_threshold_approve"
  Description: "Automatically approves transactions of less than $10000"
  DetectorId: "sample_cfn_created_detector"
  Expression: "#amount <10000"
  Language: "DETECTORPL"
  Outcomes:
    - Name: "approve"
    Inline: true
  EventType: "online_transaction"
  EventVariables:
    - Name: "amount"
    DataSource: 'EVENT'
    DataType: 'FLOAT'
    DefaultValue: '0'
    VariableType: "PRICE"
    Inline: 'true'
  EntityTypes:
    - Name: "customer"
    Inline: 'true'
  Labels:
    - Name: "legitimate"
    Inline: 'true'
    - Name: "fraudulent"
    Inline: 'true'

Learn more about AWS CloudFormation

To learn more about AWS CloudFormation, see the following resources:

- AWS CloudFormation
- AWS CloudFormation User Guide
- AWS CloudFormation API Reference
- AWS CloudFormation Command Line Interface User Guide
Get fraud predictions

You can use Amazon Fraud Detector to get fraud predictions for single event in real time or get fraud predictions offline for a set of events. To generate fraud predictions for either a single event or a set of events, you will need to provide Amazon Fraud Detector with the following information:

- Fraud prediction logic
- Event metadata

Fraud detection logic

Fraud prediction logic uses one or more rules to evaluate data associated with an event and then provides result and a fraud prediction score. You create your fraud prediction logic using the following components:

- Event types - Defines structure of the event
- Models - Defines algorithm and data requirements for predicting fraud
- Variables - Represents a data element associated with the event
- Rules - Tells Amazon Fraud Detector how to interpret the variable values during fraud prediction
- Outcomes - Results generated from a fraud prediction
- Detector version - Contains fraud prediction logic for a particular event

For more information about the components used to create fraud detection logic, see Amazon Fraud Detector concepts. Before you start generating fraud predictions, make sure you have created and published the detector version that contains your fraud prediction logic. You can create and publish detector version using the Fraud Detector Console or API. For instructions on using the console, see Get started (console). For instructions on using the API, see Create a detector version.

Event metadata

Event metadata provides details of the event being evaluated. Each event you want to evaluate must include value for each variable in the event type associated with your detector version. In addition, your event metadata must include the following:

- EVENT_ID – An identifier for the event. For example, if your event is an online transaction the EVENT_ID might be the transaction reference number provided to your customer.

Important notes about EVENT_ID

- Must be unique for that event
- Should represent information that is meaningful to your business
- Must satisfy the regular expression pattern: ^[0-9a-z_-]+$.
- Must be saved. EVENT_ID is the reference for the event and is used to perform operations on the event such as deleting the event.
- Appending timestamp to the EVENT_ID is not recommended as it might cause issues when later you want to update the event, since you will need to provide the exact same EVENT_ID.
- ENTITY_TYPE – The entity that performs the event, such as a merchant or a customer.
- ENTITY_ID - An identifier for the entity performing the event. The ENTITY_ID must satisfy the following regular expression pattern: ^[0-9a-z_-]+$.

If the ENTITY_ID is not available at the time of evaluation, pass the string unknown.
Real time prediction

You can evaluate online activities for fraud in real time by calling `GetEventPrediction` API. You provide information about a single event in each request and synchronously receive a model score and an outcome based on the fraud prediction logic associated with the specified detector.

**How real time fraud prediction works**

The `GetEventPrediction` API uses a specified detector version to evaluate the event metadata provided for the event. During the evaluation, Amazon Fraud Detector first generates model scores for models that are added to the detector version, then passes the results to the rules for evaluation. The rules are executed as specified by the rule execution mode (see Create a detector version). As part of the response, Amazon Fraud Detector provides model scores as well as any outcomes associated to the matched rules.

**Getting real time fraud prediction**

To get real time fraud predictions, make sure you have created and published a detector that contains your fraud prediction model and rules, or simply a ruleset.

You can get fraud prediction for an event in real time by calling the `GetEventPrediction` API operation using the AWS Command Line Interface (AWS CLI) or one of the Amazon Fraud Detector SDKs.

To use the API, supply information of a single event with each request. As part of the request you must specify `detectorId` that Amazon Fraud Detector will use to evaluate the event. You can optionally specify a `detectorVersionId`. If a `detectorVersionId` is not specified, Amazon Fraud Detector will use the `ACTIVE` version of the detector.

You can optionally send data to invoke an SageMaker model by passing the data in the field `externalModelEndpointBlobs`.

