More Learning Opportunities with Script Canvas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Here are some additional educational opportunities for learning more about Script Canvas.

Sample Levels

To help you get started with Script Canvas, the following sample levels are available:

• For a basic sample level, see Script Canvas Basic Sample (p. 149), which is included in your Lumberyard setup. The sample uses a tank to fire a projectile at a target.
• For a more in-depth sample level, install the Project N.E.M.O. (p. 2467) sample level, which uses a third-person camera to control a mini sub through an underwater mine field.

Video Tutorials

These video tutorials in the Tutorial Guide are also available to assist in your journey towards becoming a Script Canvas expert:

• Tour of Script Canvas (2 videos)
• Explosive Red Barrel (4-part series)
• Tank Demo (3-part series)
• Using Trigger Areas and Capturing Player Input (5-part series)

Installing the Project N.E.M.O. Sample

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Project N.E.M.O (Nautical Emergency Maneuvers and Operations) is a complete sample game level that showcases some of the key capabilities of Script Canvas. The sample level creates a short underwater navigation experience in which the player maneuvers a mini sub through obstacles and collects pickups. The sample level uses Script Canvas and script events to implement submarine functionality, mines and squid behavior, HUD display, pickups, world space UI, and game end.

To use the sample, you must first install and configure Lumberyard. Then download, configure, and build the project.

Step 1: Install and Configure Lumberyard

The following procedure shows you how to install Lumberyard and configure it for the Project N.E.M.O. sample level. If Lumberyard is already installed, start with step 2 to configure it.

To install and configure Lumberyard for the Project N.E.M.O. sample level

1. Download and run the Lumberyard installer.
2. Do one of the following:
   • If you are installing Lumberyard, click Launch Lumberyard Setup Assistant.
   • If Lumberyard is already installed, click the Lumberyard Setup Assistant icon on your desktop.
3. Click Customize.
4. In Lumberyard Setup Assistant, ensure that Create, Modify and Build projects is selected.
5. For Visual Studio Version, select the version of Visual Studio that you want to use.
6. Click Install required SDKs.
7. For Required SDKs, click Install all.
8. After the required SDKs are installed, close Lumberyard Setup Assistant.

Step 2: Download, Configure, and Build the Project

Now you are ready to download, configure, and build the sample project.

To download, configure, and build the Project N.E.M.O. sample level

1. Download the NEMO.zip file.
2. Extract the NEMO and Engine folders from the .zip file to the \texttt{lumberyard\_version\dev\} directory.
3. On your desktop, click the Project Configurator icon.
4. In Project Configurator, click the NEMO project to select it, and then click Set as default.
6. From a command window on \texttt{lumberyard\_version\dev\} directory, run the following command:
   
   
   \texttt{lmbr\_waf configure}

7. Run the version of the following command that corresponds to your version of Visual Studio.

   \texttt{lmbr\_waf build\_win\_x64\_vs2017\_profile -p game\_and\_engine}

   \textbf{Note}
   Building the project takes some time.

At this point, the Project N.E.M.O. sample level is ready. For more information about the sample and how it uses Script Canvas, see the Amazon Game Tech Blog.

**Common Tasks**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The topics in this section provide practical knowledge about common tasks associated with Script Canvas, including best practices, advice on troubleshooting, and use of the debugger.

**Topics**

- Adding Scripts to Entities (p. 2468)
- Script Canvas Best Practices (p. 2469)
- Script Canvas Errors and Troubleshooting (p. 2470)
- Script Canvas Debugging (p. 2471)

**Adding Scripts to Entities**

Like Lua scripts, you can add a script to a level or slice is by adding a Script Canvas component to an entity. The Script Canvas component adds Script Canvas capabilities to the entity and provides a field to specify a script assignment. You can specify a script with the Script Canvas component.

For more information, see the Script Canvas (p. 818) component.

For more information about adding a component to an entity, see Adding Components to an Entity (p. 479).
Script Canvas Best Practices

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Best practices for Script Canvas include using an event-driven approach and using custom nodes to simplify your graphs.

Use an Event-Driven Approach

Script Canvas nodes are by default stateless. However, by connecting to the TickBus (p. 1019), they can be configured to have a state. Engineers must manage the lifetime and performance of nodes that have a state.

In the core Script Canvas libraries, state is used primarily to drive the execution of the graph (as with the Delay node). However, an event-driven paradigm is recommended because it helps reduce the complexity of authoring and executing graphs.

We recommend that you reflect functionality to Script Canvas through the behavior context. This is true even for Script Canvas-specific functionality. Using the behavior context encourages event-driven paradigms through EBuses. This approach yields modular, decoupled behaviors that can reduce graph complexity and takes advantage of execution optimizations.

Use Custom Nodes to Simplify Your Graphs

Identify frequently used but complicated user patterns and simplify them through custom nodes and/or improved behavior context methods. Using custom nodes with EBuses can reduce the overall complexity of graphs and make graph authoring more intuitive. For information on creating custom nodes, see Creating Custom Nodes in Script Canvas (p. 2553).

Be Careful with Entity Activation Order

Sending events during entity activation can have undesired results. Because the order of activation of entities is not guaranteed, when an event is sent during activation, some entities that need to handle the event might not receive it. In particular, the On Graph Start and On Entity Activated nodes are subject to activation order issues. Be careful when sending events from them.

In order to ensure that all entities that need to listen for and handle a given script event are ready to receive the event, it is best to queue the message on the tick bus. To implement this strategy, use a Once node connected to the On Tick message, as the following image shows. This practice guarantees that when the message is sent, all entities that might be connected to that script event receive it.
Script Canvas Errors and Troubleshooting

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Script Canvas provides a mechanism to detect and report errors. Errors in Script Canvas are generally caused by invalid conditions.

In C++ Script Canvas provides the following macros for error management:

```c
#define SCRIPTCANVAS_NODE_DETECT_INFINITE_LOOP(node)  
#define SCRIPTCANVAS_RETURN_IF_NOT_GRAPH_RECOVERABLE(graph)  
#define SCRIPTCANVAS_HANDLE_ERROR(node)  
#define SCRIPTCANVAS_REPORT_ERROR(node, ...)  
#define SCRIPTCANVAS_RETURN_IF_ERROR_STATE(node)  
```

You can use these macros during a graph's execution. When triggered, they stop the execution of nodes that have an error.

You can detect errors that occur in a graph at run time and provide an error handler to respond to the errors. This helps users to gracefully handle graphs that encounter an invalid condition.

Runtime execution errors are reported to the Event Handler node. You can use this node to perform custom logging or take appropriate action when an error occurs.
You can also raise and handle errors within a graph's execution. The following simple example shows how you could use Error and Error Handler nodes to provide notification of an error in data validation. This helps to rectify the solution to ensure that the graph remains stable.

Script Canvas Debugging

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Script Canvas supports live debugging of a Script Canvas graph running in-game. You can use Lumberyard Editor or non-editor tools like game launchers as debug targets.

To open the Script Canvas debugger and choose a target

1. From the Script Canvas editor, choose Tools, Debugging. The debugger panel opens at the bottom of the Script Canvas editor.

2. On the Live tab of the debugging panel, use the dropdown menu to choose the debug target. The default target is Lumberyard Editor, but you can use Script Canvas to debug the game running in standalone mode. For more information, see In-Game Debugging (p. 2478).
Choosing Entities and Graphs to Debug

After you choose a debug target, you can choose the entities and graphs that you want to debug.

To choose entities and graphs to debug

1. To see entities with Script Canvas graphs that are available for debugging, expand the items on the Entities tab. The Entities tab displays the entities known to the debugger at edit time that have Script Canvas graphs.

   ![Entities Tab Screenshot]

   **Note**
   Running the same graph multiple times on a single entity is not supported.
2. To get a complete listing of all available Script Canvas graphs in the project, click the **Graphs** tab. Each graph in the table shows all entities that are using that graph. The **Graphs** tab is useful for debugging dynamically spawned scripts. For more information, see **Debugging a Dynamically Spawned Graph (p. 2478)** later in this topic.

![Graphs tab screenshot](image)

3. On the **Entities** tab or **Graphs** tab, select the check boxes for the entities or graphs that you want to debug.
4. To capture all instances of a selected graph, select **All Graph Instances**.

**Configuring Debugger Options**

Use the following options to configure debugger behavior.
Auto Capture

Enable this option if you want the output from a specified target to be captured as soon as the debugger connects to it. For external tools, capture starts immediately when you enable this option. For Lumberyard Editor, capture starts when the editor enters game mode.

Live Updates

Enable this option to display the data as it is captured. When disabled, the data is captured silently and displays only after the capture completes.

Note
When live updates are enabled and you capture a large amount of data, editor performance decreases noticeably. For better performance, you should disable live updates, especially for longer captures.

Running the Debugger

After you have chosen the entities or graphs to debug, you are ready to run the Script Canvas debugger.

To run the Script Canvas debugger

1. Click Capture. The Capture button puts Lumberyard into gameplay mode automatically.

Note
If Editor is selected as the capture target, the game must be running for the debugger to return results.

The Script Canvas debugger begins capturing data when the graph runs. If live updates are enabled, the data appears in the debugger panel when the graph being debugged becomes active during gameplay. Otherwise, the data appears after the capture completes.
2. After you have enough data, click **Capture** again to stop the data capture.

**Examining Captured Data**

The captured data is presented in a log that is sorted in order of processing. Each line represents the processing of a single node.

![Log of captured data](image)

**Note**

Currently, only a single instance of captured data can be stored. Previous data is lost when a new set of data is captured.

**To examine the captured data**

1. To see the Script Canvas node that corresponds to a line in the log, click the line.

   Each line typically shows the node's **In** signal and **Out** signal. If the **In** or **Out** signal is not present, the node is either the first or final node of a given execution line. As shown in the following image, the **Set Location Rotation** node is the final node in the execution line, so an **Out** signal is not present.
2. Use the up or down arrow keys to move through the log messages in the debugger panel. As you do so, the corresponding node to in Script Canvas graph is highlighted.

3. To examine the data that the node was using, expand the log message.

   **Note**
   Some nodes send additional information that appears in the form of annotations. For example, the **Print** node sends the full string that it displayed.

4. To expand all lines, click the **expand icon**.

5. To collapse all lines, click the **collapse icon**.

6. To search for a particular node name or names, use the **Search box**.
Common Tasks

Debugging a Dynamically Spawned Graph

Dynamically spawned graphs are usually part of a dynamic slice. Because dynamically spawned graphs cannot be known at edit time, you must select them by name rather than by the entity or entities on which they are used.

To debug a dynamically spawned graph

1. On the Graphs tab, select the name of the graph.
2. Follow the same steps that you use to debug any other Script Canvas graph. The debugger records the graph’s operations when the graph becomes active during gameplay.

In-Game Debugging

For in-game debugging, you use the Script Canvas debugger to connect to a running game launcher.

To debug a running game

1. Run GridHub.exe from the Bin64vcxxx directory that corresponds to the version of Visual Studio that you are using (for example, lumberyard_version\dev\Bin64vc141\GridHub.exe). GridHub is the network environment that provides connectivity between Lumberyard and its tools. For more information, see Using GridHub (p. 1954).

   Note
   GridHub must be active for non-editor targets to appear in the Live tab.

2. Run the launcher for your game (for example, lumberyard_version\dev\Bin64vc141\SamplesProjectLauncher.exe).
3. On the Live tab of the Script Canvas debugger, choose the launcher from the list of debug targets. When you choose the launcher as the debug target, Script Canvas execution is recorded for the graphs that you specify.
Notes

When using the Script Canvas debugger, keep the following points in mind.

Performance

The editor experiences a severe decrease in performance when it is capturing data. To mitigate this, disable live updates and avoid capturing lengthy sessions. Lengthy sessions can easily lead to a sharp increase in logging events. If your game runs at 60fps and you have 40 Script Canvas nodes that run on each tick, 2400 log messages must be displayed every second. After a minute, this number increases to 144,000 messages. To minimize the amount of data captured, limit the scope and intensity of logging.

Saving Issues

When you modify a graph and save it, some IDs are remapped in the asset, but not in the visualized Script Canvas scene. As a result, the unified ID used in the logging messages no longer matches the visual presentation. This mismatch causes the visual scraping to fail. To work around this, close and re-open the Script Canvas scene.

Editor Reference

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Script Canvas editor provides a visual scripting environment for creating graphs and reusable script functions. In the following topics, learn more about each menu option and editor tool, as well as valuable keyboard and mouse shortcuts to increase your productivity.

Topics

- Script Canvas Editor Shortcuts (p. 2480)
- Managing Script Canvas Variables (p. 2482)
- Working with Nodes (p. 2496)
- Script Canvas Functions (p. 2538)
# Script Canvas Editor Shortcuts

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The following table shows the keyboard shortcuts that you can use in the Script Canvas editor.

<table>
<thead>
<tr>
<th>Key Combination</th>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arrow Keys</td>
<td>Scroll graph</td>
<td>Scrolls the graph left, right, up, or down.</td>
</tr>
<tr>
<td>Ctrl+C</td>
<td>Copy</td>
<td>Copies the selected nodes and their connections to the clipboard.</td>
</tr>
<tr>
<td>Ctrl+V</td>
<td>Paste</td>
<td>Pastes copied nodes and their connections from the clipboard into the active graph.</td>
</tr>
<tr>
<td>Ctrl+D</td>
<td>Duplicate</td>
<td>Duplicates the selected nodes in the active graph. This is the equivalent of using Ctrl+C and Ctrl+V.</td>
</tr>
<tr>
<td>Ctrl+Left Arrow</td>
<td>Select inputs</td>
<td>Selects all nodes that are connected to the input pins of the currently selected node.</td>
</tr>
<tr>
<td>Ctrl+Right Arrow</td>
<td>Select outputs</td>
<td>Selects all nodes that are connected to the output pins of the currently selected node.</td>
</tr>
<tr>
<td>Ctrl+Up Arrow</td>
<td>Select connected nodes</td>
<td>Selects all nodes that are connected to the currently selected node.</td>
</tr>
<tr>
<td>ESC</td>
<td>Clear selection</td>
<td>Deselects any selected nodes.</td>
</tr>
<tr>
<td>Ctrl+Shift+P</td>
<td>Screenshot</td>
<td>Creates an image of the area around all selected nodes and adds it to the clipboard. If no nodes are selected, an image of the entire active graph is added to the clipboard.</td>
</tr>
<tr>
<td>Shift+Left Arrow</td>
<td>Align left</td>
<td>Aligns all the selected nodes along a left edge.</td>
</tr>
<tr>
<td>Shift+Right Arrow</td>
<td>Align right</td>
<td>Aligns all the selected nodes along a right edge.</td>
</tr>
<tr>
<td>Shift+Up Arrow</td>
<td>Align top</td>
<td>Aligns all the selected nodes along a top edge.</td>
</tr>
<tr>
<td>Shift+Down Arrow</td>
<td>Align bottom</td>
<td>Aligns all the selected nodes along a bottom edge.</td>
</tr>
<tr>
<td>Ctrl+Alt+M</td>
<td>Add comment</td>
<td>Adds a new comment using the properties from the default comment preset. For information about presets, see Creating Comment and Group Presets (p. 2530). <strong>Note:</strong> NVIDIA's GeForce Experience overlay uses a default setting for turning on/off the microphone that interferes with this hotkey.</td>
</tr>
<tr>
<td>Ctrl+Shift+G</td>
<td>Group selection</td>
<td>Groups the selected nodes on the graph using the properties from the default node group preset. For information about presets, see Creating Comment and Group Presets (p. 2530).</td>
</tr>
<tr>
<td>Ctrl+Shift+H</td>
<td>Ungroup</td>
<td>Ungroups the currently selected group.</td>
</tr>
</tbody>
</table>
### Key Combination

<table>
<thead>
<tr>
<th>Key Combination</th>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl + Number_Key</td>
<td>Create bookmark</td>
<td>Creates a bookmark out of the current view and assigns it to the specified number key. If you choose a number that is already assigned to a bookmark or a bookmark-enabled group, you are prompted to reassign the existing bookmark. For more information about bookmarks, see Adding Bookmarks for Script Canvas (p. 2534). For information about enabling groups as bookmarks, see Grouping Nodes (p. 2526).</td>
</tr>
<tr>
<td>Number_Key</td>
<td>Jump to bookmark</td>
<td>Jumps to the bookmark location associated with the key that is pressed.</td>
</tr>
<tr>
<td>Ctrl + Plus Sign (+)</td>
<td>Zoom in</td>
<td>Zooms the graph in.</td>
</tr>
<tr>
<td>Ctrl + Minus Sign (-)</td>
<td>Zoom out</td>
<td>Zooms the graph out.</td>
</tr>
<tr>
<td>Ctrl + Shift + Up Arrow</td>
<td>Zoom to selection</td>
<td>Centers the view on the nodes that are currently selected.</td>
</tr>
<tr>
<td>Ctrl + Shift + Down Arrow</td>
<td>Show entire graph</td>
<td>Centers the entire graph into the current display. Zooms out as much as possible to display all nodes.</td>
</tr>
<tr>
<td>Ctrl + Shift + Left Arrow</td>
<td>Show start of chain</td>
<td>Centers the view on the nodes that do not have any input connections, and are connected to the selected node through their output connections.</td>
</tr>
<tr>
<td>Ctrl + Shift + Right Arrow</td>
<td>Show end of chain</td>
<td>Centers the view on the nodes that do not have any output connections, and are connected to the selected node through their input connections.</td>
</tr>
<tr>
<td>Ctrl + K, Ctrl + C</td>
<td>Comment out selected nodes</td>
<td>Comments out the current selection of nodes and turns them gray. Commented out nodes are not run at runtime, but still exist at edit time.</td>
</tr>
<tr>
<td>Ctrl + K, Ctrl + U</td>
<td>Uncomment selected nodes</td>
<td>Uncomments the selected nodes.</td>
</tr>
</tbody>
</table>

**Note**

If a keyboard shortcut doesn’t appear to work for you, another process running in the background might have bound that key combination. Consider searching the forums to see if others have encountered this issue.

### Mouse Shortcuts

The following shortcuts use the mouse or keyboard and mouse.

<table>
<thead>
<tr>
<th>User Action</th>
<th>Result</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alt + Left Click</td>
<td>Disconnect and delete a single node or group</td>
<td>Disconnects and deletes the node or group clicked.</td>
</tr>
<tr>
<td>Alt + Left Click</td>
<td>connection</td>
<td>Deletes the connection clicked from the active graph.</td>
</tr>
<tr>
<td>Alt + Left Click</td>
<td>slot</td>
<td>Deletes any connections to the slot from the active graph.</td>
</tr>
<tr>
<td>User Action</td>
<td>Result</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------------</td>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Ensure that the connections that you want to delete are highlighted before pressing <strong>Alt+Left Click</strong>. Otherwise, you might delete the node instead.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Middle Mouse Button (Scroll Wheel) Click graph tab</td>
<td>Close graph</td>
<td>Closes the open graph that corresponds to the tab that you clicked. If the graph has changed and has not been saved, you're prompted to save it first.</td>
</tr>
<tr>
<td>Scroll mouse wheel</td>
<td>Zoom the graph</td>
<td>Zooms the graph in or out.</td>
</tr>
</tbody>
</table>

### Managing Script Canvas Variables

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **Variable Manager** shows the variables that are used in your Script Canvas graph. These variables represent the custom data required to build game logic. For example, you can use variables to make counters, store entity references, specify a direction, or define a color.

**Topics**
- Adding and Configuring Variables (p. 2482)
- Setting Default Values for Variables (p. 2484)
- Creating Get or Set Variable Nodes (p. 2485)
- Creating Value-Changed Nodes (p. 2486)
- Deleting Variables (p. 2487)
- Using Container Types (Arrays and Maps) (p. 2489)

### Adding and Configuring Variables

You can add variables to your Script Canvas graph to declare and initialize them.

**To add and configure a variable**

1. In the **Script Canvas** editor, open your Script Canvas graph or create one.
2. In the **Variable Manager**, click **Create Variable** and then choose your variable type. You can search to filter the list of variable types.

**Note**
Common variable types are pinned to the top of the list by default. You can customize the pinned list to show the variable types that you use most often. To do so, click the box to the left of a variable type to pin or unpin it.
3. In the **Node Inspector**, configure the properties for your variable.
For example, if you add a **Color** variable, you can do the following:

- **For Name**, enter a name to identify that color variable. You can also double-click the name in the **Variable Manager** to rename the variable.
- **For Color**, enter an RGB value or use the color picker.
- **For Display Order**, enter the relative order in which you want the variable to appear in the Script Canvas editor, or leave the default at -1.
- **For Scope**, select **In** to show the variable property and value under the assigned [Script Canvas (p. 818)](#) component in the **Entity Inspector**, or leave the default at **Local** to keep the variable private to the graph.

**Note**

This setting allows you to use the same Script Canvas graph for more than one entity, but customize part of the graph for a specific entity. When you change the variable value on a component, that value takes precedence over the default value that is specified in the graph.

4. In the **Script Canvas** editor, choose **File, Save** to save your changes.

## Setting Default Values for Variables

You can set the default value for variables in the **Node Inspector** or the **Variable Manager**.

### To set variable values

1. In the **Variable Manager**, select the variable that you want to update. You can search to filter the list of variables that are in your graph.
2. Do one of the following to update the properties for your variable:

   - **In the Node Inspector**, update the variable values as needed.

   - In the **Variable Manager**, update certain variable values. These values appear in a third column and can be selected or double-clicked.
3. In the **Script Canvas** editor, choose **File, Save** to save your changes to the graph.

**Creating Get or Set Variable Nodes**

You can use get and set variable nodes to retrieve or set the variable's value.

**To create get or set variable nodes**

- Do one of the following:
  - Drag the variable from the **Variable Manager** to the canvas, and then choose **Get variable name** or **Set variable name**.
  - Right-click the variable in the **Variable Manager** and choose **Get variable name** or **Set variable name**.
• Use the following keyboard shortcuts:
  • Press **Shift** and drag the variable from the **Variable Manager** to the canvas to create a get variable node.
  • Press **Alt** and drag the variable from the **Variable Manager** to the canvas to create a set variable node.

### Creating Value-Changed Nodes

You can use **OnVariableValueChanged** (value-changed) event nodes to react to a change in a variable's value.

**To create value-changed nodes**

• Do one of the following:
  • Drag the variable from the **Variable Manager** to the canvas, and then choose **On** variable name **Changed**.
  • Create a new **OnVariableValueChanged** event node in your graph and set the **Source** field to a variable using the field's gear button. For help adding a node to a graph, see **Adding and Connecting Nodes** (p. 2506).
Deleting Variables

You can delete variables from the graph or the Variable Manager.

To delete a variable

- Do one of the following:
  - Select the variable node in the canvas and press Delete.
  - Select the variable in the Variable Manager and press Delete.
  - Right-click the variable in the Variable Manager and choose Delete variable name.
Variable Manager

Create Variable

Search...

- Blue Color
- Get Direction
- Green Color
- Move Entity
- Purple Color

Get Green Color
Set Green Color
Delete Green Color
Using Container Types (Arrays and Maps)

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Script Canvas has support for arrays and maps.

Arrays

Arrays provide a dynamic continuous area of memory that can hold storage of a given type.

To create an array variable

1. In the Variable Manager, do one of the following:
   - Click Create Variable, and then click Array.
   - In the Variable Type search box, type Array, and then click Array.

2. Enter information to create your array, and then click Create.

   - For Variable Name, enter the name for your array variable.
   - For Container Type, use Array.
   - For Type, choose the data type for the array.
   - (Optional) To pin the array to the list of variables in the Variable Manager, select Pin To Variable List. Then, when you click Create Variable, the array appears in the list as Array<\text{data\_type}>. This is useful when you reuse the same type frequently.
Array Pin Icons

Some nodes, like **OnEntitiesSpawned** or **Get String Array**, provide data as arrays. The data pins for the arrays on such nodes have a square icon. The color of the icon shows the data type for the array.
Array Operation Nodes

In the Node Palette, the Containers section has nodes that you can use to add, get, and remove elements from arrays.

- **Add Element at End** – Adds the element at the end of the container.
- **Clear All Elements** – Removes all elements from the container.
- **Erase** – Erases the element at the specified index or key.
- **For Each** – Iterates through each element of a container.
- **Get Element** – Returns the element at the specified index or key.
- **Get First Element** – Returns the first element in the container.
- **Get Last Element** – Returns the last element in the container.
- **Get Size** – Returns the number of elements in the container.
- **Insert** – Inserts an element into the container at the specified index or key.
- **Is Empty** – Returns whether the container is empty.

All container operation nodes have an In pin and a Source pin.

All pins have an Out pin except For Each, which has an Each pin that is signalled after each element in the container. The For Each node also has a Break pin and a Finished pin. The Break pin stops the iteration when signalled. The Finished pin is signalled when all of the elements in the container have been iterated over or the iteration is stopped by the Break pin.

Automatic Data Pin Typing

The pins on container operation are context-sensitive. Data input and output pins automatically take on the data type of the pin to which they are connected.
Example

In the following example, the array type is `string`.

When you connect the `Array<String>` pin to the Source pin on the Add Element at End node, the following changes occur automatically:

- The Source pin changes to the string type.
- The Add Element at End node box expands to include a String text box where you can enter a string value.
- The pin icon and line colors change to the color of the data type that you are using (in the case of this example, blue).
- A Container pin for chaining output appears on the target node.

Chaining Array Operation Nodes

Array operation nodes typically have a Container output pin. You can use this output pin to chain several operations on the same array, as the following image shows.
Maps

Maps are containers of key-value pairs. Maps in the **Variable Manager** have a small split rectangular icon.

To create a map variable

1. In the **Variable Manager**, do one of the following:
   - Click **Create Variable**, and then click **Map**.
   
   or
   
   - In the **Variable Type** search box, type **Map**, and then click **Map**.

2. Enter information to create your map, and then click **Create**.
For **Variable Name**, enter the name for your map variable.

For **Container Type**, use **Map**.

For **Key**, choose a data type for the key.

For **Value**, choose a data type for the value.

(Optional) To pin the map to the list of variables in the **Variable Manager**, select **Pin To Variable List**. Then, when you click **Create Variable**, the map appears in the list as **Map<key_data_type,value_data_type>**. This is useful when you reuse the same key pair combination frequently.

**Map Pin Icons**

You can use **Get** or **Set** nodes to get values from a map or make changes to the map. The data pins for the maps have square icons with two colors. One color represents the data type for the key, the other for the value.
Map Operation Nodes, Data Pin Typing, and Chaining

Maps use the same container operation nodes as arrays. As with arrays, data pins automatically take on the data types of the map to which they are connected, as the following image shows.

As with arrays, maps provide a data output pin that you can use to chain operations on the same map.
Working with Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Games are often built with complex logic, and complex logic can produce a large number of nodes and connections. Script Canvas provides some specialized tools to help you manage this complexity.

Topics
- Understanding Script Canvas Nodes (p. 2496)
- Adding and Connecting Nodes (p. 2506)
- Adding Variable References in Script Canvas Nodes (p. 2511)
- Setting Entity Targets (p. 2514)
- Deleting Nodes (p. 2515)
- Disconnecting Nodes (p. 2516)
- Organizing Nodes (p. 2517)

Understanding Script Canvas Nodes

A node in Script Canvas consists of a title bar, inputs, and outputs.
**Title Bar** – The title bar of a node is in a colored band at the top of the node. A title bar can include a subtitle, but not all nodes have subtitles.

**Inputs** – Located on the left side of the node. An input can be an execution, or logic, input or a data input. Execution inputs cause the node to act. Data inputs provide the node with the data it requires to do processing or decision making.

**Outputs** – Located on the right side of the node. Outputs are also either execution or data related.

**Inputs, Outputs, and Connection Types**

Lumberyard has two main pin and connection types. Some inputs and outputs determine the flow of logic and order of execution. Other inputs and outputs pass data from one node to the next.

**Logic inputs, outputs, and connections**

The execution of a script is driven by triangular inputs and outputs on every node. These connections determine the order of execution. A *Script Canvas* script runs when the entity that is attached to the script is activated. Nodes are connected from the inputs on their left side. After they finish running, they activate nodes that are connected to their outputs on the right side.

An output logic pin with multiple connections runs a logic branch in sequence. The execution sequence is determined by the order that the connections were made, from earliest to most recent. If a specific execution order is required, you can specify the sequence order by using a single logic flow or a *Sequencer* node.

An incoming logic pin with multiple connections runs each time that the logic flow triggers the node. For example, if a node is triggered by three different nodes in a script, the node runs three times.

**Data inputs, outputs, and connections**

Data connections enable scripts to read and write data between nodes. Data is read from the right side of one node and then set on the left side of another node.

**Making Connections**

Connections can be made only between pins of the same type. For example, logic connections can be made only between logic pins, and data connections can be made only between data pins of the same type. You can't create connections between incompatible pins, such as logic and data.

**To make a connection**

1. In the *Script Canvas* editor canvas, drag from the input pin of one node to an output pin of another node. This creates a connection line between the two pins.

2. To move a connection from one pin to another, drag the end of a line from one pin and drop it onto another pin.

   To delete a connection, right-click and choose *Delete*. You can also press and hold *Alt*, and click the connection to delete it.

**Variable Nodes**

Variable nodes enable *Script Canvas* to read from or write to specific variables.
Another way to read or write a variable is to use variable references on a node data pin.

For more information about using variables in Script Canvas, see Managing Script Canvas Variables (p. 2482).

For more information about creating variable references, see Adding Variable References in Script Canvas Nodes (p. 2511).

**Event Nodes**

In Lumberyard's Event Bus (EBus) system (p. 1851), events can be sent or received, so Script Canvas has sender nodes and receiver nodes.

**Sender Nodes**

Event senders send events directly to a specific entity or broadcast events to all entities that are listening for and interested in handling the event. Most events are addressable, which means they can be sent to a
specific entity. Because events are usually sent to entities, the most common address type is Entity Id, although other address types can be used.

The following example uses Light events to create a sender node.

**To create a sender node**

1. In the **Node Palette** search box, type **Light**. The results show nodes related to light.

   ![Node Palette screenshot]

   In the **Node Palette**, sender events are the dark blue entries. All Light-related sender events provide a way to communicate with, configure, or alter the behavior of a given Light component. You can send any of the Light-related sender events to an entity that has a Light component. If the entity that owns the Script Canvas graph also has a Light component, it can send the event to itself.

2. Drag **Turn On** or **Turn Off** onto the canvas to create a sender node.
The **Source** pin of the sender node refers to the entity that sends the event. The default is **Self**, which means that it sends Light events for the same entity that the Script Canvas component is on. However, you can change the source to any entity in the game world.

The **State** pin is a Boolean value that controls the state of the light.

**Receiver Nodes**

An event receiver implements a particular behavior when it receives a particular event.

The following example creates a receiver node for a Light event.

**To create a receiver node**

1. In the **Node Palette** search box, type **Turn**.
In the list of results, event receivers like **Turned Off** and **Turned On** have a light blue icon.

2. Drag **Turned On** onto the canvas to create a receiver node.

The **Source** pin of the receiver node refers to the entity from which the event is received. The default is **Self**, which means the node receives Light events for the same entity that the Script Canvas component is on. You can change the target to any entity in the game world.

In Lumberyard v1.24 and later, you can also specify the target using a variable reference (p. 2511). Whenever the variable changes, the EBus handler will update the Source to match the variable reference.

3. Click **Add/Remove Events**.

Because receiver nodes are usually containers for multiple events, you can click **Add/Remove Events** to view and add any of the available event receivers for a given component. In this case, the Light component exposes two events: **Turned Off** and **Turned On**.
4. Select the **Turned Off** check box to add the **Turned Off** event to the receiver node.

A second blue band in the node appears. The node is now listening for both the **Turned On** and **Turned Off** events.
5. Click **Add/Remove Events** again, and clear the **Turned Off** check box. The **Turned Off** event is removed from the receiver node.

### Displaying and Using Connection Controls

All receiver nodes have connection-related pins, or controls, that are hidden by default. You can use these controls to manage when an event is connected or disconnected (connected means that the event is ready to receive events, and disconnected means that the event is not receiving events). The connection controls can also notify you when a node successfully connects, disconnects, or experiences an error.

The following example uses the Light component **Turned On** event node.

**To enable and use Display Connection Controls**

1. Ensure that **Node Inspector** is visible. In Script Canvas editor, choose **View, Node Inspector**, or press **Ctrl+Shift+I**.
2. Click the Light **Turned On** node to select it.
3. In **Node Inspector**, select **Display Connection Controls**.

The Light component **Turned On** receiver node expands to provide connection-related pins.

- **Connect** and **Disconnect** – Use the **Disconnect** pin to prevent the receiver node from connecting. When the event should be connected and available to receive events, use the **Connect** pin.
The **Connect** and **Disconnect** pins are especially useful when working with the **On Tick** event. For example, if you have a complex operation that you do not want processed for every tick of the game, you can disconnect the **On Tick event** until it is required.

**Note**
When you enable a receiver node's **Display Connection Controls** property, the node no longer connects automatically. In this case, Script Canvas assumes that you want to specify when the connection occurs.

- **OnConnected** – Triggered when the event connects successfully. This pin is useful if you want to continue execution along the connection path when the connection occurs.
- **OnDisconnected** – Triggered when the event disconnects successfully. This pin is useful if you want to continue execution along the disconnection path when the connection occurs.
- **OnFailure** – An event fails to connect if it requires a source and no source is provided, or an invalid source is provided. The **OnFailure** pin displays diagnostic information that you can use to verify whether address data was correctly specified to the **Source** pin of the receiver node.

**Example**

In the following example, **Display Connection Controls** is enabled for the **On Tick** event receiver node. The **Tick** event is disconnected at the start of the graph's lifetime. When the light is turned on, the example changes the light's color randomly for every tick.
Adding and Connecting Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add nodes to a canvas by dragging and dropping them from the Node Palette onto the canvas. You can also quickly add and connect nodes without using the Node Palette, as described in the following sections.

Creating a Chain of Linked Nodes

You can add nodes quickly in succession to a graph by using the daisy chaining feature. Script Canvas automatically links the pins on each new node to the previous node for you.

To create a chain of linked nodes

1. On the right side of the graph, press Shift + Right-click.
2. In the context menu search box, enter the name or partial name of the node that you want to add.
3. Press Enter to accept the search result, or click the name of another node in the result list.

The new node appears on the graph with a line extended from the output pin. The context menu opens automatically, ready for you to add another node and link it to the previous one.
4. Continue to add as many connected nodes as you want. Previously created nodes automatically scroll off to the left.

**Note**
If you start by adding nodes on the left side of the graph, the nodes that you create quickly scroll out of view. To see the previous nodes that you created, start by pressing Shift + Right-click on the right side of the graph.

5. To exit the daisy-chaining mode, press ESC.

**Creating a Node From the Output Pin of an Existing Node**

**To create a connected node from an output pin of an existing node**

1. From an output pin on the existing node, drag a line onto the canvas.
2. In the context menu search box, enter the name or partial name of the node that you want to add.
3. Press Enter to accept the search result, or click the name of another node in the result list. The pins on the new node connect automatically to the pins on the existing node.
4. To create a chain of linked nodes from the output pin of an existing node, press Shift and drag a line from the output pin onto the canvas.

**Inserting a Node Between Two Connected Nodes**

To insert a node between two connected nodes and connect the new node automatically, you can use the following methods:

- Insert an existing node between the nodes.
- Create a new node between the nodes.

**To insert an existing node between two connected nodes**

1. Drag a node over the line that connects the two nodes, and hold the new node in position.
2. When an expanding, box-shaped animation appears, the node pins are connected. Script Canvas nudges surrounding nodes aside to accommodate the new node.
3. The node-nudging feature is enabled by default. To change it, choose **Edit, Settings, Global Preferences** and select or clear the **Allow Node Nudging On Splice** option.

![Global Preferences](image)

To create a node between two connected nodes

1. Right-click the line that connects the two nodes.
2. In the context menu search box, do one of the following:
• Enter the name of the node that you want, and press Enter.
• Choose a node from the list.

The pins on the new node connect automatically to the nodes on the left and the right.

Connecting Two Existing Nodes Automatically

You can connect two nodes by dragging one node onto another node. Script Canvas connects the corresponding pins for you.

To connect two nodes automatically

1. Drag a node over the side of the node that you want to connect, briefly holding the new node in position. For example, drag the left side of one node onto the right side of the second node.
2. When an expanding, box-shaped animation appears over the overlapping nodes, the node pins have been connected.
3. Adjust the position of the new node on the graph.
Adding Variable References in Script Canvas Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Introduced in v1.24 of Lumberyard, variable references provide a shortcut for getting and setting variable values directly from the Script Canvas nodes that use them. Any data pin can be converted to a variable reference by dragging a variable from the Variable Manager directly onto the pin.

To create a variable reference

- Drag a variable from the Variable Manager onto a data input pin to create an input reference, or to a data output pin to create an output reference.
An input reference performs the same as a **Get** variable node and retrieves the value of the variable at the time of node execution.

An output reference performs the same as a **Set** variable node and assigns the output of that slot to the specified variable at the time of node execution.

**Note**
Changing the name of the variable is still supported when you have variable references to that variable. However, you might notice that the display of the new variable name is not immediately reflected in nodes containing the reference. To refresh the display of the node's variable name references, move over the node with your pointer or close and re-open Script Canvas.

**To select a different variable reference**

1. Choose the gear button next to the variable name on the data pin.
2. Select a different variable from the list.

**To convert a variable reference back to a value or into a variable node**

- Do one of the following:
  - Double-click on the data pin name to toggle between a reference and a value.
  - Right-click on the data pin and choose **Convert to Value** to restore that data pin as a value.
  - Right-click on the data pin and choose **Convert to Variable Node** to create a **Get** variable node from a data input pin, or a **Set** variable node from a data output pin.
To convert a data pin into a variable reference

1. Do one of the following:
   - Double-click on the data pin name to toggle between a value and a reference.
   - Right-click on the data pin and choose Convert to Reference.

2. Use the gear button next to the variable name field that appears and select a variable to reference.

   **Tip**
   A quicker alternative for creating a variable reference is to drag a variable from the Variable Manager onto the data pin.

To convert a variable node into a variable reference

- Do one of the following:
  - Right-click on a Get variable node and choose Convert to References. This converts the node into a variable reference on the node following it.

    **Note**
    If the data output from the Get variable node is not connected to another node, the variable node is deleted.
  - Right-click on a Set variable node and choose Convert to References. This converts the node into a variable reference on the node preceding it.
Note
If the data input to the Set variable node is not connected to another node, the variable node is deleted.

Setting Entity Targets

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Nodes can contain an entity property. These properties tell the node which entity to affect. By default, many nodes reference Self, the entity to which the Script Canvas (p. 818) component attaches the current script. You can reference a specific entity other than self.

To reference entities for a node

1. From the Node Palette, locate the node that you want to add to your script and drag it to the canvas.
2. In the node, position your pointer over the entity property and then click the target icon.
3. In the Lumberyard Editor viewport or the Entity Outliner, select the entity that you want to reference.
4. To clear the entity, position your pointer over the entity property and then click the x icon.
5. To reset a property back to self, right-double-click the entity property and choose Set to Self.

Deleting Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Script Canvas offers a variety of techniques for deleting nodes.

To delete one or more nodes and their connections

1. Select the node or nodes that you want to delete.
2. Perform one of the following steps.
   • Press Delete.
   • Right-click, and then choose Delete.

To delete a single node

• On the node that you want to delete, press Alt+Left-click. If the deleted node was connected to one other node, the connection is deleted. If the deleted node was connected to two other nodes, the remaining nodes connect to each other.

Note
You cannot use Alt+Left-click to delete more than one node at a time.

To remove all unused nodes in a graph

• In Script Canvas editor, choose Edit, Remove Unused, Nodes.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Script Canvas offers a variety of ways to delete connections between nodes.

To delete a connection using the context menu
1. Pause your pointer over the connection. The white line becomes a line of moving blue dashes.
2. Right-click the blue dashed line.
3. In the context menu, choose Delete.

To delete a connection using the Delete key
1. Pause your pointer over the connection. The white line becomes a line of moving blue dashes.
2. Left-click the blue dashed line.
3. Press Delete.

Note
You must left-click the blue dashed line before you press Delete.

To delete connections by using the Alt key
1. With the Alt key pressed, pause your pointer on the line. The line turns red.
2. Left-click the line.
To delete a node's connections by "shaking" the node

1. Using your pointer, select a connected node and move it with a shaking gesture to separate it from the other nodes. If the deleted node was connected to two other nodes, the remaining nodes connect to each other.

