AWS General Reference

The AWS General Reference provides information that is useful across Amazon Web Services.

Contents

- AWS security credentials (p. 2)
- Service endpoints and quotas (p. 16)
- AWS resources (p. 739)
- AWS IP address ranges (p. 750)
- AWS APIs (p. 759)
- Document conventions (p. 799)
- AWS glossary (p. 801)
AWS security credentials

When you interact with AWS, you specify your AWS security credentials to verify who you are and whether you have permission to access the resources that you are requesting. AWS uses the security credentials to authenticate and authorize your requests.

For example, if you want to download a protected file from an Amazon Simple Storage Service (Amazon S3) bucket, your credentials must allow that access. If your credentials aren't authorized to download the file, AWS denies your request. However, your AWS security credentials are not required to download a file in an Amazon S3 bucket that is publicly shared.

Contents
- AWS account root user credentials and IAM user credentials (p. 2)
- Understanding and getting your AWS credentials (p. 3)
- Your AWS account identifiers (p. 6)
- Best practices for managing AWS access keys (p. 7)
- AWS security audit guidelines (p. 10)

AWS account root user credentials and IAM user credentials

There are two different types of users in AWS. You are either the account owner (root user) or you are an AWS Identity and Access Management (IAM) user. The root user is created when the AWS account is created and IAM users are created by the root user or an IAM administrator for the account. All AWS users have security credentials.

Root user credentials

The credentials of the account owner allow full access to all resources in the account. You cannot use IAM policies to explicitly deny the root user access to resources. You can only use an AWS Organizations service control policy (SCP) to limit the permissions of the root user. Because of this, we recommend that you create an IAM user with administrator permissions to use for everyday AWS tasks and lock away the access keys for the root user.

There are specific tasks that are restricted to the AWS account root user. For example, only the root user can close your account. If you need to perform a task that requires the root user, sign in to the AWS Management Console using the email address and password of the root user. For more information, see Tasks that require root user credentials (p. 3).

IAM credentials

With IAM, you can securely control access to AWS services and resources for users in your AWS account. For example, if you require administrator-level permissions, you can create an IAM user, grant that user full access, and then use those credentials to interact with AWS. If you need to modify or revoke your permissions, you can delete or modify the policies that are associated with that IAM user.

If you have multiple users that require access to your AWS account, you can create unique credentials for each user and define who has access to which resources. You don't need to share credentials. For
example, you can create IAM users with read-only access to resources in your AWS account and distribute those credentials to users.

Tasks that require root user credentials

We recommend that you use an IAM user with appropriate permissions to perform tasks and access AWS resources. However, you can perform the tasks listed below only when you sign in as the root user of an account.

Tasks

- Change your account settings. This includes the account name, email address, root user password, and root user access keys. Other account settings, such as contact information, payment currency preference, and Regions, do not require root user credentials.
- Restore IAM user permissions. If the only IAM administrator accidentally revokes their own permissions, you can sign in as the root user to edit policies and restore those permissions.
- Activate IAM access to the Billing and Cost Management console.
- View certain tax invoices. An IAM user with the aws-portal:ViewBilling permission can view and download VAT invoices from AWS Europe, but not AWS Inc or Amazon Internet Services Pvt. Ltd (AISPL).
- Close your AWS account.
- Change your AWS Support plan or Cancel your AWS Support plan. For more information, see IAM for AWS Support.
- Register as a seller in the Reserved Instance Marketplace.
- Configure MFA delete for your S3 bucket.
- Edit or delete an Amazon S3 bucket policy that includes an invalid VPC ID or VPC endpoint ID.
- Sign up for GovCloud.

Troubleshooting

If you cannot complete any of these tasks using your root user credentials, your account might be a member of an organization in AWS Organizations. If your organizational administrator used a service control policy (SCP) to limit the permissions of your account, your root user permissions might be affected. For more information, see Service control policies in the AWS Organizations User Guide.

Understanding and getting your AWS credentials

AWS requires different types of security credentials depending on how you access AWS. For example, you need a user name and password to sign in to the AWS Management Console and you need access keys to make programmatic calls to AWS or to use the AWS Command Line Interface or AWS Tools for PowerShell.

Considerations

- Be sure to save the following in a secure location: the email address associated with your AWS account, the AWS account ID, the root user password, and your account access keys. If you forget or lose your root user password, you must have access to the email address associated with your account in order to reset it. If you forget or lose your access keys, you must sign into your account to create new ones.
- We strongly recommend that you create an IAM user with administrator permissions to use for everyday AWS tasks and lock away the password and access keys for the root user. Use the root user only for the tasks that are restricted to the root user.
Security credentials are account-specific. If you have access to multiple AWS accounts, you have separate credentials for each account.

Do not provide your AWS credentials to a third party.

Credentials

- Console access (p. 4)
- Programmatic access (p. 5)
- Temporary access keys (p. 6)

Console access

There are two different types of users in AWS. You are either the account owner (root user) or you are an AWS Identity and Access Management (IAM) user. How you sign in to the AWS Management Console depends on whether you are the root user or an IAM user.

Contents

- Root user email address and password (p. 4)
- IAM user name and password (p. 4)
- Multi-factor authentication (MFA) (p. 4)

Root user email address and password

When you first create an AWS account, you specify an email address for the account and a password for the root user. To sign in to your AWS account as the root user, you provide this email address and password. The root user can sign in to the AWS Management Console and change the account name, email address, and password using the Security Credentials page. If you forget the password for the root user, open the console sign-in page and choose Forgot your password? to reset your password. This process requires access to the email address for the account.

IAM user name and password

IAM users are created by the root user or an IAM administrator within the AWS account. The user who created your IAM user should provide you with either the account alias or 12-digit AWS account ID, the IAM user name, and the password for the IAM user. An IAM user can sign in using either the console sign-in page or the following sign-in URL, replacing account_id_or_alias with either the account alias or AWS account ID provided to you:

https://account_id_or_alias.signin.aws.amazon.com/console/

If you forget the password for your IAM user, contact your IAM administrator or the account owner. If your IAM administrator gave you permissions to manage your own AWS credentials, then you can change your password periodically, which is a security best practice, using the Security Credentials page.

Multi-factor authentication (MFA)

Multi-factor authentication (MFA) provides an extra level of security that you can apply to your AWS account. For additional security, we recommend that you require MFA on the AWS account root user credentials and highly privileged IAM users. For more information, see Using Multi-Factor Authentication (MFA) in AWS in the IAM User Guide.
With MFA enabled, when you sign in to your AWS account, you are prompted for your user name and password, plus an authentication code from an MFA device. Adding MFA provides increased security for your AWS account settings and resources.

By default, MFA (multi-factor authentication) is not enabled. You can enable and manage MFA devices for the AWS account root user by going to the Security Credentials page or the IAM dashboard in the AWS Management Console. For more information about enabling MFA for IAM users, see Enabling MFA Devices in the IAM User Guide.

**Programmatic access**

You must provide your AWS access keys to make programmatic calls to AWS or to use the AWS Command Line Interface or AWS Tools for PowerShell.

When you create your access keys, you create the access key ID (for example, AKIAIOSFODNN7EXAMPLE) and secret access key (for example, wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY) as a set. The secret access key is available for download only when you create it. If you don't download your secret access key or if you lose it, you must create a new one.

You can assign up to two access keys per user (root user or IAM user). Having two access keys is useful when you want to rotate them. When you disable an access key, you can't use it, but it counts toward your limit of two access keys. After you delete an access key, it's gone forever and can't be restored, but it can be replaced with a new access key.

**To manage access keys when signed in as the root user**

1. Sign in to the AWS Management Console as the root user. For more information, see Sign in as the root user in the IAM User Guide.
2. In the navigation bar on the upper right, choose your account name or number and then choose My Security Credentials.
3. Expand the Access keys (access key ID and secret access key) section.
4. Do one of the following:
   - To create an access key, choose Create New Access Key. If you already have two access keys, this button is disabled and you must delete an access key before you can create a new one. When prompted, choose either Show Access Key or Download Key File. This is your only opportunity to save your secret access key. After you've saved your secret access key in a secure location, choose Close.
   - To deactivate an access key, choose Make Inactive. When prompted for confirmation, choose Deactivate. A deactivated access key still counts toward your limit of two access keys.
   - To activate an access key, choose Make Active.
   - To delete an access key when you no longer need it, copy the access key ID and then choose Delete. Before you can delete the access key, you must choose Deactivate. We recommend that you verify that the access key is no longer in use before you permanently delete it. To confirm deletion, paste the access key ID in the text input field and then choose Delete.

**To manage access keys when signed in as an IAM user**

1. Sign in to the AWS Management Console as an IAM user. For more information, see Sign in as an IAM user in the IAM User Guide.
2. In the navigation bar on the upper right, choose your user name and then choose My Security Credentials.
   - Tip
     If you do not see the My Security Credentials page, you might be signed in as a federated user, not an IAM user. You can create and use temporary access keys (p. 6) instead.
3. Do one of the following:

- To create an access key, choose **Create access key**. If you already have two access keys, this button is disabled and you must delete an access key before you can create a new one. When prompted, choose either **Show secret access key** or **Download .csv file**. This is your only opportunity to save your secret access key. After you’ve saved your secret access key in a secure location, chose **Close**.
- To deactivate an access key, choose **Make inactive**. When prompted for confirmation, choose **Deactivate**. A deactivated access key still counts toward your limit of two access keys.
- To activate an access key, choose **Make active**. When prompted for confirmation, choose **Make active**.
- To delete an access key when you no longer need it, copy the access key ID and then choose **Delete**. This deactivates the access key. We recommend that you verify that the access key is no longer in use before you permanently delete it. To confirm deletion, paste the access key ID in the text input field and then choose **Delete**.

**Temporary access keys**

You can also create and use temporary access keys, known as **temporary security credentials**. In addition to the access key ID and secret access key, temporary security credentials include a security token that you must send to AWS when you use temporary security credentials. The advantage of temporary security credentials is that they are short term. After they expire, they’re no longer valid. You can use temporary access keys in less secure environments or distribute them to grant users temporary access to resources in your AWS account. For example, you can grant entities from other AWS accounts access to resources in your AWS account (cross-account access). You can also grant users who don’t have AWS security credentials access to resources in your AWS account (federation). For more information, see `aws sts assume-role`.

**Your AWS account identifiers**

AWS assigns the following unique identifiers to each AWS account:

**AWS account ID**

A 12-digit number, such as 123456789012, that uniquely identifies an AWS account. Many AWS resources include the account ID in their **Amazon Resource Names (ARNs)**. The account ID portion distinguishes resources in one account from the resources in another account. If you are an IAM user, you can sign in to the AWS Management Console using either the account ID or account alias.

**Canonical user ID**

An alpha-numeric identifier, such as 79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be, that is an obfuscated form of the AWS account ID. You can use this ID to identify an AWS account when granting cross-account access to buckets and objects using Amazon S3. You can retrieve the canonical user ID for your AWS account as either the root user or an IAM user.

For more information, see **Finding the canonical user ID for your AWS account** in the **Amazon S3 User Guide**.

You must be authenticated with AWS to view these identifiers.

**Warning**

Do not provide your **AWS credentials** (p. 3) to a third party that needs your AWS account identifiers to share AWS resources with you. Doing so would give them the same access to the AWS account that you have.
Finding your AWS account ID

You can find the AWS account ID in the AWS Management Console. The location of the account ID in the console depends on whether you are logged in as the root user or an IAM user. The account ID is the same whether you are logged in as the root user or an IAM user.

Prerequisite

You must be signed in to the AWS Management Console. For more information, see Signing in to the AWS Management Console in the IAM User Guide.

To find your AWS account ID when signed in as the root user

1. In the navigation bar on the upper right, choose your account name or number and then choose My Security Credentials.
2. Expand the Account identifiers section. The account number appears next to the label AWS Account ID.

To find your AWS account ID when signed in as an IAM user

1. In the navigation bar on the upper right, choose your user name and then choose My Security Credentials.

   Tip
   If you do not see the My Security Credentials page, you might be signed in as a federated user, not an IAM user.
2. At the top of the page, under Account details, the account number appears next to the label AWS account ID.

To find your AWS account ID using the AWS CLI

Use the get-caller-identity command as follows:

```
aws sts get-caller-identity --query Account --output text
```

Best practices for managing AWS access keys

When you use AWS programmatically, you provide your AWS access keys so that AWS can verify your identity in programmatic calls. Your access keys consist of an access key ID (for example, AKIAIOSFODNN7EXAMPLE) and a secret access key (for example, wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY).

Anyone who has your access keys has the same level of access to your AWS resources that you do. Consequently, AWS goes to significant lengths to protect your access keys, and, in keeping with our shared-responsibility model, you should as well.

The steps that follow can help you protect your access keys. For background information, see AWS security credentials (p. 2).

Note

Your organization may have different security requirements and policies than those described in this topic. The suggestions provided here are intended as general guidelines.
Protect or don't create your root user access key

You must use an access key (access key ID plus secret access key) to make programmatic requests to AWS. For example, when using the AWS Command Line Interface, an AWS SDK, or direct API calls. Anyone who has the access keys for your AWS account root user has unrestricted access to all resources in your AWS account, including billing information. You can't reduce the permissions associated with the access key for the AWS account root user.

For more information, see Lock away your AWS account root user access keys in the IAM User Guide.

Manage access keys for IAM users

Instead of sharing the credentials of the AWS account root user, create individual IAM users, granting each user only the permissions they require. For more information, see Managing Access Keys for IAM Users in the IAM User Guide.

Observe these precautions when using access keys:

- **Don't embed access keys directly into code.** The AWS SDKs and the AWS Command Line Tools enable you to put access keys in known locations so that you do not have to keep them in code.

  Put access keys in one of the following locations:

  - **The AWS credentials file.** The AWS SDKs and AWS CLI automatically use the credentials that you store in the AWS credentials file.

    For information about using the AWS credentials file, see the documentation for your SDK. Examples include Set up AWS Credentials and Region for Development in the AWS SDK for Java Developer Guide and Configuration and Credential Files in the AWS Command Line Interface User Guide.

    To store credentials for the AWS SDK for .NET and the AWS Tools for Windows PowerShell, we recommend that you use the SDK Store. For more information, see Using the SDK Store in the AWS SDK for .NET Developer Guide.

  - **Environment variables.** On a multitenant system, choose user environment variables, not system environment variables.

    For more information about using environment variables to store credentials, see Environment Variables in the AWS Command Line Interface User Guide.

  - **Remove unused access keys.** If a user leaves your organization, remove the corresponding IAM user so that the user can no longer access your resources. To find out when an access key was last used, use the GetAccessKeyLastUsed API (AWS CLI command: aws iam get-access-key-last-used).

  - **Configure multi-factor authentication for your most sensitive operations.** For more information, see Using Multi-Factor Authentication (MFA) in AWS in the IAM User Guide.

Use IAM roles instead of long-term access keys

In many scenarios, you don't need long-term access keys that never expire (as you have with an IAM user). Instead, you can create IAM roles and generate temporary security credentials. Temporary security credentials consist of an access key ID and a secret access key, but they also include a security token that indicates when the credentials expire.

Long-term access keys, such as those associated with IAM users and AWS account root users, remain valid until you manually revoke them. However, temporary security credentials obtained through IAM roles
and other features of the AWS Security Token Service expire after a short period of time. Use temporary security credentials to help reduce your risk in case credentials are accidentally exposed.

Use an IAM role and temporary security credentials in these scenarios:

- **You have an application or AWS CLI scripts running on an Amazon EC2 instance.** Do not use access keys directly in your application. Don't pass access keys to the application, embed them in the application, or let the application read access keys from any source. Instead, define an IAM role that has appropriate permissions for your application and launch the Amazon EC2 instance with roles for EC2. Doing this associates an IAM role with the Amazon EC2 instance. This practice also enables the application to get temporary security credentials that it can in turn use to make programatic calls to AWS. The AWS SDKs and the AWS CLI can get temporary credentials from the role automatically.

- **You need to grant cross-account access.** Use an IAM role to establish trust between accounts, and then grant users in one account limited permissions to access the trusted account. For more information, see Tutorial: Delegate Access Across AWS Accounts Using IAM Roles in the IAM User Guide.

- **You have a mobile app.** Do not embed access keys with the app, even in encrypted storage. Instead, use Amazon Cognito to manage user identities in your app. This service lets you authenticate users using Login with Amazon, Facebook, Google, or any OpenID Connect (OIDC)–compatible identity provider. You can then use the Amazon Cognito credentials provider to manage credentials that your app uses to make requests to AWS. For more information, see Using the Amazon Cognito Credentials Provider on the AWS Mobile Blog.

- **You want to federate into AWS and your organization supports SAML 2.0.** If you work for an organization that has an identity provider that supports SAML 2.0, configure the provider to use SAML. You can use SAML to exchange authentication information with AWS and get back a set of temporary security credentials. For more information, see About SAML 2.0-based Federation in the IAM User Guide.

- **You want to federate into AWS and your organization has an on-premises identity store.** If users can authenticate inside your organization, you can write an application that can issue them temporary security credentials for access to AWS resources. For more information, see Creating a URL that Enables Federated Users to Access the AWS Management Console (Custom Federation Broker) in the IAM User Guide.

### Access the mobile app using AWS access keys

You can access a limited set of AWS services and features using the AWS mobile app. The mobile app helps you support incident response while on the go. For more information and to download the app, see AWS Console Mobile Application.

You can sign in to the mobile app using your console password or your access keys. As a best practice, do not use root user access keys. Instead, we strongly recommend that in addition to using a password or biometric lock on your mobile device, you create an IAM user to manage AWS resources. If you lose your mobile device, you can remove the IAM user's access. For more information about generating access keys for an IAM user, see Managing Access Keys for IAM Users in the IAM User Guide.

#### To sign in using access keys (mobile app)

1. Open the app on your mobile device.
2. If this is the first time that you're adding an identity to the device, choose **Add an identity** and then choose **Access keys**.

   If you have already signed in using another identity, choose the menu icon and choose **Switch identity**. Then choose **Sign in as a different identity** and then **Access keys**.

3. On the **Access keys** page, enter your information:
   - **Access key ID** – Enter your access key ID.
• **Secret access key** – Enter your secret access key.
• **Identity name** – Enter the name of the identity that will appear in the mobile app. This does not need to match your IAM user name.
• **Identity PIN** – Create a personal identification number (PIN) that you will use for future sign-ins.

  **Note**
  If you enable biometrics for the AWS mobile app, you will be prompted to use your fingerprint or facial recognition for verification instead of the PIN. If the biometrics fail, you might be prompted for the PIN instead.

4. **Choose Verify and add keys.**

You can now access a select set of your resources using the mobile app.

**Learn more**

For more information about best practices for keeping your AWS account secure, see the following resources:

• **IAM Best Practices.** Contains suggestions for using the AWS Identity and Access Management (IAM) service to help secure your AWS resources.

• The following pages provide guidance for setting up the AWS SDKs and the AWS CLI to use access keys.

  • **Set up AWS Credentials and Region for Development** in the *AWS SDK for Java Developer Guide.*
  • **Using the SDK Store** in the *AWS SDK for .NET Developer Guide.*
  • **Providing Credentials to the SDK** in the *AWS SDK for PHP Developer Guide.*
  • **Configuration** in the Boto 3 (AWS SDK for Python) documentation.
  • **Using AWS Credentials** in the *AWS Tools for Windows PowerShell* guide.
  • **Configuration and Credential Files** in the *AWS Command Line Interface User Guide.*
  • **Granting Access Using an IAM Role.** Discusses how programs written using the .NET SDK can automatically get temporary security credentials when running on an Amazon EC2 instance. Similar information is available for the *AWS SDK for Java.*

**AWS security audit guidelines**

You should periodically audit your security configuration to make sure it meets your current business needs. An audit gives you an opportunity to remove unneeded IAM users, roles, groups, and policies, and to make sure that your users and software have only the permissions that are required.

Following are guidelines for systematically reviewing and monitoring your AWS resources for security best practices.

**Contents**

• When you should perform a security audit (p. 11)
• Guidelines for auditing (p. 11)
• Review your AWS account credentials (p. 11)
• Review your IAM users (p. 11)
• Review your IAM groups (p. 12)
• Review your IAM roles (p. 12)
• Review your IAM providers for SAML and OpenID Connect (OIDC) (p. 12)
When you should perform a security audit

You should audit your security configuration in the following situations:

- On a periodic basis. You should perform the steps described in this document at regular intervals as a best practice for security.
- If there are changes in your organization, such as people leaving.
- If you have stopped using one or more individual AWS services. This is important for removing permissions that users in your account no longer need.
- If you’ve added or removed software in your accounts, such as applications on Amazon EC2 instances, AWS OpsWorks stacks, AWS CloudFormation templates, etc.
- If you ever suspect that an unauthorized person might have accessed your account.

Guidelines for auditing

As you review your account's security configuration, follow these guidelines:

- **Be thorough.** Look at all aspects of your security configuration, including those you might not use regularly.
- **Don't assume.** If you are unfamiliar with some aspect of your security configuration (for example, the reasoning behind a particular policy or the existence of a role), investigate the business need until you are satisfied.
- **Keep things simple.** To make auditing (and management) easier, use IAM groups, consistent naming schemes, and straightforward policies.

Review your AWS account credentials

Take these steps when you audit your AWS account credentials:

1. If you’re not using the root access keys for your account, you can remove them. We **strongly recommend** that you do not use root access keys for everyday work with AWS, and that instead you create IAM users.
2. If you do need to keep the access keys for your account, rotate them regularly.

Review your IAM users

Take these steps when you audit your existing IAM users:

1. **List your users** and then delete users that are inactive.
2. **Remove users from groups** that they don't need to be a part of.
3. Review the policies attached to the groups the user is in. See **Tips for reviewing IAM policies** (p. 14).
4. Delete security credentials that the user doesn't need or that might have been exposed. For example, an IAM user that is used for an application does not need a password (which is necessary only to sign in to AWS websites). Similarly, if a user does not use access keys, there's no reason for the user to have one. For more information, see Managing Passwords for IAM Users and Managing Access Keys for IAM Users in the IAM User Guide.

You can generate and download a credential report that lists all IAM users in your account and the status of their various credentials, including passwords, access keys, and MFA devices. For passwords and access keys, the credential report shows how recently the password or access key has been used. Credentials that have not been used recently might be good candidates for removal. For more information, see Getting Credential Reports for your AWS Account in the IAM User Guide.

5. Rotate (change) user security credentials periodically, or immediately if you ever share them with an unauthorized person. For more information, see Managing Passwords for IAM Users and Managing Access Keys for IAM Users in the IAM User Guide.

Review your IAM groups

Take these steps when you audit your IAM groups:

1. List your groups and then delete groups that are unused.
2. Review users in each group and remove users that don't belong.
3. Review the policies attached to the group. See Tips for reviewing IAM policies (p. 14).

Review your IAM roles

Take these steps when you audit your IAM roles:

1. List your roles and then delete roles that are unused.
2. Review the role's trust policy. Make sure that you know who the principal is and that you understand why that account or user needs to be able to assume the role.
3. Review the access policy for the role to be sure that it grants suitable permissions to whoever assumes the role—see Tips for reviewing IAM policies (p. 14).

Review your IAM providers for SAML and OpenID Connect (OIDC)

If you have created an IAM entity for establishing trust with a SAML or OIDC identity provider, take these steps:

1. Delete unused providers.
2. Download and review the AWS metadata documents for each SAML provider and make sure the documents reflect your current business needs. Alternatively, get the latest metadata documents from the SAML IdPs that you want to establish trust with and update the provider in IAM.

Review Your mobile apps

If you have created a mobile app that makes requests to AWS, take these steps:

1. Make sure that the mobile app does not contain embedded access keys, even if they are in encrypted storage.
2. Get temporary credentials for the app by using APIs that are designed for that purpose. We recommend that you use Amazon Cognito to manage user identity in your app. This service lets you authenticate users using Login with Amazon, Facebook, Google, or any OpenID Connect (OIDC)–compatible identity provider. You can then use the Amazon Cognito credentials provider to manage credentials that your app uses to make requests to AWS.

If your mobile app doesn't support authentication using Login with Amazon, Facebook, Google, or any other OIDC-compatible identity provider, you can create a proxy server that can dispense temporary credentials to your app.

Review your Amazon EC2 security configuration

Take the following steps for each AWS Region:

1. Delete Amazon EC2 key pairs that are unused or that might be known to people outside your organization.
2. Review your Amazon EC2 security groups:
   - Remove security groups that no longer meet your needs.
   - Remove rules from security groups that no longer meet your needs. Make sure you know why the ports, protocols, and IP address ranges they permit have been allowed.
3. Terminate instances that aren't serving a business need or that might have been started by someone outside your organization for unapproved purposes. Remember that if an instance is started with a role, applications that run on that instance can access AWS resources using the permissions that are granted by that role.
4. Cancel Spot Instance requests that aren't serving a business need or that might have been made by someone outside your organization.
5. Review your Auto Scaling groups and configurations. Shut down any that no longer meet your needs or that might have been configured by someone outside your organization.

Review AWS policies in other services

Review the permissions for services that use resource-based policies or that support other security mechanisms. In each case, make sure that only users and roles with a current business need have access to the service's resources, and that the permissions granted on the resources are the fewest necessary to meet your business needs.

- Review your Amazon S3 bucket policies and ACLs.
- Review your Amazon SQS queue policies.
- Review your Amazon SNS topic policies.
- Review your AWS OpsWorks permissions.
- Review your AWS KMS key policies.

Monitor activity in your AWS account

Follow these guidelines for monitoring AWS activity:

- Turn on AWS CloudTrail in each account and use it in each supported Region.
- Periodically examine CloudTrail log files. (CloudTrail has a number of partners who provide tools for reading and analyzing log files.)
- Enable Amazon S3 bucket logging to monitor requests made to each bucket.
• If you believe there has been unauthorized use of your account, pay particular attention to temporary credentials that have been issued. If temporary credentials have been issued that you don’t recognize, disable their permissions.
• Enable billing alerts in each account and set a cost threshold that lets you know if your charges exceed your normal usage.

**Tips for reviewing IAM policies**

Policies are powerful and subtle, so it’s important to study and understand the permissions that are granted by each policy. Use the following guidelines when reviewing policies:

• **As a best practice**, attach policies to groups instead of to individual users. If an individual user has a policy, make sure you understand why that user needs the policy.
• Make sure that IAM users, groups, and roles have only the permissions that they need.
• Use the IAM Policy Simulator to test policies that are attached to users or groups.
• Remember that a user’s permissions are the result of all applicable policies—user policies, group policies, and resource-based policies (on Amazon S3 buckets, Amazon SQS queues, Amazon SNS topics, and AWS KMS keys). It’s important to examine all the policies that apply to a user and to understand the complete set of permissions granted to an individual user.
• Be aware that allowing a user to create an IAM user, group, role, or policy and attach a policy to the principal entity is effectively granting that user all permissions to all resources in your account. That is, users who are allowed to create policies and attach them to a user, group, or role can grant themselves any permissions. In general, do not grant IAM permissions to users or roles whom you do not trust with full access to the resources in your account. The following list contains IAM permissions that you should review closely:
  • `iam:PutGroupPolicy`
  • `iam:PutRolePolicy`
  • `iam:PutUserPolicy`
  • `iam:CreatePolicy`
  • `iam:CreatePolicyVersion`
  • `iam:AttachGroupPolicy`
  • `iam:AttachRolePolicy`
  • `iam:AttachUserPolicy`
• Make sure policies don’t grant permissions for services that you don’t use. For example, if you use AWS managed policies, make sure the AWS managed policies that are in use in your account are for services that you actually use. To find out which AWS managed policies are in use in your account, use the IAM `GetAccountAuthorizationDetails` API (AWS CLI command: `aws iam get-account-authorization-details`).
• If the policy grants a user permission to launch an Amazon EC2 instance, it might also allow the `iam:PassRole` action, but if so it should **explicitly list the roles** that the user is allowed to pass to the Amazon EC2 instance.
• Closely examine any values for the `Action` or `Resource` element that include *. It’s a best practice to grant **Allow** access to only the individual actions and resources that users need. However, the following are reasons that it might be suitable to use * in a policy:
  • The policy is designed to grant administrative-level privileges.
  • The wildcard character is used for a set of similar actions (for example, Describe*) as a convenience, and you are comfortable with the complete list of actions that are referenced in this way.
  • The wildcard character is used to indicate a class of resources or a resource path (e.g., `arn:aws:iam::account-id:users/division_abc/*`), and you are comfortable granting access to all of the resources in that class or path.
• A service action does not support resource-level permissions, and the only choice for a resource is *.

• Examine policy names to make sure they reflect the policy’s function. For example, although a policy might have a name that includes "read only," the policy might actually grant write or change permissions.

## Learn more

For information about managing IAM resources, see the following:

- IAM Users and Groups in the IAM User Guide.
- Permissions and Policies in the IAM User Guide.
- IAM Roles (Delegation and Federation) in the IAM User Guide.

For more information about Amazon EC2 security, see the following:

- Network and Security in the Amazon EC2 User Guide for Linux Instances.

For more information about monitoring an AWS account, see the re:Invent 2013 video presentation Intrusion Detection in the Cloud.
Service endpoints and quotas

The following pages describe the service endpoints and service quotas for AWS services. To connect programmatically to an AWS service, you use an endpoint. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Click one of the following links to go to the page for that service. To view the service quotas for all AWS services in the documentation without switching pages, view the information in the Service endpoints and quotas page in the PDF instead.

Alexa for Business endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

### AWS Amplify endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](p. 743).

Amazon API Gateway endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Service endpoints

Amazon API Gateway includes the API Gateway Control Plane (for creating and managing APIs) and the API Gateway Data Plane (for calling deployed APIs).

The Route 53 Hosted Zone ID column shows the Route 53 Hosted Zone IDs for API Gateway Regional endpoints. Route 53 Hosted Zone IDs are for use with the execute-api (API Gateway component service for API execution) domain. For edge-optimized endpoints, the Route 53 Hosted Zone ID is Z2FDTNDATAQYW2 for all Regions.

For more information, see Quotas in Amazon API Gateway in the API Gateway Developer Guide.
AWS AppConfig endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

AWS AppConfig is a capability of AWS Systems Manager. To view endpoints and quotas of other Systems Manager capabilities, see AWS Systems Manager endpoints and quotas (p. 692).

Service endpoints

The following sections describe the service endpoints for AWS AppConfig. AWS AppConfig uses control plane APIs for setting up and configuring AWS AppConfig applications, environments, configuration profiles, and deployment strategies. AWS AppConfig uses the AWS AppConfig Data service to call data plane APIs for retrieving stored configurations.

Topics
- Control plane endpoints (p. 32)
- Data plane endpoints (p. 34)

Control plane endpoints

The following table contains AWS Region-specific endpoints that AWS AppConfig supports for control plane operations. Control plane operations are used for creating, updating, and managing configuration data. For more information, see AWS AppConfig operations in the AWS AppConfig API Reference.

Amazon AppFlow endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

You can’t use IP allow listing in your Amazon S3 bucket policy to deny access to any other IP addresses besides Amazon AppFlow IP addresses. This is because Amazon AppFlow uses a VPC endpoint when placing data in your Amazon S3 buckets.

For more information about the IP addresses used by Amazon AppFlow, see AWS IP address ranges in the Amazon Web Services General Reference.

## AWS Application Migration Service endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](p. 739).

Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](p. 743).

</tbody>
</table>

**Rate of request tokens** is the maximum number of request tokens per second in this account in the current Region. AWS AppSync allocates tokens to mutation and query requests based on the amount of resources (processing time and memory) that they consume. For more details on tokens, see Using token counts to optimize your requests in the AWS AppSync developer guide.

Amazon Athena endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

AWS Batch endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

AWS Billing and Cost Management endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

AWS Billing and Cost Management includes the AWS Cost Explorer API, the AWS Cost and Usage Reports API, the AWS Budgets API, and the AWS Price List API.

### AWS Chatbot endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see `AWS service endpoints (p. 739)`. Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see `AWS service quotas (p. 743)`.

</table>
Amazon Chime endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Service endpoints

Amazon Chime has a single endpoint that supports HTTPS: service.chime.aws.amazon.com

### AWS CloudShell endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](p. 739).

Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](p. 743).

Amazon CloudWatch Logs endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

### Amazon Cognito Identity endpoints and quotas

Amazon Cognito Identity includes Amazon Cognito user pools and Amazon Cognito identity pools (federated identities).

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Amazon Comprehend Medical endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

**Amazon Connect Customer Profiles service quotas**

The Amazon Connect Customer Profiles Service has the following quotas.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Connect Customer Profiles domain count</td>
<td>Each supported Region: 100</td>
<td>Yes</td>
</tr>
<tr>
<td>Keys per object type</td>
<td>Each supported Region: 10</td>
<td>Yes</td>
</tr>
<tr>
<td>Maximum expiration in days</td>
<td>Each supported Region: 1,098</td>
<td>Yes</td>
</tr>
<tr>
<td>Maximum number of integrations</td>
<td>Each supported Region: 50</td>
<td>Yes</td>
</tr>
<tr>
<td>Maximum size of all objects for a profile</td>
<td>Each supported Region: 51,200 Kilobytes</td>
<td>Yes</td>
</tr>
<tr>
<td>Object and profile maximum size</td>
<td>Each supported Region: 250 Kilobytes</td>
<td>No</td>
</tr>
<tr>
<td>Object types per domain</td>
<td>Each supported Region: 100</td>
<td>Yes</td>
</tr>
<tr>
<td>Objects per profile</td>
<td>Each supported Region: 1,000</td>
<td>Yes</td>
</tr>
</tbody>
</table>

For more information, see Amazon Connect Service Quotas in the Amazon Connect Administrator Guide.

**AWS Data Exchange endpoints and quotas**

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739).

Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

### AWS DeepLens endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](p. 743).

For more information, see Amazon DocumentDB Service Quotas in the Amazon DocumentDB Developer Guide.

Amazon DynamoDB endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).
For more information about this topic specific to DynamoDB, see Quotas in Amazon DynamoDB.

### Endpoints for the EBS direct APIs

Use the EBS direct APIs endpoints to directly read the data on your Amazon EBS snapshots, and identify the difference between two snapshots. For more information, see [Use EBS direct APIs to access the contents of an Amazon EBS snapshot](#) in the Amazon Elastic Compute Cloud User Guide.

The quota for concurrent snapshot copies per destination Region is not adjustable using Service Quotas. However, you can request an increase for this quota by contacting AWS Support.

## Recycle Bin endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Amazon EC2 endpoints and quotas

**Important**
AWS Regions launched after **October 30, 2021** will no longer support Amazon EC2 API requests over connections that are established using TLSv1, TLSv1.1, or unencrypted HTTP.

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

For more information, see [Amazon EC2 Auto Scaling Service Quotas](https://docs.aws.amazon.com/autoscaling/userguide/autoscaling-limits.html) in the *Amazon EC2 Auto Scaling User Guide*.

### EC2 Image Builder endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](https://docs.aws.amazon.com/AmazonS3/latest/userguide/AWS-endpoints.html) (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](https://docs.aws.amazon.com/AmazonS3/latest/userguide/AWS-quotas.html) (p. 743).

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>South America (São Paulo)</td>
<td>sa-east-1</td>
<td>autoscaling.sa-east-1.amazonaws.com</td>
<td>HTTP and HTTPS</td>
</tr>
<tr>
<td>AWS GovCloud (US-East)</td>
<td>us-gov-east-1</td>
<td>autoscaling.us-gov-east-1.amazonaws.com</td>
<td>HTTP and HTTPS</td>
</tr>
<tr>
<td>AWS GovCloud (US-West)</td>
<td>us-gov-west-1</td>
<td>autoscaling.us-gov-west-1.amazonaws.com</td>
<td>HTTP and HTTPS</td>
</tr>
</tbody>
</table>

If you specify the general endpoint (autoscaling.amazonaws.com), Amazon EC2 Auto Scaling directs your request to the endpoint for `us-east-1`.

</table>
## Amazon ECR endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](p. 743).
**Service endpoints**

The `ecr` and `api.ecr` endpoints are used for calls to the Amazon ECR API. API actions such as `DescribeImages` and `CreateRepository` go to this endpoint. While the two endpoints function the same, the `api.ecr` endpoint is recommended and the default when using the AWS CLI or AWS SDKs. When connecting to Amazon ECR through an AWS PrivateLink VPC endpoint, you must use the `api.ecr` endpoint to make API calls. For more information, see Amazon ECR Interface VPC Endpoints (AWS PrivateLink) in the Amazon Elastic Container Registry User Guide.

For more information about FIPS endpoints, see FIPS endpoints (p. 741).

### Docker and OCI client endpoints

The Docker and OCI client endpoints are used for the Docker Registry APIs. Docker client commands such as `push` and `pull` use this endpoint.

For more information about FIPS endpoints, see [FIPS endpoints](#) (p. 741).

<table>
<thead>

<tr>
<td>Registered repositories</td>
<td>The maximum number of repositories that you can create per Region.</td>
<td>10,000</td>
<td></td>
</tr>
<tr>
<td>Image per repository</td>
<td>The maximum number of images per repository.</td>
<td>10,000</td>
<td></td>
</tr>
</tbody>
</table>

The following table provides the default rate quotas for each of the Amazon ECR API actions involved with the image push and image pull actions.

<table>
<thead>
<tr>
<th>Amazon ECR action</th>
<th>API operation</th>
<th>Description</th>
<th>Default quota value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authentication</td>
<td>Rate of GetAuthorizationToken requests</td>
<td>The rate of GetAuthorizationToken API requests that you can make per second, per Region.</td>
<td>500</td>
</tr>
<tr>
<td>Image push</td>
<td>Rate of BatchCheckLayerAvailability requests</td>
<td>The rate of BatchCheckLayerAvailability API requests that you can make per second, per Region.</td>
<td>1000</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When an image is pushed to a repository, each image layer is checked to verify if it has been uploaded before. If it has been uploaded, then the image layer is skipped.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Rate of InitiateLayerUpload requests</td>
<td>The rate of InitiateLayerUpload API requests that you can make per second, per Region.</td>
<td>100</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When an image is pushed, the InitiateLayerUpload API is called once per image layer that has not already been uploaded. Whether or not an image layer has been uploaded is determined by the BatchCheckLayerAvailability API action.</td>
<td></td>
</tr>
<tr>
<td>Amazon ECR action</td>
<td>API operation</td>
<td>Description</td>
<td>Default quota value</td>
</tr>
<tr>
<td>-------------------</td>
<td>--------------</td>
<td>-------------</td>
<td>---------------------</td>
</tr>
<tr>
<td>Rate of CompleteLayerUpload requests</td>
<td>The rate of CompleteLayerUpload API requests that you can make per second, per Region. When an image is pushed, the CompleteLayerUpload API is called once per each new image layer to verify that the upload has completed.</td>
<td>100</td>
<td></td>
</tr>
<tr>
<td>Rate of UploadLayerPart requests</td>
<td>The rate of UploadLayerPart API requests that you can make per second, per Region. When an image is pushed, each new image layer is uploaded in parts. The maximum size of each image layer part can be 20,971,520 bytes (or about 20MB). The UploadLayerPart API is called once per each new image layer part.</td>
<td>500</td>
<td></td>
</tr>
<tr>
<td>Rate of PutImage requests</td>
<td>The rate of PutImage API requests that you can make per second, per Region. When an image is pushed and all new image layers have been uploaded, the PutImage API is called once to create or update the image manifest and the tags associated with the image.</td>
<td>10</td>
<td></td>
</tr>
</tbody>
</table>
### Amazon ECR action | API operation | Description | Default quota value
--- | --- | --- | ---
Image pull | Rate of BatchGetImage requests | The rate of BatchGetImage API requests that you can make per second, per Region. When an image is pulled, the BatchGetImage API is called once to retrieve the image manifest. | 2,000

Rate of GetDownloadUrlForLayer requests | The rate of GetDownloadUrlForLayer API requests that you can make per second, per Region. When an image is pulled, the GetDownloadUrlForLayer API is called once per image layer that is not already cached. | 3,000

The following table provides other quotas for Amazon ECR and Docker images that cannot be changed.

**Note**
The layer part information mentioned in the following table is only applicable if you are calling the Amazon ECR API actions directly to initiate multipart uploads for image push operations. This is a rare action. We recommend that you use the Docker CLI to pull, tag, and push images.

<table>
<thead>
<tr>
<th>Service quota</th>
<th>Description</th>
<th>Quota value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Layer parts</td>
<td>The maximum number of layer parts. This is only applicable if you are using Amazon ECR API actions directly to initiate multipart uploads for image push operations.</td>
<td>4,200</td>
</tr>
<tr>
<td>Maximum layer size</td>
<td>The maximum size (MiB) of a layer. **</td>
<td>42,000</td>
</tr>
<tr>
<td>Minimum layer part size</td>
<td>The minimum size (MiB) of a layer part. This is only applicable if you are using Amazon ECR API actions directly to initiate multipart uploads for image push operations.</td>
<td>5</td>
</tr>
<tr>
<td>Maximum layer part size</td>
<td>The maximum size (MiB) of a layer part. This is only applicable if you are using Amazon ECR API actions directly to initiate multipart uploads for image push operations.</td>
<td>10</td>
</tr>
</tbody>
</table>
**Amazon ECR Public endpoints and quotas**

The following are the service endpoints and service quotas for this service. To connect programatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

**Service endpoints**

The `ecr-public` and `api.ecr-public` endpoints are used for calls to the Amazon ECR Public API. API actions such as `DescribeImages` and `CreateRepository` go to this endpoint. While the two endpoints function the same, the `api.ecr-public` endpoint is recommended and the default when using the AWS CLI or AWS SDKs.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>ecr-public.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>api.ecr-public.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>

**Service quotas**

For more information, see Amazon ECR Public service quotas in the Amazon ECR Public user guide.
Amazon ECS endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

### Service quotas

The following are Amazon ECS service quotas.

Most of these service quotas, but not all, are listed under the Amazon Elastic Container Service (Amazon ECS) namespace in the Service Quotas console. To request a quota increase, see Requesting a quota increase in the Service Quotas User Guide.
<table>
<thead>
<tr>
<th>Service quota</th>
<th>Description</th>
<th>Default quota value</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clusters</td>
<td>The maximum number of clusters in this account in the current Region.</td>
<td>10,000</td>
<td>Yes</td>
</tr>
<tr>
<td>Container instances per cluster</td>
<td>The maximum number of container instances per cluster.</td>
<td>2,000</td>
<td>Yes</td>
</tr>
<tr>
<td>Services per cluster</td>
<td>The maximum number of services per cluster.</td>
<td>5,000</td>
<td>Yes</td>
</tr>
<tr>
<td>Tasks per service</td>
<td>The maximum number of tasks per service (the desired count).</td>
<td>5,000</td>
<td>Yes</td>
</tr>
<tr>
<td>Tasks launched (count) per run-task</td>
<td>The maximum number of tasks that can be launched per RunTask API action.</td>
<td>10</td>
<td>No</td>
</tr>
<tr>
<td>Container instances per start-task</td>
<td>The maximum number of container instances specified in a StartTask API action.</td>
<td>10</td>
<td>No</td>
</tr>
<tr>
<td>Revisions per task definition family</td>
<td>The maximum number of revisions per task definition family. Deregistering a task definition revision does not exclude it from being included in this limit.</td>
<td>1,000,000</td>
<td>No</td>
</tr>
</tbody>
</table>

Note
Services configured to use Amazon ECS service discovery have a limit of 1,000 tasks per service. This is due to the AWS Cloud Map service quota for the number of instances per service. For more information, see AWS Cloud Map service quotas.
## AWS Fargate quotas

The following are Amazon ECS on AWS Fargate service quotas.

These service quotas are listed under the AWS Fargate namespace in the Service Quotas console. To request a quota increase, see Requesting a quota increase in the Service Quotas User Guide.

<table>
<thead>
<tr>
<th>Service quota</th>
<th>Description</th>
<th>Default quota value</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task definition size limit</td>
<td>The maximum size, in KiB, of a task definition.</td>
<td>32</td>
<td>No</td>
</tr>
<tr>
<td>Task definition max containers</td>
<td>The maximum number of containers definitions within a task definition.</td>
<td>10</td>
<td>No</td>
</tr>
<tr>
<td>Subnets specified in an awsvpcConfiguration</td>
<td>The maximum number of subnets specified within an awsvpcConfiguration.</td>
<td>16</td>
<td>No</td>
</tr>
<tr>
<td>Security groups specified in an awsvpcConfiguration</td>
<td>The maximum number of security groups specified within an awsvpcConfiguration.</td>
<td>5</td>
<td>No</td>
</tr>
<tr>
<td>Target groups per service</td>
<td>The maximum number of target groups per service, if using an Application Load Balancer or a Network Load Balancer.</td>
<td>5</td>
<td>No</td>
</tr>
<tr>
<td>Classic Load Balancers per service</td>
<td>The maximum number of Classic Load Balancers per service.</td>
<td>1</td>
<td>No</td>
</tr>
<tr>
<td>Tags per resource</td>
<td>The maximum number of tags per resource. This applies to task definitions, clusters, tasks, and services.</td>
<td>50</td>
<td>No</td>
</tr>
<tr>
<td>Tasks in the PROVISIONING state per cluster</td>
<td>The maximum number of tasks waiting in the PROVISIONING state per cluster. This quota only applies to tasks launched using an Amazon EC2 Auto Scaling group capacity provider.</td>
<td>300</td>
<td>No</td>
</tr>
</tbody>
</table>

For more information, see Amazon ECS service quotas in the Amazon Elastic Container Service Developer Guide.
Amazon Elastic Kubernetes Service endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

AWS Fargate service quotas

The following are Amazon EKS on AWS Fargate service quotas.

These service quotas are listed under the AWS Fargate namespace in the Service Quotas console. To request a quota increase, see Requesting a quota increase in the Service Quotas User Guide.

<table>
<thead>
<tr>
<th>Service quota</th>
<th>Description</th>

</tr>
</tbody>
</table>

If you specify the general endpoint (elasticmapreduce.amazonaws.com), Amazon EMR directs your request to an endpoint in the default Region. For accounts created on or after March 8, 2013, the default Region is us-west-2; for older accounts, the default Region is us-east-1.

Amazon EMR throttles the following API requests for each AWS account on a per-Region basis. For more information about how throttling is applied, see API Request Throttling in the Amazon EC2 API Reference.

### Amazon EventBridge endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Service quotas

For more information, see EventBridge Quotas in the Amazon EventBridge User Guide.