**Get a fraud prediction using the AWS SDK for Python (Boto3)**

To generate a fraud prediction, call the `GetEventPrediction` API. The example below assumes you have completed Part B: Generate real-time fraud predictions (p. 8). As part of the response, you will receive a model score as well as any matched rules and corresponding outcomes. You can find additional examples of `GetEventPrediction` requests on the aws-fraud-detector-samples GitHub repository.

```python
import boto3
fraudDetector = boto3.client('frauddetector')

fraudDetector.get_event_prediction(
    detectorId = 'sample_detector',
    eventId = '802454d3-f7d8-482d-97e8-c4b6db9a0428',
    eventTypeName = 'sample_registration',
    eventTimestamp = '2020-07-13T23:18:21Z',
    entities = [ {'entityType':'sample_customer', 'entityId':'12345'}],
    eventVariables = { 'email_address' : 'johndoe@exampledomain.com',
                      'ip_address' : '1.2.3.4'
    }
)```
Batch predictions

You can use a batch predictions job in Amazon Fraud Detector to get predictions for a set of events that do not require real-time scoring. For example, you could create a batch predictions job to perform an offline proof-of-concept, or to retrospectively evaluate the risk of events on an hourly, daily, or weekly basis.

You can create a batch prediction job using the Amazon Fraud Detector console, or by calling the CreateBatchPredictionJob API operation using the AWS Command Line Interface (AWS CLI) or one of the Amazon Fraud Detector SDKs.

Topics
- How batch predictions work (p. 51)
- Input and output files (p. 51)
- Getting batch predictions (p. 52)
- Guidance on IAM roles (p. 52)
- Get batch fraud predictions using the AWS SDK for Python (Boto3) (p. 53)

How batch predictions work

The CreateBatchPredictionJob API operation uses a specified detector version to make predictions based on data provided in an input CSV file that is located in an Amazon S3 bucket. The API then returns the resulting CSV file to an S3 bucket.

Batch prediction jobs calculate model scores and prediction outcomes in the same way as the GetEventPrediction operation. Similar to GetEventPrediction, to create a batch predictions job, you first create an event type, optionally train a model, and then create a detector version that evaluates the events in your batch job.

The pricing for event risk scores evaluated by batch prediction jobs is the same as the pricing for scores created by the GetEventPrediction API. For details, see Amazon Fraud Detector pricing.

You can only run one batch prediction job at a time.

Input and output files

The input CSV file should contain headers that match the event type that is associated with the selected detector version. The maximum size of the input data file is 50 megabytes (MB), or about 50,000 events. The number of events will vary by your event size.

Amazon Fraud Detector creates the output file in the same bucket as the input file, unless you specify a separate location for the output data. The output file contains the original data from the input file and the following appended columns:

- **MODEL_SCORES** — Details the model scores for the event from each model associated with the selected detector version.
- **OUTCOMES** — Details the event outcomes as evaluated by the selected detector version and its rules.
- **STATUS** — Indicates whether the event was evaluated successfully. If the event was not evaluated successfully, this column shows a reason code for the failure.
- **RULE_RESULTS** — A list of all the rules that matched, based on the rule execution mode.
Getting batch predictions

The following steps assume that you have already created an event type, trained a model using that event type (optional), and created a detector version for that event type.

To get a batch prediction

1. Sign in to the AWS Management Console and open the Amazon Fraud Detector console at https://console.aws.amazon.com/frauddetector.
2. In the left navigation pane of the Amazon Fraud Detector console, choose Batch Predictions, and then choose New batch prediction.
3. In Job name, specify a name for your batch prediction job. If you don’t specify a name, Amazon Fraud Detector randomly generates a job name.
4. In Detector, choose the detector for this batch prediction.
5. In Detector version, choose the detector version for this batch prediction. You can choose a detector version in any status. If your detector has a detector version in Active status, that version is automatically selected, but you can also change this selection if needed.
6. In IAM role, choose or create a role that has read and write access to your input and output Amazon S3 buckets. See Guidance on IAM roles (p. 52) for more information.

To get batch predictions, the IAM user role that calls the CreateBatchPredictionJob operation must have read permissions to your input S3 bucket and write permissions to your output S3 bucket. For more information about bucket permissions, see User policy examples in the Amazon S3 User Guide.

7. In Input data location, specify the Amazon S3 location of your input data. If you want the output file in a different S3 bucket, select Separate data location for output and provide the Amazon S3 location for your output data.
8. (Optional) Create tags for your batch prediction job.

Amazon Fraud Detector creates the batch prediction job, and the job’s status is In progress. Batch prediction job processing times vary depending on the number of events and your detector version configuration.

To stop a batch prediction job that is in progress, go to the batch prediction job detail page, choose Actions, and then choose Stop batch prediction. If you stop a batch prediction job, you won’t receive any results for the job.

When the batch prediction job’s status changes to Complete, you can retrieve the job’s output from the designated output Amazon S3 bucket. The output file’s name is in the format batch prediction job name_file creation timestamp_output.csv. For example, the output file from a job named mybatchjob is mybatchjob_1611170650_output.csv.

To search for specific events evaluated by a batch prediction job, in the left navigation pane of the Amazon Fraud Detector console, choose Search past predictions.

To delete a batch prediction job that has completed, go to the batch prediction job detail page, choose Actions and then choose Delete batch prediction.

Guidance on IAM roles

To get batch predictions, the IAM user role that calls the CreateBatchPredictionJob operation must have read permissions to your input S3 bucket and write permissions to your output S3 bucket. For more
information about bucket permissions, see User policy examples in the Amazon S3 User Guide. On the Amazon Fraud Detector console, you have three options for selecting an IAM role for Batch Predictions:

1. Create a role when creating a new Batch Prediction job.
2. Select an existing IAM role that you have previously created in Amazon Fraud Detector console. Make sure to add the S3:PutObject permission to the role before you do this step.
3. Enter a custom ARN for a previously created IAM role.

If you receive an error related to your IAM role, verify the following:

1. Your S3 input and output buckets are in the same region as your detector.
2. The IAM role you are using has the s3:GetObject permission for your input S3 bucket and the s3:PutObject permission for your output S3 bucket.
3. The IAM role you are using has a trust policy for service principal frauddetector.amazonaws.com.

Get batch fraud predictions using the AWS SDK for Python (Boto3)

The following example shows a sample request for the CreateBatchPredictionJob API. A batch prediction job must include the following existing resources: detector, detector version, and event type name. The following example assumes you have created an event type sample_registration, a detector sample_detector, and a detector version 1.

```python
import boto3
fraudDetector = boto3.client('frauddetector')

fraudDetector.create_batch_prediction_job (  
    jobId = 'sample_batch',  
    inputPath = 's3://bucket_name/input_file_name.csv'  
    outputPath = 's3://bucket_name/'  
    eventTypeName = 'sample_registration'  
    detectorName = 'sample_detector',  
    detectorVersion = '1',  
    "iamRoleArn": 'arn:aws:iam::************:role/service-role/AmazonFraudDetector-DataAccessRole-*************'
)
```
Security in Amazon Fraud Detector

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from data centers and network architectures that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. To learn about the compliance programs that apply to Amazon Fraud Detector, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company’s requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon Fraud Detector. The following topics show you how to configure Amazon Fraud Detector to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Amazon Fraud Detector resources.

Topics

- Data Protection in Amazon Fraud Detector (p. 54)
- Identity and access management for Amazon Fraud Detector (p. 58)
- Logging and monitoring in Amazon Fraud Detector (p. 72)
- Compliance validation for Amazon Fraud Detector (p. 72)
- Resilience in Amazon Fraud Detector (p. 73)
- Infrastructure Security in Amazon Fraud Detector (p. 73)

Data Protection in Amazon Fraud Detector

The AWS shared responsibility model applies to data protection in Amazon Fraud Detector. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We recommend TLS 1.2 or later.
• Set up API and user activity logging with AWS CloudTrail.
• Use AWS encryption solutions, along with all default security controls within AWS services.
• Use advanced managed security services such as Amazon Macie, which assists in discovering and securing personal data that is stored in Amazon S3.
• If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers’ email addresses, into tags or free-form fields such as a Name field. This includes when you work with Amazon Fraud Detector or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

**Encrypting data at rest**

Amazon Fraud Detector encrypts your data at rest with your choice of an encryption key. You can choose one of the following:

• An AWS owned KMS key. If you don’t specify an encryption key your data is encrypted with this key by default.
• A customer managed KMS key. You can control access to your customer managed KMS key using key policies. For information on creating and managing customer managed KMS key, see Key management (p. 55).

**Encrypting data in transit**

Amazon Fraud Detector copies data out of your account and processes it in an internal AWS system. By default, Amazon Fraud Detector uses TLS 1.2 with AWS certificates to encrypt data in transit.

**Key management**

Amazon Fraud Detector encrypts your data using one of two types of keys:

• An AWS owned KMS key. This is the default.
• A customer managed KMS key.

**Creating customer managed KMS key**

You can create customer managed KMS key using either the AWS KMS console or the CreateKey API. When creating the key make sure you,

• Select a symmetric customer managed KMS key, Amazon Fraud Detector does not support asymmetric KMS keys. For more information, see Using Symmetric and Asymmetric Keys in the AWS Key Management Service Developer Guide.
• Provide the following key policy to grant permissions to Amazon Fraud Detector to use the key.