2. You can make changes to this option in Edit, Settings, Global Preferences, Shake to Desplice.

Organizing Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Script Canvas graphs can easily grow in size and complexity and become too big to fit on one screen and still be legible. This presents a challenge to find sections of interest and keep things organized. And when you or others revisit the graph later, it can be difficult to quickly remember or pick up on the logic. To help manage this organizational challenge, the Script Canvas editor provides a handful of tools at your disposal. In the following topics, you will learn how to arrange, comment, and bookmark sections of your graph, and discover productivity-enhancing techniques for quickly selecting multiple nodes and navigating around your graphs.

Topics
- Aligning Nodes (p. 2518)
- Commenting Nodes (p. 2524)
- Grouping Nodes (p. 2526)
- Creating Comment and Group Presets (p. 2530)
- Adding Bookmarks for Script Canvas (p. 2534)
Aligning Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To align selected nodes in a Script Canvas graph, you can use the context menu, hot keys, or the following alignment icons above the graph.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Icon" /></td>
<td>Top align.</td>
</tr>
<tr>
<td><img src="image" alt="Icon" /></td>
<td>Bottom align.</td>
</tr>
<tr>
<td><img src="image" alt="Icon" /></td>
<td>Left align.</td>
</tr>
<tr>
<td><img src="image" alt="Icon" /></td>
<td>Right align.</td>
</tr>
</tbody>
</table>

To align all nodes in a selection to the topmost node

- Use one of the following methods:
  - Click Top Align (ıldır).
  - Press Shift + Up Arrow.
  - Right-click the graph, and choose Align, Align top.

The following animated images show the first two methods.
To align all nodes in a selection to the bottommost node

- Use one of the following methods:
  - Click **Bottom Align** (\(\mathbb{L}\))
  - Press **Shift + Down Arrow**.
  - Right-click the graph, and choose **Align, Align bottom**.
The following animated images show the first two methods.
To align all nodes in a selection to the leftmost node

- Use one of the following methods:
  - Click **Left Align** ( ),
  - Press **Shift + Left Arrow**,
  - Right-click the graph, and choose **Align, Align left**.

The following animated images show the first two methods.
To align all nodes in a selection to the rightmost node

- Use one of the following methods:
  - Click **Right Align** (△).
  - Press **Shift + Right Arrow**.
  - Right-click the graph, and choose **Align, Align right**.

The following animated images show the first two methods.
Commenting Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add comments to your script to describe how it works.

Contents

- Adding Comment Nodes (p. 2524)
- Adding Block Comment Nodes (p. 2524)
- Changing Comment Node Font Settings (p. 2525)

Adding Comment Nodes

A Comment node is a floating block of text that you can move in the Script Canvas editor canvas.

To add a Comment node to your script

1. In the Script Canvas editor, do one of the following:
   - In the Node Palette, click Utilities and then click and drag the Comment node to your script.
   - Right-click your script and choose Add Comment.
2. Double-click the node and then enter a description.
3. To delete a Comment node, do one of the following:
   - Select the node and press Delete.
   - Right-click the node and choose Delete Node.

Adding Block Comment Nodes

The Block Comment node is similar to the Comment node, except that you can also use block comments to contain other nodes and organize your script into sections. You can add other nodes to the Block Comment node to tag a specific region or add colors to organize the different parts of your script.

To add a Block Comment node to your script

1. In the Script Canvas editor, do one of the following:
   - In the Node Palette, click Utilities and then drag the Block Comment node to your script.
   - Right-click the canvas and choose Create Block Comment.
   - If you have a group of nodes together, right-click the canvas and choose Create Block Comment for Selection.
2. For the Block Comment node, double-click the header, and then enter a description.
3. Drag the corners of the node to resize it.
4. Drag your nodes into the **Block Comment** node or expand the **Block Comment** node to contain them.

**Example**

The following **Block Comment** node contains other nodes as a group.

![](image)

5. To move your nodes together, drag the **Block Comment** node header. All nodes inside the **Block Comment** node move together.

6. To delete the node, do one of the following:

   - Select the **Block Comment** node header and press **Delete**.
   - Right-click the header for the **Block Comment** node and choose **Delete Node**.

   **Note**
   
   Nodes inside the **Block Comment** node are not deleted.

**Changing Comment Node Font Settings**

You can change the font settings in comment nodes to label and organize your script. Font settings apply to the entire comment; you cannot specify individual sections of the comment.

**To change the font settings for comment nodes**

1. In the **Script Canvas** editor, choose **View, Node Inspector**.
2. Do one of the following:

   - For a **Comment** node, select the node.
   - For a **Block Comment** node, select the header.
3. In the **Node Inspector**, you can make the following changes:
As your Script Canvas graphs grow in size, you can group nodes to logically organize parts of a script or reduce its visual complexity. Groups can be nested, named, and color-coded.

### Creating and Managing Node Groups

**To create a node group from existing nodes and/or node groups**

1. Select the nodes that you want to group.
2. Right-click the graph and choose **Group** or **New group**.
3. Enter a name for the node group, and then press **Enter**.

**To create an empty group**

- Right-click an empty portion of the graph, and then choose **New group**. You can expand the group's borders and add nodes to it as you would on the main graph.
To collapse a group

- Do one of the following:
  - Double-click the group.
  - Right-click the group, and choose **Collapse**.
  - In **Node Inspector**, select the **Collapse Group** option.

A collapsed group has a border with a dashed line.

To expand a group

- Do one of the following:
  - Double-click the group.
  - Right-click the group, and choose **Expand**.
  - In **Node Inspector**, clear the **Collapse Group** option.

To edit the name of a group

- Do one of the following:
  - Right-click the title bar of the expanded group, and choose **Edit group title**.
  - In **Node Inspector**, in the **Group Name** box, edit the name.

To resize a group's borders to fit the contents of the group

1. To reduce empty horizontal space within the group, double-click the group's left or right border.
2. To reduce empty vertical space within the group, double-click the group's top or bottom border.
To ungroup a group

- Right-click the group, and choose Ungroup.

To delete a group

- Right-click the group, and choose Delete.

Note
Deleting a group removes all of the nodes in the group and their connections to other nodes outside of the group. If you want to remove the group container but keep its nodes and connections, choose Ungroup.

Enabling Groups as Bookmarks

To quickly navigate through the groups in your graphs, you can enable groups as bookmarks.

To bookmark a group

1. Select the group.
2. In Node Inspector, select Enable as Bookmark.

Customizing Groups

You can use the Node Inspector to customize the color of a group and to change the font settings of the group title.

To change the color of a node group

1. Select the node group.
2. In Node Inspector, do one of the following:
   - If you know the RGB values that you want to use, enter them in the Group Color text box.
   - Click the Group Color icon to use the Select Color dialog box.
3. In the Select Color dialog box, specify the color that you want to use. You can choose from basic colors, create a custom color, or click Pick Screen Color to choose a color on your screen with your pointer.
4. Click OK.

To change the font settings for the node group title

1. In Node Inspector, expand Font Settings.
2. Enter or choose the values that you want to use for the group title font. The changes that you make are immediately visible.
Font Setting | Description
--- | ---
**Font Color** | If you know the RGB values that you want to use, enter them in the text box. Otherwise, click the color icon and use the Select Color dialog box to specify a color. The default is black (0,0,0).

**Font Family** | Enter the name of a font family (for example, **Verdana** or **Arial Black**).

**Pixel Size** | Enter a size for the font. Valid values are from 1 through 200. The default is 16.

**Weight** | Choose a preselected font weight. Possible values are Thin, Extra Light, Light, Normal, Medium, Demi-Bold, Bold, or Extra Bold. The default is Normal.

**Style** | Choose a font style. Possible values are Normal, Italic, and Oblique. The default is Normal.

**Vertical Alignment** | Choose the vertical position of the title text within the group header. Possible values are Top, Middle, or Bottom. The default is Top.

**Horizontal Alignment** | Choose the horizontal position of the title text within the group header. Possible values are Left, Center, or Right. The default is Left.

---

### Creating Comment and Group Presets

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can save custom node comment and node group settings as presets that you can conveniently reuse. In a team setting, these presets can help you create your own coloring and naming conventions to improve clarity and consistency among Script Canvas graphs.

### Customizing the Look of a Comment or Group

Before you create a preset based on an existing node comment or node group, customize its color and font by using the **Background Color** and **Font Settings** options in **Node Inspector**.
For more information, see Customizing Groups (p. 2528).

Creating and Using Presets

You can create a preset in the Script Canvas editor by using an existing node group or node comment.

To create a preset from a group or comment

1. Right-click the group or comment and choose Create Preset From. The preset that you create saves the font settings and color of the original group or comment. It does not save the display text.

2. In the Set Preset Name dialog box, enter a name for the preset, and then click OK.
3. To use the preset that you created, right-click the canvas, choose **Add Comment** or **Group**, and then choose the preset comment or group that you created.

**Configuring a Default Preset**

You can define a preset as the default for either a node group or a comment. The default group or comment is created when you perform one of the following actions:

- On the Script Canvas editor toolbar, click the new comment icon.
- Press **Ctrl+Alt+M** to create a comment.
- Press **Ctrl+Shift+G** to create a group.

**To configure a default preset**

1. In the Script Canvas editor, choose **Tools, Presets Editor**.
2. For **Construct Type**, choose **Comment** or **Node Group**.
3. For **Is Default**, select the preset that you want to make the default, and then click **OK**.
Removing a Preset

To remove presets, use the Script Canvas Presets Editor.

**To remove a preset**

1. In the Script Canvas editor, choose Tools, Presets Editor.
2. For Construct Type, choose Comment or Node Group.
3. Select the preset that you want to delete.
4. Click Remove, and then click OK.
Notes

- After you configure a preset, you cannot modify it. Use the Presets Editor to remove the preset. Then recreate the preset.
- If you recreate a preset, the changes that you make do not propagate to comments or groups that you created with the earlier version of the preset.

Adding Bookmarks for Script Canvas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A bookmark is a shortcut that you can add to a specific location on your Script Canvas graph. You can then use keyboard shortcuts to move quickly to that location. For example, you may have a complex script for a massive character controller that includes sections for movement, camera, and each attack. You can add a bookmark to each section and then press the keyboard shortcut to move the graph view to the specified section.

To add a bookmark

1. In your script, navigate to the node or view that you want.
2. Press Ctrl+1 (or 2 to 9) to add a bookmark. A colored icon appears on the script.

To snap the graph view to a bookmark

- Press 1 to 9 to snap the graph view to the bookmarked location.

To manage your bookmarks

1. In the Script Canvas editor, choose View, Bookmarks.
2. In the Bookmarks window, you can do the following:
• Search for the bookmark name.
• Double-click a bookmark and then enter a new name.
• Click Create to add a bookmark at your current location.
• Select a bookmark and then click Delete to remove it.
• Assign up to nine keyboard shortcuts for your bookmarks. To move to a bookmark that does not have an assigned keyboard shortcut, click the bookmark in the Bookmarks pane.
• Double-click a shortcut and then select a new number.

Note
If you specify a number for a shortcut that a previous shortcut already uses (for example, 5), a dialog box appears. If you want to replace the previous shortcut, click Yes.

Navigating Graphs

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

If you want to visit all nodes of the same type on a graph – for example, to check their configuration – use the following procedure.

To cycle through instances of the same node
1. In the Node Palette search box, enter the name of the node.
2. In the list of results, click the name of the node whose instances you want to find.
3. To scroll to the right, starting at the leftmost node occurrence, press F8. The relevant nodes are highlighted with an orange glow.
4. To scroll to the left, starting at the rightmost node occurrence, press F7.
5. To return to the beginning or end of the cycle, press F7 or F8 again.
Selecting Nodes Using Hot Keys

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the following hot key combinations to select groups of nodes.

- To select all nodes in a graph, press **Ctrl + A**.
- To select all nodes that are connected to the input pins of the selected node, press **Ctrl+Left Arrow**.
• To select all nodes that are connected to the output pins of the selected node, press Ctrl+Right Arrow.

• To select all nodes that are connected to both the input and output pins of a selected node, press Ctrl + Up Arrow.
Script Canvas Functions

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Script Canvas editor enables you to create reusable graphs, called functions. A function is available for use as a node in your Script Canvas graphs. Similar to functions in traditional programming languages, functions in the Script Canvas editor promote code reuse and abstraction. They help simplify your graphs by replacing a group of nodes that perform a specific task with one function node. For example, you could move a series of nodes that perform linear interpolation into a function called Interpolate, and move nodes that perform acceleration clamping into a function called ClampAcceleration. Additionally, if you're using this functionality in multiple graphs, functions make updates easier because you need to make changes only in one place.

Your function appears alongside all the other Script Canvas nodes in the Node Palette, categorized under Global Functions.

When you create a function, you define the input and output variables of that function, and all the nodes in between that produce a result.

Topics
- Creating a Script Canvas Function (p. 2538)
- Using a Script Canvas Function in a Graph (p. 2541)
- Function Example: Linear Interpolation (p. 2541)

Creating a Script Canvas Function

Start creating a new function by choosing File, New Function in the Script Canvas editor.

Alternatively, you can create a new function using the function create button located in the upper right corner of the editor canvas.

Function Entry and Exit Points

Functions require entry and exit points. To create these points, right-click a node's input or output execution slot and select Expose in the context menu. Typically, you create an entry point node from the input execution slot of the first node in your function, and an exit point node from the output execution slot of the last node in your function.
**Note**
To change the names of the execution slots on the function's node, edit the name field on the entry point or exit point node.

Optionally, if you're not certain how you want to connect an entry or exit point to the rest of your function, you can create an entry or exit point node using the toolbar buttons: ![Connect its execution slot later, when you're ready.](connect.png)

**Function Data Parameters**

Functions can also have input and output data parameters. Input parameters are the values that are passed in to the function. Output parameters are the values that are returned by the function. These are both defined as variables in the Variable Manager. A function can also have local variables, which are not exposed on the function's node.
The scope of a variable determines if and where the variable will appear on the function node.

<table>
<thead>
<tr>
<th>Scope</th>
<th>Location on Node</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local</td>
<td>(None)</td>
<td>This is a local variable, for use only by the function.</td>
</tr>
<tr>
<td>In</td>
<td>Input slot</td>
<td>This is an input parameter. A value for this variable is passed in to the function.</td>
</tr>
</tbody>
</table>
### Using a Script Canvas Function in a Graph

Once a Script Canvas function has been saved, it automatically shows up in the **Node Palette**, under **Global Functions**. The default directory for new functions is your project's `scriptcanvas\functions` directory. If you save them in a subdirectory, or save them under a different project directory, the directory structure is used to categorize the functions within **Global Functions**.

Using a function is just like using any other node in Script Canvas. Simply drag and drop the function into a graph. When it's dropped, a node that represents the function is displayed on the canvas.

#### Function Example: Linear Interpolation

In this example, we create a linear interpolation function. This function is represented by the formula:

\[
\text{Result} = \text{Start} + \text{Time} \times (\text{End} - \text{Start})
\]

In this example you will learn how to do the following:

- Create entry and exit points for a function
- Create input parameter slots
- Create return values

The final function graph should look like this:
1. Start a new function using File, New Function or by using the function create button in the upper right corner of the canvas.

2. Create the following four variables in Variable Manager:
   - Start
   - End
   - Time
   - Result

3. Set the scope of Start, End, and Time to In. These are now your input parameters.

4. Set the scope of Result to Out. This is now your return value.

5. Place the Subtract, Multiply, and Add nodes onto your graph and connect them as shown in the previous image.

6. Using variable references (p. 2511), do the following:
   1. In the Subtract node, reference the End and Start variables, so that Start is subtracted from End.
   2. In the Multiply node, use the result of the subtraction and reference the Time variable, so that \((\text{End} - \text{Start})\) is multiplied by Time.
   3. In the Add node, use the result of the multiplication and reference the Start variable, so that these two values are added together. Then add a reference to the Result variable in the result slot, so that the final value is stored in Result.

7. Create entry and exit points for your function.
   1. Right-click on the Subtract node's In slot and choose Expose from the context menu.
   2. (Optional) Rename the entry point node to In, if you want to follow the naming convention for node input execution slots.
   3. Right-click on the Add node's Out slot and choose Expose from the context menu.
   4. (Optional) Rename the exit point node to Out, if you want to follow the naming convention for node output execution slots.

8. Finally, use File, Save to save the function and name it Interpolate. The function is now ready to use in a Script Canvas graph:
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

From this section you can gain a deeper understanding of how Script Canvas works with the rest of Lumberyard, and learn how to author your own custom nodes for use in Script Canvas graphs.

Script Canvas and the Behavior Context

You can use Script Canvas to expose runtime code in a visual authoring environment using the behavior context. In addition to this topic, it is recommended that you also read the Programmer’s Guide to Entities and Components (p. 973) and Behavior Context (p. 1053).

The following code architecture diagram shows the relationship between Script Canvas and the behavior context in Amazon Lumberyard.
The core Script Canvas code is built as a static library that is linked into the dependent gem and editor gem. This allows the code footprint at run time to be as small as the minimum required to run a Script Canvas graph. It also allows the Script Canvas Editor Gem to contain all the code required to author and develop Script Canvas graphs.

Script Canvas is designed to use behavior context reflection and provide access to the same objects and EBus (p. 1851) that are available in Lua. When you use the behavior context, you do not need to write any Script Canvas-specific code. However, it is important that the way in which your code is reflected to the behavior context remains intuitive in a visual scripting environment.

The behavior context for Script Canvas includes the following benefits:

- Functionality exposed through the behavior context is also available in Lua (and any other scripting solution bound to the behavior context).
- The EBus system makes it easier for you to use decoupled, event-driven programming paradigms.
- Script Canvas can use any functionality that is exposed to the behavior context, even if it comes from other gems. Therefore, when code is reflected to the behavior context, gems can enhance Script Canvas.
- Reflecting gems to the behavior context removes any need to add gem dependencies to Script Canvas.

The Light Component and Script Canvas

So that you can better understand the relationship between the behavior context and Script Canvas, this section discusses the fairly simple Light component. The example shows how its behavior context reflection translates into Script Canvas nodes.

You can use the Light component to give an entity a light. You can configure the light by setting parameters such as color, intensity, and radius. The Light component can also be turned on or off, and you can respond to these events when they occur.
Communication with an entity's Light component is done through two EBuses: LightComponentRequestBus and LightComponentNotificationBus.

A request bus provides methods that can be called on an entity. If an entity has a Light component, the Light component implements the behavior of the requests that are made to it.

Some of the requests that you can issue on a Light Component are the following. For the source code, see the file dev\Gems\LmbrCentral\Code\include\LmbrCentral\Rendering\LightComponentBus.h.

```cpp
//! Turns light on. Returns true if the light was successfully turned on
virtual bool TurnOnLight() { return false; }

//! Turns light off. Returns true if the light was successfully turned off
virtual bool TurnOffLight() { return false; }

//! Toggles light state.
virtual void ToggleLight() {}
```

These requests are part of the LightComponentRequestBus. Their behavior is implemented by LightComponent.

To make these requests accessible for scripting, they must be reflected to the behavior context. This is done in LightComponent::Reflect. The source code is in the file dev\Gems\LmbrCentral\Code\Source\Rendering\LightComponent.cpp.

```cpp
behaviorContext->EBus<LightComponentRequestBus>("Light", "LightComponentRequestBus")
    ->Attribute(AZ::Script::Attributes::Category, "Rendering")
    ->Event("TurnOn", &LightComponentRequestBus::Events::TurnOnLight, "TurnOnLight")
    ->Event("TurnOff", &LightComponentRequestBus::Events::TurnOffLight, "TurnOffLight")
    ->Event("Toggle", &LightComponentRequestBus::Events::ToggleLight, "ToggleLight")
```

When Script Canvas examines the behavior context, it finds these bindings and automatically generates the corresponding nodes for you.
You use EBuses to communicate with an entity's components. To do so, you need an address. All component EBuses derive from `AZ::ComponentBus`, which is addressable by an ID of the type `AZ::EntityId`. For this reason, all nodes from a component EBus have an entry slot for an EntityID. The presence of `Self` in the EntityID field refers to the EntityID of the entity that owns the Script Canvas graph. However, this ID can be assigned to another entity, or even changed to an invalid entity ID.
The other bus that the Light component reflects to the behavior context is `LightComponentNotificationBus`. The following source code is also in the file `dev\Gems\LmbrCentral\Code\Source\Rendering\LightComponent.cpp`.

```cpp
behaviorContext->EBus<LightComponentNotificationBus>("LightNotification",
    "LightComponentNotificationBus", "Notifications for the Light Components")
    ->Attribute(AZ::Script::Attributes::Category, "Rendering")
    ->Handler<BehaviorLightComponentNotificationBusHandler>();
```

Notification buses are also known as **event handlers**. You can use these event handlers on a component to respond to the events that happen to the component. As part of reflection to the behavior context, the preceding code specifies that the `BehaviorLightComponentNotificationBusHandler` handles events for the Light component.

The following code shows the binding for the `BehaviorLightComponentNotificationBusHandler` and defines two events: `LightTurnedOn` and `LightTurnedOff`.

```cpp
class BehaviorLightComponentNotificationBusHandler : public LightComponentNotificationBus::Handler, public AZ::BehaviorEBusHandler
{ public:
    AZ_EBUS_BEHAVIOR_BINDER(BehaviorLightComponentNotificationBusHandler, 
        "{969C5B17-10D1-41DB-8123-6664FA64B4E9}", AZ::SystemAllocator,
        LightTurnedOn, LightTurnedOff);
    // Sent when the light is turned on.
    void LightTurnedOn() override
    {
        Call(FN_LightTurnedOn);
    }
    // Sent when the light is turned off.
    void LightTurnedOff() override
    {
        Call(FN_LightTurnedOff);
    }
};
```

Script Canvas has a node that gives you access to all the events for EBus. You can handle the events that you are interested in.
Objects: The PhysicsComponent Example

Objects that are reflected to the behavior context are also available in Script Canvas. Objects become available in the form of variables.

The Light component does not provide any objects, but the PhysicsComponent provides an example of an object reflected to the behavior context. The Collision class is reflected as a behavior context object that you can access through the use of variables in Script Canvas. You can find the following source code in the file `dev\Gems\LmbrCentral\Code\Source\Physics\PhysicsComponent.cpp`.

```cpp
using Collision = PhysicsComponentNotifications::Collision;
// Information about a collision event
behaviorContext->Class<Collision>();
  ->Attribute(AZ::Script::Attributes::Storage, AZ::Script::Attributes::StorageType::Value)
  ->Property("entity", BehaviorValueProperty(&Collision::m_entity))
  ->Property("position", BehaviorValueProperty(&Collision::m_position))
  ->Property("normal", BehaviorValueProperty(&Collision::m_normal))
  ->Property("impulse", BehaviorValueProperty(&Collision::m_impulse))
  ->Property("velocities", BehaviorValueGetter(&Collision::m_velocities), nullptr)
  ->Property("masses", BehaviorValueGetter(&Collision::m_masses), nullptr)
  ->Property("surfaces", BehaviorValueGetter(&Collision::m_surfaces), nullptr)
;
```
**Note**
During the preview release of Script Canvas, properties must provide both getters and setters to be accessible on a Script Canvas node. Containers such as vectors are currently not supported. For this reason, velocities, masses, and surfaces do not provide a setter.

Most object variables are set as a result of an event. In the case of the preceding Collision example, the Collision variable is returned by the OnCollision event.

You can use the following graph to set the collision variable:
Displaying EBus Event Parameter Names in Script Canvas Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To display parameter names correctly for your EBus events, ensure that you specify custom names when you reflect your events to the behavior context.

If you do not specify names for the parameters, they are given default display names like "1", "2", or "3", as in the following image:
The following code produced the event node in the image:

```cpp
if (auto behaviorContext = azrtti_cast < AZ::BehaviorContext * >(reflectContext))
{
    behaviorContext->EBus < MyBus >("MyBus")
    // This is the category that appears in the Node Palette window
    ->Attribute (AZ::Script::Attributes::Category,
                 "Rendering") ->Event ("SomeEvent",
                           &MyBus::Events::SomeEvent);
}
```

The following version of the same code adds the parameter names `FirstParam` and `SecondParam` and corresponding tooltip text to the `Event` function:

```cpp
if (auto behaviorContext = azrtti_cast<AZ::BehaviorContext*>(reflectContext))
{
    behaviorContext->EBus<MyBus>("MyBus")
    // This is the category that appears in the Node Palette window
    ->Attribute(AZ::Script::Attributes::Category, "Rendering")
    ->Event("SomeEvent", &MyBus::Events::SomeEvent, { { "FirstParam", "First Param Tooltip" }, { "SecondParam", "Second Param Tooltip" } });
}
```

In the node palette window, the parameter names appear as specified:

**Alternate Syntax**

You can also use the following alternate syntax to create parameter override instances before passing them to the `Event` function:
if (auto behaviorContext = azrtti_cast<AZ::BehaviorContext*>(reflectContext))
{
    AZ::BehaviorParameterOverrides someEventParam1 = { "FirstParam", "First Param Tooltip" };
    AZ::BehaviorParameterOverrides someEventParam2 = { "SecondParam", "Second Param Tooltip" };
    behaviorContext->EBus<MyBus>("MyBus")
        // This is the category that appears in the Node Palette window
        ->Attribute(AZ::Script::Attributes::Category, "Rendering")
        ->Event("SomeEvent", &MyBus::Events::SomeEvent, { {someEventParam1,
            someEventParam2} });
}  

Common Programming Problems

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The following are some common problems that occur when programming with Script Canvas and the behavior context.

I reflected my class to the behavior context, but it doesn't appear in Script Canvas.

Both the serialization context and the behavior context use the same Reflect function:

```
Reflect(AZ::ReflectContext*)
```

A common mistake is to not keep the reflection scopes separate. For example, you might mistakenly place the BehaviorContext reflection within the SerializeContext scope. The following code examples show the problem and the solution.

Problem

```
void Example::Reflect(AZ::ReflectContext* context)
{
    if (AZ::SerializeContext* serializeContext = azrtti_cast<AZ::SerializeContext*>(context))
    {
        serializeContext->Class<Example>()
            ->Version(1)
            ;
        // Problem! BehaviorContext is inside the SerializeContext scope and will not get reflected.
        if (AZ::BehaviorContext* behaviorContext = azrtti_cast<AZ::BehaviorContext*>(context))
        {
            behaviorContext->Class<Example>()
                ->Method("IsValid", &Example::IsValid)
                ;
        }
    }
}
```

Solution

```
void Example::Reflect(AZ::ReflectContext* context)
```
I exposed a new EBus to the Behavior Context, but my handler is not getting called.

For example, you created an EBus handler and properly exposed it script. Yet, when you try to receive the event in Script Canvas, it does not get triggered.

This is caused by an oversight that is easy to make: newly implemented EBus handlers must be connected before they can receive events. The solution is to ensure that your component connects to the bus, as in the following example:

```cpp
MyBus::BusConnect()
```

Depending on the type of bus, you might have to specify an ID to connect to. For more information, see Working with the Event Bus (EBus) system (p. 1851).

## Creating Custom Nodes in Script Canvas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Script Canvas uses the behavior context (p. 1053). The preferred way to expose functionality in Script Canvas is through behavior context bindings. Behavior context bindings make functionality available to any scripting solution (such as Lua) that also uses the behavior context. However, if you want to create Script Canvas–specific functionality or customized visual scripting experiences, you can use the Script Canvas custom node API.

If your gem provides custom Script Canvas nodes, you must specify a dependency on the Script Canvas Gem and configure Waf appropriately to compile the nodes. Functionality that you reflect through the behavior context requires no dependency on the Script Canvas Gem.

Custom nodes in Script Canvas take advantage of Automating boilerplate with AZ Code Generator (p. 1869) and boilerplate code. This reduces complexity and lets you focus on implementing the behavior of the node.

The following diagram shows the AZ Code Generator process for Script Canvas.
In **Step 1**, AZ Code Generator processes `MyNode.h` and looks for code generation tags (source code location: `dev\Gems\ScriptCanvas\Code\Include\ScriptCanvas\CodeGen\CodeGen.h`). After processing, AZ Code Generator creates a file called `MyNode.generated.h`.

**Note**
You must include `MyNode.generated.h` in the `MyNode.h` file so that the preprocessor macro that AZ Code Generator produces is resolved by C++ during Step 3.

In **Step 2**, AZ Code Generator processes `MyNode.h` again, but this time produces a `.cpp` file.

**Note**
You must include `MyNode.generated.cpp` the in `MyNode.cpp` file. This ensures that the generated code can be compiled and has access to all the same `#include` declarations as those found in `MyNode.cpp`.

In **Step 3**, AZ Code Generator is finished and the build process continues as normal. `MyNode.cpp` is compiled and succeeds provided all the generated files are correct.

**Topics**
- Script Canvas Tags for AZ Code Generator (p. 2554)
- Dynamic Data Slots (p. 2557)
- Extendable Nodes (p. 2558)
- Implementing Node Behavior (p. 2559)
- Creating Custom Script Canvas Nodes in a Gem (p. 2563)
- Node Libraries (p. 2565)
- Node Contracts (p. 2567)

**Script Canvas Tags for AZ Code Generator**

Script Canvas provides a variety of tags that AZ Code Generator uses. These tags can be found in the source code location `dev\Gems\ScriptCanvas\Code\Include\ScriptCanvas\CodeGen\CodeGen.h`. Because the tags are well documented in the code, this guide focuses on showing how to use them rather than on covering each one in detail.
The following example shows the `Delay` node, which uses a variety of different code generation features. The source code files are located in the directory `dev\Gems\ScriptCanvas\Code\Include \ScriptCanvas\Libraries\Time`.

The first tag is `ScriptCanvas_Node`, which is in the `Countdown.h` file. This tag is used as the class declaration of a node and generates the necessary reflection for the node.

```cpp
ScriptCanvas_Node(Countdown,
    ScriptCanvas_Node::Name("Delay")
    ScriptCanvas_Node::Uuid("{FAEADF5A-F7D9-415A-A3E8-F534BD379B9A}")
    ScriptCanvas_Node::Description("Counts down time from a specified value.")
);
```

Note that while internally the class name is `Countdown`, the code specifies that `Delay` be used as the node name in Script Canvas editor. AZ Code Generator uses the `ScriptCanvas_Node` tag to produce the following code in `Countdown.generated.h`:

```cpp
#define AZ_GENERATED_Countdown
public:
    AZ_COMPONENT(Countdown, "{FAEADF5A-F7D9-415A-A3E8-F534BD379B9A}", ScriptCanvas::Node);

    static void Reflect(AZ::ReflectContext* reflection);
    void ConfigureSlots() override;
    bool IsEntryPoint() const override;
    using Node::GetInput;
    friend struct CountdownProperty;
```

The `ScriptCanvas_Node` looks like the following in the `CodeGen.h` file when you compile the project:

```cpp
define ScriptCanvas_Node(ClassName, ...) AZ_JOIN(AZ_GENERATED_, ClassName)
```

When the project is compiled, the preprocessor finds `AZ_GENERATED_Countdown` in the `Countdown.generated.h` file and replaces that macro with the generated code.

**Generating the Node Topology**

After you have declared the node, the next step is to generate the node's topology. The topology can include a variety of tags, as the following table shows.

<table>
<thead>
<tr>
<th>Tag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ScriptCanvas_In</code></td>
<td>Provides a named <code>Input</code> execution slot to the node.</td>
</tr>
<tr>
<td><code>ScriptCanvas_Out</code></td>
<td>Provides a named <code>Output</code> execution slot to the node.</td>
</tr>
<tr>
<td><code>ScriptCanvas_Property</code></td>
<td>This tag must precede a member variable in the class that you want to expose to Script Canvas for editing and scripting. By default, the property is exposed with an <code>Input</code> and <code>Output</code> slot. However, you can use the <code>Input</code> or <code>Output</code> attributes to expose only one or the other.</td>
</tr>
<tr>
<td><code>ScriptCanvas_PropertyWithDefaults</code></td>
<td>Like <code>ScriptCanvas_Property</code>, but specifies default values.</td>
</tr>
<tr>
<td><code>Property</code></td>
<td>Reflects a property to the serialization context that does not need to be an editable property or an input property. For more information, see Serializing &quot;Hidden&quot; Node Properties (p. 2563).</td>
</tr>
<tr>
<td><code>EditProperty</code></td>
<td>Reflects a property to the serialization context and to the <code>EditContext</code> with <code>EditContext</code> attribute support. For more information, see Serializing &quot;Hidden&quot; Node Properties (p. 2563).</td>
</tr>
</tbody>
</table>
Each of these tags has attributes that can be configured. For example, the `Countdown.h (Delay)` node has the following topology:

```cpp
// Inputs
ScriptCanvas_In(ScriptCanvas_In::Name("In", "When signalled, execution is delayed at this node according to the specified properties.")
  ScriptCanvas_In::Contracts({ DisallowReentrantExecutionContract }));
ScriptCanvas_In(ScriptCanvas_In::Name("Reset", "Resets the delay.")
  ScriptCanvas_In::Contracts({ DisallowReentrantExecutionContract }));

// Outputs
ScriptCanvas_Out(ScriptCanvas_Out::Name("Out", "Signalled when the delay reaches zero.")
  ScriptCanvas_Out::Contracts({ DisallowReentrantExecutionContract }));

// Data
ScriptCanvas_Property(float,
  ScriptCanvas_Property::Name("Time", "Amount of time to delay, in seconds")
  ScriptCanvas_Property::Input);
ScriptCanvas_Property(bool,
  ScriptCanvas_Property::Name("Loop", "If true, the delay will restart after triggering the Out slot")
  ScriptCanvas_Property::ChangeNotify(AZ::Edit::PropertyRefreshLevels::EntireTree)
  ScriptCanvas_Property::Input);
ScriptCanvas_Property(float,
  ScriptCanvas_Property::Name("Hold", "Amount of time to wait before restarting, in seconds")
  ScriptCanvas_Property::Visibility(&Countdown::ShowHoldTime)
  ScriptCanvas_Property::Input);
ScriptCanvas_Property(float,
  ScriptCanvas_Property::Name("Elapsed", "The amount of time that has elapsed since the delay began.")
 ScriptCanvas_Property::Visibility(false)
  ScriptCanvas_Property::Output
  ScriptCanvas_Property::OutputStorageSpec
);
```

In the **Script Canvas** editor, the node shows the **Time**, **Loop**, **Hold**, and **Elapsed** properties that were defined:
Dynamic Data Slots

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

There are cases where a single node can function on multiple different input types (for example, the Lerp Between node can function on numbers and vector objects). To reduce the number of unique nodes, you can use dynamic data slots. Dynamic data slots enable a single node to handle a variety of data types. At the same time, they allow restrictions on the data types that can be connected.

You can use the `ScriptCanvas_DynamicDataSlot` tag to add a DynamicDataSlot to any node, as shown in the following example.

```cpp
ScriptCanvas_DynamicDataSlot(ScriptCanvas::DynamicDataType::Value,
    ScriptCanvas::ConnectionType::Output,
    ScriptCanvas::DynamicDataSlot::Name("Step", "The value of the current step of the lerp.")
    ScriptCanvas::DynamicDataSlot::DynamicGroup("LerpGroup")
ScriptCanvas::DynamicDataSlot::RestrictedTypeContractTag({ Data::Type::Number(),
    Data::Type::Vector2(), Data::Type::Vector3(), Data::Type::Vector4() })
```

The `ScriptCanvas_DynamicDataSlot` tag includes the following code gen attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DynamicDataType</td>
<td>Allows the user to specify a macro category of dynamic typing information. DynamicDataType has the following supported values:</td>
</tr>
<tr>
<td></td>
<td>• Container – Maps or arrays of any data type.</td>
</tr>
<tr>
<td></td>
<td>• Value – Any non-map or non-array value.</td>
</tr>
<tr>
<td></td>
<td>• Any – Any Container or Value type.</td>
</tr>
<tr>
<td>DynamicGroup</td>
<td>Unifies a group of dynamically typed slots. When one slot has a type, all slots in the group share the same type. This attribute is useful for ensuring that passsthrough values or operands all share a common type.</td>
</tr>
<tr>
<td>RestrictedTypeContractTag</td>
<td>Restricts the data types that the dynamically typed slot accepts. Takes an argument that is a list of supported data types.</td>
</tr>
</tbody>
</table>

Important Notes about Groups

For the purposes of contract restrictions, the grouped slots act as a single unit. If one slot doesn't allow a particular type, no slots in that group allow that type. This behavior is because connection types are propagated through every member of a group and every group connected to that group. This also applies to dynamic data slots that are connected to each other and any dynamic data slots that are connected but ungrouped.

Chained Dynamic Types

When dynamic types are connected, the receiving slot takes on the data type and restrictions of the connecting slot.
Example

Like dynamic groups, any pair of dynamically typed nodes that are linked share the same restrictions. This includes any restrictions from the node group. Additionally, the slots are usually in the most unrestricted state as possible. Unless a display type gives a set of dynamically typed slots a type, the slots remain untyped.

Adding Dynamic Data Slots Programmatically

You can also add dynamic slots programmatically. Use `DynamicDataSlotConfiguration` to define the slot, and then the generic `AddSlot` method to add it, as shown in the following example.

```cpp
SlotId MyNode::AddDynamicSlot(AZStd::string_view name, AZStd::string_view toolTip,
                              ConnectionType connectionType)
{
    DynamicDataSlotConfiguration slotConfiguration;

    // Generic Slot Configuration
    slotConfiguration.m_name = name;
    slotConfiguration.m_toolTip = toolTip;
    slotConfiguration.SetConnectionType(connectionType);
    slotConfiguration.m_addUniqueSlotByNameAndType = false;

    // Contract Descs provides a list of contracts that must be satisfied for a connection to be accepted to this slot.
    //slotConfiguration.m_contractDescs.push_back(TypeRestriction);

    // DynamicDataSlot Specific Configurations
    slotConfiguration.m_dynamicGroup = "DynamicDataGroup";
    slotConfiguration.m_dynamicDataType = DynamicDataType::Value;
    //

    return AddSlot(slotConfiguration);
}
```

For information about `DynamicGroup` and `DynamicDataType`, see the `ScriptCanvas_DynamicDataSlot` attributes table earlier in this topic.

Extendable Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Certain nodes, such as the math operators, can function on an arbitrarily long list of parameters. To maintain this feature without creating a needlessly large node, extendable slots let users add as many slots as they require to a node.

The following code example shows an extendable node interface.

```cpp
// Returns whether or not the specified SlotId should be allowed to be removed from the
given node.
// This should return false, unless the slot was added dynamically through the extender
system.
virtual bool CanDeleteSlot(const SlotId& slotId) const;

virtual bool IsNodeExtendable() const;
virtual int GetNumberOfExtensions() const;

// At display time, the extendable configuration will be enumerated on for display purposes
within GraphCanvas.
// This should return the configuration that provides details about the information
necessary to display and operate
// the ExtenderSlot from graph canvas.
virtual ExtendableSlotConfiguration GetExtensionConfiguration(int extensionCount) const;

// Signals to the node to add a slot for the specific extension. Should return the SlotId
of that slot that was added
// for the specific ExtensionId.
virtual SlotId HandleExtension(AZ::Crc32 extensionId);
```

The following code example shows how to configure an extendable slot.

```cpp
struct ExtendableSlotConfiguration
{
public:
    AZ_TYPE_INFO(ExtendableSlotConfiguration, "{3EA2D6DB-1B8F-451B-A6CE-D5779E56F4A8");
    AZ_CLASS_ALLOCATOR(ExtendableSlotConfiguration, AZ::SystemAllocator, 0);
    ExtendableSlotConfiguration() = default;
    ~ExtendableSlotConfiguration() = default;

    // The name and tooltip to appear on the corresponding GraphCanvas ExtenderSlot.
    AZStd::string m_name;
    AZStd::string m_tooltip;

    // How to group the ExtenderSlot visually on the node.
    AZStd::string m_displayGroup;

    // The ExtensionId used to identifier the individual ExtenderSlots on a node from one
another in the case of
    // multiple ExtenderIds.
    AZ::Crc32 m_identifier;

    // Controls whether the GraphCanvas ExtenderSlot appears as an input pin or an output
    pin.
    ConnectionType m_connectionType = ConnectionType::Unknown;
};
```

Implementing Node Behavior

After you have defined the topology for the node, you can focus on implementing the behavior for the node.
Adding Slots

In addition to using AZ Code Generator to set up the node's topology, it is also possible to manually add execution and/or data slots if preferred. The following example from the IsNull logic node adds a Reference input slot for data reference and an Is Null output slot. The output slot returns a Boolean value depending on the evaluation of the data that was input. The source code is in the location `dev\Gems\ScriptCanvas\Code\Include\ScriptCanvas\Libraries\Logic\IsNull.cpp`.

```cpp
void IsNull::OnInit()
{
    AZStd::vector<ContractDescriptor> contracts;
    auto func = []() { return aznew IsReferenceTypeContract(); };  
    ContractDescriptor descriptor{ AZStd::move(func) }; 
    contracts.emplace_back(descriptor); 
    AddInputDatumUntypedSlot("Reference", &contracts); 
    AddOutputTypeSlot("Is Null", "", AZStd::move(Data::Type::Boolean()), OutputStorage::Optional); 
}
```

When the node is initialized, the added slots appear in the Script Canvas editor.