Amazon EventBridge Schemas endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739).

Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Amazon Fraud Detector endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

AWS Global Accelerator endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

## Amazon HealthLake endpoints and quotas

### Regions and endpoints for Amazon HealthLake

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
<td>healthlake.us-east-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>healthlake.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
<td>healthlake.us-west-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>

### Throttling and quotas for Amazon HealthLake

The following table describes throttling limits for resource management within Amazon HealthLake for each customer account. For information about limits that can be changed, see AWS Service Limits. For all operations, users will receive a `ThrottlingException` error message if throttling limits are exceeded.

A maximum quota of ten Data Stores are allowed per an account. For information about requesting a quota increase, see the console support center to create a case.

<table>
<thead>
<tr>

<tr>
<td>Maximum number of files</td>
<td>10,000</td>
</tr>
<tr>
<td>Supported file extension</td>
<td><code>.ndjson</code></td>
</tr>
</tbody>
</table>

### Amazon Honeycode endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](p. 743).

#### Service endpoints

Amazon Honeycode has a single endpoint: honeycode.us-west-2.amazonaws.com (HTTPS).
AWS Identity and Access Management endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

## Amazon Inspector endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](p. 739).
Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

For more information, see [AWS IoT Analytics quotas](#) in the [AWS IoT Analytics User Guide](#).

**AWS IoT Core endpoints and quotas**

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](#) (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](#) (p. 743).

**Service endpoints**

The following sections describe the service endpoints for AWS IoT Core.
Note
You can use these endpoints to perform the operations in the AWS IoT API Reference. The endpoints in the following sections are different from the device endpoints, which provide devices an MQTT publish/subscribe interface and a subset of the API operations. For more information about the data, credential access, and job management endpoints used by devices, see AWS IoT device endpoints.
For information about connecting to and using the AWS IoT endpoints, see Connecting devices to AWS IoT in the AWS IoT Developer Guide.

Topics
- AWS IoT Core - control plane endpoints (p. 310)
- AWS IoT Core - data plane endpoints (p. 311)
- AWS IoT Device Management - jobs data endpoints (p. 313)
- AWS IoT Device Management - secure tunneling endpoints (p. 315)
- AWS IoT Core for LoRaWAN API endpoints (p. 317)
- AWS IoT FIPS endpoints (p. 318)

AWS IoT Core - control plane endpoints

The following table contains AWS Region-specific endpoints for AWS IoT Core - control plane operations. For information about the operations supported by the AWS IoT Core - control plane endpoints, see AWS IoT operations in the AWS IoT API Reference.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>

</tbody>
</table>
## AWS IoT Core - data plane endpoints

The AWS IoT Core - data plane endpoints are specific to each AWS account and AWS Region. To find the AWS IoT Core - data plane endpoint for your AWS account and AWS Region, use the `describe-endpoint` CLI command shown here, or the `DescribeEndpoint` REST API.

```plaintext
aws iot describe-endpoint --endpoint-type iot:Data-ATS
```
This command returns your data plane API endpoint in the following format:

```
account-specific-prefix.iot.aws-region.amazonaws.com
```

For information about the actions supported by the AWS IoT Core - data plane endpoints, see AWS IoT data plane operations in the AWS IoT API Reference.

The following table contains generic representations of the AWS account-specific endpoints for each AWS Region that AWS IoT Core supports. In the Endpoint column, the account-specific-prefix from your Account-specific endpoint replaces data shown in the generic endpoint representation.

AWS IoT Device Management - jobs data endpoints

The AWS IoT Device Management - jobs data endpoints are specific to each AWS account and AWS Region. To find the AWS IoT Device Management - jobs data endpoint for your AWS account and AWS Region, use the `describe-endpoint` CLI command shown here, or the `DescribeEndpoint` REST API.

```bash
aws iot describe-endpoint --endpoint-type iot:Jobs
```

This command returns your Jobs data plane API endpoint in the following format:

```
```

For information about the actions supported by the AWS IoT Device Management - jobs dat endpoints, see AWS IoT jobs data plane operations in the AWS IoT API Reference.

The following table contains AWS Region-specific endpoints that AWS IoT Core supports for job data operations. In the Endpoint column, the `account-specific-prefix` from your Account-specific endpoint replaces `prefix` shown in the generic endpoint representation.
<table>

AWS IoT Core for LoRaWAN API endpoints

AWS IoT Core for LoRaWAN provides control plane and data plane endpoints for its API.

AWS IoT Core for LoRaWAN control plane API endpoints

The following table contains AWS Region-specific endpoints that AWS IoT Core for LoRaWAN supports for operations to manage LoRaWAN gateways and devices.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>api.iotwireless.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
<td>api.iotwireless.us-west-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Europe (Ireland)</td>
<td>eu-west-1</td>
<td>api.iotwireless.eu-west-1.amazonaws.com</td>

<td>ap-southeast-2</td>
<td>api.iotwireless.ap-southeast-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>

AWS IoT Core for LoRaWAN data plane API endpoints

The data plane API endpoints are specific to each AWS Account and Region. To find the data plane API endpoint for your AWS Account and Region, use the get-service-endpoint CLI command shown here, or the GetServiceEndpoint REST API.

```
aws iotwireless get-service-endpoint
```

This command returns information about:

- The service type for which you want to get endpoint information about, which can be CUPS or LNS.
- The CUPS or LNS server trust certificate depending on the endpoint specified.
- Your data plane API endpoint in the following format:

```
account-specific-prefix.service.lorawan.aws-region.amazonaws.com
```

where `service` can be cups or lns.

The following table contains generic representations of the AWS Account-specific LNS endpoints for each Region that AWS IoT Core supports. In the Endpoint column, the `account-specific-prefix` from your Account-specific endpoint replaces `prefix` shown in the generic endpoint representation.

LNS endpoints

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td><code>prefix.lns.lorawan.us-east-1.amazonaws.com</code></td>
<td>WSS</td>
</tr>
</tbody>
</table>
The following table contains generic representations of the AWS Account-specific CUPS endpoints for each Region that AWS IoT Core supports. In the Endpoint column, the account-specific-prefix from your Account-specific endpoint replaces prefix shown in the generic endpoint representation.

### CUPS endpoints

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>prefix.cups.lorawan.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
<td>prefix.cups.lorawan.us-west-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Europe (Ireland)</td>
<td>eu-west-1</td>
<td>prefix.cups.lorawan.eu-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Asia Pacific (Tokyo)</td>
<td>ap-northeast-1</td>
<td>prefix.cups.lorawan.ap-northeast-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Asia Pacific (Sydney)</td>
<td>ap-southeast-2</td>
<td>prefix.cups.lorawan.ap-southeast-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>

### AWS IoT FIPS endpoints

AWS IoT provides endpoints that support the Federal Information Processing Standard (FIPS) 140-2. Choose the appropriate FIPS compliant endpoint to access AWS IoT features in your AWS Region from FIPS Endpoints by Service. For more information about the FIPs endpoints provided by AWS IoT, see Connecting to AWS IoT FIPS endpoints.

### Service quotas

**Contents**

- AWS IoT Core rules engine limits and quotas (p. 319)
- AWS IoT Core API throttling limits (p. 321)
- AWS IoT Core for LoRaWAN limits and quotas (p. 337)
- AWS IoT Core Device Shadow service limits and quotas (p. 347)
- AWS IoT Core Fleet Provisioning limits and quotas (p. 348)
- AWS IoT Core message broker and protocol limits and quotas (p. 350)
- AWS IoT Core protocol-related limits and quotas (p. 357)
- AWS IoT Core credential provider limits and quotas (p. 357)
- AWS IoT Core security and identity limits and quotas (p. 358)
- MQTT-based File Delivery (p. 361)
- AWS IoT Core Device Advisor limits and quotas (p. 362)

**Note**
The limits and quotas for these AWS IoT Device Management features: AWS IoT registry, AWS IoT Fleet Indexing, AWS IoT Jobs, AWS IoT Secure Tunneling, and Fleet Hub for AWS IoT Device Management can be found in AWS IoT Device Management Service quotas (p. 376).

## AWS IoT Core rules engine limits and quotas

This section describes the limits and quotas of the AWS IoT Core rules engine.

### AWS IoT Core rules engine

<table>
<thead>
<tr>
<th>Limit display name</th>
<th>Description</th>
<th>Default value</th>
<th>Default value in select AWS Regions</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of actions per rule</td>
<td>The maximum number of entries in the rule's actions property.</td>
<td>10</td>
<td>10</td>
<td>No</td>
</tr>
<tr>
<td>Maximum number of rules per AWS account</td>
<td>The maximum number of rules that can be defined in a single AWS account.</td>
<td>1000</td>
<td>1000</td>
<td>Yes</td>
</tr>
<tr>
<td>Rule evaluations per second per AWS account</td>
<td>The maximum number of rules that can be evaluated per second per AWS account. This quota includes rule evaluations that result from inbound Basic Ingest messages.</td>
<td>20000</td>
<td>2000</td>
<td>Yes</td>
</tr>
<tr>
<td>Rule size</td>
<td>The maximum size that a rule document definition can contain, measured by number of UTF-8 encoded characters, including white spaces.</td>
<td>256 Kilobytes</td>
<td>256 Kilobytes</td>
<td>No</td>
</tr>
</tbody>
</table>
Select AWS Regions: Europe (Stockholm), Middle East (Bahrain), Europe (Paris), Asia Pacific (Hong Kong), AWS GovCloud (US-East), AWS GovCloud (US-West), US West (N. California), Canada (Central), China (Ningxia)

AWS IoT Core rules engine HTTP actions limits and quotas

AWS IoT Core HTTP action

<table>
<thead>
<tr>
<th>Limit display name</th>
<th>Description</th>
<th>Default value</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP Action: Maximum length of an endpoint URL</td>
<td>Maximum length of an endpoint URL for topic rule HTTP Action.</td>
<td>2 Kilobytes</td>
<td>No</td>
</tr>
<tr>
<td>HTTP Action: Maximum number of headers per action</td>
<td>Maximum number of headers per HTTP action. When specifying the list of headers to include in the HTTP request, it must contain a header key and a header value. To learn more, see <a href="https://docs.aws.amazon.com/iot/latest/developerguide/https-rule-action.html">https://docs.aws.amazon.com/iot/latest/developerguide/https-rule-action.html</a>.</td>
<td>100</td>
<td>No</td>
</tr>
<tr>
<td>HTTP Action: Maximum size of a header key</td>
<td>Maximum size of a header key for topic rule HTTP action. The header file for a HTTP request includes this header key and a header value.</td>
<td>256 Bytes</td>
<td>No</td>
</tr>
<tr>
<td>HTTP Action: Maximum topic rule destinations per AWS account</td>
<td>Maximum number of topic rule destinations per AWS account for topic rule HTTPS action. You must confirm and enable HTTPS endpoints before the rules engine can use them. For more information, see <a href="https://docs.aws.amazon.com/iot/latest/developerguide/rule-destination.html">https://docs.aws.amazon.com/iot/latest/developerguide/rule-destination.html</a>.</td>
<td>1000</td>
<td>No</td>
</tr>
<tr>
<td>HTTP Action: Request timeout</td>
<td>Request timeout for topic rule HTTP action. The AWS IoT rules engine retries the HTTPS action until the</td>
<td>3000 Milliseconds</td>
<td>No</td>
</tr>
</tbody>
</table>
Service quotas

Limit display name | Description | Default value | Adjustable
--- | --- | --- | ---
 | total time to complete a request exceeds the timeout quota. | | | 

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP ports used for HTTP actions</td>
<td>443, 8443</td>
<td>No</td>
</tr>
</tbody>
</table>

AWS IoT Core rules engine Apache Kafka actions limits and quotas

<table>
<thead>
<tr>
<th>Resource</th>
<th>Limits</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap server ports</td>
<td>9000-9100</td>
</tr>
<tr>
<td>Kerberos key distribution center (KDC)</td>
<td>88</td>
</tr>
</tbody>
</table>

AWS IoT Core rules engine VPC actions limits and quotas

<table>
<thead>
<tr>
<th>Resource</th>
<th>Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of VPC destinations</td>
<td>5 per account per Region</td>
</tr>
</tbody>
</table>

AWS IoT Core API throttling limits

This table describes the maximum number of transactions per second (TPS) that can be made to each of these AWS IoT Core API actions.

AWS IoT Core API rate limits

<table>
<thead>
<tr>
<th>Limit display name</th>
<th>Description</th>
<th>Default value</th>
<th>Default value in select AWS Regions</th>
<th>Adjustable</th>

**AWS IoT Core for LoRaWAN API throttling**

The following tables describes the maximum number of transactions per second (TPS) that can be made to each action in the AWS IoT Wireless API, which includes AWS IoT Core for LoRaWAN and Amazon Sidewalk Integration.

**AWS IoT Wireless gateway API throttling**

This table describes the maximum TPS for APIs used with LoRaWAN gateways. The gateways route messages between LoRaWAN devices and AWS IoT Core for LoRaWAN.

**AWS IoT Wireless gateway API throttling**

</tr>
<tr>
<td><strong>Maximum size of a JSON state document</strong></td>
<td>Each individual shadow document must be 8KB or less in size. Metadata doesn't</td>
<td>8 Kilobytes</td>
<td>8 Kilobytes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
## Service quotas

<table>
<thead>
<tr>
<th>Limit display name</th>
<th>Description</th>
<th>Default value</th>
<th>Default value in select AWS Regions</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Maximum thing name size</td>
<td>Maximum size of a thing name, which is 128 bytes of UTF-8 encoded characters.</td>
<td>128 Bytes</td>
<td>128 Bytes</td>
<td>No</td>
</tr>
<tr>
<td>Requests per second per thing</td>
<td>The Device Shadow service supports up to 20 requests per second per thing. This quota is per thing, not per API.</td>
<td>20</td>
<td>20</td>
<td>No</td>
</tr>
</tbody>
</table>

*Select AWS Regions:* Europe (Paris), Europe (Stockholm), Asia Pacific (Hong Kong), South America (São Paulo), Canada (Central), Middle East (Bahrain), China (Ningxia), AWS GovCloud (US-East), AWS GovCloud (US-West)

The levels in the desired and reported sections of the Device Shadow's JSON state document are counted as shown here for the desired object.

```json
"desired": {
  "one": {
    "two": {
      "three": {
        "four": {
          "five":{}
        }
      }
    }
  }
}
```

**Note**

AWS IoT Core deletes a Device Shadow document after the creating account is deleted or upon customer request. For operational purposes, AWS IoT service backups are retained for 6 months.

### AWS IoT Core Fleet Provisioning limits and quotas

Following are throttling limits for some fleet provisioning APIs per AWS account.

<table>
<thead>
<tr>
<th>Limit display name</th>
<th>Description</th>
<th>Default value</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>100</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**AWS IoT Core fleet provisioning limits and quotas**
# Service quotas

## Fleet Provisioning

<table>
<thead>
<tr>
<th>Limit display name</th>
<th>Description</th>
<th>Default value</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fleet Provisioning CreateCertificateFromCsr MQTT API TPS</td>
<td>The maximum number of transactions per second (TPS) that can be made for the Fleet Provisioning CreateCertificateFromCsr MQTT API.</td>
<td>10</td>
<td>Yes</td>
</tr>
<tr>
<td>Fleet Provisioning CreateKeysAndCertificate MQTT API TPS</td>
<td>The maximum number of transactions per second (TPS) that can be made for the Fleet Provisioning CreateKeysAndCertificate MQTT API.</td>
<td>10</td>
<td>Yes</td>
</tr>
<tr>
<td>Fleet Provisioning RegisterThing MQTT API TPS</td>
<td>The maximum number of transactions per second (TPS) that can be made for the Fleet Provisioning RegisterThing MQTT API.</td>
<td>10</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Fleet provisioning also has these limits, which can't be changed.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Description</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Versions per fleet provisioning template</td>
<td>The maximum number of versions that a fleet provisioning template can have. Each template version has a version ID and a creation date for devices that connect to AWS IoT using fleet provisioning.</td>
<td>5</td>
</tr>
<tr>
<td>Fleet provisioning templates per customer</td>
<td>The maximum number of fleet provisioning templates per customer. Use fleet provisioning templates to generate certificates and private keys for your devices to securely connect to AWS IoT.</td>
<td>256</td>
</tr>
<tr>
<td>Fleet provisioning template size</td>
<td>The maximum size of a fleet provisioning template in Kilobytes. Fleet provisioning templates allow you to generate certificates and private keys for your devices to securely connect to AWS IoT.</td>
<td>10 Kilobytes</td>
</tr>
</tbody>
</table>
## AWS IoT Core message broker and protocol limits and quotas

### AWS IoT Core message broker limits and quotas

<table>

### AWS IoT Device Defender endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](p. 743).

AWS IoT Device Management endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

### Service endpoints

#### Topics
- AWS IoT Core - control plane endpoints (p. 368)
- AWS IoT Core - data plane endpoints (p. 370)
- AWS IoT Device Management - jobs data endpoints (p. 371)
- AWS IoT Device Management - secure tunneling endpoints (p. 373)
- AWS IoT FIPS endpoints (p. 376)

### AWS IoT Core - control plane endpoints

The following table contains AWS Region-specific endpoints for AWS IoT Core - control plane operations. For information about the operations supported by the AWS IoT Core - control plane endpoints, see AWS IoT operations in the *AWS IoT API Reference*.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>

AWS IoT Core - data plane endpoints

The AWS IoT Core - data plane endpoints are specific to each AWS account and AWS Region. To find the AWS IoT Core - data plane endpoint for your AWS account and AWS Region, use the `describe-endpoint` CLI command shown here, or the `DescribeEndpoint` REST API.

```
aws iot describe-endpoint --endpoint-type iot:Data-ATS
```

This command returns your Data Plane API endpoint in the following format:

```
account-specific-prefix.iot.aws-region.amazonaws.com
```

For information about the actions supported by the AWS IoT Core - data plane endpoints, see AWS IoT data plane operations in the AWS IoT API Reference.

The following table contains generic representations of the AWS account-specific endpoints for each AWS Region that AWS IoT Core supports. In the Endpoint column, the `account-specific-prefix` from your Account-specific endpoint replaces data shown in the generic endpoint representation.

<table>
<thead>
<tr>

### AWS IoT Device Management - jobs data endpoints

The AWS IoT Device Management - jobs data endpoints are specific to each AWS account and AWS Region. To find the AWS IoT Device Management - jobs data endpoint for your AWS account and AWS Region, use the `describe-endpoint` CLI command shown here, or the `DescribeEndpoint` REST API.

```bash
da-ats.iot.us-gov-east-1.amazonaws.com
```

This command returns your Jobs data plane API endpoint in the following format:

```text
```

For information about the actions supported by the AWS IoT Device Management - jobs dat endpoints, see [AWS IoT jobs data plane operations](awsiotapi) in the [AWS IoT API Reference](awsiotapi).

---

Version 1.0

371
The following table contains AWS Region-specific endpoints that AWS IoT Core supports for job data operations. In the **Endpoint** column, the `account-specific-prefix` from your Account-specific endpoint replaces `prefix` shown in the generic endpoint representation.

AWS IoT FIPS endpoints

AWS IoT provides endpoints that support the Federal Information Processing Standard (FIPS) 140-2. Choose the appropriate FIPS compliant endpoint to access AWS IoT features in your AWS Region from FIPS Endpoints by Service. For more information about the FIPs endpoints provided by AWS IoT, see Connecting to AWS IoT FIPS endpoints.

Service quotas

Contents
- AWS IoT Core thing resource limits and quotas (p. 376)
- AWS IoT Core thing group resource limits and quotas (p. 377)
- AWS IoT Core bulk thing registration limits and quotas (p. 379)
- AWS IoT Core billing group restrictions (p. 379)
- AWS IoT Device Management API action limits (p. 380)
- AWS IoT Fleet Indexing (p. 386)
- AWS IoT Jobs (p. 389)
- AWS IoT Secure Tunneling (p. 393)
- Fleet Hub for AWS IoT Device Management (p. 394)

AWS IoT Core thing resource limits and quotas

<table>
<thead>
<tr>
<th>Limit display name</th>
<th>Description</th>
<th>Default value</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of thing attributes for a thing with a thing type</td>
<td>Maximum number of thing attributes for a thing with a thing type. Thing types are optional and make it easier to discover things. Things with a thing type can have up to 50 attributes.</td>
<td>50</td>
<td>Yes</td>
</tr>
<tr>
<td>Maximum number of thing attributes for a thing</td>
<td>Maximum number of thing attributes for a thing without a thing type. Things without a thing type can have up to 3 attributes.</td>
<td>3</td>
<td>No</td>
</tr>
</tbody>
</table>
### Limit display name

#### without a thing type

- **Description**: thing type can have up to three attributes.

---

#### Maximum thing name size

- **Description**: Maximum size of a thing name, which is 128 bytes of UTF-8 encoded characters.
- **Default value**: 128 Bytes
- **Adjustable**: No

---

#### Number of thing types that can be associated with a thing

- **Description**: Number of thing types that can be associated with a thing, which can be zero or one. Thing types are optional and their use makes it easier to discover things.
- **Default value**: 1
- **Adjustable**: No

---

#### Size of thing attributes per thing

- **Description**: The size of thing attributes per thing, which is 47 kilobytes. Thing attributes are optional name-value pairs that store information about the thing, which makes their use easier to discover things.
- **Default value**: 47 Kilobytes
- **Adjustable**: Yes

---

### Note

**Thing types**

The number of thing types that can be defined in an AWS account is not limited. Thing types allow you to store description and configuration information that is common to all things associated with the same thing type.

---

### AWS IoT Core thing group resource limits and quotas

#### AWS IoT Core thing group limits and quotas

<table>
<thead>
<tr>
<th>Limit display name</th>
<th>Description</th>
<th>Default value</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Maximum depth of a thing group hierarchy</strong></td>
<td>The maximum depth of a hierarchy of thing groups. When you build a hierarchy of groups, the policy attached to the parent group is inherited by its child group, and by all the things in the group and its child groups. This makes it easier to manage permissions for large number of things.</td>
<td>7</td>
<td>No</td>
</tr>
<tr>
<td>Limit display name</td>
<td>Description</td>
<td>Default value</td>
<td>Adjustable</td>

<tr>
<td>--------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------</td>
<td>------------</td>
</tr>
<tr>
<td>Maximum number of attributes associated with a thing group</td>
<td>Maximum number of attributes associated with a thing group. Attributes are name-value pairs you can use to store information about a group. You can add, delete, or update the attributes of a group.</td>
<td>50</td>
<td>No</td>
</tr>
<tr>
<td>Maximum number of direct child groups</td>
<td>The maximum number of direct child groups that a thing group can have in a thing group hierarchy.</td>
<td>100</td>
<td>No</td>
</tr>
<tr>
<td>Maximum number of dynamic groups</td>
<td>Maximum number of dynamic groups.</td>
<td>100</td>
<td>No</td>
</tr>
<tr>
<td>Maximum number of thing groups a thing can belong to</td>
<td>A thing can be added to a maximum of 10 thing groups. But you cannot add a thing to more than one group in the same hierarchy. This means that a thing cannot be added to two groups that share a common parent.</td>
<td>10</td>
<td>No</td>
</tr>
<tr>
<td>Maximum size of a thing group attribute name, in chars</td>
<td>Maximum size of a thing group attribute name, in chars.</td>
<td>128</td>
<td>No</td>
</tr>
<tr>
<td>Maximum size of a thing group attribute value, in chars</td>
<td>Maximum size of a thing group attribute value, in chars.</td>
<td>800</td>
<td>No</td>
</tr>
<tr>
<td>Maximum thing group name size</td>
<td>Maximum thing group name size.</td>
<td>128 Bytes</td>
<td>No</td>
</tr>
</tbody>
</table>

**Note**

**Thing group assignment**
The maximum number of things that can be assigned to a thing group is not limited.

AWS IoT Core bulk thing registration limits and quotas

AWS IoT Core bulk thing registration

<table>
<thead>
<tr>
<th>Limit display name</th>
<th>Description</th>
<th>Default value</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allowed registration tasks</td>
<td>For any given AWS account, only one bulk registration task can run at a time.</td>
<td>1</td>
<td>No</td>
</tr>
<tr>
<td>Data retention policy</td>
<td>After the bulk registration task (which can be long lived) is complete, data related to bulk thing registration is permanently deleted after 30 days.</td>
<td>2592000 Seconds</td>
<td>No</td>
</tr>
<tr>
<td>Maximum line length</td>
<td>Each line in an Amazon S3 input JSON file can't exceed 256K in length.</td>
<td>256000</td>
<td>No</td>
</tr>
<tr>
<td>Registration task termination</td>
<td>Any pending or incomplete bulk registration tasks are terminated after 30 days.</td>
<td>2592000 Seconds</td>
<td>No</td>
</tr>
</tbody>
</table>

For more information about the JSON file used for bulk registration, see Amazon S3 input JSON file.

AWS IoT Core billing group restrictions

- A thing can belong to exactly one billing group.
- Unlike thing groups, billing groups cannot be organized into hierarchies.
- For its usage to be registered for tagging or billing purposes, a device must:
  - Be registered as a thing in AWS IoT Core.
  - Communicate with AWS IoT Core using MQTT only.
  - Authenticate with AWS IoT Core using only its thing name as the client ID.
  - Use an X.509 certificate or Amazon Cognito Identity to authenticate.

For more information, see Managing Devices with AWS IoT, Authentication, and Device Provisioning. You can use the AttachThingPrincipal API operation to attach a certificate or other credential to a thing.

- The maximum number of billing groups per AWS account is 20,000.
## AWS IoT Device Management API action limits

AWS IoT Events endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Service endpoints

Control plane endpoints

The following table contains AWS Region-specific endpoints that AWS IoT Events supports for control plane operations. For more information, see AWS IoT Events operations in the AWS IoT Events API Reference.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
<td>iotevents.us-east-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>iotevents.us-east-1.amazonaws.com</td>

### AWS IoT Greengrass V1 endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](p. 739).

Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](p. 743).

#### Service endpoints

**Control Plane Operations**

The following table contains AWS Region-specific endpoints that AWS IoT Greengrass supports for group management operations.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
<td>greengrass.us-east-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>greengrass.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>us-west-1</td>
<td>greengrass.us-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
<td>greengrass.us-west-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>

<td>greengrass.us-gov-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>greengrass-at-s.ats.iot.us-gov-west-1.amazonaws.com</td>
<td>MQTT and HTTPS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>greengrass.us-gov-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>

**AWS IoT Device Operations**

The following table contains AWS Region-specific Amazon Trust Services (ATS) endpoints for AWS IoT device management operations, such as shadow sync. This is a data plane API.

To look up your account-specific endpoint, use the `aws iot describe-endpoint --endpoint-type iot:Data-ATS` command.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
<td>prefix-ats.iot.us-east-2.amazonaws.com</td>
<td>HTTPS, MQTT</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>prefix-ats.iot.us-east-1.amazonaws.com</td>
<td>HTTPS, MQTT</td>
</tr>
</tbody>
</table>
### AWS General Reference Reference guide

<tr>
<td>AWS GovCloud (US-East)</td>
<td>us-gov-east-1</td>
<td><code>prefix-ats.iot.us-gov-east-1.amazonaws.com</code></td>
<td>HTTPS, MQTT</td>
</tr>
</tbody>
</table>

**Note**

Legacy Verisign endpoints are currently supported for some Regions (p. 401), but we recommend that you use ATS endpoints with ATS root certificate authority (CA) certificates. For more information, see [Server Authentication](#) in the *AWS IoT Developer Guide*.

### Discovery Operations

The following table contains AWS Region-specific ATS endpoints for device discovery operations using the AWS IoT Greengrass Discovery API. This is a data plane API.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
<td><code>greengrass-ats.iot.us-east-2.amazonaws.com</code></td>
<td>HTTPS</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td><code>greengrass-ats.iot.us-east-1.amazonaws.com</code></td>
<td>HTTPS</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
<td><code>greengrass-ats.iot.us-west-2.amazonaws.com</code></td>
<td>HTTPS</td>
</tr>
</tbody>
</table>
### Service endpoints

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asia Pacific (Mumbai)</td>
<td>ap-south-1</td>
<td>greengrass-ats.iot.ap-south-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Asia Pacific (Seoul)</td>
<td>ap-northeast-2</td>
<td>greengrass-ats.iot.ap-northeast-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Asia Pacific (Singapore)</td>
<td>ap-southeast-1</td>
<td>greengrass-ats.iot.ap-southeast-1.amazonaws.com</td>

<td>HTTPS</td>
</tr>
<tr>
<td>AWS GovCloud (US-West)</td>
<td>us-gov-west-1</td>
<td>greengrass-ats.iot.us-gov-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>AWS GovCloud (US-East)</td>
<td>us-gov-east-1</td>
<td>greengrass-ats.iot.us-gov-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>

**Note**

Legacy Verisign endpoints are currently supported for some Regions (p. 401), but we recommend that you use ATS endpoints with ATS root CA certificates. For more information, see Server authentication in the AWS IoT Developer Guide.

### Supported Legacy Endpoints

We recommend that you use the ATS endpoints in the preceding tables with ATS root CA certificates. For backward compatibility, AWS IoT Greengrass currently supports legacy Verisign endpoints in the following AWS Regions. This support is expected to end in the future. For more information, see Server authentication in the AWS IoT Developer Guide.

When using legacy Verisign endpoints, you must use Verisign root CA certificates.

**AWS IoT Device Operations (Legacy Endpoints)**

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>prefix.iot.us-east-1.amazonaws.com</td>
<td>HTTPS, MQTT</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
<td>prefix.iot.us-west-2.amazonaws.com</td>
<td>HTTPS, MQTT</td>
</tr>
</tbody>
</table>
## Service quotas

### AWS IoT Greengrass Cloud API

<table>
<thead>
<tr>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of AWS IoT devices per AWS IoT Greengrass group.</td>
<td>2500</td>
</tr>
<tr>
<td>Maximum number of Lambda functions per group.</td>
<td>200</td>
</tr>
<tr>
<td>Maximum number of resources per Lambda function.</td>
<td>20</td>
</tr>
<tr>
<td>Maximum number of resources per group.</td>
<td>200</td>
</tr>
</tbody>
</table>
Service quotas

### Description

<table>
<thead>
<tr>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of transactions per second (TPS) on the AWS IoT Greengrass APIs.</td>
<td>See the section called &quot;TPS&quot; (p. 403).</td>
</tr>
<tr>
<td>Maximum number of subscriptions per group.</td>
<td>10000</td>
</tr>
<tr>
<td>Maximum number of subscriptions that specify Cloud as the source per group.</td>
<td>50</td>
</tr>
<tr>
<td>Maximum length of a core thing name.</td>
<td>124 bytes of UTF-8 encoded characters.</td>
</tr>
</tbody>
</table>

**TPS**

The default quota for the maximum number of transactions per second on the AWS IoT Greengrass APIs depends on the API and the AWS Region where AWS IoT Greengrass is used.

For most APIs and supported AWS Regions (p. 398), the default quota is 30. Exceptions are noted in the following tables.

**API exceptions**

<table>
<thead>
<tr>
<th>API</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>CreateDeployment</td>
<td>20</td>
</tr>
</tbody>
</table>

**AWS Region exceptions**

<table>
<thead>
<tr>
<th>AWS Region</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>China (Beijing)</td>
<td>10</td>
</tr>
<tr>
<td>AWS GovCloud (US-West)</td>
<td>10</td>
</tr>
<tr>
<td>AWS GovCloud (US-East)</td>
<td>10</td>
</tr>
</tbody>
</table>

This quota applies per account and per API. For example, in the US East (N. Virginia) Region, each account has a default quota of 30 TPS, which is the aggregate of all API operation requests. Each API (such as CreateGroupVersion or ListFunctionDefinitions) has a quota of 30 TPS. This includes control plane and data plane operations. Requests that exceed the account or API quotas are throttled. To request account and API quota increases, including quotas for specific APIs, contact your AWS Enterprise Support representative.

**AWS IoT Greengrass Core**

<table>
<thead>
<tr>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of routing table entries that specify Cloud as the source.</td>
<td>50 (matches AWS IoT subscription quota)</td>
</tr>
<tr>
<td>Maximum size of messages sent by an AWS IoT device.</td>
<td>128 KB (matches AWS IoT message size quota)</td>
</tr>
<tr>
<td>Minimum message queue size in the Greengrass core router.</td>
<td>256 KB</td>
</tr>
<tr>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Maximum length of a topic string.</td>
<td>256 bytes of UTF-8 encoded characters.</td>
</tr>
<tr>
<td>Maximum number of forward slashes (/) in a topic or topic filter.</td>
<td>7</td>
</tr>
<tr>
<td>Minimum disk space needed to run the Greengrass Core software.</td>
<td>128 MB</td>
</tr>
<tr>
<td></td>
<td>400 MB when using <strong>OTA updates</strong></td>
</tr>
<tr>
<td>Minimum RAM to run the Greengrass Core software.</td>
<td>128 MB</td>
</tr>
<tr>
<td></td>
<td>198 MB when using <strong>stream manager</strong></td>
</tr>
</tbody>
</table>

The Greengrass Core software provides a service to detect the IP addresses of your Greengrass core devices. It sends this information to the AWS IoT Greengrass cloud service and allows AWS IoT devices to download the IP address of the Greengrass core they need to connect to.

Do not use this feature if any of the following is true:

- The IP address of a Greengrass core device changes frequently.
- The Greengrass core device is not always available to AWS IoT devices in its group.
- The Greengrass core has multiple IP addresses and an AWS IoT device is unable to reliably determine which address to use.
- Your organization’s security policies don’t allow you to send devices’ IP addresses to the AWS Cloud.

**AWS IoT Greengrass V2 endpoints and quotas**

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see **AWS service endpoints** (p. 739).

Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see **AWS service quotas** (p. 743).

**Service endpoints**

**Control Plane Operations**

The following table contains AWS Region-specific endpoints that AWS IoT Greengrass V2 supports for operations to manage components, devices, and deployments.

<table>
<thead>
<tr>

**AWS IoT Device Operations**

The following table contains AWS Region-specific Amazon Trust Services (ATS) endpoints for AWS IoT device management operations, such as shadow sync. This is a data plane API.

To look up your account-specific endpoint, use the `aws iot describe-endpoint --endpoint-type iot:Data-ATS` command.
### Region Name | Region | Endpoint | Protocol |
<table>
<thead>
<tr>

<tr>
<td>AWS GovCloud (US-East)</td>
<td>us-gov-east-1</td>
<td>prefix-ats.iot.us-gov-east-1.amazonaws.com</td>
<td>HTTPS, MQTT</td>
</tr>
</tbody>
</table>

**Note**
Legacy Verisign endpoints are currently supported for some Regions (p. 407), but we recommend that you use ATS endpoints with ATS root certificate authority (CA) certificates. For more information, see Server Authentication in the AWS IoT Developer Guide.

### Date Plane Operations

The following table contains AWS Region-specific ATS endpoints for data plane API operations, such as ResolveComponentCandidates.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>

</tr>
<tr>
<td>Europe (Frankfurt)</td>
<td>eu-central-1</td>
<td>greengrass-ats.iot.eu-central-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Europe (Ireland)</td>
<td>eu-west-1</td>
<td>greengrass-ats.iot.eu-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Europe (London)</td>
<td>eu-west-2</td>
<td>greengrass-ats.iot.eu-west-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>AWS GovCloud (US-West)</td>
<td>us-gov-west-1</td>
<td>greengrass-ats.iot.us-gov-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>AWS GovCloud (US-East)</td>
<td>us-gov-east-1</td>
<td>greengrass-ats.iot.us-gov-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>

**Note**

Legacy Verisign endpoints are currently supported for some Regions (p. 407), but we recommend that you use ATS endpoints with ATS root CA certificates. For more information, see Server authentication in the *AWS IoT Developer Guide*.

**Supported Legacy Endpoints**

We recommend that you use the ATS endpoints in the preceding tables with ATS root CA certificates. For backward compatibility, AWS IoT Greengrass V2 currently supports legacy Verisign endpoints in the following AWS Regions. This support is expected to end in the future. For more information, see Server authentication in the *AWS IoT Developer Guide*.

When using legacy Verisign endpoints, you must use Verisign root CA certificates.
AWS IoT Device Operations (Legacy Endpoints)

</tr>
</tbody>
</table>

Service quotas

The following tables describe quotas in AWS IoT Greengrass V2. For more information about quotas and how to request quota increases, see AWS service quotas (p. 743).
## Quotas for core devices

<table>
<thead>
<tr>
<th>Resource</th>
<th>Quota</th>
<th>Adjustable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum length of a core device thing name</td>
<td>124 bytes of UTF-8 encoded characters</td>
<td>No</td>
<td></td>
</tr>
</tbody>
</table>

## Quotas for components

<table>
<thead>
<tr>
<th>Resource</th>
<th>Quota</th>
<th>Adjustable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of components</td>
<td>5,000 components per Region</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>Maximum number of component versions</td>
<td>5,000 versions per component per Region</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>Maximum size of component recipe</td>
<td>8 KB</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>Maximum total size of component artifacts</td>
<td>2 GB</td>
<td>No</td>
<td>This quota applies to the sum of all artifacts for a component.</td>
</tr>
<tr>
<td>Request rate for CreateComponentVersion</td>
<td>1 request per second per Region</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>Request rate for other API operations</td>
<td>30 requests per second per Region</td>
<td>No</td>
<td>This quota applies per API operation.</td>
</tr>
</tbody>
</table>

**Exceptions**

- China (Beijing) – 10 requests per second per Region
- AWS GovCloud (US-West) – 10 requests per second per Region
- AWS GovCloud (US-East) – 10 requests per second per Region

## Quotas for deployments

<table>
<thead>
<tr>
<th>Resource</th>
<th>Quota</th>
<th>Adjustable</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum size of deployment document for a thing deployment (without large configuration support)</td>
<td>7 KB</td>
<td>No</td>
<td>The deployment document includes the component configurations, deployment configurations, and payload overhead.</td>
</tr>
</tbody>
</table>
### AWS IoT RoboRunner endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](p. 739).

Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](p. 743).

Amazon Kinesis Data Analytics endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

AWS Launch Wizard endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

## Amazon Location Service endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](p. 743).

### Service endpoints

Amazon Location is available in the following AWS Regions:

<table>
<thead>
<tr>
<th>Region name</th>
<th>Region code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asia Pacific (Tokyo)</td>
<td>ap-northeast-1</td>
</tr>
<tr>
<td>Asia Pacific (Singapore)</td>
<td>ap-southeast-1</td>
</tr>
<tr>
<td>Asia Pacific (Sydney)</td>
<td>ap-southeast-2</td>
</tr>
<tr>
<td>Europe (Frankfurt)</td>
<td>eu-central-1</td>
</tr>
<tr>
<td>Europe (Ireland)</td>
<td>eu-west-1</td>
</tr>
<tr>
<td>Europe (Stockholm)</td>
<td>eu-north-1</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
</tr>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
</tr>
</tbody>
</table>

---

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum certificates</td>
<td>Each supported Region: 20</td>
<td>No</td>
</tr>
<tr>
<td>Maximum keys per bucket</td>
<td>Each supported Region: 2</td>
<td>No</td>
</tr>
<tr>
<td>Minimum block storage disk space</td>
<td>Each supported Region: 8 Gigabytes</td>
<td>No</td>
</tr>
<tr>
<td>Origins per distribution</td>
<td>Each supported Region: 1</td>
<td>No</td>
</tr>
<tr>
<td>Parallel RDP connections using the browser-based RDP client</td>
<td>Each supported Region: 1</td>
<td>No</td>
</tr>
<tr>
<td>Parallel SSH connections using the browser-based SSH client</td>
<td>Each supported Region: 5</td>
<td>No</td>
</tr>
<tr>
<td>Response timeout per origin for a distribution</td>
<td>Each supported Region: 60 Seconds</td>
<td>No</td>
</tr>
<tr>
<td>Static IP addresses</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
</tr>
<tr>
<td>Tags</td>
<td>Each supported Region: 50</td>
<td>No</td>
</tr>
<tr>
<td>Total attached block storage disk space</td>
<td>Each supported Region: 20,000 Gigabytes</td>
<td>No</td>
</tr>
</tbody>
</table>
The general syntax for an Amazon Location regional endpoint is as follows:

```
protocol://service-code.geo.region-code.amazonaws.com
```

Within this syntax, Amazon Location uses the following service codes:

<table>
<thead>
<tr>
<th>Service</th>
<th>Service code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Location Maps</td>
<td>maps</td>
</tr>
<tr>
<td>Amazon Location Places</td>
<td>places</td>
</tr>
<tr>
<td>Amazon Location Routes</td>
<td>routes</td>
</tr>
<tr>
<td>Amazon Location Geofences</td>
<td>geofencing</td>
</tr>
<tr>
<td>Amazon Location Trackers</td>
<td>tracking</td>
</tr>
</tbody>
</table>

For example, the regional endpoint for Amazon Location Maps for US East (N. Virginia) is: https://maps.geo.us-east-1.amazonaws.com.

### Service quotas

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Geofence Collection resources per account</td>
<td>Each supported Region: 1,000</td>
<td>Yes</td>
</tr>
<tr>
<td>Geofences per Geofence Collection</td>
<td>Each supported Region: 50,000</td>
<td>Yes</td>
</tr>
<tr>
<td>Map resources per account</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
</tr>
<tr>
<td>Place Index resources per account</td>
<td>Each supported Region: 20</td>
<td>Yes</td>
</tr>
<tr>
<td>Rate of AssociateTrackerConsumer API requests</td>
<td>Each supported Region: 10</td>
<td>Yes</td>
</tr>
<tr>

### AWS Mainframe Modernization endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

<td>Yes</td>
</tr>
</tbody>
</table>
For information about attributes of Starter Edition and Standard Edition networks, such as the number of members per network, peer nodes per member, available instance types, and more, see Amazon Managed Blockchain Pricing.

AWS Management Console service endpoints

AWS Management Console has Regional endpoints that allow you to directly access the console in a given AWS Region. The general syntax of a Regional endpoint is as follows:

https://region-code.console.aws.amazon.com

For example, https://us-west-2.console.aws.amazon.com is the endpoint for the AWS Management Console service in the US West (Oregon) Region.

The table below lists the name, code, and endpoint of each AWS Region.

<table>
<thead>
<tr>

AWS Marketplace endpoints and quotas

AWS Marketplace is a curated digital catalog that makes it easy for customers to find, buy, deploy, and manage third-party software and services that customers need to build solutions and run their businesses.

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Service endpoints

The AWS Marketplace website is available globally. The AWS Marketplace console is available in the US East (N. Virginia) Region. The product vendor determines the Regions in which their products are available.

AWS Elemental MediaConvert endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Service endpoints

Use these endpoints only to request an account-specific endpoint, using the DescribeEndpoints operation. Send all your transcoding requests to the account-specific endpoint that the service returns. For more information, see Getting Started with the API in the MediaConvert API Reference.

MediaLive

### AWS Elemental MediaLive endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

#### Service endpoints

When you submit requests using the AWS CLI or SDKs, either leave the Region and endpoint unspecified, or specify us-east-1 as the Region. When you submit requests using the MediaLive API, use the us-east-1 Region to sign requests. For more information about signing MediaLive API requests, see Signature Version 4 signing process (p. 761).

AWS Migration Hub endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739).

Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Service endpoints

The migration tools that integrate with AWS Migration Hub send migration status to the Migration Hub in the home Region you choose. For information about choosing a home Region, see The AWS Migration Hub Home Region in the AWS Migration Hub User Guide.

For more information, see [AWS Network Firewall quotas](#) in the Network Firewall Developer Guide.
Transit Gateway Network Manager endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

AWS OpsWorks endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Service endpoints

AWS OpsWorks CM

You can create and manage AWS OpsWorks for Chef Automate and AWS OpsWorks for Puppet Enterprise servers in the following Regions. Resources can be managed only in the Region in which they are created. Resources that are created in one Regional endpoint are not available, nor can they be cloned to, another Regional endpoint.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>

</tr>
</tbody>
</table>

**AWS OpsWorks Stacks**

You can create and manage AWS OpsWorks resources in all of the following Regions. The Canada (Central) Region Region is API-only; you cannot create stacks in Canada (Central) Region by using the AWS Management Console. Resources can be managed only in the Region in which they are created. Resources that are created in one Regional endpoint are not available—nor can they be cloned to—another Regional endpoint.
### Service quotas

The following quotas are for AWS OpsWorks CM.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automated (scheduled) backup generations per server</td>
<td>Each supported Region: 10</td>
<td>Yes</td>
</tr>
<tr>
<td>Chef Automate or Puppet Enterprise servers</td>
<td>Each supported Region: 5</td>
<td>Yes</td>
</tr>
<tr>
<td>Manual backups per server</td>
<td>Each supported Region: 10</td>
<td>Yes</td>
</tr>
</tbody>
</table>

The following quotas are for AWS OpsWorks stacks.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apps per stack</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
</tr>
<tr>

<td>Each supported Region: 40</td>
<td>Yes</td>
</tr>
<tr>
<td>Layers per stack</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
</tr>
<tr>
<td>Stacks</td>
<td>Each supported Region: 40</td>
<td>Yes</td>
</tr>
</tbody>
</table>
AWS Organizations endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Service endpoints

Because AWS Organizations is a global service, there is a single global endpoint for all of the AWS Regions in each partition.

Amazon Pinpoint endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Amazon Pinpoint includes the Amazon Pinpoint API and the Amazon Pinpoint SMS and Voice API.