```
{
  "Effect": "Allow",
```
"Principal": {
    "Service": "frauddetector.amazonaws.com"
},
"Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:DescribeKey",
    "kms:CreateGrant",
    "kms:RetireGrant"
],
"Resource": "*"

For information on key policies, see Using Key Policies in AWS KMS in the AWS Key Management Service Developer Guide.

## Encrypting data using customer managed KMS key

Use Amazon Fraud Detector’s [PutKMSEncryptionKey](https://docs.aws.amazon.com/AmazonFraudDetector/latest/developerguide/put-kms-encryption-key.html) API to encrypt your Amazon Fraud Detector data at rest using the customer managed KMS key. You can change the encryption configuration at any time using PutKMSEncryptionKey API.

### Important notes about encrypted data

- Data generated after setting up the customer managed KMS key is encrypted. Data generated before setting up the customer managed KMS key will remain unencrypted.
- If customer managed KMS key is changed, the data that was encrypted using the previous encryption configuration will not be re-encrypted.

### View data

When you use customer managed KMS key to encrypt your Amazon Fraud Detector data, the data encrypted using this method is not searchable using filters in the Search Past Predictions area of the Amazon Fraud Detector console. To ensure complete search results, use one or more of the following properties to filter results:

- Event ID
- Evaluation timestamp
- Detector status
- Detector version
- Model version
- Model type
- Rule evaluation status
- Rule execution mode
- Rule match status
- Rule version
- Variable data source

If customer managed KMS key was either deleted or is scheduled for deletion, your data might not be available. For more information, see [Deleting KMS key](https://docs.aws.amazon.com/AmazonFraudDetector/latest/developerguide/support.html).
Amazon Fraud Detector and interface VPC endpoints
(AWS PrivateLink)

You can establish a private connection between your VPC and Amazon Fraud Detector by creating an interface VPC endpoint. Interface endpoints are powered by AWS PrivateLink, a technology that enables you to privately access Amazon Fraud Detector APIs without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC don't need public IP addresses to communicate with Amazon Fraud Detector APIs. Traffic between your VPC and Amazon Fraud Detector does not leave the Amazon network.

Each interface endpoint is represented by one or more Elastic Network Interfaces in your subnets.

For more information, see Interface VPC endpoints (AWS PrivateLink) in the Amazon VPC User Guide.

Considerations for Amazon Fraud Detector VPC endpoints

Before you set up an interface VPC endpoint for Amazon Fraud Detector, ensure that you review Interface endpoint properties and limitations in the Amazon VPC User Guide.

Amazon Fraud Detector supports making calls to all of its API actions from your VPC.

VPC endpoint policies are supported for Amazon Fraud Detector. By default, full access to Amazon Fraud Detector is allowed through the endpoint. For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.

Creating an interface VPC endpoint for Amazon Fraud Detector

You can create a VPC endpoint for the Amazon Fraud Detector service using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Creating an interface endpoint in the Amazon VPC User Guide.

Create a VPC endpoint for Amazon Fraud Detector using the following service name:

- com.amazonaws.region.frauddetector

If you enable private DNS for the endpoint, you can make API requests to Amazon Fraud Detector using its default DNS name for the Region, for example, frauddetector.us-east-1.amazonaws.com.

For more information, see Accessing a service through an interface endpoint in the Amazon VPC User Guide.

Creating a VPC endpoint policy for Amazon Fraud Detector

You can create a policy for interface VPC endpoints for Amazon Fraud Detector to specify the following:

- The principal that can perform actions
- The actions that can be performed
- The resources on which actions can be performed

For more information, see Controlling Access to Services with VPC Endpoints in the Amazon VPC User Guide.

The following example VPC endpoint policy specifies that all users who have access to the VPC interface endpoint are allowed to access the Amazon Fraud Detector detector named my_detector.