Receiving Input Signals

Nodes can receive input signals when a node's execution slot is triggered. To detect which signal has been triggered, implement `OnInputSignal`, as in the following example.

```cpp
void OnInputSignal(const SlotIds) override;
```

To get the ID of the input signal, AZ Code Generator provides some convenient helper functions in a namespace that corresponds to the generated node. These helper functions make it easier to access the node's properties and slot IDs.

As an example, in the Delay node two input slots can be signaled: In and Reset.
In the following code, the Delay node's In and Reset slots use the generated helper functions CountdownProperty::GetInSlotId(this); and CountdownProperty::GetResetSlotId(this); to get their IDs. The source code is from dev\Gems\ScriptCanvas\Code\Include\ScriptCanvas\Libraries\Time\Countdown.cpp.

```cpp
void Countdown::OnInputSignal(const SlotId& slot)
{
    const SlotId& inSlotId = CountdownProperty::GetInSlotId(this);
    const SlotId& resetSlotId = CountdownProperty::GetResetSlotId(this);
    if (slot == resetSlotId || (slot == inSlotId && !AZ::TickBus::Handler::BusIsConnected()))
    {
        // Disconnect required when resetting
        AZ::TickBus::Handler::BusDisconnect();
        m_countdownSeconds = CountdownProperty::GetTime(this);
        m_looping = CountdownProperty::GetLoop(this);
        m_holdTime = CountdownProperty::GetHold(this);
        m_currentTime = m_countdownSeconds;
        AZ::TickBus::Handler::BusConnect();
    }
}
```

You can use these IDs to determine what action the node should take.

**Sending Output Signals**

After the Delay node is finished, it uses the SignalOutput(outSlot) function to signal the output slot that execution is ready to continue.

To call the function, you must know the output slot ID to pass. The following example is from Duration.cpp.
const SlotId doneSlot = DurationProperty::GetDoneSlotId(this);
[...]
SignalOutput(doneSlot);

**Note**
If your node is connected to one or more buses during its lifetime, ensure that it disconnects from those buses before it exits. Otherwise, your node might be handling events that it no longer should.

### Querying Inbound Data

The **Delay** node example has the inbound data slots **Time**, **Loop**, and **Hold**.

![Delay node example](image)

Script Canvas properties that specify the `ScriptCanvas_Property::Input` attribute can be queried by the node to do necessary processing. To do this, use the code-generated convenience helpers `CountdownProperty::Get(PropertyName)(this)`.

```cpp
m_countdownSeconds = CountdownProperty::GetTime(this);
m_looping = CountdownProperty::GetLoop(this);
m_holdTime = CountdownProperty::GetHold(this);
```

You can often use these properties on the stack; you do not have to assign these properties to member variables. In the **Delay** node example, member variables are used to cache the values.

### Sending Outbound Data

Many nodes might want to return a value or push forward data as a result of a computation. In the **Delay** node example, the **Elapsed** slot outputs the elapsed time.

![Delay node example](image)
To output the elapsed time, the node gets the ID of the Elapsed slot and then pushes a data value into it (dev\Gems\ScriptCanvas\Code\Include\ScriptCanvas\Libraries\Time\Countdown.cpp).

```cpp
const SlotId elapsedSlot = CountdownProperty::GetElapsedSlotId(this);
Datum o(Data::Type::Number(), Datum::eOriginality::Copy);
o.Set(m_elapsedTime);
if (auto* slot = GetSlot(elapsedSlot))
{
    PushOutput(o, *slot);
}
```

### Serializing "Hidden" Node Properties

In some cases you might want your node to serialize its properties but not expose them as slots on a node. In this case, the Property and EditProperty tags are useful.

You can use the Property tag to serialize any property without exposing it to the node's property grid. Because it is not exposed, it is not user configurable.

The EditProperty tag both serializes and provides an EditContext for the specified property. This makes the property user configurable through the node's property grid.

### Creating Custom Script Canvas Nodes in a Gem

To have a gem support custom Script Canvas nodes, you must configure it to take a dependency on Script Canvas and then configure Waf. The following procedure uses the Starting Point Input Gem as an example.

**To create a Script Canvas dependency for a gem**

1. Open the gem's gem.json file. (For reference, see the source at \dev\Gems\StartingPointInput\gem.json)

```json
{
    "Dependencies": [,
    {
        "Uuid": "59b1b2acc1974aae9f18faddcaddac5b",
        "VersionConstraints": [
            "~>0.1"
        ],
        "_comment": "InputManagementFramework"
    },
    {
        "Uuid": "869a0d0ec11a45c299917d45c81555e6",
        "VersionConstraints": [">
```
2. In the Dependencies key at the beginning of the file, add the following entry for Script Canvas:

```json
{
    "Uuid" : "869a0d0ec11a45c299917d45c81555e6",
    "VersionConstraints" : [">=0.1.0"],
    "_comment" : "ScriptCanvas"
}
```

**Note**
To use this dependency, the Script Canvas Gem must be enabled in the Project Configurator when your gem is enabled.

3. Configure Waf to find the path to the AzCodeGeneration driver. To see how to do this, you can follow the example of the Starting Point Input Gem's .wscript file.

The following is the full text of the .wscript file. Substeps are provided after the full text.

```python
def build(bld):
    # Need to build a /dev relative path; otherwise, a gem/code relative path is used.
    import os
    driver_node = bld.path.find_or_declare('Gems/ScriptCanvas/Code/Include/ScriptCanvas/
    gem_node = bld.path.find_or_declare('Gems/StartingPointInput/Code/
    script_canvas_dir = driver_node.path_from(gem_node)
    AZ_CODEGEN_ARGS = az_code_gen = [{
        'files'   : ['Source/InputNode.h'],
        'scripts' : [os.path.join(script_canvas_dir, 'CodeGen/Drivers/ScriptCanvasNode.py')],
        'arguments' : [
#'-OnlyRunDiagnosticsOnMainFile=true',
#'-SuppressDiagnostics=false',
#'-SuppressErrorsAsWarnings=false',
#'-output-redirection=file',
#'-SuppressIncludeNotFoundError=false',
],
        'options' : ['PrintOutputRedirectionFile']
    }]
    bld.DefineGem(
    use    = [ 'AzFramework', 'ScriptCanvas' ],
    includes = [ bld.Path('Code/CryEngine/CryAction'),
                 bld.Path('Code/CryEngine')
                ],
    export_includes = [bld.Path('Code/CryEngine')],
    # Suppressing level 1 warning C4351 on windows
    # new behavior: elements of array 'array' will be default initialized
    win_cxxflags = ['/wd4351'],
    features = ['az_code_gen'],
    win_defines = [],
    file_list = [ 'startingpointinput.waf_files' ],
    test_all_file_list = [ 'startingpointinput_tests.waf_files' ],
    az_code_gen = AZ_CODEGEN_ARGS,
    editor = dict(
        az_code_gen = AZ_CODEGEN_ARGS,
        file_list = [ 'startingpointinput_editor.waf_files' ],
    )
```

Version 1.28
2564
a. In the first section of the .wscript file, tell AZ Code Generator where to find the Script Canvas drivers and templates. This section is required.

```python
import os
driver_node = bld.path.find_or_declare('Gems/ScriptCanvas/Code/Include/ScriptCanvas/')
gem_node = bld.path.find_or_declare('Gems/StartingPointInput/Code/')
script_canvas_dir = driver_node.path_from(gem_node)
```

b. In the next section, create a configuration object that specifies the files that you want AZ Code Generator to process. For build performance, AZ Code Generator runs only on the files that you specify in the wscript file. Therefore you must add to the `files` section the source files for any new node on which you want to use AZ Code Generator:

```python
AZ_CODEGEN_ARGS = az_code_gen = [{
    'files'   : ['Source/InputNode.h'],
    'scripts' : [os.path.join(script_canvas_dir, 'CodeGen/Drivers/ScriptCanvasNode.py')],
}
# Note: Only the files specified in the above 'files' section will be run through AZ Code Generator!
```

c. Configure the gem to use AZ Code Generator.

```python
use             = [ 'AzFramework', 'ScriptCanvas' ],  # Ensures that the core ScriptCanvas code is statically linked.
features        = ['az_code_gen'], # Enables AZ Code Generator for this gem.
az_code_gen     = AZ_CODEGEN_ARGS, # Applies the configuration parameters that you previously defined.
```

d. In the last section, provide configuration for the Editor Gem.

```python
editor = dict(  
az_code_gen = AZ_CODEGEN_ARGS,  
file_list = ['startingpointinputEditor.waf_files'],
)
```

Because Script Canvas is both an edit time tool and a runtime system, it requires that your gem provide an Editor Gem. This ensures that the proper .dll files are loaded with the relevant symbols both when the project is compiled and at run time.

---

**Node Libraries**

Nodes in a gem are typically stored in node libraries. These libraries aid in the registration of the nodes with the Script Canvas Gem. They also help organize the nodes within the Script Canvas editor’s **Node Palette**.

The following procedure uses the Script Canvas Diagnostic Library Gem, which is an example of how to create gems that extend Script Canvas. The source code files are in the directory `\dev\Gems\ScriptCanvasDiagnosticLibrary\Code\Source`.

**To create a node library for a gem with Script Canvas**

1. Declare your library. The following example (Debug.h) shows a library declaration from the Script Canvas Diagnostic Library Gem.
struct Debug : public Library::LibraryDefinition
{
    AZ_RTTI(Debug, "{3E28E41D-F4C9-4542-A08F-2B1F5DAA9509}",
             Library::LibraryDefinition);
    static void Reflect(AZ::ReflectContext*);
    static void InitNodeRegistry(NodeRegistry& nodeRegistry);
    static AZStd::vector<AZ::ComponentDescriptor*> GetComponentDescriptors();
};

2. After you declare the library, reflect it. The following example is from Debug.cpp.

void Debug::Reflect(AZ::ReflectContext* reflection)
{
    AZ::SerializeContext* serializeContext =
        azrtti_cast<AZ::SerializeContext*>(reflection);
    if (serializeContext)
    {
        serializeContext->Class<Debug, Library::LibraryDefinition>()
            ->Version(1);
        AZ::EditContext* editContext = serializeContext->GetEditContext();
        if (editContext)
        {
            editContext->Class<Debug>("Debug","")
                ->ClassElement(AZ::Edit::ClassElements::EditorData,"")
                ->Attribute(AZ::Edit::Attributes::Icon,
                             "Editor/Icons/ScriptCanvas/Debug.png")
        }
    }
}

3. Use the InitNodeRegistry and AddNodeToRegistry functions to register the library's nodes (Debug.cpp).

void Debug::InitNodeRegistry(NodeRegistry& nodeRegistry)
{
    Library::AddNodeToRegistry<Debug, Nodes::Debug::Log>(nodeRegistry);
}
AZStd::vector<AZ::ComponentDescriptor*> Debug::GetComponentDescriptors()
{
    return AZStd::vector<AZ::ComponentDescriptor*>({
        Nodes::Debug::Log::CreateDescriptor()});
}

4. Ensure that your library and its nodes are reflected in your gem's Reflect function.

ScriptCanvas::Libraries::Debug::Reflect(context);

5. Add the following code your gem's Init function. The following example is from ScriptCanvasDiagnosticSystemComponent.cpp. This code is important because it inserts your gem's nodes into the Script Canvas Gem's environment.

AZ::EnvironmentVariable<ScriptCanvas::NodeRegistry> nodeRegistryVariable =
    AZ::Environment::FindVariable<ScriptCanvas::NodeRegistry>(ScriptCanvas::s_nodeRegistryName);
if (nodeRegistryVariable)
{
    ScriptCanvas::NodeRegistry& nodeRegistry = nodeRegistryVariable.Get();
    ScriptCanvas::Libraries::Debug::InitNodeRegistry(nodeRegistry);
6. Make sure the library's descriptor is registered in your gem's module. The following code is from ScriptCanvasDiagnosticLibraryGem.cpp.

```cpp
Module::Module()
    : AZ::Module()
{
    m_descriptors.insert(m_descriptors.end(), {
        ScriptCanvasDiagnostics::SystemComponent::CreateDescriptor(),
    });
    AZStd::vector<AZ::ComponentDescriptor*> componentDescriptors(ScriptCanvas::Libraries::Debug::GetComponentDescriptors());
    m_descriptors.insert(m_descriptors.end(), componentDescriptors.begin(), componentDescriptors.end());
}
```

### Node Contracts

Script Canvas uses contracts to validate which node's slots are permitted to connect to other slots. These contracts have validation rules that prevent runtime connections between invalid configurations. The Script Canvas editor uses these contracts to prevent users from creating invalid operations.

Script Canvas has a built-in set of contracts that are used to validate nodes that are reflected to the behavior context. If you create a custom node, you can choose to create or specify contracts directly on slots.

The `Delay` node has the following example of a contract on a custom node:

```cpp
ScriptCanvas_In(ScriptCanvas_In::Name("In", "When signalled, execution is delayed at this
node in accordance with the specified properties.")
    ScriptCanvas_In::Contracts({ DisallowReentrantExecutionContract }));
```

In this case, the DisallowReentrantExecutionContract is specified for the `In` slot. This means that the node does not permit its `Out` slot to connect directly back into its `In` slot.

Slots can have (and often do have) multiple contracts.

### Script Canvas Node Reference

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This reference includes the various types of Script Canvas editor nodes, their uses, and their inputs and outputs.

**Tip**

On the Node Palette or on the node canvas, you can pause on the node name and the node parameters for more information.

**Topics**

- Rendering Nodes (p. 2568)

Some nodes are hidden from the default Script Canvas editor view.
To show hidden nodes in the Script Canvas editor

1. In Lumberyard Editor, choose **Tools, Script Canvas**.
2. In the **Script Canvas** editor, choose **Edit, Settings, Global Preferences**.
3. In the **Global Preferences** window, choose **Show nodes excluded from preview**.

### Rendering Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

See the following **Rendering** nodes for the **Script Canvas** editor.

**Topics**
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use environment nodes in the Script Canvas to configure sky elements, such as sun position, moon position, and the skybox material. You can use these nodes to have specific control over the individual elements.

Some environment nodes (for example, Set Sun Latitude (p. 2577)) have a Force Update parameter. You can use this parameter to make sudden changes to the sky appearance. Since time normally passes slowly with only gradual changes in sky appearance, Lumberyard updates only a portion of the sky for each frame, for better performance. When the sky appearance changes gradually, players are unlikely to notice this optimization. However, if the sky appearance suddenly changes by a large amount, players can notice unusual effects. To avoid this, specify True for the Force Update parameter to update the entire sky in a single frame.

You can use the time of day system to manage high-level control for automatically updating the appearance of the sky. For more information, see Adding Sky Effects (p. 1265) and Time of Day Nodes (p. 2672).

Material Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the **Script Canvas** editor to interact with materials in two ways. The following section describes how to access and manipulate materials directly, which affects all entities to which the material is applied. For example, you can load materials, get and set parameters, and apply the material to entities. Changes made to a material affect all entities that use that material.

You can also use the **Script Canvas** editor to manipulate materials on a single entity. For more information, see Material Owner Nodes (p. 2591).

**Topics**

- Clone (p. 2579)
- Find by Name (p. 2580)
- Find Sub-Material (p. 2581)
- Get Param Color (p. 2583)
- Get Param Number (p. 2584)
- Get Param Vector3 (p. 2584)
- Get Param Vector4 (p. 2585)
- Load by Name (p. 2586)
- Set Param Color (p. 2587)
- Set Param Number (p. 2588)
- Set Param Vector3 (p. 2589)
- Set Param Vector4 (p. 2590)

**Clone**

Creates a copy of the specified material. The material must already be loaded into memory, so that the node can find the material. If the material is not found, the node returns Invalid.
In some cases, you might need to store the material to use later. For more information, see Material Variables (p. 2676).

**Warning**
Don’t trigger this node for every frame. Each time the In event is received, a copy of the material is created.

**Contents**
- Inputs (p. 2580)
- Outputs (p. 2580)

**Inputs**

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>In</td>
<td>Event</td>
<td>Triggers the node.</td>
</tr>
<tr>
<td>Material</td>

<td>The material to be cloned.</td>
</tr>
</tbody>
</table>

**Outputs**

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when the node is finished.</td>
</tr>
<tr>
<td>Material</td>
<td>Material</td>
<td>The cloned material.</td>
</tr>
</tbody>
</table>

**Find by Name**

Finds and returns the material with the specified name. The material must be loaded into memory in order to be found.

In some cases, the **Find by Name** node might not find the material as expected.

**Example**

1. You have an entity named *Crate* that has a material file named *crate.mtl*.
2. In your script, you use the **Find by Name (p. 2580)** node to access the *crate.mtl* file. You want to trigger the node when the graph starts with the **On Graph Start** node. However, it's possible that the **Find by Name (p. 2580)** node can't load the material immediately. It might take additional frames before the entity finishes loading the material file.
3. In this example, you can use one of the following nodes to detect when the *Crate* entity finishes loading the *crate.mtl* file:
• Use the **Load by Name (p. 2586)** node instead of the **Find by Name (p. 2580)** node.
• Use the **On Ready (p. 2599)** node instead of the **On Graph Start** node.

In some cases, you might need to store the material for later use. For more information, see [Material Variables (p. 2676)](#).

<td>Material</td>
<td>Material</td>
<td>The material that was found. Returns Invalid if the material is not found.</td>
</tr>
</tbody>
</table>

**Find Sub-Material**

Finds and returns the submaterial with the specified name and submaterial ID.

Lumberyard has two types of material assets:

- **Materials** – A basic single item that represents one material.
- **Multimaterials** – A material that contains multiple submaterials inside it.
You can use the **Find Sub-Material** node to access a submaterial that is inside a multimaterial. To access the submaterial, specify the name of the multimaterial and the ID of one of its submaterials. Material IDs range from the number of available submaterials. For example, if a multimaterial has five submaterials, you can specify a value from 1 to 5.

To access a single material, you can use the **Find by Name (p. 2580)** node.

**Contents**

- Inputs (p. 2582)

Material Owner Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Script Canvas editor to interact with materials in two ways. The following section describes how to manipulate materials on a single entity. When you apply changes to the entity that owns the material, the entity's material is automatically cloned. The changes don't affect other entities that have the same material.

An entity is considered a material owner if it has a component that supports materials. This includes the Mesh (p. 684) and Decal (p. 585) components. The Actor (p. 536) component is not supported at this time.

You can also access and manipulate materials directly, which affects all entities to which the material is applied. For more information, see Material Nodes (p. 2579).
Important
Depending on the material owner type, the material asset might not be available when the script is first activated (OnActivate in Lua or the On Graph Start node in Script Canvas). This lack of availability can occur when assets are still loading. You can use the On Ready node instead of the On Graph Start node, or use the Is Ready node.

Topics
- Get Material (p. 2592)
- Get Param Color (p. 2593)
- Get Param Number (p. 2594)
- Get Param Vector3 (p. 2595)
- Get Param Vector4 (p. 2597)
- Is Ready (p. 2598)
- On Ready (p. 2599)
- Set Material (p. 2600)
- Set Param Color (p. 2601)
- Set Param Number (p. 2602)
- Set Param Vector3 (p. 2603)
- Set Param Vector4 (p. 2604)

Get Material
Returns an entity's current material.

Contents
- Inputs (p. 2592)
- Outputs (p. 2593)

Get Material

\[
\text{Material Owner}
\]

\[
\begin{array}{|c|c|}
\hline
\text{Pin} & \text{Type} & \text{Description} \\
\hline
\text{In} & \text{Event} & \text{Triggers the node.} \\
\text{Source} & \text{EntityID} & \text{References a specific entity from which events are generated. By default, it references Self, the entity to which the Script} \\
\hline
\end{array}
\]

Note
If you use the Set Material node and specify an invalid material and then call the Get Material node, Get Material returns the entity's default material instead of Invalid.
## Outputs

<table>
<thead>
<tr>
<th>Pin</th>

</tr>
</tbody>
</table>

### On Ready

This node is triggered when the material owner finishes loading its assets. We recommend that you use this event to trigger functions for the Get Param* and Set Param* nodes (for example, the Get Param Color (p. 2593) and Set Param Color (p. 2601) nodes). Otherwise, the material asset might not be available when the script is first activated. For example, a Mesh (p. 684) component does not load its mesh until at least one frame after the script starts.

### Contents
- Inputs (p. 2599)
- Outputs (p. 2600)

### Inputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>EntityID</td>
<td>References a specific entity from which events are generated. By default, it references Self, the entity to which the Script Canvas (p. 818) component attaches the current script. You can also specify another entity. For more information, see Setting Entity Targets (p. 2514).</td>
</tr>
</tbody>
</table>
## Outputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when the material owner's material is available for use.</td>
</tr>
</tbody>
</table>

## Set Material

Sets an entity's material. If the material is `Invalid`, this node removes the entity's material override. The entity uses its default material, if it has one.

### Contents
- Inputs (p. 2600)
- Outputs (p. 2600)

**Post Effects Nodes**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/sdk-for-unity/) or visit the [AWS Game Tech blog](https://aws.amazon.com/en/about-aws/solutions/game-tech/) to learn more.

You can configure the following post effect nodes in the **Script Canvas** editor. Post effects are useful if you want to enhance a scene after it renders, such as color, blur, or water effects. You can enable an effect once and the effect remains active until you disable it. If you want to animate the settings of an effect or transition in or out, you can trigger the **Enable** node for each frame with different settings.

**Important**

To use post effects nodes, you must enable the **Graphics Scripting** (p. 1143) gem for your game project. For more information, see **Enabling Gems** (p. 1064).

**Topics**

- [Apply Effect Group At Position](p. 2606)
- [Disable Blur](p. 2607)
- [Disable Color Correction](p. 2608)
- [Disable Depth of Field](p. 2608)
- [Disable Directional Blur](p. 2609)
- [Disable Effect Group](p. 2610)
Apply Effect Group At Position

Applies an effect group at a specific position in the world. You must use this node instead of the Enable Effect Group (p. 2622) node for effect group xml files that include the fadeDistance parameter.

The strength of the effect depends on the camera's proximity to the specified location. You can call this node multiple times to apply the same effect group at multiple locations. The effect strength is cleared for each frame, so the node needs to be triggered every frame.

For more information, see Setting Effect Strength Based on Camera Distance (p. 1772).

Contents

**Disable Water Flow**

Disables water flow effects.

To enable the effect, see *Enable Water Flow (p. 2634)*.

**Contents**

- Inputs (p. 2615)
- Outputs (p. 2615)
Enable Blur

Sets the blur filter, which uses Gaussian blur.

To disable the effect, see Disable Blur (p. 2607).

Contents

- Inputs (p. 2616)
- Outputs (p. 2617)

![Enable Blur Node](image)

Example

![Example Image](image)

Inputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>In</td>
<td>Event</td>
<td>Triggers the node.</td>
</tr>
</tbody>
</table>
## Enable Color Correction

Sets color correction parameters. You can use this node to specify the CMYK, brightness, contrast, saturation, and hue in a scene. Most color correction properties aren't updated smoothly, so it's recommended that you hide stronger color correction changes with cuts or fading between scenes.

You can also apply color correction in the Track View. See Color Correction Node (p. 1599).

To disable the effect, see Disable Color Correction (p. 2608).

### Contents
- **Inputs** (p. 2618)
- **Outputs** (p. 2619)

### Example

In the following example, the **Saturation** value is 2.0.
## Inputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>In</td>
<td>Event</td>
<td>Triggers the node.</td>
</tr>
<tr>
<td>Cyan</td>
<td>Number</td>
<td>Adjusts cyan to enhance the color of the scene.</td>
</tr>
<tr>
<td>Magenta</td>
<td>Number</td>
<td>Adjusts magenta to enhance color of the scene.</td>
</tr>
<tr>
<td>Yellow</td>
<td>Number</td>
<td>Adjusts yellow to enhance color of the scene.</td>
</tr>
<tr>
<td>Luminance</td>
<td>Number</td>
<td>Adjusts luminance to enhance the color of the scene.</td>
</tr>
<tr>
<td>Brightness</td>
<td>Number</td>
<td>Adjusts brightness to enhance light and darkness of the scene.</td>
</tr>
<tr>
<td>Contrast</td>
<td>Number</td>
<td>Adjusts contrast to enhance the bias of highlights and shadows of the scene.</td>
</tr>
<tr>
<td>Saturation</td>
<td>Number</td>
<td>Adjusts saturation to enhance the color intensity of the scene.</td>
</tr>
<tr>
<td>Hue</td>
<td>Number</td>
<td>Adjusts hue to enhance the color globally.</td>
</tr>
</tbody>
</table>
Enable Depth of Field

Configures the depth of field (DOF) effect, which gives you control over distance, range, and amount. You can use the node to add realism to scenes by simulating the way a real-world camera works. You can use a broad depth of field to focus on the entire scene, or use a shallow depth of field to have sharp focus only on objects that are a specific distance from the camera.

To disable the effect, see Disable Depth of Field (p. 2608).

You can also apply depth of field in the Track View. See Adding a Depth of Field Node (p. 1600).

Contents

- Inputs (p. 2620)
- Outputs (p. 2621)
Example

Inputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>In</td>
<td>Event</td>
<td>Triggers the node.</td>
</tr>
<tr>
<td>Focus Distance</td>
<td>Number</td>
<td>Distance the focus is from the camera. Positive values are in front of the camera while negative values are behind the camera.</td>
</tr>
<tr>
<td>Focus Range</td>
<td>Number</td>
<td>Distance toward and away from the camera until maximum blurriness is reached.</td>
</tr>
<tr>
<td>Blur Amount</td>
<td>Number</td>
<td>Maximum blurriness value.</td>
</tr>
<tr>
<td>CoC Scale</td>
<td>Number</td>
<td>Sets the circle of confusion scale when a cone of light in a specific area appears unfocused or blurry. For example, a cone of light from a lens focuses on a specific point, but the light does not appear in perfect focus. This is also known as the blur circle of a blur spot.</td>
</tr>
<tr>
<td>Center Weight</td>
<td>Number</td>
<td>Sets the central samples weight.</td>
</tr>
</tbody>
</table>
Outputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when the node is finished.</td>
</tr>
</tbody>
</table>

**Enable Directional Blur**

Applies a directional blur filter. To enable this node, you must enable the `r_MotionBlur` console variable. For more information, see Using the Console Window (p. 210).

To disable the effect, see Disable Directional Blur (p. 2609).

**Contents**

- Inputs (p. 2622)

</tbody>
</table>

### Enable Effect Group

Enables a specific group of effects setting that are defined in an `xml` file.

**Note**

You must use the **Apply Effect Group At Position (p. 2606)** node for effect group `xml` files that include the `fadeDistance` parameter.

To disable the effect, see **Disable Effect Group (p. 2610)**.
For more information about effect group files, see Customizing Post-Processing Effects (p. 1769).

Contents
- Inputs (p. 2623)
- Outputs (p. 2623)

**Enable Effect Group**

**Inputs**

</tbody>
</table>
| Amount       | Number | Enables raindrops. A value of 0 disables raindrops.  
|              |        | Default value: 1                                |
| Spaw Time Distance | Number | Sets the spawn time distance for the raindrops.  
|              |        | Default value: 0.35                             |
|              |        | For example, a value of 0.35 means the node waits at least 0.35 seconds between drops. |
| Size         | Number | Specifies the raindrop size.                    |
|              |        | Default value: 5.0                              |
| Size Variation| Number | Sets raindrops variation.                       |
|              |        | Default value: 2.5                              |

**Outputs**

#### Enable Volumetric Scattering

Adds a volumetric effect for simulating fog, snow, or other environments. You can specify the color, speed, and amount for each effect, so that you can simulate various environments, such as lava.

**Note**

This effect has high performance impact and can negatively affect the frame rate.

To disable the effect, see [Disable Volumetric Scattering](p. 2614).

</tbody>
</table>

**Screen Fader**

Controls fading the screen to a color and/or a texture. You can use this node to script cinematic transitions, such as fading to black or fading to a loading screen texture. The fade is a screen overlay that is rendered on top of the scene. The size and position of this overlay can be adjusted to a different size than full screen. This is useful if you want to draw letter boxes at the top and bottom of the screen. If you use custom positioning with a texture, you can use this node as a quick way to draw decorative borders around the frame.

To use the **Screen Fader** node in the Track View, see Screen Fader Node (p. 1600).

**Topics**
- Inputs (p. 2637)
- Outputs (p. 2639)
- ScreenFader EBuses (p. 2639)

**Example**

In the following script, the screen first fades in, out, and then fades in again.
Example

See the following screen fading in a game.

<tr>
<td></td>
<td></td>
<td>The default is full screen (0, 0, 1, 1).</td>
</tr>
</tbody>
</table>

**Color Property Behavior**

The following table shows the actual color values that are blended to cause the fading transition.

- **Fading** – Refers to whether a fade-in or fade-out effect was triggered.
- **Use Current Color** – The node's **Use Current Color** input setting.
- **Start Color** – The color used to render the overlay at the beginning of the transition.
- **Final Color** – The color used at the end of the transition.
- **Color** – The node's **Color** input setting.
- **Current Color** – The color that the fader actively renders, including the alpha channel. This is generally whatever color is left over from prior fading activity.

<table>
<thead>

</tbody>
</table>

**Note**

Most Script Canvas graphics features are available in Lua. However, ScreenFader is a single node in Script Canvas, and an EBus in Lua. For more information, see the ScreenFader EBuses (p. 2639).

**ScreenFader EBuses**

Provides the Lua scripting equivalent to the Screen Fader (p. 2636) node in Script Canvas.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

**Contents**

**ScreenFaderRequestBus FadeOut**

Triggers fading out to a solid color.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>color</td>
<td>Color</td>
<td>The color to fade out to. The use of the Color property depends on the value of Use Current Color, and whether you are fading in or fading out.</td>
</tr>
<tr>
<td>duration</td>
<td>Float</td>
<td>Duration of the fade out in seconds.</td>
</tr>
<tr>
<td>useCurrentColor</td>
<td>Boolean</td>
<td>When true, the transition uses the current color for the fade overlay. When false, the transition begins fully transparent.</td>
</tr>
</tbody>
</table>
Parameter | Type     | Description
---         | ---      | ---
Current Color | is the color that is rendered by the fader, including the alpha channel. This is generally whatever color is left over from prior fading activity.
The Color Property Behavior (p. 2638) table shows the color values that are blended to create the fading transition.

updateAlways | Boolean | Continues fading even when the game is paused.

ScreenFaderRequestBus FadeIn
Triggers fading in to a solid color.

Parameter | Type     | Description
---         | ---      | ---
color | Color | The color to fade through. Ignored if Use Current Color is true.
duration | Float | Duration of the fade in seconds.
useCurrentColor | Boolean | When true, the transition uses the current color for the fade overlay. When false, the transition begins from the target color.
updateAlways | Boolean | Continues fading even when the game is paused.

ScreenFaderRequestBus SetTexture
Sets a texture for the fade overlay.

Parameter | Type     | Description
---         | ---      | ---
textureName | String | The name of a texture from or to which to fade. To clear the texture, specify an empty string.
For more information, see Finding the Texture Name (p. 2682).

ScreenFaderRequestBus SetScreenCoordinates
Sets the screen coordinates where the fade overlay is drawn.

Parameter | Type     | Description
---         | ---      | ---
screenCoordinates | Vector4 | Sets the screen coordinates (left, top, right, and bottom) where the fade overlay is drawn.
The default is full screen (0, 0, 1, 1).

ScreenFaderRequestBus GetCurrentColor
Returns the current color of the fade overlay.
**ScreenFaderNotificationBus OnFadeOutComplete**

A callback function that is called when fading out is complete.

**ScreenFaderNotificationBus OnFadeInComplete**

A callback function that is called when fading in is complete.

**ScreenFaderManagementRequestBus GetNumFaderIDs**

Returns the number of available fader IDs. The number returned is not necessarily the number of faders that have been created.

**Set Color Chart**

Applies a color chart texture for color grading.

**Note**

When you call the node for the first time, you must set a default color chart for the fade to work correctly. The Set Color Chart node uses this color chart as a reference to fade into the next color chart. If the Set Color Chart node doesn't have a default color chart to fade from, the node will immediately fade to the first color chart, regardless of the fade time.

For an example script, see Example Set Color Chart Script (p. 2646).

**Contents**

Version 1.28

2641
Creating a Color Chart

You can create a color chart to apply color grading to your project. A color chart uses a reference image that can be an example image from your game or an image that contains a wide variety of color. You then modify the image, such as changing the hue, saturation, brightness, and so on.

When you specify the color chart file with the Set Color Chart (p. 2641) node, Lumberyard takes the image and its color chart and applies the color changes to your level. For example, you can use a color chart with negative saturation to make your game appear dark and muted.

To create a color chart

1. Make a copy of the color chart file default_cch.tiff. You can find the color chart file in the lumberyard_version\dev\Engine\EngineAssets\Textures directory.

   Note
   You must use this exact file so that the Resource Compiler can detect the color chart and use it to process the color charts that you create.

   The following is an example color chart image:

2. Use a reference image that shows a wide range of colors and that has not been color corrected yet, and do the following:

   Note
   • You don't need to use a high resolution or large reference image.
   • You can use any image as a reference, such as screenshot from your game.

   a. Copy and paste the color chart image into the reference image.
   b. Flatten all layers for the image.
   c. Save the image as filename_cch.tif, such as default_startergame_cch.tif.

      Note
      You do not need to include the _cch suffix for the image file.

Example default color chart image

The following image is from Starter Game Sample (p. 148) and includes the color chart in the bottom right.
3. Make a copy of the image and then do the following:

   a. Modify the image so that it has the color correction that you want. Avoid extreme color correction changes, which can result in overlapping colors when the scene is processed.

   b. Save the image as `filename_cch.tif`, such as `saturation_cch.tif`.

**Example modified color chart image**

The following image lowers the saturation.

4. Move all three files (`default_cch.tif` and your color charts) to your game project directory, such as `lumberyard_version\dev\StarterGame\textures\defaults\`. 
4. You use this directory to specify the file path to the color chart file in the **Set Color Chart** node. For more information, see **Finding the Texture Name** (p. 2682).

5. To compile your images so that Lumberyard Editor recognizes them as color charts, do one of the following:

   - In Lumberyard Editor, in the **Asset Browser**, navigate to the color chart file and double-click it.
   - If you have the RC Shell Commands plugin installed, right-click the image and choose **RC Compile Image**.

6. In the Resource Compiler, verify that **ColorChart** is selected, click **Generate Output**, and then click **OK**.

**Note**
You can install the plugin in Lumberyard Setup Assistant. For more information, see **Using Lumberyard Setup Assistant to Set Up Your Development Environment** (p. 16).
Note

- You can clear the **Tiled** option to preview the image correctly. This option does not affect your color chart.

- To see more information about **ColorChart** settings, click **Show preset info**. You can find these settings in the rc.ini file, located in the `lumberyard_version\dev\Bin64\vc141\rc` directory.
For more information, see Using the Resource Compiler Image Tool (p. 283).

7. Repeat steps 5 and 6 for all your color chart images.

8. In the Script Canvas editor, create a script. In the Set Color Chart (p. 2641) nodes, specify the path to the color chart files that you created, and the Fade Time.

**Example Set Color Chart Script**

The example script does the following:

1. When the graph starts, the Set Color Chart node sets a default color chart with the `default_startergame_cch.tif` file.
2. The Delay node waits three seconds.
3. During the next five seconds, the Set Color Chart node fades the screen to the color chart with the `saturation_cch.tif` file.

9. Attach the Script Canvas (p. 818) component to an entity and specify the script. For more information, see Working with Components (p. 479).

10. To test your script in game mode, press Ctrl+G.

**Example**

The following example demonstrates the script.
11. To exit game mode, press Esc.

**Console Variables for Color Charts**

You can use the following console variables for working with color charts. For more information, see *Using the Console Window (p. 210).*

<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Description</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>r_ColorGrading</td>
<td>Enables color grading.</td>
<td>0 = Off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = On (default)</td>
</tr>
<tr>
<td>r_ColorGradingCharts</td>
<td>Enables color grading with color charts.</td>
<td>0 = Off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = On (default)</td>
</tr>
<tr>
<td>r_ColorGradingChartsCache</td>
<td>Enables cache updates for the color grading charts.</td>
<td>0 = Always update.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = Update every other frame.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2 = Update every two frames.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3 = Update every three frames.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>4 = Update every four frames (default).</td>
</tr>
<tr>

</tbody>
</table>

### Procedural Material Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard supports Allegorithmic Substance for working with procedurally-generated materials. Procedural materials are materials in which you can modify their textures during runtime.

You can use the Allegorithmic Substance Designer to author procedural materials and then import them into Lumberyard Editor. You can then use the Script Canvas editor or Lua to modify the procedural material's textures at runtime.

To enable this feature, you must enable the Allegorithmic Substance gem. For more information, see Add modular features and assets with Gems (p. 1064).

For more information, see Working with Substances (p. 1760) and Lumberyard Substance Integration.

To work with procedural materials in scripts

1. **Reference the procedural material file**
   - To reference the procedural material, use the Find by Name (p. 2650) or Find by Name and Index (p. 2652) node.

2. **Modify the parameter values for the procedural material**
   - Use the Set Input <Type> nodes to modify the parameter values for the procedural material. The values that you specify in the nodes modify the parameters that update the procedural material's textures. You can modify parameters for multiple procedural materials in a single frame.

   **Note**

   *Input parameters* are the parameters that you modify for the procedural material. You can find the parameters for a material in the Substance Editor. For example, the sample procedural material brickWall_04 has input parameters such as *Age, Mortar, and Depth*. To modify these input parameters during runtime, specify the parameter name and its value in a node such as Set Input Number (p. 2664).

3. **Render the procedural materials**
   - After you specify the changes that you want, use the Render Asynchronous (p. 2661) or Render Synchronous (p. 2662) node to update the procedural material's texture. The render node applies to all procedural materials in which their parameters have changed, so at most, call a render node once per frame.

**Example**

The Allegorithmic Substance gem includes a sample procedural material named brickWall_04. You can import this file into Lumberyard and write a script that dynamically changes the *Age* and *Mortar* input parameter values, so that the wall appears to erode over time.
See the following example script to enable this effect.

1. The **Find by Name and Index** node (1) retrieves the brickWall_04 procedural material and sends the material to all **Set Input Number** nodes (3, 4, 6, 7).
2. The **Duration** node (2) runs the aging process for four seconds through the **Out** pin, which is triggered every frame. The node finalizes the aging process through the **Done** pin.
3. The first **Set Input Number** node (3) transitions the **Age** parameter from 0 to 0.5 over four seconds.
4. The second **Set Input Number** node (4) transitions the **Mortar** parameter from 0 to 1 over four seconds.
5. The **Render Asynchronous** node (5) applies these changes to the procedural material's textures.

6. For the **Duration** node (2), the **Done** pin triggers one last update with the final **Age** value of 0.5 (node 6) and the **Mortar** value of 1.0 (node 7).

7. With the **Force** parameter enabled, the **Render Asynchronous** node (8) applies these changes to the procedural material's textures.

   **Note**

   Steps 6 and 7 are not always required, but are examples of how you can use the **Render Asynchronous** node's **Force** parameter to guarantee that a final update is applied. For more information, see **Render Asynchronous** (p. 2661).

**Find by Name**

Finds a procedural material by the substance file name and graph name. All substance files contain one or more graphs, and these graphs correspond to a procedural material.

**Contents**

- Inputs (p. 2652)
- Outputs (p. 2652)
To find the substance name for a procedural material

1. In Lumberyard Editor, choose **Tools, Plug-ins, Substance Editor**.
2. Browse to the substance material that you want. The substance material name appears in the **Substance** field and the graph name appears in the tab.

**Example**

The substance material path is `materials/substance/brickwall_04.sbsar` and the graph name is `BrickWall_04`.

3. Copy the substance material path and in the **Find by Name** node, do the following:
   a. For **Substance Name**, paste the substance material path.
   b. For **Graph Name**, enter the graph name.
Inputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>In</td>
<td>Event</td>
<td>Triggers the node.</td>
</tr>
<tr>
<td>Substance Name</td>
<td>String</td>
<td>The path name of the substance material .sbsar or .smtl file to find.</td>
</tr>
<tr>
<td>Graph Name</td>
<td>String</td>
<td>Name of the specific graph in the substance material.</td>
</tr>
<tr>
<td>Force Load</td>
<td>Boolean</td>
<td>Forces the procedural material to load, if it's not already loaded.</td>
</tr>
</tbody>
</table>

Outputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when the node is finished.</td>
</tr>
<tr>
<td>Procedural Material</td>
<td>Procedural material</td>
<td>The specified procedural material. Returns Invalid if the material can't be found.</td>
</tr>
</tbody>
</table>

Find by Name and Index

Finds a procedural material by the substance file name and the index of a graph. All substance files contain one or more graphs, and these graphs correspond to a procedural material.