</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>aps.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>
Service quotas

Amazon Managed Service for Prometheus has the following quotas for series, labels, and API requests. The Possible error message column shows what error message you might see if your Prometheus data exceeds a limit. If you see one of these error messages, you should request an increase to the corresponding limit.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Default quota</th>
<th>Possible error message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active series (metrics that have reported data in the past 5 minutes) per workspace</td>
<td>1,000,000. You can request a quota increase.</td>
<td>per-user series limit of 1000000 exceeded, please contact administrator to raise it</td>
</tr>
<tr>
<td>Active series per metric name</td>
<td>200,000. You can request a quota increase.</td>
<td>per-metric series limit of 200000 exceeded, please contact administrator</td>
</tr>
<tr>
<td>Resource</td>
<td>Default quota</td>
<td>Possible error message</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Ingestion rate</td>
<td>70,000 samples per second. You can request a quota increase.</td>
<td>ingestion rate limit (...) exceeded</td>
</tr>
<tr>
<td>Ingestion burst size</td>
<td>1,000,000 samples. You can request a quota increase.</td>
<td>ingestion rate limit (...) exceeded</td>
</tr>
<tr>
<td>Labels per metric series.</td>
<td>70. You can request a quota increase.</td>
<td>series has too many labels (... series: '%s'</td>
</tr>
<tr>
<td>Query bytes for instant queries</td>
<td>750MB that can be scanned by a single instant query. This quota can't be changed.</td>
<td>the query hit the aggregated chunks size limit (A chunk stores raw samples of series for a certain time span.)</td>
</tr>
<tr>
<td>Query bytes for range queries</td>
<td>750MB that can be scanned per 24-hour interval in a single range query. This quota can't be changed.</td>
<td>the query hit the aggregated chunks size limit (A chunk stores raw samples of series for a certain time span.)</td>
</tr>
<tr>
<td>Query time range</td>
<td>32 days between the start time and the end time of a PromQL query. This quota cannot be changed.</td>
<td>the query time range exceeds the limit (query length: xxx, limit: yyy)</td>
</tr>
<tr>
<td>Query samples</td>
<td>12,000,000 samples that can be scanned during a single query. This quota can't be changed.</td>
<td>query processing would load too many samples into memory in query execution</td>
</tr>
<tr>
<td>Retention time for ingested data</td>
<td>150 days. Data older than this is deleted from the workspace.</td>
<td></td>
</tr>
</tbody>
</table>
### Additional quotas for ingested data

Amazon Managed Service for Prometheus has additional quotas for data that's ingested into Amazon Managed Service for Prometheus workspaces.
• Metric samples older than 1 hour are refused from being ingested.
• Every sample and metadata must have a metric name.
• Maximum length accepted for label names: 1024 bytes
• Maximum length accepted for label value: 2048 bytes
• Maximum number of metadata per metric: 10
• Maximum size of ingestion or query request: 1 MB
• Maximum length accepted for metric metadata, which includes metric name, HELP, and UNIT: 1024 bytes
• Maximum number of active metrics with metadata per workspace: 20,000
• Maximum retention time for ingested metrics: 150 days. Data older than this is deleted from the workspace.

AWS Proton endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

The following are differences for certain Amazon Rekognition features and AWS Regions.

**Amazon Rekognition Video streaming API**

The Amazon Rekognition Video streaming API is available in the following Regions only.

- US East (N. Virginia)
- US West (Oregon)
• Asia Pacific (Tokyo)
• Europe (Frankfurt)
• Europe (Ireland)

Amazon Rekognition Custom Labels

Amazon Rekognition Custom Labels is available in the following Regions only.

• US East (N. Virginia)
• US East (Ohio)
• US West (Oregon)
• Europe (Ireland)
• Europe (London)
• Europe (Frankfurt)
• Asia Pacific (Mumbai)
• Asia Pacific (Singapore)
• Asia Pacific (Sydney)
• Asia Pacific (Tokyo)
• Asia Pacific (Seoul)

Canada (Central) Region

The Canada (Central) Region supports the following operations only.

• CompareFaces
• CreateCollection
• DeleteCollection
• DeleteFaces
• DescribeCollection
• DetectFaces
• IndexFaces
• ListCollections
• ListFaces
• SearchFaces
• SearchFacesByImage

Note
These operations are only available through use of the AWS CLI or SDK, as the Canada (Central) Region doesn't currently provide a console experience for these operations.

Service quotas

The quotas listed on this page are defaults. You can request a quota increase for Amazon Rekognition using the AWS Support Center. To request a quota increase for a Amazon Rekognition Transactions Per Second (TPS) limit, follow the instructions at Default Quotas in Amazon Rekognition.
**Note**
These limits may be different in different Regions. Making a case to change a limit affects the API operation you request, in the Region you request it. Other API operations and Regions are not affected.

<td>No</td>
</tr>
</tbody>
</table>

**Amazon Route 53 endpoints and quotas**

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](p. 743).

**Service endpoints**

**Hosted zones, records, health checks, DNS query logs, reusable delegation sets, traffic policies, and cost allocation tags**

When you use the [AWS CLI](https://docs.aws.amazon.com/cli/latest/userguide/cli-chap-get-started.html) or [SDKs](https://docs.aws.amazon.com/sdk-for-java/v1/developer-guide/java-demos.html) to submit requests, you can either leave the Region and endpoint unspecified, or specify the applicable Region:

- Route 53 in AWS Regions other than the Beijing and Ningxia Regions: specify us-east-1 as the Region.
- Route 53 in the Beijing and Ningxia Regions: specify cn-northwest-1.

When you use the [Route 53 API](https://docs.aws.amazon.com/Route53/latest/DeveloperGuide/using-the-route53-api.html) to submit requests, use the same Regions as above to sign requests. For more information about signing Route 53 API requests, see [Signature Version 4 signing process](p. 761).

### Requests for Route 53 auto naming

Amazon Route 53 auto naming has been released as a separate service, AWS Cloud Map. For a list of service endpoints, see Service endpoints (p. 105). For AWS Cloud Map documentation, see AWS Cloud Map Documentation.

### Service quotas

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon VPCs that you can associate with a private hosted zone</td>
<td>Each supported Region: 300</td>

</tbody>
</table>

For more information, see [Route 53 quotas](https://docs.aws.amazon.com/Route53/latest/DeveloperGuide/route53-limits.html) in the *Amazon Route 53 Developer Guide*.

### Amazon SageMaker endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](https://docs.aws.amazon.com/AmazonS3/latest/API/AMZ_S3_FIPS.html). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](https://docs.aws.amazon.com/AmazonS3/latest/API/AMZ_S3_Limits.html).
# Service endpoints

The following table provides a list of Region-specific endpoints that SageMaker supports for training and deploying models. This include creating and managing notebook instances, training jobs, model, endpoint configurations, and endpoints.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>

## Service quotas

Depending on your activities and resource usage over time, your SageMaker quotas might be different from the default SageMaker quotas listed in the following tables. The default quotas in this page are based on new accounts. If you encounter error messages that you’ve exceeded your quota, use AWS Support to request a service limit increase for SageMaker resources you want to scale up. For instructions on how to request a service limit increase, see Supported Regions and Quotas in the Amazon SageMaker Developer Guide. For information on Amazon EC2 instance types, see Amazon EC2 Instance Types.

### SageMaker Studio

- **Longest run time for a processing job**: 5 days
- **Number of instances across a single processing job**: 4
- **Total number of instances across all processing jobs**: 20
- **Size of EBS volume for an instance**: 1 TB
Note
In case of SageMaker training, on-demand and spot instance quotas are tracked and modified separately. For example, with the default quotas, you can run up to 20 training jobs with ml.m4.xlarge on-demand instances and up to 20 training jobs with ml.m4.xlarge spot instances simultaneously.

### SageMaker Autopilot

<table>
<thead>
<tr>
<th>Resource</th>
<th>Regions</th>
<th>Default limits</th>
<th>Can be increased up to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size of input dataset</td>
<td>All</td>
<td>100 GB</td>
<td>Hundreds of GBs</td>
</tr>
<tr>
<td>Size of a single Parquet file*</td>
<td>All</td>
<td>2 GB</td>
<td>Tens of GBs</td>
</tr>
<tr>
<td>Target dataset size for subsampling**</td>
<td>All</td>
<td>5 GB</td>
<td>Hundreds of GBs</td>
</tr>
<tr>
<td>Number of concurrent SageMaker Autopilot jobs</td>
<td>us-east-1, us-east-2, us-west-2, ap-northeast-1, eu-west-1, eu-central-1</td>
<td>4</td>
<td>Hundreds</td>
</tr>
<tr>
<td></td>
<td>ap-northeast-2, ap-southeast-2, eu-west-2, ap-southeast-1</td>
<td>2</td>
<td>Hundreds</td>
</tr>
<tr>
<td></td>
<td>All other regions</td>
<td>1</td>
<td>Tens</td>
</tr>
</tbody>
</table>

**Note**

*This 2 GB size limit is for a single compressed Parquet file. You can provide a Parquet dataset that includes multiple compressed Parquet files. After the files are decompressed, they may each expand to a larger size.

**SageMaker Autopilot automatically subsamples input datasets that are larger than the target dataset size while accounting for class imbalance and preserving rare class labels.
The resource quotas documented in the following sections are valid for versions of Amazon SageMaker Studio 3.22.2 and higher. For information on updating your version of SageMaker Studio, see Update SageMaker Studio and Studio Apps. You can increase these limits by contacting AWS Support Center. For instructions on how to request increases, see Update SageMaker Studio and Studio Apps.

AWS Secrets Manager endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

AWS Security Token Service endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739).

Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Service endpoints

By default, the AWS Security Token Service (AWS STS) is available as a global service, and all STS requests go to a single endpoint at https://sts.amazonaws.com. AWS recommends using Regional STS endpoints to reduce latency, build in redundancy, and increase session token validity. Most Regional endpoints are active by default, but you must manually enable endpoints for some Regions, such as Asia Pacific (Hong Kong). You can deactivate STS endpoints for any Regions that are enabled by default if you do not intend to use those Regions.

For more information, see Activating and Deactivating AWS STS in an AWS Region in the IAM User Guide.

AWS Server Migration Service endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739).

Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

<td>HTTP and HTTPS</td>
</tr>
</tbody>
</table>
### Service quotas

The following quotas determine how many Amazon SNS resources you can create in your AWS account, and they determine the rate at which you can issue Amazon SNS API requests.

#### Amazon SNS resource

To request an increase, submit an SNS Quota Increase case.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topics</td>
<td>• Standard: 100,000 per account&lt;br&gt;• FIFO: 1,000 per account</td>
</tr>
<tr>
<td>Subscriptions</td>
<td>• Standard: 12,500,000 per topic&lt;br&gt;For Kinesis Data Firehose delivery streams, 5 per topic, per subscription owner&lt;br&gt;• FIFO: 100 per topic</td>
</tr>
<tr>
<td>Pending subscriptions</td>
<td>5,000 per account</td>
</tr>
<tr>
<td>Account spend threshold for SMS</td>
<td>1.00 USD per account</td>
</tr>
<tr>
<td>Delivery rate for promotional SMS messages</td>
<td>20 messages per second</td>
</tr>
</tbody>
</table>

### FIFO topics

FIFO topics are supported in all Regions except the following:

- AWS GovCloud (US-East)
- AWS GovCloud (US-West)
<table>
<thead>
<tr>
<th>Resource</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delivery rate for transactional SMS messages</td>
<td>20 messages per second</td>
</tr>
<tr>
<td>Delivery rate for email messages</td>
<td>10 messages per second</td>
</tr>
<tr>
<td>Maximum number of messages in PublishBatchRequest</td>
<td>10 PublishBatchRequestEntries</td>
</tr>
<tr>
<td>Subscription filter policies</td>
<td>200 per account</td>
</tr>
</tbody>
</table>

**Amazon SNS API throttling**

The following quotas throttle the rate at which you can issue Amazon SNS API requests.

**Hard**

The following quotas cannot be increased.

<table>
<thead>
<tr>
<th>API</th>
<th>Transactions per second</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckIfPhoneNumberIsOptedOut</td>
<td>50</td>
</tr>
<tr>
<td>CreateSMSSandboxPhoneNumber</td>
<td>1</td>
</tr>
<tr>
<td>DeleteSMSSandboxPhoneNumber</td>
<td>1</td>
</tr>
<tr>

<td>100</td>
</tr>
<tr>
<td>Unsubscribe</td>
<td>100</td>
</tr>
<tr>
<td>VerifySMSSandboxPhoneNumber</td>
<td>1</td>
</tr>
</tbody>
</table>
Soft

The following quotas vary by AWS Region. The messages per second quota is based on the number of messages published to an Amazon SNS region, combining Publish and PublishBatch API requests.

For example, if your regional quota is 30,000 messages per second, there are a few ways this quota can be reached:

- Using the Publish action at a rate of 30,000 API requests per second to publish 30,000 messages (one message per API request).
- Using the PublishBatch action at a rate of 3,000 API requests per second to publish 30,000 messages (10 messages per batch API request).
- Using the Publish action at a rate of 10,000 API requests per second to publish 10,000 messages (one message per API request) and the PublishBatch action at a rate of 2,000 API requests per second to publish 20,000 messages (10 messages per batch API request) for a total of 30,000 messages published per second.

Publish API throttling

Amazon Simple Queue Service endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

**Amazon S3 dual-stack endpoints support requests to S3 buckets over IPv6 and IPv4. For more information, see Using Dual-Stack Endpoints.**

***You must enable this Region before you can use it.***

When using the preceding endpoints the following additional considerations apply:

- The s3-control endpoints are used with Amazon S3 account-level operations
- The s3-accesspoint endpoints are used only to make requests through Amazon S3 Access Points. For more information, see Working with Amazon S3 Access Points.
- Amazon S3 renamed the US Standard Region to the US East (N. Virginia) Region to be consistent with AWS Regional naming conventions. There is no change to the endpoint, and you do not need to make any changes to your application.
If you use a Region other than the US East (N. Virginia) endpoint to create a bucket, you must set the LocationConstraint bucket parameter to the same Region. Both the AWS SDK for Java and AWS SDK for .NET use an enumeration for setting location constraints (Region for Java, S3Region for .NET). For more information, see PUT Bucket in the Amazon Simple Storage Service API Reference.

Amazon S3 website endpoints

When you configure your bucket as a website, the website is available using the following Region-specific website endpoints. Note that the website endpoints are different than the REST API endpoints listed in the preceding table. For more information about hosting websites on Amazon S3, see Hosting Websites on Amazon S3 in the Amazon Simple Storage Service User Guide. You need the hosted zone IDs when using the Amazon Route 53 API to add an alias record to your hosted zone.

**Note**

Amazon S3 website endpoints do not support HTTPS or Amazon S3 Access Points. If you want to use HTTPS, you can use Amazon CloudFront to serve a static website hosted on Amazon S3. For more information, see Configuring a static website using a custom domain registered with Route 53 and Improving the performance of your website using CloudFront in the Amazon S3 User Guide.

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

For more information, see Amazon SWF Quotas in the Amazon Simple Workflow Service Developer Guide.

Amazon SimpleDB endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

For AWS Regions that the hardware appliance is supported in, see Storage Gateway hardware appliance regions (p. 687).

**Storage Gateway hardware appliance regions**

The Storage Gateway hardware appliance is available for shipping worldwide where it is legally allowed and permitted for exporting by the US government.

Storage Gateway hardware appliance is supported in the following AWS Regions.

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- South America (São Paulo)

For more information, see [Storage Gateway quotas](#) in the *AWS Storage Gateway User Guide*. 
Amazon Sumerian endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

</tr>
</tbody>
</table>
Inventory data expiration

If you terminate an instance, inventory data for that instance is deleted immediately. For running instances, inventory data older than 30 days is deleted. If you need to store inventory data longer than 30 days, you can use AWS Config to record history or periodically query and upload the data to an Amazon S3 bucket. For more information, see [Recording Amazon EC2 managed instance inventory in the AWS Config Developer Guide](#).

Amazon Textract endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Amazon Timestream endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Service endpoints

Use the following endpoints to acquire the endpoints for the write API.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
<td>ingest.timestream.us-east-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ingest.timestream-fips.us-east-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>ingest.timestream.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ingest.timestream-fips.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
<td>ingest.timestream.us-west-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ingest.timestream-fips.us-west-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Europe (Frankfurt)</td>
<td>eu-central-1</td>
<td>ingest.timestream.eu-central-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Europe (Ireland)</td>
<td>eu-west-1</td>
<td>ingest.timestream.eu-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>

Use the following endpoints to acquire the endpoints for the query API.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
<th>Endpoint</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
<td>query.timestream.us-east-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>query.timestream-fips.us-east-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
<td>query.timestream.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>query.timestream-fips.us-east-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
<td>query.timestream.us-west-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>query.timestream-fips.us-west-2.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Europe (Frankfurt)</td>
<td>eu-central-1</td>
<td>query.timestream.eu-central-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
<tr>
<td>Europe (Ireland)</td>
<td>eu-west-1</td>
<td>query.timestream.eu-west-1.amazonaws.com</td>
<td>HTTPS</td>
</tr>
</tbody>
</table>
For more information, see Using the API in the Amazon Timestream Developer Guide.

AWS Transfer Family endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739).
Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

AWS WAF endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

Note
This page provides information related the latest version of AWS WAF, released in November 2019. The names of the entities that you use to access AWS WAF, like endpoints and namespaces, all have the versioning information added, like v2 or v2, to distinguish from the prior version.

For more information, see [AWS WAF quotas](https://docs.aws.amazon.com/waf/latest/developerguide/aws-waf-quota-overview.html) in the *AWS WAF Developer Guide*.

## AWS WAF Classic endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see [AWS service endpoints](https://docs.aws.amazon.com/general/latest/gn_index.html#gn-index-endpoints). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see [AWS service quotas](https://docs.aws.amazon.com/general/latest/gn_index.html#gn-index-quotas).

**Note**

This page provides information related to **AWS WAF Classic**. If you created AWS WAF resources, like rules and web ACLs, in AWS WAF prior to November 2019, and you have not migrated your web ACLs over yet, you must use AWS WAF Classic to access those resources. Otherwise, do not use this version.

For information related to the latest version of **AWS WAF**, see [AWS WAF endpoints and quotas](https://docs.aws.amazon.com/waf/latest/developerguide/aws-waf-endpoint-overview.html).

Service quotas

For more information, see Amazon WorkMail Quotas.

WorkSpaces endpoints and quotas

The following are the service endpoints and service quotas for this service. To connect programmatically to an AWS service, you use an endpoint. In addition to the standard AWS endpoints, some AWS services offer FIPS endpoints in selected Regions. For more information, see AWS service endpoints (p. 739). Service quotas, also referred to as limits, are the maximum number of service resources or operations for your AWS account. For more information, see AWS service quotas (p. 743).

AWS resources

The following pages provide information that helps you work with AWS resources.

Contents
- AWS service endpoints (p. 739)
- Managing AWS Regions (p. 741)
- AWS service quotas (p. 743)
- Tagging AWS resources (p. 744)
- Amazon Resource Names (ARNs) (p. 748)

AWS service endpoints

To connect programmatically to an AWS service, you use an endpoint. An endpoint is the URL of the entry point for an AWS web service. The AWS SDKs and the AWS Command Line Interface (AWS CLI) automatically use the default endpoint for each service in an AWS Region. But you can specify an alternate endpoint for your API requests.

If a service supports Regions, the resources in each Region are independent of similar resources in other Regions. For example, you can create an Amazon EC2 instance or an Amazon SQS queue in one Region. When you do, the instance or queue is independent of instances or queues in all other Regions.

Contents
- Regional endpoints (p. 739)
- View the service endpoints (p. 740)
- FIPS endpoints (p. 741)
- Learn more (p. 741)

Regional endpoints

Most Amazon Web Services offer a Regional endpoint that you can use to make your requests. The general syntax of a Regional endpoint is as follows.

```
protocol://service-code.region-code.amazonaws.com
```

For example, https://dynamodb.us-west-2.amazonaws.com is the endpoint for the Amazon DynamoDB service in the US West (Oregon) Region.

The following table lists the name and code of each Region.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>us-west-1</td>
</tr>
</tbody>
</table>
Some services, such as IAM, do not support Regions. The endpoints for these services do not include
a Region. Other services, such as Amazon EC2, support Regions but let you specify an endpoint that
does not include a Region, such as https://ec2.amazonaws.com. When you use an endpoint with
no Region, AWS routes the Amazon EC2 request to US East (N. Virginia) (us-east-1), which is the default
Region for API calls.

### View the service endpoints

You can view the AWS service endpoints using the following options:

- Open Service endpoints and quotas (p. 16), search for the service name, and click the link to open
  the page for that service. To view the supported endpoints for all AWS services in the documentation
  without switching pages, view the information in the Service Endpoints and Quotas page in the PDF
  instead.
- To programmatically check for service availability using the SDK for Java, see Checking for Service
  Availability in an AWS Region in the AWS SDK for Java Developer Guide.
• To programmatically view Region and service information using Systems Manager, see Calling AWS Service, Region, and Endpoint Public Parameters in the AWS Systems Manager User Guide. For information about how to use public parameters, see Query for AWS Regions, Endpoints, and More Using AWS Systems Manager Parameter Store.

• To see the supported AWS services in each Region (without endpoints), see the Region Table.

FIPS endpoints

Some AWS services offer FIPS endpoints in selected Regions. Unlike standard AWS endpoints, FIPS endpoints use a TLS software library that complies with Federal Information Processing Standard (FIPS) 140-2. These endpoints might be required by enterprises that interact with the United States government. For more information, see Federal Information Processing Standard (FIPS) 140-2 on the AWS Compliance site.

To use a FIPS endpoint with an AWS operation, use the mechanism provided by the AWS SDK or tool to specify a custom endpoint. For example, the AWS SDKs provide an AWS_USE_FIPS_ENDPOINT environment variable. The AWS Command Line Interface provides the --endpoint-url option. The following example uses the FIPS endpoint for the US West (Oregon) Region with an operation for AWS Key Management Service (AWS KMS).

```
aws kms create-key --endpoint-url https://kms-fips.us-west-2.amazonaws.com
```

Minimum TLS version for FIPS endpoints

With FIPS endpoints, the minimum requirement is TLS 1.2. AWS revoked the ability to use TLS 1.0 and TLS 1.1 on all FIPS endpoints in all Regions as of March 31, 2021. For information about how to determine whether your applications were impacted by this change, see this AWS Security Blog post from May 3, 2021.

Learn more

You can find endpoint information from the following sources:

• To learn about enabling Regions that are disabled by default, see Managing AWS Regions (p. 741).

• For information about the AWS services and endpoints available in the China Regions, see China (Beijing) Region Endpoints and China (Ningxia) Region Endpoints.

Managing AWS Regions

An AWS Region is a collection of AWS resources in a geographic area. Each AWS Region is isolated and independent of the other Regions. Regions provide fault tolerance, stability, and resilience, and can also reduce latency. They enable you to create redundant resources that remain available and unaffected by a Regional outage. For a list of Region names and codes, see this table (p. 739).

The resources that you create in one Region do not exist in any other Region unless you explicitly use a replication feature offered by an AWS service. For example, Amazon S3 and Amazon EC2 support cross-Region replication. Some services, such as AWS Identity and Access Management (IAM), do not have Regional resources.

You can use policy conditions to control access to AWS services in an AWS Region. For a table of AWS services supported in each Region (without endpoints), see the Region Table.
Regions introduced before March 20, 2019 are enabled by default. You can begin creating and managing resources in these Regions immediately. You cannot enable or disable a Region that is enabled by default.

Enabling a Region

If a Region is disabled by default, you must enable it before you can create and manage resources. The following Regions are disabled by default:

- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Jakarta)
- Europe (Milan)
- Middle East (Bahrain)

When you enable a Region, AWS performs actions to prepare your account in that Region, such as distributing your IAM resources to the Region. This process takes a few minutes for most accounts, but this can take several hours. You cannot use the Region until this process is complete.

Requirements

To enable a Region that is disabled by default, you must have permission to enable Regions. To view an example IAM policy, see Allow enabling and disabling AWS Regions in the IAM User Guide.

To enable a Region

1. Sign in to the AWS Management Console.
2. In the upper right corner of the console, choose your account name or number and then choose Account.
3. In the AWS Regions section, next to the name of the Region that you want to enable, choose Enable.
4. In the dialog box, review the informational text and choose Enable Region.
5. Wait until the Region is ready to use.

Disabling a Region

You cannot disable a Region that is enabled by default. If you enabled one of the following Regions, then you can disable it as needed:

- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Jakarta)
- Europe (Milan)
- Middle East (Bahrain)

After you disable a Region, the resources in this Region become unavailable based on eventual consistency. However, they are not deleted.

Requirements

- To disable a Region, you must have permission to disable Regions. To view an example IAM policy, see Allow enabling and disabling AWS Regions in the IAM User Guide.
Before you disable a Region, we recommend that you remove all resources from that Region. After you disable a Region, you can no longer view or manage resources in the Region from that account through the AWS Management console or AWS APIs with IAM principals. However, resources in that Region can continue to incur charges. For more information, see Enabling and disabling Regions in the *AWS Billing and Cost Management User Guide*.

**To disable a Region**

1. Sign in to the AWS Management Console.
2. In the upper right corner of the console, choose your account name or number and then choose **My Account**.
3. In the **AWS Regions** section, next to the name of the Region that you want to disable, choose **Disable**.
4. In the dialog box, review the informational text and choose **Disable Region**.

**Describing your Regions using the AWS CLI**

Use the `describe-regions` command to describe the Regions available for your account, whether they are enabled or disabled.

```bash
aws ec2 describe-regions --all-regions
```

If the Region is enabled by default, the output includes the following:

```json
"OptInStatus": "opt-in-not-required"
```

If the Region is not enabled, the output includes the following:

```json
"OptInStatus": "not-opted-in"
```

After an opt-in Region is enabled, the output includes the following:

```json
"OptInStatus": "opted-in"
```

**AWS service quotas**

Your AWS account has default quotas, formerly referred to as limits, for each AWS service. Unless otherwise noted, each quota is Region-specific. You can request increases for some quotas, and other quotas cannot be increased.

Service Quotas is an AWS service that helps you manage your quotas for many AWS services, from one location. Along with looking up the quota values, you can also request a quota increase from the Service Quotas console.

AWS Support might approve, deny, or partially approve your requests.

**To view service quotas**

You can view service quotas using the following options:

- Open the *Service endpoints and quotas (p. 16)* page in the documentation, search for the service name, and click the link to go to the page for that service. To view the service quotas for all AWS
services in the documentation without switching pages, view the information in the Service Endpoints and Quotas page in the PDF instead.

- Open the Service Quotas console. In the navigation pane, choose AWS services and select a service.
- Use the list-service-quotas and list-aws-default-service-quotas AWS CLI commands.

**To request a quota increase**

You can request a quota increase using Service Quotas and AWS Support Center. If a service is not yet available in Service Quotas, use AWS Support Center instead. Increases are not granted immediately. It might take a couple of days for your increase to become effective.

- (Recommended) Open the Service Quotas console. In the navigation pane, choose AWS services. Select a service, select a quota, and follow the directions to request a quota increase. For more information, see Requesting a Quota Increase in the Service Quotas User Guide.
- Use the request-service-quota-increase AWS CLI command.
- Open the AWS Support Center page, sign in if necessary, and choose Create case. Choose Service limit increase. Complete and submit the form.

**Tagging AWS resources**

You can assign metadata to your AWS resources in the form of tags. Each tag is a label consisting of a user-defined key and value. Tags can help you manage, identify, organize, search for, and filter resources. You can create tags to categorize resources by purpose, owner, environment, or other criteria.

Each tag has two parts:

- A tag key (for example, CostCenter, Environment, or Project). Tag keys are case sensitive.
- A tag value (for example, 111122223333 or Production). Like tag keys, tag values are case sensitive.

You can use tags to categorize resources by purpose, owner, environment, or other criteria.

AWS supports tagging on all core infrastructure resources that incur charges. Most other AWS resources also support tagging. See the documentation for an individual service for information about that service's native tagging operations.

Do not add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including billing. Tags are not intended to be used for private or sensitive data.

**Best practices**

As you create a tagging strategy for AWS resources, follow best practices:

- Do not store personally identifiable information (PII) or other confidential or sensitive information in tags.
- Use a standardized, case-sensitive format for tags, and apply it consistently across all resource types.
- Consider tag guidelines that support multiple purposes, like managing resource access control, cost tracking, automation, and organization.
- Use automated tools to help manage resource tags. AWS Resource Groups and the Resource Groups Tagging API enable programmatic control of tags, making it easier to automatically manage, search, and filter tags and resources.
- Use too many tags rather than too few tags.
• Remember that it is easy to change tags to accommodate changing business requirements, but consider the consequences of future changes. For example, changing access control tags means you must also update the policies that reference those tags and control access to your resources.

• You can automatically enforce the tagging standards that your organization chooses to adopt by creating and deploying tag policies using AWS Organizations. Tag policies let you specify tagging rules that define valid key names and the values that are valid for each key. You can choose to only monitor, giving you an opportunity to evaluate and clean up your existing tags. Once your tags are in compliance with your chosen standards, you can then turn on enforcement in the tag policies to prevent non-compliant tags from being created. For more information, see Tag policies in the AWS Organizations User Guide.

Tagging categories

Companies that are most effective in their use of tags typically create business-relevant tag groupings to organize their resources along technical, business, and security dimensions. Companies that use automated processes to manage their infrastructure also include additional, automation-specific tags.

<table>
<thead>
<tr>
<th>Technical tags</th>
<th>Tags for automation</th>
<th>Business tags</th>
<th>Security tags</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Name – Identify individual resources</td>
<td>• Date/Time – Identify the date or time a resource should be started, stopped, deleted, or rotated</td>
<td>• Project – Identify projects that the resource supports</td>
<td>• Confidentiality – An identifier for the specific data confidentiality level a resource supports</td>
</tr>
<tr>
<td>• Application ID – Identify resources that are related to a specific application</td>
<td>• Opt in/Opt out – Indicate whether a resource should be included in an automated activity such as starting, stopping, or resizing instances</td>
<td>• Owner – Identify who is responsible for the resource</td>
<td>• Compliance – An identifier for workloads that must adhere to specific compliance requirements</td>
</tr>
<tr>
<td>• Application Role – Describe the function of a particular resource (such as web server, message broker, database)</td>
<td>• Security – Determine requirements, such as encryption or enabling of Amazon VPC flow logs; identify route tables or security groups that need extra scrutiny</td>
<td>• Cost Center/Business Unit – Identify the cost center or business unit associated with a resource, typically for cost allocation and tracking</td>
<td></td>
</tr>
<tr>
<td>• Cluster – Identify resource farms that share a common configuration and perform a specific function for an application</td>
<td></td>
<td>• Customer – Identify a specific client that a particular group of resources serves</td>
<td></td>
</tr>
<tr>
<td>• Environment – Distinguish between development, test, and production resources</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Version – Help distinguish between versions of resources or applications</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Tag naming limits and requirements

The following basic naming and usage requirements apply to tags:
- Each resource can have a maximum of 50 user created tags.
- System created tags that begin with `aws:` are reserved for AWS use, and do not count against this limit. You can’t edit or delete a tag that begins with the `aws:` prefix.
- For each resource, each tag key must be unique, and each tag key can have only one value.
- The tag key must be a minimum of 1 and a maximum of 128 Unicode characters in UTF-8.
- The tag value must be a minimum of 0 and a maximum of 256 Unicode characters in UTF-8.
- Allowed characters can vary by AWS service. For information about what characters you can use to tag resources in a particular AWS service, see its documentation. In general, the allowed characters are letters, numbers, spaces representable in UTF-8, and the following characters: _ . : / = + - @.
- Tag keys and values are case sensitive. As a best practice, decide on a strategy for capitalizing tags, and consistently implement that strategy across all resource types. For example, decide whether to use `Costcenter`, `costcenter`, or `CostCenter`, and use the same convention for all tags. Avoid using similar tags with inconsistent case treatment.

**Common tagging strategies**

Use the following tagging strategies to help identify and manage AWS resources.

**Contents**

- Tags for resource organization (p. 746)
- Tags for cost allocation (p. 746)
- Tags for automation (p. 747)
- Tags for access control (p. 747)

**Tags for resource organization**

Tags are a good way to organize AWS resources in the AWS Management Console. You can configure tags to be displayed with resources, and can search and filter by tag. With the AWS Resource Groups service, you can create groups of AWS resources based on one or more tags or portions of tags. You can also create groups based on their occurrence in an AWS CloudFormation stack. Using Resource Groups and Tag Editor, you can consolidate and view data for applications that consist of multiple services, resources, and Regions in one place.

**Tags for cost allocation**

AWS Cost Explorer and detailed billing reports let you break down AWS costs by tag. Typically, you use business tags such as `cost center/business unit`, `customer`, or `project` to associate AWS costs with traditional cost-allocation dimensions. But a cost allocation report can include any tag. This lets you associate costs with technical or security dimensions, such as specific applications, environments, or compliance programs. The following is an example of a partial cost allocation report.
For some services, you can use an AWS-generated `createdBy` tag for cost allocation purposes, to help account for resources that might otherwise go uncategorized. The `createdBy` tag is available only for supported AWS services and resources. Its value contains data associated with specific API or console events. For more information, see AWS-Generated Cost Allocation Tags in the AWS Billing and Cost Management User Guide.

### Tags for automation

Resource or service-specific tags are often used to filter resources during automation activities. Automation tags are used to opt in or opt out of automated tasks or to identify specific versions of resources to archive, update, or delete. For example, you can run automated `start` or `stop` scripts that turn off development environments during nonbusiness hours to reduce costs. In this scenario, Amazon Elastic Compute Cloud (Amazon EC2) instance tags are a simple way to identify instances to opt out of this action. For scripts that find and delete stale, out-of-date, or rolling Amazon EBS snapshots, snapshot tags can add an extra dimension of search criteria.

### Tags for access control

IAM policies support tag-based conditions, letting you constrain IAM permissions based on specific tags or tag values. For example, IAM user or role permissions can include conditions to limit EC2 API calls to specific environments (such as development, test, or production) based on their tags. The same strategy can be used to limit API calls to specific Amazon Virtual Private Cloud (Amazon VPC) networks. Support for tag-based, resource-level IAM permissions is service specific. When you use tag-based conditions for access control, be sure to define and restrict who can modify the tags. For more information about using tags to control API access to AWS resources, see AWS services that work with IAM in the IAM User Guide.

### Tagging governance

An effective tagging strategy uses standardized tags and applies them consistently and programmatically across AWS resources. You can use both reactive and proactive approaches for governing tags in your AWS environment.

- **Reactive governance** is for finding resources that are not properly tagged using tools such as the Resource Groups Tagging API, AWS Config Rules, and custom scripts. To find resources manually, you can use Tag Editor and detailed billing reports.

- **Proactive governance** uses tools such as AWS CloudFormation, AWS Service Catalog, tag policies in AWS Organizations, or IAM resource-level permissions to ensure standardized tags are consistently applied at resource creation.

  For example, you can use the AWS CloudFormation `Resource` Tags property to apply tags to resource types. In AWS Service Catalog, you can add portfolio and product tags that are combined and
applied to a product automatically when it is launched. More rigorous forms of proactive governance include automated tasks. For example, you can use the Resource Groups Tagging API to search an AWS environment’s tags, or run scripts to quarantine or delete improperly tagged resources.

Learn more

This page provides general information on tagging AWS resources. For more information about tagging resources in a particular AWS service, see its documentation. The following are also good sources of information about tagging:

- For information about the AWS Resource Groups Tagging API, see the Resource Groups Tagging API Reference Guide.
- For information about Tag Editor, see Working with Tag Editor in the AWS Resource Groups User Guide.
- For information about using tags to control access to AWS resources, see Control Access Using IAM Tags in the IAM User Guide.

Amazon Resource Names (ARNs)

Amazon Resource Names (ARNs) uniquely identify AWS resources. We require an ARN when you need to specify a resource unambiguously across all of AWS, such as in IAM policies, Amazon Relational Database Service (Amazon RDS) tags, and API calls.

The Service Authorization Reference lists the ARNs that you can use in IAM policies.

ARN format

The following are the general formats for ARNs. The specific formats depend on the resource. To use an ARN, replace the italicized text with the resource-specific information. Be aware that the ARNs for some resources omit the Region, the account ID, or both the Region and the account ID.

```
arn:partition:service:region:account-id:resource-id
arn:partition:service:region:account-id:resource-type/resource-id
arn:partition:service:region:account-id:resource-type:resource-id
```

partition

The partition in which the resource is located. A partition is a group of AWS Regions. Each AWS account is scoped to one partition.

The following are the supported partitions:
- aws - AWS Regions
- aws-cn - China Regions
- aws-us-gov - AWS GovCloud (US) Regions

service

The service namespace that identifies the AWS product. For example, s3 for Amazon S3. To find a service namespace, open the Service Authorization Reference, open the page for the service, and find the phrase "service prefix" in the first sentence. For example, the following text appears in the first sentence on the page for Amazon S3:

```
(service prefix: s3)
```
**region**

The Region code. For example, `us-east-2` for US East (Ohio). For the list of Region codes, see [Regional endpoints](p. 739).

**account-id**

The ID of the AWS account that owns the resource, without the hyphens. For example, `123456789012`.

**resource-id**

The resource identifier. This part of the ARN can be the name or ID of the resource or a resource path (p. 749). For example, `user/Bob` for an IAM user or `instance/i-1234567890abcdef0` for an EC2 instance. Some resource identifiers include a parent resource (`sub-resource-type/parent-resource/sub-resource`) or a qualifier such as a version (`resource-type:resource-name:qualifier`).

---

**Paths in ARNs**

Resource ARNs can include a path. For example, in Amazon S3, the resource identifier is an object name that can include slashes (`/`) to form a path. Similarly, IAM user names and group names can include paths.

Paths can include a wildcard character, namely an asterisk (`*`). For example, if you are writing an IAM policy, you can specify all IAM users that have the path `product_1234` using a wildcard as follows:

```
arn:aws:iam::123456789012:user/Development/product_1234/*
```

Similarly, you can specify `user/*` to mean all users or `group/*` to mean all groups, as in the following examples:

```
"Resource":"arn:aws:iam::123456789012:user/*"
"Resource":"arn:aws:iam::123456789012:group/*"
```

The following example shows ARNs for an Amazon S3 bucket in which the resource name includes a path:

```
arn:aws:s3:::my_corporate_bucket/*
arn:aws:s3:::my_corporate_bucket/Development/*
```

**Incorrect wildcard usage**

You cannot use a wildcard in the portion of the ARN that specifies the resource type, such as the term `user` in an IAM ARN. For example, the following is not allowed.

```
arn:aws:iam::123456789012:u*  <= not allowed
```
AWS IP address ranges

Amazon Web Services (AWS) publishes its current IP address ranges in JSON format. To view the current ranges, download the .json file. To maintain history, save successive versions of the .json file on your system. To determine whether there have been changes since the last time that you saved the file, check the publication time in the current file and compare it to the publication time in the last file that you saved.

Contents

• Download (p. 750)
• Syntax (p. 750)
• Filtering the JSON file (p. 752)
• Implementing egress control (p. 755)
• AWS IP address ranges notifications (p. 756)
• Release notes (p. 758)

Download

Download ip-ranges.json.

If you access this file programmatically, it is your responsibility to ensure that the application downloads the file only after successfully verifying the TLS certificate presented by the server.

Syntax

The syntax of ip-ranges.json is as follows.

```json
{
    "syncToken": "0123456789",
    "createDate": "yyyy-mm-dd-hh-mm-ss",
    "prefixes": [
        {
            "ip_prefix": "cidr",
            "region": "region",
            "network_border_group": "network_border_group",
            "service": "subset"
        }
    ],
    "ipv6_prefixes": [
        {
            "ipv6_prefix": "cidr",
            "region": "region",
            "network_border_group": "network_border_group",
            "service": "subset"
        }
    ]
}
```
syncToken

The publication time, in Unix epoch time format.

Type: String

Example: "syncToken": "1416435608"

createDate

The publication date and time, in UTC YY-MM-DD-hh-mm-ss format.

Type: String

Example: "createDate": "2014-11-19-23-29-02"

prefixes

The IP prefixes for the IPv4 address ranges.

Type: Array

ipv6_prefixes

The IP prefixes for the IPv6 address ranges.

Type: Array

ip_prefix

The public IPv4 address range, in CIDR notation. Note that AWS may advertise a prefix in more specific ranges. For example, prefix 96.127.0.0/17 in the file may be advertised as 96.127.0.0/21, 96.127.8.0/21, 96.127.32.0/19, and 96.127.64.0/18.

Type: String

Example: "ip_prefix": "198.51.100.2/24"

ipv6_prefix

The public IPv6 address range, in CIDR notation. Note that AWS may advertise a prefix in more specific ranges.

Type: String

Example: "ipv6_prefix": "2001:db8:1234::/64"

network_border_group

The name of the network border group, which is a unique set of Availability Zones or Local Zones from where AWS advertises IP addresses.

Type: String

Example: "network_border_group": "us-west-2-lax-1"

region

The AWS Region or GLOBAL for edge locations. The CLOUDFRONT and ROUTE53 ranges are GLOBAL.

Type: String

Valid values: ap-east-1 | ap-northeast-1 | ap-northeast-2 | ap-northeast-3 | ap-south-1 | ap-southeast-1 | ap-southeast-2 | ca-central-1 | cn-north-1 | cn-northwest-1 | eu-
Filtering the JSON file

You can download a command line tool to help you filter the information to just what you are looking for.

Windows

The AWS Tools for Windows PowerShell includes a cmdlet, Get-AWSPublicIpAddressRange, to parse this JSON file. The following examples demonstrate its use. For more information, see Querying the Public IP Address Ranges for AWS and Get-AWSPublicIpAddressRange.

Example 1. Get the creation date

```
PS C:\> Get-AWSPublicIpAddressRange -OutputPublicationDate

Wednesday, August 22, 2018 9:22:35 PM
```

Example 2. Get the information for a specific Region

```
PS C:\> Get-AWSPublicIpAddressRange -Region us-east-1

<table>
<thead>
<tr>
<th>IpPrefix</th>
<th>Region</th>
<th>NetworkBorderGroup</th>
<th>Service</th>
</tr>
</thead>
<tbody>
<tr>
<td>23.20.0.0/14</td>
<td>us-east-1</td>
<td>us-east-1</td>
<td>AMAZON</td>
</tr>
<tr>
<td>50.16.0.0/15</td>
<td>us-east-1</td>
<td>us-east-1</td>
<td>AMAZON</td>
</tr>
<tr>
<td>50.19.0.0/16</td>
<td>us-east-1</td>
<td>us-east-1</td>
<td>AMAZON</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Example 3. Get all IP addresses

```
PS C:\> (Get-AWSPublicIpAddressRange).IpPrefix
23.20.0.0/14
27.0.0.0/22
43.250.192.0/24
```
Example 4. Get all IPv4 addresses

```
PS C:\> Get-AWSPublicIpAddressRange | where {$_._IpAddressFormat -eq "Ipv4"} | select IpPrefix
IpPrefix
--------
23.20.0.0/14
27.0.0.0/22
43.250.192.0/24
...
```

Example 5. Get all IPv6 addresses

```
PS C:\> Get-AWSPublicIpAddressRange | where {$_._IpAddressFormat -eq "Ipv6"} | select IpPrefix
IpPrefix
--------
2a05:d07c:2000::/40
2a05:d000:8000::/40
2406:dafe:2000::/40
...
```

Example 6. Get all IP addresses for a specific service

```
PS C:\> Get-AWSPublicIpAddressRange -ServiceKey CODEBUILD | select IpPrefix
IpPrefix
--------
52.47.73.72/29
13.55.255.216/29
52.15.247.208/29
...
```

Linux

The following example commands use the `jq` tool to parse a local copy of the JSON file.

Example 1. Get the creation date

```
$ jq .createDate < ip-ranges.json
"2016-02-18-17-22-15"
```

Example 2. Get the information for a specific Region

```
$ jq '.prefixes[] | select(.region=="us-east-1")' < ip-ranges.json
{
  "ip_prefix": "23.20.0.0/14",
```
Example 3. Get all IPv4 addresses

```
$ jq -r '.prefixes | .[].ip_prefix' < ip-ranges.json
23.20.0.0/14
27.0.0.0/22
43.250.192.0/24
...
```

Example 4. Get all IPv6 addresses

```
$ jq -r '.ipv6_prefixes | .[].ipv6_prefix' < ip-ranges.json
2a05:d07c:2000::/40
2a05:d000:8000::/40
2406:dafe:2000::/40
...
```

Example 5. Get all IPv4 addresses for a specific service

```
$ jq -r '.prefixes[] | select(.service=="CODEBUILD") | .ip_prefix' < ip-ranges.json
52.47.73.72/29
13.55.255.216/29
52.15.247.208/29
...
```

Example 6. Get all IPv4 addresses for a specific service in a specific Region

```
$ jq -r '.prefixes[] | select(.region=="us-east-1") | select(.service=="CODEBUILD") | .ip_prefix' < ip-ranges.json
34.228.4.208/28
```

Example 7. Get information for a certain network border group

```
$ jq -r '.prefixes[] | select(.region=="us-west-2") | select(.network_border_group=="us-west-2-lax-1") | .ip_prefix' < ip-ranges.json
70.224.192.0/18
52.95.230.0/24
```
Implementing egress control

To allow an instance to access only AWS services, create a security group with rules that allow outbound traffic to the CIDR blocks in the AMAZON list, minus the CIDR blocks that are also in the EC2 list. IP addresses in the EC2 list can be assigned to EC2 instances.

Windows PowerShell

The following PowerShell example shows you how to get the IP addresses that are in the AMAZON list but not the EC2 list. Copy the script and save it in a file named Select_address.ps1.

```powershell
$amazon_addresses = Get-AWSPublicIpAddressRange -ServiceKey amazon
$ec2_addresses = Get-AWSPublicIpAddressRange -ServiceKey ec2

ForEach ($address in $amazon_addresses)
{
    if( $ec2_addresses.IpPrefix -notcontains $address.IpPrefix)
    {
        ($address).IpPrefix
    }
}
```

You can run this script as follows:

```
PSC:\> .\Select_address.ps1
13.32.0.0/15
13.35.0.0/16
13.248.0.0/20
13.248.16.0/21
13.248.24.0/22
13.248.28.0/22
27.0.0.0/22
43.250.192.0/24
43.250.193.0/24
...
```

jq

The following example shows you how to get the IP addresses that are in the AMAZON list but not the EC2 list, for all Regions:

```
jq -r `.[prefixes[] | select(.service=="AMAZON").ip_prefix] - .[prefixes[] | select(.service=="EC2").ip_prefix] | .[]' < ip-ranges.json
```

52.94.22.0/24
52.94.17.0/24
52.95.154.0/23
52.95.212.0/22
54.239.0.240/28
54.239.54.0/23
52.119.224.0/21
...
The following example shows you how to filter the results to one Region:

```bash
jq -r '[[.prefixes[] | select(.region=="us-east-1" and .service=="AMAZON").ip_prefix] -
  [.prefixes[] | select(.region=="us-east-1" and .service=="EC2").ip_prefix] | []' < ip-ranges.json
```

**Python**

The following python script shows you how to get the IP addresses that are in the AMAZON list but not the EC2 list. Copy the script and save it in a file named `get_ips.py`.