```json
{
```
Opting out

In this example, the following are denied:

- Other Amazon Fraud Detector API actions
- Invoking Amazon Fraud Detector GetEventPrediction API

Note

In this example, users can still take other Amazon Fraud Detector API actions from outside the VPC. For information about how to restrict API calls to those from within the VPC, see Amazon Fraud Detector identity-based policies (p. 63).

Opting out of using your data for service improvement

Historical event data you provide to train models and generate predictions is used solely to provide and maintain the service and, unless you opt out as provided below, this data may be used to improve the quality of Amazon Fraud Detector and other AWS fraud prevention services. Your trust, privacy, and the security of your content are our highest priority and we implement appropriate and sophisticated technical and physical controls, including encryption at rest and in transit, designed to prevent unauthorized access to, or disclosure of, your content and ensure that our use complies with our commitments to you. See Data Privacy FAQ for more information. You may opt out of having your data used to develop or improve the quality of Amazon Fraud Detector and other AWS fraud prevention services using the following process:

1. Create an Account and billing support case using the AWS Support Center in the AWS Console.
2. Select Account for Type.
4. Enter "Opt out of having my data used to improve Amazon Fraud Detector" in Subject.
5. Enter a message such as "I would like to opt out of having my data used to improve the quality of Amazon Fraud Detector and other AWS fraud prevention services." for Description.
6. Select your preferred contact option, and choose Submit.

A support case will be created that you can use to track your opt-out request. Response times will vary depending on your support plan.

Identity and access management for Amazon Fraud Detector

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Amazon Fraud Detector resources. IAM is an AWS service that you can use with no additional charge.
Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in Amazon Fraud Detector.

Service user – If you use the Amazon Fraud Detector service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Amazon Fraud Detector features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon Fraud Detector, see Troubleshooting Amazon Fraud Detector identity and access (p. 70).

Service administrator – If you’re in charge of Amazon Fraud Detector resources at your company, you probably have full access to Amazon Fraud Detector. It’s your job to determine which Amazon Fraud Detector features and resources your employees should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Amazon Fraud Detector, see How Amazon Fraud Detector works with IAM (p. 63).

IAM administrator – If you’re an IAM administrator, you might want to learn details about how you can write policies to manage access to Amazon Fraud Detector. To view example Amazon Fraud Detector identity-based policies that you can use in IAM, see Amazon Fraud Detector identity-based policy examples (p. 66).

 Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. For more information about signing in using the AWS Management Console, see Signing in to the AWS Management Console as an IAM user or root user in the IAM User Guide.

You must be authenticated (signed in to AWS) as the AWS account root user, an IAM user, or by assuming an IAM role. You can also use your company’s single sign-on authentication or even sign in using Google or Facebook. In these cases, your administrator previously set up identity federation using IAM roles. When you access AWS using credentials from another company, you are assuming a role indirectly.

To sign in directly to the AWS Management Console, use your password with your root user email address or your IAM user name. You can access AWS programmatically using your root user or IAM users access keys. AWS provides SDK and command line tools to cryptographically sign your request using your credentials. If you don’t use AWS tools, you must sign the request yourself. Do this using Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 signing process in the AWS General Reference.

Regardless of the authentication method that you use, you might also be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.
AWS account root user

When you first create an AWS account, you begin with a single sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you do not use the root user for your everyday tasks, even the administrative ones. Instead, adhere to the best practice of using the root user only to create your first IAM user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks.

IAM Users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. An IAM user can have long-term credentials such as a user name and password or a set of access keys. To learn how to generate access keys, see Managing access keys for IAM users in the IAM User Guide. When you generate access keys for an IAM user, make sure you view and securely save the key pair. You cannot recover the secret access key in the future. Instead, you must generate a new access key pair.

An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary IAM user permissions** – An IAM user can assume an IAM role to temporarily take on different permissions for a specific task.

- **Federated user access** – Instead of creating an IAM user, you can use existing identities from AWS Directory Service, your enterprise user directory, or a web identity provider. These are known as federated users. AWS assigns a role to a federated user when access is requested through an identity provider. For more information about federated users, see Federated users and roles in the IAM User Guide.

- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
Managing access using policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. You can sign in as the root user or an IAM user, or you can assume an IAM role. When you then make a request, AWS evaluates the related identity-based or resource-based policies. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

Every IAM entity (user or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the iam:GetRole action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

Identity-based policies can be further categorized as inline policies or managed policies. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that
you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the IAM User Guide.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can’t use AWS managed policies from IAM in a resource-based policy.

Access Control Lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the Amazon Simple Storage Service Developer Guide.

Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity’s identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the IAM User Guide.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the AWS Organizations User Guide.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session’s permissions are the intersection of the user or role’s identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the IAM User Guide.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the IAM User Guide.
How Amazon Fraud Detector works with IAM

Before you use IAM to manage access to Amazon Fraud Detector, you should understand what IAM features are available to use with Amazon Fraud Detector. To get a high-level view of how Amazon Fraud Detector and other AWS services work with IAM, see AWS Services That Work with IAM in the IAM User Guide.

Topics

- Amazon Fraud Detector identity-based policies (p. 63)
- Amazon Fraud Detector resource-based policies (p. 65)
- Authorization Based on Amazon Fraud Detector Tags (p. 65)
- Amazon Fraud Detector IAM roles (p. 65)

Amazon Fraud Detector identity-based policies

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. Amazon Fraud Detector supports specific actions, resources, and condition keys. To learn about all of the elements that you use in a JSON policy, see IAM JSON Policy Elements Reference in the IAM User Guide.

To get started with Amazon Fraud Detector, we recommend creating an IAM user with access restricted to Amazon Fraud Detector operations and required permissions. You can add other permissions as needed. The following policies provide the required permission to use Amazon Fraud Detector: AmazonFraudDetectorFullAccessPolicy and AmazonS3FullAccess. For more information on setting up Amazon Fraud Detector using these policies see Set up Amazon Fraud Detector (p. 4).

Actions

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as permission-only actions that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called dependent actions.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Amazon Fraud Detector use the following prefix before the action: frauddetector:. For example, to create a rule with the Amazon Fraud Detector CreateRule API operation, you include the frauddetector:CreateRule action in the policy. Policy statements must include either an Action or NotAction element. Amazon Fraud Detector defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": [  
   "frauddetector:action1",  
   "frauddetector:action2"
]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action:

```
"Action": "frauddetector:Describe**"
```
To see a list of Amazon Fraud Detector actions, see Actions Defined by Amazon Fraud Detector in the IAM User Guide.

**Resources**

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as resource-level permissions.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

**Resource Types Defined by Amazon Fraud Detector** lists all Amazon Fraud Detector resource ARNs.

For example, to specify the `my_detector` detector in your statement, use the following ARN:

```
"Resource": "arn:aws:frauddetector:us-east-1:123456789012:detector/my_detector"
```

For more information about the format of ARNs, see Amazon Resource Names (ARNs) and AWS Service Namespaces.

To specify all detectors that belong to a specific account, use the wildcard (*):

```
"Resource": "arn:aws:frauddetector:us-east-1:123456789012:detector/*"
```

Some Amazon Fraud Detector actions, such as those for creating resources, cannot be performed on a specific resource. In those cases, you must use the wildcard (*).