Contents

- Inputs (p. 2653)
- Outputs (p. 2654)
To find the substance name

1. In Lumberyard Editor, choose **Tools, Plug-ins, Substance Editor**.
2. Browse to the substance material that you want. The substance material name appears in the **Substance** field and the graph name appears in the tab.

**Example**

The substance material path is `materials/substance/brickwall_04.sbsar` and the graph name `BrickWall_04` appears in the tab.

3. Copy the substance material path and in the **Find by Name and Index** node, do the following:
   a. For **Substance Name**, paste the substance material path.
   b. For **Graph Index**, specify the graph that you want. The far-left tab is index 0, the next is 1, and so on. If the substance material has only one graph, leave the **Graph Index** field as 0.

**Inputs**

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>In</td>
<td>Event</td>
<td>Triggers the node.</td>
</tr>
<tr>
<td>Substance Name</td>
<td>String</td>
<td>The path name of the substance material <code>.sbsar</code> or <code>.smtl</code> file to find.</td>
</tr>
<tr>
<td>Graph Index</td>
<td>Number</td>
<td>Index of the specific graph in the substance material. Default value: 0</td>
</tr>
<tr>
<td>Force Load</td>
<td>Boolean</td>
<td>Forces the procedural material to load, if it's not already loaded.</td>
</tr>
</tbody>
</table>
Outputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when the node is finished.</td>
</tr>
<tr>
<td>Procedural Material</td>
<td>Procedural material</td>
<td>The specified procedural material to return.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Returns Invalid if the material can't be found.</td>
</tr>
</tbody>
</table>

Get Input Color

Returns the value of an input parameter as a color. The color channels are assumed to be a floating point, including the alpha channel. Use this node with the Float4 substance data type.

**Note**
You can use this node with all substance data types: Float1 through Float4 and Integer1 through Integer4. However, if the input parameter has fewer dimensions, the extra dimensions are assigned a value of 0.

The node does not perform any range conversion. For example, if an Integer4 substance data type has a value of (255, 0, 0, 255), this is returned as (255.0, 0.0, 0.0, 255.0), which is outside the normal 0.0 to 1.0 range of a color value.

Contents
- Inputs (p. 2654)
- Outputs (p. 2655)
Outputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when the node is finished.</td>
</tr>
<tr>
<td>Color</td>
<td>Color</td>
<td>The value of the specified input parameter. Returns (0.0, 0.0, 0.0, 0.0) if the value can't be found.</td>
</tr>
</tbody>
</table>

Get Input Number

Returns the value of an input parameter as a number. Use this node with the Float1 and Integer1 substance data types.

**Note**
You can use this node with all substance data types: Float1 through Float4 and Integer1 through Integer4. However, if the dimensions don't match, the extra dimensions from the input parameter are ignored.

Contents
- Inputs (p. 2655)
- Outputs (p. 2656)

![Get Input Number Node](image)

Inputs

<table>
<thead>
<tr>
<th>Pin</th>

<td>Number</td>
<td>The value of the specified input parameter.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Returns 0 if the value can't be found.</td>
</tr>
</tbody>
</table>

Get Input String

Returns the value of an input parameter as a string or image.

If the input parameter is a string type, the node returns the text value. If the input parameter is an image type, the node returns the path name of the image file.

Contents
- Inputs (p. 2656)
- Outputs (p. 2656)

</table>
## Get Input Vector2

Returns the value of an input parameter as a Vector2. Use this node with the Float2 and Integer2 substance data types.

**Note**
You can use this node with all substance data types: Float1 through Float4 and Integer1 through Integer4. However, if the input parameter has fewer dimensions, the extra dimensions are assigned a value of 0. If there are more dimensions, they are ignored.

<td>Vector4</td>
<td>The value of the specified input parameter.  Returns 0 if the value can't be found.</td>
</tr>
</tbody>
</table>

**On Render Finished**

This node is triggered when an update for a procedural material finishes rendering.

You can use the node to detect when texture updates scheduled by the Render Asynchronous (p. 2661) node are complete.
Contents

- Outputs (p. 2661)

To verify that the render update is the event that you want, compare the Render ID values that the Render Asynchronous (p. 2661) and On Render Finished nodes return. You can use the Equal To (==) node, such as in the following example.
Outputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when a procedural material render update is complete.</td>
</tr>
<tr>
<td>Render ID</td>
<td>Number</td>
<td>Unique ID for the scheduled render process.</td>
</tr>
</tbody>
</table>

**Render Asynchronous**

Schedules all procedural materials that have pending parameter changes to regenerate their texture maps. This update is done asynchronously, so that the textures are updated within a few frames. Use this node (instead of the **Render Synchronous** (p. 2662) node) for changes made during gameplay.

The node returns a **Render ID**, which you can use with the **On Render Finished** (p. 2659) node to detect when the textures finish updating. This should only be necessary if you need to synchronize another action with the texture update.

If the **Force** parameter is disabled, the node renders only procedural materials that are not currently rendering. Use this option when updating procedural materials every frame. Otherwise, the render queue can back up and may not catch up.

When the **Force** parameter is enabled, the node is guaranteed to render the changes. Use this option to make only occasional updates to the procedural material, or if you previously updated the procedural material every frame and you want a final update to guarantee that the update is not missed.

For an example script with the **Render Asynchronous** node, see the example script (p. 2649).

**Note**

If the **Set Input <Type>** nodes don't modify a procedural material, which means the procedural material doesn't have pending parameter changes, the **Render Asynchronous** node ignores the material.

**Contents**

- **Outputs** (p. 2662)

---

**Inputs**

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>In</td>
<td>Event</td>
<td>Triggers the node.</td>
</tr>
</tbody>
</table>
### Pin Types

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Force</td>
<td>Boolean</td>
<td>Forces the render to be scheduled. Specify <code>false</code> for better performance on high frequency updates.</td>
</tr>
</tbody>
</table>

### Outputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when the node is finished.</td>
</tr>
<tr>
<td>Render ID</td>
<td>Number</td>
<td>Unique ID for the scheduled render process. The value is 0 if a render was not scheduled.</td>
</tr>
</tbody>
</table>

### Render Synchronous

Regenerates the texture maps for all procedural materials that have pending parameter changes. This update is done synchronously, so that the textures are updated by the time the node completes. In general, use this node in cases where the frame rate isn't a concern and you want to avoid the complexity of the [Render Asynchronous](p. 2661) node.

**Note**

If the [Set Input <Type>](p. 2662) nodes don't modify a procedural material, which means the procedural material doesn't have pending parameter changes, the [Render Synchronous](p. 2661) node ignores the material.

### Contents

- [Inputs](p. 2662)
- [Outputs](p. 2663)

### Render Synchronous

- **Procedural Material**
  - In
  - Out

### Inputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>In</td>
<td>Event</td>
<td>Triggers the node.</td>
</tr>
</tbody>
</table>
Outputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when the node is finished.</td>
</tr>
</tbody>
</table>

**Set Input Color**

Sets the value of an input parameter as a color. The color channels are assumed to be floating point, including an alpha channel. Use this node with the `Float4` substance data type.

**Note**

You can use this node with all substance data types: `Float1` through `Float4` and `Integer1` through `Integer4`. However, if the input parameter has fewer dimensions, the extra dimensions are ignored.

If the input parameter is an integer type, the numbers that you specify are rounded down to the nearest integer value (for example, a value of 4.7 resolves to 4). For example, if you use a 50% gray opaque color to set a `Float4`, this results in a value of (0.5, 0.5, 0.5, 1.0). If you use the same color to set an `Integer4`, this results in a value of (0, 0, 0, 1).

Outputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when the node is finished.</td>
</tr>
</tbody>
</table>

**Set Input Number**

Sets the value of an input parameter as a number. You can use this node with the Float1 and Integer1 substance data types.

If the input parameter is an integer type, the numbers that you specify are rounded down to the nearest integer value. For example, a value of 4.7 resolves to 4.

**Note**

You can use this node with all substance data types: Float1 through Float4 and Integer1 through Integer4. However, if the input parameter has more dimensions, the extra dimensions are assigned a value of 0.

**Contents**

<td>Sends when the node is finished.</td>
</tr>
</tbody>
</table>

## Set Input String

Sets the value for an input parameter as a string or an image.

If the input parameter is a string type, the node sets the text value that the procedural material uses.

If the input parameter is an image type, this sets the path name of the image file that the procedural material uses.

Time of Day Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use time of day nodes in the **Script Canvas** editor to set the current time, change the speed of time progression, and load predefined time of day configuration files.

For more information about configuring time of day effects, see Adding Sky Effects (p. 1265) and Creating Time of Day Sky Effects (p. 1269).

**Topics**

- Get Speed (p. 2672)
- Get Time (p. 2673)
- Load Definition File (p. 2673)
- Set Speed (p. 2674)
- Set Time (p. 2675)

**Get Speed**

Returns the current time of day speed multiplier. The value is specified in conversion units of hours per second. For example, a value of 1 runs through an entire time of day cycle in 24 seconds.

**Contents**

- Inputs (p. 2672)
- Outputs (p. 2673)

Inputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>In</td>
<td>Event</td>
<td>Triggers the node.</td>
</tr>
</tbody>
</table>
Outputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when the node is finished.</td>
</tr>
<tr>
<td>Speed</td>
<td>Number</td>
<td>Current speed multiplier that determines how quickly the time of day changes.</td>
</tr>
</tbody>
</table>

Get Time

Returns the current time of day for the level. Time values are specified as decimal numbers from 0.0 to 24.0. For example, a value of 13.75 is 1:45 PM. A value of 0.0 or 24.0 is 12:00 AM.

Contents

- Inputs (p. 2673)
- Outputs (p. 2673)

Inputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>In</td>
<td>Event</td>
<td>Triggers the node.</td>
</tr>
</tbody>
</table>

Outputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when the node is finished.</td>
</tr>
<tr>
<td>Time</td>
<td>Number</td>
<td>Time of day in hours. Default value: 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values: 0.0 to 24.0</td>
</tr>
</tbody>
</table>

Load Definition File

Loads a time of day preset XML file file_name.xml and then updates the sky. For example, the preset file can be named Time_Of_Day.xml.
Contents

- Inputs (p. 2674)
- Outputs (p. 2674)

## Inputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>In</td>
<td>Event</td>
<td>Triggers the node to load the time of day preset .xml file.</td>
</tr>
<tr>
<td>File Name</td>
<td>String</td>
<td>Path to the time of day preset .xml file.</td>
</tr>
</tbody>
</table>

## Outputs

<table>
<thead>
<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when the node is finished.</td>
</tr>
<tr>
<td>Success</td>
<td>Boolean</td>
<td>Returns true if the file loads successfully.</td>
</tr>
</tbody>
</table>

### Set Speed

Sets the current time of day speed multiplier. The value is specified in conversion units of hours per second.

For example, a value of 0.0 stops automatic time progression, although you can change the time manually with the **Set Time (p. 2675)** node.

A value of 1.0 runs through an entire time of day cycle in 24 seconds.

**Note**

- To make simulations similar to real-world time, specify a value of 0.0003.

<tr>
<th>Pin</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out</td>
<td>Event</td>
<td>Sends when the node is finished.</td>
</tr>
</tbody>
</table>

### Set Time

Sets a time value for the time of day system. Time values are specified as decimal numbers from 0.0 to 24.0. For example, a value of 13.75 is 1:45 P.M. A value of 0.0 or 24.0 is 12:00 A.M. Once the time of day is set, the time of day continues as specified by the speed setting.

Material Variables

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When you use a node such as Find by Name (p. 2580), Load by Name (p. 2586), or Clone (p. 2579), the script can only use the material for that one frame. After the frame, the material is then invalid. If you want to reuse the material in your script, you can store the material in a Variable Material node. You can also use this node when you want to find or load a material only once when the game starts.

For more information about creating variable nodes, see Managing Script Canvas Variables (p. 2482).

Note

To use a material variable node, you must assign the variable to a valid material with a node such as Find by Name (p. 2580), Load by Name (p. 2586), or Clone (p. 2579).

### Material Variable Node Example

The following example uses a material variable node to make a material flash red.

1. The **Variable Manager** defines a variable material node named *MyMaterial*.
2. The **Load by Name (p. 2586)** node specifies the `materials/gettingstarted/materials/grid` material file and the result of the node is stored in a variable with a **Set MyMaterial** node.
3. Every 0.5 seconds, the **Get MyMaterial** node uses the variable with the **Set Param Color (p. 2587)** node to change the material's **diffuse** parameter from red to white.

### Example

One entity has the `primitive_cylinder.cfg` mesh and the other entity has the `primitive_sphere.cfg` mesh. Both entities share the same `grid.mtl` material file. When the Script Canvas graph runs, it changes the appearance of every entity that has this material applied.
Finding the Material Name

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can specify material names to reference for nodes in the Script Canvas editor. The material name is generally the path that starts at the top asset directory but without the `.mtl` file name extension.

**To find the material name**

1. In Lumberyard Editor, choose Tools, Material Editor.
2. In the Material Editor, navigate to the material file.
3. Right-click the material file and choose Copy Path to Clipboard. This copies the path to the file.

**Example**

In the Samples Project, the material name for `logo_white.mtl` is `materials/gettingstartedmaterials/logo_white`. 
Finding the Material Parameter Name

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can specify material parameter names for some Script Canvas editor nodes. In the Material Editor, you can find the material parameter names in the following sections:

- **Opacity Settings**
- **Lighting Settings**
- **Shader Params**

You can find common parameters in the **Opacity Settings** and **Lighting Settings** sections. You can find parameters that are specific to the selected shader in the **Shader Params** section.
To find the material parameter name

1. In Lumberyard Editor, choose Tools, Material Editor.
2. In the Material Editor, navigate to the material file.
3. In the Opacity Settings, Lighting Settings, and Shader Params sections, pause on a parameter to find the script parameter name.

Example

For Diffuse Color (Tint), the script parameter name is diffuse.

Example

For Emittance Map Gamma, the script parameter name is EmittanceMapGamma.
The following parameter names are commonly available and built in all materials.

### Material Param Names

<table>
<thead>
<tr>
<th>Param</th>
<th>Type</th>
<th>Display Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>opacity</td>
<td>Float</td>
<td>Opacity</td>
<td>Sets the transparency amount. Uses 0 to 99 to set Alpha Blend and 100 for Opaque and Alpha Test.</td>
</tr>
<tr>
<td>alpha</td>
<td>Float</td>
<td>AlphaTest</td>
<td>Uses the alpha mask and refines the transparent edge. Uses 0 to 50 to bias toward white or 50 to 100 to bias toward black.</td>
</tr>
<tr>
<td>diffuse</td>
<td>Color</td>
<td>Diffuse Color (Tint)</td>
<td>Tints the material diffuse color. Physically based materials should be left at white.</td>
</tr>
<tr>
<td>specular</td>
<td>Color</td>
<td>Specular Color</td>
<td>Shininess and color of reflective highlights.</td>
</tr>
<tr>
<td>shininess</td>
<td>Float</td>
<td>Smoothness</td>
<td>Smoothness or glossiness simulating how light bounces off the surface.</td>
</tr>
<tr>
<td>emissive_intensity</td>
<td>Float</td>
<td>Emissive Intensity (kcd/m2)</td>
<td>Brightness simulating light emitting from the surface, making an object glow.</td>
</tr>
<tr>
<td>emissive_color</td>
<td>Color</td>
<td>Emissive Color</td>
<td>Tints the emissive color.</td>
</tr>
</tbody>
</table>

### Finding the Texture Name

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can specify texture names for nodes in the Script Canvas editor. The texture name is generally the path that starts at the top asset directory.

**To find the texture name**

1. In Lumberyard Editor, choose **Tools, Asset Browser**.
2. From the Asset Browser, navigate to the texture file.
3. Right-click the texture file and choose **Copy Path to Clipboard**. This copies the path to the file.
4. Delete parts of the path to get the texture name.

**Examples**

<table>
<thead>
<tr>
<th>Asset Location</th>
<th>Copied Path</th>
<th>Path to Delete</th>
<th>Texture Name to Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Project</td>
<td><code>lumberyard_version\dev\SamplesProject\textures\defaults\white.tif</code></td>
<td><code>\SamplesProject\defaults\white.tif</code></td>
<td></td>
</tr>
<tr>
<td>Gem</td>
<td><code>lumberyard_version\dev\Gems\Rain\Assets\Textures\Rain\rainfall.tif</code></td>
<td><code>\Gems\Rain\Assets\Textures\Rain\rainfall.tif</code></td>
<td></td>
</tr>
<tr>
<td>Editor</td>
<td><code>lumberyard_version\dev\Editor\Plugins\ParticleEditorPlugin\defaults\feather01.tif</code></td>
<td><code>\Editor\Plugins\ParticleEditorPlugin\defaults\feather01.tif</code></td>
<td></td>
</tr>
<tr>
<td>Engine</td>
<td><code>lumberyard_version\dev\Engine\textures\skys\night\half_moon.tif</code></td>
<td><code>\Engine\textures\skys\night\half_moon.tif</code></td>
<td></td>
</tr>
</tbody>
</table>

**Writing Lua Scripts**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

**Topics**

- Learning Lua (p. 2684)
- Learning Lua in Lumberyard (p. 2684)
- Adding Lua Scripts to Component Entities (p. 2684)
- Basic Structure of a Component Entity Lua Script (p. 2686)
- Properties Table (p. 2687)
Learning Lua

For learning the Lua language itself, the lua.org website is a good place to start.

- **Official Lua Documentation** – Provides a central location for information about Lua, including a **Getting started** page.
- **Programming in Lua** – This text is a resource for getting started with Lua programming.
- **Lua 5.1 Reference Manual** – Provides a reference of all the functions that are available by default in Lua.

Learning Lua in Lumberyard

After you read through this tutorial on writing Lua scripts for the component entity system, learn more about using Lua in Lumberyard by consulting the following resources.

- For information on Lumberyard's built-in Lua editor, see Lua Editor (p. 2696).
- For sample Lua scripts, see the Lumberyard dev\SamplesProject\Scripts directory and its subdirectories.
- For information about Lua API operations in Lumberyard, see the Component Entity Lua API Reference (p. 2705).
- For information about the Lumberyard EBus, see Working with the Event Bus (EBus) system (p. 1851).

Adding Lua Scripts to Component Entities

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard makes it easy for you to add script functionality to your game entities by using the Lua Script component. The following steps show you how to do this in Lumberyard Editor.

**To add a Lua script to a component entity in Lumberyard Editor**

1. With the Entity Inspector view pane visible, select the entity in the viewport.
2. Click Add Component, and then open Scripting, Lua Script.
3. Scroll down to the **Scripting** section, and then click **Lua Script**.

4. A **Lua Script** component appears in the inspector. Use the file selection button (…) to select the Lua script from the file hierarchy that you want to use.
You can select either a .lua file (a text copy of the original), or a .luac file (a precompiled version of the script). The functionality should be the same. The precompiled version is preferable because it loads faster and is usually smaller. However, you can use .lua files if you experience any issues.

5. After the script is loaded, click Edit Script (j) to launch the Lua IDE and make changes to your script.

Basic Structure of a Component Entity Lua Script

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Scripts to be used as components contain a table (referred to as the script table), which provides the functionality for the script. In Lua, this table is treated like a class. The script table generally consists of the following:

- An optional Properties table within the script table. The Properties table provides an interface that you can use to customize the script behavior from the editor.
- An OnActivate() function that the engine calls when the entity that has the script is activated.
- An OnDeactivate() function called by the engine when the entity that has the script is deactivated.

The following example shows a skeleton script.

```lua
-- ScriptName.lua
local ScriptName =
{
    Properties =
    {
        -- Property definitions
```
For each Lua script component, Lumberyard creates a table called the entity table. The script table in the referenced script is the metatable for the entity table. Because of this relationship, when any method in the script is called, the self parameter (implicit in most cases) refers to the entity table.

The entity table then has the following properties and methods available to it:

- A `Properties` table, copied from the script table's `Properties` table. Default values are provided where appropriate.
- An `entityId` property, which contains an object of type `EntityId` that refers to the current entity.
- An `IsMaster` function, callable by the script, to check whether the currently executing script is on the primary node or a proxy node. This function is available only if the script component is network enabled.

**Built-in Types and Methods**

The Lumberyard engine provides a number of types and methods that are useful for making games. Many of the types and methods available are listed in the class view available in Lumberyard's Lua IDE. For more information on the class view, see Lua Editor (p. 2696).

**Properties Table**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The `Properties` table configures the editor interface for customizing the behavior of a script. With the properties table, you can modify numeric values, select states, and turn flags on and off. The table can even provide a reference to entities that your script can interact with.

The properties inside the `Properties` table are exposed to the editor. Properties outside the `Properties` table are private and not displayed in the editor.

The following example is a properties table from the **Controllable Chicken** sample level.

```lua
-- Example Properties Table
local ChickenMannequinControllerSM = {
    Properties = {
        MoveSpeed = { default = 3.0, description = "How fast the chicken moves.", suffix = " m/s" },
        RotationSpeed = { default = 360.0, description = "How fast (in degrees per second) the chicken can turn.", suffix = " deg/sec" },
    }
}
```
The result is the following Properties user interface in Lumberyard Editor:

The type that you provide as the default value determines how the property is appears in the editor user interface. You can further customize the representation of the property in the editor by specifying additional attributes in a table format. All property types support a description field that appears when you pause your mouse on the property name in the editor.

**Supported Types**

Properties can have the types described in this section.

**Boolean Values (True, False)**

The following examples are Boolean values.

```lua
DebugMovement = false,
AllowMovement = { default = true, description = "Allow or restrict movement of the object." },
```

In Lumberyard Editor, Boolean values are represented by a check box.

**Numeric Values (Integer or Floating Point Numbers)**

The following examples are numeric values.

```lua
Count = 5,
Velocity = { default = 1.0, suffix = "m/s", description = "Initial Velocity Of The Object" },
```
Distance = { default = 5.0, min = 2.0, max = 10.0, step = 2.0, suffix = "m", description = "The Distance An Object Can Travel In Meters" },

In Lumberyard Editor, numeric values are represented by an edit field with increase/decrease arrows. Numeric values can do the following:

- Provide a custom suffix to indicate units.
- Set minimum and maximum values.
- Provide a step value (how much the value increases or decreases when the user clicks the arrows on the right side of the edit field).

**Strings**

The following examples are strings.

DebugPrefix = "d_.",
Name = { default = "Default Name", description = "The name of the entity" },
StartingState = { "Idle", description = "Specify the starting state. Valid starting states are Idle and Fidget" },

In Lumberyard Editor, string values are represented by a text edit box.

**Reflected Classes**

You can use any class that is reflected to both the BehaviorContext and the EditContext as a property. A good example of this is the EntityId type, which references other entities.

```-- Entity Examples
ParentEntity = { default = EntityId(), description = "The Entity that this one will follow"},
Target = EntityId()
```

The editor representation is the default editor for the type reflected. For example, for EntityId, it's the entity reference picker. For most reflected types, it is a tree of the type's properties.

**Arrays**

Properties can contain resizable arrays of any of the types mentioned. To create a simple array, declare the default value as a keyless table of values. For example, the property definitions in the following code produce the properties shown in the image that follows.

```local ExampleScript = {
    Properties = {
        Speed = 4,
        ExampleArray = { default = { 1, 2, 3, 4 } },
    }
} return ExampleScript```
In the Entity Inspector, you can use the green + and red X icons to add and remove entries in real time. You can also use EntityId() to make the array elements entity references, as in the following example from the `lumberyard_version\dev\Gems\LyShineExamples\Assets\UI\Scripts\LyShineExamples\Image\ImageFillTypes.lua` file.

```lua
local ImageFillTypes = {
  Properties = {
    FilledImages = { default = { EntityId(), EntityId(), EntityId(), EntityId() } },
    Dropdowns = { default = { EntityId(), EntityId(), EntityId(), EntityId() } },
    RadialStartAngleSlider = { default = EntityId() },
    SpriteRadioButtonGroup = { default = EntityId() },
  },
}
...
```

### Grouping Properties

The following code example shows how you can use variables within the `Properties` table to expose named groupings of properties.

```lua
local Test = {
  Properties = {
    Movement = {
      TopSpeed = 4,
      Acceleration = 2,
      TurnSpeed = 12,
    },
    Combat = {
      ProjectileDamage = 50,
      RateOfFire = 3,
      AmmoCapacity = 12,
    },
  },
}
return Test
```

When rendered in the UI, the property groupings and properties are sorted alphabetically irrespective of their order in the code.
Attributes

You can add attributes to a property by placing them alongside the default value in a property table. Attribute keys are not case sensitive. The following common attributes can be added to any property.

Common Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>is the text of the tool tip for the property.</td>
</tr>
<tr>
<td>UI</td>
<td>Specifies (overrides) the UI handler that the property uses.</td>
</tr>
</tbody>
</table>

Network Binding Properties

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

For network binding features to function, you must have a Creating a NetBindable Component (p. 2055).

Properties

You can configure networking binding for properties by adding the netSynched table to the description of the variable inside of the Properties table.

```lua
local ExampleScript = {
    Properties = {
        Speed = {
            default = 0, -- Supports numbers, strings, booleans, and nils for net bindings.
            min = 0,
            max = 100,
            step = 1,
            description = "Speed in m/s for the ...",
```
Network Binding Properties

-- If this table is missing, it is assumed the value is not networked.

netSynched =
{
   -- Optional fields
   OnNewValue = <function> -- OnNewValue is called whenever the property has a
   -- new value. OnNewValue accepts one
   parameter, which
   -- is the entity table for the instance that
   changed.
   -- The following flags are mainly here for debugging and profiling
   Enabled = true          -- Controls whether the field is network enabled.
   -- missing, assumes true.
   ForceIndex = [1..32]    -- Profiling helper tool to force a property to use
   -- specific DataSet to make understanding what data
   -- being used where easier.
}

return ExampleScript

After you add networking to a property, any changes to the property are reflected across the network.

RPCs

Exposing RPCs to scripts involves creating a new table inside of the component table, but outside of the
properties table, as shown in the following example.

local ExampleScript = {
   Properties = {
      -- ...
   },

   -- Table of remote procedure calls (RPCs) that the script wants to implement.
   NetRPCs =
   {
      RPCNoParam = {
         OnMaster = <function> -- The function to be called on the Primary Script.
         -- The function should return a bool value that
         -- indicates whether or not proxy components can
         -- execute the RPC on themselves. Required.
         OnProxy = <function> -- The function to be called on the Proxy Script.
         -- This function is optional and can be excluded if
         -- the master never allows proxies to execute the
         function call.
      }
   }

return ExampleScript

You can invoke the RPC just like any other function. There is no need to specify the OnMaster/OnProxy
from the calling script. For example, you can call RPCs as in the following example.

self.NetRPCs.RPCNoParam()
self.NetRPCs.RPCParam(1.0)
Using EBuses in Lua

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Components provide interfaces that allow scripts to send them information and receive notifications when certain actions take place. Communication is established by creating two different objects in Lua: senders and handlers. A sender or a handler is an interface to an EBus (p. 1851), a communication system used extensively in the Lumberyard Engine. When a sender is created, it can call functions, which in turn send information to a component. When a handler is created, the component calls certain functions that the Lua script defines. These senders and handlers are created with an entity ID. You can use the entity ID to communicate with components that are attached to entities other than the one the script itself is running on. The main script table always provides a field called entityId that contains the ID of the entity to which the script is attached. Other entity IDs can be passed to the script through the Properties interface.

Order of Component Activation

Keep in mind the following points regarding the order of activation of Lua components:

- Lua components are activated after all C++ components have been activated.
- If an entity has multiple Lua components, there is no guarantee regarding which Lua component is activated first.

Communicating with Components

When a Lua script creates a handler object, it notifies a component attached to an entity that it should call the script handler functions when certain events occur. For example, in the first sample below, the script creates a Spawner (p. 859) notification bus handler when OnActivate() is called. This tells the spawner component attached to the entity that has the script to call the OnSpawnBegin(), OnSpawnEnd(), and OnEntitySpawned() functions when the spawner instantiates a new dynamic slice (p. 524). Subsequently, the handler is explicitly disconnected and set back to nil in the OnDeactivate function. This ensures that processing time is not wasted when the entity attached to the script isn't active. As long as the entity is active, these functions are called by the spawner component at the appropriate time.

The following code example shows a spawner component handler.

```lua
local SpawnerScriptSample = { }

function SpawnerScriptSample:OnActivate()
    -- Register our handlers to receive notification from the spawner attached to this entity.
    if( self.spawnerNotiBusHandler == nil ) then
        self.spawnerNotiBusHandler = SpawnerComponentNotificationBus.CreateHandler(self,
                        self.entityId)
    end
end

-- This handler is called when we start spawning a slice.
function SpawnerScriptSample:OnSpawnBegin(sliceTicket)
    -- Do something so we know if/when this is being called
    Debug.Log("Slice Spawn Begin")
end

-- This handler is called when we're finished spawning a slice.
```
function SpawnerScriptSample:OnSpawnEnd(sliceTicket)
    -- Do something so we know if/when this is being called
    Debug.Log("Slice Spawn End")
end

-- This handler is called whenever an entity is spawned.
function SpawnerScriptSample:OnEntitySpawned(sliceTicket, entityId)
    -- Do something so we know if/when this is being called
    Debug.Log("Entity Spawned: " .. tostring(entityId) )
end

function SpawnerScriptSample:OnDeactivate()
    -- Disconnect our spawner notification
    if self.spawnerNotiBusHandler ~= nil then
        self.spawnerNotiBusHandler:Disconnect()
        self.spawnerNotiBusHandler = nil
    end
end

return SpawnerScriptSample

Noncomponent Notifications

Some event buses that are available to Lua are not associated with components. For example, the system's tick bus (p. 1019) is not a component bus and does not require an entity ID. It provides both the amount of time that has passed since the last engine tick and the current time point. To gain access to this information, write a script that implements the `OnTick()` function and creates the handler. The handler receives notifications from the system whenever the engine ticks.

The following example shows how to register with the tick bus.

```lua
local TestScript = { }
function TestScript:OnActivate()
    -- Inform the tick bus that you want to receive event notifications
    self.tickBusHandler = TickBus.CreateHandler(self)
    self.tickBusHandler:Connect()
end

-- This callback is called every frame by the tick bus after this entity activates
function TestScript:OnTick(deltaTime, timePoint)
    -- Add script to be executed every frame here...
    end

function TestScript:OnDeactivate()
    -- Inform the tick bus that you no longer want to receive notifications
    self.tickBusHandler:Disconnect()
end

return TestScript
```

**Note**

Instead of calling `CreateHandler` and then calling `Connect` on the handler, you can use the Lua shortcut function `TickBus.Connect`. The `Connect` function uses the following syntax to create a handler and automatically connect the handler to the bus.

```
handler = TickBus.Connect(handlerTable[, connectionId])
```

Sending Events to a Component

In addition to receiving notifications from components, a script must sometimes exercise control over components. Control is accomplished by sending events to components using the `Event` table and
calling the functions implemented on it. In the example script that follows, the **Spawner** (p. 859) component is sent an event that tells the component to spawn a dynamic slice by calling the `Spawn()` function. The first argument to an `Event` function is always the ID of the listener that you send the event to; the remaining arguments follow.

The following example shows how to send EBus events.

```lua
local SpawnerScript = { }
function SpawnerScript:OnActivate()
    SpawnerComponentRequestBus.Event.Spawn(self.entityId)
end
return SpawnerScript
```

You can request information from some event sending functions that return values. The next example script uses a `TransformBus` to get the current local transform of the entity and uses the `GetLocalTM()` function, which returns a transform object. This object is stored in a variable in the main script table. `TransformBus` is used again to reset the transform of the object to the identity.

The following example shows how to use the transform bus.

```lua
function samplescript:OnActivate()
    -- Retrieve the object's local transform and store it for later use
    self.myOldTransform = TransformBus.Event.GetLocalTM(self.entityId)

    -- Reset the object's local transform to the identity matrix
    TransformBus.Event.SetLocalTM(self.entityId, Transform.CreateIdentity())
end
```

**Communicating with Components Attached to Other Entities**

You can also send events and create handlers to communicate with components that are attached to other entities. The following example defines a parent entity in the properties table and requests its transform. This allows it to set its transform to that of another entity.

```lua
local ParentScriptSample = { }
    Properties = {
        ParentEntity = {default = EntityId()}
    }
}

function ParentScriptSample:OnActivate()
    if self.Properties.ParentEntity:IsValid() then
    end
end

function ParentScriptSample:OnEntityActivated()
    TransformBus.Event.SetLocalTM(self.entityId, parentTransform)
end
return ParentScriptSample
```

**Important**

If you have a Lua script that is attached to an entity that needs to get information from another entity, your script must subscribe to the target entity's `OnEntityActivated` event. Your script should wait for the target entity to be activated before requesting the relevant information. Otherwise, your script might return nil.
Using AZStd::vector and AZStd::array

Vectors and arrays in Lua behave very similarly to tables, with a few limitations. Both vector and array have the following features.

Length Operator #

You can obtain the length of a collection by prefixing the name of the collection with the length operator #, as in the following example.

```
#myCollection
```

Indexing []

To obtain the elements in a collection, use indexing in square brackets as the following syntax shows. Indexing is 1 based, just like Lua tables.

```
myCollection[index]
```

Vector also has the following methods for mutating the collection.

**push_back**

Use the `push_back` method to append elements to the vector, as in the following example.

```
myCollection:push_back(5)
```

**pop_back**

Use the `pop_back` method to remove the last element of the vector, as in the following example.

```
myCollection:pop_back()
```

**clear**

Use the `clear` method to remove all elements from the vector, as in the following example.

```
myCollection:clear()
```

Using AZStd::any

You can pass any Lua primitive type excluding tables to any bus or function that takes AZStd::any as a parameter (for example, GameplayNotificationBus::OnEventBegin). You can also pass any type reflected from C++ (for example, vectors or EntityId values). There is no syntax required to pass a value as an any—just call the bus or function.

The following example shows the use of AZStd::any.

```
GameplayNotificationBus.Broadcast.OnEventBegin(self.eventId, "The value I'd like to pass to the handler")
```

Lua Editor

This feature is in preview release and is subject to change.
Lumberyard Lua Editor (Lua IDE) offers an intuitive integrated development environment (IDE) that makes it easy to author, debug, and edit Lua scripts when you create or extend your game. Lua Editor is a standalone application, but can be opened directly from Lumberyard Editor using the Tools menu.

**Tutorial: Using Lua Editor for Debugging with Lumberyard Editor**

This tutorial shows you how to use Lumberyard Editor to create a sample level in the **SamplesProject** project with a component entity that contains a Lua script component. You will learn how to open the script in Lua Editor and perform some sample debugging steps on the script.

**Debugging Lua scripts using Lua Editor**

1. Set the **SamplesProject** as the default project using Project Configurator.
2. In Lumberyard Editor, create a new level by performing one of the following steps:
   - In the **Welcome to Lumberyard Editor** window, click **New level**
   - Click **File**, **New**
   - Press **Ctrl+N**
3. In the **New Level** dialog box, give the level a name, and then click **OK**.
4. In **Asset Browser**, expand **SamplesProject**, **Objects**, and **SamplesAssets**.
5. Drag **mover_display_smooth.cgf** to the perspective viewport.
6. In **Entity Inspector**, click **Add Component**, and then choose **Scripting**, **Lua Script**.
7. In the **Entity Inspector** window, locate the **Lua Script** component, and then click the **Pick Lua Script** button next to the empty **Script** field.
8. In the **Pick Lua Script** window, expand **SamplesProject**, **Scripts**, and **Components**.
9. Click **ConstantRotation.lua**, and then click **OK**.
10. In the **Lua Script** component, click the **Open in Lua Editor** button to launch Lua Editor.

Because the debugging functionality is enabled through network sockets, you must connect Lua Editor to the target that is running the script before you can debug. In this tutorial, you connect to Lumberyard Editor.
Note
Connection is facilitated by GridHub (p. 1954), which is Lumberyard's central connection hub for debugging. GridHub starts automatically when Lua Editor is started and must be running in the background for Lua Editor to find targets it can connect to.

11. In the Lua Editor toolbar, click **Target: None**, and then click **Editor(ID)** to connect to Lumberyard Editor.

Note
You may need to expand the Lua Editor window to see the buttons on the Lua Editor toolbar for the next few steps.

12. In the Lua Editor toolbar, leave **Context** setting at **Default** for the debugging context. The default setting is good for debugging component entity scripts such as the one in this tutorial. The **Cry** context option is for debugging legacy scripts such as those associated with Cry entities or the Game SDK.

13. The **Debugging** icon turns green to show that Lua Editor and Lumberyard Editor are connected:

Click **Classes** in the **Class Reference** to show the available Lua libraries. You can do the same for **EBuses** and **Globals**.
Note
The class reference feature is active only for the default context and component entity scripts. This feature is not active in the Cry context, which exists only for backward compatibility.

After you connect, you can pause the execution of a given script by setting breakpoints.

14. In the Lua Editor toolbar, click the **Breakpoints** icon ![Breakpoints icon](image) to show the **Breakpoints** window.

15. In Lua Editor, click one or more line numbers in the `constantrotation.lua` script to set one or more breakpoints. As you add breakpoints, the line number and script path for each are added to the **Breakpoints** window.

16. In Lumberyard Editor, press **Ctrl+G** to run the game, or click the **Simulate** icon at the bottom of the viewport to enable game simulation and run scripts. Lua Editor opens with a yellow marker stopped on the first breakpoint that it encounters.
When execution is halted at a breakpoint, more information becomes available in the Lua Locals, Stack, and Watched Variables panes.

17. Click the Stack icon to show the Stack window.

18. Click the Lua Locals icon to show local Lua variables.

19. Click Watched Variables icon to open the Watched Variables window, where you can specify variables to watch.

20. Press F11 a few times to step through the code. Note how the contents of the Stack, Lua Locals, and Watched Variables windows change.

   **Tip**
   For greater convenience, you can float or dock these windows.

21. To detach from debugging, click Debugging.

22. In Lumberyard Editor, Press Esc to stop the game.

**Options Available While Debugging**

The following table summarizes common options available while debugging.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Action</th>
<th>Keyboard Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="icon" alt="run_in_editor" /></td>
<td>Run in Editor</td>
<td>Alt+F5</td>
<td>Run in Lumberyard Editor.</td>
</tr>
<tr>
<td><img src="icon" alt="run_on_target" /></td>
<td>Run on Target</td>
<td>Ctrl+F5</td>
<td>Send script to the connected target and run it.</td>
</tr>
<tr>
<td><img src="icon" alt="run_continue" /></td>
<td>Run/Continue</td>
<td>F5</td>
<td>Run or continue running the current script.</td>
</tr>
<tr>
<td><img src="icon" alt="step_into" /></td>
<td>Step Into</td>
<td>F11</td>
<td>Step into the function called on the current line.</td>
</tr>
<tr>
<td><img src="icon" alt="step_out" /></td>
<td>Step Out</td>
<td>Shift+F11</td>
<td>Step out of the called function.</td>
</tr>
<tr>
<td><img src="icon" alt="step_over" /></td>
<td>Step Over</td>
<td>F10</td>
<td>Step over the function called on the current line.</td>
</tr>
<tr>
<td>Icon</td>
<td>Action</td>
<td>Keyboard Shortcut</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>--------------------</td>
<td>-------------------</td>
<td>------------------------------------------------------------</td>
</tr>
<tr>
<td>🕵️‍♂️</td>
<td>Toggle Breakpoint</td>
<td>F9</td>
<td>Enable or disable a breakpoint on the current line.</td>
</tr>
</tbody>
</table>

**Maintaining Separate Search Results**

In addition to the usual search capabilities, the **Find** feature can display the results of four different searches separately.

**To maintain separate search results**

1. Click the **Find** icon 🕵️‍♂️ or press **Ctrl+F** to perform searches in the currently open file, or in all open files.

2. Before starting a search, choose **Find 1**, **Find 2**, **Find 3**, or **Find 4** to choose the window in which you want to see the results. You can maintain the results of four searches separately in the tabbed windows. The search results in the other windows remain unchanged.
3. To go directly to the line in the code which a search result was found, double-click the line in the search results.

   **Note**
   In Lua Editor Preview, the line number shown in the **Find Results** window and the line number in the script pane differ by one.

   **Tip**
   For convenience, you can also dock or float the **Find Results** window.

**Editing**

Lua Editor can open multiple scripts at the same time. Each script has its own tab in the editor. The editor provides a standard set of capabilities for text editing but also includes useful features for editing source code.

The following table summarizes the options available while editing and debugging.

<table>
<thead>
<tr>
<th>Action</th>
<th>Keyboard Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td>Comment selected block</td>
<td>Ctrl+K</td>
</tr>
<tr>
<td>Copy</td>
<td>Ctrl+C</td>
</tr>
<tr>
<td>Cut</td>
<td>Ctrl+X</td>
</tr>
<tr>
<td>Find</td>
<td>Ctrl+F</td>
</tr>
<tr>
<td>Find in open files</td>
<td>Ctrl+Shift+F</td>
</tr>
<tr>
<td>Find next</td>
<td>F3</td>
</tr>
<tr>
<td>Fold source functions</td>
<td>Alt+0</td>
</tr>
<tr>
<td>Go to line</td>
<td>Ctrl+G</td>
</tr>
<tr>
<td>Paste</td>
<td>Ctrl+V</td>
</tr>
<tr>
<td>Quick find local</td>
<td>Ctrl+F3</td>
</tr>
<tr>
<td>Quick find local reverse</td>
<td>Ctrl+Shift+F3</td>
</tr>
<tr>
<td>Redo</td>
<td>Ctrl+Y</td>
</tr>
<tr>
<td>Replace</td>
<td>Ctrl+R</td>
</tr>
<tr>
<td>Replace in open files</td>
<td>Ctrl+Shift+R</td>
</tr>
<tr>
<td>Select all</td>
<td>Ctrl+A</td>
</tr>
<tr>
<td>Select to brace¹</td>
<td>Ctrl+Shift+]</td>
</tr>
</tbody>
</table>
### Debugging Lua Scripts

Lumberyard provides Lua scripts with several functions to make debugging easier.

#### Logging to the Console

To print text to Lumberyard Editor and the game console, use the `Debug.Log()` function.

The following example shows the use of the `Debug.Log()` function.