```python
#!/usr/bin/env python
import requests

ip_ranges = requests.get('https://ip-ranges.amazonaws.com/ip-ranges.json').json()['prefixes']
amazon_ips = [item['ip_prefix'] for item in ip_ranges if item['service'] == 'AMAZON']
ec2_ips = [item['ip_prefix'] for item in ip_ranges if item['service'] == 'EC2']

amazon_ips_less_ec2 = []
for ip in amazon_ips:
    if ip not in ec2_ips:
        amazon_ips_less_ec2.append(ip)

for ip in amazon_ips_less_ec2:
    print(str(ip))
```

You can run this script as follows:

```
$ python ./get_ips.py
13.32.0.0/15
13.35.0.0/16
13.248.0.0/20
13.248.16.0/21
13.248.24.0/22
13.248.28.0/22
27.0.0.0/22
43.250.192.0/24
43.250.193.0/24
...
```

**AWS IP address ranges notifications**

Whenever there is a change to the AWS IP address ranges, we send notifications to subscribers of the AmazonIpSpaceChanged topic. The payload contains information in the following format:

```json
{
    "create-time":"yyyymm-ddThh:mm:ss+00:00",
    "syncToken":"0123456789",
    "md5":"6a45316e8bc9463c9e926d5d37836d33",
    "url":"https://ip-ranges.amazonaws.com/ip-ranges.json"
}
```

**create-time**

The creation date and time.
Notifications could be delivered out of order. Therefore, we recommend that you check the timestamps to ensure the correct order.

**synctoken**

The publication time, in Unix epoch time format.

**md5**

The cryptographic hash value of the `ip-ranges.json` file. You can use this value to check whether the downloaded file is corrupted.

**url**

The location of the `ip-ranges.json` file.

If you want to be notified whenever there is a change to the AWS IP address ranges, you can subscribe as follows to receive notifications using Amazon SNS.

**To subscribe to AWS IP address range notifications**

2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must select this Region because the SNS notifications that you are subscribing to were created in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Choose **Create subscription**.
5. In the **Create subscription** dialog box, do the following:
   a. For **Topic ARN**, copy the following Amazon Resource Name (ARN):
      
      ```
      arn:aws:sns:us-east-1:806199016981:AmazonIpSpaceChanged
      ```
   b. For **Protocol**, choose the protocol to use (for example, Email).
   c. For **Endpoint**, type the endpoint to receive the notification (for example, your email address).
   d. Choose **Create subscription**.
6. You’ll be contacted on the endpoint that you specified and asked to confirm your subscription. For example, if you specified an email address, you’ll receive an email message with the subject line **AWS Notification - Subscription Confirmation**. Follow the directions to confirm your subscription.

Notifications are subject to the availability of the endpoint. Therefore, you might want to check the JSON file periodically to ensure that you’ve got the latest ranges. For more information about Amazon SNS reliability, see https://aws.amazon.com/sns/faqs/#Reliability.

If you no longer want to receive these notifications, use the following procedure to unsubscribe.

**To unsubscribe from AWS IP address ranges notifications**

2. In the navigation pane, choose **Subscriptions**.
3. Select the check box for the subscription.
4. Choose **Actions, Delete subscriptions**.
5. When prompted for confirmation, choose **Delete**.

For more information about Amazon SNS, see the Amazon Simple Notification Service Developer Guide.
Release notes

The following table describes updates to the AWS IP address ranges. We also add new Region codes with each Region launch.

<table>
<thead>
<tr>
<th>Description</th>
<th>Release date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Added the CLOUDFRONT_ORIGIN_FACING service code.</td>
<td>October 12, 2021</td>
</tr>
<tr>
<td>Added the ROUTE53_RESOLVER service code.</td>
<td>June 24, 2021</td>
</tr>
<tr>
<td>Added the EBS service code.</td>
<td>May 12, 2021</td>
</tr>
<tr>
<td>Added the KINESIS_VIDEO_STREAMS service code.</td>
<td>November 19, 2020</td>
</tr>
<tr>
<td>Added the CHIME_MEETINGS and CHIME_VOICECONNECTOR service codes.</td>
<td>June 19, 2020</td>
</tr>
<tr>
<td>Added the AMAZON_APPFLOW service code.</td>
<td>June 9, 2020</td>
</tr>
<tr>
<td>Add support for the network border group.</td>
<td>April 7, 2020</td>
</tr>
<tr>
<td>Added the WORKSPACES_GATEWAYS service code.</td>
<td>March 30, 2020</td>
</tr>
<tr>
<td>Added the ROUTE53_HEALTHCHECK_PUBLISHING service code.</td>
<td>January 30, 2020</td>
</tr>
<tr>
<td>Added the API_GATEWAY service code.</td>

AWS APIs

The following pages provide information that is useful when using an AWS API.

Contents

• Error retries and exponential backoff in AWS (p. 759)
• Signing AWS API requests (p. 760)
• AWS SDK support for Amazon S3 client-side encryption (p. 796)

Error retries and exponential backoff in AWS

Numerous components on a network, such as DNS servers, switches, load balancers, and others can generate errors anywhere in the life of a given request. The usual technique for dealing with these error responses in a networked environment is to implement retries in the client application. This technique increases the reliability of the application and reduces operational costs for the developer.

Each AWS SDK implements automatic retry logic. The AWS SDK for Java automatically retries requests, and you can configure the retry settings using the `ClientConfiguration` class. For example, you might want to turn off the retry logic for a web page that makes a request with minimal latency and no retries. Use the `ClientConfiguration` class and provide a `maxErrorRetry` value of 0 to turn off the retries.

If you’re not using an AWS SDK, you should retry original requests that receive server (5xx) or throttling errors. However, client errors (4xx) indicate that you need to revise the request to correct the problem before trying again.

In addition to simple retries, each AWS SDK implements exponential backoff algorithm for better flow control. The idea behind exponential backoff is to use progressively longer waits between retries for consecutive error responses. You should implement a maximum delay interval, as well as a maximum number of retries. The maximum delay interval and maximum number of retries are not necessarily fixed values, and should be set based on the operation being performed, as well as other local factors, such as network latency.

Most exponential backoff algorithms use jitter (randomized delay) to prevent successive collisions. Because you aren’t trying to avoid such collisions in these cases, you don’t need to use this random number. However, if you use concurrent clients, jitter can help your requests succeed faster. For more information, see the blog post for Exponential Backoff and Jitter.

The following pseudo code shows one way to poll for status using an increasing delay.

```
Do some asynchronous operation.
retries = 0
DO
  wait for (2^retries * 100) milliseconds
  status = Get the result of the asynchronous operation.
  IF status = SUCCESS
     retry = false
  ELSE IF status = NOT_READY
     retry = true
  ELSE IF status = THROTTLED
     retry = true
  ELSE IF status = TOO_MANY_REQUESTS
     retry = true
  ELSE
     retry = false
  IF retry = false
     break
  retries += 1
```

Signing AWS API requests

Important
The AWS SDKs, AWS Command Line Interface (AWS CLI), and other AWS tools sign API requests for you using the access key that you specify when you configure the tool. When you use these tools, you don’t need to learn how to sign API requests. The following documentation explains how to sign API requests, but is only useful if you're writing your own code to send and sign AWS API requests. We recommend that you use the AWS SDKs or other AWS tools to send API requests, instead of writing your own code.

When you send API requests to AWS, you sign the requests so that AWS can identify who sent them. You sign requests with your AWS access key, which consists of an access key ID and secret access key. Some requests don’t need to be signed, including anonymous requests to Amazon Simple Storage Service (Amazon S3) and some API operations in AWS Security Token Service (AWS STS) such as AssumeRoleWithWebIdentity.

When to sign requests

When you write custom code to send API requests to AWS, you need to include code to sign the requests. You might do this for the following reasons:

- You are working with a programming language for which there is no AWS SDK.
- You want complete control over how a request is sent to AWS.

You don’t need to sign requests when you use the AWS CLI or one of the AWS SDKs. These tools calculate the signature for you, and also manage the connection details, handle request retries, and provide error handling. In most cases, they also contain sample code, tutorials, and other resources to help you get started writing applications that interact with AWS.

Why requests are signed

The signing process helps secure requests in the following ways:

- **Verify the identity of the requester**
  
  Signing makes sure that the request has been sent by someone with a valid access key. For more information, see Understanding and getting your AWS credentials (p. 3).

- **Protect data in transit**

  To prevent tampering with a request while it's in transit, some of the request elements are used to calculate a hash (digest) of the request, and the resulting hash value is included as part of the request. When an AWS service receives the request, it uses the same information to calculate a hash and matches it against the hash value in your request. If the values don't match, AWS denies the request.

- **Protect against potential replay attacks**
In most cases, a request must reach AWS within five minutes of the time stamp in the request. Otherwise, AWS denies the request.

## Signing requests

To sign a request, you first calculate a hash (digest) of the request. Then you use the hash value, some other information from the request, and your secret access key to calculate another hash known as the signature. Then you add the signature to the request in one of the following ways:

- Using the HTTP Authorization header.
- Adding a query string value to the request. Because the signature is part of the URL in this case, this type of URL is called a presigned URL.

## Signature versions

AWS supports Signature Version 4 (SigV4) and Signature Version 2 (SigV2). All AWS services in all AWS Regions support SigV4, except Amazon SimpleDB which requires SigV2. The AWS SDKs, including the AWS CLI, automatically use SigV4 for all services that support it. If you manually sign API requests, you should do the same.

AWS is rolling out an extension to SigV4 called Signature Version 4A (SigV4A). This extension enables signatures that are valid in more than one AWS Region. This is required for signing multi-Region API requests, for example with Amazon S3 Multi-Region Access Points. The AWS SDKs and AWS CLI support SigV4A and use it automatically when it's needed.

### Note

To use SigV4A with temporary security credentials—for example, when using IAM roles—make sure that you request the temporary credentials from a regional endpoint in AWS Security Token Service (AWS STS). Don't use the global endpoint for AWS STS (sts.amazonaws.com), because by default temporary credentials from the global endpoint don't work with SigV4A. You can use any of the regional endpoints for AWS STS.

## Signature Version 4 signing process

**Important**

The AWS SDKs, AWS Command Line Interface (AWS CLI), and other AWS tools sign API requests for you using the access key that you specify when you configure the tool. **When you use these tools, you don't need to learn how to sign API requests. The following documentation explains how to sign API requests, but is only useful if you're writing your own code to send and sign AWS API requests.** We recommend that you use the AWS SDKs or other AWS tools to send API requests, instead of writing your own code.

Signature Version 4 (SigV4) is the process to add authentication information to AWS API requests sent by HTTP. For security, most requests to AWS must be signed with an access key. The access key consists of an access key ID and secret access key, which are commonly referred to as your security credentials. For details on how to obtain credentials for your account, see Understanding and getting your AWS credentials (p. 3).

### How Signature Version 4 works

1. Create a canonical request.
2. Use the canonical request and additional metadata to create a string for signing.
3. Derive a signing key from your AWS secret access key. Then use the signing key, and the string from the previous step, to create a signature.
4. Add the resulting signature to the HTTP request in a header or as a query string parameter.

When an AWS service receives the request, it performs the same steps that you did to calculate the signature you sent in your request. AWS then compares its calculated signature to the one you sent with the request. If the signatures match, the request is processed. If the signatures don't match, the request is denied.

For more information, see the following resources:

- To get started with the signing process, see Signing AWS requests with Signature Version 4 (p. 764).
- For sample signed requests, see Examples of the complete Signature Version 4 signing process (Python) (p. 779).
- If you have questions about Signature Version 4, post your question in the AWS Identity and Access Management forum.

Changes in Signature Version 4

Signature Version 4 is the current AWS signing protocol. It includes several changes from the previous Signature Version 2:

- To sign your message, you use a *signing key* that is derived from your secret access key rather than using the secret access key itself. For more information about deriving keys, see Task 3: Calculate the signature for AWS Signature Version 4 (p. 772).
- You derive your signing key from the *credential scope*, which means that you don't need to include the key itself in the request. Credential scope is represented by a slash-separated string of dimensions in the following order:
  1. Date information as an eight-digit string representing the year (YYYY), month (MM), and day (DD) of the request (for example, 20150830). For more information about handling dates, see Handling dates in Signature Version 4 (p. 776).
  2. Region information as a lowercase alphanumeric string. Use the Region name that is part of the service's endpoint. For services with a globally unique endpoint such as IAM, use us-east-1.
  3. Service name information as a lowercase alphanumeric string (for example, iam). Use the service name that is part of the service's endpoint. For example, the IAM endpoint is https://iam.amazonaws.com, so you use the string iam as part of the Credential parameter.
  4. A special termination string: aws4_request.
- You use the credential scope in each signing task:
  - If you add signing information to the query string, include the credential scope as part of the X-Amz-Credential parameter when you create the canonical request in Task 1: Create a canonical request for Signature Version 4 (p. 766).
  - You must include the credential scope as part of your string to sign in Task 2: Create a string to sign for Signature Version 4 (p. 771).
  - Finally, you use the date, Region, and service name components of the credential scope to derive your signing key in Task 3: Calculate the signature for AWS Signature Version 4 (p. 772).

Elements of an AWS Signature Version 4 request

Each HTTP/HTTPS request that uses version 4 signing must contain these elements.

- Endpoint Specification
- Action
- Required and Optional Parameters
• Date
• Authentication Parameters

Endpoint specification

This is specified as the Host header in HTTP/1.1 requests. This header specifies the DNS name of the computer to which you send the request, like dynamodb.us-east-1.amazonaws.com.

You must include the Host header with HTTP/1.1 requests. For HTTP/2 requests, you can use the :authority header or the Host header. Use only the :authority header for compliance with the HTTP/2 specification. Not all services support HTTP/2 requests, so check the service documentation for details.

The endpoint usually contains the service name and Region, both of which you must use as part of the Credential authentication parameter. For example, the Amazon DynamoDB endpoint for the eu-west-1 Region is dynamodb.eu-west-1.amazonaws.com. If you don't specify a Region, a web service uses the default Region, us-east-1. If you use a service like IAM that uses a globally unique endpoint, use the default Region (us-east-1), as part of the Credential authentication parameter (described later in this topic).

For a complete list of endpoints supported by AWS, see Regions and Endpoints.

Action

This element specifies the action that you want a web service to perform, such as the DynamoDB CreateTable action or the Amazon EC2 DescribeInstances action. The specified action determines the parameters used in the request. For query APIs, the action is an API name. For non-query APIs (such as RESTful APIs), see the service documentation for the appropriate actions.

Required and optional parameters

This element specifies the parameters to the request action. Each action in a web service has a set of required and optional parameters that define an API call. The API version is usually a required parameter. See the service documentation for the details of required and optional parameters.

Date

This is the date and time at which you make the request. Including the date in the request helps prevent third parties from intercepting your request and resubmitting it later. The date is specified using the ISO8601 Basic format via the x-amz-date header in the YYYYMMDD'T'HHMMSS'Z' format.

Authentication parameters

Each request that you send must include the following set of parameters that AWS uses to ensure the validity and authenticity of the request.

• Algorithm. The hash algorithm that you're using as part of the signing process. For example, if you use SHA-256 to create hashes, use the value AWS4-HMAC-SHA256.
• Credential scope. A string separated by slashes ("/") that is formed by concatenating your access key ID and your credential scope components. Credential scope includes the date in YYYYMMDD format, the AWS Region, the service name, and a special termination string (aws4_request). For example, the following string represents the Credential parameter for an IAM request in the us-east-1 Region.

AKIAIOSFODNN7EXAMPLE/20111015/us-east-1/iam/aws4_request

Important
You must use lowercase characters for the Region, service name, and special termination string.
• **SignedHeaders** A list delimited by semicolons (";") of HTTP/HTTPS headers to include in the signature.
• **Signature** A hexadecimal-encoded string that represents the output of the signature operation described in Task 3: Calculate the signature for AWS Signature Version 4 (p. 772). You must calculate the signature using the algorithm that you specified in the `Algorithm` parameter.

To view sample signed requests, see Examples of the complete Signature Version 4 signing process (Python) (p. 779).

### Signing AWS requests with Signature Version 4

This section explains how to create a signature and add it to an HTTP request to AWS.

![Summary of signing steps]

**Summary of signing steps**

To create a signed request, complete the following:

• **Task 1: Create a canonical request for Signature Version 4** (p. 766)

  Arrange the contents of your request (host, action, headers, etc.) into a standard (canonical) format. The canonical request is one of the inputs used to create a string to sign.

• **Task 2: Create a string to sign for Signature Version 4** (p. 771)

  Create a string to sign with the canonical request and extra information such as the algorithm, request date, credential scope, and the digest (hash) of the canonical request.

• **Task 3: Calculate the signature for AWS Signature Version 4** (p. 772)

  Derive a signing key by performing a succession of keyed hash operations (HMAC operations) on the request date, Region, and service, with your AWS secret access key as the key for the initial hashing operation. After you derive the signing key, you then calculate the signature by performing a keyed hash operation on the string to sign. Use the derived signing key as the hash key for this operation.

• **Task 4: Add the signature to the HTTP request** (p. 774)

  After you calculate the signature, add it to an HTTP header or to the query string of the request.

**Important**

The AWS SDKs handle the signature calculation process for you, so you do not have to manually complete the signing process. For more information, see Tools for Amazon Web Services.

### Additional resources

The following resources illustrate aspects of the signing process:

• **Examples of how to derive a signing key for Signature Version 4** (p. 776). This page shows how to derive a signing key using Java, C#, Python, Ruby, and JavaScript.

• **Examples of the complete Signature Version 4 signing process (Python)** (p. 779). This set of programs in Python provide complete examples of the signing process. The examples show signing with a POST request, with a GET request that has signing information in a request header, and with a GET request that has signing information in the query string.
What signing looks like in a request

The following example shows what an HTTPS request might look like as it is sent from your client to AWS, without any signing information.

```
GET https://iam.amazonaws.com/?Action=ListUsers&Version=2010-05-08 HTTP/1.1
Content-Type: application/x-www-form-urlencoded; charset=utf-8
Host: iam.amazonaws.com
X-Amz-Date: 20150830T123600Z
```

After you complete the signing tasks, you add the authentication information to the request. You can add the authentication information in two ways:

**Authorization header**

You can add the authentication information to the request with an Authorization header. Although the HTTP header is named Authorization, the signing information is actually used for authentication to establish who the request came from.

The Authorization header includes the following information:

- Algorithm you used for signing (AWS4-HMAC-SHA256)
- Credential scope (with your access key ID)
- List of signed headers
- Calculated signature. The signature is based on your request information, and you use your AWS secret access key to produce the signature. The signature confirms your identity to AWS.

The following example shows what the preceding request might look like after you've created the signing information and added it to the request in the Authorization header.

```
GET https://iam.amazonaws.com/?Action=ListUsers&Version=2010-05-08 HTTP/1.1
Authorization: AWS4-HMAC-SHA256
Credential=AKIDEXAMPLE/20150830/us-east-1/iam/aws4_request,
SignedHeaders=content-type;host;x-amz-date,
Signature=5d672d79c15b13162d9279b0855cfba6789a8edb4c82c400e06b5924a6f2b5d7
content-type: application/x-www-form-urlencoded; charset=utf-8
host: iam.amazonaws.com
x-amz-date: 20150830T123600Z
```

**Query string**

As an alternative to adding authentication information with an HTTP request header, you can include it in the query string. The query string contains everything that is part of the request, including the name and parameters for the action, the date, and the authentication information.

The following example shows how you might construct a GET request with the action and authentication information in the query string.

```
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIDEXAMPLE%2F20150830%2Fus-east-1%2Fiam%2Faws4_request
&X-Amz-Date=20150830T123600Z
&X-Amz-Expires=60
```

Note that in the actual request, the Authorization header would appear as a continuous line of text. The version below has been formatted for readability.

```
GET https://iam.amazonaws.com/?Action=ListUsers&Version=2010-05-08 HTTP/1.1
Authorization: AWS4-HMAC-SHA256
Credential=AKIDEXAMPLE/20150830/us-east-1/iam/aws4_request,
SignedHeaders=content-type;host;x-amz-date,
Signature=5d672d79c15b13162d9279b0855cfba6789a8edb4c82c400e06b5924a6f2b5d7
content-type: application/x-www-form-urlencoded; charset=utf-8
host: iam.amazonaws.com
x-amz-date: 20150830T123600Z
```

Query string
GET and POST requests in the Query API

The query API that many AWS services support lets you make requests using either HTTP GET or POST. (In the query API, you can use GET even if you're making requests that change state; that is, the query API is not inherently RESTful.) Because GET requests pass parameters on the query string, they are limited to the maximum length of a URL. If a request includes a large payload (for example, you might upload a large IAM policy or send many parameters in JSON format for a DynamoDB request), you generally use a POST request.

The signing process is the same for both types of requests.

Task 1: Create a canonical request for Signature Version 4

To begin the signing process, create a string that includes information from your request in a standardized (canonical) format. This ensures that when AWS receives the request, it can calculate the same signature that you calculated.

Follow the steps here to create a canonical version of the request. Otherwise, your version and the version calculated by AWS won't match, and the request will be denied.

The following example shows the pseudocode to create a canonical request.

Example Canonical request pseudocode

```plaintext
CanonicalRequest = HTTPRequestMethod + '\n' + CanonicalURI + '\n' + CanonicalQueryString + '\n' + CanonicalHeaders + '\n' + SignedHeaders + '\n' + HexEncode(Hash(RequestPayload))
```

In this pseudocode, Hash represents a function that produces a message digest, typically SHA-256. (Later in the process, you specify which hashing algorithm you're using.) HexEncode represents a function that returns the base-16 encoding of the digest in lowercase characters. For example, HexEncode(“m”) returns the value 6d rather than 6D. Each input byte must be represented as exactly two hexadecimal characters.

Signature Version 4 does not require that you use a particular character encoding to encode the canonical request. However, some AWS services might require a specific encoding. For more information, consult the documentation for that service.

The following examples show how to construct the canonical form of a request to IAM. The original request might look like this as it is sent from the client to AWS, except that this example does not include the signing information yet.

Example Request

```
GET https://iam.amazonaws.com/?Action=ListUsers&Version=2010-05-08 HTTP/1.1
Host: iam.amazonaws.com
Content-Type: application/x-www-form-urlencoded; charset=utf-8
X-Amz-Date: 20150830T123600Z
```

The preceding example request is a GET request (method) that makes a ListUsers API (action) call to AWS Identity and Access Management (host). This action takes the Version parameter.
To create a canonical request, concatenate the following components from each step into a single string:

1. Start with the HTTP request method (GET, PUT, POST, etc.), followed by a newline character.

   **Example Request method**

   ```
   GET
   ```

2. Add the canonical URI parameter, followed by a newline character. The canonical URI is the URI-encoded version of the absolute path component of the URI, which is everything in the URI from the HTTP host to the question mark character (?) that begins the query string parameters (if any).

   Normalize URI paths according to RFC 3986. Remove redundant and relative path components. Each path segment must be URI-encoded **twice** (except for Amazon S3 which only gets URI-encoded once).

   **Example Canonical URI with encoding**

   ```
   /documents%2520and%2520settings/
   ```

   **Note**

   In exception to this, you do not normalize URI paths for requests to Amazon S3. For example, if you have a bucket with an object named `my-object//example//photo.user`, use that path. Normalizing the path to `my-object/example/photo.user` will cause the request to fail. For more information, see Task 1: Create a Canonical Request in the Amazon Simple Storage Service API Reference.

   If the absolute path is empty, use a forward slash (/). In the example IAM request, nothing follows the host in the URI, so the absolute path is empty.

   **Example Canonical URI**

   ```
   /
   ```

3. Add the canonical query string, followed by a newline character. If the request does not include a query string, use an empty string (essentially, a blank line). The example request has the following query string.

   **Example Canonical query string**

   ```
   Action=ListUsers&Version=2010-05-08
   ```

   To construct the canonical query string, complete the following steps:

   a. Sort the parameter names by character code point in ascending order. Parameters with duplicate names should be sorted by value. For example, a parameter name that begins with the uppercase letter F precedes a parameter name that begins with a lowercase letter b.

   b. URI-encode each parameter name and value according to the following rules:

      - Do not URI-encode any of the unreserved characters that RFC 3986 defines: A-Z, a-z, 0-9, hyphen (-), underscore (_), period (.), and tilde (~).

      - Percent-encode all other characters with %XY, where X and Y are hexadecimal characters (0-9 and uppercase A-F). For example, the space character must be encoded as %20 (not using '+', as some encoding schemes do) and extended UTF-8 characters must be in the form %XY%ZA.
• Double-encode any equals (=) characters in parameter values.

c. Build the canonical query string by starting with the first parameter name in the sorted list.

d. For each parameter, append the URI-encoded parameter name, followed by the equals sign character (=), followed by the URI-encoded parameter value. Use an empty string for parameters that have no value.

e. Append the ampersand character (&) after each parameter value, except for the last value in the list.

One option for the query API is to put all request parameters in the query string. For example, you can do this for Amazon S3 to create a presigned URL. In that case, the canonical query string must include not only parameters for the request, but also the parameters used as part of the signing process—the hashing algorithm, credential scope, date, and signed headers parameters.

The following example shows a query string that includes authentication information. The example is formatted with line breaks for readability, but the canonical query string must be one continuous line of text in your code.

Example Authentication parameters in a query string

```plaintext
Action=ListUsers&
Version=2010-05-08&
X-Amz-Algorithm=AWS4-HMAC-SHA256&
X-Amz-Credential=AKIDEXAMPLE%2F20150830%2Fus-east-1%2Fiam%2Faws4_request&
X-Amz-Date=20150830T123600Z&
X-Amz-SignedHeaders=content-type%3Bhost%3Bx-amz-date
```

For more information about authentication parameters, see Task 2: Create a string to sign for Signature Version 4 (p. 771).

Note

You can use temporary security credentials provided by the AWS Security Token Service (AWS STS) to sign a request. The process is the same as using long-term credentials, but when you add signing information to the query string you must add an additional query parameter for the security token. The parameter name is X-Amz-Security-Token, and the parameter's value is the URI-encoded session token (the string you received from AWS STS when you obtained temporary security credentials).

For some services, you must include the X-Amz-Security-Token query parameter in the canonical (signed) query string. For other services, you add the X-Amz-Security-Token parameter at the end, after you calculate the signature. For details, see the API reference documentation for that service.

4. Add the canonical headers, followed by a newline character. The canonical headers consist of a list of all the HTTP headers that you are including with the signed request.

For HTTP/1.1 requests, you must include the host header at a minimum. Standard headers like content-type are optional. For HTTP/2 requests, you must include the :authority header instead of the host header. Different services might require other headers.

Example Canonical headers

```plaintext
content-type:application/x-www-form-urlencoded; charset=utf-8
host:iam.amazonaws.com
x-amz-date:20150830T123600Z
```

To create the canonical headers list, convert all header names to lowercase and remove leading spaces and trailing spaces. Convert sequential spaces in the header value to a single space.
The following pseudocode describes how to construct the canonical list of headers:

```plaintext
CanonicalHeaders =
  CanonicalHeadersEntry0 + CanonicalHeadersEntry1 + ... + CanonicalHeadersEntryN
CanonicalHeadersEntry =
  Lowercase(HeaderName) + ':' + Trimall(HeaderValue) + '\n'
```

Lowercase represents a function that converts all characters to lowercase. The Trimall function removes excess white space before and after values, and converts sequential spaces to a single space.

Build the canonical headers list by sorting the (lowercase) headers by character code and then iterating through the header names. Construct each header according to the following rules:

- Append the lowercase header name followed by a colon.
- Append a comma-separated list of values for that header. Do not sort the values in headers that have multiple values.
- Append a new line ('\n').

The following examples compare a more complex set of headers with their canonical form:

**Example Original headers**

```plaintext
Host:iam.amazonaws.com\nContent-Type:application/x-www-form-urlencoded; charset=utf-8\nMy-header1: a b c\nX-Amz-Date:20150830T123600Z\nMy-Header2: "a b c"\n```

**Example Canonical form**

```plaintext
content-type:application/x-www-form-urlencoded; charset=utf-8\nhost:iam.amazonaws.com\nmy-header1:a b c\nmy-header2: "a b c"\nx-amz-date:20150830T123600Z\n```

**Note**

Each header is followed by a newline character, meaning the complete list ends with a newline character.

In the canonical form, the following changes were made:

- The header names were converted to lowercase characters.
- The headers were sorted by character code.
- Leading and trailing spaces were removed from the `my-header1` and `my-header2` values.
- Sequential spaces in `a b c` were converted to a single space for the `my-header1` and `my-header2` values.

**Note**

You can use temporary security credentials provided by the AWS Security Token Service (AWS STS) to sign a request. The process is the same as using long-term credentials, but when you include signing information in the `Authorization` header you must add an
additional HTTP header for the security token. The header name is X-Amz-Security-Token, and the header's value is the session token (the string you received from AWS STS when you obtained temporary security credentials).

5. Add the signed headers, followed by a newline character. This value is the list of headers that you included in the canonical headers. By adding this list of headers, you tell AWS which headers in the request are part of the signing process and which ones AWS can ignore (for example, any additional headers added by a proxy) for purposes of validating the request.

For HTTP/1.1 requests, the host header must be included as a signed header. For HTTP/2 requests that include the :authority header instead of the host header, you must include the :authority header as a signed header. If you include a date or x-amz-date header, you must also include that header in the list of signed headers.

To create the signed headers list, convert all header names to lowercase, sort them by character code, and use a semicolon to separate the header names. The following pseudocode describes how to construct a list of signed headers.

SignedHeaders = Lowercase(HeaderName0) + ';' + Lowercase(HeaderName1) + ';' + ... + Lowercase(HeaderNameN)

Build the signed headers list by iterating through the collection of header names, sorted by lowercase character code. For each header name except the last, append a semicolon (\';\') to the header name to separate it from the following header name.

Example Signed headers

```
content-type;host;x-amz-date\n```

6. Use a hash (digest) function like SHA256 to create a hashed value from the payload in the body of the HTTP or HTTPS request. Signature Version 4 does not require that you use a particular character encoding to encode text in the payload. However, some AWS services might require a specific encoding. For more information, consult the documentation for that service.

Example Structure of payload

```
HashedPayload = Lowercase(HexEncode(Hash(requestPayload)))
```

When you create the string to sign, you specify the signing algorithm that you used to hash the payload. For example, if you used SHA256, you will specify AWS4-HMAC-SHA256 as the signing algorithm. The hashed payload must be represented as a lowercase hexadecimal string.

If the payload is empty, use an empty string as the input to the hash function. In the IAM example, the payload is empty.

Example Hashed payload (empty string)

```
e3b0c44298fc1c149afbf4c8996fb92427ae41e4649b934ca495991b7852b855
```

7. To construct the finished canonical request, combine all the components from each step as a single string. As noted, each component ends with a newline character. If you follow the canonical request pseudocode explained earlier, the resulting canonical request is shown in the following example.
Example Canonical request

GET
/Action=ListUsers&Version=2010-05-08
content-type:application/x-www-form-urlencoded; charset=utf-8
host:iam.amazonaws.com
x-amz-date:20150830T123600Z
content-type;host;x-amz-date
e3b0c44298fc1c149afbf4c8996fb92427ae41e4649b934ca495991b7852b855

8. Create a digest (hash) of the canonical request with the same algorithm that you used to hash the payload.

Note
Signature Version 4 does not require that you use a particular character encoding to encode the canonical request before calculating the digest. However, some AWS services might require a specific encoding. For more information, consult the documentation for that service.

The hashed canonical request must be represented as a string of lowercase hexadecimal characters. The following example shows the result of using SHA-256 to hash the example canonical request.

Example Hashed canonical request

| e3b0c44298fc1c149afbf4c8996fb92427ae41e4649b934ca495991b7852b855 |

You include the hashed canonical request as part of the string to sign in Task 2: Create a string to sign for Signature Version 4 (p. 771).

Task 2: Create a string to sign for Signature Version 4

The string to sign includes meta information about your request and about the canonical request that you created in Task 1: Create a canonical request for Signature Version 4 (p. 766). You will use the string to sign and a derived signing key that you create later as inputs to calculate the request signature in Task 3: Calculate the signature for AWS Signature Version 4 (p. 772).

To create the string to sign, concatenate the algorithm, date and time, credential scope, and digest of the canonical request, as shown in the following pseudocode:

Structure of string to sign

```
StringToSign = Algorithm + \n + RequestDateTime + \n + CredentialScope + \n + HashedCanonicalRequest
```

The following example shows how to construct the string to sign with the same request from Task 1: Create A Canonical Request (p. 766).

Example HTTPS request

```
GET https://iam.amazonaws.com/?Action=ListUsers&Version=2010-05-08 HTTP/1.1
Host: iam.amazonaws.com
Content-Type: application/x-www-form-urlencoded; charset=utf-8
```
To create the string to sign

1. Start with the algorithm designation, followed by a newline character. This value is the hashing algorithm that you use to calculate the digests in the canonical request. For SHA256, AWS4-HMAC-SHA256 is the algorithm.

   AWS4-HMAC-SHA256

2. Append the request date value, followed by a newline character. The date is specified with ISO8601 basic format in the x-amz-date header in the format YYYYMMDD'T'HHMMSS'Z'. This value must match the value you used in any previous steps.

   20150830T123600Z

3. Append the credential scope value, followed by a newline character. This value is a string that includes the date, the Region you are targeting, the service you are requesting, and a termination string ("aws4_request") in lowercase characters. The Region and service name strings must be UTF-8 encoded.

   20150830/us-east-1/iam/aws4_request

   • The date must be in the YYYYMMDD format. Note that the date does not include a time value.
   • Verify that the Region you specify is the Region that you are sending the request to.

4. Append the hash of the canonical request that you created in Task 1: Create a canonical request for Signature Version 4 (p. 766). This value is not followed by a newline character. The hashed canonical request must be lowercase base-16 encoded, as defined by Section 8 of RFC 4648.

   f536975d06c0309214f805bb90ccff089219ecd68b2577efef23edd43b7e1a59

The following string to sign is a request to IAM on August 30, 2015.

**Example string to sign**

AWS4-HMAC-SHA256

20150830T123600Z

20150830/us-east-1/iam/aws4_request

f536975d06c0309214f805bb90ccff089219ecd68b2577efef23edd43b7e1a59

**Task 3: Calculate the signature for AWS Signature Version 4**

Before you calculate a signature, you derive a signing key from your AWS secret access key. Because the derived signing key is specific to the date, service, and Region, it offers a greater degree of protection. You don't just use your secret access key to sign the request. You then use the signing key and the string to sign that you created in Task 2: Create a string to sign for Signature Version 4 (p. 771) as the inputs to a keyed hash function. The hex-encoded result from the keyed hash function is the signature.

Signature Version 4 does not require that you use a particular character encoding to encode the string to sign. However, some AWS services might require a specific encoding. For more information, consult the documentation for that service.
To calculate a signature

1. Derive your signing key. To do this, use your secret access key to create a series of hash-based message authentication codes (HMACs). This is shown in the following pseudocode, where HMAC(key, data) represents an HMAC-SHA256 function that returns output in binary format. The result of each hash function becomes input for the next one.

**Pseudocode for deriving a signing key**

```
kSecret = your secret access key
kDate = HMAC("AWS4" + kSecret, Date)
kRegion = HMAC(kDate, Region)
kService = HMAC(kRegion, Service)
kSigning = HMAC(kService, "aws4_request")
```

Note that the date used in the hashing process is in the format YYYYMMDD (for example, 20150830), and does not include the time.

Make sure you specify the HMAC parameters in the correct order for the programming language you are using. This example shows the key as the first parameter and the data (message) as the second parameter, but the function that you use might specify the key and data in a different order.

Use the digest (binary format) for the key derivation. Most languages have functions to compute either a binary format hash, commonly called a digest, or a hex-encoded hash, called a hexdigest. The key derivation requires that you use a binary-formatted digest.

The following example show the inputs to derive a signing key and the resulting output, where kSecret = wJalrXUtnFEMI/K7MDENG+bPxRfiCYEXAMPLEKEY.

The example uses the same parameters from the request in Task 1 and Task 2 (a request to IAM in the us-east-1 Region on August 30, 2015).

**Example inputs**

```
HMAC(HMAC(HMAC(HMAC("AWS4" + kSecret,"20150830"),"us-east-1"),"iam"),"aws4_request")
```

The following example shows the derived signing key that results from this sequence of HMAC hash operations. This shows the hexadecimal representation of each byte in the binary signing key.

**Example signing key**

```
c4afb1cc5771d871763a393e44b703571b55cc28424d1a5e86da6ed3c154a4b9
```

For more information about how to derive a signing key in different programming languages, see Examples of how to derive a signing key for Signature Version 4 (p. 776).

2. Calculate the signature. To do this, use the signing key that you derived and the string to sign as inputs to the keyed hash function. After you calculate the signature, convert the binary value to a hexadecimal representation.

The following pseudocode shows how to calculate the signature.

```
signature = HexEncode(HMAC(derived signing key, string to sign))
```

**Note**

Make sure you specify the HMAC parameters in the correct order for the programming language you are using. This example shows the key as the first parameter and the data
(message) as the second parameter, but the function that you use might specify the key and data in a different order.

The following example shows the resulting signature if you use the same signing key and the string to sign from Task 2:

**Example signature**

```
5d672d79c15b13162d9279b0855cfba6789a8edb4c82c400e06b5924a6f2b5d7
```

**Task 4: Add the signature to the HTTP request**

After you calculate the signature, add it to the request. You can add the signature to a request in one of two ways:

- An HTTP header named Authorization
- The query string

You cannot pass signing information in both the Authorization header and the query string.

**Note**

You can use temporary security credentials provided by the AWS Security Token Service (AWS STS) to sign a request. The process is the same as using long-term credentials, but requires an additional HTTP header or query string parameter for the security token. The name of the header or query string parameter is X-Amz-Security-Token, and the value is the session token (the string you received from AWS STS when you obtained temporary security credentials).

When you add the X-Amz-Security-Token parameter to the query string, some services require that you include this parameter in the canonical (signed) request. For other services, you add this parameter at the end, after you calculate the signature. For details, see the API reference documentation for that service.

**Adding signing information to the authorization header**

You can include signing information by adding it to an HTTP header named Authorization. The contents of the header are created after you calculate the signature as described in the preceding steps, so the Authorization header is not included in the list of signed headers. Although the header is named Authorization, the signing information is actually used for authentication.

The following pseudocode shows the construction of the Authorization header.

```
Authorization: algorithm Credential=access key ID/credential scope, SignedHeaders=SignedHeaders, Signature=signature
```

The following example shows a finished Authorization header.

Note that in the actual request, the authorization header would appear as a continuous line of text. The version below has been formatted for readability.

```
Authorization: AWS4-HMAC-SHA256 Credential=AKIDEXAMPLE/20150830/us-east-1/iam/aws4_request, SignedHeaders=content-type;host;x-amz-date, Signature=5d672d79c15b13162d9279b0855cfba6789a8edb4c82c400e06b5924a6f2b5d7
```

Note the following:
• There is no comma between the algorithm and Credential. However, the SignedHeaders and Signature are separated from the preceding values with a comma.
• The Credential value starts with the access key ID, which is followed by a forward slash (/), which is followed by the credential scope that you calculated in Task 2: Create a string to sign for Signature Version 4 (p. 771). The secret access key is used to derive the signing key for the signature, but is not included in the signing information sent in the request.

Adding signing information to the Query string

You can make requests and pass all request values in the query string, including signing information. This is sometimes referred to as a presigned URL, because it produces a single URL with everything required in order to make a successful call to AWS. It’s commonly used in Amazon S3. For more information, see Authenticating Requests by Using Query Parameters (AWS Signature Version 4) in the Amazon Simple Storage Service API Reference.

Important
If you make a request in which all parameters are included in the query string, the resulting URL represents an AWS action that is already authenticated. Therefore, treat the resulting URL with as much caution as you would treat your actual credentials. We recommend you specify a short expiration time for the request with the X-Amz-Expires parameter.

When you use this approach, all the query string values (except the signature) are included in the canonical query string that is part of the canonical query that you construct in the first part of the signing process (p. 766).

The following pseudocode shows the construction of a query string that contains all request parameters.

```plaintext
querystring = Action=action
querystring += &X-Amz-Algorithm=algorithm
querystring += &X-Amz-Credential=urlencode(access_key_ID + '/' + credential_scope)
querystring += &X-Amz-Date=date
querystring += &X-Amz-Expires=timeout_interval
querystring += &X-Amz-SignedHeaders=signed_headers
```

After the signature is calculated (which uses the other query string values as part of the calculation), you add the signature to the query string as the X-Amz-Signature parameter:

```plaintext
querystring += &X-Amz-Signature=signature
```

The following example shows what a request might look like when all the request parameters and the signing information are included in query string parameters.

Note that in the actual request, the authorization header would appear as a continuous line of text. The version below has been formatted for readability.

```plaintext
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIEXAMPLE%2F20150830%2Fus-east-1%2Fiams%2Faws4_request
&X-Amz-Date=20150830T123600Z
&X-Amz-Expires=60
&X-Amz-SignedHeaders=content-type%3Bhost
&X-Amz-Signature=37ac2f4de60b0ac9bd9eadeb459b1bbe6224158d66e7ae5fcadb70b2d181d02
```

Note the following:
• For the signature calculation, query string parameters must be sorted in code point order from low to high, and their values must be URI-encoded. See the step about creating a canonical query string in Task 1: Create a canonical request for Signature Version 4 (p. 766).
• Set the timeout interval (X-Amz-Expires) to the minimal viable time for the operation you're requesting.

Handling dates in Signature Version 4

The date that you use as part of your credential scope must match the date of your request. You can include the date as part of your request in several ways. You can use a date header, an x-amz-date header or include x-amz-date as a query parameter. For example requests, see Examples of the complete Signature Version 4 signing process (Python) (p. 779).

The time stamp must be in UTC and in the following ISO 8601 format: YYYYMMDD'T'HHMMSS'Z'. For example, 20150830T123600Z is a valid time stamp. Do not include milliseconds in the time stamp.

AWS first checks the x-amz-date header or parameter for a time stamp. If AWS can't find a value for x-amz-date, it looks for the date header. AWS then checks the credential scope for an eight-digit string representing the year (YYYY), month (MM), and day (DD) of the request. For example, if the x-amz-date header value is 20111015T080000Z and the date component of the credential scope is 20111015, AWS allows the authentication process to proceed.

If the dates don't match, AWS rejects the request, even if the time stamp is only seconds away from the date in the credential scope. For example, AWS will reject a request that has an x-amz-date header value of 20151014T235959Z and a credential scope that has the date 20151015.

Examples of how to derive a signing key for Signature Version 4

This page shows examples in several programming languages for how to derive a signing key for Signature Version 4. The examples on this page show only how to derive a signing key, which is just one part of signing AWS requests. For examples that show the complete process, see Examples of the complete Signature Version 4 signing process (Python) (p. 779).

Important
If you are using one of the AWS SDKs (including the SDK for Java, .NET, Python, Ruby, or JavaScript), you do not have to manually perform the steps of deriving a signing key and adding authentication information to a request. The SDKs perform this work for you. You need to manually sign requests only if you are directly making HTTP or HTTPS requests.

Examples
• Deriving a signing key using Java (p. 776)
• Deriving a signing key using .NET (C#) (p. 777)
• Deriving a signing key using Python (p. 777)
• Deriving a signing key using Ruby (p. 777)
• Deriving a signing key using JavaScript (Node.js) (p. 777)
• Deriving a signing key using other languages (p. 778)
• Common coding errors (p. 778)

Deriving a signing key using Java

```java
static byte[] HmacSHA256(String data, byte[] key) throws Exception {
    String algorithm="HmacSHA256";
    Mac mac = Mac.getInstance(algorithm);
    mac.init(new SecretKeySpec(key, algorithm));
    return mac.doFinal(data.getBytes("UTF-8"));
}

static byte[] getSignatureKey(String key, String dateStamp, String regionName, String serviceName) throws Exception {
```

Version 1.0

776
byte[] kSecret = ("AWS4" + key).getBytes("UTF-8");
byte[] kDate = HmacSHA256(dateStamp, kSecret);
byte[] kRegion = HmacSHA256(regionName, kDate);
byte[] kService = HmacSHA256(serviceName, kRegion);
byte[] kSigning = HmacSHA256("aws4_request", kService);
return kSigning;
}

Deriving a signing key using .NET (C#)

static byte[] HmacSHA256(String data, byte[] key)
{
    String algorithm = "HmacSHA256";
    KeyedHashAlgorithm kha = KeyedHashAlgorithm.Create(algorithm);
    kha.Key = key;
    return kha.ComputeHash(Encoding.UTF8.GetBytes(data));
}
static byte[] getSignatureKey(String key, String dateStamp, String regionName, String serviceName)
{
    byte[] kSecret = Encoding.UTF8.GetBytes(("AWS4" + key).ToCharArray());
    byte[] kDate = HmacSHA256(dateStamp, kSecret);
    byte[] kRegion = HmacSHA256(regionName, kDate);
    byte[] kService = HmacSHA256(serviceName, kRegion);
    byte[] kSigning = HmacSHA256("aws4_request", kService);
    return kSigning;
}

Deriving a signing key using Python

def sign(key, msg):
    return hmac.new(key, msg.encode("utf-8"), hashlib.sha256).digest()

def getSignatureKey(key, dateStamp, regionName, serviceName):
    kDate = sign(("AWS4" + key).encode("utf-8"), dateStamp)
    kRegion = sign(kDate, regionName)
    kService = sign(kRegion, serviceName)
    kSigning = sign(kService, "aws4_request")
    return kSigning

Deriving a signing key using Ruby

def getSignatureKey key, dateStamp, regionName, serviceName
    kDate = OpenSSL::HMAC.digest('sha256', "AWS4" + key, dateStamp)
    kRegion = OpenSSL::HMAC.digest('sha256', kDate, regionName)
    kService = OpenSSL::HMAC.digest('sha256', kRegion, serviceName)
    kSigning = OpenSSL::HMAC.digest('sha256', kService, "aws4_request")
    kSigning
end

Deriving a signing key using JavaScript (Node.js)

The following example uses the crypto-js library. For more information, see https://www.npmjs.com/package/crypto-js and https://code.google.com/archive/p/crypto-js/.

```javascript
var crypto = require("crypto-js");
```
function getSignatureKey(key, dateStamp, regionName, serviceName) {
    var kDate = crypto.HmacSHA256(dateStamp, "AWS4" + key);
    var kRegion = crypto.HmacSHA256(regionName, kDate);
    var kService = crypto.HmacSHA256(serviceName, kRegion);
    var kSigning = crypto.HmacSHA256("aws4_request", kService);
    return kSigning;
}

Deriving a signing key using other languages

If you need to implement this logic in a different programming language, we recommend testing the
intermediary steps of the key derivation algorithm against the values in this section. The following
example in Ruby prints the results using the hexEncode function after each step in the algorithm.

```ruby
def hexEncode bindata
    result=""
    data=bindata.unpack("C*")
    data.each {|b| result+= "%02x" % b}
    result
end
```

Given the following test input:

```ruby
key = 'wJalrXUtFEMI/K7MDENG+bPxRfiCYEXAMPLEKEY'
dateStamp = '20120215'
regionName = 'us-east-1'
serviceName = 'iam'
```

Your program should generate the following values for the values in getSignatureKey. Note that
these are hex-encoded representations of the binary data; the key itself and the intermediate values
should be in binary format.

```ruby
kSecret  = '4157534774a616c72555746e46454d492f4b374d44454e472b62507852666943594558414d504l454b4559'
kDate    = '969fbb94eb542b71ed6f87e4d5fa29c78342bf040747670f0c2489e0a0d'
kRegion  = '69daa0209cd9c5f5c8ca446469f4252e981430b10e3d3f8e2f197d7a70c'
kService = 'f72cfd46f26bc647e70f6a1eab6b6c0ba18780c19a8da0c31ace6712b5e3c87f'
kSigning = 'f4780e2d9f65fa895f9c67b32ce1baf0b0d8a43505a000a9e090d414db404d'
```

Common coding errors

To simplify your task, avoid the following common coding errors.