```
"Resource": "*"
```

To see a list of Amazon Fraud Detector resource types and their ARNs, see Resources Defined by Amazon Fraud Detector in the IAM User Guide. To learn which actions you can specify the ARN of each resource, see Actions Defined by Amazon Fraud Detector.

**Condition keys**

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Condition element (or Condition block) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.
You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the IAM User Guide.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

Amazon Fraud Detector defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS Global Condition Context Keys in the IAM User Guide.

To see a list of Amazon Fraud Detector condition keys, see Condition Keys for Amazon Fraud Detector in the IAM User Guide. To learn which actions and resources you can use a condition key, see Actions Defined by Amazon Fraud Detector.

Examples

To view examples of Amazon Fraud Detector identity-based policies, see Amazon Fraud Detector identity-based policy examples (p. 66).

Amazon Fraud Detector resource-based policies

Amazon Fraud Detector does not support resource-based policies.

Authorization Based on Amazon Fraud Detector Tags

You can attach tags to Amazon Fraud Detector resources or pass tags in a request to Amazon Fraud Detector. To control access based on tags, you provide tag information in the condition element of a policy using the aws:ResourceTag/key-name, aws:RequestTag/key-name, or aws:TagKeys condition keys.

Amazon Fraud Detector IAM roles

An IAM role is an entity within your AWS account that has specific permissions.

Using temporary credentials with Amazon Fraud Detector

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling AWS STS API operations such as AssumeRole or GetFederationToken.

Amazon Fraud Detector supports using temporary credentials.

Service-linked roles

Service-linked roles allow AWS services to access resources in other services to complete an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view but not edit the permissions for service-linked roles.

Amazon Fraud Detector does not support service-linked roles.

Service roles

This feature allows a service to assume a service role on your behalf. This role allows the service to access resources in other services to complete an action on your behalf. Service roles appear in your IAM account and are owned by the account. This means that an IAM administrator can change the permissions for this role. However, doing so might break the functionality of the service.
Amazon Fraud Detector supports service roles.

**Amazon Fraud Detector identity-based policy examples**

By default, IAM users and roles don't have permission to create or modify Amazon Fraud Detector resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating Policies on the JSON Tab in the *IAM User Guide*.

**Topics**

- Policy best practices (p. 66)
- AWS-managed (predefined) policy for Amazon Fraud Detector (p. 66)
- Allow users to view their own permissions (p. 67)
- Allowing full access to Amazon Fraud Detector resources (p. 68)
- Allowing read-only access to Amazon Fraud Detector resources (p. 68)
- Allowing access to a specific resource (p. 68)
- Limiting access based on tags (p. 69)

**Policy best practices**

Identity-based policies are very powerful. They determine whether someone can create, access, or delete Amazon Fraud Detector resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started using AWS managed policies** – To start using Amazon Fraud Detector quickly, use AWS managed policies to give your employees the permissions they need. These policies are already available in your account and are maintained and updated by AWS. For more information, see Get started using permissions with AWS managed policies in the *IAM User Guide*.

- **Grant least privilege** – When you create custom policies, grant only the permissions required to perform a task. Start with a minimum set of permissions and grant additional permissions as necessary. Doing so is more secure than starting with permissions that are too lenient and then trying to tighten them later. For more information, see Grant least privilege in the *IAM User Guide*.

- **Enable MFA for sensitive operations** – For extra security, require IAM users to use multi-factor authentication (MFA) to access sensitive resources or API operations. For more information, see Using multi-factor authentication (MFA) in AWS in the *IAM User Guide*.

- **Use policy conditions for extra security** – To the extent that it's practical, define the conditions under which your identity-based policies allow access to a resource. For example, you can write conditions to specify a range of allowable IP addresses that a request must come from. You can also write conditions to allow requests only within a specified date or time range, or to require the use of SSL or MFA. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.

**AWS-managed (predefined) policy for Amazon Fraud Detector**

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. These AWS managed policies grant necessary permissions for common use cases.
so that you can avoid having to investigate which permissions are needed. For more information, see AWS Managed Policies in the IAM User Guide.

The following AWS managed policy, which you can attach to users in your account, is specific to Amazon Fraud Detector:

AmazonFraudDetectorFullAccess: Grants full access to Amazon Fraud Detector resources, actions and the supported operations including:

- List and describe all model endpoints in Amazon SageMaker
- List all IAM roles in the account
- List all Amazon S3 buckets
- Allow IAM Pass Role to pass a role to Amazon Fraud Detector

This policy does not provide unrestricted S3 access. If you need to upload model training datasets to S3, the AmazonS3FullAccess managed policy (or scoped-down custom Amazon S3 access policy) is also required.

You can review the policy's permissions by signing in to the IAM console and searching by the policy name. You can also create your own custom IAM policies to allow permissions for Amazon Fraud Detector actions and resources as you need them. You can attach these custom policies to the IAM users or groups that require them.

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "ViewOwnUserInfo",
         "Effect": "Allow",
         "Action": [
            "iam:GetUserPolicy",
            "iam:ListGroupsForUser",
            "iam:ListAttachedUserPolicies",
            "iam:ListUserPolicies",
            "iam:GetUser"
         ],
         "Resource": ["arn:aws:iam::*:user/${aws:username}"],
      },
      {
         "Sid": "NavigateInConsole",
         "Effect": "Allow",
         "Action": [
            "iam:GetGroupPolicy",
            "iam:GetPolicyVersion",
            "iam:GetPolicy",
            "iam:ListAttachedGroupPolicies",
            "iam:ListGroupPolicies",
            "iam:ListPolicyVersions",
            "iam:ListPolicies",
            "iam:ListUsers"
         ],
         "Resource": "*"
      }
   ]
}
```
Allowing full access to Amazon Fraud Detector resources

The following example gives an IAM user in your AWS account full access to all Amazon Fraud Detector resources and actions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "frauddetector:*"
      ],
      "Resource": "*"
    }
  ]
}
```

Allowing read-only access to Amazon Fraud Detector resources

In this example, you grant an IAM user in your AWS account read-only access to your Amazon Fraud Detector resources.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "frauddetector:GetEventTypes",
        "frauddetector:BatchGetVariable",
        "frauddetector:DescribeDetector",
        "frauddetector:GetModelVersion",
        "frauddetector:GetEventPrediction",
        "frauddetector:GetExternalModels",
        "frauddetector:GetLabels",
        "frauddetector:GetVariables",
        "frauddetector:GetDetectors",
        "frauddetector:GetRules",
        "frauddetector:ListTagsForResource",
        "frauddetector:GetKMSEncryptionKey",
        "frauddetector:DescribeModelVersions",
        "frauddetector:GetDetectorVersion",
        "frauddetector:GetPrediction",
        "frauddetector:GetOutcomes",
        "frauddetector:GetEntityTypes",
        "frauddetector:GetModels"
      ],
      "Resource": "*"
    }
  ]
}
```