```lua
local LoggingTest = { }
function LoggingTest:OnActivate()
    componentName = "MyComponent"
    Debug.Log(componentName .. " has been activated.")
end
```

---

**Perforce Integration**

Lua Editor includes Perforce integration features. When you open a file from your Perforce environment, Lua Editor displays the file's status in the top right of the text editing window.

The Source Control menu offers Check Out/Check In functionality.

---

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Using an Assert to Detect Potential Issues

You can use the `assert` function to display an error message in the console when conditions are detected that might result in an execution fault. The `assert` function takes two arguments: a condition that evaluates to true or false, and a message to display if the condition is false.

The following example shows the use of the `assert` function.

```lua
function SampleScript:DoStuff()
    -- This value should never be negative
    assert( self.positiveValue >= 0, "Expected a positive value! Got: " ..
            self.positiveValue )
end

-- Console output when the value of self.positiveValue is -5:
-- [Error] Lua error (2 - [string "q:/lyengine/branches/systems/dev/samplespro...":61: Expected a positive value! Got: -5) during call samplescript:DoStuff

Communicating Errors

You can use the `Debug.Error()` function to display an error in the console and halt execution of the current script function. This does not halt all execution of the script. If you have active handlers, they can still be called when the engine posts notifications. The `Debug.Error()` function takes arguments similar to the `Debug.Assert` function: a condition and a message. The message is displayed in bright red and execution halts only if the condition is false.

The following example shows the use of the `Debug.Error()` function.

```lua
function SampleScript:CheckAndError()
    -- This value should never be negative
    Debug.Error( self.positiveValue >= 0, "Detected a negative value: " ..
                      self.positiveValue )
end

-- Console output when the value of self.positiveValue is -5:
-- [Error] Error on argument 0: Detected a negative value: -5

Displaying a Warning When User Attention Is Required

A script condition can occur that does not adversely affect the execution of the script but might be useful for the user to know about. The `Debug.Warning()` function uses arguments similar to those of the `Error` and `Assert` functions but just displays an orange warning message in the console. It does not halt execution.

The following example shows the use of the `Debug.Warning()` function.

```lua
function SampleScript:CheckValue()
    -- This value should probably never be negative
    Debug.Warning( self.positiveValue >= 0, "Detected a negative value: " ..
                      self.positiveValue )
end

-- Console output when the value of self.positiveValue is -5:
-- [Warning] Warning on argument 0: Detected a negative value: -5

Version 1.28
The Lua Environment (Advanced)

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

By default, the Lumberyard component entity Lua environment is a single Lua environment (or `lua_State`). This environment is bound to the `BehaviorContext` that is owned by the `ComponentApplication`. Because of this, it has access to all API operations that are reflected on startup.

Adding Other VMs

You may add more `ScriptContext` instances using the `ScriptSystemBus` (either call `AddContextWithId`, or create your own and call `AddContext`). If you want your new context to be available for debugging, you must register it with `ScriptDebugAgentBus::RegisterContext`.

Reusing Code

Lua provides the capability to load and execute scripts from other Lua files using the built-in Lua `require` function. It's important to note that this function requires a special path format. The file path is delimited by periods instead of slashes, has no `.lua` file name extension, and is relative to the Lumberyard assets directory. For example, if you want to use the `require` function to give your scripts some common functionality from the project's `Scripts` directory, you can use code similar to the following example.

```lua
local library = require("Scripts.MyLibraryFile")
```

Component Entity Lua API Reference

This documentation is preliminary and subject to change.

BehaviorTreeComponentRequestBus

Represents a request submitted by a user of the current component.

StartBehaviorTree

Starts an inactive behavior tree associated with the current entity.

Syntax
void BehaviorTreeComponent::StartBehaviorTree()

StopBehaviorTree

Stops an active behavior tree associated with the current entity.

Syntax

void BehaviorTreeComponent::StopBehaviorTree()

GetVariableNameCrcs

Gets a list of cyclic redundancy check values for variable names.

Syntax

AZStd::vector<AZ::Crc32> GetVariableNameCrcs()

Returns: A list of the 32-bit cyclic redundancy check values for all variable names.

Return Type: AZStd::vector

Default Return: s_defaultEmptyVariableIds

GetVariableValue

Gets the value for the specified variable name CRC-32 checksum.

Syntax

bool GetVariableValue(AZ::Crc32 variableNameCrc)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>variableNameCrc</td>
<td>AZ::Crc32</td>
<td>The CRC-32 checksum for the variable name.</td>
</tr>
</tbody>
</table>

Returns: true if successful; otherwise, false.

Return Type: bool

Default Return: false

SetVariableValue

Set the value associated with a variable.

Syntax

void SetVariableValue(AZ::Crc32 variableNameCrc, bool newValue)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>variableNameCrc</td>
<td>AZ::Crc32</td>
<td>The CRC-32 checksum for the variable name.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>----------</td>
<td>------------------------------------</td>
</tr>
<tr>
<td>newValue</td>
<td>bool</td>
<td>The new value for the variable.</td>
</tr>
</tbody>
</table>

**NavigationComponentRequestBus**

Requests serviced by the navigation component.

**FindPathToEntity**

Creates a path finding request to navigate towards the specified entity.

**Syntax**

```lua
PathfindRequest::NavigationRequestId FindPathToEntity(AZ::EntityId entityId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>entityId</td>
<td>AZ::EntityId</td>
<td>Request EntityId of the entity we want to navigate towards.</td>
</tr>
</tbody>
</table>

**Returns:** A unique identifier to the pathfinding request.

**Return Type:** PathfindRequest::NavigationRequestId

**Default Return:** PathfindResponse::kInvalidRequestId

**Stop**

Stops all pathfinding operations for the specified requestId. The ID is used to make sure that the request being cancelled is the request that is currently being processed. If the specified requestId is different from the ID of the current request, the stop command can be safely ignored.

**Syntax**

```lua
void Stop(PathfindRequest::NavigationRequestId requestId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>PathfindRequest::NavigationRequestId</td>
<td>ID of the request that is being cancelled.</td>
</tr>
</tbody>
</table>

**NavigationComponentNotificationBus**

Notifications sent by the Navigation component.

**OnSearchingForPath**

Indicates that the pathfinding request has been submitted to the navigation system.

**Syntax**

```lua
void OnSearchingForPath(PathfindRequest::NavigationRequestId requestId)
```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>PathfindRequest::NavigationRequestId</td>
<td>ID of the request for the path that is being searched.</td>
</tr>
</tbody>
</table>

**OnTraversalStarted**

Indicates that traversal for the indicated request has started.

**Syntax**

```c
void OnTraversalStarted(PathfindRequest::NavigationRequestId requestId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>PathfindRequest::NavigationRequestId</td>
<td>ID of the request for which traversal has started.</td>
</tr>
</tbody>
</table>

**OnTraversalInProgress**

Indicates that traversal for the indicated request has started.

**Syntax**

```c
void OnTraversalInProgress(PathfindRequest::NavigationRequestId requestId, float distanceRemaining)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>PathfindRequest::NavigationRequestId</td>
<td>ID of the request for which traversal is in progress.</td>
</tr>
<tr>
<td>distanceRemaining</td>
<td>float</td>
<td>The remaining distance in the current path.</td>
</tr>
</tbody>
</table>

**OnTraversalComplete**

Indicates that traversal for the indicated request has completed successfully.

**Syntax**

```c
void OnTraversalComplete(PathfindRequest::NavigationRequestID requestId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>PathfindRequest::NavigationRequestId</td>
<td>ID of the request for which traversal has finished.</td>
</tr>
</tbody>
</table>

**OnTraversalCancelled**

Indicates that traversal for the indicated request was cancelled before it could be successfully completed.

**Syntax**

```c
```
void OnTraversalCancelled(PathfindRequest::NavigationRequestId requestId)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>PathfindRequest::NavigationRequestId</td>
<td>ID of the request for which traversal was cancelled.</td>
</tr>
</tbody>
</table>

**NavigationSystemRequestBus**

Requests serviced by the navigation system component. This currently contains the single function `RayCast`.

**RayCast**

Creates a path finding request to navigate towards the specified entity.

**Syntax**

```cpp
definition RayCast(const AZ::Vector3& begin, const AZ::Vector3& direction, float maxDistance) { return NavRayCastResult() }
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>begin</td>
<td>Vector3</td>
<td>The origin of the ray.</td>
</tr>
<tr>
<td>direction</td>
<td>Vector3</td>
<td>The direction for the ray to travel.</td>
</tr>
<tr>
<td>maxDistance</td>
<td>float</td>
<td>The maximum distance the ray travels.</td>
</tr>
</tbody>
</table>

**Returns:** A `NavRayCastResult`.

`NavRayCastResult` has the following structure.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>m_collision</td>
<td>Boolean</td>
<td>Returns true if there was a collision. The default is false.</td>
</tr>
<tr>
<td>m_position</td>
<td>Vector3</td>
<td>The position of the hit in world space. The default is AZ::Vector3::CreateZero().</td>
</tr>
<tr>
<td>m_meshId</td>
<td>NavigationMeshId</td>
<td>The mesh ID of the navigation mesh hit. This is callable from Lua script. The default is 0.</td>
</tr>
</tbody>
</table>

**AttachmentComponentRequestBus**

Messages serviced by the AttachmentComponent. The AttachmentComponent lets an entity "stick" to a particular bone on a target entity.

**Attach**

Change the attachment target. The entity will detach from any previous target.
Syntax

```cpp
void Attach(AZ::EntityId targetId, const char* targetBoneName, const AZ::Transform& offset)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>targetId</td>
<td>AZ::EntityId</td>
<td>Specifies the ID of the entity to attach to.</td>
</tr>
<tr>
<td>targetBoneName</td>
<td>char</td>
<td>Specifies the bone on the target entity to attach to. If the target bone is not found, then attach to the target entity's transform origin.</td>
</tr>
<tr>
<td>offset</td>
<td>AZ::Transform</td>
<td>The attachment's offset from the target.</td>
</tr>
</tbody>
</table>

**Detach**

Detaches an entity from its target.

**Syntax**

```cpp
void Detach()
```

**SetAttachmentOffset**

Update an entity's offset from its target.

**Syntax**

```cpp
void SetAttachmentOffset(const AZ::Transform& offset)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>offset</td>
<td>AZ::Transform</td>
<td>The offset from the target.</td>
</tr>
</tbody>
</table>

**AttachmentComponentNotificationBus**

This EBus interface handles events emitted by the AttachmentComponent. The AttachmentComponent lets an entity "stick" to a particular bone on a target entity.

**OnAttached**

The entity has attached to the target.

**Syntax**

```cpp
void OnAttached(AZ::EntityId targetId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>targetId</td>
<td>AZ::EntityId</td>
<td>The target being attached to.</td>
</tr>
</tbody>
</table>
OnDetached

The entity is detaching from the target.

Syntax

void OnDetached(AZ::EntityId targetId)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>targetId</td>
<td>AZ::EntityId</td>
<td>The target being detached from.</td>
</tr>
</tbody>
</table>

CharacterAnimationRequestBus

General character animation requests serviced by the CharacterAnimationManager component.

SetBlendParameter

Sets a custom blend parameter.

Syntax

void SetBlendParameter(AZ::u32 blendParameter, float value)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>blendParameter</td>
<td>AZ::u32</td>
<td>Corresponds to EMotionParamID.</td>
</tr>
<tr>
<td>value</td>
<td>float</td>
<td>The value to set.</td>
</tr>
</tbody>
</table>

SetAnimationDrivenMotion

Enables or disables animation-driven root motion.

Syntax

void SetAnimationDrivenMotion(bool useAnimDrivenMotion)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>useAnimDrivenMotion</td>
<td>bool</td>
<td>Specify true to enable animation-driven root motion; false to disable.</td>
</tr>
</tbody>
</table>

MannequinRequestsBus

Services provided by the Mannequin component.

QueueFragment

Queues the specified Mannequin fragment.
Syntax

```plaintext
FragmentRequestId QueueFragment(int priority, const char* fragmentName, const char* fragTags, bool isPersistent)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>priority</td>
<td>int</td>
<td>Specifies priority. A higher number means higher priority</td>
</tr>
<tr>
<td>fragmentName</td>
<td>char</td>
<td>Name of the fragment to be played.</td>
</tr>
<tr>
<td>fragTags</td>
<td>char</td>
<td>Fragment tags to be applied.</td>
</tr>
<tr>
<td>isPersistent</td>
<td>bool</td>
<td>Specifies persistence.</td>
</tr>
</tbody>
</table>

**Returns**: A request ID that can be used to identify and make modifications to the request.

**Return Type**: FragmentRequestId

**Default Return**: MannequinRequests::s_invalidRequestId

### PauseAll

Pauses all actions being managed by the current Mannequin component.

**Syntax**

```plaintext
void PauseAll()
```

### ResumeAll

Resumes all actions being managed by the current Mannequin component.

**Syntax**

```plaintext
void ResumeAll(IActionController::EResumeFlags resumeFlag)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resumeFlag</td>
<td>IActionController::EResumeFlags</td>
<td>Indicates how the animations are to be resumed. See the EResumeFlags enum for possible values.</td>
</tr>
</tbody>
</table>

```plaintext
eenum EResumeFlags
{
    ERF_RestartAnimations = BIT(0),
    ERF_RestoreLoopingAnimationTime = BIT(1),
    ERF_RestoreNonLoopingAnimationTime = BIT(2),
    ERF_Default = ERF_RestartAnimations | ERF_RestoreLoopingAnimationTime | ERF_RestoreNonLoopingAnimationTime
};
```
SetTag

Sets the specified tag for the action controller.

**Syntax**

```cpp
void SetTag(const char* tagName)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tagName</td>
<td>char</td>
<td>The name of the tag to set.</td>
</tr>
</tbody>
</table>

ClearTag

Clears the specified tag for the action controller.

**Syntax**

```cpp
void ClearTag(const char* tagName)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tagName</td>
<td>char</td>
<td>The name of the tag to be cleared.</td>
</tr>
</tbody>
</table>

SetGroupTag

Sets a tag in the specified group.

**Syntax**

```cpp
void SetGroupTag(const char* groupName, const char* tagName)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupName</td>
<td>char</td>
<td>The name of the group.</td>
</tr>
<tr>
<td>tagName</td>
<td>char</td>
<td>The name of the tag.</td>
</tr>
</tbody>
</table>

ClearGroup

Clears tags for the indicated group.

**Syntax**

```cpp
void ClearGroup(const char* groupName)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupName</td>
<td>char</td>
<td>The name of the group.</td>
</tr>
</tbody>
</table>
SetScopeContext

Sets the scope context for the current animation controller.

Syntax

```c
void SetScopeContext(const char* scopeContextName, const AZ::EntityId entityId, const char* animationDatabaseName)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scopeContextName</td>
<td>char</td>
<td>Name of the scope context that the animation database (.adb) file is to be attached to.</td>
</tr>
<tr>
<td>entityId</td>
<td>AZ::EntityId</td>
<td>Reference to an entity whose character instance will be bound to this scope context.</td>
</tr>
<tr>
<td>animationDatabaseName</td>
<td>char</td>
<td>The path to the animation database file.</td>
</tr>
</tbody>
</table>

ClearScopeContext

Clears the specified scope context.

Syntax

```c
void ClearScopeContext(const char* scopeContextName)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scopeContextName</td>
<td>char</td>
<td>Name of the scope context that is to be cleared.</td>
</tr>
</tbody>
</table>

StopRequest

Stops the actions associated with the specified request.

Syntax

```c
void StopRequest(FragmentRequestId requestId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>FragmentRequestId</td>
<td>Specifies the ID of the request for which actions should be stopped.</td>
</tr>
</tbody>
</table>

GetRequestStatus

Retrieves the status of the specified request.

Syntax

```c
IAction::EStatus GetRequestStatus(FragmentRequestId requestId)
```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>FragmentRequestId</td>
<td>The ID of the request to retrieve status for.</td>
</tr>
</tbody>
</table>

**Returns:** The status of the request.

**Return Type:** IAction::EStatus

**Default Return:** IAction::EStatus::None

**ForceFinishRequest**

Forces the actions associated with the specified request to finish.

**Syntax**

```cpp
void ForceFinishRequest(FragmentRequestId requestId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>FragmentRequestId</td>
<td>The ID of the request.</td>
</tr>
</tbody>
</table>

**SetRequestSpeedBias**

Sets the speed bias for the actions associated with the specified request.

**Syntax**

```cpp
void SetRequestSpeedBias(FragmentRequestId requestId, float speedBias)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>FragmentRequestId</td>
<td>The request ID.</td>
</tr>
<tr>
<td>speedBias</td>
<td>float</td>
<td>The speed bias for this animation</td>
</tr>
</tbody>
</table>

**GetRequestSpeedBias**

Gets the speed bias for the actions associated with the specified request.

**Syntax**

```cpp
float GetRequestSpeedBias(FragmentRequestId requestId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>FragmentRequestId</td>
<td>The ID of the request.</td>
</tr>
</tbody>
</table>

**Returns:** The speed bias for the indicated request.

**Return Type:** float
**Default Return:** -1

**SetRequestAnimWeight**
Sets the animation weight for the actions associated with the specified request.

**Syntax**

```lua
void SetRequestAnimWeight(FragmentRequestId requestId, float animWeight)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>FragmentRequestId</td>
<td>The ID of the request.</td>
</tr>
<tr>
<td>animWeight</td>
<td>float</td>
<td>The weight for the animation.</td>
</tr>
</tbody>
</table>

**GetRequestAnimWeight**
Gets the animation weight for the actions associated with the specified request.

**Syntax**

```lua
float GetRequestAnimWeight(FragmentRequestId requestId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>FragmentRequestId</td>
<td>The ID of the request.</td>
</tr>
</tbody>
</table>

**Returns:** The animation weight for the indicated request.

**Return Type:** float

**Default Return:** -1

**SimpleAnimationComponentRequestBus**

Services provided by the Simple Animation component. The Simple Animation component provides basic animation functionality for the entity. If the entity has a mesh component with a skinned mesh attached (a .chr or .cdf file), the Simple Animation component will provide a list of all valid animations specified in the associated .chrparams file. The Simple Animation component does not provide interaction with Mannequin and should be used for light-weight environment or background animation.

**StartDefaultAnimations**

Plays the default animations along with default looping and speed parameters that were set up as a part of the current component. Components allow for multiple layers to be set up with defaults. The `StartDefaultAnimations` method starts the playback of all the default animations of the component.

**Syntax**

```lua
SimpleAnimationComponentRequests::Result StartDefaultAnimations()
```

**Returns:** A Result indicating whether the animations were started successfully.
Return Type: SimpleAnimationComponentRequests::Result

Default Return: SimpleAnimationComponentRequests::Result::Failure

StartAnimation

Starts playback of the animation of the specified animatedLayer.

Syntax

```cpp
SimpleAnimationComponentRequests::Result StartAnimation(const AnimatedLayer& animatedLayer)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>animatedLayer</td>
<td>AnimatedLayer</td>
<td>A layer configured with the animation that is to be played on it.</td>
</tr>
</tbody>
</table>

Returns: A Result indicating whether the animation was started.

Return Type: SimpleAnimationComponentRequests::Result

Default Return: SimpleAnimationComponentRequests::Result::Failure

StartAnimationByName

Plays the animation with the specified name.

Syntax

```cpp
Result StartAnimationByName(const char* name, AnimatedLayer::LayerId layerId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>char</td>
<td>The name of the animation to play.</td>
</tr>
<tr>
<td>layerId</td>
<td>AnimatedLayer::LayerId</td>
<td>The layer in which to play the animation</td>
</tr>
</tbody>
</table>

Returns: A Result indicating whether the animation was started.

Return Type: SimpleAnimationComponentRequests::Result

Default Return: SimpleAnimationComponentRequests::Result::Failure

StopAllAnimations

Stops all animations that are being played on all layers.

Syntax

```cpp
Result StopAllAnimations()
```

Returns: A Result indicating whether all animations were stopped.

Return Type: SimpleAnimationComponentRequests::Result
**Default Return:** SimpleAnimationComponentRequests::Result::Failure

**StopAnimationsOnLayer**
Stops the animation currently playing on the specified layer.

**Syntax**
```
Result StopAnimationsOnLayer(AnimatedLayer::LayerId layerId, float blendOutTime)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>layerId</td>
<td>AnimatedLayer::LayerId</td>
<td>Identifier for the layer that is to stop its animation (0 - AnimatedLayer::s_maxActiveAnimatedLayers)</td>
</tr>
<tr>
<td>blendOutTime</td>
<td>float</td>
<td>Time that the animations take to blend out.</td>
</tr>
</tbody>
</table>

**Returns:** A Result indicating whether the animation on the indicated layer was stopped.

**Return Type:** SimpleAnimationComponentRequests::Result

**Default Return:** SimpleAnimationComponentRequests::Result::Failure

**SetPlaybackSpeed**
Changes the playback speed for a particular layer.

**Syntax**
```
Result SetPlaybackSpeed(AnimatedLayer::LayerId layerId, float playbackSpeed)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>layerId</td>
<td>AnimatedLayer::LayerId</td>
<td>Identifier for the layer whose speed should be changed.</td>
</tr>
<tr>
<td>playbackSpeed</td>
<td>float</td>
<td>The playback speed.</td>
</tr>
</tbody>
</table>

**Returns:** A Result indicating whether the animation on the indicated layer was updated or not. A failure likely indicated that no animation is playing on the specified layer.

**Return Type:** SimpleAnimationComponentRequests::Result

**Default Return:** SimpleAnimationComponentRequests::Result::Failure

**SimpleAnimationComponentNotificationBus**
This EBus interfaces handles events sent by the simple animation component.

**OnAnimationStarted**
Informs all listeners about an animation being started on a layer.

**Syntax**
void OnAnimationStarted(const AnimatedLayer& animatedLayer)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>animatedLayer</td>
<td>AnimatedLayer</td>
<td>Specifies the name and parameters of the animation that was started.</td>
</tr>
</tbody>
</table>

**OnAnimationStopped**

Informs all listeners about an animation being stopped on the indicated layer.

**Syntax**

void OnAnimationStopped(const AnimatedLayer::LayerId animatedLayer)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>animatedLayer</td>
<td>AnimatedLayer::LayerId</td>
<td>Specifies the name and parameters of the animation that was stopped.</td>
</tr>
</tbody>
</table>

**AudioEnvironmentComponentRequestBus**

This EBus interface handles messages serviced by AudioEnvironmentComponent instances. The environment refers to the effects (primarily the auxiliary effects) that the bus sends. See AudioEnvironmentComponent.cpp for details.

**SetAmount**

Sets an environment amount on the default assigned environment.

**Syntax**

void SetAmount(float amount)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>amount</td>
<td>float</td>
<td>The amount for the environment.</td>
</tr>
</tbody>
</table>

**SetEnvironmentAmount**

Set an environment amount, specify an environment name at run time (that is, a script).

**Syntax**

void SetEnvironmentAmount(const char* environmentName,float amount)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>environmentName</td>
<td>char</td>
<td>The name of the environment.</td>
</tr>
</tbody>
</table>
### Component Entity Lua API Reference

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>amount</td>
<td>float</td>
<td>The amount for the environment.</td>
</tr>
</tbody>
</table>

#### AudioListenerComponentRequestBus

This EBus interface handles messages serviced by `AudioListenerComponent` instances.

#### SetRotationEntity

Sets the entity for which the audio listener tracks rotation.

**Syntax**

```c
void SetRotationEntity(const AZ::EntityId entityId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>entityId</td>
<td>AZ::EntityId</td>
<td>The ID of the entity.</td>
</tr>
</tbody>
</table>

#### SetPositionEntity

Sets the entity for which the audio listener tracks position.

**Syntax**

```c
void SetPositionEntity(const AZ::EntityId entityId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>entityId</td>
<td>AZ::EntityId</td>
<td>The ID of the entity.</td>
</tr>
</tbody>
</table>

#### SetFullTransformEntity

Essentially the same as calling `SetRotationEntity` and `SetPositionEntity` on the same entity.

**Syntax**

```c
void SetFullTransformEntity(const AZ::EntityId entityId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>entityId</td>
<td>AZ::EntityId</td>
<td>The ID of the entity.</td>
</tr>
</tbody>
</table>

#### AudioRtpcComponentRequestBus

This EBus interface handles messages serviced by `AudioRtpcComponent` instances. RTPC stands for Real-Time Parameter Control. The `AudioRtpcComponent` is used by the game to configure parameters in the audio engine. See `AudioRtpcComponent.cpp` for details.
**SetValue**

Sets an RTPC value for the RTPC name that has been serialized with the component.

**Syntax**

```c
void SetValue(float value)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>float</td>
<td>The RTPC value to set.</td>
</tr>
</tbody>
</table>

**SetRtpcValue**

Use to manually specify an RTPC name and value at run time for use in scripting.

**Syntax**

```c
void SetRtpcValue(const char* rtpcName, float value)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rtpcName</td>
<td>char</td>
<td>Specifies an RTPC name to use.</td>
</tr>
<tr>
<td>value</td>
<td>float</td>
<td>Specifies a value for the RTPC name supplied.</td>
</tr>
</tbody>
</table>

**AudioSwitchComponentRequestBus**

This EBus interface handles messages serviced by AudioSwitchComponent instances. A Switch is an object that can be in one State at a time, but whose State value can be changed at run time. For example, a Switch called SurfaceMaterial might have states such as 'Grass', 'Snow', 'Metal', or 'Wood'. See AudioSwitchComponent.h for details.

**SetState**

Sets the name of the state on the default assigned switch.

**Syntax**

```c
void SetState(const char* stateName)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stateName</td>
<td>char</td>
<td>Specifies the name of the state to set.</td>
</tr>
</tbody>
</table>

**SetSwitchState**

Sets the specified switch to the specified state.

**Syntax**

```c
```
```c
void SetSwitchState(const char* switchName, const char* stateName)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>switchName</td>
<td>char</td>
<td>The name of the switch to set.</td>
</tr>
<tr>
<td>stateName</td>
<td>char</td>
<td>The name of the state to set on the specified switch.</td>
</tr>
</tbody>
</table>

**AudioTriggerComponentRequestBus**

This EBus interface handles messages serviced by AudioTriggerComponent instances. You can use the AudioTriggerComponent to execute, stop, and control ATL triggers. You can serialize the name of the trigger with the component or manually specify the name at run time for use in scripting. Only one AudioTriggerComponent is allowed on an entity, but the interface supports firing multiple ATL triggers.

**Play**

Executes the play trigger if the play trigger is set.

**Syntax**

```c
void Play()
```

**Stop**

Executes the stop trigger if one is set; otherwise, stops the play trigger.

**Syntax**

```c
void Stop()
```

**ExecuteTrigger**

Executes the specified ATL trigger.

**Syntax**

```c
void ExecuteTrigger(const char* triggerName)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>triggerName</td>
<td>char</td>
<td>Specifies the name of the trigger to execute.</td>
</tr>
</tbody>
</table>

**KillTrigger**

Kills the specified ATL Trigger.

**Syntax**

```c
void KillTrigger(const char* triggerName)
```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>triggerName</td>
<td>char</td>
<td>Specifies the name of the trigger to remove.</td>
</tr>
</tbody>
</table>

**KillAllTriggers**

Forces a removal of triggers that are active on the underlying proxy.

**Syntax**

```cpp
void KillAllTriggers()
```

**SetMovesWithEntity**

Specifies whether the trigger should be repositioned as the entity moves.

**Syntax**

```cpp
void SetMovesWithEntity(bool shouldTrackEntity)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>shouldTrackEntity</td>
<td>bool</td>
<td>Specify true to have the trigger track the entity.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Specify false to have the trigger not track the entity.</td>
</tr>
</tbody>
</table>

**AudioTriggerComponentNotificationBus**

This EBus interface handles messages sent by AudioTriggerComponent instances.

**OnTriggerFinished**

Notifies when a trigger instance has finished.

**Syntax**

```cpp
void OnTriggerFinished(const Audio::TAudioControlID triggerID)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>triggerID</td>
<td>Audio::TAudioControlID</td>
<td>The ID of the trigger.</td>
</tr>
</tbody>
</table>

**FloatGameplayNotificationBus (AZ::GameplayNotificationBus<float>)**

This version of the GameplayNotificationBus EBus interface handles float-based gameplay notifications.

**OnGameplayEventAction**

Event sent when the specified GameplayEventAction has occurred.
OnGameplayEventFailed
Event sent when the given GameplayEventAction has failed.

Vector3GameplayNotificationBus
This version of the GameplayNotificationBus EBus interface handles Vector3-based gameplay notifications.

OnGameplayEventAction
Event sent when the given GameplayEventAction has occurred.

OnGameplayEventFailed
Event sent when the given GameplayEventAction has failed.

StringGameplayNotificationBus
(AZ::GameplayNotificationBus<const AZStd::wstring>)
This version of the GameplayNotificationBus EBus interface handles string-based gameplay notifications.

OnGameplayEventAction
Event sent when the given GameplayEventAction has occurred.

OnGameplayEventFailed
Event sent when the given GameplayEventAction has failed.

EntityIdGameplayNotificationBus
(AZ::GameplayNotificationBus<AZ::EntityId>)
This EBus interface handles EntityId-based gameplay notifications. It is a specialization of the GameplayNotificationBus.

OnGameplayEventAction
Event sent when the given GameplayEventAction has occurred.

OnGameplayEventFailed
Event sent when the given GameplayEventAction has failed.

CryCharacterPhysicsRequestBus
This EBus interface handles messages serviced by Cry character physics.

Move
Requests movement from Living Entity.

Syntax
void Move(const AZ::Vector3& velocity, int jump)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>velocity</td>
<td>AZ::Vector3</td>
<td>Requested velocity (direction and magnitude).</td>
</tr>
<tr>
<td>jump</td>
<td>int</td>
<td>Controls how the value for the velocity parameter is applied within a Living Entity. To change the velocity to the new value, specify 1. To add the value to the current velocity, specify 2.</td>
</tr>
</tbody>
</table>

**ConstraintComponentRequestBus**

This EBus interface handles messages serviced by instances of the Constraint component. A Constraint component facilitates the creation of a physics constraint between two entities or an entity and a point in the world. Both entities must have a component that provides the physics service.

**SetConstraintEntities**

Sets the entity that owns the constraint and the target of the constraint.

**Syntax**

```cpp
void SetConstraintEntities(const AZ::EntityId& owningEntity, const AZ::EntityId& targetEntity)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>owningEntity</td>
<td>AZ::EntityId</td>
<td>Specifies the ID of the entity that owns the constraint.</td>
</tr>
<tr>
<td>targetEntity</td>
<td>AZ::EntityId</td>
<td>Specifies the ID of the entity that is the target of the constraint. The target is invalid if constrained to world space.</td>
</tr>
</tbody>
</table>

**SetConstraintEntitiesWithPartIds**

Sets the entity that owns the constraint, the target entity, and the animation part IDs (bone IDs) for the constraint to be attached to.

**Syntax**

```cpp
void SetConstraintEntitiesWithPartIds(const AZ::EntityId& owningEntity, int ownerPartId, const AZ::EntityId& targetEntity, int targetPartId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>owningEntity</td>
<td>AZ::EntityId</td>
<td>Specifies the ID of the entity that owns the constraint.</td>
</tr>
<tr>
<td>ownerPartId</td>
<td>int</td>
<td>Specifies the ID of the owner part (the bone ID) for the constraint.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>targetEntity</td>
<td>AZ::EntityId</td>
<td>Specifies the ID of the entity that is the target of the constraint.</td>
</tr>
<tr>
<td>targetPartId</td>
<td>int</td>
<td>Specifies the ID of the target part (the bone ID) for the constraint.</td>
</tr>
</tbody>
</table>

**EnableConstraint**

Enable all constraints on the current entity.

**Syntax**

```plaintext
void EnableConstraint()
```

**DisableConstraint**

Disable all constraints on the current entity.

**Syntax**

```plaintext
void DisableConstraint()
```

**ConstraintComponentNotificationBus**

This EBus interface handles messages dispatched by the Constraint component.

**OnConstraintEntitiesChanged**

This event fires when either the constraint owner or target changes. The target is invalid if constrained to world space.

**Note**

This event also fires when `partId` values change.

**Syntax**

```plaintext
void OnConstraintEntitiesChanged(const AZ::EntityId& oldOwner, const AZ::EntityId& oldTarget, const AZ::EntityId& newOwner, const AZ::EntityId& newTarget)
```
OnConstraintEnabled
Fires when constraints have been enabled on the current entity.

Syntax

void OnConstraintEnabled()

OnConstraintDisabled
Fires when a constraint has been disabled.

Syntax

void OnConstraintDisabled()

PhysicsComponentRequestBus
This EBus interface handles messages serviced by the in-game Physics component.

EnablePhysics
Makes the entity a participant in the physics simulation.

Syntax

void EnablePhysics()

DisablePhysics
Stops the entity from participating in the physics simulation

Syntax

void DisablePhysics()

IsPhysicsEnabled
Checks if physics are enabled on the current entity.

Syntax

bool IsPhysicsEnabled()

Returns: true if physics are enabled; false otherwise.

Return Type: bool

Default Return: false

AddImpulse
Applies the specified impulse to the entity.

Syntax
void AddImpulse(const AZ::Vector3& impulse)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>impulse</td>
<td>AZ::Vector3</td>
<td>Vector of the impulse.</td>
</tr>
</tbody>
</table>

**AddAngularImpulse**

Applies an angular impulse to the entity.

**Syntax**

void AddAngularImpulse(const AZ::Vector3& /*impulse*/, const AZ::Vector3& worldSpacePivot)

| Parameter  | Type                              | Description                                                         |
|------------|-----------------------------------|                                                                    |
| impulse    | AZ::Vector3                        | Vector of the impulse.                                              |
| worldSpacePivot | AZ::Vector3               | Vector of the world space pivot to apply to the entity.             |

**GetVelocity**

Retrieves the velocity of the entity.

**Syntax**

AZ::Vector3 GetVelocity()

**Returns:** The velocity of the entity.

**Return Type:** AZ::Vector3

**Default Return:** AZ::Vector3::CreateZero()

**SetVelocity**

Sets the velocity of the entity.

**Syntax**

void SetVelocity(const AZ::Vector3& velocity)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>velocity</td>
<td>AZ::Vector3</td>
<td>Specifies the velocity to set.</td>
</tr>
</tbody>
</table>

**GetAcceleration**

Gets the linear acceleration of the entity.
Syntax

```python
AZ::Vector3 GetAcceleration()
```

**Returns:** A vector containing the linear acceleration of the entity.

**Return Type:** AZ::Vector3

**Default Return:** AZ::Vector3::CreateZero()

**GetAngularVelocity**

Gets the angular velocity of the entity.

**Syntax**

```python
AZ::Vector3 GetAngularVelocity()
```

**Returns:** A vector containing the angular velocity of the entity.

**Return Type:** AZ::Vector3

**Default Return:** AZ::Vector3::CreateZero()

**SetAngularVelocity**

Sets the angular velocity of the entity to the specified amount.

**Syntax**

```python
void SetAngularVelocity(const AZ::Vector3& angularVelocity)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>angularVelocity</td>
<td>AZ::Vector3</td>
<td>The angular velocity to set.</td>
</tr>
</tbody>
</table>

**GetAngularAcceleration**

Gets the angular acceleration of the entity

**Syntax**

```python
AZ::Vector3 GetAngularAcceleration()
```

**Returns:** A vector containing the angular acceleration of the entity.

**Return Type:** AZ::Vector3

**Default Return:** AZ::Vector3::CreateZero()

**GetMass**

Retrieves the mass of the entity.
Syntax

float GetMass()

Returns: The mass of the entity.
Return Type: float
Default Return: 0.0f

PhysicsComponentNotificationBus

This bus handles events emitted by a Physics component and by the Physics system.

OnPhysicsEnabled

Fires when an entity begins participating in the physics simulation. If the entity is active when a handler connects to the bus, then OnPhysicsEnabled() is immediately dispatched.

Note
If physics is enabled, OnPhysicsEnabled fires immediately upon connecting to the bus.

Syntax

void OnPhysicsEnabled()

OnPhysicsDisabled

Fires when an entity ends its participation in the physics simulation.

Syntax

void OnPhysicsDisabled()

OnCollision

Fires when an entity collides with another entity.

Syntax

void OnCollision(const Collision& collision)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>collision</td>
<td>Collision</td>
<td>Contains information about the collision that occurred. See the following Collision struct.</td>
</tr>
</tbody>
</table>

struct Collision
{
    AZ_TYPE_INFO(Collision, "{33756BD4-24D4-4DAE-A849-537114D52F7D}");
    AZ_CLASS_ALLOCATOR(Collision, AZ::SystemAllocator, 0);
    AZ::EntityId m_entity; // ID of other entity involved in event
```csharp
AZ::Vector3 m_position;       // Contact point in world coordinates
AZ::Vector3 m_normal;         // Normal to the collision
float m_impulse;              // Impulse applied by the collision resolver
AZ::Vector3 m_velocityA;      // Velocities of the first entity involved in the collision
AZ::Vector3 m_velocityB;      // Velocities of the second entity involved in the collision
float m_massA;                // Masses of the first entity involved in the collision
float m_massB;                // Masses of the second entity involved in the collision
}

PhysicsSystemRequestBus

Requests for the physics system

RayCast

Casts a ray and retrieves a list of results.

Syntax

RayCastHit RayCast(const AZ::Vector3& begin, const AZ::Vector3& direction, float maxDistance, AZ::u32 maxHits, AZ::u32 query)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>begin</td>
<td>const AZ::Vector3&amp;</td>
<td>The origin of the ray</td>
</tr>
<tr>
<td>direction</td>
<td>const AZ::Vector3&amp;</td>
<td>The direction for the ray to travel</td>
</tr>
<tr>
<td>maxDistance</td>
<td>float</td>
<td>The maximum distance the ray will travel</td>
</tr>
<tr>
<td>maxHits</td>
<td>AZ::u32</td>
<td>The maximum number of hits to return from the search.</td>
</tr>
<tr>
<td>query</td>
<td>AZ::u32</td>
<td>The entity types to hit. See the PhysicalEntityTypes enum that follows.</td>
</tr>
</tbody>
</table>

Returns: A RayCastHit struct. For details, see the code listing that follows.

Return Type: PhysicsSystemRequests::RayCastHit

Default Return: RayCastHit()

struct RayCastHit
{
    AZ_TYPE_INFO(RayCastHit, "{3D8FA68C-A145-44B4-BA18-F3405D83A9DF}");
    AZ_CLASS_ALLOCATOR(RayCastHit, AZ::SystemAllocator, 0);

    float m_distance = 0.0f;       // The distance from RayCast begin to the hit.
    AZ::Vector3 m_position;        // The position of the hit in world space.
    AZ::Vector3 m_normal;          // The normal of the surface hit.
    AZ::EntityId m_entityId;       // The ID of the AZ::Entity hit, or
    // AZ::InvalidEntityId if hit object is not an AZ::Entity.
};
```
**RagdollPhysicsRequestBus**

Messages serviced by the Cry character physics ragdoll behavior.