Tip

Examine the HTTP request that you're sending to AWS with a tool that shows you what your raw
HTTP requests look like. This can help you spot issues that aren't evident from your code.

- Don't include an extra newline character, or forget one where it's required.
- Don't format the date incorrectly in the credential scope, such as using a time stamp instead of
  YYYYMMDD format.
- Make sure the headers in the canonical headers and the signed headers are the same.
- Don't inadvertently swap the key and the data (message) when calculating intermediary keys. The
  result of the previous step's computation is the key, not the data. Check the documentation for your
  cryptographic primitives carefully to ensure that you place the parameters in the proper order.
- Don't forget to add the string "AWS4" in front of the key for the first step. If you implement the key
derivation using a for loop or iterator, don't forget to special-case the first iteration so that it includes
  the "AWS4" string.
For more information about possible errors, see Troubleshooting AWS Signature Version 4 errors (p. 786).

Examples of the complete Signature Version 4 signing process (Python)

This section shows example programs written in Python that illustrate how to work with Signature Version 4 in AWS. We deliberately wrote these example programs to be simple (to use few Python-specific features) to make it easier to understand the overall process of signing AWS requests.

**Note**

If you are using one of the AWS SDKs (including the SDK for C++, SDK for Go, SDK for Java, AWS SDK for JavaScript, AWS SDK for .NET, SDK for PHP, SDK for Python (Boto3), or SDK for Ruby), you do not have to manually perform the steps of deriving a signing key and adding authentication information to a request. The SDKs perform this work for you. You need to manually sign requests only if you are directly making HTTP or HTTPS requests.

In order to work with these example programs, you need the following:

- Python 2.x installed on your computer, which you can get from the Python site. These programs were tested using Python 2.7 and 3.6.
- The Python requests library, which is used in the example script to make web requests. A convenient way to install Python packages is to use pip, which gets packages from the Python package index site. You can then install requests by running `pip install requests` at the command line.
- An access key (access key ID and secret access key) in environment variables named `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. Alternatively, you can keep these values in a credentials file and read them from that file. As a best practice, we recommend that you do *not* embed credentials in code. For more information, see Best Practices for Managing AWS Access Keys in the Amazon Web Services General Reference.

The following examples use UTF-8 to encode the canonical request and string to sign, but Signature Version 4 does not require that you use a particular character encoding. However, some AWS services might require a specific encoding. For more information, consult the documentation for that service.

**Examples**

- Using GET with an authorization header (Python) (p. 779)
- Using POST (Python) (p. 782)
- Using GET with authentication information in the Query string (Python) (p. 784)

Using GET with an authorization header (Python)

The following example shows how to make a request using the Amazon EC2 query API without SDK for Python (Boto3). The request makes a GET request and passes authentication information to AWS using the Authorization header.
# ABOUT THIS PYTHON SAMPLE: This sample is part of the AWS General Reference
# Signing AWS API Requests top available at
# https://docs.aws.amazon.com/general/latest/gr/sigv4-signed-request-examples.html

# AWS Version 4 signing example

# EC2 API (DescribeRegions)

# See: http://docs.aws.amazon.com/general/latest/gr/sigv4_signing.html
# This version makes a GET request and passes the signature
# in the Authorization header.
import sys, os, base64, datetime, hashlib, hmac
import requests # pip install requests

# ************* REQUEST VALUES *************
method = 'GET'
service = 'ec2'
host = 'ec2.amazonaws.com'
region = 'us-east-1'
endpoint = 'https://ec2.amazonaws.com'
request_parameters = 'Action=DescribeRegions&Version=2013-10-15'

# Key derivation functions. See:
# http://docs.aws.amazon.com/general/latest/gr/signature-v4-examples.html#signature-v4-
# examples-python
def sign(key, msg):
    return hmac.new(key, msg.encode('utf-8'), hashlib.sha256).digest()

def getSignatureKey(key, dateStamp, regionName, serviceName):
    kDate = sign(('AWS4' + key).encode('utf-8'), dateStamp)
    kRegion = sign(kDate, regionName)
    kService = sign(kRegion, serviceName)
    kSigning = sign(kService, 'aws4_request')
    return kSigning

# Read AWS access key from env. variables or configuration file. Best practice is NOT
# to embed credentials in code.
access_key = os.environ.get('AWS_ACCESS_KEY_ID')
secret_key = os.environ.get('AWS_SECRET_ACCESS_KEY')
if access_key is None or secret_key is None:
    print('No access key is available.')
    sys.exit()

# Create a date for headers and the credential string
        t = datetime.datetime.utcnow()
amzdate = t.strftime('%Y%m%dT%H%M%SZ')
datestamp = t.strftime('%Y%m%d') # Date w/o time, used in credential scope

# ************* TASK 1: CREATE A CANONICAL REQUEST *************
# http://docs.aws.amazon.com/general/latest/gr/sigv4-create-canonical-request.html

# Step 1 is to define the verb (GET, POST, etc.)--already done.

# Step 2: Create canonical URI--the part of the URI from domain to query
# string (use '/' if no path)
canonical_uri = '/'

# Step 3: Create the canonical query string. In this example (a GET request),
# request parameters are in the query string. Query string values must
# be URL-encoded (space=%20). The parameters must be sorted by name.
# For this example, the query string is pre-formatted in the request_parameters variable.
canonical_querystring = request_parameters
# Step 4: Create the canonical headers and signed headers. Header names
# must be trimmed and lowercase, and sorted in code point order from
# low to high. Note that there is a trailing \n.
canonical_headers = 'host:' + host + '\n' + 'x-amz-date:' + amzdate + '\n'

# Step 5: Create the list of signed headers. This lists the headers
# in the canonical_headers list, delimited with ";" and in alpha order.
# Note: The request can include any headers; canonical_headers and
# signed_headers lists those that you want to be included in the
# hash of the request. "Host" and "x-amz-date" are always required.
signed_headers = 'host;x-amz-date'

# Step 6: Create payload hash (hash of the request body content). For GET
# requests, the payload is an empty string ('').
payload_hash = hashlib.sha256('').hexdigest()

# Step 7: Combine elements to create canonical request
canonical_request = method + '\n' + canonical_uri + '\n' + canonical_querystring + '\n' + canonical_headers + '\n' + signed_headers + '\n' + payload_hash

# ************* TASK 2: CREATE THE STRING TO SIGN*************
# Match the algorithm to the hashing algorithm you use, either SHA-1 or
# SHA-256 (recommended)
algorithm = 'AWS4-HMAC-SHA256'
credential_scope = datestamp + '/' + region + '/' + service + '/' + 'aws4_request'
string_to_sign = algorithm + '\n' + amzdate + '\n' + credential_scope + '\n' +
    hashlib.sha256(canonical_request.encode('utf-8')).hexdigest()

# ************* TASK 3: CALCULATE THE SIGNATURE *************
# Create the signing key using the function defined above.
signing_key = getSignatureKey(secret_key, datestamp, region, service)
# Sign the string_to_sign using the signing_key
signature = hmac.new(signing_key, (string_to_sign).encode('utf-8'),
    hashlib.sha256).hexdigest()

# ************* TASK 4: ADD SIGNING INFORMATION TO THE REQUEST *************
# The signing information can be either in a query string value or in
# a header named Authorization. This code shows how to use a header.
# Create authorization header and add to request headers
authorization_header = algorithm + '/' + 'Credential=' + access_key + '/' +
    credential_scope + '/' + 'SignedHeaders=' + signed_headers + '/' +
    'Signature=' + signature

# The request can include any headers, but MUST include "host", "x-amz-date",
# and (for this scenario) "Authorization". "host" and "x-amz-date" must
# be included in the canonical_headers and signed_headers, as noted
# earlier. Order here is not significant.
# Python note: The 'host' header is added automatically by the Python 'requests' library.
headers = {'x-amz-date':amzdate, 'Authorization':authorization_header}

# ************* SEND THE REQUEST *************
request_url = endpoint + '?' + canonical_querystring
print('BEGIN REQUEST++++++++++++++++++++++++++++++++++++')
print('Request URL = ' + request_url)
r = requests.get(request_url, headers=headers)
print('RESPONSE++++++++++++++++++++++++++++++++++++')
print('Response code: %d
% r.status_code)
print(r.text)
Using POST (Python)

The following example shows how to make a request using the Amazon DynamoDB query API without SDK for Python (Boto3). The request makes a POST request and passes values to AWS in the body of the request. Authentication information is passed using the Authorization request header.

```python
import sys, os, base64, datetime, hashlib, hmac
import requests # pip install requests

# ************* REQUEST VALUES *************
method = 'POST'
service = 'dynamodb'
host = 'dynamodb.us-west-2.amazonaws.com'
region = 'us-west-2'
endpoint = 'https://dynamodb.us-west-2.amazonaws.com/'
content_type = 'application/x-amz-json-1.0'
amz_target = 'DynamoDB_20120810.CreateTable'
request_parameters = '{
    "KeySchema": [{"KeyType": "HASH","AttributeName": "Id"}],
    "TableName": "TestTable","AttributeDefinitions": [{"AttributeName": "Id","AttributeType": "S"}],
    "ProvisionedThroughput": {
        "WriteCapacityUnits": 5,"ReadCapacityUnits": 5
    }
}

# Key derivation functions. See:
# http://docs.aws.amazon.com/general/latest/gr/signature-v4-examples.html#signature-v4-examples-python

def sign(key, msg):
    return hmac.new(key, msg.encode("utf-8"), hashlib.sha256).digest()

def getSignatureKey(key, date_stamp, regionName, serviceName):
    kDate = sign(('AWS4' + key).encode('utf-8'), date_stamp)
    kRegion = sign(kDate, regionName)
    kService = sign(kRegion, serviceName)
```
kSigning = sign(kService, 'aws4_request')
return kSigning

# Read AWS access key from env. variables or configuration file. Best practice is NOT
# to embed credentials in code.
access_key = os.environ.get('AWS_ACCESS_KEY_ID')
secret_key = os.environ.get('AWS_SECRET_ACCESS_KEY')
if access_key is None or secret_key is None:
  print('No access key is available.')
sys.exit()

# Create a date for headers and the credential string
t = datetime.datetime.utcnow()
amz_date = t.strftime('%Y%m%dT%H%M%SZ')
date_stamp = t.strftime('%Y%m%d') # Date w/o time, used in credential scope

# ************* TASK 1: CREATE A CANONICAL REQUEST *************
# http://docs.aws.amazon.com/general/latest/gr/sigv4-create-canonical-request.html

# Step 1 is to define the verb (GET, POST, etc.)--already done.

# Step 2: Create canonical URI--the part of the URI from domain to query
# string (use '/' if no path)
canonical_uri = '/'

## Step 3: Create the canonical query string. In this example, request
# parameters are passed in the body of the request and the query string
# is blank.
canonical_querystring = ''

# Step 4: Create the canonical headers. Header names must be trimmed
# and lowercase, and sorted in code point order from low to high.
# Note that there is a trailing \n.
canonical_headers = 'content-type:' + content_type + '\n' + 'host:' + host + '\n' + 'x-amz-date:' + amz_date + '\n' + 'x-amz-target:' + amz_target + '\n'

# Step 5: Create the list of signed headers. This lists the headers
# in the canonical_headers list, delimited with ';' and in alpha order.
# Note: The request can include any headers: canonical_headers and
# signed_headers include those that you want to be included in the
# hash of the request. "Host" and "x-amz-date" are always required.
# For DynamoDB, content-type and x-amz-target are also required.
signed_headers = 'content-type;host;x-amz-date;x-amz-target'

# Step 6: Create payload hash. In this example, the payload (body of
# the request) contains the request parameters.
payload_hash = hashlib.sha256(request_parameters.encode('utf-8')).hexdigest()

# Step 7: Combine elements to create canonical request
canonical_request = method + '\n' + canonical_uri + '\n' + canonical_querystring + '\n' +
canonical_headers + '\n' + signed_headers + '\n' + payload_hash

# ************* TASK 2: CREATE THE STRING TO SIGN*************
# Match the algorithm to the hashing algorithm you use, either SHA-1 or
# SHA-256 (recommended)
algorithm = 'AWS4-HMAC-SHA256'
credential_scope = date_stamp + '/' + region + '/' + service + '/' + 'aws4_request'
string_to_sign = algorithm + '\n' + amz_date + '\n' + credential_scope + '\n' +
    hashlib.sha256(canonical_request.encode('utf-8')).hexdigest()

# ************* TASK 3: CALCULATE THE SIGNATURE *************
# Create the signing key using the function defined above.
signing_key = getSignatureKey(secret_key, date_stamp, region, service)
Signature Version 4 signing process

# Sign the string_to_sign using the signing_key
signature = hmac.new(signing_key, (string_to_sign).encode('utf-8'),
                      hashlib.sha256).hexdigest()

# ************* TASK 4: ADD SIGNING INFORMATION TO THE REQUEST *************
# Put the signature information in a header named Authorization.
authorization_header = algorithm + ' ' + 'Credential=' + access_key + '/
                      ' + credential_scope + ', ' + 'SignedHeaders=' + signed_headers + ', ' + 'Signature=' + signature

# For DynamoDB, the request can include any headers, but MUST include "host", "x-amz-date",
# "x-amz-target", "content-type", and "Authorization". Except for the authorization
# header, the headers must be included in the canonical_headers and signed_headers values, as
# noted earlier. Order here is not significant.
# # Python note: The 'host' header is added automatically by the Python 'requests' library.
headers = {'Content-Type':content_type,
           'X-Amz-Date':amz_date,
           'X-Amz-Target':amz_target,
           'Authorization':authorization_header}

# ************* SEND THE REQUEST *************
print('\nBEGIN REQUEST++++++++++++++++++++++++++++++++++++')
print('Request URL = ' + endpoint)
r = requests.post(endpoint, data=request_parameters, headers=headers)
print('\nRESPONSE++++++++++++++++++++++++++++++++++++')
print('Response code: %d
' % r.status_code)
print(r.text)

Using GET with authentication information in the Query string (Python)

The following example shows how to make a request using the IAM query API without SDK for Python
(Boto3). The request makes a GET request and passes parameters and signing information using the
query string.

# Copyright 2010-2019 Amazon.com, Inc. or its affiliates. All Rights Reserved.

# language governing permissions and limitations under the License.
# # ABOUT THIS PYTHON SAMPLE: This sample is part of the AWS General Reference
# Signing AWS API Requests top available at
# https://docs.aws.amazon.com/general/latest/gr/sigv4-signed-request-examples.html
# # AWS Version 4 signing example
# # IAM API (CreateUser)
# # See: http://docs.aws.amazon.com/general/latest/gr/sigv4_signing.html
Signature Version 4 signing process

This version makes a GET request and passes request parameters
and authorization information in the query string

```python
import sys, os, datetime, hashlib, hmac, urllib.parse
import requests # pip install requests

# ************* REQUEST VALUES *************
method = 'GET'
service = 'iam'
host = 'iam.amazonaws.com'
region = 'us-east-1'
endpoint = 'https://iam.amazonaws.com'

# Key derivation functions. See:
# http://docs.aws.amazon.com/general/latest/gr/signature-v4-examples.html#signature-v4-examples-python

def sign(key, msg):
    return hmac.new(key, msg.encode('utf-8'), hashlib.sha256).digest()

def getSignatureKey(key, dateStamp, regionName, serviceName):
    kDate = sign(('AWS4' + key).encode('utf-8'), dateStamp)
    kRegion = sign(kDate, regionName)
    kService = sign(kRegion, serviceName)
    kSigning = sign(kService, 'aws4_request')
    return kSigning

access_key = os.environ.get('AWS_ACCESS_KEY_ID')
secret_key = os.environ.get('AWS_SECRET_ACCESS_KEY')
if access_key is None or secret_key is None:
    print('No access key is available.')
sys.exit()

# Create a date for headers and the credential string
# amz_date = t.strftime('%Y%m%dT%H%M%SZ') # Format date as YYYYMMDD'T'HHMMSS'Z'
datetstamp = t.strftime('%Y%m%d') # Date w/o time, used in credential scope

# ************* TASK 1: CREATE A CANONICAL REQUEST *************
# http://docs.aws.amazon.com/general/latest/gr/sigv4-create-canonical-request.html

# Because almost all information is being passed in the query string,
# the order of these steps is slightly different than examples that
# use an authorization header.
# Step 1: Define the verb (GET, POST, etc.)--already done.
# Step 2: Create canonical URI--the part of the URI from domain to query
# string (use '/' if no path)
canonical_uri = '/'

# Step 3: Create the canonical headers and signed headers. Header names
# must be trimmed and lowercase, and sorted in code point order from
# low to high. Note trailing \n in canonical_headers.
# signed_headers is the list of headers that are being included
# as part of the signing process. For requests that use query strings,
# only "host" is included in the signed headers.
canonical_headers = 'host:' + host + '

# Match the algorithm to the hashing algorithm you use, either SHA-1 or
# SHA-256 (recommended)
algorithm = 'AWS4-HMAC-SHA256'
credential_scope = datetstamp + '/' + region + '/' + service + '/' + 'aws4_request'
```

Version 1.0

785
# Step 4: Create the canonical query string. In this example, request parameters are in the query string. Query string values must be URL-encoded (space=%20). The parameters must be sorted by name.

```python
canonical_querystring = 'Action=CreateUser&UserName=NewUser&Version=2010-05-08'
canonical_querystring += '&X-Amz-Algorithm=AWS4-HMAC-SHA256'
canonical_querystring += '&X-Amz-Credential=' + urllib.parse.quote_plus(access_key + '/' + credential_scope)
canonical_querystring += '&X-Amz-Date=' + amz_date
canonical_querystring += '&X-Amz-Expires=30'
canonical_querystring += '&X-Amz-SignedHeaders=' + signed_headers
```

# Step 5: Create payload hash. For GET requests, the payload is an empty string ("").
```
payload_hash = hashlib.sha256('').encode('utf-8')).hexdigest()
```

# Step 6: Combine elements to create canonical request
```
canonical_request = method + '
' + canonical_uri + '
' + canonical_querystring + '
' + canonical_headers + '
' + signed_headers + '
' + payload_hash
```

# ************* TASK 2: CREATE THE STRING TO SIGN*************
```
string_to_sign = algorithm + '
' + amz_date + '
' + credential_scope + '
' + hashlib.sha256(canonical_request.encode('utf-8')).hexdigest()
```

# ************* TASK 3: CALCULATE THE SIGNATURE *************
```
# Create the signing key
signing_key = getSignatureKey(secret_key, datestamp, region, service)

# Sign the string_to_sign using the signing_key
signature = hmac.new(signing_key, (string_to_sign).encode("utf-8"),
hashlib.sha256).hexdigest()
```

# ************* TASK 4: ADD SIGNING INFORMATION TO THE REQUEST *************
```
# The auth information can be either in a query string value or in a header named Authorization. This code shows how to put everything into a query string.
canonical_querystring += '&X-Amz-Signature=' + signature
```

# ************* SEND THE REQUEST *************
```
# The 'host' header is added automatically by the Python 'request' lib. But it must exist as a header in the request.
request_url = endpoint + '?' + canonical_querystring
```
```
print('
BEGIN REQUEST++++++++++++++++++++++++++++++++++++

RESPONSE++++++++++++++++++++++++++++++++++++
Response code: %d
' % r.status_code)
print(r.text)
```

---

**Troubleshooting AWS Signature Version 4 errors**

When you develop code that implements Signature Version 4, you might receive errors from AWS products that you test against. The errors typically come from an error in the canonicalization of the request, the incorrect derivation or use of the signing key, or a validation failure of signature-specific parameters sent along with the request.

**Errors**
Troubleshooting canonicalization errors

Consider the following request:

```
https://iam.amazonaws.com/?MaxItems=100
&Action=ListGroupsForUser
&UserName=Test
&Version=2010-05-08
&X-Amz-Date=20120223T063000Z
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIAIOSFODNN7EXAMPLE/20120223/us-east-1/iam/aws4_request
&X-Amz-SignedHeaders=host
&X-Amz-Signature=<calculated value>
```

If you incorrectly calculate the canonical request or the string to sign, the signature verification step performed by the service fails. The following example is a typical error response, which includes the canonical string and the string to sign as computed by the service. You can troubleshoot your calculation error by comparing the returned strings with the canonical string and your calculated string to sign.

```
  <Error>
    <Type>Sender</Type>
    <Code>SignatureDoesNotMatch</Code>
    <Message>The request signature we calculated does not match the signature you provided. Check your AWS Secret Access Key and signing method. Consult the service documentation for details.

    The canonical string for this request should have been 'GET /' 
    Action=ListGroupsForUser&MaxItems=100&UserName=Test&Version=2010-05-08&X-Amz- 
    Algorithm=AWS4-HMAC-SHA256&X-Amz-Credential=AKIAIOSFODNN7EXAMPLE/20120223/us-east-1/iam/aws4_request 
    &X-Amz-SignedHeaders=host

    host
    <hashed-value>'

    The String-to-Sign should have been
    'AWS4-HMAC-SHA256
    20120223T063000Z
    20120223/us-east-1/iam/aws4_request
    <hashed-value>'
  </Message>
</Error>
</ErrorResponse>
```

Troubleshooting credential scope errors

AWS products validate credentials for proper scope; the credential parameter must specify the correct service, Region, and date. For example, the following credential references the Amazon RDS service:

```
Credential=AKIAIOSFODNN7EXAMPLE/20120224/us-east-1/rds/aws4_request
```

If you use the same credentials to submit a request to IAM, you’ll receive the following error response:
The credential must also specify the correct Region. For example, the following credential for an IAM request incorrectly specifies the US West (N. California) Region.

```
Credential=AKIAIOSFODNN7EXAMPLE/20120224/us-west-1/iam/aws4_request
```

If you use the credential to submit a request to IAM, which accepts only the `us-east-1` Region specification, you'll receive the following response:

```
  <Error>
    <Type>Sender</Type>
    <Code>SignatureDoesNotMatch</Code>
    <Message>Credential should be scoped to a valid Region, not 'us-west-1'. </Message>
  </Error>
  <RequestId>8e229682-5f27-11e1-88f2-4b1b00f424ae</RequestId>
</ErrorResponse>
```

You'll receive the same type of invalid Region response from AWS products that are available in multiple Regions if you submit requests to a Region that differs from the Region specified in your credential scope.

The credential must also specify the correct Region for the service and action in your request.

The date that you use as part of the credential must match the date value in the `x-amz-date` header. For example, the following `x-amz-date` header value does not match the date value used in the Credential parameter that follows it.

```
x-amz-date: "20120224T213559Z"
```

```
Credential=AKIAIOSFODNN7EXAMPLE/20120225/us-east-1/iam/aws4_request
```

If you use this pairing of `x-amz-date` header and credential, you'll receive the following error response:

```
  <Error>
    <Type>Sender</Type>
    <Code>SignatureDoesNotMatch</Code>
    <Message>Date in Credential scope does not match YYYYMMDD from ISO-8601 version of date from HTTP: '20120225' != '20120224', from '20120224T213559Z'.</Message>
  </Error>
  <RequestId>9d6ddd2b-5f27-11e1-88f2-4b1b00f424ae</RequestId>
</ErrorResponse>
```

An expired signature can also generate an error response. For example, the following error response was generated due to an expired signature.

```
  <Error>
    <Type>Sender</Type>
    <Code>SignatureDoesNotMatch</Code>
  </Error>
  <RequestId>9d6ddd2b-5f27-11e1-88f2-4b1b00f424ae</RequestId>
</ErrorResponse>
```
Troubleshooting key signing errors

Errors that are caused by an incorrect derivation of the signing key or improper use of cryptography are more difficult to troubleshoot. The error response will tell you that the signature does not match. If you verified that the canonical string and the string to sign are correct, the cause of the signature mismatch is most likely one of the two following issues:

- The secret access key does not match the access key ID that you specified in the Credential parameter.
- There is a problem with your key derivation code.

To check whether the secret key matches the access key ID, you can use your secret key and access key ID with a known working implementation. One way is to use one of the AWS SDKs to write a program that makes a simple request to AWS using the access key ID and secret access key that you want to use.

To check whether your key derivation code is correct, you can compare it to our example derivation code. For more information, see Examples of how to derive a signing key for Signature Version 4 (p. 776).

Service-specific reference for Signature Version 4

To learn more about making and signing HTTP requests in the context of specific AWS services, see the documentation for the following services:

- Amazon API Gateway
- Amazon CloudSearch
- Amazon CloudWatch
- AWS Data Pipeline
- Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon Elastic Transcoder
- Amazon S3 Glacier
- Amazon Mobile Analytics
- Amazon Relational Database Service (Amazon RDS)
- Amazon Simple Email Service (Amazon SES)
- Amazon Simple Queue Service (Amazon SQS)
- Amazon Simple Storage Service (Amazon S3)
- Amazon Simple Workflow Service (Amazon SWF)
- AWS WAF

Signature Version 2 signing process

Important

The AWS SDKs, AWS Command Line Interface (AWS CLI), and other AWS tools sign API requests for you using the access key that you specify when you configure the tool. When you use these tools, you don’t need to learn how to sign API requests. The following documentation explains how to sign API requests, but is only useful if you’re writing your own code to send
**and sign AWS API requests.** We recommend that you use the AWS SDKs or other AWS tools to send API requests, instead of writing your own code. If you must write your own code to sign AWS API requests, use Signature Version 4 (SigV4) (p. 761).

**Supported Regions and services**

You can use Signature Version 2 to sign API requests for some AWS services in some AWS Regions. Otherwise, you must use Signature Version 4 to sign API requests.

**Regions that support Signature Version 2**

- US East (N. Virginia) Region
- US West (N. California) Region
- US West (Oregon) Region
- Europe (Ireland) Region
- Asia Pacific (Tokyo) Region
- Asia Pacific (Singapore) Region
- Asia Pacific (Sydney) Region
- South America (São Paulo) Region

**Services that support Signature Version 2**

- Amazon EC2 Auto Scaling
- AWS CloudFormation
- Amazon CloudWatch
- AWS Elastic Beanstalk
- Amazon Elastic Compute Cloud (Amazon EC2)
- Elastic Load Balancing
- Amazon EMR
- Amazon ElastiCache
- AWS Identity and Access Management (IAM)
- AWS Import/Export
- Amazon Relational Database Service (Amazon RDS)
- Amazon Simple Notification Service (Amazon SNS)
- Amazon Simple Queue Service (Amazon SQS)
- Amazon SimpleDB

**Services deprecating Signature Version 2**

- Amazon Simple Storage Service (Amazon S3) - Amazon S3 Update - SigV2 Deprecation
- Amazon Simple Email Service (Amazon SES)

**Components of a query request for Signature Version 2**

AWS requires that each HTTP or HTTPS Query request formatted for Signature Version 2 contains the following:
Endpoint

Also known as the host part of an HTTP request. This is the DNS name of the computer where you send the Query request. This is different for each AWS Region.

Action

The action you want a web service to perform. This value determines the parameters used in the request.

AWSAccessKeyId

A value distributed by AWS when you sign up for an AWS account.

SignatureMethod

The hash-based protocol used to calculate the signature. This can be either HMAC-SHA1 or HMAC-SHA256 for Signature Version 2.

SignatureVersion

The version of the AWS signature protocol.

Timestamp

The time at which you make the request. Include this in the Query request to help prevent third parties from intercepting your request.

Required and optional parameters

Each action has a set of required and optional parameters that define the API call.

Signature

The calculated value that ensures the signature is valid and has not been tampered.

The following is an example Amazon EMR Query request formatted as an HTTPS GET request.

- The endpoint, elasticmapreduce.amazonaws.com, is the default endpoint and maps to the Region us-east-1.
- The action is DescribeJobFlows, which requests information about one or more job flows.

Note

In the actual Query request, there are no spaces or newline characters. The request is a continuous line of text. The version below is formatted for human readability.

```plaintext
https://elasticmapreduce.amazonaws.com?
&AWSAccessKeyId=AKIAIOSFODNN7EXAMPLE
&Action=DescribeJobFlows
&SignatureMethod=HmacSHA256
&SignatureVersion=2
&Timestamp=2011-10-03T15:19:30
&Version=2009-03-31
&Signature=calculated value
```

How to generate a signature for a Query request

Web service requests are sent across the Internet and are vulnerable to tampering. To check that the request has not been altered, AWS calculates the signature to determine if any of the parameters or parameter values were changed en route. AWS requires a signature as part of every request.

Be sure to URI encode the request. For example, blank spaces in your request should be encoded as %20. Although an unencoded space is normally allowed by the HTTP protocol specification, unencoded
characters create an invalid signature in your Query request. Do not encode spaces as a plus sign (+) as this will cause errors.

The following topics describe the steps needed to calculate a signature using AWS Signature Version 2.

**Task 1: Format the Query request**

Before you can sign the Query request, format the request in a standardized (canonical) format. This is needed because the different ways to format a Query request will result in different HMAC signatures. Format the request in a canonical format before signing. This ensures your application and AWS will calculate the same signature for a request.

To create the string to sign, you concatenate the Query request components. The following example generates the string to sign for the following call to the Amazon EMR API.

```plaintext
https://elasticmapreduce.amazonaws.com?
Action=DescribeJobFlows
&Version=2009-03-31
&AWSAccessKeyId=AKIAIOSFODNN7EXAMPLE
&SignatureVersion=2
&SignatureMethod=HmacSHA256
&Timestamp=2011-10-03T15:19:30
```

**Note**

In the preceding request, the last four parameters (AWSAccessKeyId through Timestamp) are called authentication parameters. They’re required in every Signature Version 2 request. AWS uses them to identify who is sending the request and whether to grant the requested access.

**To create the string to sign**

1. Start with the request method (either GET or POST), followed by a newline character. For human readability, the newline character is represented as \n.

```
GET
```

2. Add the HTTP host header (endpoint) in lowercase, followed by a newline character. The port information is omitted if it is the standard port for the protocol (port 80 for HTTP and port 443 for HTTPS), but included if it is a nonstandard port.

```
elasticmapreduce.amazonaws.com
```

3. Add the URL-encoded version of each path segment of the URI, which is everything between the HTTP host header to the question mark character (?) that begins the query string parameters, followed by a newline character. Don’t encode the forward slash (/) that delimits each path segment.

In this example, if the absolute path is empty, use a forward slash (/).

```
/
```

4. a. Add the query string components, as UTF-8 characters which are URL encoded (hexadecimal characters must be uppercase). You do not encode the initial question mark character (?) in the request. For more information, see RFC 3986.

b. Sort the query string components by byte order. Byte ordering is case sensitive. AWS sorts these components based on the raw bytes.

For example, this is the original order for the query string components.
The query string components would be reorganized as the following:

AWSAccessKeyId=AKIAIOSFODNN7EXAMPLE&Action=DescribeJobFlows&SignatureMethod=HmacSHA256&SignatureVersion=2&Timestamp=2011-10-03T15%3A19%3A30&Version=2009-03-31

5. To construct the finished canonical request, combine all the components from each step. As shown, each component ends with a newline character.

GET
elasticmapreduce.amazonaws.com
/

AWSAccessKeyId=AKIAIOSFODNN7EXAMPLE&Action=DescribeJobFlows&SignatureMethod=HmacSHA256&SignatureVersion=2&Timestamp=2011-10-03T15%3A19%3A30&Version=2009-03-31

Task 2: Calculate the signature

After you've created the canonical string as described in Task 1: Format the Query request (p. 792), calculate the signature by creating a hash-based message authentication code (HMAC) that uses either the HMAC-SHA1 or HMAC-SHA256 protocols. The HMAC-SHA256 is preferred.

In this example, the signature is calculated with the following canonical string and secret key as inputs to a keyed hash function:

- Canonical query string:
Sample secret key:

wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY

The resulting signature must be base-64 encoded.

i9lnKc4PWAt0JJIdXwz9HxZCJdIy6cf%2FMj6vPxyYIs%3D

Add the resulting value to the query request as a `Signature` parameter. When you add this parameter to the request, you must URI encode it just like any other parameter. You can use the signed request in an HTTP or HTTPS call.

https://elasticmapreduce.amazonaws.com?
AWSAccessKeyId=AKIAIOSFODNN7EXAMPLE&Action=DescribeJobFlows&SignatureMethod=HmacSHA256&SignatureVersion=2&Timestamp=2011-10-03T15%3A19%3A30&Version=2009-03-31&Signature=i9lnKc4PWAt0JJIdXwz9HxZCJdIy6cf%2FMj6vPxyYIs%3D

**Note**

You can use temporary security credentials provided by AWS Security Token Service (AWS STS) to sign a request. The process is the same as using long-term credentials, but requests require an additional parameter for the security token.

The following request uses a temporary access key ID and the `SecurityToken` parameter.

**Example Example request with temporary security credentials**

https://sdb.amazonaws.com/
?Action=GetAttributes
&AWSAccessKeyId=access-key-from-AWS Security Token Service
&DomainName=MyDomain
&ItemName=MyItem
&SignatureVersion=2
&SignatureMethod=HmacSHA256
&Timestamp=2010-01-25T15%3A03%3A07-07%3A00
&Version=2009-04-15
&Signature=signature-calculated-using-the-temporary-access-key
&SecurityToken=session-token

For more information, see the following resources:

- The [Amazon EMR Developer Guide](https://docs.aws.amazon.com/emr/latest/developerguide/) has information about Amazon EMR API calls.
- The API documentation for each service has information about requirements and specific parameters for an action.
- The AWS SDKs offer functions to generate Query request signatures. To see an example using the AWS SDK for Java, see [Using the Java SDK to sign a Query request](https://docs.aws.amazon.com/sdkforjava/latest/api/com/amazonaws/services/s3/AWS SDK for Java (p. 795)).

**Troubleshooting request signatures**

This section describes some error codes you might see when you are initially developing code to generate the signature to sign Query requests.
SignatureDoesNotMatch signing error in a web service

The following error response is returned when a web service attempts to validate the request signature by recalculating the signature value and generates a value that does not match the signature you appended to the request. This can occur because the request was altered between the time you sent it and the time it reached a web service endpoint (which is what the signature is designed to detect) or because the signature was calculated improperly. A common cause of the following error message is not properly creating the string to sign, such as forgetting to URL-encode characters such as the colon (:) and the forward slash (/) in Amazon S3 bucket names.

  <Error>
    <Type>Sender</Type>
    <Code>SignatureDoesNotMatch</Code>
    <Message>The request signature we calculated does not match the signature you provided.
    Check your AWS Secret Access Key and signing method.
    Consult the service documentation for details.</Message>
  </Error>
  <RequestId>7589637b-e4b0-11e0-95d9-639f87241c66</RequestId>
</ErrorResponse>

IncompleteSignature signing error in a web service

The following error indicates that signature is missing information or has been improperly formed.

  <Error>
    <Type>Sender</Type>
    <Code>IncompleteSignature</Code>
    <Message>Request must contain a signature that conforms to AWS standards</Message>
  </Error>
  <RequestId>7146d0dd-e48e-11e0-a276-bd10ea0cbb74</RequestId>
</ErrorResponse>

Using the Java SDK to sign a Query request

The following example uses the amazon.webservices.common package of the AWS SDK for Java to generate an AWS Signature Version 2 Query request signature. To do so, it creates an RFC 2104-compliant HMAC signature. For more information about HMAC, see HMAC: Keyed-Hashing for Message Authentication.

Note
Java is used as an example implementation. You can use the programming language of your choice to implement the HMAC algorithm to sign Query requests.

```java
import java.security.SignatureException;
import javax.crypto.Mac;
import javax.crypto.spec.SecretKeySpec;
import com.amazonaws.util.*;

/**
 * This class defines common routines for generating
 * authentication signatures for AWS Platform requests.
 */
public class Signature {
    private static final String HMAC_SHA256_ALGORITHM = "HmacSHA256";
```
/**
   * Computes RFC 2104-compliant HMAC signature.
   * @param data
   * The signed data.
   * @param key
   * The signing key.
   * @return
   * The Base64-encoded RFC 2104-compliant HMAC signature.
   * @throws
   * java.security.SignatureException when signature generation fails
   */
public static String calculateRFC2104HMAC(String data, String key)
throws java.security.SignatureException
{
    String result;
    try {
        // Get an hmac_sha256 key from the raw key bytes.
        SecretKeySpec signingKey = new SecretKeySpec(key.getBytes("UTF-8"),
HMAC_SHA256_ALGORITHM);
        // Get an hmac_sha256 Mac instance and initialize with the signing key.
        Mac mac = Mac.getInstance(HMAC_SHA256_ALGORITHM);
        mac.init(signingKey);
        // Compute the hmac on input data bytes.
        byte[] rawHmac = mac.doFinal(data.getBytes("UTF-8"));
        // Base64-encode the hmac by using the utility in the SDK
        result = BinaryUtils.toBase64(rawHmac);
    } catch (Exception e) {
        throw new SignatureException("Failed to generate HMAC : " + e.getMessage());
    }
    return result;
}
AWS SDK features for Amazon S3 client-side encryption

To use the Amazon S3 client-side encryption feature to encrypt data before uploading to Amazon S3, you must provide a master key to the Amazon S3 encryption client. You can provide a client-side master key or use the AWS Key Management Service (AWS KMS)–managed master keys feature. The AWS KMS–managed master keys feature provides an easy way to create and manage keys that are used to encrypt data. For more information about these features, choose the links provided in the Feature column.

For details about how to use the features for a particular SDK, see the SDK's developer guide.

In the following table, each column indicates whether the AWS Command Line Interface or SDK for a specific language supports the features used in client-side encryption.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Java</th>
<th>.NET</th>
<th>Ruby v2</th>
<th>AWS CLI</th>
<th>Boto3</th>
<th>PHP v3</th>
<th>JavaScrip</th>
<th>Go</th>

For information about the v2 Amazon S3 encryption clients that support client-side encryption, see our blog post about Updates to the Amazon S3 Encryption Client.

For more details about the legacy v1 Amazon S3 encryption client, see the following blog posts.

- Client-Side Data Encryption for Amazon S3 Using the AWS SDK for Java
- Client Side Data Encryption with AWS SDK for .NET and Amazon S3
- Using Client-Side Encryption for Amazon S3 in the AWS SDK for Ruby
- Using the AWS SDK for Go Encryption Client
- Amazon S3 Encryption Client Now Available for C++ Developers

Amazon S3 encryption client cryptographic algorithms

The following table lists the algorithms that each language–specific AWS SDK supports for encrypting keys and data when using the Amazon S3 encryption client.

<table>

For more information about authenticated and encryption-only modes, see the Amazon S3 Client-Side Authenticated Encryption blog post.
Document conventions

The following are the common typographical conventions for AWS technical publications.

**Inline code (for example, commands, operations, parameters, constants, XML elements, and regular expressions)**

Formatting: Text in a monospace font

Example: `java -version`

**Example blocks (for example, sample code and scripts)**

Formatting: Text in a monospace font inside a shaded block

Example:

```
# ls -l /var/www/html/index.html
# date
Wed Jun 21 09:33:42 EDT 2006
```

**Mutually exclusive options**

Formatting: Text separated by vertical bars

Example: `(start | stride | edge)`

**Optional parameters**

Formatting: Text enclosed in square brackets

Example: `[-n, -quiet]`

**Definitions**

Formatting: Text in italics

Example: *Amazon Machine Image* (AMI)

**Technical publications**

Formatting: Text in italics

Example: *Amazon Simple Storage Service User Guide*

**Elements in the user interface**

Formatting: Text in bold

Example: Choose *File, Properties.*

**User input (text that a user types)**

Formatting: Text in a monospace font

Example: For the name, type `my-new-resource`.

**Placeholder text for a required value**

Formatting: Text in *italics*
Example:

```bash
aws ec2 register-image --image-location my-s3-bucket/image.manifest.xml
```
AWS glossary

Numbers and symbols

100-continue

A method that gives a client the ability to see whether a server can accept a request before actually sending it. For large PUT requests, this method can save both time and bandwidth charges.

A

AAD

See additional authenticated data.

Access Analyzer

A feature of AWS Identity and Access Management (IAM) that helps you identify the resources in your organization and accounts, such as Amazon S3 buckets or IAM roles that are shared with an external entity. See Also https://aws.amazon.com/about-aws/whats-new/2019/12/introducing-aws-identity-and-access-management-access-analyzer/.

access control list (ACL)

A document that defines who can access a particular bucket or object. Each bucket and object in Amazon S3 has an ACL. The document defines what each type of user can do, such as write and read permissions.

access identifiers

See credentials.

access key

The combination of an access key ID (for example, AKIAIOSFODNN7EXAMPLE) and a secret access key (for example, wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY). You use access keys to sign API requests that you make to AWS.

access key ID

A unique identifier that's associated with a secret access key; the access key ID and secret access key are used together to sign programmatic AWS requests cryptographically.

Version 1.0

801
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>access key rotation</td>
<td>A method to increase security by changing the AWS access key ID. You can use this method to retire an old key at your discretion.</td>
</tr>
<tr>
<td>access policy language</td>
<td>A language for writing documents (specifically, policies (p. 843)) that specify who can access a particular AWS resource (p. 848) and under what conditions.</td>
</tr>
<tr>
<td>account</td>
<td>A formal relationship with AWS that's associated with all of the following:</td>
</tr>
<tr>
<td></td>
<td>• The owner email address and password</td>
</tr>
<tr>
<td></td>
<td>• The control of resources created under its umbrella</td>
</tr>
<tr>
<td></td>
<td>• Payment for the AWS activity related to those resources</td>
</tr>
<tr>
<td>The AWS account has permission to do anything and everything with all the AWS account resources. This is in contrast to a user (p. 857), which is an entity contained within the account.</td>
<td></td>
</tr>
<tr>
<td>account activity</td>
<td>A webpage showing your month-to-date AWS usage and costs. The account activity page is located at <a href="https://aws.amazon.com/account-activity/">https://aws.amazon.com/account-activity/</a>.</td>
</tr>
<tr>
<td>ACL</td>
<td>See access control list (ACL).</td>
</tr>
<tr>
<td>ACM</td>
<td>See the section called “ACM”.</td>
</tr>
<tr>
<td>ACM PCA</td>
<td>See the section called “ACM Private CA”.</td>
</tr>
<tr>
<td>ACM Private CA</td>
<td>See the section called “ACM Private CA”.</td>
</tr>
<tr>
<td>action</td>
<td>An API function. Also called operation or call. The activity the principal (p. 844) has permission to perform. The action is B in the statement “A has permission to do B to C where D applies.” For example, Jane sends a request to Amazon SQS (p. 809) with Action=ReceiveMessage.</td>
</tr>
<tr>
<td>Amazon CloudWatch</td>
<td>Amazon CloudWatch (p. 803): The response initiated by the change in an alarm's state (for example, from OK to ALARM). The state change might be caused by a metric reaching the alarm threshold, or by a SetAlarmState request. Each alarm can have one or more actions assigned to each state. Actions are performed once each time the alarm changes to a state that has an action assigned, such as an Amazon Simple Notification Service (p. 808) notification, the running of an Amazon EC2 Auto Scaling (p. 804) policy (p. 843), or an Amazon EC2 (p. 804) instance (p. 834) stop/terminate action.</td>
</tr>
<tr>
<td>active trusted key groups</td>
<td>A list showing each of the trusted key groups (p. 857), and the IDs of the public keys in each key group, that are active for a distribution in Amazon CloudFront. CloudFront can use the public keys in these key groups to verify the signatures of CloudFront signed URLs and signed cookies.</td>
</tr>
<tr>
<td>active trusted signers</td>
<td>See active trusted key groups (p. 802).</td>
</tr>
<tr>
<td>additional authenticated data</td>
<td>Information that's checked for integrity but not encrypted, such as headers or other contextual metadata.</td>
</tr>
<tr>
<td>administrative suspension</td>
<td>Amazon EC2 Auto Scaling (p. 804) might suspend processes for Auto Scaling group (p. 811) that repeatedly fail to launch instances. Auto Scaling groups that most commonly experience administrative suspension have zero running instances, have been trying to launch instances for more than 24 hours, and have not succeeded in that time.</td>
</tr>
</tbody>
</table>
| alarm                         | An item that watches a single metric over a specified time period and starts an Amazon SNS (p. 808) topic (p. 856) or an Amazon EC2 Auto Scaling (p. 804)
policy (p. 843) if the value of the metric crosses a threshold value over a predetermined number of time periods.

allow One of two possible outcomes (the other is deny (p. 826)) when an IAM (p. 814) access policy (p. 843) is evaluated. When a user makes a request to AWS, AWS evaluates the request based on all permissions that apply to the user and then returns either allow or deny.

Amazon API Gateway A fully managed service that makes it easy for developers to create, publish, maintain, monitor, and secure APIs at any scale. See Also https://aws.amazon.com/api-gateway.

Amazon AppStream 2.0 A fully managed, secure service for streaming desktop applications to users without rewriting those applications. See Also https://aws.amazon.com/appstream/.