Allowing access to a specific resource

In this example of a resource-level policy, you grant an IAM user in your AWS account access to all actions and resources except for one particular Detector resource.
Identity-based policy examples

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["frauddetector:*"],
            "Resource": "*"
        },
        {
            "Effect": "Deny",
            "Action": ["frauddetector:*Detector"],
            "Resource": "arn:${Partition}:frauddetector:${Region}:${Account}:detector/${detector-name}"
        }
    ]
}
```

**Limiting access based on tags**

This example policy demonstrates how to limit access to Amazon Fraud Detector based on resource tags. This example assumes that:

- In your AWS account you have defined two different IAM groups, named Team1 and Team2
- You have created four detectors
- You want to allow members of Team1 to make API calls on 2 detectors
- You want to allow members of Team2 to make API calls on the other 2 detectors

To control access to API calls (example)

1. Add a tag with the key `Project` and value `A` to the detectors used by Team1.
2. Add a tag with the key `Project` and value `B` to the detectors used by Team2.
3. Create an IAM policy with a `ResourceTag` condition that denies access to detectors that have tags with key `Project` and value `B`, and attach that policy to Team1.
4. Create an IAM policy with a `ResourceTag` condition that denies access to detectors that have tags with key `Project` and value `A`, and attach that policy to Team2.

The following is an example of a policy that denies all API calls on any Amazon Fraud Detector resource that has a tag with a key of `Project` and a value of `B`:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "frauddetector:*",
            "Resource": "*"
        },
        {
            "Effect": "Deny",
            "Action": "frauddetector:*",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                }
            }
        }
    ]
}
```
You can modify the scope of this policy by listing the specific action or actions that will be allowed or denied by the policy in the **Action** element.

**Troubleshooting Amazon Fraud Detector identity and access**

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon Fraud Detector and IAM.

**Topics**

- I am not authorized to perform an action in Amazon Fraud Detector (p. 70)
- I am not authorized to perform iam:PassRole (p. 70)
- I want to view my access keys (p. 71)
- I'm an administrator and want to allow others to access Amazon Fraud Detector (p. 71)
- I want to allow people outside of my AWS account to access my Amazon Fraud Detector resources (p. 71)
- Amazon Fraud Detector could not assume the given role (p. 72)

**I am not authorized to perform an action in Amazon Fraud Detector**

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password.

The following example error occurs when the **mateojackson** IAM user tries to use the console to view details about a **detector** but does not have **frauddetector:GetDetectors** permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform: frauddetector:GetDetectors on resource: my-example-detector
```

In this case, Mateo asks his administrator to update his policies to allow him to access the **my-example-detector** resource using the **frauddetector:GetDetectors** action.

**I am not authorized to perform iam:PassRole**

If you receive an error that you're not authorized to perform the **iam:PassRole** action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password. Ask that person to update your policies to allow you to pass a role to Amazon Fraud Detector.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named **marymajor** tries to use the console to perform an action in Amazon Fraud Detector. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole

In this case, Mary asks her administrator to update her policies to allow her to perform the iam:PassRole action.

I want to view my access keys

After you create your IAM user access keys, you can view your access key ID at any time. However, you can't view your secret access key again. If you lose your secret key, you must create a new access key pair.

Access keys consist of two parts: an access key ID (for example, AKIAIOSFODNN7EXAMPLE) and a secret access key (for example, wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY). Like a user name and password, you must use both the access key ID and secret access key together to authenticate your requests. Manage your access keys as securely as you do your user name and password.

**Important**
Do not provide your access keys to a third party, even to help find your canonical user ID. By doing this, you might give someone permanent access to your account.

When you create an access key pair, you are prompted to save the access key ID and secret access key in a secure location. The secret access key is available only at the time you create it. If you lose your secret access key, you must add new access keys to your IAM user. You can have a maximum of two access keys. If you already have two, you must delete one key pair before creating a new one. To view instructions, see Managing access keys in the *IAM User Guide*.

I'm an administrator and want to allow others to access Amazon Fraud Detector

To allow others to access Amazon Fraud Detector, you must create an IAM entity (user or role) for the person or application that needs access. They will use the credentials for that entity to access AWS. You must then attach a policy to the entity that grants them the correct permissions in Amazon Fraud Detector.

To get started right away, see Creating your first IAM delegated user and group in the *IAM User Guide*.

I want to allow people outside of my AWS account to access my Amazon Fraud Detector resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon Fraud Detector supports these features, see How Amazon Fraud Detector works with IAM (p. 63).
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the *IAM User Guide*.

Version latest
71
Amazon Fraud Detector could not assume the given role

If you receive an error that Amazon Fraud Detector could not assume the given role, then you must update the trust relationship for the specified role. By specifying Amazon Fraud Detector as a trusted entity, the service can assume the role. When you use Amazon Fraud Detector to create a role, this trust relationship is automatically set. You only need to establish this trust relationship for IAM roles that are not created by Amazon Fraud Detector.

To establish a trust relationship for an existing role to Amazon Fraud Detector

1. Open the IAM console at https://console.aws.amazon.com/iam/
2. In the navigation pane choose Roles.
3. Choose the name of the role that you want to modify, and choose the Trust relationships tab.
5. Under Policy Document, paste the following, and then choose Update Trust Policy.