**EnterRagdoll**

Causes an entity with a skinned mesh component to disable its current physics and enable ragdoll physics.

**Syntax**

```plaintext
void EnterRagdoll()
```

**ExitRagdoll**

Causes the ragdoll component to deactivate itself and reenable the entity's physics component.

**Syntax**

```plaintext
void ExitRagdoll()
```

**DecalComponentRequestBus**

This EBus interface handles messages serviced by the Decal component.

**SetVisibility**

Specifies the decal's visibility.

**Syntax**

```plaintext
void SetVisibility(bool visible)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>visible</td>
<td>bool</td>
<td>Specify true to make the decal visible, false to hide it.</td>
</tr>
</tbody>
</table>

**Show**

Makes the decal visible.

**Syntax**

```plaintext
void Show()
```

**Hide**

Hides the decal.

**Syntax**

```plaintext
void Hide()
```
**LensFlareComponentRequestBus**

This EBus interface handles messages serviced by the Lens Flare component.

**SetLensFlareState**

Controls the lens flare state.

**Syntax**

```lua
void SetLensFlareState(State state)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>state</td>
<td>State</td>
<td>Specify <code>on</code> to turn on the lens flare; specify <code>off</code> to turn it off.</td>
</tr>
</tbody>
</table>

**TurnOnLensFlare**

Turns the lens flare on.

**Syntax**

```lua
void TurnOnLensFlare()
```

**TurnOffLensFlare**

Turns the lens flare off.

**Syntax**

```lua
void TurnOffLensFlare()
```

**ToggleLensFlare**

Toggles the lens flare state.

**Syntax**

```lua
void ToggleLensFlare()
```

**LensFlareComponentNotificationBus**

This EBus interface handles events dispatched by the Lens Flare component.

**LensFlareTurnedOn**

Notifies that the lens flare has been turned on.

**Syntax**

```lua
void LensFlareTurnedOn()
```
**LensFlareTurnedOff**

Notifies that the lens flare has been turned off.

**Syntax**

```lua
void LensFlareTurnedOff()
```

**LightComponentRequestBus**

This EBus interfaces handles messages serviced by the light component.

**SetLightState**

Controls the light state.

**Syntax**

```lua
void SetLightState(State state)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>state</td>
<td>State</td>
<td>Specify <strong>On</strong> to turn on the light; specify <strong>Off</strong> to turn it off.</td>
</tr>
</tbody>
</table>

**TurnOnLight**

Turns the light on.

**Syntax**

```lua
void TurnOnLight()
```

**TurnOffLight**

Turns the light off.

**Syntax**

```lua
void TurnOffLight()
```

**ToggleLight**

Toggles the light state.

**Syntax**

```lua
void ToggleLight()
```

**LightComponentNotificationBus**

Light component notifications.
LightTurnedOn

Event sent when a light component is turned on.

Syntax

```lua
void LightTurnedOn()
```

LightTurnedOff

Event sent when a light component is turned off.

Syntax

```lua
void LightTurnedOff()
```

ParticleComponentRequestBus

Provides access to the particle component.

SetVisibility

Specifies the visibility of the particle component.

Syntax

```lua
void SetVisibility(bool visible)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>visible</td>
<td>bool</td>
<td>Specify true to make the particle component visible; false to hide it.</td>
</tr>
</tbody>
</table>

Show

Makes the particle component visible.

Syntax

```lua
void Show()
```

Hide

Hides the particle component.

Syntax

```lua
void Hide()
```

SetupEmitter

Sets up an effect emitter with the specified name and settings.
Syntax

void SetupEmitter(const AZStd::string& emitterName, const ParticleEmitterSettings& settings)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>emitterName</td>
<td>const AZStd::string&amp;</td>
<td>The name of the emitter to set up.</td>
</tr>
<tr>
<td>settings</td>
<td>const ParticleEmitterSettings&amp;</td>
<td>Contains particle emitter settings. For more information, see ParticleComponent.cpp.</td>
</tr>
</tbody>
</table>

**SimpleStateComponentRequestBus**

This EBus interface handles messages serviced by the Simple State component. The Simple State component provides a simple state machine. Each state is represented by a name and zero or more entities that are activated when the state is entered and deactivated when the state is left.

**SetState**

Sets the active state

**Syntax**

```cpp
void SetState(const char* stateName)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stateName</td>
<td>char</td>
<td>The name of the state.</td>
</tr>
</tbody>
</table>

**SetStateByIndex**

Sets the active state using a 0-based index.

**Syntax**

```cpp
void SetStateByIndex(AZ::u32 stateIndex)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stateIndex</td>
<td>AZ::u32</td>
<td>The 0-based index of the state.</td>
</tr>
</tbody>
</table>

**SetToNextState**

Advances to the next state. If the next state is null, the first state is set.

**Syntax**

```cpp
void SetToNextState()
```
**SetToPreviousState**
Sets the previous state. If the previous state is null, the end state is set.

**Syntax**

```c
void SetToPreviousState()
```

**SetToFirstState**
Sets the first state.

**Syntax**

```c
void SetToFirstState()
```

**SetToLastState**
Sets the last state.

**Syntax**

```c
void SetToLastState()
```

**GetNumStates**
Get the number of states.

**Syntax**

```c
AZ::u32 GetNumStates()
```

**Returns:** The number of states.

**Return Type:** AZ::u32

**Default Return:** 0

**GetCurrentState**
Gets the current state.

**Syntax**

```c
const char* GetCurrentState()
```

**Returns:** The current state.

**Return Type:** const char*

**Default Return:** nullptr

**SimpleStateComponentNotificationBus**

This EBus interface handles events dispatched by the Simple State component.
**OnStateChanged**

Notify that the state has changed from `oldState` to `newState`.

**Syntax**

```c
void OnStateChanged(const char* oldState, const char* newState)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oldState</td>
<td>char</td>
<td>The name of the old state.</td>
</tr>
<tr>
<td>newState</td>
<td>char</td>
<td>The name of the new state.</td>
</tr>
</tbody>
</table>

**SpawnerComponentRequestBus**

This EBus interface handles messages serviced by the `SpawnerComponent`.

**Spawn**

Spawns the selected slice at the entity's location.

**Syntax**

```c
AzFramework::SliceInstantiationTicket Spawn()
```

**Returns:** A slice instantiation ticket.

**Return Type:** `AzFramework::SliceInstantiationTicket`

**Default Return:** `AzFramework::SliceInstantiationTicket()`

**SpawnRelative**

Spawns the selected slice at the entity's location with the specified relative offset.

**Syntax**

```c
AzFramework::SliceInstantiationTicket SpawnRelative(const AZ::Transform& relative)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relative</td>
<td>AZ::Transform</td>
<td>Relative offset from the entity's location.</td>
</tr>
</tbody>
</table>

**Returns:** A slice instantiation ticket.

**Return Type:** `AzFramework::SliceInstantiationTicket`

**Default Return:** `AzFramework::SliceInstantiationTicket()`

**SpawnAbsolute**

Spawns the selected slice at the specified world transform.

**Syntax**
AzFramework::SliceInstantiationTicket SpawnAbsolute(const AZ::Transform& world)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>world</td>
<td>const AZ::Transform&amp;</td>
<td>Specifies the world transform at which to spawn the selected slice.</td>
</tr>
</tbody>
</table>

**Returns:** A slice instantiation ticket.

**Return Type:** AzFramework::SliceInstantiationTicket

**Default Return:** AzFramework::SliceInstantiationTicket()

### SpawnerComponentNotificationBus

This EBus interface handles events dispatched by the SpawnerComponent.

**OnSpawnBegin**

Notifies that a slice has been spawned, but that its entities have not yet been activated. OnEntitySpawned events are about to be dispatched.

**Syntax**

```cpp
void OnSpawnBegin(const AzFramework::SliceInstantiationTicket& ticket)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ticket</td>
<td>AzFramework::SliceInstantiationTicket</td>
<td>The slice instantiation ticket.</td>
</tr>
</tbody>
</table>

**OnSpawnEnd**

Notifies that a spawn has been completed. All OnEntitySpawned events have been dispatched.

**Syntax**

```cpp
void OnSpawnEnd(const AzFramework::SliceInstantiationTicket& ticket)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ticket</td>
<td>AzFramework::SliceInstantiationTicket</td>
<td>The slice instantiation ticket.</td>
</tr>
</tbody>
</table>

**OnEntitySpawned**

Notifies that an entity has spawned. This event is called once for each entity spawned in a slice.

**Syntax**

```cpp
void OnEntitySpawned(const AzFramework::SliceInstantiationTicket& ticket, const AZ::EntityId& spawnedEntities)
```
**Component Entity Lua API Reference**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ticket</td>
<td>AzFramework::SliceInstantiationTicket</td>
<td>The slice instantiation ticket.</td>
</tr>
<tr>
<td>spawnedEntityId</td>
<td>AZ::EntityId</td>
<td>The ID of the spawned entity.</td>
</tr>
</tbody>
</table>

**TagComponentRequestBus**

Provides services for managing tags on entities.

**HasTag**

Checks for a specified tag on an entity.

**Syntax**

```c
bool HasTag(const Tag&)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tag</td>
<td>Tag</td>
<td>The tag to query for.</td>
</tr>
</tbody>
</table>

**Returns**: true if the entity has the specified tag; false otherwise.

**Return Type**: bool

**Default Return**: false

**AddTag**

Adds the specified tag to the entity if it doesn't already have it.

**Syntax**

```c
void AddTag(const Tag&)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tag</td>
<td>Tag</td>
<td>The tag to add.</td>
</tr>
</tbody>
</table>

**AddTags**

Adds a specified list of tags to the entity if the list does not exist on the entity.

**Syntax**

```c
void AddTags(const Tags& tags)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tags</td>
<td>Tags</td>
<td>The list of tags to add.</td>
</tr>
</tbody>
</table>
RemoveTag

Removes a specified tag from the entity if the tag is present.

Syntax

```c
void RemoveTag(const Tag& tag);
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tag</td>
<td>Tag</td>
<td>The tag to remove.</td>
</tr>
</tbody>
</table>

RemoveTags

Removes the specified list of tags from the entity if the list exists on the entity.

Syntax

```c
void RemoveTags(const Tags& tags);
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tags</td>
<td>Tags</td>
<td>The list of tags to remove.</td>
</tr>
</tbody>
</table>

GetTags

Retrieves the list of tags on the entity.

Syntax

```c
const Tags& GetTags();
```

Returns: A list of the tags on the entity.

Return Type: static Tags

Default Return: s_emptyTags

TagGlobalRequestBus

Provides services for querying Tags on entities.

RequestTaggedEntities

Queries for tagged entities. Handlers respond if they have the tag (that is, they are listening on the tag’s channel). Use AZ::EBusAggregateResults to handle more than the first responder.

Syntax

```c
const AZ::EntityId RequestTaggedEntities();
```

Returns: The ID of an entity that has a tag.

Return Type: const AZ::EntityId
Default Return: s_invalidEntityId

TagGlobalNotificationBus

Handler for global Tag component notifications.

OnEntityTagAdded

Notifies that a tag has been added to an entity. When connecting to the tag global notification bus, your OnEntityTagAdded handler fires once for each entity that already has a tag. After the initial connection, you are alerted whenever a new entity gains or loses a tag.

Syntax

void OnEntityTagAdded(const AZ::EntityId&)

OnEntityTagRemoved

Notifies that a Tag has been removed from an entity.

Syntax

void OnEntityTagRemoved(const AZ::EntityId&)

TagComponentNotificationsBus

Provides notifications regarding tags on entities.

OnTagAdded

Notifies listeners when a tag has been added.

Syntax

void OnTagAdded(const Tag&)

OnTagRemoved

Notifies listeners when a tag is removed.

Syntax

void OnTagRemoved(const Tag&)

TriggerAreaRequestsBus

This EBus interface services requests made to the Trigger Area component.

AddRequiredTag

Adds a required tag to the activation filtering criteria of the current component.

Syntax

void AddRequiredTag(const Tag& requiredTag)
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requiredTag</td>
<td>Tag</td>
<td>The tag to add to the activation filtering criteria.</td>
</tr>
</tbody>
</table>

**RemoveRequiredTag**

Removes a required tag from the activation filtering criteria of the current component.

**Syntax**

```cpp
void RemoveRequiredTag(const Tag& requiredTag)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requiredTag</td>
<td>Tag</td>
<td>The tag to remove from the activation filtering criteria.</td>
</tr>
</tbody>
</table>

**AddExcludedTag**

Adds an excluded tag to the activation filtering criteria of the current component.

**Syntax**

```cpp
void AddExcludedTag(const Tag& excludedTag)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>excludedTag</td>
<td>Tag</td>
<td>The excluded tag to add to the activation filtering criteria.</td>
</tr>
</tbody>
</table>

**RemoveExcludedTag**

Removes an excluded tag from the activation filtering criteria of the current component.

**Syntax**

```cpp
void RemoveExcludedTag(const Tag& excludedTag)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>excludedTag</td>
<td>Tag</td>
<td>The excluded tag to remove from the activation filtering criteria.</td>
</tr>
</tbody>
</table>

**TriggerAreaNotificationBus**

This EBus handles events for a given trigger area when an entity enters or leaves.

**OnTriggerAreaEntered**

Notifies when an entity enters the trigger area.
Syntax

```c
void OnTriggerAreaEntered(AZ::EntityId enteringEntityId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enteringEntityId</td>
<td>AZ::EntityId</td>
<td>The ID of the entity that entered the trigger area.</td>
</tr>
</tbody>
</table>

**OnTriggerAreaExited**

Notifies when an entity exits the trigger area.

Syntax

```c
void OnTriggerAreaExited(AZ::EntityId exitingEntityId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exitingEntityId</td>
<td>AZ::EntityId</td>
<td>The ID of the entity that exited the trigger area.</td>
</tr>
</tbody>
</table>

**TriggerAreaEntityNotificationBus**

Events fired for a specified trigger when the trigger area has been entered or exited.

**OnEntityEnteredTriggerArea**

Notifies when an `enteringEntityId` instance has entered the specified trigger area.

Syntax

```c
void OnEntityEnteredTriggerArea(AZ::EntityId triggerId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>triggerId</td>
<td>AZ::EntityId</td>
<td>The ID of the trigger that has been entered.</td>
</tr>
</tbody>
</table>

**OnEntityExitedTriggerArea**

Notifies when an `enteringEntityId` instance has exited the specified trigger area.

Syntax

```c
void OnEntityExitedTriggerArea(AZ::EntityId triggerId)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>triggerId</td>
<td>AZ::EntityId</td>
<td>The ID of the trigger that has been exited.</td>
</tr>
</tbody>
</table>
BoxShapeComponentRequestsBus

Services provided by the Box Shape component.

GetBoxConfiguration

Retrieves the box configuration.

Syntax

BoxShapeConfiguration GetBoxConfiguration()

Return Type: BoxShapeConfiguration
Default Return: BoxShapeConfiguration()

SetBoxDimensions

Sets new dimensions for the Box Shape.

Syntax

void SetBoxDimensions(AZ::Vector3 newDimensions)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>newDimensions</td>
<td>AZ::Vector3</td>
<td>Specifies dimensions along the X, Y, and Z axes.</td>
</tr>
</tbody>
</table>

CapsuleShapeComponentRequestsBus

Services provided by the Capsule Shape Component.

GetCapsuleConfiguration

Retrieves the capsule configuration.

Syntax

CapsuleShapeConfiguration GetCapsuleConfiguration()

Returns: The capsule configuration.
Return Type: CapsuleShapeConfiguration
Default Return: CapsuleShapeConfiguration()

SetHeight

Sets the end to end height of capsule, including the cylinder and both caps.

Syntax

void SetHeight(float newHeight)
### Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>newHeight</td>
<td>float</td>
<td>Specifies the new height of the capsule.</td>
</tr>
</tbody>
</table>

### SetRadius

Sets the radius of the capsule.

**Syntax**

```c
void SetRadius(float newRadius)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>newRadius</td>
<td>float</td>
<td>Specifies the new radius of the capsule.</td>
</tr>
</tbody>
</table>

### CylinderShapeComponentRequestsBus

This EBus interface handles messages for the Cylinder Shape component.

#### GetCylinderConfiguration

Retrieves the cylinder configuration.

**Syntax**

```c
CylinderShapeConfiguration GetCylinderConfiguration()
```

**Returns:** The cylinder configuration.

**Return Type:** CylinderShapeConfiguration

**Default Return:** CylinderShapeConfiguration()

#### SetHeight

Sets the height of the cylinder.

**Syntax**

```c
void SetHeight(float newHeight)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>newHeight</td>
<td>float</td>
<td>Specifies the height of the cylinder.</td>
</tr>
</tbody>
</table>

### SetRadius

Sets the radius of the cylinder.
Syntax

```c
void SetRadius(float newRadius)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>newRadius</td>
<td>float</td>
<td>Specifies the radius of the cylinder.</td>
</tr>
</tbody>
</table>

ShapeComponentRequestsBus

Handles requests for services provided by the Shape component.

**GetShapeType**

Retrieves the type of shape of a component.

**Syntax**

```c
AZ::Crc32 GetShapeType()
```

**Returns:** A Crc32 value that indicates the type of shape of the current component.

**Return Type:** AZ::Crc32

**Default Return:** AZ::Crc32()

**IsPointInside**

Checks if a given point is inside or outside a shape.

**Syntax**

```c
bool IsPointInside(const AZ::Vector3& point)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>point</td>
<td>AZ::Vector3</td>
<td>Specifies the coordinates of the point to be tested.</td>
</tr>
</tbody>
</table>

**Returns:** A bool value that indicates whether the point is inside or out.

**Return Type:** bool

**Default Return:** false

**DistanceFromPoint**

Retrieves the minimum distance the specified point is from the shape.

**Syntax**

```c
float DistanceFromPoint(const AZ::Vector3& point)
```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>point</td>
<td>AZ::Vector3</td>
<td>Specifies the coordinates of the point from which to calculate distance.</td>
</tr>
</tbody>
</table>

**Returns:** A float that indicates the distance the point is from the shape.

**Return Type:** float

**Default Return:** 0.f

### DistanceSquaredFromPoint

Retrieves the minimum squared distance the specified point is from the shape.

**Syntax**

```lua
float DistanceSquaredFromPoint(const AZ::Vector3& point)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>point</td>
<td>AZ::Vector3</td>
<td>Specifies the coordinates of the point from which to calculate the squared distance.</td>
</tr>
</tbody>
</table>

**Returns:** A float that contains the minimum squared distance the specified point is from the shape.

**Return Type:** float

**Default Return:** 0.f

### ShapeComponentNotificationsBus

Notifications sent by the shape component.

**OnShapeChanged**

Notifies that the shape component has been modified.

**Syntax**

```lua
void OnShapeChanged(ShapeChangeReasons changeReason)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>changeReason</td>
<td>ShapeChangeReasons</td>
<td>Informs listeners of the reason for this shape change (transform change, the shape dimensions being altered.)</td>
</tr>
</tbody>
</table>

### SphereShapeComponentRequestsBus

Services provided by the Sphere Shape Component
GetSphereConfiguration
Retrieve the sphere configuration.

Syntax
```
SphereShapeConfiguration GetSphereConfiguration()
```

**Returns:** The sphere configuration.

**ReturnType:** SphereShapeConfiguration

**Default Return:** SphereShapeConfiguration()

SetRadius
Sets the specified radius for the sphere shape component.

Syntax
```
void SetRadius(float newRadius)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>newRadius</td>
<td>float</td>
<td>Specifies the radius of the sphere shape.</td>
</tr>
</tbody>
</table>

EntityBus
Dispatches events specific to a given entity.

OnEntityActivated
Notifies when entity activation has completed. If the entity is active when a handler connects to the bus, then the OnEntityActivated event is sent immediately.

Syntax
```
void OnEntityActivated(const AZ::EntityId&)
```

OnEntityDeactivated
Notifies when the entity is about to be deactivated.

Syntax
```
void OnEntityDeactivated(const AZ::EntityId&)
```

TickBus
Tick events are executed on the main game or component thread.

**Note**
Warning: Adding mutex to the tick bus degrades performance in most cases.
OnTick

Notifies the delta time if the delta from the previous tick (in seconds) and time point is its absolute value.

**Syntax**

```lua
void OnTick(float deltaTime, ScriptTimePoint time)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deltaTime</td>
<td>float</td>
<td>The latest time between ticks.</td>
</tr>
<tr>
<td>time</td>
<td>ScriptTimePoint</td>
<td>The time at the current tick.</td>
</tr>
</tbody>
</table>

TickRequestBus

Make requests from this bus to get the frame time or return the current time as seconds.

GetTickDeltaTime

Gets the latest time between ticks.

**Syntax**

```lua
float GetTickDeltaTime()
```

**Returns:** The latest time between ticks.

**Return Type:** float

**Default Return:** 0.f

GetTimeAtCurrentTick

Gets the time in seconds at the current tick.

**Syntax**

```lua
ScriptTimePoint GetTimeAtCurrentTick()
```

**Returns:** The time in seconds at the current tick.

**Return Type:** ScriptTimePoint

**Default Return:** ScriptTimePoint()

TransformNotificationBus

This EBus is a listener for transform changes.

OnTransformChanged

Notifies when the local transform of the entity has changed. A local transform update always implies a world transform change.
Syntax

```cpp
void OnTransformChanged(const Transform& local, const Transform& world)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>local</td>
<td>Transform</td>
<td>The local transform of the entity.</td>
</tr>
<tr>
<td>world</td>
<td>Transform</td>
<td>The world transform.</td>
</tr>
</tbody>
</table>

**OnParentChanged**

Notifies when the parent of an entity has changed. When the old or new parent is invalid, the invalid EntityId is equal to InvalidEntityId.

**Syntax**

```cpp
void OnParentChanged(EntityId oldParent, EntityId newParent)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oldParent</td>
<td>EntityId</td>
<td>The entity ID of the old parent.</td>
</tr>
<tr>
<td>newParent</td>
<td>EntityId</td>
<td>The entity ID of the new parent.</td>
</tr>
</tbody>
</table>

**GameEntityContextRequestBus**

This EBus interfaces makes requests to the game entity context component.

**DestroyGameEntity**

Destroys an entity. The entity is deactivated immediately and is destroyed in the next tick.

**Syntax**

```cpp
void DestroyGameEntity(const AZ::EntityId& id)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>AZ::EntityId</td>
<td>The ID of the entity to be destroyed.</td>
</tr>
</tbody>
</table>

**DestroyGameEntityAndDescendants**

Destroys an entity and all its descendants, the entity and its descendants are deactivated immediately and will be destroyed the next tick.

**Syntax**

```cpp
void DestroyGameEntityAndDescendants(AZ::EntityId& id)
```
### Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>AZ::EntityId</td>
<td>The ID of the entity to be destroyed. The entity's descendants will also be destroyed.</td>
</tr>
</tbody>
</table>

### ActivateGameEntity

Activates an entity by the specified ID.

**Syntax**

```c++
void ActivateGameEntity(AZ::EntityId& id)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>AZ::EntityId</td>
<td>The ID of the entity to activate.</td>
</tr>
</tbody>
</table>

### DeactivateGameEntity

Deactivates an entity by the specified ID.

**Syntax**

```c++
void DeactivateGameEntity(AZ::EntityId& id)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>AZ::EntityId</td>
<td>The ID of the entity to deactivate.</td>
</tr>
</tbody>
</table>

### DestroySliceByEntity

Destroys the slice instance that contains the entity with the specified ID.

**Syntax**

```c++
bool DestroySliceByEntity(AZ::EntityId& id)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>AZ::EntityId</td>
<td>The ID of the entity to destroy.</td>
</tr>
</tbody>
</table>

**Returns**: true if the slice instance was successfully destroyed.

**Return Type**: bool

**Default Return**: false

### RandomManagerBus

Provides functions for random numbers.

**Version**: 1.28

**2752**
**RandomFloat**

Generates a random float value.

**Syntax**

```lua
float RandomFloat()
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tag</td>
<td>AZStd::string</td>
<td>The tag.</td>
</tr>
</tbody>
</table>

**Returns:** A random value between [0.0f, 1.0f).

**ReturnType:** float

**Default Return:** 0.0f

**RandomBool**

Generates a random Boolean value.

**Syntax**

```lua
bool RandomBool(const AZStd::string& tag)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tag</td>
<td>AZStd::string</td>
<td>The tag.</td>
</tr>
</tbody>
</table>

**Returns:** A random Boolean value.

**ReturnType:** bool

**Default Return:** false

**RandomInt**

Generates a random unsigned integer value.

**Syntax**

```lua
unsigned int RandomInt(const AZStd::string& tag)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tag</td>
<td>AZStd::string</td>
<td>The tag.</td>
</tr>
</tbody>
</table>

**Returns:** A random unsigned integer value.

**ReturnType:** unsigned int

**Default Return:** 0
**RandomInRange**

Generates a random unsigned integer value within a specified range.

**Syntax**

```cpp
unsigned int RandomInRange(const AZStd::string& tag, unsigned int min, unsigned int max)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tag</td>
<td>AZStd::string</td>
<td>The tag.</td>
</tr>
<tr>
<td>min</td>
<td>unsigned int</td>
<td>The minimum value that can be returned.</td>
</tr>
<tr>
<td>max</td>
<td>unsigned int</td>
<td>The maximum value that can be returned.</td>
</tr>
</tbody>
</table>

**Returns:** A random unsigned integer value within the specified range.

**Return Type:** unsigned int

**Default Return:** 0

**CameraRequestBus**

Provides access to camera properties and services.

**GetFov**

Gets the camera's field of view in degrees

**Syntax**

```cpp
float GetFOV()
```

**Returns:** The camera's field of view as a float.

**Return Type:** float

**Default Return:** s_defaultFoV

**GetNearClipDistance**

Gets the camera's distance from the near clip plane in meters.

**Syntax**

```cpp
float GetNearClipDistance()
```

**Returns:** The camera's distance from the near clip plane as a float in meters.

**Return Type:** float

**Default Return:** s_defaultNearPlaneDistance

**GetFarClipDistance**

Gets the camera's distance from the far clip plane in meters.
Syntax

```lua
float GetFarClipDistance()
```

**Returns:** The camera's distance from the far clip plane as a float in meters.

**Return Type:** float

**Default Return:** s_defaultFarClipPlaneDistance

---

**GetFrustumWidth**

Gets the camera frustum's width.

Syntax

```lua
float GetFrustumWidth()
```

**Returns:** The camera frustum's width as a float.

**Return Type:** float

**Default Return:** s_defaultFrustumDimension

---

**GetFrustumHeight**

Gets the camera frustum's height.

Syntax

```lua
float GetFrustumHeight()
```

**Returns:** The camera frustum's height as a float.

**Return Type:** float

**Default Return:** s_defaultFrustumDimension

---

**SetFov**

Sets the camera's field of view in degrees.

Syntax

```lua
void SetFov(float fov)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fov</td>
<td>float</td>
<td>The field of view in degrees. Possible values are 0 &lt; fov &lt; 180.</td>
</tr>
</tbody>
</table>

---

**SetNearClipDistance**

Sets the near clip plane to the specified distance from the camera in meters.

Syntax
void SetNearClipDistance(float nearClipDistance)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nearClipDistance</td>
<td>float</td>
<td>The distance from the camera in meters. The value should be small, but greater than 0.</td>
</tr>
</tbody>
</table>

**SetFarClipDistance**

Sets the far clip plane to the specified distance from the camera in meters.

**Syntax**

void SetFarClipDistance(float farClipDistance)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>farClipDistance</td>
<td>float</td>
<td>The distance from the camera in meters.</td>
</tr>
</tbody>
</table>

**SetFrustumWidth**

Sets the camera frustum's width.

**Syntax**

void SetFrustumWidth(float width)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>float</td>
<td>The camera frustum's width.</td>
</tr>
</tbody>
</table>

**SetFrustumHeight**

Sets the camera frustum's height.

**Syntax**

void SetFrustumHeight(float height)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>height</td>
<td>float</td>
<td>The camera frustum's height.</td>
</tr>
</tbody>
</table>

**MakeActiveView**

Makes the camera the active view.

**Syntax**
void MakeActiveView()

**HttpClientComponentNotificationBus**

Event handler for HTTP requests.

**OnHttpRequestSuccess**

Notifies when an HTTP request is successful.

**Syntax**

```lua
void OnHttpRequestSuccess(int responseCode, AZStd::string responseBody)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>responseCode</td>
<td>int</td>
<td>The response code.</td>
</tr>
<tr>
<td>responseBody</td>
<td>AZStd::string</td>
<td>The body of the response.</td>
</tr>
</tbody>
</table>

**OnHttpRequestFailure**

Sent when an HTTP request failed.

**Syntax**

```lua
void OnHttpRequestFailure(int responseCode)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>responseCode</td>
<td>int</td>
<td>The response code.</td>
</tr>
</tbody>
</table>

**HttpClientComponentRequestBus**

Provides services to make HTTP requests.

**MakeHttpRequest**

Makes an HTTP request.

**Syntax**

```lua
void MakeHttpRequest(AZStd::string url, AZStd::string method, AZStd::string jsonBody)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>AZStd::string</td>
<td>The request URL.</td>
</tr>
<tr>
<td>method</td>
<td>AZStd::string</td>
<td>The HTTP request method.</td>
</tr>
<tr>
<td>jsonBody</td>
<td>AZStd::string</td>
<td>The JSON body of the request.</td>
</tr>
</tbody>
</table>
HMDDeviceRequestBus

HMD device bus used to communicate with the rest of the engine. Every device supported by the engine lives in its own Gem and supports this bus. A device wraps the underlying SDK into a single object for easy use by the rest of the system. Every device created should register with the EBus in order to be picked up as a usable device during initialization by the EBus function BusConnect().

GetTrackingState

Gets the most recent HMD tracking state.

**Syntax**

```cpp
TrackingState* GetTrackingState()
```

**Returns:** The tracking state.

**Return Type:** TrackingState*

**Default Return:** nullptr

RecenterPose

Center the current pose for the HMD based on the current direction in which the viewer is looking.

**Syntax**

```cpp
void RecenterPose()
```

SetTrackingLevel

Set the current tracking level of the HMD. Supported tracking levels are defined in struct TrackingLevel.

**Syntax**

```cpp
void SetTrackingLevel(const AZ::VR::HMDTrackingLevel level)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>level</td>
<td>AZ::VR::HMDTrackingLevel</td>
<td>The tracking level to use with the current HMD. Possible values: kHead - The sensor reads as if the player is standing. kFloor - The sensor reads as if the player is seated or on the floor.</td>
</tr>
</tbody>
</table>

OutputHMDInfo

Outputs the information about the currently connected HMD (contained in the struct HMDDeviceInfo object) to the console and log file.

**Syntax**

```cpp
void OutputHMDInfo()
```
GetDeviceInfo

Get the device info object for this particular HMD.

**Syntax**

```cpp
HMDDeviceInfo* GetDeviceInfo()
```

**Returns:** A pointer to the current HMD's struct HMDDeviceInfo (p. 3261).

**Return Type:** HMDDeviceInfo*

**Default Return:** nullptr

IsInitialized

Gets whether or not the HMD has been initialized. The HMD has been initialized when it has fully established an interface with its required SDK and is ready to be used.

**Syntax**

```cpp
bool IsInitialized()
```

**Returns:** true if the device has been initialized and is usable; otherwise, returns false.

**Return Type:** bool

**Default Return:** false

ControllerRequestBus

Provides information about HMD device controllers.

GetTrackingState

Returns a TrackingState object that contains tracking info about a connected controller. For more information, see struct TrackingState (p. 3261).

**Syntax**

```cpp
TrackingState* GetTrackingState(ControllerIndex controllerIndex)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controllerIndex</td>
<td>int</td>
<td>Specify 0 for the left controller; 1 for the right controller.</td>
</tr>
</tbody>
</table>

**Returns:** A pointer to the TrackingState object for the connected controller.

**Return Type:** TrackingState*

**Default Return:** nullptr

IsConnected

Returns whether the specified controller is connected.
Syntax

```cpp
bool IsConnected(ControllerIndex controllerIndex)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controllerIndex</td>
<td>int</td>
<td>Specify 0 for the left controller; 1 for the right controller.</td>
</tr>
</tbody>
</table>

**Returns:** A Boolean that indicates whether the specified controller is connected.

**Return Type:** bool

**Default Return:** false

**VideoPlaybackRequestBus**

Provides access to video playback services.

**Play**

Start or resume playing a movie that is attached to the current entity.

**Syntax**

```cpp
void Play()
```

**Pause**

Pause a movie that is attached to the current entity.

**Syntax**

```cpp
void Pause()
```

**Stop**

Stop playing a movie that is attached to the current entity.

**Syntax**

```cpp
void Stop()
```

**EnableLooping**

Set whether or not the movie attached to the current entity loops.

**Syntax**

```cpp
void EnableLooping(bool enable)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>bool</td>
<td>Specify true to loop; false to not loop.</td>
</tr>
</tbody>
</table>
**IsPlaying**

Returns whether or not the video is currently playing

**Syntax**

```lua
bool IsPlaying()
```

**Returns:** true if the video is currently playing; false if the video is paused or stopped.

**Return Type:** bool

**Default Return:** false

**SetPlaybackSpeed**

Sets the playback speed based on a factor of the current playback speed.

**Syntax**

```lua
void SetPlaybackSpeed(float speedFactor)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>speedFactor</td>
<td>float</td>
<td>The speed modification factor to apply to playback speed. For example, specify 0.5f to play at half speed or 2.0f to play at double speed.</td>
</tr>
</tbody>
</table>

**VideoPlaybackNotificationBus**

This bus contains event handlers for video playback services.

**OnPlaybackStarted**

Event that fires when the movie starts playback.

**Syntax**

```lua
void OnPlaybackStarted()
```

**OnPlaybackPaused**

Event that fires when the movie pauses playback.

**Syntax**

```lua
void OnPlaybackPaused()
```

**OnPlaybackStopped**

Event that fires when the movie stops playback.

**Syntax**

```lua
void OnPlaybackStopped()
```
OnPlaybackFinished

Event that fires when the movie completes playback.

Syntax

```c
void OnPlaybackFinished()
```

Using Script Events

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Scripting in Lumberyard is designed around event driven paradigms. Rather than directly accessing information from a given entity or one of its components, you use events to send and receive information and take action in a decoupled environment.

Like entities and components, scripts can use events to communicate with each other. These events are called script events.

To author script events, use the Asset Editor or Lua. Script Canvas and Lua can send or receive the events that you create. In Script Canvas, you can add nodes that send or receive script events. Events sent from Script Canvas can be handled in Lua. Likewise, events sent from Lua can be handled in Script Canvas.

Prerequisites

To use script events, you must enable the Script Events gem in your project. For information about enabling gems, see Enabling Gems (p. 1064).

Topics

- Creating Script Events in Script Canvas (p. 2762)
- Using Script Events in Script Canvas (p. 2765)
- Using Script Events in Lua (p. 2766)
- Script Events Best Practices (p. 2769)

Creating Script Events in Script Canvas

In Lumberyard Editor, you can create script events by using the Asset Editor.

To create a script event

1. In Lumberyard Editor, choose Tools, Asset Editor.
2. In the Asset Editor, choose File, New, Script Events.
3. In the **Asset Editor**, enter the information that defines the script event.

<table>
<thead>
<tr>
<th>Script Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name that identifies the script event in Lua and in the Script Canvas editor <strong>Node Palette</strong>. Event names must have only alphanumeric characters and cannot start with a number or contain white space.</td>
</tr>
</tbody>
</table>
Creating Script Events in Script Canvas

<table>
<thead>
<tr>
<th>Script Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Category</strong></td>
<td>Enter a name for the category in the Script Canvas editor <strong>Node Palette</strong> in which the script events appear. The default category is <strong>Script Events</strong>. To nest categories, use the syntax <code>category/sub_category/sub_category</code>.</td>
</tr>
<tr>
<td><strong>Tooltip</strong></td>
<td>Enter a description for the script event. The description appears when the user pauses a pointer on the script event in the <strong>Node Palette</strong> or on the event node in a graph.</td>
</tr>
<tr>
<td><strong>Address Type</strong></td>
<td>(Optional). Choose a data type for the value that addresses this script event. Possible types are <strong>String</strong>, <strong>Entity Id</strong>, or <strong>Tag</strong>.</td>
</tr>
<tr>
<td><strong>Events</strong></td>
<td>Specify a list of events that are sent and received by the scripting system. Define the events in the same way that you define functions in a programming language. The events that you create are available for dragging and dropping from the Script Canvas <strong>Node Palette</strong>.</td>
</tr>
</tbody>
</table>

**Event Properties**

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>The name of the event.</td>
</tr>
<tr>
<td><strong>Tooltip</strong></td>
<td>Enter the description for the event that appears when the user pauses a pointer on the event name.</td>
</tr>
<tr>
<td><strong>Return value type</strong></td>
<td>(Optional). Choose the data type of the value that the handler of the event returns to the sender of the event. If Return Type is not None, a value of the specified type must be connected from the receiver node to the sender node.</td>
</tr>
<tr>
<td><strong>Parameters</strong></td>
<td>Click the plus (+) icon to add one or more parameters for the event function.</td>
</tr>
</tbody>
</table>

**Parameter Properties**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Enter the name of a function parameter.</td>
</tr>
<tr>
<td><strong>Tooltip</strong></td>
<td>Enter the description for the parameter that appears when the user pauses a pointer on the parameter name.</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Choose the data type of the parameter.</td>
</tr>
</tbody>
</table>

4. Choose **File**, **Save**, or press **Ctrl+S**.
5. In the **Save As** dialog box, enter a file name for your `.scriptevents` file, and click **Save**.

**Note**

To ensure that the script event asset saved correctly, check the bottom of the Asset Editor for the message "file_name.scriptevents - Asset loaded!" message. If you see the error message Failed to save asset due to validation error, check the Lumberyard Editor **Console** window or the `lumberyard_version\dev\Cache\project_name\pc\user\log\Editor.log` file for more information.
Using Script Events in Script Canvas

Script Canvas scans for and detects script event assets, so after you define a script event, you can use it in Script Canvas.

Script Events in the Node Palette

Script event assets appear by default in the Script Events category in the Script Canvas editor Node Palette.

Note
To change the name of the category, open the script event's asset definition in the Asset Editor and edit the Category property.

Sending Events

You can send an event by adding a Send method_name node to a Script Canvas graph.

To send an event

1. Drag and drop the method that you want to send onto the Script Canvas graph.
2. In the context menu, choose Send method_name.

A method send node is added to the graph.

3. Connect this node to the appropriate logic and data inputs. When the Script Canvas graph runs, it sends the event to the entities or systems to which the node is connected.
Handling Events

You can handle an event by adding a Receive `method_name` node to a Script Canvas graph.

To handle an event

1. Drag and drop a script event method onto the canvas.
2. In the context menu, choose Receive `method_name`.

An event handler method node is added to the graph.

3. Connect your event handling logic to the Out pin of the node.
4. Connect the data pin as needed.

Using Script Events in Lua

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lua scripts can use script events to communicate with each other. There are two example scripts that show this communication, both available in the `lumberyard_version\dev\Gems\ScriptEvents\Assets\Scripts\Example` directory. They are called `ScriptEvents_Addressable.lua` and `ScriptEvents_Broadcast.lua`. If an EBus is addressed, events are sent to a specific address ID. Events that are broadcast globally are received at all addresses. For more information, see Working with the Event Bus (EBus) system (p. 1851).

`ScriptEvents_Addressable.lua`
The `ScriptEvents_Addressable.lua` example script implements a handler for a script event that requires an address for a handler to be invoked. It broadcasts a method, but only handlers connected to the address that match the one specified in the event can invoke it.

**Example**

```lua
-- ScriptEvents_Addressable.lua
function ScriptTrace(txt)
    Debug.Log(txt)
end

function ScriptExpectTrue(condition, msg)
    if (not condition) then
        ScriptTrace(msg)
    end
end

-- This example shows how to implement a handler for a Script Event that requires an address
-- in order for a handler to be invoked.
luaScriptEventWithId = {
    MethodWithId0 = function(self, param1, param2)
        ScriptTrace("Handler: " .. tostring(param1) .. " " .. tostring(param2))
        ScriptExpectTrue(typeid(param1) == typeid(0), "Type of param1 must be " .. tostring(typeid(0)))
        ScriptExpectTrue(typeid(param2) == typeid(EntityId()), "Type of param2 must be " .. tostring(typeid(EntityId())))
        ScriptExpectTrue(param1 == 1, "The first parameter must be 1")
        ScriptExpectTrue(param2 == EntityId(12345), "The received entity Id must match the one sent")
        ScriptTrace("MethodWithId0 handled")
        return true
    end,
    MethodWithId1 = function(self)
        ScriptTrace("MethodWithId1 handled")
    end
}