Amazon Athena An interactive query service that makes it easy to analyze data in Amazon S3 using ANSI SQL. Athena is serverless, so there's no infrastructure to manage. Athena scales automatically and is simple to use, so you can start analyzing your datasets within seconds. See Also https://aws.amazon.com/athena/.

Amazon Aurora A fully managed MySQL-compatible relational database engine that combines the speed and availability of commercial databases with the simplicity and cost-effectiveness of open-source databases. See Also https://aws.amazon.com/rds/aurora/.

Amazon Chime A secure, real-time, unified communications service that transforms meetings by making them more efficient and easier to conduct. See Also https://aws.amazon.com/chime/.

Amazon Cloud Directory (Cloud Directory) A service that provides a highly scalable directory store for your application's multihierarchical data. See Also https://aws.amazon.com/cloud-directory/.

Amazon CloudFront An AWS content delivery service that helps you improve the performance, reliability, and availability of your websites and applications. See Also https://aws.amazon.com/cloudfront.

Amazon CloudSearch A fully managed service in the AWS Cloud that makes it easy to set up, manage, and scale a search solution for your website or application.

Amazon CloudWatch A web service that you can use to monitor and manage various metrics, and configure alarm actions based on data from those metrics. See Also https://aws.amazon.com/cloudwatch.

Amazon CloudWatch Events A web service that you can use to deliver a timely stream of system events that describe changes in AWS resource (p. 848)s to AWS Lambda (p. 815) functions, streams in Amazon Kinesis Data Streams (p. 806), Amazon Simple Notification Service (p. 808) topics, or built-in targets. See Also https://aws.amazon.com/cloudwatch.

Amazon CloudWatch Logs A web service for monitoring and troubleshooting your systems and applications from your existing system, application, and custom log files. You can send your existing log files to CloudWatch Logs and monitor these logs in near-real time. See Also https://aws.amazon.com/cloudwatch.

Amazon Cognito A web service that makes it easy to save mobile user data, such as app preferences or game state, in the AWS Cloud without writing any backend
code or managing any infrastructure. Amazon Cognito offers mobile identity management and data synchronization across devices. See Also https://aws.amazon.com/cognito/.

Amazon Comprehend
A natural language processing (NLP) service that uses machine learning to find insights and relationships in text. See Also https://aws.amazon.com/comprehend/.

Amazon Comprehend Medical
A HIPAA-eligible natural language processing (NLP) service that uses machine learning to extract health data from medical text. See Also https://aws.amazon.com/comprehend/medical/.

Amazon Connect
A service solution that offers easy, self-service configuration and provides dynamic, personal, and natural customer engagement at any scale. See Also https://aws.amazon.com/connect/.

Amazon Corretto
A no-cost, multiplatform, production-ready distribution of the Open Java Development Kit (OpenJDK). See Also https://aws.amazon.com/corretto/.

Amazon Detective
A service that collects log data from your AWS resources to analyze and identify the root cause of security findings or suspicious activities. The Detective behavior graph provides visualizations to help you to determine the nature and extent of possible security issues and conduct an efficient investigation. See Also https://aws.amazon.com/detective/.

Amazon DocumentDB (with MongoDB compatibility)
A managed database service that you can use to set up, operate, and scale MongoDB-compatible databases in the cloud. See Also https://aws.amazon.com/documentdb/.

Amazon DynamoDB
A fully managed NoSQL database service that provides fast and predictable performance with seamless scalability. See Also https://aws.amazon.com/dynamodb/.

Amazon DynamoDB Encryption Client
A software library that helps you protect your table data before you send it to Amazon DynamoDB (p. 804).

Amazon DynamoDB Storage Backend for Titan
A storage backend for the Titan graph database implemented on top of Amazon DynamoDB. Titan is a scalable graph database optimized for storing and querying graphs. See Also https://aws.amazon.com/dynamodb/.

Amazon DynamoDB Streams
An AWS service that captures a time-ordered sequence of item-level modifications in any Amazon DynamoDB table, and stores this information in a log for up to 24 hours. Applications can access this log and view the data items as they appeared before and after they were modified, in near real time. See Also https://aws.amazon.com/dynamodb/.

Amazon EBS-backed AMI
A type of Amazon Machine Image (AMI) (p. 807) whose instance (p. 834)s use an Amazon EBS (p. 805) volume (p. 859) as their root device. Compare this with instances launched from instance store-backed AMI (p. 834)s, which use the instance store (p. 834) as the root device.

Amazon EC2
A web service for launching and managing Linux/UNIX and Windows Server instance (p. 834)s in Amazon's data centers. See Also Amazon Elastic Compute Cloud (Amazon EC2), https://aws.amazon.com/ec2.

Amazon EC2 Auto Scaling
A web service designed to launch or terminate instance (p. 834)s automatically based on user-defined policies (p. 843), schedules, and health check (p. 832)s.
<table>
<thead>
<tr>
<th>Service</th>
<th>Description</th>
<th>See Also</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Elastic Store (Amazon EBS)</td>
<td>A service that provides block level storage volume (p. 859)s for use with EC2 instance (p. 827)s.</td>
<td>See Also <a href="https://aws.amazon.com/ebs">https://aws.amazon.com/ebs</a>.</td>
</tr>
<tr>
<td>Amazon Elastic Compute Cloud (Amazon EC2)</td>
<td>A web service for launching and managing Linux/UNIX and Windows Server instance (p. 834)s in Amazon's data centers.</td>
<td>See Also <a href="https://aws.amazon.com/ec2">https://aws.amazon.com/ec2</a>.</td>
</tr>
<tr>
<td>Amazon Elastic Container Registry (Amazon ECR)</td>
<td>A fully managed Docker container registry that makes it easy for developers to store, manage, and deploy Docker container images. Amazon ECR is integrated with Amazon Elastic Container Service (Amazon ECS) (p. 805) and AWS Identity and Access Management (IAM) (p. 814).</td>
<td>See Also <a href="https://aws.amazon.com/ecr">https://aws.amazon.com/ecr</a>.</td>
</tr>
<tr>
<td>Amazon Elastic Container Service (Amazon ECS)</td>
<td>A highly scalable, fast, container (p. 822) management service that makes it easy to run, stop, and manage Docker containers on a cluster (p. 821) of EC2 instance (p. 827)s.</td>
<td>See Also <a href="https://aws.amazon.com/ecs">https://aws.amazon.com/ecs</a>.</td>
</tr>
<tr>
<td>Amazon Elastic File System (Amazon EFS)</td>
<td>A file storage service for EC2 (p. 804) instance (p. 834)s. Amazon EFS is easy to use and provides a simple interface with which you can create and configure file systems. Amazon EFS storage capacity grows and shrinks automatically as you add and remove files.</td>
<td>See Also <a href="https://aws.amazon.com/efs/">https://aws.amazon.com/efs/</a>.</td>
</tr>
<tr>
<td>Amazon Elastic Kubernetes Service (Amazon EKS)</td>
<td>A managed service that simplifies running Kubernetes on AWS without your needing to stand up or maintain your own Kubernetes control plane.</td>
<td>See Also <a href="https://aws.amazon.com/eks/">https://aws.amazon.com/eks/</a>.</td>
</tr>
<tr>
<td>Amazon Elastic Transcoder</td>
<td>A cloud-based media transcoding service. Elastic Transcoder is a highly scalable tool for converting (or transcoding) media files from their source format into versions that play on devices such as smartphones, tablets, and PCs.</td>
<td>See Also <a href="https://aws.amazon.com/elastictranscoder/">https://aws.amazon.com/elastictranscoder/</a>.</td>
</tr>
<tr>
<td>Amazon ElastiCache</td>
<td>A web service that simplifies deploying, operating, and scaling an in-memory cache in the cloud. The service improves the performance of web applications by providing information retrieval from fast, managed, in-memory caches, instead of relying entirely on slower disk-based databases.</td>
<td>See Also <a href="https://aws.amazon.com/elasticache/">https://aws.amazon.com/elasticache/</a>.</td>
</tr>
<tr>
<td>Amazon OpenSearch Service (OpenSearch Service)</td>
<td>An AWS managed service for deploying, operating, and scaling OpenSearch, an open-source search and analytics engine, in the AWS Cloud. Amazon OpenSearch Service (OpenSearch Service) also offers security options, high availability, data durability, and direct access to the OpenSearch API.</td>
<td>See Also <a href="https://aws.amazon.com/elasticsearch-service">https://aws.amazon.com/elasticsearch-service</a>.</td>
</tr>
<tr>
<td>Amazon EMR</td>
<td>A web service that makes it easy to process large amounts of data efficiently. Amazon EMR uses Hadoop (p. 832) processing combined with several AWS products to do such tasks as web indexing, data mining, log file analysis, machine learning, scientific simulation, and data warehousing.</td>
<td>See Also <a href="https://aws.amazon.com/elasticmapreduce/">https://aws.amazon.com/elasticmapreduce/</a>.</td>
</tr>
<tr>
<td>Amazon EventBridge</td>
<td>A serverless event bus service that you can use to connect your applications with data from a variety of sources and routes that data to targets such as AWS Lambda. You can set up routing rules to determine where to send your data to build application architectures that react in real time to all of your data sources.</td>
<td>See Also <a href="https://aws.amazon.com/eventbridge/">https://aws.amazon.com/eventbridge/</a>.</td>
</tr>
</tbody>
</table>
Amazon Forecast
A fully managed service that uses statistical and machine learning algorithms to produce highly accurate time-series forecasts. See Also https://aws.amazon.com/forecast/.

Amazon GameLift
A managed service for deploying, operating, and scaling session-based multiplayer games. See Also https://aws.amazon.com/gamelift/.

Amazon GuardDuty
A continuous security monitoring service. Amazon GuardDuty can help to identify unexpected and potentially unauthorized or malicious activity in your AWS environment. See Also https://aws.amazon.com/guardduty/.

Amazon Inspector
An automated security assessment service that helps improve the security and compliance of applications deployed on AWS. Amazon Inspector automatically assesses applications for vulnerabilities or deviations from best practices. After performing an assessment, Amazon Inspector produces a detailed report with prioritized steps for remediation. See Also https://aws.amazon.com/inspector/.

Amazon Kinesis
A platform for streaming data on AWS. Kinesis offers services that simplify the loading and analysis of streaming data. See Also https://aws.amazon.com/kinesis/.

Amazon Kinesis Data Firehose
A fully managed service for loading streaming data into AWS. Kinesis Data Firehose can capture and automatically load streaming data into Amazon S3 (p. 809) and Amazon Redshift (p. 808), enabling near real-time analytics with existing business intelligence tools and dashboards. Kinesis Data Firehose automatically scales to match the throughput of your data and requires no ongoing administration. It can also batch, compress, and encrypt the data before loading it. See Also https://aws.amazon.com/kinesis/firehose/.

Amazon Kinesis Data Streams
A web service for building custom applications that process or analyze streaming data for specialized needs. Amazon Kinesis Data Streams can continuously capture and store terabytes of data per hour from hundreds of thousands of sources. See Also https://aws.amazon.com/kinesis/strean/.

Amazon Lightsail
Lightsail is designed to be the easiest way to launch and manage a virtual private server with AWS. Lightsail offers bundled plans that include everything you need to deploy a virtual private server, for a low monthly rate. See Also https://aws.amazon.com/lightsail/.

Amazon Lookout for Equipment
A machine learning service that uses data from sensors mounted on factory equipment to detect abnormal behavior so you can take action before machine failures occur. See Also https://aws.amazon.com/lookout-for-equipment/.

Amazon Lookout for Vision
A machine learning service that uses computer vision (CV) to find defects in industrial products. Amazon Lookout for Vision can identify missing components in an industrial product, damage to vehicles or structures, irregularities in production lines, and even minuscule defects in silicon wafers—or any other physical item where quality is important. See Also https://aws.amazon.com/lookout-for-vision/.

Amazon Lumberyard
A cross-platform, 3D game engine for creating high-quality games. You can connect games to the compute and storage of the AWS Cloud and engage fans on Twitch.
### Amazon Machine Image (AMI)
An encrypted machine image stored in Amazon Elastic Block Store (Amazon EBS) (p. 805) or Amazon Simple Storage Service (p. 809). AMIs function similar to a template of a computer's root drive. They contain the operating system and can also include software and layers of your application, such as database servers, middleware, and web servers.

### Amazon Machine Learning
A cloud-based service that creates machine learning (ML) models by finding patterns in your data, and uses these models to process new data and generate predictions.
See Also http://aws.amazon.com/machine-learning/.

### Amazon Macie
A security service that uses machine learning to automatically discover, classify, and protect sensitive data in AWS.
See Also http://aws.amazon.com/macie/.

### Amazon Managed Blockchain
A fully managed service for creating and managing scalable blockchain networks using popular open source frameworks.
See Also http://aws.amazon.com/managed-blockchain/.

### Amazon Managed Grafana
A fully managed and secure data visualization service that you can use to instantly query, correlate, and visualize operational metrics, logs, and traces from multiple data sources.
See Also https://aws.amazon.com/grafana/.

### Amazon Managed Service for Prometheus
A service that provides highly available, secure, and managed monitoring for your containers.
See Also https://aws.amazon.com/prometheus/.

### Amazon ML
See Amazon Machine Learning.

### Amazon Mobile Analytics (Mobile Analytics)
A service for collecting, visualizing, understanding, and extracting mobile app usage data at scale.
See Also https://aws.amazon.com/mobileanalytics.

### Amazon Monitron
An end-to-end system that uses machine learning (ML) to detect abnormal behavior in industrial machinery. Use Amazon Monitron to implement predictive maintenance and reduce unplanned downtime.
See Also https://aws.amazon.com/monitron/.

### Amazon MQ
A managed message broker service for Apache ActiveMQ that makes it easy to set up and operate message brokers in the cloud.
See Also https://aws.amazon.com/amazon-mq/.

### Amazon Neptune
A managed graph database service that you can use to build and run applications that work with highly connected datasets. Neptune supports the popular graph query languages Apache TinkerPop Gremlin and W3C's SPARQL, enabling you to build queries that efficiently navigate highly connected datasets.
See Also https://aws.amazon.com/neptune/.

### Amazon Personalize
An artificial intelligence service for creating individualized product and content recommendations.
See Also https://aws.amazon.com/personalize/.

### Amazon Polly
A text-to-speech (TTS) service that turns text into natural-sounding human speech. Amazon Polly provides dozens of lifelike voices across a broad set of languages so that you can build speech-enabled applications that work in many different countries.
See Also https://aws.amazon.com/polly/.

Amazon QuickSight  A fast, cloud-powered business analytics service that makes it easy to build visualizations, perform analysis, and quickly get business insights from your data. See Also https://aws.amazon.com/quicksight/.

Amazon Rekognition  A machine learning service that identifies objects, people, text, scenes, and activities, including inappropriate content, in either image or video files. With Amazon Rekognition Custom Labels, you can create a customized ML model that detects objects and scenes specific to your business in images. See Also https://aws.amazon.com/rekognition/.

Amazon Redshift  A fully managed, petabyte-scale data warehouse service in the cloud. With Amazon Redshift, you can analyze your data using your existing business intelligence tools. See Also https://aws.amazon.com/redshift/.

Amazon Relational Database Service (Amazon RDS)  A web service that makes it easier to set up, operate, and scale a relational database in the cloud. It provides cost-efficient, resizable capacity for an industry-standard relational database and manages common database administration tasks. See Also https://aws.amazon.com/rds.

Amazon Resource Name (ARN)  A standardized way to refer to an AWS resource (p. 848) (for example, arn:aws:iam::123456789012:user/division_abc/subdivision_xyz/Bob).

Amazon Route 53  A web service you can use to create a new DNS service or to migrate your existing DNS service to the cloud. See Also https://aws.amazon.com/route53.

Amazon S3  Storage for the internet. You can use it to store and retrieve any amount of data at any time, from anywhere on the web. See Also Amazon Simple Storage Service (Amazon S3), https://aws.amazon.com/s3.

Amazon S3-Backed AMI  See instance store-backed AMI.

Amazon S3 Glacier  A secure, durable, and low-cost storage service for data archiving and long-term backup. You can reliably store large or small amounts of data for significantly less than on-premises solutions. S3 Glacier is optimized for infrequently accessed data, where a retrieval time of several hours is suitable. See Also https://aws.amazon.com/glacier/.

AWS Security Hub  A service that provides a comprehensive view of the security state of your AWS resources. Security Hub collects security data from AWS accounts and services and helps you analyze your security trends to identify and prioritize the security issues across your AWS environment. See Also https://aws.amazon.com/security-hub/.

Amazon Silk  A next-generation web browser available only on Fire OS tablets and phones. Built on a split architecture that divides processing between the client and the AWS Cloud, Amazon Silk is designed to create a faster, more responsive mobile browsing experience.

Amazon Simple Email Service (Amazon SES)  An easy-to-use, cost-effective email solution for applications. See Also https://aws.amazon.com/ses.

Amazon Simple Notification Service (Amazon SNS)  A web service that applications, users, and devices can use to instantly send and receive notifications from the cloud. See Also https://aws.amazon.com/sns.
<p>| <strong>Amazon Simple Queue Service (Amazon SQS)</strong> | Reliable and scalable hosted queues for storing messages as they travel between computers. See Also <a href="https://aws.amazon.com/sqs">https://aws.amazon.com/sqs</a>. |
| <strong>Amazon Simple Storage Service (Amazon S3)</strong> | Storage for the internet. You can use it to store and retrieve any amount of data at any time, from anywhere on the web. See Also <a href="https://aws.amazon.com/s3">https://aws.amazon.com/s3</a>. |
| <strong>Amazon Simple Workflow Service (Amazon SWF)</strong> | A fully managed service that helps developers build, run, and scale background jobs that have parallel or sequential steps. Amazon SWF functions similar to a state tracker and task coordinator in the AWS Cloud. See Also <a href="https://aws.amazon.com/swf/">https://aws.amazon.com/swf/</a>. |
| <strong>Amazon Sumerian</strong> | A set of tools for creating and running high-quality 3D, augmented reality (AR), and virtual reality (VR) applications on the web. See Also <a href="https://aws.amazon.com/sumerian/">https://aws.amazon.com/sumerian/</a>. |
| <strong>Amazon Textract</strong> | A service that automatically extracts text and data from scanned documents. Amazon Textract goes beyond simple optical character recognition (OCR) to also identify the contents of fields in forms and information stored in tables. See Also <a href="https://aws.amazon.com/textract/">https://aws.amazon.com/textract/</a>. |
| <strong>Amazon Transcribe</strong> | A machine learning service that uses automatic speech recognition (ASR) to quickly and accurately convert speech to text. See Also <a href="https://aws.amazon.com/transcribe/">https://aws.amazon.com/transcribe/</a>. |
| <strong>Amazon Transcribe Medical</strong> | An automatic speech recognition (ASR) service for adding medical speech-to-text capabilities to voice-enabled clinical documentation applications. See Also <a href="https://aws.amazon.com/transcribe/medical/">https://aws.amazon.com/transcribe/medical/</a>. |
| <strong>Amazon Translate</strong> | A neural machine translation service that delivers fast, high-quality, and affordable language translation. See Also <a href="https://aws.amazon.com/translate/">https://aws.amazon.com/translate/</a>. |
| <strong>Amazon Virtual Private Cloud (Amazon VPC)</strong> | A web service for provisioning a logically isolated section of the AWS Cloud virtual network that you define. You control your virtual networking environment, including selection of your own IP address range, creation of subnet (p. 854)s, and configuration of route table (p. 849)s and network gateways. See Also <a href="https://aws.amazon.com/vpc">https://aws.amazon.com/vpc</a>. |
| <strong>Amazon VPC</strong> | See Amazon Virtual Private Cloud (Amazon VPC). |
| <strong>Amazon Web Services (AWS)</strong> | An infrastructure web services platform in the cloud for companies of all sizes. See Also <a href="https://aws.amazon.com/what-is-cloud-computing/">https://aws.amazon.com/what-is-cloud-computing/</a>. |
| <strong>Amazon WorkDocs</strong> | A managed, secure enterprise document storage and sharing service with administrative controls and feedback capabilities. See Also <a href="https://aws.amazon.com/workdocs/">https://aws.amazon.com/workdocs/</a>. |
| <strong>Amazon WorkLink</strong> | A cloud-based service that provides secure access to internal websites and web apps from mobile devices. See Also <a href="https://aws.amazon.com/worklink/">https://aws.amazon.com/worklink/</a>. |
| <strong>Amazon WorkMail</strong> | A managed, secure business email and calendar service with support for existing desktop and mobile email clients. See Also <a href="https://aws.amazon.com/workmail/">https://aws.amazon.com/workmail/</a>. |
| <strong>Amazon WorkSpaces</strong> | A managed, secure desktop computing service for provisioning cloud-based desktops and providing users access to documents, applications, and resource (p. 848) s from supported devices. |</p>
<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Amazon WorkSpaces Application Manager (Amazon WAM)</strong></td>
<td>A web service for deploying and managing applications for WorkSpaces. Amazon WAM accelerates software deployment, upgrades, patching, and retirement by packaging Windows desktop applications into virtualized application containers. See Also <a href="https://aws.amazon.com/workspaces/applicationmanager">https://aws.amazon.com/workspaces/applicationmanager</a>.</td>
</tr>
<tr>
<td><strong>AMI</strong></td>
<td>See Amazon Machine Image (AMI).</td>
</tr>
<tr>
<td><strong>analysis scheme</strong></td>
<td>Amazon CloudSearch (p. 803): Language-specific text analysis options that are applied to a text field to control stemming and configure stopwords and synonyms.</td>
</tr>
<tr>
<td><strong>application</strong></td>
<td>AWS Elastic Beanstalk (p. 813): A logical collection of components, including environments, versions, and environment configurations. An application is conceptually similar to a folder. AWS CodeDeploy (p. 812): A name that uniquely identifies the application to be deployed. AWS CodeDeploy uses this name to ensure the correct combination of revision, deployment configuration, and deployment group are referenced during a deployment.</td>
</tr>
<tr>
<td><strong>Application Auto Scaling</strong></td>
<td>A web service that you can use to configure automatic scaling for AWS resources beyond Amazon EC2, such as Amazon ECS services, Amazon EMR clusters, and DynamoDB tables. See Also <a href="https://aws.amazon.com/autoscaling/">https://aws.amazon.com/autoscaling/</a>.</td>
</tr>
<tr>
<td><strong>Application Billing</strong></td>
<td>The location where your customers manage the Amazon DevPay products they've purchased. The web address is <a href="http://www.amazon.com/dp-applications">http://www.amazon.com/dp-applications</a>.</td>
</tr>
<tr>
<td><strong>application revision</strong></td>
<td>AWS CodeDeploy (p. 812): An archive file containing source content—such as source code, webpages, executable files, and deployment scripts—along with an application specification file (p. 810). Revisions are stored in Amazon S3 (p. 809) bucket (p. 819)s or GitHub (p. 831) repositories. For Amazon S3, a revision is uniquely identified by its Amazon S3 object key and its ETag, version, or both. For GitHub, a revision is uniquely identified by its commit ID.</td>
</tr>
<tr>
<td><strong>application specification file</strong></td>
<td>AWS CodeDeploy (p. 812): A YAML-formatted file used to map the source files in an application revision to destinations on the instance. The file is also used to specify custom permissions for deployed files and specify scripts to be run on each instance at various stages of the deployment process.</td>
</tr>
<tr>
<td><strong>application version</strong></td>
<td>AWS Elastic Beanstalk (p. 813): A specific, labeled iteration of an application that represents a functionally consistent set of deployable application code. A version points to an Amazon S3 (p. 809) object (a JAVA WAR file) that contains the application code.</td>
</tr>
<tr>
<td><strong>AppSpec file</strong></td>
<td>See application specification file.</td>
</tr>
<tr>
<td><strong>ARN</strong></td>
<td>See Amazon Resource Name (ARN).</td>
</tr>
<tr>
<td><strong>artifact</strong></td>
<td>AWS CodePipeline (p. 812): A copy of the files or changes that will be worked upon by the pipeline.</td>
</tr>
<tr>
<td><strong>asymmetric encryption</strong></td>
<td>Encryption (p. 828) that uses both a public key and a private key.</td>
</tr>
<tr>
<td><strong>asynchronous bounce</strong></td>
<td>A type of bounce (p. 819) that occurs when a receiver (p. 846) initially accepts an email message for delivery and then subsequently fails to deliver it.</td>
</tr>
<tr>
<td><strong>atomic counter</strong></td>
<td>DynamoDB: A method of incrementing or decrementing the value of an existing attribute without interfering with other write requests.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>----------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>attribute</td>
<td>A fundamental data element, something that doesn’t need to be broken down any further. In DynamoDB, attributes are similar in many ways to fields or columns in other database systems.</td>
</tr>
<tr>
<td>AUC</td>
<td>Area Under a Curve. An industry-standard metric to evaluate the quality of a binary classification machine learning model. AUC measures the ability of the model to predict a higher score for positive examples, those that are “correct,” than for negative examples, those that are “incorrect.” The AUC metric returns a decimal value from 0 to 1. AUC values near 1 indicate an ML model that’s highly accurate.</td>
</tr>
<tr>
<td>Aurora</td>
<td>See the section called “Amazon Aurora.”</td>
</tr>
<tr>
<td>authenticated encryption</td>
<td>Encryption (p. 828) that provides confidentiality, data integrity, and authenticity assurances of the encrypted data.</td>
</tr>
<tr>
<td>authentication</td>
<td>The process of proving your identity to a system.</td>
</tr>
<tr>
<td>Auto Scaling group</td>
<td>A representation of multiple EC2 instance (p. 827)s that share similar characteristics, and that are treated as a logical grouping for the purposes of instance scaling and management.</td>
</tr>
<tr>
<td>Availability Zone</td>
<td>A distinct location within a Region (p. 847) that’s insulated from failures in other Availability Zones, and provides inexpensive, low-latency network connectivity to other Availability Zones in the same Region.</td>
</tr>
<tr>
<td>AWS</td>
<td>See Amazon Web Services (AWS).</td>
</tr>
<tr>
<td>AWS Application Discovery Service</td>
<td>A web service that helps you plan to migrate to AWS by identifying IT assets in a data center—including servers, virtual machines, applications, application dependencies, and network infrastructure. See Also <a href="https://aws.amazon.com/about-aws/whats-new/2016/04/aws-application-discovery-service/">https://aws.amazon.com/about-aws/whats-new/2016/04/aws-application-discovery-service/</a>.</td>
</tr>
<tr>
<td>AWS AppSync</td>
<td>An enterprise level, fully managed GraphQL service with real-time data synchronization and offline programming features. See Also <a href="https://aws.amazon.com/appsync/">https://aws.amazon.com/appsync/</a>.</td>
</tr>
<tr>
<td>AWS Auto Scaling</td>
<td>A fully managed service that you can use to quickly discover the scalable AWS resources that are part of your application and configure dynamic scaling. See Also <a href="https://aws.amazon.com/autoscaling/">https://aws.amazon.com/autoscaling/</a>.</td>
</tr>
<tr>
<td>AWS Backup</td>
<td>A managed backup service that you can use to centralize and automate the backup of data across AWS services in the cloud and on premises. See Also <a href="https://aws.amazon.combackup/">https://aws.amazon.combackup/</a>.</td>
</tr>
<tr>
<td>AWS Billing and Cost Management</td>
<td>The AWS Cloud computing model where you pay for services on demand and use as much or as little as you need. While resource (p. 848)s are active under your account, you pay for the cost of allocating those resources. You also pay for any incidental usage associated with those resources, such as data transfer or allocated storage. See Also <a href="https://aws.amazon.com/billing/new-user-faqs/">https://aws.amazon.com/billing/new-user-faqs/</a>.</td>
</tr>
<tr>
<td>AWS Blockchain Templates</td>
<td>A service for creating and deploying open-source blockchain frameworks on AWS, such as Ethereum and Hyperledger Fabric. See Also <a href="https://aws.amazon.com/blockchain/templates/">https://aws.amazon.com/blockchain/templates/</a>.</td>
</tr>
<tr>
<td>Service Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>AWS Cloud Development Kit (CDK)</td>
<td>An open-source software development framework for defining your cloud infrastructure in code and provisioning it through AWS CloudFormation.</td>
</tr>
<tr>
<td>AWS Cloud Map</td>
<td>A service that you use to create and maintain a map of the backend services and resources that your applications depend on. With AWS Cloud Map, you can name and discover your AWS Cloud resources.</td>
</tr>
<tr>
<td>AWS CloudFormation</td>
<td>A service for writing or changing templates that create and delete related AWS resources together as a unit.</td>
</tr>
<tr>
<td>AWS CloudHSM</td>
<td>A web service that helps you meet corporate, contractual, and regulatory compliance requirements for data security by using dedicated hardware security module (HSM) appliances within the AWS Cloud.</td>
</tr>
<tr>
<td>AWS CloudTrail</td>
<td>A web service that records AWS API calls for your account and delivers log files to you. The recorded information includes the identity of the API caller, the time of the API call, the source IP address of the API caller, the request parameters, and the response elements returned by the AWS service.</td>
</tr>
<tr>
<td>AWS CodeBuild</td>
<td>A fully managed continuous integration service that compiles source code, runs tests, and produces software packages that are ready to deploy.</td>
</tr>
<tr>
<td>AWS CodeCommit</td>
<td>A fully managed source control service that makes it easy for companies to host secure and highly scalable private Git repositories.</td>
</tr>
<tr>
<td>AWS CodeDeploy</td>
<td>A service that automates code deployments to any instance, including EC2 instance (p. 827) and instance (p. 834) running on-premises.</td>
</tr>
<tr>
<td>AWS CodeDeploy agent</td>
<td>A software package that, when installed and configured on an instance, enables that instance to be used in CodeDeploy deployments.</td>
</tr>
<tr>
<td>AWS Command Line Interface (AWS CLI)</td>
<td>A unified downloadable and configurable tool for managing AWS services. Control multiple AWS services from the command line and automate them through scripts.</td>
</tr>
<tr>
<td>AWS Service</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>AWS Config</td>
<td>A fully managed service that provides an AWS resource inventory, configuration history, and configuration change notifications for better security and governance. You can create rules that automatically check the configuration of AWS resources that AWS Config records.</td>
</tr>
<tr>
<td>AWS Database Migration Service</td>
<td>A web service that can help you migrate data to and from many widely used commercial and open-source databases.</td>
</tr>
<tr>
<td>AWS Data Pipeline</td>
<td>A web service for processing and moving data between different AWS compute and storage services, as well as on-premises data sources, at specified intervals.</td>
</tr>
<tr>
<td>AWS Device Farm (Device Farm)</td>
<td>An app testing service that allows developers to test Android, iOS, and Fire OS devices on real, physical phones and tablets that are hosted by AWS.</td>
</tr>
<tr>
<td>AWS Direct Connect</td>
<td>A web service that simplifies establishing a dedicated network connection from your premises to AWS. Using AWS Direct Connect, you can establish private connectivity between AWS and your data center, office, or colocation environment.</td>
</tr>
<tr>
<td>AWS Directory Service</td>
<td>A managed service for connecting your AWS resource(s) to an existing on-premises Microsoft Active Directory or to set up and operate a new, standalone directory in the AWS Cloud.</td>
</tr>
<tr>
<td>AWS Elemental MediaConnect</td>
<td>A service that broadcasters and other premium video providers can reliably use to ingest live video into the AWS Cloud and distribute it to multiple destinations inside or outside the AWS Cloud.</td>
</tr>
<tr>
<td>AWS Elemental MediaLive</td>
<td>A video service that you can use to create live outputs for broadcast and streaming delivery.</td>
</tr>
<tr>
<td>AWS Elemental MediaPackage</td>
<td>A just-in-time packaging and origination service that you can use to format highly secure and reliable live outputs for a variety of devices.</td>
</tr>
<tr>
<td>AWS Elemental MediaStore</td>
<td>A storage service optimized for media that provides the performance, consistency, and low latency required to deliver live and on-demand video content at scale.</td>
</tr>
<tr>
<td>AWS Elemental MediaTailor</td>
<td>A video service that you can use to serve targeted ads to viewers while maintaining broadcast quality in over-the-top (OTT) video applications.</td>
</tr>
<tr>
<td>AWS Encryption SDK</td>
<td>A client-side encryption library designed to make it easy for everyone to encrypt and decrypt data using industry standards and best practices.</td>
</tr>
</tbody>
</table>
AWS Firewall Manager

A service that you use with AWS WAF to simplify your AWS WAF administration and maintenance tasks across multiple accounts and resources. With AWS Firewall Manager, you set up your firewall rules only once. The service automatically applies your rules across your accounts and resources, even as you add new resources.

See Also https://aws.amazon.com/firewall-manager.

AWS Global Accelerator

A network layer service that you use to create accelerators that direct traffic to optimal endpoints over the AWS global network. This improves the availability and performance of your internet applications that are used by a global audience.

See Also https://aws.amazon.com/global-accelerator.

AWS Glue

A fully managed extract, transform, and load (ETL) (p. 830) service that you can use to catalog data and load it for analytics. With AWS Glue, you can discover your data, develop scripts to transform sources into targets, and schedule and run ETL jobs in a serverless environment.

See Also https://aws.amazon.com/glue.

AWS GovCloud (US)

An isolated AWS Region designed to host sensitive workloads in the cloud, ensuring that this work meets the US government's regulatory and compliance requirements. The AWS GovCloud (US) Region adheres to United States International Traffic in Arms Regulations (ITAR), Federal Risk and Authorization Management Program (FedRAMP) requirements, Department of Defense (DOD) Cloud Security Requirements Guide (SRG) Levels 2 and 4, and Criminal Justice Information Services (CJIS) Security Policy requirements.

See Also https://aws.amazon.com/govcloud-us/.

AWS Identity and Access Management (IAM)

A web service that Amazon Web Services (AWS) (p. 809) customers can use to manage users and user permissions within AWS.

See Also https://aws.amazon.com/iam.

AWS Import/Export

A service for transferring large amounts of data between AWS and portable storage devices.

See Also https://aws.amazon.com/importexport.

AWS IoT Core

A managed cloud platform that lets connected devices easily and securely interact with cloud applications and other devices.

See Also https://aws.amazon.com/iot.

AWS IoT 1-Click

A service that simple devices can use to launch AWS Lambda functions.

See Also https://aws.amazon.com/iot-1-click.

AWS IoT Analytics

A fully managed service used to run sophisticated analytics on massive volumes of IoT data.

See Also https://aws.amazon.com/iot-analytics.

AWS IoT Device Defender

An AWS IoT security service that you can use to audit the configuration of your devices, monitor your connected devices to detect abnormal behavior, and to mitigate security risks.

See Also https://aws.amazon.com/iot-device-defender.

AWS IoT Device Management

A service used to securely onboard, organize, monitor, and remotely manage IoT devices at scale.

See Also https://aws.amazon.com/iot-device-management.

AWS IoT Events

A fully managed AWS IoT service that makes it easy to detect and respond to events from IoT sensors and applications.

See Also https://aws.amazon.com/iot-events.
AWS IoT Greengrass | Software that you can use to run local compute, messaging, data caching, sync, and ML inference capabilities for connected devices in a secure way. See Also https://aws.amazon.com/greengrass.

AWS IoT SiteWise | A managed service that you can use to collect, organize, and analyze data from industrial equipment at scale. See Also https://aws.amazon.com/iot-sitewise.

AWS IoT Things Graph | A service that makes it easy to visually connect different devices and web services to build IoT applications. See Also https://aws.amazon.com/iot-things-graph.

AWS Key Management Service (AWS KMS) | A managed service that simplifies the creation and control of encryption (p. 828) keys that are used to encrypt data. See Also https://aws.amazon.com/kms.

AWS Lambda | A web service that you can use to run code without provisioning or managing servers. You can run code for virtually any type of application or backend service with zero administration. You can set up your code to automatically start from other AWS services or call it directly from any web or mobile app. See Also https://aws.amazon.com/lambda/.

AWS managed key | One type of customer master key (CMK) (p. 824) in AWS Key Management Service (AWS KMS) (p. 815).

AWS managed policy | An IAM (p. 814) managed policy (p. 838) that's created and managed by AWS.

AWS Management Console | A graphical interface to manage compute, storage, and other cloud resources (p. 848). See Also https://aws.amazon.com/console.

AWS Management Portal for vCenter | A web service for managing your AWS resources using VMware vCenter. You install the portal as a vCenter plugin within your existing vCenter environment. Once installed, you can migrate VMware VMs to Amazon EC2 (p. 804) and manage AWS resources from within vCenter. See Also https://aws.amazon.com/ec2/vcenter-portal/.

AWS Marketplace | A web portal where qualified partners market and sell their software to AWS customers. AWS Marketplace is an online software store that helps customers find, buy, and immediately start using the software and services that run on AWS. See Also https://aws.amazon.com/partners/aws-marketplace/.

AWS Migration Hub | A service that provides a single location to track migration tasks across multiple AWS tools and partner solutions. See Also https://aws.amazon.com/migration-hub/.

AWS Mobile Hub (Mobile Hub) | An integrated console for building, testing, and monitoring mobile apps. See Also https://aws.amazon.com/mobile.

AWS Mobile SDK | A software development kit whose libraries, code examples, and documentation help you build high quality mobile apps for the iOS, Android, Fire OS, Unity, and Xamarin platforms. See Also https://aws.amazon.com/mobile/sdk.

AWS OpsWorks | A configuration management service that helps you use Chef to configure and operate groups of instances and applications. You can define the application's architecture and the specification of each component including package installation, software configuration, and resources (p. 848) such as storage. You can automate tasks based on time, load, lifecycle events, and more. See Also https://aws.amazon.com/opsworks/.
<table>
<thead>
<tr>
<th>AWS Organizations</th>
<th>An account management service that you can use to consolidate multiple AWS accounts into an organization that you create and centrally manage. See Also <a href="https://aws.amazon.com/organizations/">https://aws.amazon.com/organizations/</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS Resource Access Manager</td>
<td>A service that you can use to share your resources with any AWS account or organization in AWS Organizations. See Also <a href="https://aws.amazon.com/ram/">https://aws.amazon.com/ram/</a>.</td>
</tr>
<tr>
<td>AWS ParallelCluster</td>
<td>An AWS supported open source cluster management tool that helps you to deploy and manage high performance computing (HPC) clusters in the AWS Cloud.</td>
</tr>
<tr>
<td>AWS SDK for C++</td>
<td>A software development kit for that provides C++ APIs for many AWS services including Amazon S3 (p. 809), Amazon EC2 (p. 804), Amazon DynamoDB (p. 804), and more. The single, downloadable package includes the AWS C++ library, code examples, and documentation. See Also <a href="https://aws.amazon.com/sdk-for-cpp/">https://aws.amazon.com/sdk-for-cpp/</a>.</td>
</tr>
<tr>
<td>AWS SDK for Go</td>
<td>A software development kit for integrating your Go application with the full suite of AWS services. See Also <a href="https://aws.amazon.com/sdk-for-go/">https://aws.amazon.com/sdk-for-go/</a>.</td>
</tr>
<tr>
<td>AWS SDK for Java</td>
<td>A software development kit that provides Java API operations for many AWS services including Amazon S3 (p. 809), Amazon EC2 (p. 804), Amazon DynamoDB (p. 804), and more. The single, downloadable package includes the AWS Java library, code examples, and documentation. See Also <a href="https://aws.amazon.com/sdk-for-java/">https://aws.amazon.com/sdk-for-java/</a>.</td>
</tr>
<tr>
<td>AWS SDK for JavaScript in the Browser</td>
<td>A software development kit for accessing AWS services from JavaScript code running in the browser. Authenticate users through Facebook, Google, or Login with Amazon using web identity federation. Store application data in Amazon DynamoDB (p. 804), and save user files to Amazon S3 (p. 809). See Also <a href="https://docs.aws.amazon.com/sdk-for-javascript/v2/developer-guide/">https://docs.aws.amazon.com/sdk-for-javascript/v2/developer-guide/</a>.</td>
</tr>
<tr>
<td>AWS SDK for JavaScript in Node.js</td>
<td>A software development kit for accessing AWS services from JavaScript in Node.js. The SDK provides JavaScript objects for AWS services, including Amazon S3 (p. 809), Amazon EC2 (p. 804), Amazon DynamoDB (p. 804), and Amazon Simple Workflow Service (Amazon SWF) (p. 809). The single, downloadable package includes the AWS JavaScript library and documentation. See Also <a href="https://docs.aws.amazon.com/sdk-for-javascript/v2/developer-guide/">https://docs.aws.amazon.com/sdk-for-javascript/v2/developer-guide/</a>.</td>
</tr>
<tr>
<td>AWS SDK for .NET</td>
<td>A software development kit that provides .NET API operations for AWS services including Amazon S3 (p. 809), Amazon EC2 (p. 804), IAM (p. 814), and more. You can download the SDK as multiple service-specific packages on NuGet. See Also <a href="https://aws.amazon.com/sdk-for-net/">https://aws.amazon.com/sdk-for-net/</a>.</td>
</tr>
<tr>
<td>AWS SDK for PHP</td>
<td>A software development kit and open-source PHP library for integrating your PHP application with AWS services such as Amazon S3 (p. 809), Amazon S3 Glacier (p. 808), and Amazon DynamoDB (p. 804). See Also <a href="https://aws.amazon.com/sdk-for-php/">https://aws.amazon.com/sdk-for-php/</a>.</td>
</tr>
<tr>
<td>AWS SDK for Python (Boto)</td>
<td>A software development kit for using Python to access AWS services such as Amazon EC2 (p. 804), Amazon EMR (p. 805), Amazon EC2 Auto Scaling (p. 804), Amazon Kinesis (p. 806), or AWS Lambda (p. 815). See Also <a href="http://boto.readthedocs.org/en/latest/">http://boto.readthedocs.org/en/latest/</a>.</td>
</tr>
<tr>
<td>AWS SDK for Ruby</td>
<td>A software development kit for accessing AWS services from Ruby. The SDK provides Ruby classes for many AWS services including Amazon S3 (p. 809), Amazon EC2 (p. 804), Amazon DynamoDB (p. 804) and more. The single, downloadable package includes the AWS Ruby Library and documentation.</td>
</tr>
</tbody>
</table>
AWS Secrets Manager
A service for securely encrypting, storing, and rotating credentials for databases and other services.
See Also https://aws.amazon.com/secrets-manager/.

AWS Security Token Service (AWS STS)
A web service for requesting temporary, limited-privilege credentials for AWS Identity and Access Management (IAM) (p. 814) users or for users that you authenticate (federated users (p. 830)).
See Also https://aws.amazon.com/iam/.

AWS Service Catalog
A web service that helps organizations create and manage catalogs of IT services that are approved for use on AWS. These IT services can include anything from virtual machine images, servers, software, and databases to complete multilayer application architectures.
See Also https://aws.amazon.com/servicecatalog/.

AWS Shield
A service that helps to protect your resources—such as Amazon EC2 instances, Elastic Load Balancing load balancers, Amazon CloudFront distributions, and Route 53 hosted zones—against DDoS attacks. AWS Shield is automatically included at no extra cost beyond what you already pay for AWS WAF and your other AWS services. For added protection against DDoS attacks, AWS offers AWS Shield Advanced.
See Also https://aws.amazon.com/shield.

AWS Single Sign-On
A cloud-based service that simplifies managing SSO access to AWS accounts and business applications. You can control SSO access and user permissions across all your AWS accounts in AWS Organizations.
See Also https://aws.amazon.com/single-sign-on/.

AWS Step Functions
A web service that coordinates the components of distributed applications as a series of steps in a visual workflow.
See Also https://aws.amazon.com/step-functions/.

AWS Snowball
A petabyte-scale data transport solution that uses devices designed to be secure to transfer large amounts of data into and out of the AWS Cloud.
See Also https://aws.amazon.com/snowball.

Storage Gateway
A web service that connects an on-premises software appliance with cloud-based storage. Storage Gateway provides seamless and secure integration between an organization’s on-premises IT environment and AWS storage infrastructure.
See Also https://aws.amazon.com/storagegateway/.

AWS Toolkit for Eclipse
An open-source plugin for the Eclipse Java integrated development environment (IDE) that makes it easier to develop, debug, and deploy Java applications using Amazon Web Services.
See Also https://aws.amazon.com/eclipse/.

AWS Toolkit for JetBrains
An open-source plugin for the integrated development environments (IDEs) from JetBrains that makes it easier to develop, debug, and deploy serverless applications using Amazon Web Services.

AWS Toolkit for Visual Studio
An extension for Visual Studio that helps in developing, debugging, and deploying .NET applications using Amazon Web Services.
See Also https://aws.amazon.com/visualstudio/.

AWS Toolkit for Visual Studio Code
An open-source plugin for the Visual Studio Code (VS Code) editor that makes it easier to develop, debug, and deploy applications using Amazon Web Services.
AWS Tools for PowerShell
A set of PowerShell cmdlets to help developers and administrators manage their AWS services from the PowerShell scripting environment.
See Also https://aws.amazon.com/powershell/.

AWS Toolkit for Microsoft Azure DevOps
Provides tasks you can use in build and release definitions in VSTS to interact with AWS services.
See Also https://aws.amazon.com/vsts/.

AWS Trusted Advisor
A web service that inspects your AWS environment and makes recommendations for saving money, improving system availability and performance, and helping to close security gaps.
See Also https://aws.amazon.com/premiumsupport/trustedadvisor/.

AWS VPN CloudHub
Enables secure communication between branch offices using a simple hub-and-spoke model, with or without a VPC (p. 859).

AWS WAF
A web application firewall service that controls access to content by allowing or blocking web requests based on criteria that you specify. For example, you can filter access based on the header values or the IP addresses that the requests originate from. AWS WAF helps protect web applications from common web exploits that could affect application availability, compromise security, or consume excessive resources.
See Also https://aws.amazon.com/waf/.

AWS X-Ray
A web service that collects data about requests that your application serves. X-Ray provides tools that you can use to view, filter, and gain insights into that data to identify issues and opportunities for optimization.
See Also https://aws.amazon.com/xray/.

basic monitoring
Monitoring of AWS provided metrics derived at a 5-minute frequency.

batch
See document batch.