```
{
    "Version": "2012-10-17",
    "Statement": [ {
        "Effect": "Allow",
        "Principal": { 
            "Service": "frauddetector.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
    } ]
}
```

Logging and monitoring in Amazon Fraud Detector

AWS provides the following monitoring tools to watch Amazon Fraud Detector, report when something is wrong, and take automatic actions when appropriate:

- Amazon CloudWatch monitors your AWS resources and the applications you run on AWS in real time. For more information on CloudWatch, see the Amazon CloudWatch User Guide.
- AWS CloudTrail captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. For more information an CloudTrail, see the AWS CloudTrail User Guide.

For more information on monitoring Amazon Fraud Detector, see Monitor Amazon Fraud Detector (p. 74).

Compliance validation for Amazon Fraud Detector

Third-party auditors assess the security and compliance of AWS services as part of multiple AWS compliance programs, such as SOC, PCI, FedRAMP, and HIPAA.

To learn whether Amazon Fraud Detector or other AWS services are in scope of specific compliance programs, see AWS Services in Scope by Compliance Program. For general information, see AWS Compliance Programs.
You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company’s compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.
- **Architecting for HIPAA Security and Compliance Whitepaper** – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.

  **Note**
  Not all services are compliant with HIPAA.

- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.
- **Evaluating Resources with Rules** in the *AWS Config Developer Guide* – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.
- **AWS Audit Manager** – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

### Resilience in Amazon Fraud Detector

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see [AWS Global Infrastructure](https://aws.amazon.com/about-aws/global-infrastructure/).

### Infrastructure Security in Amazon Fraud Detector

As a managed service, Amazon Fraud Detector is protected by the AWS global network security procedures that are described in the *Amazon Web Services: Overview of Security Processes* whitepaper.

You use AWS published API calls to access Amazon Fraud Detector through the network. Clients must support Transport Layer Security (TLS) 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the *AWS Security Token Service* (AWS STS) to generate temporary security credentials to sign requests.
Monitor Amazon Fraud Detector

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Fraud Detector and your other AWS solutions. AWS provides the following monitoring tools to watch Amazon Fraud Detector, report when something is wrong, and take automatic actions when appropriate:

- **Amazon CloudWatch** monitors your AWS resources and the applications you run on AWS in real time. You can collect and track metrics, create customized dashboards, and set alarms that notify you or take actions when a specified metric reaches a threshold that you specify. For more information, see the Amazon CloudWatch User Guide.

- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the AWS CloudTrail User Guide.

**Topics**
- Monitoring Amazon Fraud Detector with Amazon CloudWatch (p. 74)
- Logging Amazon Fraud Detector API Calls with AWS CloudTrail (p. 78)

Monitoring Amazon Fraud Detector with Amazon CloudWatch

You can monitor Amazon Fraud Detector using CloudWatch, which collects raw data and processes it into readable, near real-time metrics. These statistics are kept for 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing. You can also set alarms that watch for certain thresholds, and send notifications or take actions when those thresholds are met. For more information, see the Amazon CloudWatch User Guide.

**Topics**
- Using CloudWatch Metrics for Amazon Fraud Detector (p. 74)
- Amazon Fraud Detector Metrics (p. 76)

Using CloudWatch Metrics for Amazon Fraud Detector

To use metrics, you must specify the following information:

- The metric dimension or no dimension. A *dimension* is a name-value pair that helps you to uniquely identify a metric.
- The metric name, such as `GetEventPrediction`.

You can get monitoring data for Amazon Fraud Detector by using the AWS Management Console, the AWS CLI, or the CloudWatch API. You can also use the CloudWatch API through one of the Amazon AWS Software Development Kits (SDKs) or the CloudWatch API tools. The console displays a series of graphs based on the raw data from the CloudWatch API. Depending on your needs, you might prefer to use either the graphs displayed in the console or retrieved from the API.
The following list shows some common uses for the metrics. These are suggestions to get you started, not a comprehensive list.

<table>
<thead>
<tr>
<th>How Do I?</th>
<th>Relevant Metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>How do I track the number of predictions that have been performed?</td>
<td>Monitor the GetEventPrediction metric.</td>
</tr>
<tr>
<td>How can I monitor the latency of GetEventPrediction calls?</td>
<td>Use the GetEventPredictionLatency metric.</td>
</tr>
</tbody>
</table>

You must have the appropriate CloudWatch permissions to monitor Amazon Fraud Detector with CloudWatch. For more information, see Authentication and Access Control for Amazon CloudWatch.

**Access Amazon Fraud Detector Metrics**

The following steps show how to access Amazon Fraud Detector metrics using the CloudWatch console.

**To view metrics (console)**

2. Choose Metrics, choose the All Metrics tab, and then choose Fraud Detector.
3. Choose the metric dimension.
4. Choose the desired metric from the list, and choose a time period for the graph.

**Create an Alarm**

You can create a CloudWatch alarm that sends an Amazon Simple Notification Service (Amazon SNS) message when the alarm changes state. An alarm watches a single metric over a time period that you specify. It performs one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or an Auto Scaling policy.

Alarms invoke actions for sustained state changes only. CloudWatch alarms don't invoke actions simply because they are in a particular state. The state must have changed and have been maintained for a specified number of time periods.

**To set an alarm (console)**

1. Sign in to the AWS Management Console and open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. In the navigation pane, choose Alarms, and choose Create Alarm. This opens the Create Alarm Wizard.
3. Choose Select metric.
4. In the All metrics tab, choose Fraud Detector.
5. Choose By Detector ID, and then choose the GetEventPrediction metric.
6. Choose the Graphed metrics tab.
7. For Statistic, choose Sum.
8. Choose Select metric.
9. For **Conditions**, choose **Static** for **Threshold type** and **Greater** for **Whenever...**, and then enter a maximum value of your choice. Choose **Next**.

10. To send alarms to an existing Amazon SNS topic, for **Send notification to:**, choose an existing SNS topic. To set the name and email addresses for a new email subscription list, choose **New list**. CloudWatch saves the list and displays it in the field so you can use it to set future alarms.