-- "Script_Event" will be the name of the callable Script Event. It requires the address type to be a string.
luaScriptEventDefinition = ScriptEvent("Script_Event", typeid("") -- Event address is of string type

-- Define some methods for handlers to implement.
luaScriptEventDefinition:AddMethod("MethodWithId0", typeid(false)) -- Return value is Boolean
method0:AddParameter("Param0", typeid(0))
method0:AddParameter("Param1", typeid(EntityId()))

-- NOTE: Types are specified using the typeid keyword with a VALUE of the type you want. For example, typeid("EntityId")
-- produces the type id for a string, not the EntityId type.
luaScriptEventDefinition:AddMethod("MethodWithId1") -- No return, no parameters.
```
-- After the Script Event is defined, call Register to enable it. Typically this should be done within the OnActivate method.
scriptEventDefinition:Register()

-- At this point, the script event is usable. Use the Script_Event.Connect method to connect a handler to it. The following example
-- uses luaScriptEventWithId as the handler that implements the methods defined earlier. Notice that the call connects using
-- the string "ScriptEventAddress" as the address for this event. Methods sent to a different address will not be handled by
-- this handler.
scriptEventHandler = Script_Event.Connect(luaScriptEventWithId, "ScriptEventAddress")

-- Now invoke the event and specify "ScriptEventAddress" as the address. The handler previously
-- connected will be able to handle this event.
local returnValue = Script_Event.Event.MethodWithId0("ScriptEventAddress", 1,
EntityId(12345))

-- "Method0" should return true. Verify the result.
ScriptExpectTrue(returnValue, "Method0's return value must be true")

-- Finally, send MethodWithId1. This method does not require any parameters, but does require the address.
ScriptEvento.MethodWithId1("ScriptEventAddress")

ScriptEvents_Broadcast.lua

The ScriptEvents_Broadcast.lua example script implements a handler for a broadcast script event. Because broadcast script events do not specify an address type, any handler can connect to them.

Example

-- ScriptEvents_Broadcast.lua
function ScriptTrace(txt)
    Debug.Log(txt)
end

function ScriptExpectTrue(condition, msg)
    if (not condition) then
        ScriptTrace(msg)
    end
end

-- This example shows how to implement a handler for a broadcast script event.
-- Because broadcast script events do not specify an address type, they can be handled
-- by simply connecting to them.
luaScriptEventBroadcast = {

    -- The following method is called as a result of a broadcast call on the script event.
    BroadcastMethod0 = function(self, param1, param2)
        ScriptTrace("Handler: ", tostring(param1) .. " ", tostring(param2))
        ScriptExpectTrue(typeid(param1) == typeid(0), "Type of param1 must be ":tostring(typeid(0)))
        ScriptExpectTrue(typeid(param2) == typeid(EntityId()), "Type of param2 must be ":tostring(typeid(EntityId())))
        ScriptExpectTrue(param1 == 2, "The first parameter must be 2")
        ScriptExpectTrue(param2 == EntityId(23456), "The received entity Id must match the one sent")
        ScriptTrace("BroadcastMethod0 Called")
    end

    BroadcastMethod1 = function(self, param1, param2)
        ScriptTrace("Handler: ", tostring(param1) .. " ", tostring(param2))
        ScriptExpectTrue(typeid(param1) == typeid(0), "Type of param1 must be ":tostring(typeid(0)))
        ScriptExpectTrue(typeid(param2) == typeid(EntityId()), "Type of param2 must be ":tostring(typeid(EntityId())))
        ScriptExpectTrue(param1 == 2, "The first parameter must be 2")
        ScriptExpectTrue(param2 == EntityId(23456), "The received entity Id must match the one sent")
        ScriptTrace("BroadcastMethod1 Called")
    end

    BroadcastMethod2 = function(self, param1, param2)
        ScriptTrace("Handler: ", tostring(param1) .. " ", tostring(param2))
        ScriptExpectTrue(typeid(param1) == typeid(0), "Type of param1 must be ":tostring(typeid(0)))
        ScriptExpectTrue(typeid(param2) == typeid(EntityId()), "Type of param2 must be ":tostring(typeid(EntityId())))
        ScriptExpectTrue(param1 == 2, "The first parameter must be 2")
        ScriptExpectTrue(param2 == EntityId(23456), "The received entity Id must match the one sent")
        ScriptTrace("BroadcastMethod2 Called")
    end

}
return true
end,

BroadcastMethod1 = function(self)
    ScriptTrace("BroadcastMethod1 Called")
end
}

local scriptEventDefinition = ScriptEvent("Script_Broadcast") -- Script_Broadcast is the
-- name of the callable script event.
-- Define methods for Script_Broadcast
local method0 = scriptEventDefinition:AddMethod("BroadcastMethod0", typeid(false)) -- To
-- add a method, provide a method name and an optional return type.
method0:AddParameter("Param0", typeid(0))
method0:AddParameter("Param1", typeid(EntityId()))

-- NOTE: Types are specified using the typeid keyword with a VALUE of the type you want. For example, typeid("EntityId")
-- produces the type id for a string, not the EntityId type.

scriptEventDefinition:AddMethod("BroadcastMethod1")
-- After the Script Event is defined, call Register to enable it. Typically this should be
done within the OnActivate method.
scriptEventDefinition:Register()

-- At this point, the script event is usable. Use the Script_Broadcast.Connect method to
-- connect a handler to it. The following example
-- uses luaScriptEventWithId as the handler that implements the methods defined earlier.
scriptEventHandler = Script_Broadcast.Connect(luaScriptEventBroadcast)

-- To test the event, broadcast BroadcastMethod0. As defined, the method expects two
parameters and returns a boolean value.
local returnValue = Script_Broadcast.Broadcast.BroadcastMethod0(2, EntityId(23456))

-- BroadcastMethod0 should return true. Verify the result.
ScriptExpectTrue(returnValue, "BroadcastMethod0's return value must be true")

-- To broadcast an event without a return or parameters, invoke BroadcastMethod1.
Script_Broadcast.Broadcast.BroadcastMethod1()

---

Script Events Best Practices

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The following are some best practices for using script events.

Ensure Entities are Activated Before Events are Sent

Sending events during entity activation can have undesired results. Because the order of activation of entities is not guaranteed, when an event is sent during activation, some entities that need to handle the event might not receive it. In particular, the On Graph Start and On Entity Activated events are subject to activation order issues.

To ensure that all entities that need to listen for and handle a given script event are ready to receive the event, queue the message on the tick bus (p. 1019). One way to implement this strategy in Script
Canvas is to connect the **On Graph Start** node to a **Tick Delay** node. The delay helps to ensure that when a script event message is sent, all entities that could possibly be connected to that script event receive the event.

---

**Be Aware of Script Event Asset Versioning**

Because Script Events are user-created assets, problems can occur when an asset that is referenced in existing scripts or Script Canvas graphs changes.

**Note**

Script Canvas provides Script Event version validation. When a Script Event asset is modified, Script Canvas updates the Script Event nodes that reference it. If you open a graph that has a Script Event that has been modified, the graph is marked as modified. To update the Script Event nodes to their latest versions, save the graph.

**Use Script Events Instead of the Gameplay Notification Bus System**

Script events offer the following advantages over the gameplay bus (p. 1030) system. Script events:

- Are data driven.
- Support more data types.
- Require less maintenance.
- Can be used in both Script Canvas and Lua.

For these reasons, script events supersede the gameplay notification bus system and the following GameplayNotificationBus related classes:

- GameplayNotificationBus
- GameplayNotificationId
- BehaviorGameplayNotificationBusHandler
- GameplayEventHandlerNode (Legacy)

**Migrating to Script Events**

If your project uses GameplayNotificationBus, you can modify it to use script events.
To migrate from GameplayNotificationBus to script events

1. Create a new Script Event that performs the event messaging that you require.
2. Identify the Script Canvas graphs or Lua scripts that use GameplayNotificationBus.
3. Replace the nodes or code that use GameplayNotificationBus with either a Script Event Send or a Script Event Receive.
Simulating physics behavior with the PhysX system

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard’s PhysX system acts upon entities to create realistic physical effects such as collision detection and rigid body dynamics simulation. To use the PhysX system, install the PhysX SDK using the Lumberyard Setup Assistant (p. 16).

**Note**
Lumberyard’s PhysX system does not interact with Physics (Legacy) (p. 534) component entities or the legacy Physics.

**Topics**
- PhysX Gems (p. 2772)
- PhysX Components (p. 2773)
- PhysX Configuration (p. 2773)
- PhysX Materials (p. 2773)
- PhysX Debugging (p. 2774)
- Configuring the PhysX System (p. 2774)
- Physics materials (p. 2797)
- PhysX Scene Queries (p. 2804)
- Dynamic joints with PhysX (p. 2813)
- Create global or localized wind forces with PhysX (p. 2822)
- Debugging PhysX (p. 2826)
- PhysX Best Practices (p. 2832)
- Simulated destruction with NVIDIA Blast (p. 2833)
- Simulate cloth with NVIDIA Cloth (p. 2857)

**PhysX Gems**

The PhysX system uses the following gems, which you can enable (p. 1064) in the Project Configurator:

- **PhysX (p. 1188)** – Provides integration for the NVIDIA PhysX SDK into Lumberyard. The integration provided includes a suite of components, configuration via the editor, Script Canvas integration, PhysX Visual Debugger integration, and a simplified API abstraction layer for games.

  For more information, see PhysX (p. 1188).

- **PhysX Characters (p. 1188)** – Provides integration for character controllers and ragdolls. To enable the PhysX Characters gem, you must first enable the PhysX (p. 1188) gem.

  For more information, see PhysX Characters (p. 1188).
• **PhysX Debug (p. 1188)** – Provides debug visualizations of PhysX scene geometry that you can enable with console commands and other tools.

For more information, see PhysX Debug (p. 1188).

### PhysX Components

The **PhysX** gem has the following components, which you can add (p. 479) to entities by using the Entity Inspector (p. 475):

- **PhysX Collider (p. 735)** – Enables physics objects to collide with other physics objects. An entity that does not have a PhysX Rigid Body Physics component is a static collider, while an entity with the component is a dynamic collider.

- **PhysX Force Region (p. 746)** – Enables an entity to specify a region that applies physical force to entities. For each physics simulation frame, the component applies force to entities that are in the bounds of the region.

- **PhysX Rigid Body (p. 759)** – Enables an entity to be simulated by physics. Rigid body mode can be kinematic or dynamic. Dynamic rigid bodies respond to collision events with other rigid bodies. Kinematic rigid bodies are not affected by outside forces and gravity; their motion is driven by scripting.

- **PhysX Terrain (p. 767)** – Implements physical interaction with the terrain. It exports terrain and saves it as an asset that loads at runtime.

The **PhysX Characters** gem has the following components:

- **PhysX Character Controller (p. 729)** – Implements basic character interactions with the physical world. For example, it can control interactions with slopes and steps, manage interactions with other characters, and prevent characters from walking through walls or passing through terrain.

- **PhysX Ragdoll (p. 757)** – Enables animation of certain character behaviors. The physical representation is usually a hierarchical collection of rigid bodies with simple shapes connected by joints.

You can use the following video tutorial to learn about PhysX components in Lumberyard.

Nvidia PhysX Lumberyard Integration: Adding the Terrain, Collider, and Rigid Body Components

### PhysX Configuration

Use the **PhysX Configuration** window in Lumberyard Editor to configure global settings, collision layers, collision groups, and PhysX Visual Debugger settings.

For more information, see Configuring the PhysX System (p. 2774).

You can use the following video tutorial to learn about the collision layers and groups in Lumberyard.

NVIDIA PhysX Lumberyard Integration: Using Collision Filtering

### PhysX Materials

PhysX materials allow simulation properties to be configured by entity. Materials customize how an object reacts when it hits a surface and control qualities like friction and bounciness. You use the Asset
Editor to create a material library, assign the library to a collider, and then select a specific material from the library for the collider.

For more information, see Physics materials (p. 2797).

You can use the following video tutorial to learn about the PhysX materials in Lumberyard,

NVIDIA PhysX Lumberyard Integration: Physical Material Creation

# PhysX Debugging

To verify the implementation of interactions in the simulated world, the following tools are available.

- **PhysX Debug gem** – The PhysX Debug gem is recommended if you are a developer or technical artist. You can use this tool to view the physics world in real time in Lumberyard Editor's editor mode or game mode. To activate the tool, you use console commands or an immediate mode graphical user interface (ImGui). The tool displays PhysX debug lines within the editor and game modes.

  For more information, see PhysX Debug (p. 1188).

- **PhysX Visual Debugger** – The PhysX Visual Debugger (PVD) is a third party tool provided by NVIDIA that is useful for deep inspection of the PhysX world. Lumberyard can connect PhysX worlds and scenes to a running PVD application instance. You can use the PVD to step through your simulation and examine various properties at your own pace in detail.

  For information on configuring Lumberyard's connection to PVD, see Debugger Configuration (p. 2790).

For more information, see Debugging PhysX (p. 2826).

# Configuring the PhysX System

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The PhysX (p. 1188) gem can be configured for each project for your game. Your settings are saved in your project's `lumberyard_version\dev\project_name\default.physxconfiguration` file. If you use a version control system, include this file.

To configure PhysX settings, use the PhysX Configuration tool.

**To open the PhysX Configuration tool**

- In Lumberyard Editor, choose Tools, PhysX Configuration.

Topics
- Global Configuration (p. 2775)
- Collision Layers (p. 2785)
- Collision Groups (p. 2787)
- Debugger Configuration (p. 2790)
- PhysX World Programming Notes (p. 2796)
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

On the **Global Configuration** tab, you can configure world settings and editor settings.

![Global Configuration tab](image)

**World Configuration**

The following table describes the settings for **World Configuration**.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Max Time Step</td>
<td>Specifies the largest time step that the simulation can process. This setting prevents instability in the simulation if m_fixedTimeStep is not large enough.</td>
</tr>
<tr>
<td>Fixed Time Step</td>
<td>Specifies the fixed time step that the simulation can process. This setting prevents instability in the simulation if m_fixedTimeStep is not large enough.</td>
</tr>
</tbody>
</table>
**Description**

set.
It also prevents the simulation from taking too long.

If the time between frames is greater than \( m_{\text{maxTimeStep}} \), the time is limited to this value. Specify small increments.

The default is \( 0.05 \) (1/20th of a second).
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed Time Step</td>
<td>Controls the frequency of the fixedTimeStep interval at which Lumberyard does the simulation. The default is 0.017 (1/60th of a second).</td>
</tr>
</tbody>
</table>

**Note**

- A lower value results in a more accurate simulation, but at a higher runtime cost.
- Higher values can cause results that are less stable.
- If this value is set to 0, the
simulation does not use the fixed time and uses the time between frames, which can vary.

- If the frame time is greater than this value, Lumberyard splits the time to the number of steps yielded by the following calculation:

\[
\frac{\text{frame time}}{\text{m_fixedTimeStep}}
\]
**Global Configuration**

**Property**  
**Description**

**Gravity**
- Gravity vector in the world.
- The default X, Y, and Z values are 0.0, 0.0, and -9.81.

**Raycast Buffer Size**
- Maximum number of hits that can be returned from a raycast query.
- The default is 32.

**Shapecast Buffer Size**
- Maximum number of hits that can be returned from a shapecast query.
- The default is 32.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overlap Query Buffer Size</td>
<td>Maximum number of hits that can be returned from an overlap query. The default is 32.</td>
</tr>
<tr>
<td>Continuous Collision Detection</td>
<td>Enables continuous collision detection in the world. Disabled by default.</td>
</tr>
</tbody>
</table>
**Persistent Contact Manifold**

to improve the calculation of the entities that are colliding and preserves this data between frames.

Enabled by default, which is the recommended setting.

Persistent manifolds store the contact data created in one frame for potential reuse in subsequent frames. For example, if the corner of box A collides with
the side of box B, the contact data is stored and the manifold stores the collision point. If box A's corner no longer collides in approximately in the same location in the next frame, the data is disregarded.

If box A moves too far (for example, if it rotates so far that the corner
no longer touches), that data is discarded. Otherwise, the manifold provides faster collision results by using the data from the previous frame to calculate the collision. Although persistent manifolds require more memory, they improve performance and the accuracy of the simulation by reducing jitter and other unwanted physics artifacts.
Editor Configuration

The following options relate to the Debug Draw COM (center of mass) option of the PhysX Rigid Body (p. 759) component.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug Draw</td>
<td>Debug Draw Center of Mass Color</td>
</tr>
<tr>
<td>Center Size</td>
<td>The size of the debug draw circle that represents the center of the mass.</td>
</tr>
<tr>
<td></td>
<td>Possible values are from 0.1 to 5.0 meters.</td>
</tr>
<tr>
<td></td>
<td>The default value is 0.1.</td>
</tr>
<tr>
<td>Color</td>
<td>The color of the debug draw circle that represents the center of the mass.</td>
</tr>
<tr>
<td></td>
<td>To specify a color, enter its RGB values.</td>
</tr>
</tbody>
</table>
Collision Layers

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use collision layers to group objects of the same type. Use collision groups to define what the collision layers collide with. You can have a maximum of 64 layers per game.

Common types of layers are objects like the following:

- Terrain
- Static objects
- Players
- Enemies
- Projectiles

The layers that you define are specific to your game. When a collider is created, it is assigned a collision layer with index [0] called Default. This can't be changed.
To create a collision layer

1. In Lumberyard Editor, choose **Tools, PhysX Configuration**.
2. Click the **Layers** tab.
3. Type the name of the layer into an available text field. Layer names must be 32 characters or less.

![PhysX Configuration (PREVIEW)](image)

To assign a collision layer to a collider

1. In the Lumberyard Editor viewport, create an entity and select it.
2. In the **Entity Inspector**, add a **PhysX Collider** component to the entity.
3. In the **PhysX Collider** component, for **Collision Layer**, choose one of the colliders that you created from the drop-down list.

![PhysX Collider](image)
Notes

- If you rename a layer, its references are updated automatically, but you can't reorder layers.
- If an entity with a PhysX Collider component is selected in the viewport and you use the PhysX Configuration window to create, rename, or delete a collision layer, the changes do not appear in the Entity Inspector. To see the changes, deselect and reselect the entity in the viewport.

Collision Groups

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use collision groups to define the layers that a collider interacts with. A collision group is similar to a mask with specific bits set in which each bit corresponds to a collision layer.

Two colliders interact if their collision layers are in each other's collision group. If one collision layer is not present in the other layer's collision group, the colliders don't interact.

To create a collision group

1. In Lumberyard Editor, choose Tools, PhysX Configuration.
2. Click the Collision Groups tab. The layers that are configured on the Layers tab appear here as columns.
3. Click Add, and then enter the name of the group into the text box.
4. Select or clear the check boxes to specify the layers to include in each collision group.
5. Close the configuration tool. The configuration tool must be closed for changes to the groups to take effect.

To assign a collision group to a collider

1. In the Lumberyard Editor viewport, select the entity that has the collider.
2. In the Entity Inspector, in the PhysX Collider component, for Collides With, choose one of the collision groups that you created from the drop-down list.
Example Collision Group Configuration

The following example defines Player, Enemy, Bullet, Foliage, and Terrain layers, and the following collision groups:

- **PlayerBullet** – Collides with Enemy and Terrain.
- **EnemyBullet** – Collides with Player and Terrain.
- **TerrainCollision** – Collides with Player, Enemy, Bullet, and Terrain.
- **PlayerCollision** – Collides with Enemy, Bullet, and Terrain.

A bullet fired by the player has the following layer and group:

- **Layer**: Bullet
- **Group**: PlayerBullet
A bullet fired by the enemy has the following layer and group:

- **Layer:** Bullet
- **Group:** EnemyBullet

**Note**
You don't have to define an "enemy bullet" or a "player bullet" layer. Instead, you have a single Bullet layer and create separate collision groups to specify the objects that it collides with.

### Creating Collision Layers and Groups Programmmatically

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The API for collision layers and groups is defined in the Collision.h and CollisionBus.h headers. The following code shows example include statements.

```cpp
#include <AzFramework/Physics/Collision.h>
#include <AzFramework/Physics/CollisionBus.h>
// For the rest of the examples:
using namespace AzFramework;
using namespace Physics;
```

For source code, see the `lumberyard_version\dev\Code\Framework\AzFramework\AzFramework\Physics\Collision.*` files.

### Retrieving Layers and Groups

You can use the `layer(layer_name)` and `group(group_name)` methods to retrieve instances of collision layers and groups that you created in Lumberyard Editor (p. 2787). These methods perform a lookup of the definitions defined in the PhysX Configuration tool. If no collision layer is found that matches the name, the default layer (0) is returned.

```cpp
CollisionLayer layer("MyLayer");
CollisionGroup group("MyGroup");
```

You can also use a bus to look up layers and groups, as in the following code:

```cpp
CollisionLayer layer;
CollisionRequestBus::BroadcastResult(layer, &Physics::CollisionRequests::GetCollisionLayerByName, layerName);
CollisionGroup group;
CollisionRequestBus::BroadcastResult(group, &Physics::CollisionRequests::GetCollisionGroupByName, groupName);
```

### Creating Collision Groups in Code

Unlike the predefined collision groups that you create in Lumberyard Editor, you can use code to create collision groups at runtime. This is useful when you don’t know the layers involved in advance at therefore must define a collision group at runtime.
The following example code creates a collision group at runtime that contains an Enemy layer and a Tree layer. This handles the situation in which the identity of the tree and the enemy are not known prior to the start of gameplay.

```
CollisionLayer layer1("Enemy"), layer2("Tree");
CollisionGroup group = AzFramework::Physics::CollisionGroup::None;
group.SetLayer(layer1, true);
group.SetLayer(layer2, true);
```

If all the layers required to construct the collision group are known at the same time, you can use overloaded operators, as in the following example:

```
CollisionGroup group = CollisionLayer("Layer1") | CollisionLayer("Layer2") |
CollisionLayer("Layer3");
```

## Debugger Configuration

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.

Download O3DE or visit the AWS Game Tech blog to learn more.

In the PhysX Configuration tool, you can specify how to interact with the PhysX Visual Debugger (PVD). The PVD is a third-party application that records your PhysX data from Lumberyard Editor. You can then review this data to see how your physics effects appear.

For more information, see the NVIDIA PhysX Visual Debugger (PVD) documentation.

**To configure the PhysX Visual Debugger**

1. To get started, download the PVD.

   **Note**
   You must have a NVIDIA account to download the PVD. If you don’t already have an account, follow the steps to create and then sign in your account.

2. Follow the installation steps.
3. After you install the application, open the PVD. This application must be running if you want to record data from Lumberyard Editor.
4. In Lumberyard Editor, open a level or create one that has entities with PhysX components. For example, you can create a dynamic entity that falls. For more information, see Creating a Dynamic PhysX Entity (p. 762).
5. In Lumberyard Editor, choose Tools, PhysX Configuration.
6. Click the Debugger tab.
7. You can specify the following settings.
<table>
<thead>
<tr>
<th>Description</th>
<th>Settings</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PVD Host</strong></td>
<td>127.0.0.1</td>
</tr>
<tr>
<td><strong>PVD Port</strong></td>
<td>5425</td>
</tr>
<tr>
<td><strong>PVD Timeout</strong></td>
<td>10</td>
</tr>
<tr>
<td><strong>PVD Transport Type</strong></td>
<td>Network</td>
</tr>
<tr>
<td><strong>PVD Auto Connect</strong></td>
<td>Disabled</td>
</tr>
<tr>
<td><strong>PVD Reconnect</strong></td>
<td></td>
</tr>
</tbody>
</table>

**PhysXption**

**PVD Settings**

**PVD Host**
address of the PVD. The default is 127.0.0.1 (localhost).

**PVD Port**
the PVD monitors. The default is 5425.
### PhysX Option

#### PVD Settings

<table>
<thead>
<tr>
<th>PVD Settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timeout</td>
<td>Timeout, in seconds, used to connect to the PVD. The default is 10.</td>
</tr>
</tbody>
</table>
PhysX

PVD Settings

Transport Type

Supports writing to a TCP/IP network or a file. You can specify the following options:

- **Network**
  - All scene information is sent through the network to the debugger.

- **File**
  - All scene information is written to a file. The file can be loaded into the debugger offline.

The default
**PhysX Option**

**PVD Settings** is **Network**.

**PVD** automatically **Autoconnects** the **Lumberyard Editor** to the PhysX Visual Debugger.

You can specify the following options:

- **Disabled**
- **Editor**
- **Game**

To set this option, you must enable the **PhysX Debug** (p. 1188) gem.
<table>
<thead>
<tr>
<th>PVD Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reconnect</td>
<td>Specifies whether to reconnect when switching between editor and gameplay mode.</td>
</tr>
</tbody>
</table>

Enabled by default.

As a best practice, leave this setting enabled. If you clear this option, the PhysX Visual Debugger continues to record data. This can impact performance.

To set this option, you must enable the PhysX Debug (p. 1188) gem.
8. To verify that the PVD is connected to Lumberyard, for **PVD Auto Connect**, choose **Game** or **Editor** and then enter gameplay or editor mode. Depending on what you choose, the following message appears in the console.

   (PhysX) – Successfully connected to the PhysX Visual Debugger (PVD).

9. Open the PhysX Visual Debugger to view the recorded information.

**Example**

![PhysX Visual Debugger](image)

10. You can also manually connect or disconnect from the PVD using the following console variable commands.

   ```
   physx_PvdConnect
   physx_PvdDisconnect
   ```

   For more information, see *Debugging PhysX (p. 2826).*

### PhysX World Programming Notes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
For physics objects to be simulated, they must exist inside a world. Multiple worlds can have uses like the following:

- To simulate the result of an action in the first world. For example, the second world might show what a tower of blocks might look like five seconds from now if it were knocked over in the first world.
- To simulate a subset of objects that you don't want to interact with the rest of the world. For example, you could simulate the movement of objects attached to a player's belt.
- To overcome hardware or software limits on a single large world. By tiling the single world into multiple smaller worlds and moving objects among them, you can create the illusion of a single large world.

The PhysX gem automatically creates a world inside ActionGame with the default ID of AZPhysicalWorld. By default, all objects are added to this world and simulated each frame. You can find the source code in the following directory: lumberyard_version\dev\Gems\CryLegacy\Code\Source\CryAction\ActionGame.*

World ID

Every world created in the PhysX gem is addressable by an ID of type AZ::Crc32. Use this ID to address the WorldRequestBus.

If you have a single world in your game, you can use BroadcastResult to invoke WorldRequestBus, as in the following example:

```c++
// Single world setup
RayCastHit choose;
WorldRequestBus::BroadcastResult(choose, &WorldRequests::RayCast, request);
```

If you have a multi-world game, use EventResult and pass in the world ID, as in the following example:

```c++
// Multiple world setup
RayCastHit choose;
WorldRequestBus::EventResult(choose, AZ_CRC("AZPhysicalWorld"), &WorldRequests::RayCast, request);
```

**Note**

If your game creates multiple worlds, it must manage the objects that are added into those worlds.

### Step Constants

You can configure step constants for Physics::WorldSettings when PhysXWorld is created. For more information, see World Configuration (p. 2775).

## Physics materials

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Physics materials define how a PhysX collider reacts to collisions through properties like friction and restitution (bounce). In Lumberyard, you specify physics materials for each PhysX collider and store
them inside a physics material library that you create with the Asset Editor. One library can store all the physics materials for a project or separate libraries can be made for different physics material types.

**Tip**
Having one library makes it easier to see all the physics materials and their properties in a project.

**Topics**
- Physics material properties (p. 2798)
- Create a physics material (p. 2799)
- Assign a physics material library (p. 2800)
- Assign a physics material (p. 2802)
- Assign physics materials per face (p. 2802)
- Terrain physics materials (p. 2803)

### Physics material properties

![Asset Editor](image)

**Surface Type**
Name of the physics material.

**Dynamic Friction**
The friction coefficient when the PhysX collider is moving.

\[0.0\]: No friction.

**Static Friction**
The friction coefficient when the PhysX collider is still.
Create a physics material

Physics materials define the physical properties of PhysX colliders. To create physics materials, you first create a physics material library.

To create a physics material

1. Choose Asset Editor from the Tools menu.
2. In the Asset Editor, choose New, Physics Material from the File menu to create a new physics material library.
3. Create a physics material in the library by clicking the + on the right.

4. Name the physics material by editing the **Surface Type** property. Set the material properties as desired.

   **Note**
   You can add additional physics materials to the library by repeating the preceding two steps.

5. Choose **Save As** from the **File** menu in the Asset Editor to save the library and physics material.

### Assign a physics material library

Physics materials can be assigned to entire PhysX colliders, or on a per-face basis if the PhysX mesh is a triangle mesh. To assign a material, you first assign the library containing the desired physics material.
To assign a physics material library

1. Your project has a default physics material library. When new PhysX collider components are added to entities, the default physics material library is assigned to the collider. To change the default physics material library, choose PhysX Configuration from the Tools menu. In the Global Configuration tab, click the ... button to the right of Default Physics Material Library to change the default library.

![PhysX Configuration Screen](image)

Note
The default physics material library cannot be removed. If the default physics material library is deleted or invalid, a new library named SurfaceTypeMaterialLibrary is created automatically when the editor is opened.

2. Newly added PhysX Collider components have the default physics material library assigned. A default physics material library assignment appears in gray text in the component properties. To change the physics material library assigned to a collider, click the ... button to the right of Physics Material - Library in the PhysX Collider component properties. To reset to the default physics material library, click the x button to the right of Physics Material - Library in the PhysX Collider component properties.

![PhysX Collider Screen](image)
Assign a physics material

When the Physics Asset shape is selected, and Physics Materials from Mesh is enabled, the physics material for this collider is automatically set based on the surface type in the mesh's material. To manually set the physics material, uncheck the Physics Materials from Mesh property and select the physics material from the Mesh Surfaces - Entire object property list to assign it.

Warning

There is a known issue where switching physics material libraries between colliders such as Ragdoll PhysX components will not update the physics material list to the newly assigned physics material library. To update the physics material list, click on another collider, then back on the initial collider.

Assign physics materials per face

Static entities that have PhysX collider triangle mesh assets can have physics materials assigned per face. You define physics material placement by assigning placeholder materials to the faces of the triangle collision mesh in a content creation application. The names of placeholder materials become physics material properties of the collider component.

For more information on creating PhysX collider mesh assets, see FBX Settings PhysX export (p. 439).

Note

You can use the names of the placeholder materials to automate material assignment in Lumberyard by using an _ in the placeholder material name. The FBX exporter
parses placeholder material names found on PhysX collider mesh assets as PropertyName_PhysicsMaterialName.

- A placeholder material named Road creates a physics material property named Road on the collider component under Mesh Surfaces.
- A placeholder material named Road_Dirt creates a physics material property named Road and attempts to assign the physics material named Dirt to the Road property, assuming that the assigned physics material library contains a physics material named Dirt.

In the example below, the PhysX collider mesh asset has two placeholder materials, Mud and Grass. The FBX exporter creates physics material properties using the placeholder material names, and corresponding physics materials are assigned from the physics material library.

**Terrain physics materials**

Terrain is assigned the default physics material. Use the Terrain Texture Layers (p. 1232) editor to assign materials to different surface types.
Lumberyard User Guide

PhysX Scene Queries

Note

- To add terrain physics materials, you must have a PhysX Terrain (p. 767) component in your scene.
- To ensure that the engine generates a unique surface ID that can be assigned with the physics material, you must change the layer's material. If multiple layers share the same surface ID, they must have the same physics material assigned.

PhysX Scene Queries

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use physics raycast and shape cast queries to determine whether a specific line segment intersects physics geometry. For example, you might want to determine what object is in front of another object, or test a line of sight. For a shape cast, the line segment is in the form of a desired
shape (for example, a sphere). All scene queries are performed on a `Physics::World` object. For more information, see PhysX World Programming Notes (p. 2796).

You can use scene queries to find nearby objects using the following methods.

**Topics**
- Raycast (p. 2805)
- Shapecast (p. 2808)
- Overlap (p. 2810)

**Note**
Scene queries can have a performance cost.

**Raycast**

Raycast queries are the most common scene query. A raycast query takes a point and direction, with a distance, and returns the closest collider that intersected the ray.

**Example**

The raycast query intersects the pentagon only.

To perform a raycast query, use the `WorldRequestBus`.

**Example RayCast Closest**

```cpp
Physics::RayCastRequest request;
Physics::RayCastHit result;
WorldRequestBus::BroadcastResult(result, &WorldRequests::RayCast, request);
```

You can also retrieve objects that intersect with the ray by using the multiple version.

**Example RayCast Multiple**

```cpp
Physics::RayCastRequest request;
vector<Physics::RayCastHit> results;
WorldRequestBus::BroadcastResult(result, &WorldRequests::RayCastMultiple, request);
```
**Note**
You can specify the maximum number of hits that can be collected from a RayCastMultiple query. You can specify the **RayCast Buffer Size** property in the **PhysX Configuration** window. For more information, see World Configuration (p. 2775).

The following tables describe the properties for the RayCastRequest and RayCastHit objects.

### RayCastRequest Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>m_distance</strong></td>
<td>Maximum distance along the ray to test for intersections.</td>
</tr>
<tr>
<td><strong>m_start</strong></td>
<td>World space point where the ray starts.</td>
</tr>
<tr>
<td><strong>m_direction</strong></td>
<td>Direction to cast the ray. This vector must be normalised.</td>
</tr>
<tr>
<td><strong>m_collisionGroup</strong></td>
<td>Specifies which layers to test against. Use this to test only against specific layers.</td>
</tr>
<tr>
<td><strong>m_filterCallback</strong></td>
<td>Custom callback function provided</td>
</tr>
</tbody>
</table>
**Raycast**

*Property*

**m_queryType**

Include either static, dynamic objects, or both.

---

**RayCastHit Properties**

*Property*

**m_distance**

Distance along the ray at which the hit was found.

**m_position**

Position in world space of the hit.

**m_normal**

Normal in world space of the hit surface.

**m_body**

Body that was hit.
Shapecast

A shapecast query is similar to a raycast query except that a shapecast query takes a shape as well as a point and direction. The shape is swept along the ray to form a volume. Anything that intersects with this volume is returned from the query.

Example

The shapecast query is in the shape of a sphere and intersects with the rectangle and pentagon entities.

Example ShapeCast Closest

```cpp
Physics::ShapeCastRequest request;
Physics::RayCastHit result;
WorldRequestBus::BroadcastResult(result, &WorldRequests::ShapeCast, request);
```

Similar to raycasting, there is a multiple version for retrieving all objects that intersect with the volume.
Example ShapeCast Multiple

```cpp
Physics::ShapeCastRequest request;
vector<Physics::RayCastHit> results;
WorldRequestBus::BroadcastResult(results, &WorldRequests::ShapeCastMultiple, request);
```

**Note**
You can specify the maximum number of hits that can be collected from a ShapeCastMultiple query. You can specify the **Shapecast Buffer Size** value in the **PhysX Configuration** window. For more information, see World Configuration (p. 2775).

ShapeCastRequest Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>m_distance</td>
<td>Maximum distance along m_direction to test.</td>
</tr>
<tr>
<td>m_start</td>
<td>Transform in world space where the shape cast begins.</td>
</tr>
<tr>
<td>m_direction</td>
<td>Direction to cast. The vector must be normalised.</td>
</tr>
<tr>
<td>m_shapeConfiguration</td>
<td>Shape that should be swept along the ray.</td>
</tr>
<tr>
<td>m_collisionGroup</td>
<td>Specifies which layers to test against. Use</td>
</tr>
</tbody>
</table>
**Overlap**

Overlap queries are simpler, as they don’t take a direction or distance. Overlap queries simply return all objects that intersect a shape at specified location in the world. There is only one multiple version using this method.

**Example**

The overlap query is a sphere shape that intersects with both entities.
Example Overlap Closest

```cpp
Physics::OverlapRequest request;
vector<Physics::OverlapHit> results;
WorldRequestBus::BroadcastResult(results, &WorldRequests::Overlap, request);
```

**Note**
You can specify the maximum number of hits that can be collected from an overlap query. You can specify the Overlap Query Buffer Size value in the PhysX Configuration window. For more information, see World Configuration (p. 2775).

OverlapRequest Properties

- **m_pose**: Transform in world space of the shape.
- **m_shapeConfiguration**: Shape to use for the overlap.
- **m_collisionGroup**: Specifies which layers to
Overlap

Property

Description

test against. Use this to test only against specific layers.

m_filterCallback

Custom callback function provided by the same to filter out specific entities.

m_queryType

Includes static, dynamic, or both.

OverlapHit Properties

Property

Description

m_body

Body that was hit.

m_shape

Shape on the body that was hit.

m_material

Material on the shape that was hit.
Dynamic joints with PhysX

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

PhysX joint components constrain the position and orientation of one PhysX rigid body called the **follower**, relative to another PhysX rigid body, called the **leader**. The leader rigid body will have rotational freedom in zero, one, or two axes around the joint, depending on the type of PhysX joint.

The example image below is a simple demonstration of the three joint types. In each example, the blue sphere is the follower rigid body. The joints are centered on their respective follower rigid bodies. The red sphere is the leader rigid body. For clarity, the ball joint and hinge joint follower rigid bodies are set to fixed positions, but they can be dynamic rigid bodies like the fixed joint example. Also note that the joints can be offset from the follower rigid body using the **Local Position** and **Local Rotation** properties of the joint component.

Contents
- PhysX joint types (p. 2814)
- PhysX joint setup (p. 2814)
- PhysX Joint configuration (p. 2815)
  - Position mode (p. 2815)
  - Rotation mode (p. 2815)
  - Snap position mode (p. 2816)
- Snap rotation mode (p. 2817)
- Maximum Force and Maximum Torque modes (p. 2818)
- Swing limits mode (p. 2819)
- Twist limits mode (p. 2820)
- Stiffness and Damping modes (p. 2821)
- Notes on stability (p. 2822)

PhysX joint types

See the linked component reference below for information on the three PhysX joint types:

- PhysX Ball Joint component reference (p. 726) - The PhysX Ball Joint component allows freedom of rotation of the leader rigid body in two axes.
- PhysX Fixed Joint component reference (p. 745) - The PhysX Fixed Joint component does not allow freedom of rotation of the leader rigid body in any axis.
- PhysX Hinge Joint component reference (p. 755) - The PhysX Hinge Joint component allows freedom of rotation of the leader rigid body in one axis.

PhysX joint setup

The setup for each joint type is the same.

To set up a PhysX joint

1. Create an entity for the joint and the follower rigid body.
   a. Create a new entity. Right click in Perspective and choose Create entity from the context menu.
   b. Add a PhysX Rigid Body component to the entity.
   c. Add a PhysX Collider component to the entity. This is required for angle limits to work correctly. Joints still work without a PhysX Collider component but angle limits and might not be enforced. This is also true when using trigger colliders.
   d. Add one of the PhysX joint components:
      - PhysX Ball Joint
      - PhysX Fixed Joint
      - PhysX Hinge Joint
   e. The joint's position and orientation are expressed as an offset from the follower. Adjust the position and orientation of the joint by changing the Local Position and Local Rotation fields in the PhysX joint component.

2. Create an entity for the leader rigid body.
   a. Create a new entity.
   b. Add a PhysX Rigid Body component to the entity.
   c. Add a PhysX Collider component to the entity.

3. Assign the leader entity to the Lead Entity property of the PhysX joint.
   a. In the Joint component, click the Target button to the right of the Lead Entity property to start entity selection.
   b. In Perspective, click on the leader entity to select it and assign it to the Lead Entity property.
PhysX Joint configuration

Joint components have an **Edit** button that enables component edit mode. In component edit mode, you can edit the properties of the joint in **Perspective**. You can use one of several edit contexts in component edit mode. Press the **Tab** key to cycle through the edit mode contexts. The current context is displayed at the bottom of the **Perspective** pane.

**Position mode**

**Applies to:** All Joints

Position mode displays a translate gizmo that you can click and drag to adjust the **Local Position** of the joint relative to the entity transform.

**Rotation mode**

**Applies to:** All Joints
Rotation mode displays a rotation gizmo that you can click and drag on any axis to adjust the Local Rotation of the joint relative to the entity transform.

**Snap position mode**

**Applies to:** Ball Joint and Hinge Joint
Snap position mode displays a highlight bounding box and target when you hover over an entity. Click the entity to snap the joint **Local Position** to the highlighted entity's position. If **Select Lead on Snap** is enabled in the joint properties, the entity will be assigned to the joint's **Lead Entity** property. Any entity can be selected except the follower entity.

**Snap rotation mode**

**Applies to:** Ball Joint
Snap rotation mode displays a highlight bounding box and target when you hover over an entity. Click the entity to snap the joint **Local Rotation** to the highlighted entity's rotation. Any entity can be selected except the leader entity.

**Maximum Force and Maximum Torque modes**

**Applies to:** All Joints
Maximum force and maximum torque modes display a gray box that you can click and drag to adjust the **Maximum Force** and **Maximum Torque** properties. The maximum force and maximum torque modes and properties are available only when the **Breakable** property is enabled for the joint.

### Swing limits mode

**Applies to:** Ball Joint
Swing limits mode displays a ring gizmo at the local root of the joint that you can use to rotate the swing limits on the joint's x-axis, and a scale gizmo that you can use to scale the swing limits uniformly or non-uniformly on the joint's y- and z-axes. Swing limits mode is available only when the Limits property is enabled for the ball joint component.

**Twist limits mode**

**Applies to:** Hinge Joint
Twist limits mode displays two ring gizmos that you can click and drag to adjust the **Positive angular limit** and **Negative angular limit** properties. The red ring adjusts the positive limit and the green ring adjusts the negative limit. Twist limits mode is available only when the **Limits** property is enabled for the hinge joint component.

**Stiffness and Damping modes**

**Applies to:** Ball Joint and Hinge Joint
Stiffness and damping modes display a gray box that you can click and drag to adjust the Stiffness and Damping properties. The stiffness and damping modes and properties are available only when the Soft limit property is enabled for the joint.

Notes on stability

The iterative solver used by PhysX joints may not be able to maintain constraints in some configurations. For example, the solver might fail to converge. The result is unstable or unexpected motion during simulation. The PhysX documentation describes configurations that could help avoid such occurrences. Please see Configuring Joints for Best Behavior in NVIDIA’s PhysX Joint documentation.

Create global or localized wind forces with PhysX

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can create global wind forces or wind forces contained within a collider volume with the PhysX Force Region component. Wind forces act on PhysX entities, such as Cloth, that can be affected by wind.
1. Create an entity for the wind provider.

2. Add a Tag component to the entity. The Tag component will specify whether the wind force is global or localized to a collider volume.

3. Specify whether the wind provider will be global or localized. To determine what value to use for the tag component, from the File menu, choose PhysX Configuration. At the bottom of the Global Configuration tab there is a section labeled Wind Configuration.

<table>
<thead>
<tr>
<th>Wind Configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global wind tag</td>
</tr>
<tr>
<td>Local wind tag</td>
</tr>
</tbody>
</table>

Wind Configuration has properties for a Global wind tag and a Local wind tag. You may use the default values or set them as desired. These tags are used by the PhysX wind system to detect entities that provide wind data.

For this example use the Global wind tag property value. In the Tag component of the entity, add a tag element and give it the value global_wind.

**Note**
If you choose to use the Local wind tag, the wind will only affect entities that are inside the volume of the PhysX Collider you create in the next step.

4. Add a PhysX Collider component. If you are using the Local wind tag, this collider will define the volume of the wind force. With the Global wind tag, the size and position of this collider does not matter because the wind will be global, however, the collider will provide a useful visualization for the global wind force.

5. Set the PhysX Collider component’s Shape property to Box.

6. Scale and position the PhysX Collider component. Use the move tool to place the entity in the level, and set the Box Dimensions property in the PhysX Collider component as desired.

7. Add a PhysX Force Region component to the entity. The PhysX Force Region component creates the wind force.

8. In the PhysX Force Region component, specify 10.0 in the Direction property’s Y component to set a direction for the wind force.

9. In the PhysX Force Region component, specify 50.0 in the Magnitude property to create magnitude for the wind force.

The PhysX collider box in Perspective displays cones and vectors representative of the wind force direction.
10. To test the wind provider, add an entity with a **Cloth** mesh. There is an example slice asset you can drag into **Perspective** from **Asset Browser**. Navigate to **Gems\NvCloth\Assets\slices** in **Asset Browser**. Locate the `cloth_locked_corners_two.slice` and drag and drop the slice into **Perspective**.

11. Use the **Move** tool to place the cloth entity. If you are using the **Local wind tag**, you must place the cloth asset inside the **PhysX Collider** volume.
12. Press **Control + G** to test the wind simulation.
Debugging PhysX

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The PhysX system has the following features that you can use to debug issues.

**Note**
You must first enable the **PhysX Debug** (p. 1188) gem.

**Topics**
- PhysX Debug Console Variables (p. 2826)
- Debugging with the ImGui Tool (p. 2827)
- Debug Options in the PhysX Configuration (p. 2832)

**PhysX Debug Console Variables**

Enter the following console variables to debug your PhysX issues.

Sets your preferences for debugging. As a recommended best practice, enter this console variable command as your first step for debugging.

**Example**

```
physx_Debug 1
```

You can specify the following values:

- **1** – Enable debug visualizations. By default, this value enables the collision shapes and edges for your PhysX entities.
• 2 – Enables all configuration options. This enables all the available visualization options.
• 3 – Toggles the proximity based collider visualization. This value applies only to mesh colliders. See Physics asset colliders (p. 739).
• 0 – Disables debug visualizations.

Toggles a visual culling box frame.

**Example**

```plaintext
physx_CullingBox 1
```

Adjusts the culling box size to **100**. Enter 0 to disable culling.