BGP ASN
Border Gateway Protocol Autonomous System Number. A unique identifier for a network, for use in BGP routing. Amazon EC2 (p. 804) supports all 2-byte ASN numbers in the range of 1 – 65535, with the exception of 7224, which is reserved.

batch prediction
Amazon Machine Learning: An operation that processes multiple input data observations at one time (asynchronously). Unlike real-time predictions, batch predictions aren’t available until all predictions have been processed.
See Also real-time predictions.

billing
See the section called “Billing and Cost Management”.

binary attribute
Amazon Machine Learning: An attribute for which one of two possible values is possible. Valid positive values are 1, y, yes, t, and true answers. Valid negative values are 0, n, no, f, and false. Amazon Machine Learning outputs 1 for positive values and 0 for negative values.
See Also attribute.
### Binary Classification Model

**Definition:** A machine learning model that predicts the answer to questions where the answer can be expressed as a binary variable. For example, questions with answers of “1” or “0”, “yes” or “no”, “will click” or “will not click” are questions that have binary answers. The result for a binary classification model is always either a “1” (for a “true” or affirmative answers) or a “0” (for a “false” or negative answers).

### Block

**Definition:** A dataset. Amazon EMR breaks large amounts of data into subsets. Each subset is called a data block. Amazon EMR assigns an ID to each block and uses a hash table to keep track of block processing.

### Block Device

**Definition:** A storage device that supports reading and (optionally) writing data in fixed-size blocks, sectors, or clusters.

### Block Device Mapping

**Definition:** A mapping structure for every AMI and instance that specifies the block devices attached to the instance.

### Blue/Green Deployment

**Definition:** CodeDeploy: A deployment method where the instances in a deployment group (the original environment) are replaced by a different set of instances (the replacement environment).

### Bootstrap Action

**Definition:** A user-specified default or custom action that runs a script or an application on all nodes of a job flow before Hadoop starts.

### Border Gateway Protocol Autonomous System Number

**Definition:** See BGP ASN.

### Bounce

**Definition:** A failed email delivery attempt.

### Breach

**Definition:** Amazon EC2 Auto Scaling: The condition where a user-set threshold (upper or lower boundary) is passed. If the duration of the breach is significant, as set by a breach duration parameter, it can possibly start a scaling activity.

### Bucket

**Definition:** Amazon Simple Storage Service (Amazon S3): A container for stored objects. Every object is contained in a bucket. For example, if the object named photos/puppy.jpg is stored in the DOC-EXAMPLE-BUCKET bucket, then authorized users can access the object with the URL https://s3-bucket-endpoint/DOC-EXAMPLE-BUCKET/photos/puppy.jpg.

### Bucket Owner

**Definition:** The person or organization that owns a bucket in Amazon S3. In the same way that Amazon is the only owner of the domain name Amazon.com, only one person or organization can own a bucket.

### Bundling

**Definition:** A commonly used term for creating an Amazon Machine Image (AMI). It specifically refers to creating instance store-backed AMI.

<tr>
<td>content delivery network (CDN)</td>
<td>A web service that speeds up distribution of your static and dynamic web content—such as .html, .css, .js, media files, and image files—to your users by using a worldwide network of data centers. When a user requests your content, the request is routed to the data center that provides the lowest latency (time delay). If the content is already in the location with the lowest latency, the CDN delivers it immediately. If not, the CDN retrieves it from an origin that you specify (for example, a web server or an Amazon S3 bucket). With some CDNs, you can help secure your content by configuring an HTTPS connection between users and data centers, and between data centers and your origin. Amazon CloudFront is an example of a CDN.</td>

**continuous delivery**
A software development practice where code changes are automatically built, tested, and prepared for a release to production.
See Also https://aws.amazon.com/devops/continuous-delivery/.

**continuous integration**
A software development practice where developers regularly merge code changes into a central repository, after which automated builds and tests are run.
See Also https://aws.amazon.com/devops/continuous-integration/.

**cooldown period**
Amount of time that Amazon EC2 Auto Scaling (p. 804) doesn't allow the desired size of the Auto Scaling group (p. 811) to be changed by any other notification from an Amazon CloudWatch (p. 803) alarm (p. 802).

**core node**
An EC2 instance (p. 827) that runs Hadoop (p. 832) map and reduce tasks and stores data using the Hadoop Distributed File System (HDFS). Core nodes are managed by the master node (p. 838), which assigns Hadoop tasks to nodes and monitors their status. The EC2 instances you assign as core nodes are capacity that must be allotted for the entire job flow run. Because core nodes store data, you can't remove them from a job flow. However, you can add more core nodes to a running job flow.

Core nodes run both the DataNodes and TaskTracker Hadoop daemons.

**corpus**
Amazon CloudSearch (p. 803): A collection of data that you want to search.

**coverage**
Amazon Personalize (p. 807): An evaluation metric that tells you the proportion of unique items that Amazon Personalize might recommend using your model out of the total number of unique items in Interactions and Items datasets. To make sure Amazon Personalize recommends more of your items, use a model with a higher coverage score. Recipes that feature item exploration, such as user-personalization, have higher coverage than those that don't, such as popularity-count.
See Also metrics, Items dataset, Interactions dataset, item exploration, user-personalization recipe, popularity-count recipe.

**credential helper**
AWS CodeCommit (p. 812): A program that stores credentials for repositories and supplies them to Git when making connections to those repositories. The AWS CLI (p. 812) includes a credential helper that you can use with Git when connecting to CodeCommit repositories.

**credentials**
Also called access credentials or security credentials. In authentication and authorization, a system uses credentials to identify who is making a call and whether to allow the requested access. In AWS, these credentials are typically the access key ID (p. 801) and the secret access key (p. 850).

**cross-account access**
The process of permitting limited, controlled use of resource (p. 848)s in one AWS account (p. 802) by a user in another AWS account. For example, in AWS CodeCommit (p. 812) and AWS CodeDeploy (p. 812) you can configure cross-account access so that a user in AWS account A can access an CodeCommit repository created by account B. Or a pipeline in AWS CodePipeline (p. 812) created by account A can use CodeDeploy resources created by account B. In IAM (p. 814) you use a role (p. 848) to delegate (p. 825) temporary access to a user (p. 857) in one account to resources in another.

**cross-Region replication**
A solution for replicating data across different AWS Regions (p. 847), in near-real time.

**customer gateway**
A router or software application on your side of a VPN tunnel that’s managed by Amazon VPC (p. 809). The internal interfaces of the customer gateway are...
attached to one or more devices in your home network. The external interface is attached to the virtual private gateway (VGW) (p. 858) across the VPN tunnel.

customer managed policy
An IAM (p. 814) managed policy (p. 838) that you create and manage in your AWS account (p. 802).

customer master key (CMK)
The fundamental resource (p. 848) that AWS Key Management Service (AWS KMS) (p. 815) manages. CMKs can be either customer managed keys or AWS managed keys. Use CMKs inside AWS KMS to encrypt (p. 828) or decrypt up to 4 kilobytes of data directly or to encrypt generated data keys, which are then used to encrypt or decrypt larger amounts of data outside of the service.

dashboard
See service health dashboard.

data consistency
A concept that describes when data is written or updated successfully and all copies of the data are updated in all AWS Regions (p. 847). However, it takes time for the data to propagate to all storage locations. To support varied application requirements, Amazon DynamoDB (p. 804) supports both eventually consistent and strongly consistent reads. See Also eventual consistency, eventually consistent read, strongly consistent read.

data node
Amazon OpenSearch Service (OpenSearch Service) (p. 805): An OpenSearch instance that holds data and responds to data upload requests. See Also dedicated master node, node.

data schema
See schema.

data source
The database, file, or repository that provides information required by an application or database. For example, in AWS OpsWorks (p. 815), valid data sources include an instance (p. 834) for a stack’s MySQL layer or a stack’s Amazon RDS (p. 808) service layer. In Amazon Redshift (p. 808), valid data sources include text files in an Amazon S3 (p. 809) bucket (p. 819), in an Amazon EMR (p. 805) cluster, or on a remote host that a cluster can access through an SSH connection. See Also datasource.

database engine
The database software and version running on the DB instance (p. 825).

database name
The name of a database hosted in a DB instance (p. 825). A DB instance can host multiple databases, but databases hosted by the same DB instance must each have a unique name within that instance.

dataset
Amazon Personalize (p. 807): A container for the data used by Amazon Personalize. There are three types of Amazon Personalize datasets: Users, Items, and Interactions. See Also Interactions dataset, Users dataset, Items dataset.

dataset group
Amazon Personalize (p. 807): A container for Amazon Personalize components, including datasets, event trackers, solutions, filters, campaigns, and batch inference jobs. A dataset group organizes your resources into independent
collections, so resources from one dataset group can't influence resources in any other dataset group.
See Also dataset, event tracker, solution, campaign.

datasource
Amazon Machine Learning (p. 807): An object that contains metadata about the input data. Amazon ML reads the input data, computes descriptive statistics on its attributes, and stores the statistics—along with a schema and other information—as part of the datasource object. Amazon ML uses datasources to train and evaluate a machine learning model and generate batch predictions.
See Also data source.

DB compute class
The size of the database compute platform used to run the instance.

DB instance
An isolated database environment running in the cloud. A DB instance can contain multiple user-created databases.

DB instance identifier
User-supplied identifier for the DB instance. The identifier must be unique for that user in an AWS Region (p. 847).

DB parameter group
A container for database engine parameter values that apply to one or more DB instance (p. 825)s.

DB security group
A method that controls access to the DB instance (p. 825). By default, network access is turned off to DB instances. After inbound traffic is configured for a security group (p. 850), the same rules apply to all DB instances associated with that group.

DB snapshot
A user-initiated point backup of a DB instance (p. 825).

Dedicated Host
A physical server with EC2 instance (p. 827) capacity fully dedicated to a user.

Dedicated Instance
An instance (p. 834) that's physically isolated at the host hardware level and launched within a VPC (p. 859).

dedicated master node
Amazon OpenSearch Service (OpenSearch Service) (p. 805): An OpenSearch instance that performs cluster management tasks, but doesn't hold data or respond to data upload requests. Amazon OpenSearch Service (OpenSearch Service) uses dedicated master nodes to increase cluster stability.
See Also data node, node.

Dedicated Reserved Instance
An option that you purchase to guarantee that sufficient capacity will be available to launch Dedicated Instance (p. 825)s into a VPC (p. 859).

delegation
Within a single AWS account (p. 802): Giving AWS user (p. 857)s access to resource (p. 848)s in your AWS account.

Between two AWS accounts: Setting up a trust between the account that owns the resource (the trusting account), and the account that contains the users that need to access the resource (the trusted account).
See Also trust policy.

delete marker
An object with a key and version ID, but without content. Amazon S3 (p. 809) inserts delete markers automatically into versioned bucket (p. 819)s when an object is deleted.

deliverability
The likelihood that an email message will arrive at its intended destination.

deliveries
The number of email messages, sent through Amazon SES (p. 808), that were accepted by an internet service provider (ISP) (p. 834) for delivery to recipient (p. 846)s over a period of time.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny</td>
<td>The result of a policy statement that includes deny as the effect, so that a specific action or actions are expressly forbidden for a user, group, or role. Explicit deny take precedence over explicit allow.</td>
</tr>
<tr>
<td>deployment configuration</td>
<td>AWS CodeDeploy: A set of deployment rules and success and failure conditions used by the service during a deployment.</td>
</tr>
<tr>
<td>deployment group</td>
<td>AWS CodeDeploy: A set of individually tagged instance, EC2 instance, Auto Scaling group, or both.</td>
</tr>
<tr>
<td>detailed monitoring</td>
<td>Monitoring of AWS provided metrics derived at a 1-minute frequency.</td>
</tr>
<tr>
<td>Description property</td>
<td>A property added to parameters, resource, resource properties, mappings, and outputs to help you to document AWS CloudFormation template elements.</td>
</tr>
<tr>
<td>dimension</td>
<td>A name–value pair (for example, InstanceType=m1.small, or EngineName=mysql), that contains additional information to identify a metric.</td>
</tr>
<tr>
<td>discussion forums</td>
<td>A place where AWS users can post technical questions and feedback to help accelerate their development efforts and to engage with the AWS community. For more information, see the Amazon Web Services Discussion Forums.</td>
</tr>
<tr>
<td>distribution</td>
<td>A link between an origin server (such as an Amazon S3 bucket) and a domain name, which CloudFront automatically assigns. Through this link, CloudFront identifies the object you have stored in your origin server.</td>
</tr>
<tr>
<td>DKIM</td>
<td>DomainKeys Identified Mail. A standard that email senders use to sign their messages. ISPs use those signatures to verify that messages are legitimate. For more information, see <a href="https://tools.ietf.org/html/rfc6376">https://tools.ietf.org/html/rfc6376</a>.</td>
</tr>
<tr>
<td>DNS</td>
<td>See Domain Name System.</td>
</tr>
<tr>
<td>Docker image</td>
<td>A layered file system template that's the basis of a Docker container. Docker images can comprise specific operating systems or applications.</td>
</tr>
<tr>
<td>document</td>
<td>Amazon CloudSearch: An item that can be returned as a search result. Each document has a collection of fields that contain the data that can be searched or returned. The value of a field can be either a string or a number. Each document must have a unique ID and at least one field.</td>
</tr>
<tr>
<td>document batch</td>
<td>Amazon CloudSearch: A collection of add and delete document operations. You use the document service API to submit batches to update the data in your search domain.</td>
</tr>
<tr>
<td>document service API</td>
<td>Amazon CloudSearch: The API call that you use to submit document batches to update the data in a search domain.</td>
</tr>
<tr>
<td>document service endpoint</td>
<td>Amazon CloudSearch: The URL that you connect to when sending document updates to an Amazon CloudSearch domain. Each search domain has a unique document service endpoint that remains the same for the life of the domain.</td>
</tr>
<tr>
<td>domain</td>
<td>Amazon OpenSearch Service: The hardware, software, and data exposed by Amazon OpenSearch Service endpoints. An OpenSearch Service domain is a service wrapper around an OpenSearch cluster. An OpenSearch Service domain encapsulates the engine instances that process OpenSearch Service requests, the indexed data that you want to search, snapshots of the domain, access policies, and metadata.</td>
</tr>
</tbody>
</table>
See Also cluster, Elasticsearch.

Domain Name System
A service that routes internet traffic to websites by translating friendly domain names (for example, www.example.com) into the numeric IP addresses, such as 192.0.2.1 that computers use to connect to each other.

Donation button
An HTML-coded button to provide an easy and secure way for US-based, IRS-certified 501(c)3 nonprofit organizations to solicit donations.

DynamoDB stream
An ordered flow of information about changes to items in an Amazon DynamoDB (p. 804) table. When you enable a stream on a table, DynamoDB captures information about every modification to data items in the table. See Also Amazon DynamoDB Streams.

E

EBS
See Amazon Elastic Block Store (Amazon EBS).

EC2
See Amazon EC2.

EC2 compute unit (ECU)
An AWS standard for compute CPU and memory. You can use this measure to evaluate the CPU capacity of different EC2 instance (p. 827) types.

EC2 instance
A compute instance (p. 834) in the Amazon EC2 (p. 804) service. Other AWS services use the term EC2 instance to distinguish these instances from other types of instances they support.

ECR
See the section called “Amazon ECR”.

ECS
See Amazon Elastic Container Service (Amazon ECS).

edge location
A data center that an AWS service uses to perform service-specific operations. For example, CloudFront (p. 803) uses edge locations to cache copies of your content, so the content is closer to your users and can be delivered faster regardless of their location. Route 53 (p. 808) uses edge locations to speed up the response to public DNS queries.

EFS
See Amazon Elastic File System (Amazon EFS).

Elastic
A company that provides open-source solutions—including OpenSearch, Logstash, Kibana, and Beats—that are designed to take data from any source and search, analyze, and visualize it in real time.

Amazon OpenSearch Service (OpenSearch Service) is an AWS managed service for deploying, operating, and scaling OpenSearch in the AWS Cloud. See Also Amazon OpenSearch Service (OpenSearch Service), Elasticsearch.

Elastic Block Store
See Amazon Elastic Block Store (Amazon EBS).

Elastic IP address
A fixed (static) IP address that you have allocated in Amazon EC2 (p. 804) or Amazon VPC (p. 809) and then attached to an instance (p. 834). Elastic IP addresses are associated with your account, not a specific instance. They are elastic because you can easily allocate, attach, detach, and free them as your
needs change. Unlike traditional static IP addresses, Elastic IP addresses allow you to mask instance or Availability Zone failures by rapidly remapping your public IP addresses to another instance.

Elastic Load Balancing
A web service that improves an application’s availability by distributing incoming traffic between two or more EC2 instances. See Also https://aws.amazon.com/elasticloadbalancing.

elastic network interface
An additional network interface that can be attached to an instance. Elastic network interfaces include a primary private IP address, one or more secondary private IP addresses, an Elastic IP Address (optional), a MAC address, membership in specified security group, a description, and a source/destination check flag. You can create an elastic network interface, attach it to an instance, detach it from an instance, and attach it to another instance.

Elasticsearch
An open-source, real-time distributed search and analytics engine used for full-text search, structured search, and analytics. OpenSearch was developed by the Elastic company.

Amazon OpenSearch Service (OpenSearch Service) is an AWS managed service for deploying, operating, and scaling OpenSearch in the AWS Cloud. See Also Amazon OpenSearch Service (OpenSearch Service), Elastic.

EMR
See Amazon EMR.

encrypt
To use a mathematical algorithm to make data unintelligible to unauthorized user. Encryption also gives authorized users a method (such as a key or password) to convert the altered data back to its original state.

encryption context
A set of key–value pairs that contains additional information associated with AWS Key Management Service (AWS KMS)–encrypted information.

endpoint
A URL that identifies a host and port as the entry point for a web service. Every web service request contains an endpoint. Most AWS products provide endpoints for a Region to enable faster connectivity.

Amazon ElastiCache: The DNS name of a cache node.
Amazon RDS: The DNS name of a DB instance.
AWS CloudFormation: The DNS name or IP address of the server that receives an HTTP request.

endpoint port
Amazon ElastiCache: The port number used by a cache node.
Amazon RDS: The port number used by a DB instance.

envelope encryption
The use of a master key and a data key to algorithmically protect data. The master key is used to encrypt and decrypt the data key and the data key is used to encrypt and decrypt the data itself.

environment
AWS Elastic Beanstalk: A specific running instance of an application. The application has a CNAME and includes an application version and a customizable configuration (which is inherited from the default container type).
AWS CodeDeploy: Instances in a deployment group in a blue/green deployment. At the start of a blue/green deployment, the deployment group is made up of instances in the original environment. At the end of the deployment, the deployment group is made up of instances in the replacement environment.
environment configuration A collection of parameters and settings that define how an environment and its
associated resources behave.

ephemeral store See instance store.

epoch The date from which time is measured. For most Unix environments, the epoch is
January 1, 1970.

ETL See extract, transform, and load (ETL).

evaluation Amazon Machine Learning: The process of measuring the predictive performance
of a machine learning (ML) model.

Also a machine learning object that stores the details and result of an ML model
evaluation.

evaluation datasource The data that Amazon Machine Learning uses to evaluate the predictive accuracy
of a machine learning model.

event Amazon Personalize (p. 807): A user activity—such as a click, a purchase, or a
video viewing—that you record and upload to an Amazon Personalize Interactions
dataset. You record events individually in real time or record and upload events in
bulk.
See Also dataset, Interactions dataset.

event tracker Amazon Personalize (p. 807): Specifies a destination dataset group for event
data that you record in real time. When you record events in real time, you
provide the ID of the event tracker so that Amazon Personalize knows where to
add the data.
See Also dataset group, event.

eventual consistency The method that AWS services use to achieve high availability, which involves
replicating data across multiple servers in Amazon's data centers. When data is
written or updated and Success is returned, all copies of the data are updated.
However, it takes time for the data to propagate to all storage locations. The data
will eventually be consistent, but an immediate read might not show the change.
Consistency is usually reached within seconds.
See Also data consistency, eventually consistent read, strongly consistent read.

eventually consistent read A read process that returns data from only one Region and might not show the
most recent write information. However, if you repeat your read request after a
short time, the response should eventually return the latest data.
See Also data consistency, eventual consistency, strongly consistent read.

eviction The deletion by CloudFront (p. 803) of an object from an edge
location (p. 827) before its expiration time. If an object in an edge location
isn't frequently requested, CloudFront might evict the object (remove the object
before its expiration date) to make room for objects that are more popular.

exbibyte (EiB) A contraction of exa binary byte, an exbibyte is 2^60 or
1,152,921,504,606,846,976 bytes. An exabyte (EB) is 10^18 or
1,000,000,000,000,000,000 bytes. 1,024 EiB is a zebibyte (ZiB) (p. 859).

expiration For CloudFront (p. 803) caching, the time when CloudFront stops responding to
user requests with an object. If you don't use headers or CloudFront
distribution (p. 826) settings to specify how long you want objects to stay in
an edge location (p. 827), the objects expire after 24 hours. The next time a
user requests an object that has expired, CloudFront forwards the request to the
origin (p. 842).
explicit impressions: Amazon Personalize (p. 807): A list of items that you manually add to an Amazon Personalize Interactions dataset to influence future recommendations. Unlike implicit impressions, where Amazon Personalize automatically derives the impressions data, you choose what to include in explicit impressions. See also recommendations, Interactions dataset, impressions data, implicit impressions.

explicit launch permission: An Amazon Machine Image (AMI) (p. 807) launch permission granted to a specific AWS account (p. 802).

exponential backoff: A strategy that incrementally increases the wait between retry attempts in order to reduce the load on the system and increase the likelihood that repeated requests will succeed. For example, client applications might wait up to 400 milliseconds before attempting the first retry, up to 1600 milliseconds before the second, and up to 6400 milliseconds (6.4 seconds) before the third.

equation: Amazon CloudSearch (p. 803): A numeric expression that you can use to control how search hits are sorted. You can construct Amazon CloudSearch expressions using numeric fields, other rank expressions, a document’s default relevance score, and standard numeric operators and functions. When you use the sort option to specify an expression in a search request, the expression is evaluated for each search hit and the hits are listed according to their expression values.

extract, transform, and load (ETL): A process that’s used to integrate data from multiple sources. Data is collected from sources (extract), converted to an appropriate format (transform), and written to a target data store (load) for purposes of analysis and querying. ETL tools combine these three functions to consolidate and move data from one environment to another. AWS Glue (p. 814) is a fully managed ETL service for discovering and organizing data, transforming it, and making it available for search and analytics.

F

facet: Amazon CloudSearch (p. 803): An index field that represents a category that you want to use to refine and filter search results.

facet enabled: Amazon CloudSearch (p. 803): An index field option that enables facet information to be calculated for the field.

FBL: See feedback loop (FBL).

feature transformation: Amazon Machine Learning: The machine learning process of constructing more predictive input representations or “features” from the raw input variables to optimize a machine learning model’s ability to learn and generalize. Also known as data transformation or feature engineering.

federated identity management (FIM): Allows individuals to sign in to different networks or services, using the same group or personal credentials to access data across all networks. With identity federation in AWS, external identities (federated users) are granted secure access to resource (p. 848)s in an AWS account (p. 802) without having to create IAM user (p. 857)s. These external identities can come from a corporate identity store (such as LDAP or Windows Active Directory) or from a third party (such as...
Login with Amazon, Facebook, or Google). AWS federation also supports SAML 2.0.

**federated user**
See federated identity management (FIM).

**federation**
See federated identity management (FIM).

**feedback loop (FBL)**
The mechanism by which a mailbox provider (for example, an internet service provider (ISP) (p. 834)) forwards a recipient (p. 846)'s complaint (p. 821) back to the sender (p. 850).

**field weight**
The relative importance of a text field in a search index. Field weights control how much matches in particular text fields affect a document's relevance score.

**filter**
A criterion that you specify to limit the results when you list or describe your Amazon EC2 (p. 804) resource (p. 848)s.

**filter query**
A way to filter search results without affecting how the results are scored and sorted. Specified with the Amazon CloudSearch (p. 803) \( \text{fq} \) parameter.

**FIM**
See federated identity management (FIM).

**Firehose**
See Amazon Kinesis Data Firehose.

**format version**
See template format version.

**forums**
See discussion forums.

**function**
See intrinsic function.

**fuzzy search**
A simple search query that uses approximate string matching (fuzzy matching) to correct for typographical errors and misspellings.

**geospatial search**
A search query that uses locations specified as a latitude and longitude to determine matches and sort the results.

**gibibyte (GiB)**
A contraction of giga binary byte, a gibibyte is \( 2^{30} \) or 1,073,741,824 bytes. A gigabyte (GB) is \( 10^9 \) or 1,000,000,000 bytes. 1,024 GiB is a tebibyte (TiB) (p. 856).

**GitHub**
A web-based repository that uses Git for version control.

**global secondary index**
An index with a partition key and a sort key that can be different from those on the table. A global secondary index is considered global because queries on the index can span all of the data in a table, across all partitions. See Also local secondary index.

**grant**
AWS Key Management Service (AWS KMS) (p. 815): A mechanism for giving AWS principal (p. 844)s long-term permissions to use customer master key (CMK) (p. 824)s.

**grant token**
A type of identifier that allows the permissions in a grant (p. 831) to take effect immediately.
ground truth

The observations used in the machine learning (ML) model training process that include the correct value for the target attribute. To train an ML model to predict house sales prices, the input observations would typically include prices of previous house sales in the area. The sale prices of these houses constitute the ground truth.

group

A collection of IAM (p. 814) user (p. 857) s. You can use IAM groups to simplify specifying and managing permissions for multiple users.

H

Hadoop

Software that enables distributed processing for big data by using clusters and simple programming models. For more information, see http://hadoop.apache.org.

hard bounce

A persistent email delivery failure such as "mailbox does not exist."

hardware VPN

A hardware-based IPsec VPN connection over the internet.

health check

A system call to check on the health status of each instance in an Amazon EC2 Auto Scaling (p. 804) group.

high-quality email

Email that recipients find valuable and want to receive. Value means different things to different recipients and can come in such forms as offers, order confirmations, receipts, or newsletters.

highlights

Amazon CloudSearch (p. 803): Excerpts returned with search results that show where the search terms appear within the text of the matching documents.

highlight enabled

Amazon CloudSearch (p. 803): An index field option that enables matches within the field to be highlighted.

hit

A document that matches the criteria specified in a search request. Also referred to as a search result.

HMAC

Hash-based Message Authentication Code. A specific construction for calculating a message authentication code (MAC) involving a cryptographic hash function in combination with a secret key. You can use it to verify both the data integrity and the authenticity of a message at the same time. AWS calculates the HMAC using a standard, cryptographic hash algorithm, such as SHA-256.

hosted zone

A collection of resource record (p. 848) sets that Amazon Route 53 (p. 808) hosts. Similar to a traditional DNS zone file, a hosted zone represents a collection of records that are managed together under a single domain name.

HRNN

Amazon Personalize (p. 807): A hierarchical recurrent neural network machine learning algorithm that models changes in user behavior and predicts the items that a user might interact with in personal recommendation applications.

HTTP-Query

See Query.

HVM virtualization

Hardware Virtual Machine virtualization. Allows the guest VM to run as though it's on a native hardware platform, except that it still uses paravirtual (PV) network and storage drivers for improved performance. See Also PV virtualization.
IAM
- See AWS Identity and Access Management (IAM).

IAM group
- See group.

IAM policy simulator
- See policy simulator.

IAM role
- See role.

IAM user
- See user.

Identity and Access Management
- See AWS Identity and Access Management (IAM).

Identity provider (IdP)
- An IAM (p. 814) entity that holds metadata about external identity providers.

IdP
- See identity provider (IdP).

image
- See Amazon Machine Image (AMI).

import/export station
- A machine that uploads or downloads your data to or from Amazon S3 (p. 809).

import log
- A report that contains details about how AWS Import/Export (p. 814) processed your data.

implicit impressions
- Amazon Personalize (p. 807): The recommendations that your application shows a user. Unlike explicit impressions, where you manually record each impression, Amazon Personalize automatically derives implicit impressions from your recommendation data.
- See Also recommendations, impressions data, explicit impressions.

impressions data
- Amazon Personalize (p. 807): The list of items that you presented to a user when they interacted with a particular item such as by clicking it, watching it, or purchasing it. Amazon Personalize uses impressions data to calculate the relevance of new items for a user based on how frequently users have selected or ignored the same item.
- See Also explicit impressions, implicit impressions.

in-place deployment
- CodeDeploy: A deployment method where the application on each instance in the deployment group is stopped, the latest application revision is installed, and the new version of the application is started and validated. You can choose to use a load balancer so each instance is deregistered during its deployment and then restored to service after the deployment is complete.

index
- See search index.

index field
- A name–value pair that's included in an Amazon CloudSearch (p. 803) domain's index. An index field can contain text or numeric data, dates, or a location.

indexing options
- Configuration settings that define an Amazon CloudSearch (p. 803) domain's index fields, how document data is mapped to those index fields, and how the index fields can be used.

inline policy
- An IAM (p. 814) policy (p. 843) that's embedded in a single IAM user (p. 857), group (p. 832), or role (p. 848).
input data
Amazon Machine Learning: The observations that you provide to Amazon Machine Learning to train and evaluate a machine learning model and generate predictions.

instance
A copy of an Amazon Machine Image (AMI) running as a virtual server in the AWS Cloud.

instance family
A general instance type grouping using either storage or CPU capacity.

instance group
A Hadoop cluster contains one master instance group that contains one master node, a core instance group containing one or more core nodes and an optional task node instance group, which can contain any number of task nodes.

instance profile
A container that passes IAM role information to an EC2 instance at launch.

instance store
Disk storage that's physically attached to the host computer for an EC2 instance, and therefore has the same lifespan as the instance. When the instance is terminated, you lose any data in the instance store.

instance store-backed AMI
A type of Amazon Machine Image whose instances use an instance store volume as the root device. Compare this with instances launched from Amazon EBS-backed AMIs, which use an Amazon EBS volume as the root device.

instance type
A specification that defines the memory, CPU, storage capacity, and usage cost for an instance. Some instance types are designed for standard applications, whereas others are designed for CPU-intensive, memory-intensive applications, and so on.

Interactions dataset
Amazon Personalize: A container for historical and real-time data collected from interactions between users and items (called events). Interactions data can include impressions data and contextual metadata.

internet gateway
Connects a network to the internet. You can route traffic for IP addresses outside your VPC to the internet gateway.

internet service provider (ISP)
A company that provides subscribers with access to the internet. Many ISPs are also mailbox providers. Mailbox providers are sometimes referred to as ISPs, even if they only provide mailbox services.

intrinsic function
A special action in a AWS CloudFormation template that assigns values to properties not available until runtime. These functions follow the format `Fn::Attribute`, such as `Fn::GetAtt`. Arguments for intrinsic functions can be parameters, pseudo parameters, or the output of other intrinsic functions.

IP address
A numerical address (for example, 192.0.2.44) that networked devices use to communicate with one another using the Internet Protocol (IP). Each EC2 instance is assigned two IP addresses at launch, which are directly mapped to each other through network address translation (NAT): a private IP address (following RFC 1918) and a public IP address. Instances launched in a VPC are assigned only a private IP address. Instances launched in your default VPC are assigned both a private IP address and a public IP address.

IP match condition
AWS WAF: An attribute that specifies the IP addresses or IP address ranges that web requests originate from. Based on the specified IP
addresses, you can configure AWS WAF to allow or block web requests to AWS resource (p. 848)s such as Amazon CloudFront (p. 803) distributions.

ISP

See internet service provider (ISP).

issuer

The person who writes a policy (p. 843) to grant permissions to a resource (p. 848). The issuer (by definition) is always the resource owner. AWS doesn't permit Amazon SQS (p. 809) users to create policies for resources they don't own. If John is the resource owner, AWS authenticates John's identity when he submits the policy he's written to grant permissions for that resource.

item

A group of attributes that's uniquely identifiable among all of the other items. Items in Amazon DynamoDB (p. 804) are similar in many ways to rows, records, or tuples in other database systems.

item exploration

Amazon Personalize (p. 807): The process that Amazon Personalize uses to test different item recommendations, including recommendations of new items with no or very little interaction data, and learn how users respond. You configure item exploration at the campaign level for solution versions created with the user-personalization recipe.
See Also recommendations, campaign, solution version, user-personalization recipe.

item-to-item similarities

(A SIMS) recipe

Amazon Personalize (p. 807): A RELATED_ITEMS recipe that uses the data from an Interactions dataset to make recommendations for items that are similar to a specified item. The SIMS recipe calculates similarity based on the way users interact with items instead of matching item metadata, such as price or age.
See Also recipe, RELATED_ITEMS recipes, Interactions dataset.

Items dataset

Amazon Personalize (p. 807): A container for metadata about items, such as price, genre, or availability.
See Also dataset.

job flow

Amazon EMR (p. 805): One or more step (p. 853)s that specify all of the functions to be performed on the data.

job ID

A five-character, alphanumeric string that uniquely identifies an AWS Import/Export (p. 814) storage device in your shipment. AWS issues the job ID in response to a CREATE JOB email command.

job prefix

An optional string that you can add to the beginning of an AWS Import/Export (p. 814) log file name to prevent collisions with objects of the same name.
See Also key prefix.

JSON

JavaScript Object Notation. A lightweight data interchange format. For information about JSON, see http://www.json.org/.

junk folder

The location where email messages that various filters determine to be of lesser value are collected so that they don't arrive in the recipient (p. 846)'s inbox but are still accessible to the recipient. This is also referred to as a spam (p. 852) or bulk folder.
**key**

A credential that identifies an AWS account (p. 802) or user (p. 857) to AWS (such as the AWS secret access key (p. 850)).

**Amazon Simple Storage Service (Amazon S3) (p. 809), Amazon EMR (p. 805):**

The unique identifier for an object in a bucket (p. 819). Every object in a bucket has exactly one key. Because a bucket and key together uniquely identify each object, you can think of Amazon S3 as a basic data map between the bucket + key, and the object itself. You can uniquely address every object in Amazon S3 through the combination of the web service endpoint, bucket name, and key, as in this example: http://doc.s3.amazonaws.com/2006-03-01/AmazonS3.wsdl, where doc is the name of the bucket, and 2006-03-01/AmazonS3.wsdl is the key.

**AWS Import/Export (p. 814):** The name of an object in Amazon S3. It's a sequence of Unicode characters whose UTF-8 encoding can't exceed 1024 bytes. If a key (for example, logPrefix + import-log-JOBID) is longer than 1024 bytes, AWS Elastic Beanstalk (p. 813) returns an InvalidManifestField error.

**IAM (p. 814):** In a policy (p. 843), a specific characteristic that's the basis for restricting access (such as the current time or the IP address of the requester).

Tagging resources: A general tag (p. 855) label that acts like a category for more specific tag values. For example, you might have EC2 instance (p. 827) with the tag key of Owner and the tag value of Jan. You can tag an AWS resource (p. 848) with up to 10 key–value pairs. Not all AWS resources can be tagged.

**key pair**

A set of security credentials that you use to prove your identity electronically. A key pair consists of a private key and a public key.

**key prefix**

A string of characters that is a subset of an object key name, starting with the first character. The prefix can be any length, up to the maximum length of the object key name (1,024 bytes).

**kibibyte (KiB)**

A contraction of kilo binary byte, a kibibyte is 2^10 or 1,024 bytes. A kilobyte (KB) is 10^3 or 1,000 bytes. 1,024 KiB is a mebibyte (MiB) (p. 838).

**KMS**

See AWS Key Management Service (AWS KMS).

---

**labeled data**

In machine learning, data for which you already know the target or “correct” answer.

**launch configuration**

A set of descriptive parameters used to create new EC2 instance (p. 827)s in an Amazon EC2 Auto Scaling (p. 804) activity.
A template that an **Auto Scaling group** (p. 811) uses to launch new EC2 instances. The launch configuration contains information such as the **Amazon Machine Image (AMI)** (p. 807) ID, the instance type, key pairs, **security group** (p. 850)s, and block device mappings, among other configuration settings.

**launch permission**

An **Amazon Machine Image (AMI)** (p. 807) attribute that allows users to launch an AMI.

**lifecycle**

The lifecycle state of the **EC2 instance** (p. 827) contained in an **Auto Scaling group** (p. 811). EC2 instances progress through several states over their lifespan; these include **Pending**, **InService**, **Terminating** and **Terminated**.

**lifecycle action**

An action that can be paused by Auto Scaling, such as launching or terminating an EC2 instance.

**lifecycle hook**

A feature for pausing Auto Scaling after it launches or terminates an EC2 instance so that you can perform a custom action while the instance isn't in service.

**link to VPC**

The process of linking (or attaching) an **EC2-Classic instance** (p. 834) to a **ClassicLink-enabled VPC** (p. 859).

See Also **ClassicLink**, **unlink from VPC**.

**load balancer**

A DNS name combined with a set of ports, which together provide a destination for all requests intended for your application. A load balancer can distribute traffic to multiple application instances across every **Availability Zone** (p. 811) within a **Region** (p. 847). Load balancers can span multiple Availability Zones within an AWS Region into which an **Amazon EC2** (p. 804) instance was launched. But load balancers can't span multiple Regions.

**local secondary index**

An index that has the same partition key as the table, but a different sort key. A local secondary index is local in the sense that every partition of a local secondary index is scoped to a table partition that has the same partition key value.

See Also **local secondary index**.

**logical name**

A case-sensitive unique string within an **AWS CloudFormation** (p. 812) template that identifies a **resource** (p. 848), **mapping** (p. 838), parameter, or output. In an AWS CloudFormation template, each parameter, resource (p. 848), property, mapping, and output must be declared with a unique logical name. You use the logical name when dereferencing these items using the `Ref` function.

---

**Mail Transfer Agent (MTA)**

Software that transports email messages from one computer to another by using a client-server architecture.

**mailbox provider**

An organization that provides email mailbox hosting services. Mailbox providers are sometimes referred to as **internet service provider (ISP)** (p. 834)s, even if they only provide mailbox services.

**mailbox simulator**

A set of email addresses that you can use to test an **Amazon SES** (p. 808)-based email-sending application without sending messages to actual recipients. Each
email address represents a specific scenario (such as a bounce or complaint) and generates a typical response that's specific to the scenario.

**main route table**

The default route table (p. 849) that any new VPC (p. 859) subnet (p. 854) uses for routing. You can associate a subnet with a different route table of your choice. You can also change which route table is the main route table.

**managed policy**

A standalone IAM (p. 814) policy (p. 843) that you can attach to multiple user (p. 857)s, group (p. 832)s, and role (p. 848)s in your IAM account (p. 802). Managed policies can either be AWS managed policies (which are created and managed by AWS) or customer managed policies (which you create and manage in your AWS account).

**manifest**

When sending a create job request for an import or export operation, you describe your job in a text file called a manifest. The manifest file is a YAML-formatted file that specifies how to transfer data between your storage device and the AWS Cloud.

**manifest file**

Amazon Machine Learning: The file used for describing batch predictions. The manifest file relates each input data file with its associated batch prediction results. It's stored in the Amazon S3 output location.

**mapping**

A way to add conditional parameter values to an AWS CloudFormation (p. 812) template. You specify mappings in the template's optional Mappings section and retrieve the desired value using the `**FN::FindInMap**` function.

**marker**

See pagination token.

**master node**

A process running on an Amazon Machine Image (AMI) (p. 807) that keeps track of the work its core and task nodes complete.

**maximum price**

The maximum price you will pay to launch one or more Spot Instance (p. 853)s. If your maximum price exceeds the current Spot price (p. 853) and your restrictions are met, Amazon EC2 (p. 804) launches instances on your behalf.

**maximum send rate**

The maximum number of email messages that you can send per second using Amazon SES (p. 808).

**mean reciprocal rank at 25**

Amazon Personalize (p. 807): An evaluation metric that assesses the relevance of a model's highest ranked recommendation. Amazon Personalize calculates this metric using the average accuracy of the model when ranking the most relevant recommendation out of the top 25 recommendations over all requests for recommendations. See Also metrics, recommendations.

**mebibyte (MiB)**

A contraction of mega binary byte, a mebibyte is 2^20 or 1,048,576 bytes. A megabyte (MB) is 10^6 or 1,000,000 bytes. 1,024 MiB is a gibibyte (GiB) (p. 831).

**member resources**

See resource.

**message ID**

Amazon Simple Email Service (Amazon SES) (p. 808): A unique identifier that's assigned to every email message that's sent.

Amazon Simple Queue Service (Amazon SQS) (p. 809): The identifier returned when you send a message to a queue.

**metadata**

Information about other data or objects. In Amazon Simple Storage Service (Amazon S3) (p. 809) and Amazon EMR (p. 805) metadata takes the form of
name–value pairs that describe the object. These include default metadata such as the date last modified and standard HTTP metadata (for example, Content-Type). Users can also specify custom metadata at the time they store an object. In Amazon EC2 (p. 804) metadata includes data about an EC2 instance (p. 827) that the instance can retrieve to determine things about itself, such as the instance type or the IP address.

metric
An element of time-series data defined by a unique combination of exactly one namespace (p. 840), exactly one metric name, and between zero and ten dimensions. Metrics and the statistics derived from them are the basis of Amazon CloudWatch (p. 803).

metrics
Amazon Personalize (p. 807): Evaluation data that Amazon Personalize generates when you train a model. You use metrics to evaluate the performance of the model, view the effects of modifying a solution's configuration, and compare results between solutions that use the same training data but were created with different recipes. See Also solution, recipe.

metric name
The primary identifier of a metric, used in combination with a namespace (p. 840) and optional dimensions.

MFA
See multi-factor authentication (MFA).

micro instance
A type of EC2 instance (p. 827) that's more economical to use if you have occasional bursts of high CPU activity.

MIME
See Multipurpose Internet Mail Extensions (MIME).

ML model
In machine learning (ML), a mathematical model that generates predictions by finding patterns in data. Amazon Machine Learning supports three types of ML models: binary classification, multiclass classification, and regression. Also known as a predictive model. See Also binary classification model, multiclass classification model, regression model.

MTA
See Mail Transfer Agent (MTA).

Multi-AZ deployment
A primary DB instance (p. 825) that has a synchronous standby replica in a different Availability Zone (p. 811). The primary DB instance is synchronously replicated across Availability Zones to the standby replica.

multiclass classification model
A machine learning model that predicts values that belong to a limited, pre-defined set of permissible values. For example, "Is this product a book, movie, or clothing?"

multi-factor authentication (MFA)
An optional AWS account (p. 802) security feature. Once you enable AWS MFA, you must provide a six-digit, single-use code in addition to your sign-in credentials whenever you access secure AWS webpages or the AWS Management Console (p. 815). You get this single-use code from an authentication device that you keep in your physical possession. See Also https://aws.amazon.com/mfa/.

multi-valued attribute
An attribute with more than one value.

multipart upload
A feature that you can use to upload a single object as a set of parts.

Multipurpose Internet Mail Extensions (MIME)
An internet standard that extends the email protocol to include non-ASCII text and nontext elements, such as attachments.
Multitool

A cascading application that provides a simple command-line interface for managing large datasets.

N

namespace

An abstract container that provides context for the items (names, or technical terms, or words) it holds, and allows disambiguation of homonym items residing in different namespaces.

NAT

Network address translation. A strategy of mapping one or more IP addresses to another while data packets are in transit across a traffic routing device. This is commonly used to restrict internet communication to private instances while allowing outgoing traffic.

See Also Network Address Translation and Protocol Translation, NAT gateway, NAT instance.

NAT gateway

A NAT (p. 840) device, managed by AWS, that performs network address translation in a private subnet (p. 854), to secure inbound internet traffic. A NAT gateway uses both NAT and port address translation.

See Also NAT instance.

NAT instance

A NAT (p. 840) device, configured by a user, that performs network address translation in a VPC (p. 859) public subnet (p. 854) to secure inbound internet traffic.

See Also NAT gateway.

network ACL

An optional layer of security that acts as a firewall for controlling traffic in and out of a subnet (p. 854). You can associate multiple subnets with a single network ACL (p. 801), but a subnet can be associated with only one network ACL at a time.

Network Address Translation and Protocol Translation (NAT (p. 840)-PT) An internet protocol standard defined in RFC 2766.

See Also NAT instance, NAT gateway.

n-gram processor

A processor that performs n-gram transformations.

See Also n-gram transformation.

n-gram transformation

Amazon Machine Learning: A transformation that aids in text string analysis. An n-gram transformation takes a text variable as input and outputs strings by sliding a window of size $n$ words, where $n$ is specified by the user, over the text, and outputting every string of words of size $n$ and all smaller sizes. For example, specifying the n-gram transformation with window size =2 returns all the two-word combinations and all of the single words.

Nice Desktop Cloud Visualization

A remote visualization technology for securely connecting users to graphic-intensive 3D applications hosted on a remote, high-performance server.

node

Amazon OpenSearch Service (OpenSearch Service) (p. 805): An OpenSearch instance. A node can be either a data instance or a dedicated master instance.

See Also dedicated master node.

NoEcho

A property of AWS CloudFormation (p. 812) parameters that prevent the otherwise default reporting of names and values of a template parameter.
Declaring the `NoEcho` property causes the parameter value to be masked with asterisks in the report by the `cfn-describe-stacks` command.

**normalized discounted cumulative gain (NCDG) at K (5/10/25)**

Amazon Personalize (p. 807): An evaluation metric that tells you about the relevance of your model's highly ranked recommendations, where K is a sample size of 5, 10, or 25 recommendations. Amazon Personalize calculates this by assigning weight to recommendations based on their position in a ranked list, where each recommendation is discounted (given a lower weight) by a factor dependent on its position. The normalized discounted cumulative gain at K assumes that recommendations that are lower on a list are less relevant than recommendations higher on the list.

See Also metrics, recommendations.

**NoSQL**

Nonrelational database systems that are highly available, scalable, and optimized for high performance. Instead of the relational model, NoSQL databases (for example, Amazon DynamoDB (p. 804)) use alternate models for data management, such as key-value pairs or document storage.

**null object**

A null object is one whose version ID is null. Amazon S3 (p. 809) adds a null object to a bucket (p. 819) when versioning (p. 858) for that bucket is suspended. It’s possible to have only one null object for each key in a bucket.

**number of passes**

The number of times that you allow Amazon Machine Learning to use the same data records to train a machine learning model.

---

**Numbers and symbols**

- `A` (p. 801)
- `B` (p. 818)
- `C` (p. 819)
- `D` (p. 824)
- `E` (p. 827)
- `F` (p. 830)
- `G` (p. 831)
- `H` (p. 832)
- `I` (p. 833)
- `J` (p. 835)
- `K` (p. 836)
- `L` (p. 836)
- `M` (p. 837)
- `N` (p. 840)
- `O` (p. 841)
- `P` (p. 842)
- `Q` (p. 845)
- `R` (p. 846)
- `S` (p. 849)
- `T` (p. 855)
- `U` (p. 857)
- `V` (p. 858)
- `W` (p. 859)
- `X`, `Y`, `Z` (p. 859)

**object**

Amazon Simple Storage Service (Amazon S3) (p. 809): The fundamental entity type stored in Amazon S3. Objects consist of object data and metadata. The data portion is opaque to Amazon S3.