   **Note**
   If you use **New list** to create a new Amazon SNS topic, the email addresses must be verified before the intended recipients receive notifications. Amazon SNS sends email only when the alarm enters an alarm state. If this alarm state change happens before the email addresses are verified, intended recipients don't receive a notification.

11. Choose **Next**. Add a name and optional description for your alarm. Choose **Next**.

12. Choose **Create Alarm**.

## Amazon Fraud Detector Metrics

Amazon Fraud Detector sends the following metrics to CloudWatch. All metrics support these statistics: **Average**, **Minimum**, **Maximum**, **Sum**.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetEventPrediction</td>
<td>The number of GetEventPrediction API requests.</td>
</tr>
<tr>
<td></td>
<td>Valid Dimensions: DetectorID</td>
</tr>
<tr>
<td>GetEventPredictionLatency</td>
<td>The interval of time taken to respond to a client request from the GetEventPrediction request.</td>
</tr>
<tr>
<td></td>
<td>Valid Dimensions: DetectorID</td>
</tr>
<tr>
<td></td>
<td>Unit: Milliseconds</td>
</tr>
<tr>
<td>GetEventPrediction4XXError</td>
<td>The number of GetEventPrediction requests where Amazon Fraud Detector returned a 4xx HTTP response code. For each 4xx response, 1 is sent.</td>
</tr>
<tr>
<td></td>
<td>Valid Dimensions: DetectorID</td>
</tr>
<tr>
<td>GetEventPrediction5XXError</td>
<td>The number of GetEventPrediction requests where Amazon Fraud Detector returned a 5xx HTTP response code. For each 5xx response, 1 is sent.</td>
</tr>
<tr>
<td></td>
<td>Valid Dimensions: DetectorID</td>
</tr>
<tr>
<td>Prediction</td>
<td>The number of predictions. 1 is sent if successful.</td>
</tr>
<tr>
<td></td>
<td>Valid Dimensions: DetectorID, DetectorVersionID</td>
</tr>
<tr>
<td>PredictionLatency</td>
<td>The interval of time taken for a prediction operation.</td>
</tr>
<tr>
<td></td>
<td>Valid Dimensions: DetectorID, DetectorVersionID</td>
</tr>
<tr>
<td></td>
<td>Unit: Milliseconds</td>
</tr>
<tr>
<td>PredictionError</td>
<td>The number of predictions where Amazon Fraud Detector encountered an error. 1 is sent if an error is encountered.</td>
</tr>
</tbody>
</table>
### Amazon Fraud Detector Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>VariableUsed</strong></td>
<td>The number of GetEventPrediction requests where the variable was used as part of the evaluation. &lt;br&gt;Valid Dimensions: DetectorID, DetectorVersionID, VariableName</td>
</tr>
<tr>
<td><strong>VariableDefaultReturned</strong></td>
<td>The number of GetEventPrediction requests where the variable was not present as part of the Event Attributes and therefore the default value for the variable was used during evaluation. &lt;br&gt;Valid Dimensions: DetectorID, DetectorVersionID, VariableName</td>
</tr>
<tr>
<td><strong>RuleNotEvaluated</strong></td>
<td>The number of GetEventPrediction requests where the rule was not evaluated because a prior rule matched. &lt;br&gt;Valid Dimensions: DetectorID, DetectorVersionID, RuleID</td>
</tr>
<tr>
<td><strong>RuleEvaluateTrue</strong></td>
<td>The number of GetEventPrediction requests where the rule triggered as True and the rule outcome was returned. &lt;br&gt;Valid Dimensions: DetectorID, DetectorVersionID, RuleID</td>
</tr>
<tr>
<td><strong>RuleEvaluateFalse</strong></td>
<td>The number of GetEventPrediction requests where the rule evaluated to False. &lt;br&gt;Valid Dimensions: DetectorID, DetectorVersionID, RuleID</td>
</tr>
<tr>
<td><strong>RuleEvaluateError</strong></td>
<td>The number of GetEventPrediction requests where the rule evaluates in error &lt;br&gt;Valid Dimensions: DetectorID, DetectorVersionID, RuleID</td>
</tr>
<tr>
<td><strong>OutcomeReturned</strong></td>
<td>The number of GetEventPrediction calls where the specified outcome was returned. &lt;br&gt;Valid Dimensions: DetectorID, DetectorVersionID, OutcomeName</td>
</tr>
<tr>
<td><strong>ModelInvocation (Amazon SageMaker model endpoint)</strong></td>
<td>The number of GetEventPrediction requests where the SageMaker model endpoint was invoked as part of the evaluation. &lt;br&gt;Valid Dimensions: DetectorID, DetectorVersionID, ModelEndpoint</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>ModelInvocationError (Amazon SageMaker model endpoint)</td>
<td>The number of GetEventPrediction requests where the invoked SageMaker model endpoint returned an error during evaluation. Valid Dimensions: DetectorID, DetectorVersionID, ModelEndpoint</td>
</tr>
<tr>
<td>ModelInvocationLatency (Amazon SageMaker model endpoint)</td>
<td>The interval of time taken by the imported Model to respond as viewed from Amazon Fraud Detector. This interval includes only the model invocation. Valid Dimensions: DetectorID, DetectorVersionID, ModelEndpoint Unit: Milliseconds</td>
</tr>
<tr>
<td>ModelInvocation</td>
<td>The number of GetEventPrediction requests where the model was invoked as part of the evaluation. Valid Dimensions: DetectorID, DetectorVersionID, ModelType, ModelID</td>
</tr>
<tr>
<td>ModelInvocationError</td>
<td>The number of GetEventPrediction requests where the Amazon Fraud Detector model returned an error during evaluation. Valid Dimensions: DetectorID, DetectorVersionID, ModelType, ModelID</td>
</tr>
<tr>
<td>ModelInvocationLatency</td>
<td>The interval of time taken by the Amazon Fraud Detector Model to respond as viewed from Amazon Fraud Detector. This interval includes only the model invocation. Valid Dimensions: DetectorID, DetectorVersionID, ModelType, ModelID Unit: Milliseconds</td>
</tr>
</tbody>
</table>

Logging Amazon Fraud Detector API Calls with AWS CloudTrail

Amazon Fraud Detector is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Amazon Fraud Detector. CloudTrail captures all API calls for Amazon Fraud Detector as events, including calls from the Amazon Fraud Detector console and calls from code to the Amazon Fraud Detector APIs.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Amazon Fraud Detector. If you don’t configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request that was made to Amazon Fraud Detector, the IP address that the request was made from, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.
Amazon Fraud Detector Information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Amazon Fraud Detector, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for Amazon Fraud Detector, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data that's collected in CloudTrail logs. For more information, see the following:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

Amazon Fraud Detector supports logging every action (API operation) as an event in CloudTrail log files. For more information, see Actions.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.

Understanding Amazon Fraud Detector Log File Entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the GetDetectors operation.

```json
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "principal-id",
    "arn": "arn:aws:iam::user-arn",
    "accountId": "account-id",

Quotas

Your AWS account has default quotas, formerly referred to as limits, for each Amazon Web Service. Unless otherwise noted, each quota is Region-specific. You can request a quota increase for all adjustable quotas mentioned in the tables below. For more information, see Requesting a quota increase.

The following tables outline Amazon Fraud Detector quotas by component.

### Amazon Fraud Detector models

<table>
<thead>
<tr>
<th>Quota name</th>
<th>Default quota</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Training data size</td>
<td>5 GB</td>
<td>No</td>