Amazon CloudFront (p. 803): Any entity that can be served either over HTTP or a version of RTMP.

**observation**

Amazon Machine Learning: A single instance of data that Amazon Machine Learning (Amazon ML) uses to either train a machine learning model how to predict or to generate a prediction. Each row in an Amazon ML input data file is an observation.

**On-Demand Instance**

An Amazon EC2 (p. 804) pricing option that charges you for compute capacity by the hour or second (minimum of 60 seconds) with no long-term commitment.

**operation**

An API function. Also called an action.

**optimistic locking**

A strategy to ensure that an item that you want to update has not been modified by others before you perform the update. For Amazon DynamoDB (p. 804), optimistic locking support is provided by the AWS SDKs.

**organization**

AWS Organizations (p. 816): An entity that you create to consolidate and manage your AWS accounts. An organization has one management account along with zero or more member accounts.

**organizational unit**

AWS Organizations (p. 816): A container for accounts within a root (p. 848) of an organization. An organizational unit (OU) can contain other OUs.
origin access identity

Also called OAI. When using Amazon CloudFront (p. 803) to serve content with an Amazon S3 (p. 809) bucket (p. 819) as the origin, a virtual identity that you use to require users to access your content through CloudFront URLs instead of Amazon S3 URLs. Usually used with CloudFront private content (p. 844).

origin server

The Amazon S3 (p. 809) bucket (p. 819) or custom origin containing the definitive original version of the content you deliver through CloudFront (p. 803).

original environment

The instances in a deployment group at the start of an CodeDeploy blue/green deployment.

OSB transformation

Orthogonal sparse bigram transformation. In machine learning, a transformation that aids in text string analysis and that's an alternative to the n-gram transformation. OSB transformations are generated by sliding the window of size $n$ words over the text, and outputting every pair of words that includes the first word in the window.

See Also n-gram transformation.

OU

See organizational unit.

output location

Amazon Machine Learning: An Amazon S3 location where the results of a batch prediction are stored.

pagination

The process of responding to an API request by returning a large list of records in small separate parts. Pagination can occur in the following situations:

- The client sets the maximum number of returned records to a value below the total number of records.
- The service has a default maximum number of returned records that's lower than the total number of records.

When an API response is paginated, the service sends a subset of the large list of records and a pagination token that indicates that more records are available. The client includes this pagination token in a subsequent API request, and the service responds with the next subset of records. This continues until the service responds with a subset of records and no pagination token, indicating that all records have been sent.

pagination token

A marker that indicates that an API response contains a subset of a larger list of records. The client can return this marker in a subsequent API request to retrieve the next subset of records until the service responds with a subset of records and no pagination token, indicating that all records have been sent.

See Also pagination.

paid AMI

An Amazon Machine Image (AMI) (p. 807) that you sell to other Amazon EC2 (p. 804) users on AWS Marketplace (p. 815).

paravirtual virtualization

See PV virtualization.

part

A contiguous portion of the object's data in a multipart upload request.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>partition key</td>
<td>A simple primary key, composed of one attribute (also known as a hash attribute). See Also partition key, sort key.</td>

<tr>
<td>PAT</td>
<td>Port address translation.</td>
</tr>
<tr>
<td>pebibyte (PiB)</td>
<td>A contraction of peta binary byte, a pebibyte is $2^{50}$ or 1,125,899,906,422,624 bytes. A petabyte (PB) is $10^{15}$ or 1,000,000,000,000,000 bytes. 1,024 PiB is an exbibyte (EiB) (p. 829).</td>
</tr>
<tr>
<td>period</td>
<td>See sampling period.</td>
</tr>
<tr>
<td>permission</td>
<td>A statement within a policy (p. 843) that allows or denies access to a particular resource (p. 848). You can state any permission in the following way: “A has permission to do B to C.” For example, Jane (A) has permission to read messages (B) from John's Amazon SQS (p. 809) queue (C). Whenever Jane sends a request to Amazon SQS to use John's queue, the service checks to see if she has permission. It further checks to see if the request satisfies the conditions John set forth in the permission.</td>
</tr>
<tr>
<td>persistent storage</td>
<td>A data storage solution where the data remains intact until it's deleted. Options within AWS (p. 809) include: Amazon S3 (p. 809), Amazon RDS (p. 808), Amazon DynamoDB (p. 804), and other services.</td>
</tr>
<tr>
<td>PERSONALIZED_RANKING recipes</td>
<td>Amazon Personalize (p. 807): Recipes that provide item recommendations in ranked order based on the predicted interest for a user. See Also recipe, recommendations, personalized-ranking recipe, popularity-count recipe.</td>
</tr>
<tr>
<td>personalized-ranking recipe</td>
<td>Amazon Personalize (p. 807): A PERSONALIZED_RANKING recipe that ranks a collection of items that you provide based on the predicted interest level for a specific user. Use the personalized-ranking recipe to create curated lists of items or ordered search results that are personalized for a specific user. See Also recipe, PERSONALIZED_RANKING recipes.</td>
</tr>
<tr>
<td>physical name</td>
<td>A unique label that AWS CloudFormation (p. 812) assigns to each resource (p. 848) when creating a stack (p. 853). Some AWS CloudFormation commands accept the physical name as a value with the --physical-name parameter.</td>
</tr>
<tr>
<td>pipeline</td>
<td>AWS CodePipeline (p. 812): A workflow construct that defines the way software changes go through a release process.</td>
</tr>
<tr>
<td>plaintext</td>
<td>Information that has not been encrypted (p. 828), as opposed to ciphertext (p. 820).</td>
</tr>
<tr>
<td>policy</td>
<td>IAM (p. 814): A document defining permissions that apply to a user, group, or role; the permissions in turn determine what users can do in AWS. A policy typically allow (p. 803)s access to specific actions, and can optionally grant that the actions are allowed for specific resource (p. 848)s, such as EC2 instance (p. 827)s or Amazon S3 (p. 809) bucket (p. 819)s. Policies can also explicitly deny (p. 826) access. Amazon EC2 Auto Scaling (p. 804): An object that stores the information needed to launch or terminate instances for an Auto Scaling group. Running the policy causes instances to be launched or terminated. You can configure an alarm (p. 802) to invoke an Auto Scaling policy.</td>
</tr>
<tr>
<td>policy generator</td>
<td>A tool in the IAM (p. 814) AWS Management Console (p. 815) that helps you build a policy (p. 843) by selecting elements from lists of available options.</td>
</tr>
</tbody>
</table>
policy simulator A tool in the IAM (p. 814) AWS Management Console (p. 815) that helps you test and troubleshoot policies (p. 843) so you can see their effects in real-world scenarios.

policy validator A tool in the IAM (p. 814) AWS Management Console (p. 815) that examines your existing IAM access control policies (p. 843) to ensure that they comply with the IAM policy grammar.

popularity-count recipe Amazon Personalize (p. 807): A USER_PERSONALIZATION recipe that recommends the items that have had the most interactions with unique users. See Also recipe, USER_PERSONALIZATION recipes.

precision at K (5/10/25) Amazon Personalize (p. 807): An evaluation metric that tells you how relevant your model’s recommendations are based on a sample size of K (5, 10, or 25) recommendations. Amazon Personalize calculates this metric based on the number of relevant recommendations out of the top K recommendations, divided by K, where K is 5, 10, or 25. See Also metrics, recommendations.

prefix See job prefix.

Premium Support A one-on-one, fast-response support channel that AWS customers can subscribe to for support for AWS infrastructure services. See Also https://aws.amazon.com/premiumsupport/.

presigned URL A web address that uses query string authentication (p. 845).

primary key One or two attributes that uniquely identify each item in a Amazon DynamoDB (p. 804) table, so that no two items can have the same key. See Also partition key, sort key.

primary shard See shard.

principal The user (p. 857), service, or account (p. 802) that receives permissions that are defined in a policy (p. 843). The principal is A in the statement “A has permission to do B to C.”

private content When using Amazon CloudFront (p. 803) to serve content with an Amazon S3 (p. 809) bucket (p. 819) as the origin, a method of controlling access to your content by requiring users to use signed URLs. Signed URLs can restrict user access based on the current date and time, the IP addresses that the requests originate from, or both.

private IP address A private numerical address (for example, 192.0.2.44) that networked devices use to communicate with one another using the Internet Protocol (IP). Each EC2 instance (p. 827) is assigned two IP addresses at launch, which are directly mapped to each other through network address translation (NAT (p. 840)): a private address (following RFC 1918) and a public address. Exception: Instances launched in Amazon VPC (p. 809) are assigned only a private IP address.

private subnet A VPC (p. 859) subnet (p. 854) whose instances can’t be reached from the internet.

product code An identifier provided by AWS when you submit a product to AWS Marketplace (p. 815).

properties See resource property.

property rule A JSON (p. 835)-compliant markup standard for declaring properties, mappings, and output values in an AWS CloudFormation (p. 812) template.
Provisioned IOPS

A storage option designed to deliver fast, predictable, and consistent I/O performance. When you specify an IOPS rate while creating a DB instance, Amazon RDS (p. 808) provisions that IOPS rate for the lifetime of the DB instance.

pseudo parameter

A predefined setting (for example, AWS:StackName) that can be used in AWS CloudFormation (p. 812) templates without having to declare them. You can use pseudo parameters anywhere you can use a regular parameter.

public AMI

An Amazon Machine Image (AMI) (p. 807) that all AWS accounts (p. 802) have permission to launch.

public dataset

A large collection of public information that can be seamlessly integrated into applications that are based in the AWS Cloud. Amazon stores public datasets at no charge to the community and, similar to other AWS services, users pay only for the compute and storage they use for their own applications. These datasets currently include data from the Human Genome Project, the US Census, Wikipedia, and other sources. See Also https://aws.amazon.com/publicdatasets.

public IP address

A public numerical address (for example, 192.0.2.44) that networked devices use to communicate with one another using the Internet Protocol (IP). Each EC2 instance (p. 827) is assigned two IP addresses at launch, which are directly mapped to each other through Network Address Translation (NAT (p. 840)): a private address (following RFC 1918) and a public address. Exception: Instances launched in Amazon VPC (p. 809) are assigned only a private IP address.

public subnet

A subnet (p. 854) whose instances can be reached from the internet.

PV virtualization

Paravirtual virtualization. Allows guest VMs to run on host systems that don't have special support extensions for full hardware and CPU virtualization. Because PV guests run a modified operating system that doesn't use hardware emulation, they can't provide hardware-related features, such as enhanced networking or GPU support. See Also HVM virtualization.

quartile binning transformation

Amazon Machine Learning: A process that takes two inputs, a numerical variable and a parameter called a bin number, and outputs a categorical variable. Quartile binning transformations discover non-linearity in a variable's distribution by enabling the machine learning model to learn separate importance values for parts of the numeric variable's distribution.

Query

A type of web service that generally uses only the GET or POST HTTP method and a query string with parameters in the URL. See Also REST.

query string authentication

An AWS feature that you can use to place the authentication information in the HTTP request query string instead of in the Authorization header, which provides URL-based access to objects in a bucket (p. 819).

queue

A sequence of messages or jobs that are held in temporary storage awaiting transmission or processing.
queue URL
A web address that uniquely identifies a queue.

quota
The maximum value for your resources, actions, and items in your AWS account.

R

range GET
A request that specifies a byte range of data to get for a download. If an object is large, you can break up a download into smaller units by sending multiple range GET requests that each specify a different byte range to GET.

raw email
A type of sendmail request with which you can specify the email headers and MIME types.

RDS
See Amazon Relational Database Service (Amazon RDS).

read replica
Amazon RDS (p. 808): An active copy of another DB instance. Any updates to the data on the source DB instance are replicated to the read replica DB instance using the built-in replication feature of MySQL 5.1.

real-time predictions
Amazon Machine Learning: Synchronously generated predictions for individual data observations.
See Also batch prediction.

recipe
Amazon Personalize (p. 807): An Amazon Personalize algorithm that's preconfigured to predict the items that a user will interact with (for USER_PERSONALIZATION recipes), or calculate items that are similar to specific items that a user has shown interest in (for RELATED_ITEMS recipes), or rank a collection of items that you provide based on the predicted interest for a specific user (for PERSONALIZED_RANKING recipes).
See Also USER_PERSONALIZATION recipes, RELATED_ITEMS recipes, PERSONALIZED_RANKING recipes.

recommendations
Amazon Personalize (p. 807): A list of items that Amazon Personalize predicts that a user will interact with. Depending on the Amazon Personalize recipe used, recommendations can be either a list of items (with USER_PERSONALIZATION recipes and RELATED_ITEMS recipes), or a ranking of a collection of items you provided (with PERSONALIZED_RANKING recipes).
See Also recipe, campaign, solution version, USER_PERSONALIZATION recipes, RELATED_ITEMS recipes, PERSONALIZED_RANKING recipes.

receipt handle
Amazon SQS (p. 809): An identifier that you get when you receive a message from the queue. This identifier is required to delete a message from the queue or when changing a message's visibility timeout.

receiver
The entity that consists of the network systems, software, and policies that manage email delivery for a recipient (p. 846).

recipient
Amazon Simple Email Service (Amazon SES) (p. 808): The person or entity receiving an email message. For example, a person named in the "To" field of a message.

Redis
A fast, open-source, in-memory key-value data structure store. Redis comes with a set of versatile in-memory data structures with which you can easily create a variety of custom applications.
| **reference** | A means of inserting a property from one AWS resource (p. 848) into another. For example, you could insert an Amazon EC2 (p. 804) security group (p. 850) property into an Amazon RDS (p. 808) resource. |
| **Region** | A named set of AWS resources (p. 848) in the same geographical area. A Region comprises at least two Availability Zone (p. 811)s. |
| **regression model** | Amazon Machine Learning: Preformatted instructions for common data transformations that fine-tune machine learning model performance. |
| **regression model** | A type of machine learning model that predicts a numeric value, such as the exact purchase price of a house. |
| **regularization** | A machine learning (ML) parameter that you can tune to obtain higher-quality ML models. Regularization helps prevent ML models from memorizing training data examples instead of learning how to generalize the patterns it sees (called overfitting). When training data is overfitted, the ML model performs well on the training data, but doesn’t perform well on the evaluation data or on new data. |
| **RELATED_ITEMS recipes** | Amazon Personalize (p. 807) Recipes that recommend items that are similar to a specified item, such as the item-to-item (SIMS) recipe. See Also recipe, item-to-item similarities (SIMS) recipe. |
| **replacement environment** | The instances in a deployment group after the CodeDeploy blue/green deployment. |
| **replica shard** | See shard. |
| **reply path** | The email address that an email reply is sent to. This is different from the return path (p. 848). |
| **representational state transfer** | See REST. |
| **reputation** | 1. An Amazon SES (p. 808) metric, based on factors that might include bounce (p. 819)s, complaint (p. 821)s, and other metrics, regarding whether or not a customer is sending high-quality email.  
2. A measure of confidence, as judged by an internet service provider (ISP) (p. 834) or other entity that an IP address that they are receiving email from isn’t the source of spam (p. 852). |
| **requester** | The person (or application) that sends a request to AWS to perform a specific action. When AWS receives a request, it first evaluates the requester's permissions to determine whether the requester is allowed to perform the request action (if applicable, for the requested resource (p. 848)). |
| **Requester Pays** | An Amazon S3 (p. 809) feature that allows a bucket owner (p. 819) to specify that anyone who requests access to objects in a particular bucket (p. 819) must pay the data transfer and request costs. |
| **reservation** | A collection of EC2 instance (p. 827)s started as part of the same launch request. Not to be confused with a Reserved Instance (p. 847). |
| **Reserved Instance** | A pricing option for EC2 instance (p. 827)s that discounts the on-demand (p. 841) usage charge for instances that meet the specified parameters. Customers pay for the entire term of the instance, regardless of how they use it. |
| **Reserved Instance Marketplace** | An online exchange that matches sellers who have reserved capacity that they no longer need with buyers who are looking to purchase additional capacity. |
Reserved Instances (p. 847) that you purchase from third-party sellers have less than a full standard term remaining and can be sold at different upfront prices. The usage or reoccurring fees remain the same as the fees set when the Reserved Instances were originally purchased. Full standard terms for Reserved Instances available from AWS run for one year or three years.

resource
An entity that users can work with in AWS, such as an EC2 instance (p. 827), an Amazon DynamoDB (p. 804) table, an Amazon S3 (p. 809) bucket (p. 819), an IAM (p. 814) user, or an AWS OpsWorks (p. 815) stack (p. 853).

resource property
A value required when including an AWS resource (p. 848) in an AWS CloudFormation (p. 812) stack (p. 853). Each resource can have one or more properties associated with it. For example, an AWS::EC2::Instance resource might have a UserData property. In an AWS CloudFormation template, resources must declare a properties section, even if the resource has no properties.

resource record
Also called resource record set. The fundamental information elements in the Domain Name System (DNS). See Also Domain Name System in Wikipedia.

REST
Representational state transfer. A simple stateless architecture that generally runs over HTTPS/TLS. REST emphasizes that resources have unique and hierarchical identifiers (URIs), are represented by common media types (such as HTML, XML, or JSON (p. 835)), and that operations on the resources are either predefined or discoverable within the media type. In practice, this generally results in a limited number of operations. See Also Query, WSDL, SOAP.

RESTful web service
Also known as RESTful API. A web service that follows REST (p. 848) architectural constraints. The API operations must use HTTP methods explicitly; expose hierarchical URIs; and transfer either XML, JSON (p. 835), or both.

return enabled
Amazon CloudSearch (p. 803): An index field option that enables the field's values to be returned in the search results.

return path
The email address that bounced email is returned to. The return path is specified in the header of the original email. This is different from the reply path (p. 847).

revision
AWS CodePipeline (p. 812): A change made to a source that’s configured in a source action, such as a pushed commit to a GitHub (p. 831) repository or an update to a file in a versioned Amazon S3 (p. 809) bucket (p. 819).

role
A tool for giving temporary access to AWS resource (p. 848)s in your AWS account (p. 802).

rollback
A return to a previous state that follows the failure to create an object, such as AWS CloudFormation (p. 812) stack (p. 853). All resource (p. 848)s associated with the failure are deleted during the rollback. For AWS CloudFormation, you can override this behavior using the --disable-rollback option on the command line.

root
AWS Organizations (p. 816): A parent container for the accounts in your organization. If you apply a service control policy (p. 851) to the root, it applies to every organizational unit (p. 841) and account in the organization.

root credentials
Authentication information associated with the AWS account (p. 802) owner.

root device volume
A volume (p. 859) that contains the image used to boot the instance (p. 834) (also known as a root device). If you launched the instance from an AMI (p. 807) backed by instance store (p. 834), this is an instance store volume (p. 859)
created from a template stored in [Amazon S3](p. 809). If you launched the instance from an AMI backed by [Amazon EBS](p. 805), this is an Amazon EBS volume created from an Amazon EBS snapshot.

**route table**

A set of routing rules that controls the traffic leaving any subnet (p. 854) that's associated with the route table. You can associate multiple subnets with a single route table, but a subnet can be associated with only one route table at a time.

**row identifier**

Amazon Machine Learning: An attribute in the input data that you can include in the evaluation or prediction output to make it easier to associate a prediction with an observation.

**rule**

[AWS WAF](p. 818): A set of conditions that AWS WAF searches for in web requests to AWS resource (p. 848)s such as [Amazon CloudFront](p. 803) distributions. You add rules to a web ACL (p. 859), and then specify whether you want to allow or block web requests based on each rule.

**S**

- **S3**

  See [Amazon Simple Storage Service (Amazon S3)](p. 8).

- **sampling period**

  A defined duration of time, such as one minute, which [Amazon CloudWatch](p. 803) computes a statistic (p. 853) over.

- **sandbox**

  A testing location where you can test the functionality of your application without affecting production, incurring charges, or purchasing products.

  **Amazon SES** (p. 808): An environment that's designed for developers to test and evaluate the service. In the sandbox, you have full access to the Amazon SES API, but you can only send messages to verified email addresses and the mailbox simulator. To get out of the sandbox, you need to apply for production access. Accounts in the sandbox also have lower sending limits (p. 851) than production accounts.

- **scale in**

  To remove EC2 instances from an [Auto Scaling group](p. 811).

- **scale out**

  To add EC2 instances to an [Auto Scaling group](p. 811).

- **scaling policy**

  A description of how Auto Scaling should automatically scale an [Auto Scaling group](p. 811) in response to changing demand. See Also [scale in, scale out](p. 811).

- **scaling activity**

  A process that changes the size, configuration, or makeup of an [Auto Scaling group](p. 811) by launching or terminating instances.

- **scheduler**

  The method used for placing [task](p. 855)s on [container instance](p. 822)s.

- **schema**

  Amazon Machine Learning: The information needed to interpret the input data for a machine learning model, including attribute names and their assigned data types, and the names of special attributes.

- **score cut-off value**

  Amazon Machine Learning: A binary classification model outputs a score that ranges from 0 to 1. To decide whether an observation should be classified as 1 or 0, you pick a classification threshold, or cut-off, and Amazon ML compares the
score against it. Observations with scores higher than the cut-off are predicted as target equals 1, and scores lower than the cut-off are predicted as target equals 0.

**SCP**
See service control policy.

**search API**
Amazon CloudSearch (p. 803): The API that you use to submit search requests to a search domain (p. 850).

**search domain**
Amazon CloudSearch (p. 803): Encapsulates your searchable data and the search instances that handle your search requests. You typically set up a separate Amazon CloudSearch domain for each different collection of data that you want to search.

**search domain configuration**
Amazon CloudSearch (p. 803): A domain's indexing options, analysis scheme (p. 810)s, expression (p. 830)s, suggester (p. 854)s, access policies, and scaling and availability options.

**search enabled**
Amazon CloudSearch (p. 803): An index field option that enables the field data to be searched.

**search endpoint**
Amazon CloudSearch (p. 803): The URL that you connect to when sending search requests to a search domain. Each Amazon CloudSearch domain has a unique search endpoint that remains the same for the life of the domain.

**search index**
Amazon CloudSearch (p. 803): A representation of your searchable data that facilitates fast and accurate data retrieval.

**search instance**
Amazon CloudSearch (p. 803): A compute resource (p. 848) that indexes your data and processes search requests. An Amazon CloudSearch domain has one or more search instances, each with a finite amount of RAM and CPU resources. As your data volume grows, more search instances or larger search instances are deployed to contain your indexed data. When necessary, your index is automatically partitioned across multiple search instances. As your request volume or complexity increases, each search partition is automatically replicated to provide additional processing capacity.

**search request**
Amazon CloudSearch (p. 803): A request that's sent to an Amazon CloudSearch domain's search endpoint to retrieve documents from the index that match particular search criteria.

**search result**
Amazon CloudSearch (p. 803): A document that matches a search request. Also referred to as a search hit.

**secret access key**
A key that's used in conjunction with the access key ID (p. 801) to cryptographically sign programmatic AWS requests. Signing a request identifies the sender and prevents the request from being altered. You can generate secret access keys for your AWS account (p. 802), individual IAM user (p. 857)s, and temporary sessions.

**security group**
A named set of allowed inbound network connections for an instance. (Security groups in Amazon VPC (p. 809) also include support for outbound connections.) Each security group consists of a list of protocols, ports, and IP address ranges. A security group can apply to multiple instances, and multiple groups can regulate a single instance.

**sender**
The person or entity sending an email message.

**Sender ID**
A Microsoft-controlled version of SPF (p. 853). An email authentication and anti-spoofing system. For more information about Sender ID, see Sender ID in Wikipedia.
sending limits
The sending quota (p. 851) and maximum send rate (p. 838) that are associated with every Amazon SES (p. 808) account.

sending quota
The maximum number of email messages that you can send using Amazon SES (p. 808) in a 24-hour period.

server-side encryption (SSE)
The encrypting (p. 828) of data at the server level. Amazon S3 (p. 809) supports three modes of server-side encryption: SSE-S3, where Amazon S3 manages the keys; SSE-C, where the customer manages the keys; and SSE-KMS, where AWS Key Management Service (AWS KMS) (p. 815) manages keys.

service control policy
AWS Organizations (p. 816): A policy-based control that specifies the services and actions that users and roles can use in the accounts that the service control policy (SCP) affects.

service endpoint
See endpoint.

service health dashboard
A webpage showing up-to-the-minute information about AWS service availability. The dashboard is located at http://status.aws.amazon.com/.

Service Quotas
A service for viewing and managing your quotas easily and at scale as your AWS workloads grow. Quotas, also referred to as limits, are the maximum number of resources that you can create in an AWS account.

service role
An IAM (p. 814) role (p. 848) that grants permissions to an AWS service so it can access AWS resource (p. 848)s. The policies that you attach to the service role determine which AWS resources the service can access and what it can do with those resources.

SES
See Amazon Simple Email Service (Amazon SES).

session
The period when the temporary security credentials provided by AWS Security Token Service (AWS STS) (p. 817) allow access to your AWS account.

SHA
Secure Hash Algorithm. SHA1 is an earlier version of the algorithm, which AWS has replaced with SHA256.

shard
Amazon OpenSearch Service (OpenSearch Service) (p. 805): A partition of data in an index. You can split an index into multiple shards, which can include primary shards (original shards) and replica shards (copies of the primary shards). Replica shards provide failover, which means that a replica shard is promoted to a primary shard if a cluster node that contains a primary shard fails. Replica shards also can handle requests.

shared AMI
An Amazon Machine Image (AMI) (p. 807) that a developer builds and makes available for others to use.

shutdown action
Amazon EMR (p. 805): A predefined bootstrap action that launches a script that runs a series of commands in parallel before terminating the job flow.

signature
Refers to a digital signature, which is a mathematical way to confirm the authenticity of a digital message. AWS uses signatures to authenticate the requests you send to our web services. For more information, to https://aws.amazon.com/security.

SIGNATURE file
AWS Import/Export (p. 814): A file you copy to the root directory of your storage device. The file contains a job ID, manifest file, and a signature.

Signature Version 4
Protocol for authenticating inbound API requests to AWS services in all AWS Regions.
Simple Mail Transfer Protocol  See **SMTP**.
Simple Object Access Protocol  See **SOAP**.
Simple Storage Service  See **Amazon Simple Storage Service (Amazon S3)**.
SIMS recipe  See **item-to-item similarities (SIMS) recipe**.
Single Sign-On  See **AWS Single Sign-On**.
Single-AZ DB instance  A standard (non-Multi-AZ) **DB instance** (p. 825) that's deployed in one **Availability Zone** (p. 811), without a standby replica in another **Availability Zone**. See Also **Multi-AZ deployment**.
sloppy phrase search  A search for a phrase that specifies how close the terms must be to one another to be considered a match.
SMTP  Simple Mail Transfer Protocol. The standard that's used to exchange email messages between internet hosts for the purpose of routing and delivery.
snapshot  **Amazon Elastic Block Store (Amazon EBS)** (p. 805): A backup of your **volume** (p. 859) that's stored in **Amazon S3** (p. 809). You can use these snapshots as the starting point for new Amazon EBS volumes or to protect your data for long-term durability. See Also **DB snapshot**.
SNS  See **Amazon Simple Notification Service (Amazon SNS)**.
SOAP  Simple Object Access Protocol. An XML-based protocol that you can use to exchange information over a particular protocol (for example, HTTP or SMTP) between applications. See Also **REST, WSDL**.
soft bounce  A temporary email delivery failure such as one resulting from a full mailbox.
software VPN  A software appliance-based VPN connection over the internet.
solution  **Amazon Personalize** (p. 807): The recipe, customized parameters, and trained models (solution versions) that can be used to generate recommendations. See Also **recipe, solution version, recommendations**.
solution version  **Amazon Personalize** (p. 807): A trained model that you create as part of a solution in Amazon Personalize. You deploy a solution version in a campaign to generate recommendations. See Also **solution, campaign, recommendations**.
sort enabled  **Amazon CloudSearch** (p. 803): An index field option that enables a field to be used to sort the search results.
sort key  An attribute used to sort the order of partition keys in a composite primary key (also known as a **range attribute**). See Also **partition key, primary key**.
source/destination checking  A security measure to verify that an **EC2 instance** (p. 827) is the origin of all traffic that it sends and the ultimate destination of all traffic that it receives; that is, that the instance isn't relaying traffic. Source/destination checking is turned on by default. For instances that function as gateways, such as **VPC** (p. 859) **NAT** (p. 840) instances, source/destination checking must be disabled.
spam  Unsolicited bulk email.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>spamtrap</td>
<td>An email address that's set up by an anti-spam (p. 852) entity, not for correspondence, but to monitor unsolicited email. This is also called a <strong>honeypot</strong>.</td>
</tr>
<tr>
<td>SPF</td>
<td>Sender Policy Framework. A standard for authenticating email.</td>
</tr>
<tr>
<td>Spot Instance</td>
<td>A type of EC2 instance (p. 827) that you can bid on to take advantage of unused Amazon EC2 (p. 804) capacity.</td>
</tr>
<tr>
<td>Spot price</td>
<td>The price for a Spot Instance (p. 853) at any given time. If your maximum price exceeds the current price and your restrictions are met, Amazon EC2 (p. 804) launches instances on your behalf.</td>
</tr>
<tr>
<td>SQL injection match condition</td>
<td>AWS WAF (p. 818): An attribute that specifies the part of web requests (such as a header or a query string) that AWS WAF inspects for malicious SQL code. Based on the specified conditions, you can configure AWS WAF to allow or block web requests to an AWS resource (p. 848), such as an Amazon CloudFront (p. 803) distribution.</td>
</tr>
<tr>
<td>SQS</td>
<td>See Amazon Simple Queue Service (Amazon SQS).</td>
</tr>
<tr>
<td>SSE</td>
<td>See server-side encryption (SSE).</td>
</tr>
<tr>
<td>SSL</td>
<td>Secure Sockets Layer&lt;br&gt;See Also Transport Layer Security (TLS).</td>
</tr>
<tr>
<td>SSO</td>
<td>See AWS Single Sign-On.</td>
</tr>
<tr>
<td>stack</td>
<td>AWS CloudFormation (p. 812): A collection of AWS resources that you create and delete as a single unit.</td>
</tr>
<tr>
<td></td>
<td>AWS OpsWorks (p. 815): A set of instances that you manage collectively, typically because they have a common purpose such as serving PHP applications. A stack serves as a container and handles tasks that apply to the group of instances as a whole, such as managing applications and cookbooks.</td>
</tr>
<tr>
<td>station</td>
<td>AWS CodePipeline (p. 812): A portion of a pipeline workflow where one or more actions are performed.</td>
</tr>
<tr>
<td></td>
<td>A place at an AWS facility where your AWS Import/Export data is transferred on to, or off of, your storage device.</td>
</tr>
<tr>
<td>statistic</td>
<td>One of five functions of the values submitted for a given sampling period (p. 849). These functions are Maximum, Minimum, Sum, Average, and SampleCount.</td>
</tr>
<tr>
<td>stem</td>
<td>The common root or substring shared by a set of related words.</td>
</tr>
<tr>
<td>stemming</td>
<td>The process of mapping related words to a common stem. This enables matching on variants of a word. For example, a search for &quot;horse&quot; could return matches for horses, horseback, and horning, as well as horse. Amazon CloudSearch (p. 803) supports both dictionary based and algorithmic stemming.</td>
</tr>
<tr>
<td>step</td>
<td>Amazon EMR (p. 805): A single function applied to the data in a job flow (p. 835). The sum of all steps comprises a job flow.</td>
</tr>
<tr>
<td>step type</td>
<td>Amazon EMR (p. 805): The type of work done in a step. There are a limited number of step types, such as moving data from Amazon S3 (p. 809) to Amazon EC2 (p. 804) or from Amazon EC2 to Amazon S3.</td>
</tr>
<tr>
<td>sticky session</td>
<td>A feature of the Elastic Load Balancing (p. 828) load balancer that binds a user's session to a specific application instance so that all requests coming from the user during the session are sent to the same application instance. By contrast, a load session would distribute the requests among all available application instances.</td>
</tr>
</tbody>
</table>
balancer defaults to route each request independently to the application instance with the smallest load.

stopping
The process of filtering stop words from an index or search request.

stopword
A word that isn't indexed and is automatically filtered out of search requests because it's either insignificant or so common that including it would result in too many matches to be useful. Stopwords are language specific.

streaming
Amazon EMR (p. 805): A utility that comes with Hadoop (p. 832) that you can use to develop MapReduce executables in languages other than Java.

Amazon CloudFront (p. 803): The ability to use a media file in real time—as it's transmitted in a steady stream from a server.

streaming distribution
A special kind of distribution (p. 826) that serves streamed media files using a Real Time Messaging Protocol (RTMP) connection.

Streams
See Amazon Kinesis Data Streams.

string-to-sign
Before you calculate an HMAC (p. 832) signature, you first assemble the required components in a canonical order. The preencrypted string is the string-to-sign.

string match condition
AWS WAF (p. 818): An attribute that specifies the strings that AWS WAF searches for in a web request, such as a value in a header or a query string. Based on the specified strings, you can configure AWS WAF to allow or block web requests to an AWS resource (p. 848), such as a CloudFront (p. 803) distribution.

strongly consistent read
A read process that returns a response with the most up-to-date data, reflecting the updates from all prior write operations that were successful—regardless of the Region.

See Also data consistency, eventual consistency, eventually consistent read.

structured query
Search criteria specified using the Amazon CloudSearch (p. 803) structured query language. You use the structured query language to construct compound queries that use advanced search options and combine multiple search criteria using Boolean operators.

STS
See AWS Security Token Service (AWS STS).

subnet
A segment of the IP address range of a VPC (p. 859) that an EC2 instance (p. 827) can be attached to. You can create subnets to group instances according to security and operational needs.

Subscription button
An HTML-coded button that provides an easy way to charge customers a recurring fee.

suggester
Amazon CloudSearch (p. 803): Specifies an index field for getting autocomplete suggestions and options that can enable fuzzy matches and control how suggestions are sorted.

suggestions
Documents that contain a match for the partial search string in the field designated by the suggester (p. 854). Amazon CloudSearch (p. 803) suggestions include the document IDs and field values for each matching document. To be a match, the string must match the contents of the field starting from the beginning of the field.

supported AMI
An Amazon Machine Image (AMI) (p. 807) similar to a paid AMI (p. 842), except that the owner charges for additional software or a service that customers use with their own AMIs.
SWF

See Amazon Simple Workflow Service (Amazon SWF).

symmetric encryption

Encryption (p. 828) that uses a private key only.
See Also asymmetric encryption.

synchronous bounce

A type of bounce (p. 819) that occurs while the email servers of the sender (p. 850) and receiver (p. 846) are actively communicating.

synonym

A word that's the same or nearly the same as an indexed word and that should produce the same results when specified in a search request. For example, a search for "Rocky Four" or "Rocky 4" should return the fourth Rocky movie. This can be done by designating that four and 4 are synonyms for IV. Synonyms are language specific.

T

table

A collection of data. Similar to other database systems, DynamoDB stores data in tables.

tag

Metadata that you can define and assign to AWS resource (p. 848)s, such as an EC2 instance (p. 827). Not all AWS resources can be tagged.

tagging

Tagging resources: Applying a tag (p. 855) to an AWS resource (p. 848).

Amazon SES (p. 808): Also called labeling. A way to format return path (p. 848) email addresses so that you can specify a different return path for each recipient of a message. You can use tagging to support VERP (p. 858). For example, if Andrew manages a mailing list, he can use the return paths andrew+recipient1@example.net and andrew+recipient2@example.net so that he can determine which email bounced.

target attribute

Amazon Machine Learning (Amazon ML): The attribute in the input data that contains the "correct" answers. Amazon ML uses the target attribute to learn how to make predictions on new data. For example, if you were building a model for predicting the sale price of a house, the target attribute would be "target sale price in USD."

target revision

AWS CodeDeploy (p. 812): The most recent version of the application revision that has been uploaded to the repository and will be deployed to the instances in a deployment group. In other words, the application revision currently targeted for deployment. This is also the revision that will be pulled for automatic deployments.

task

An instantiation of a task definition (p. 855) that's running on a container instance (p. 822).

task definition

The blueprint for your task. Specifies the name of the task (p. 855), revisions, container definition (p. 822)s, and volume (p. 859) information.

task node

An EC2 instance (p. 827) that runs Hadoop (p. 832) map and reduce tasks, but doesn't store data. Task nodes are managed by the master node (p. 838), which assigns Hadoop tasks to nodes and monitors their status. While a job flow is running you can increase and decrease the number of task nodes. Because they
don't store data and can be added and removed from a job flow, you can use task nodes to manage the EC2 instance capacity your job flow uses, increasing capacity to handle peak loads and decreasing it later.

Task nodes only run a TaskTracker Hadoop daemon.

tebibyte (TiB)  A contraction of tera binary byte, a tebibyte is 2^40 or 1,099,511,627,776 bytes. A terabyte (TB) is 10^12 or 1,000,000,000,000 bytes. 1,024 TiB is a pebibyte (PiB) (p. 843).

template format version  The version of an AWS CloudFormation (p. 812) template design that determines the available features. If you omit the AWSTemplateFormatVersion section from your template, AWS CloudFormation assumes the most recent format version.

template validation  The process of confirming the use of JSON (p. 835) code in an AWS CloudFormation (p. 812) template. You can validate any AWS CloudFormation template using the cfn-validate-template command.

temporary security credentials  Authentication information that's provided by AWS STS (p. 817) when you call an STS API action. Includes an access key ID (p. 801), a secret access key (p. 850), a session token (p. 851) token, and an expiration time.

throttling  The automatic restricting or slowing down of a process based on one or more limits. Examples: Amazon Kinesis Data Streams (p. 806) throttles operations if an application (or group of applications operating on the same stream) attempts to get data from a shard at a rate faster than the shard limit. Amazon API Gateway (p. 803) uses throttling to limit the steady-state request rates for a single account. Amazon SES (p. 808) uses throttling to reject attempts to send email that exceeds the sending limits (p. 851).

time-series data  Data provided as part of a metric. The time value is assumed to be when the value occurred. A metric is the fundamental concept for Amazon CloudWatch (p. 803) and represents a time-ordered set of data points. You publish metric data points into CloudWatch and later retrieve statistics about those data points as a time-series ordered dataset.

timestamp  A date/time string in ISO 8601 format.

TLS  See Transport Layer Security (TLS).

tokenization  The process of splitting a stream of text into separate tokens on detectable boundaries such as white space and hyphens.

topic  A communication channel to send messages and subscribe to notifications. It provides an access point for publishers and subscribers to communicate with each other.

Traffic Mirroring  An Amazon VPC feature that you can use to copy network traffic from an elastic network interface of Amazon EC2 instances, and then send it to out-of-band security and monitoring appliances for content inspection, threat monitoring, and troubleshooting.

See Also  https://aws.amazon.com/vpc/.

training datasource  A datasource that contains the data that Amazon Machine Learning uses to train the machine learning model to make predictions.

transition  AWS CodePipeline (p. 812): The act of a revision in a pipeline continuing from one stage to the next in a workflow.
Transport Layer Security (TLS) A cryptographic protocol that provides security for communication over the internet. Its predecessor is Secure Sockets Layer (SSL).

trust policy An IAM (p. 814) policy (p. 843) that's an inherent part of an IAM role (p. 848). The trust policy specifies which principals are allowed to use the role.

trusted key groups Amazon CloudFront key groups whose public keys CloudFront can use to verify the signatures of CloudFront signed URLs and signed cookies.

trusted signers See trusted key groups (p. 857).

tuning Selecting the number and type of AMIs (p. 807) to run a Hadoop (p. 832) job flow most efficiently.

tunnel A route for transmission of private network traffic that uses the internet to connect nodes in the private network. The tunnel uses encryption and secure protocols such as PPTP to prevent the traffic from being intercepted as it passes through public routing nodes.

U

unbounded The number of potential occurrences isn't limited by a set number. This value is often used when defining a data type that's a list (for example, maxOccurs="unbounded"), in WSDL (p. 859).

unit Standard measurement for the values submitted to Amazon CloudWatch (p. 803) as metric data. Units include seconds, percent, bytes, bits, count, bytes/second, bits/second, count/second, and none.

unlink from VPC The process of unlinking (or detaching) an EC2-Classic instance (p. 834) from a ClassicLink-enabled VPC (p. 859). See Also ClassicLink, link to VPC.

usage report An AWS record that details your usage of a particular AWS service. You can generate and download usage reports from https://aws.amazon.com/usage-reports/.

user A person or application under an account (p. 802) that needs to make API calls to AWS products. Each user has a unique name within the AWS account, and a set of security credentials not shared with other users. These credentials are separate from the security credentials for the AWS account. Each user is associated with one and only one AWS account.

Users dataset Amazon Personalize (p. 807): A container for metadata about your users, such as age, gender, or loyalty membership. See Also dataset.

user-personalization recipe Amazon Personalize (p. 807): An HRNN-based USER_PERSONALIZATION recipe that predicts the items that a user will interact with. The user-personalization recipe can use item exploration and impressions data to generate recommendations for new items. See Also HRNN, recipe, USER_PERSONALIZATION recipes, item exploration, impressions data, recommendations.
Amazon Personalize (p. 807): Recipes used to build a recommendation system that predicts the items that a user will interact with based on data provided in Interactions, Items, and Users datasets. See Also recipe, user-personalization recipe, popularity-count recipe, HRNN.

validation

value

Tagging resources: A specific tag label that acts as a descriptor within a tag category (key). For example, you might have EC2 instance with the tag key of Owner and the tag value of Jan. You can tag an AWS resource with up to 10 key–value pairs. Not all AWS resources can be tagged.

Variable Envelope Return Path

verification

The process of confirming that you own an email address or a domain so that you can send email from or to it.

VERP

Variable Envelope Return Path. A way that email-sending applications can match bounce email with the undeliverable address that caused the bounce by using a different return path for each recipient. VERP is typically used for mailing lists. With VERP, the recipient's email address is embedded in the address of the return path, which is where bounced email is returned. This makes it possible to automate the processing of bounced email without having to open the bounce messages, which might vary in content.

versioning

Every object in Amazon S3 has a key and a version ID. Objects with the same key, but different version IDs can be stored in the same bucket. Versioning is enabled at the bucket layer using PUT Bucket versioning.

VGW

See virtual private gateway (VGW).

virtualization

Allows multiple guest virtual machines (VM) to run on a host operating system. Guest VMs can run on one or more levels above the host hardware, depending on the type of virtualization. See Also PV virtualization, HVM virtualization.

virtual private cloud

See VPC.

virtual private gateway (VGW)

The Amazon side of a VPN connection that maintains connectivity. The internal interfaces of the virtual private gateway connect to your VPC through the VPN attachment. The external interfaces connect to the VPN connection, which leads to the customer gateway.

visibility timeout

The period of time that a message is invisible to the rest of your application after an application component gets it from the queue. During the visibility timeout, the component that received the message usually processes it, and then deletes it from the queue. This prevents multiple components from processing the same message.
### VM Import/Export
A service for importing virtual machine (VM) images from your existing virtualization environment to Amazon EC2 and then exporting them back. See Also https://aws.amazon.com/ec2/vm-import.

### volume
A fixed amount of storage on an instance (p. 834). You can share volume data between more than one container (p. 822) and persist the data on the container instance (p. 822) when the containers are no longer running.

### VPC
Virtual private cloud. An elastic network populated by infrastructure, platform, and application services that share common security and interconnection.

### VPC endpoint
A feature that you can use to create a private connection between your VPC (p. 859) and another AWS service without requiring access over the internet, through a NAT (p. 840) instance, a VPN connection (p. 859), or AWS Direct Connect (p. 813).

### VPG
See virtual private gateway (VGW).

### VPN CloudHub
See AWS VPN CloudHub.

### VPN connection
Amazon Web Services (AWS) (p. 809): The IPsec connection between a VPC (p. 859) and some other network, such as a corporate data center, home network, or colocation facility.

### W

**Numbers and symbols (p. 801)**
- A (p. 801)
- B (p. 818)
- C (p. 819)
- D (p. 824)
- E (p. 827)
- F (p. 830)
- G (p. 831)
- H (p. 832)
- I (p. 833)
- J (p. 835)
- K (p. 836)
- L (p. 836)
- M (p. 837)
- N (p. 840)
- O (p. 841)
- P (p. 842)
- Q (p. 845)
- R (p. 846)
- S (p. 849)
- T (p. 855)
- U (p. 857)
- V (p. 858)
- W (p. 859)
- X (p. 859)
- Y (p. 859)
- Z (p. 859)

**WAM**
See Amazon WorkSpaces Application Manager (Amazon WAM).

**web access control list (web ACL)**
AWS WAF (p. 818): A set of rules that defines the conditions that AWS WAF searches for in web requests to an AWS resource (p. 848), such as a Amazon CloudFront (p. 803) distribution. A web access control list (web ACL) specifies whether to allow, block, or count the requests.

**Web Services Description Language**
See WSDL.

**WSDL**
Web Services Description Language. A language used to describe the actions that a web service can perform, along with the syntax of action requests and responses. See Also REST, SOAP.

### X, Y, Z

**X.509 certificate**
A digital document that uses the X.509 public key infrastructure (PKI) standard to verify that a public key belongs to the entity described in the certificate (p. 820).

**yobibyte (YiB)**
A contraction of yotta binary byte, a yobibyte is $2^{80}$ or $1,208,925,819,642,974,706,176$ bytes. A yottabyte (YB) is $10^{24}$ or $1,000,000,000,000,000,000,000,000$ bytes.

**zebibyte (ZiB)**
A contraction of zetta binary byte, a zebibyte is $2^{70}$ or $1,180,591,620,717,411,303,424$ bytes. A zettabyte (ZB) is $10^{21}$ or $1,000,000,000,000,000,000,000$ bytes. 1,024 ZiB is a yobibyte (YiB) (p. 859).
zone awareness

Amazon OpenSearch Service (OpenSearch Service) (p. 805): A configuration that distributes nodes in a cluster across two Availability Zone (p. 811)s in the same Region. Zone awareness helps to prevent data loss and minimizes downtime in the event of node and data center failure. If you enable zone awareness, you must have an even number of data instances in the instance count, and you also must use the Amazon OpenSearch Service Configuration API to replicate your data for your OpenSearch cluster.