```plaintext
physx_CullingBoxSize 100
```

Connects to the PhysX Visual Debugger. You must have the PhysX Visual Debugger open to run this command. See Debugger Configuration (p. 2790).

```plaintext
physx_PvdConnect
```

Disconnects from the PhysX Visual Debugger. You must have the PhysX Visual Debugger open to run this command. See Debugger Configuration (p. 2790).

```plaintext
physx_PvdDisconnect
```

For more information, see Using the Console Window (p. 210).

**Debugging with the ImGui Tool**

In game mode, you can configure the PhysX debug settings using the immediate mode graphical user interface (ImGui) tool.

**Note**
You must enable the ImGui gem to access this tool. For more information, see Enabling Gems (p. 1064).

**To debug with the ImGui tool**

1. Press **Ctrl+G** to enter gameplay mode.
2. Press the **Home** key to open the **ImGui** tool. The **PhysX Debug** menu appears under the **Perspective** viewport.
3. Click **PhysX Debug**.
Example

4. You can make the following changes.

<table>
<thead>
<tr>
<th>PhysX Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug visualizations</td>
<td>Enables debug visualizations mode.</td>
</tr>
<tr>
<td>PhysX Color Mappings</td>
<td></td>
</tr>
<tr>
<td>Visualize Colliders</td>
<td>Enables colliders to appear.</td>
</tr>
<tr>
<td>Culling</td>
<td></td>
</tr>
<tr>
<td>Collisions</td>
<td></td>
</tr>
<tr>
<td>Body</td>
<td></td>
</tr>
<tr>
<td>Contact</td>
<td></td>
</tr>
<tr>
<td>Character</td>
<td></td>
</tr>
</tbody>
</table>

This is the same as the `physx_Debug` console variable.

<table>
<thead>
<tr>
<th>PhysX Debug</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physics Debug</td>
<td></td>
</tr>
<tr>
<td>Disable all settings</td>
<td></td>
</tr>
<tr>
<td>PhysX Scale</td>
<td></td>
</tr>
</tbody>
</table>

Version 1.28
2828
Debugging with the ImGui Tool

### PhysX Debug Settings

- **console variable.**

### Culling

can specify the following options:

- **Wireframe**
  - Displays wireframes in the viewport.
- **Size**
  - Click and drag the slider to specify the size of the wireframes.
  
  As a best practice, keep this value small to prevent performance issues.
**Debugging with the ImGui Tool**

### Debug Settings

#### Collisions

Enables debugging for collision types. You can specify the following options:

- Shapes
- Edges
- Normals
- Aabbs
- Axis
- Compounds
- Static
- Dynamic

#### Bodies

Enables debugging for body types. You can specify the following options:

- Axes
- Mass Axes
- Linear Velocity
- Angular Velocity
**Contact**

deb ginning for contact types.
You can specify the following options:

- Point
- Normal

**Character**

deb ginning for characters.
You can specify the following options:

- Joint Limits
- Mbp Regions
- Actor Axes

**PhysX Color Mappings**

color mappings.
### Debug Options in the PhysX Configuration

You can also specify debug settings in the **PhysX Configuration** tool. See [Debugger Configuration](#) (p. 2790).

### PhysX Best Practices

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the [AWS Game Tech blog](#) to learn more.

See the following best practices when working with PhysX.

- Colliders intersecting with terrain can result in unexpected behavior. For example, the object might rocket into space, jitter, or slow down performance. Avoid intersecting colliders with terrain. If you need to intersect a collider with terrain, use a small value for the collider size. These scenarios can be...
mitigated by clearing the Persistent Contact Manifold check box in the Global Configuration tab in the PhysX Configuration tool.

- The PhysX Character Controller component must be on the same entity as the Actor component in order to work with the Animation Editor.

- If you select the Static check box in the Transform component for an entity that also has a PhysX Rigid Body component, the rigid body behaves statically and a warning appears about the incompatibility of the PhysX Rigid Body component and the Static transform option.

- When adding the PhysX Collider component to entities, prefer a primitive shape (box, capsule, or sphere) for the collider. These shape colliders offer better performance and should be used when possible.

**Warning**
Avoid non-uniform scaling on entities that have PhysX components.
If you must apply a non-uniform scale to an entity that has PhysX components, do the following:
1. Create a child entity under the entity with the PhysX components.
2. On the child entity, add a Mesh component.
3. Ensure that the Transform component uses non-uniform scaling.
4. Update the PhysX Collider dimensions as needed.
5. Update the center of mass so that it is the center of the object.

## Simulated destruction with NVIDIA Blast

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

With NVIDIA Blast in Amazon Lumberyard, you can simulate destruction by authoring blast assets in SideFX Houdini and creating entities with the Blast Family and Blast Family Mesh Data components.

To use NVIDIA Blast, you must enable the NVIDIA Blast gem (p. 1181).

**Note**
NVIDIA Blast for Lumberyard requires a SideFX Houdini commercial or indie license to create assets. The apprentice license is not sufficient. For more information on Houdini, see SideFX's home page.
The precompiled Houdini plug-ins supplied with the NVIDIA Blast gem require Houdini 18.0.

## NVIDIA Blast features

These are the features that NVIDIA Blast provides:

- Fracture geometry and author blast assets in SideFX Houdini with the provided Houdini plug-ins and Houdini Digital Assets (HDAs).
- Create multiple levels of destruction for simulation.
- Automatically process and quickly set up assets with the provided Python Asset Builder for NVIDIA Blast.
- Create blast materials to define the forces required to trigger destruction simulation on blast assets.
Using NVIDIA Blast

See the following topics for detailed information about NVIDIA Blast.

- **Blast Family component (p. 564)** - Blast Family component reference.
- **Blast Family Mesh Data component (p. 566)** - Blast Family Mesh Data component reference.
- **Install NVIDIA Blast plug-ins (p. 2835)** - Install the NVIDIA Blast plug-ins and Houdini Digital Assets.
- **Create assets for NVIDIA Blast (p. 2836)** - Fracture meshes in Houdini and export assets for NVIDIA Blast.
- **Processing assets for NVIDIA Blast (p. 2842)** - Process NVIDIA Blast assets for Lumberyard.
- **Simulate destruction with NVIDIA Blast (p. 2845)** - Create entities with NVIDIA Blast assets and simulate destruction.
- **Partial destruction with NVIDIA Blast (p. 2849)** - Use attributes to create partial destruction.
- **Specify destruction properties with Blast materials (p. 2851)** - Use a blast material to define the force required to trigger destruction.
- **NVIDIA Blast visual debugger (p. 2854)** - Use the visual debugger for NVIDIA Blast.
- **Script Canvas nodes for NVIDIA Blast (p. 2856)** - Script destruction simulation in Script Canvas.

**NVIDIA Blast references**

NVIDIA Blast documentation at the NVIDIA GAMEWORKS developer portal.

Install SideFX Houdini plug-ins for NVIDIA Blast

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To create NVIDIA Blast assets, you must install a set of plug-ins and Houdini Digital Assets for SideFX Houdini.

**Note**
NVIDIA Blast for Lumberyard requires a SideFX Houdini commercial or indie license to create assets. The apprentice license is not sufficient. For more information on Houdini, see SideFX's home page.

The precompiled Houdini plug-ins supplied with the NVIDIA Blast gem require Houdini 18.0.
Install NVIDIA Blast plug-ins

To install plug-ins

1. Run `install_plugin.bat` from the `houdini` directory located at `lumberyard_installation\dev\Gems\Blast\houdini`.
2. Grant the installer script administrator privileges when requested.
   
   The plug-ins are installed into various directories in `C:\Users\user_name\Documents\houdini18.0`.
3. To verify the installation, you can check for the following files in your Houdini user directory.
   
   The `C:\Users\user_name\Documents\houdini18.0\otls` directory contains these three files:
   - `blastExport.hda`
   - `fractureHierarchy.hda`
   - `fractureSingle.hda`

   The `C:\Users\user_name\Documents\houdini18.0\toolbar` directory contains these three files:
   - `default.shelf`
   - `Fracture.shelf`
   - `shelf_tool_assets.json`

   The `C:\Users\user_name\Documents\houdini18.0\dso` directory contains these five files:
   - `BlastExportPlugin.dll`
   - `BlastExportPlugin.exp`
   - `BlastExportPlugin.ilk`
   - `BlastExportPlugin.lib`
   - `BlastExportPlugin.pdb`

   The `C:\Users\user_name\Documents\houdini18.0\dependencies` directory contains eleven `NvBlast*\.dll` files and four `PhysX*\.dll` files.
4. Verify that the installation script has added your `houdini` user directory to the `PATH` environment variable in Windows:

   `C:\Users\user_name\Documents\houdini18.0`
Enable the Blast tool shelf

The NVIDIA Blast installation for Houdini includes a tool shelf that you can enable to speed up the process of creating assets for NVIDIA Blast.

To enable the Blast tool shelf

1. In Houdini, choose the + button in the Toolbar to the far right.
2. From the list, choose Shelves to expose the Shelf list.
3. From the Shelf list choose Fracture tools for Blast to add the shelf to the Toolbar.

Create assets for NVIDIA Blast

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Assets for NVIDIA Blast are created in Houdini with the provided tools and plug-ins. Follow the steps below to create and export blast assets for Lumberyard.

Note

These steps can be applied to any mesh. For best results, the mesh should be fully enclosed. Custom normals, UV sets, and vertex color streams can be applied to the root mesh and the resulting chunks.

Contents

- Fracture a mesh for NVIDIA Blast (p. 2837)
- Export an asset for NVIDIA Blast (p. 2841)
Fracture a mesh for NVIDIA Blast

To fracture a mesh

1. Create an object in Houdini containing a mesh. To avoid potential warnings and errors when runtime assets are generated, ensure you add UV and Normal attributes to the mesh.
2. At the SOP level, append a Name SOP to the geometry to be fractured.
3. In the Name SOP, enter root for the Name parameter. This applies a name primitive attribute to the geometry with the value root so that the root mesh can be identified.
4. You can use the Fracture Selection tool to automatically set up a fracture network. Before you continue, it's important to understand the two Houdini Digital Assets provided by the NVIDIA Blast gem to fracture geometry, Fracture Single and Fracture Hierarchy:
   - Fracture Single fractures the provided geometry into a specified number of chunks. Multiple levels of fracture can be created by appending a Fracture Single SOP to already fractured geometry.
   - Fracture Hierarchy fractures the provided geometry, and fractures the resulting chunks for each additional level specified by the Fracture levels parameter. If you specify 2 Fracture levels and 10
Fractures per level, the root geometry is fractured into ten chunks and each chunk is fractured into ten chunks.

Warning
The number of chunks generated by Fracture Hierarchy grows exponentially. Setting the Fracture levels and Fractures per level too high can generate assets that are too large to load and simulate with NVIDIA Blast. For fine control over multiple fracture levels, use multiple Fracture Single SOPs.

Note
Both Fracture Single and Fracture Hierarchy Houdini Digital Assets (HDAs) are created with standard Houdini SOPs. You can open these HDAs to view their network contents and use them as the basis for custom fracture SOPs for your projects.

The provided Fracture Selection tool adds a Fracture Single SOP and feeds the root mesh and the resulting chunks from the fracture operation into a Merge SOP.

With the Name SOP selected, choose Fracture Selection from the Fracture tools for Blast shelf. A Fracture Single SOP is appended to the network and input into a Merge SOP along with the root mesh. Note that the Fracture Single SOP specifies root as the Group to fracture and chunk as the Chunk name prefix.

5. To visualize the fracture:
   a. Ensure the Display flag is enabled on the Merge SOP.
   b. Choose the Display groups and attribute list toggle from the Display options toolbar to the right of the Perspective viewport. This enables the groups and attributes overlay in the Perspective viewport.
   c. In the groups and attributes overlay, choose the Gear button to open the list options.
d. In the list options, choose Attributes and select name to visualize the geometry by its name attribute. You can see the hierarchy of geometry in the list, and the mesh chunks are colored by their name primitive attribute in the perspective viewport.

Note
With Houdini’s geometry select mode set to primitive, you can press the S key to enter select mode and click on any chunk, at any level, in the groups and attributes overlay, to select that chunk and its descendants.

6. It might be difficult to see where the mesh is fractured if the root geometry is complex. You can use Exploded View to better inspect the fracture result. To see an exploded view of the fractured mesh:

   a. Append a Partition SOP to the Merge SOP.
   b. Append an Exploded View SOP to the Partition SOP.
   c. Enable the Display flag on the Exploded View SOP.
7. Fractures can be hierarchical, that is, a fracture chunk can be further fractured. To add an additional fracture level:
   
a. Add a Fracture Single SOP to the network.

b. Connect the output of the Fracture_root SOP to the input of the newly added Fracture Single SOP.

c. Connect the output of the newly added Fracture Single SOP to the input of the Merge SOP.

d. In the Fracture Single SOP, specify a chunk to fracture. In the example below, chunk1 (the rabbit's face) is specified in the Group to fracture parameter using the path root/chunk1.
Export an asset for NVIDIA Blast

With the mesh fractured, you must export .fbx and .blast assets to be processed by Asset Processor for use in Amazon Lumberyard.

To export an asset

1. Add a Blast Export SOP to the network.
2. Connect the output of the Merge SOP to the input of the Blast Export SOP.
3. Ensure the Root Name and Chunk name prefix parameters are properly set.
4. Set the Object name parameter to the desired name. The exported .fbx and .blast files are named by this parameter’s value.
5. Set the Output Directory parameter. By default, the .fbx and .blast files are exported to the directory where the Houdini scene file is saved.
6. Disable the Static root parameter.

- If the Static root parameter is enabled, the root mesh is a static rigid body and unaffected by gravity. Sufficient force fractures the root mesh and the chunks are dynamically simulated.
- If the Static root parameter is disabled, the root mesh is dynamic, treated like a rigid body, and affected by gravity. Sufficient force fractures the root mesh and the chunks are dynamically simulated.

Note
All chunks are simulated as dynamic rigid bodies. You can make non-root chunks into static rigid bodies by adding the word static to the name primitive attribute of the non-root
chunk. This is useful for scenarios where you want to destroy part of an entity while leaving part of the entity in place. For more information, see Partial destruction with NVIDIA Blast (p. 2849).

7. Choose **Export Blast Asset** to generate a `.blast` asset.

8. Choose **Export FBX** to generate a `.fbx` asset.

### Processing assets for NVIDIA Blast

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. **Download O3DE** or visit the **AWS Game Tech blog** to learn more.

Blast assets that are exported from Houdini must be processed by **Asset Processor** to generate run-time assets. There are two methods for processing Blast assets for use in Lumberyard: an automated method using Python Asset Builder, and a manual method where you select the meshes to be processed.

**Important**

Processing meshes automatically is less time consuming than manually setting up blast meshes to process. It is important to understand both processes, however. You might use the automatic process for the initial export and then manually edit the mesh assets to add modifiers for custom normals or vertex color streams.
Once you have manually edited the .fbx asset in FBX Settings, a .assetinfo file is created for the .fbx asset. The .assetinfo file prevents the mesh assets from being processed automatically by Python Asset Builder. Any further changes made to the source .fbx file, such as adding or removing fracture levels or chunks, must be manually edited in FBX Settings.

Contents

- Process Blast assets automatically (p. 2843)
- Process Blast mesh assets manually (p. 2844)

Process Blast assets automatically

When blast assets are processed automatically, a blast slice asset is created that adds the blast mesh chunks to the Blast Family Mesh Data component. If you have a blast asset with dozens of chunks, automatic processing with the Python asset builder for NVIDIA Blast can save some time.

**Note**
Automatically processing assets for NVIDIA Blast requires that your project has been built with the Python Asset Builder and EditorPythonBidnings gems enabled. For more information, see Python Asset Builder gem (p. 1192).

To process Blast assets automatically

1. Copy the .blast and .fbx files for your Blast asset into an asset directory in your project.
2. Start Lumberyard Editor. Asset Processor detects the .blast and .fbx files and generates the runtime mesh assets, a blast asset, and a blast slice asset.
3. You can verify that the assets have processed successfully in the Jobs tab of Asset Processor. If you need to reprocess the assets, do the following:
   a. In Asset Processor, select the Assets tab.
   b. Right-click the asset in the asset list to open the context menu.
   c. Choose Reprocess File from the context menu.
Process Blast mesh assets manually

Manually processing blast assets requires you to add a mesh group for each chunk mesh so that Asset Processor can generate the run-time asset. Manual processing also requires you to add each run-time mesh to the Blast Family Mesh Data component. If you need to add modifiers to the blast mesh chunks, such as specifying a vertex color stream, you must use this manual process.

To process Blast assets manually

1. Copy the .blast and .fbx files for your Blast asset into an asset directory in your project.
2. Start Lumberyard Editor.
3. Locate the .fbx asset in Asset Browser and double-click on the asset to open FBX Settings.
4. Choose the Meshes tab.
5. Create one Mesh group for each mesh in the .fbx asset.
   a. If there is an existing Mesh group, ensure it has only the first mesh selected from the Select Meshes list.
   b. Add a new Mesh group by choosing Add another mesh.
   c. Add the next mesh to the new Mesh group by choosing the Hierarchy button to the right of Select meshes and selecting the next mesh from the list.
   d. Repeat steps b and c until each mesh in the mesh list is assigned to its own Mesh group.
6. **Optional:** If the meshes require special processing, such as a vertex color stream provided by the *Mesh (Advanced)* modifier, add modifiers to each mesh group as required.

7. Choose the **Update** button in the bottom right of *FBX Settings*. *Asset Processor* generates the run-time assets. A **File progress** window appears and displays feedback about the process.

**Simulate destruction with NVIDIA Blast**

This feature is an **experimental** release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. **Download O3DE** or visit the **AWS Game Tech blog** to learn more.
To use NVIDIA Blast assets in Lumberyard, create an entity, add a **Blast Family** component, add a **Blast Family Mesh Data** component, and then assign the blast assets to the components.

**Note**

To quickly test NVIDIA Blast simulation, the following steps assume that the assets have been exported from Houdini with **Static root** disabled in the **Blast Export** SOP. With **Static root** disabled, the NVIDIA Blast asset is dynamic, and destruction can be triggered by dropping the entity on a PhysX collision surface such as **PhysX Terrain**. If **Static root** is enabled, the root asset is static, and destruction must be triggered by an external force, such as a projectile impact. For more information, see Create assets for NVIDIA Blast (p. 2836).

**Contents**

- Create an entity for NVIDIA Blast (p. 2846)
- Add automatically processed mesh assets to a NVIDIA Blast entity (p. 2847)
- Add manually created mesh assets to a NVIDIA Blast entity (p. 2847)
- Test NVIDIA Blast destruction simulation (p. 2848)

### Create an entity for NVIDIA Blast

When you create an entity, you add the NVIDIA Blast functionality and define how the asset destructs.

**To create an entity for NVIDIA Blast**

1. Ensure that the terrain has a **PhysX Terrain** level component. In **Level inspector**, choose **Add Component** and select **PhysX Terrain** from the component list.
2. Create a new entity. Right-click in **Perspective** and choose **Create entity** from the context menu.
3. Add a **Blast Family** component to the entity. In **Entity Inspector**, choose **Add Component** and select **Blast Family** from the component list. The **Blast Family** component adds NVIDIA Blast functionality to the entity. For more information, see **Blast Family component** (p. 564).
4. Set the **Blast asset** for the **Blast Family** component. Click the **Folder** button to the right of the **Blast asset** property and choose the `.blast` asset in the Blast Asset selection window.
5. Set the **Blast Material** for the **Blast Family** component. Blast materials define how much damage various forces cause to the bonds holding the fractured asset together, and how much damage is required to cause destruction. For more information see Specify destruction properties with Blast materials (p. 2851).

6. Add a **Blast Family Mesh Data** component to the entity. In Entity Inspector, Choose Add Component and select **Blast Family Mesh Data** from the component list. The **Blast Family Mesh Data** component adds NVIDIA Blast meshes to the entity. For more information, see **Blast Family Mesh Data component** (p. 566).

If you have processed your mesh assets with **Python Asset Builder**, follow the steps in the section: Add automatically processed mesh assets to a NVIDIA Blast entity (p. 2847).

If you have manually edited your mesh assets with **FBX Settings**, follow the steps in the section: Add manually created mesh assets to a NVIDIA Blast entity (p. 2847).

**Add automatically processed mesh assets to a NVIDIA Blast entity**

**Python Asset Builder** creates a blast_slice asset when it processes your NVIDIA Blast assets. The blast slice automatically adds the mesh assets and material to the **Blast Family Mesh Data** component.

**To add automatically processed mesh assets**

1. In the **Blast Family Mesh Data** component, set a material for the Blast mesh. Click the **Folder** button to the right of the **Material** property and select a material from the material selection window.

2. In the **Blast Family Mesh Data** component, set the **Blast Slice** property. Click the **Folder** button to the right of the **Blast Slice** property and select the asset from the Blast Slice selection window.

Enable the **Show mesh assets** property if you would like to view the mesh list.

3. The entity is now set up to simulate destruction. Continue to the section: Test NVIDIA Blast destruction simulation (p. 2848).

**Add manually created mesh assets to a NVIDIA Blast entity**

If your NVIDIA Blast mesh assets have been manually edited in **FBX Settings**, use the following steps to add the mesh assets to the entity.
To add manually processed assets

1. In the **Blast Family Mesh Data** component, set a material for the Blast mesh. Click the **Folder** button to the right of the **Material** property and select a material from the material selection window.

2. In the **Blast family mesh data** component, enable the **Show mesh assets** property to show the mesh asset list.

3. Add a mesh slot to the list. Choose the + button to the right of **Mesh assets** to add a mesh slot to the **Mesh assets** list.

4. Add a mesh to the list. Click the **Folder** button to the right of the numbered mesh slot property and select a mesh asset from the **Static Mesh** selection window.

5. Repeat steps 3 and 4 until all of the meshes for the blast asset have been added to the **Blast family mesh data** component.

6. The entity is now set up to simulate destruction. Continue to the section: Test NVIDIA Blast destruction simulation (p. 2848).

Test NVIDIA Blast destruction simulation

Because the blast asset has been exported from Houdini with **Static root** disabled, and a **PhysX Terrain** level component has been added to the level, destruction can be tested by dropping the object on the terrain.

To test the destruction simulation

1. With the entity selected, press the Z key to enable the move tool.

2. Click and drag on the Z axis of the move gizmo to move the entity several units above the terrain.

3. Press Control + P to view simulation. The entity drops and shatters when it collides with the terrain.

4. Press Control + P to end the simulation.
Partial destruction with NVIDIA Blast

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In some scenarios, you might want to partly destroy an entity. For example, you create a destructible wall, but want the bottom of the wall to remain in place as a static mesh with colliders after the top of the wall takes damage from a projectile and is destroyed. You can achieve this by adding static to the name primitive attribute of non-root mesh chunks in Houdini.

Make non-root chunks static in NVIDIA Blast

Use Houdini to make non-root chunks static, which results in partial destruction of the asset.
To make non-root chunks static

1. In Houdini, add an Attribute String Edit SOP to the network.
2. Wire the Attribute String Edit SOP into the network.
   a. Connect the output of the Merge SOP to the input of the Attribute String Edit SOP.
   b. Connect the output of the Attribute String Edit SOP to the input of the Blast Export SOP.
3. In the Attribute String Edit SOP, in the Attributes tab, enable the Primitives parameter, and select the name attribute from its list.
4. In the Attribute String Edit SOP, in the Filter tab, set the From parameter to the path name of a chunk you would like to make static, such as root/chunk5.
5. In the Attribute String Edit SOP, in the Filter tab, set the To parameter to the same path as above. Append static to the path; for example, root/chunk5static.

   **Important**
   If the specified chunk has been fractured, its descendants are also static when exported to Lumberyard.
6. You can add additional chunks to the Attribute String Edit SOP. Choose the + icon next to the Number of filters parameter to add a filter. Repeat steps 4 and 5 to make another chunk static.

In the image below, the chunks that comprise the back half of the rabbit have been made static. Note that 12 filters have been added to the filter list in the Attribute String Edit SOP. You can see the renamed chunks in the groups and attributes overlay in the perspective viewport.

7. Enable the Static root parameter in the Blast Export SOP before exporting the asset.

See the result simulation in Lumberyard below. A large, invisible PhysX rigid body collider is dropped on the rabbit. The front half of the rabbit is destroyed. The chunks are simulated as dynamic rigid bodies while the back of the rabbit remains in place.
Specify destruction properties with Blast materials

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The chunks of blast assets are held together by bonds. Blast materials determine what types of forces can damage the bonds, the minimum amount of force that can damage the bonds, and how much damage the bonds can sustain before breaking.

Important
Blast materials are critical component in creating realistic destructible entities. Passive forces like gravity can have a cumulative damage effect on a blast asset, causing destruction to trigger when no obvious external force or collider has acted on the asset. Large-scale destructible assets such as buildings have large chunks that require stronger bonds and higher damage thresholds to prevent premature triggering of destruction.

Contents
• Create Blast materials (p. 2852)
• NVIDIA Blast configuration (p. 2852)
• Blast material properties (p. 2852)
Create Blast materials

Blast materials are stored in a blast material library. The blast material library for the project is set in the Blast Configuration editor. You can assign a blast material in the Blast Family component of the entity. 

To create a blast material

1. In the Tools menu, choose Asset Editor.
2. In Asset Editor, choose New from the File menu, and select Blast Material. A new Blast Material appears in the Asset Editor.
3. Set the Material name property. This property is the identifier that you use to assign the blast material to a Blast Family component.
4. Set the blast material properties. For information, see Blast material properties (p. 2852) below.
5. Additional Blast materials can be created by choosing the + button in the upper right corner of the Blast material list.
6. Save the Blast material library. In Asset Editor, in the File menu, choose Save as.
7. In the Save as... window, navigate to an appropriate directory in your project, give the blast material library a name, and choose Save.

NVIDIA Blast configuration

The blast material library for the project is set in Blast Configuration.

To use Blast Configuration

1. From the Tools menu, choose Blast Configuration.

2. Set the Blast material library for your project. Choose the Folder button to the right of Blast material library and select the blast material library that you created.
3. Set the Stress solver iterations property. Stress damage is generated by impact forces. This property sets the number of iterations that the stress solver computes per tick, for each Blast Family component. Valid values range from 0 to 50000.

You can now assign blast materials from the blast material library to Blast Family components.

Blast material properties

Blast materials function on the concepts of health and damage. Chunks are held together by bonds. Each bond has some amount of health. Damage to the bonds is dealt by impulse forces acting on the chunks. Impulse forces generate damage in two ways:

- **Vector damage** is generated by impulse forces such as a shock wave, wind, or gravity applied to the Blast entity.
• **Stress damage** is generated by impulse forces from impacts such as a projectile colliding with the Blast entity.

Material name

The name of the material. Use this identifier to select the material from the library for **Blast Family** components.

**Health**

Each bond has a default health of 1.0. The Health property is multiplied by the default bond health to set the health of all bonds in the Blast asset.

Vector damage is subtracted from Health. When Health reaches 0.0, the bond is destroyed.

Stress damage treats Health as a threshold. Damage is not applied unless the threshold is exceeded in a given tick.

**Force Divider**

Force Divider is a hardness divisor that keeps the scale of impulse forces in a reasonable range to limit stress damage.

Vector damage is given as a scalar and is not affected by Force Divider.

Stress damage calculations factor in the number of connected bonds, making the asset significantly harder to destroy. Stress damage is computed as StressDamage = ImpulseForce / (ForceDivider * ConnectedBonds).

**Minimum damage threshold**

The floor value for vector damage. If the vector damage value is less than the minimum threshold value, then the damage is ignored. If the vector damage value is greater than the minimum threshold value, then the vector damage value is checked against the **Maximum damage threshold**.

**Maximum damage threshold**

The ceiling value for vector damage. If the vector damage value is less than the maximum threshold value, then the damage is subtracted from Health. If the vector damage value is greater than the maximum threshold value, then only the value of Maximum damage threshold is subtracted from Health.

**Stress linear factor**

A factor applied to linear forces during stress damage. The default value is 1.0.
Stress angular factor

A factor applied to angular forces during stress damage. The default value is 1.0.

NVIDIA Blast visual debugger

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To use the visual debugger for NVIDIA Blast, enable the BLAST_DEBUG console variable.

To enable the variable

1. In the editor console, enter `BLAST_DEBUG 1`.
2. Click in Perspective to make the viewport active.
3. Press the F3 key to set the view to wireframe.
4. Press Control + P to run the simulation and view the debugger.
5. Press Control + P to exit the simulation.

In the below example, as the rabbit drops, the bonds between the fractured chunks are shown as green lines. On impact, the bonds change to orange as they weaken and red when they break.
Script Canvas nodes for NVIDIA Blast

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The NVIDIA Blast gem includes several Script Canvas nodes to script destructible assets. The nodes can be found in the Blast group in Script Canvas.

Contents
- BlastFamilyComponentNotificationBus nodes (p. 2856)
- BlastFamilyComponentNotificationBus nodes (p. 2856)
- BlastFamilyDamageRequestBus nodes (p. 2856)

BlastFamilyComponentNotificationBus nodes

On Actor Created

Event notification that is invoked whenever an actor is created from a destroyed object used in the given entity.

On Actor Destroyed

Notification that is invoked whenever an actor is destroyed from a destroyed object used in the given entity.

BlastFamilyComponentNotificationBus nodes

Get Actors Data

Obtains the actor data, such as entity id and whether actor is static or not, from a destructible object used in the given entity.

BlastFamilyDamageRequestBus nodes

Capsule Damage

Full damage is dealt to all chunks and bonds that are not farther than minRadius from either position0 or position1. Linearly decreasing damage is applied if the distance is less than maxRadius.

Destroy Actor

Destroys the actors from a destroyed object used in the given entity.

Get Family Id

Get the entity id of the Blast Family in the given entity.

Impact Spread Damage

Full damage is dealt to all chunks and bonds that are not farther than minRadius from position. Decreasing damage is applied if the distance is less than maxRadius. Decreasing damage is calculated using BFS on the support graph instead of Euclidean distances.
Radial Damage

Full damage is dealt to all chunks and bonds that are not farther than \texttt{minRadius} from \texttt{position}. Linearily decreasing damage is applied if the distance is less than \texttt{maxRadius}.

Shear Damage

Deals full damage to bonds that are orthogonal to \texttt{normal}. No damage is dealt to bonds that are parallel. Damage to chunks is dependent on distance to \texttt{position}. The damage falloff between \texttt{minRadius} and \texttt{maxRadius} is linear.

Stress Damage

Stress damage is applied using \texttt{force} vector instead of a scalar value. Damage is propagated between bonds based on the support graph.

Triangle Damage

Full damage is dealt to all chunks and bonds that intersect with a triangle described by the given vertices defined by \texttt{position0}, \texttt{position1}, and \texttt{position2}.

Simulate cloth with NVIDIA Cloth

This feature is in \texttt{preview} release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

With NVIDIA Cloth in Amazon Lumberyard you can create realistic cloth simulations for entities that contain \texttt{Actor} or \texttt{Mesh} components. The NVIDIA Cloth gem provides a component you can use to simulate cloth on any mesh that has been processed with a \texttt{Cloth} modifier applied in \texttt{FBX Settings}.

To use NVIDIA Cloth you must enable the NVIDIA Cloth gem (p. 1182).

NVIDIA Cloth features

- Apply cloth data to meshes imported from .fbx files.
- Add cloth simulation to entities containing \texttt{Mesh} and \texttt{Actor} components.
- Cloth mesh simplification and static triangle removal allow you to use complex cloth meshes and yield faster cloth simulation.
- Define \texttt{Inverse mass}, \texttt{Motion constraints}, and \texttt{Backstop} per cloth particle with vertex color streams you create.
- Blend between cloth simulation and actor keyframe animation with motion constraints.
- Add cloth colliders to actors with \texttt{Animation Editor}.
- Add local wind forces to your cloth simulations or use force regions to simulate wind.
- Simulate cloth in parallel across available CPU cores, or simulate cloth on a discrete GPU that supports NVIDIA CUDA (Windows 10 only).
- NVIDIA Cloth gem's public API allows other systems and gems to access cloth simulation functionality.
• Debug cloth simulations and constraints with real-time cloth debug visualizations.

Using NVIDIA Cloth

Cloth component (p. 575) - Cloth component reference.

Cloth for Mesh components (p. 2858) - Create cloth for entities containing Mesh components.

Cloth for Actor components (p. 2861) - Create cloth for entities containing Actor components.

Per vertex properties for cloth (p. 2866) - Use per vertex properties to define the Inverse mass, Motion constraints, and Backstop to create higher quality and more predictable cloth simulations.

Cloth simulation constraints (p. 2867) - An overview of how Motion constraints and Backstop work to improve the results of cloth simulations.

Cloth visual debugger (p. 2869) - Enable the visual debugger for cloth simulations.

GPU cloth simulation with NVIDIA CUDA (p. 2871) - Install NVIDIA CUDA to enable GPU acceleration for NVIDIA Cloth.

NVIDIA Cloth references

NVIDIA Cloth documentation at the NVIDIA GAMEWORKS developer portal.

Cloth for Mesh components

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To use Cloth, you must enable the NVIDIA Cloth gem. For more information, see the NVIDIA Cloth gem (p. 1182) documentation.

You can create cloth assets for entities with Mesh components in the content creation application of your choice and import them into Lumberyard from an .fbx file. The mesh asset should have the following:

• A cloth mesh that will be simulated and rendered in Lumberyard.
  • Cloth data can be added to define per vertex mass and constraint properties using the vertex color tool in your content creation application. For more information see Per vertex properties for cloth (p. 2866).
  • Optional - Any other static mesh. For example, if you create a flag to be simulated as cloth, then you can include a mesh for the flag pole.

Note
Sample Mesh component cloth assets are located in the NVIDIA Cloth gem directory, which is located at /dev/Gems/NvCloth/Assets/Objects/cloth/Environment/.

For information on exporting mesh assets, see FBX Settings mesh export (p. 436)
Add Cloth to Mesh components

Create cloth by adding the Cloth component to an entity that has a Mesh component, and then setting the properties of the Cloth component.

1. In Lumberyard Editor, add a new entity to the level.
2. Add a Mesh component to the entity, and reference the mesh asset and material.
3. Add a Cloth component to the entity.
4. Set the cloth data of the mesh asset.
   a. Click the button beside the Mesh node property to open the FBX Settings window.

   ![FBX Settings Window]

   b. In the FBX Settings window, on the Meshes tab, and choose Add Modifier, Cloth.

   c. In the Cloth modifier area:
      i. Select the cloth mesh from the drop-down list.
      ii. When applicable, select the vertex color stream and channel that includes the Inverse Masses data. If data is not provided, then cloth defaults to an inverse mass value of 1.0 for all vertices.
      iii. When applicable, select the vertex color stream and channel that include the Motion Constraints data. If data is not provided, then cloth defaults to a motion constraint value of 1.0 for all vertices.
      iv. When applicable, select the vertex color streams and channels that includes the Backstop Offset and Backstop Radius data. If data is not provided, then no backstop constraints will be applied in the simulation.
d. Choose the **Update** button. **Asset Processor** then updates the asset and includes the cloth data.

5. Configure the cloth component.
   a. Select the cloth mesh node from the drop-down list.
b. Adjust cloth properties to obtain the desired cloth behavior. For more information, see Cloth Component (p. 575).

**View the Cloth Simulation**

In Lumberyard Editor, press **Ctrl+G** or press the **Play** button to run your project.

**Cloth for Actor components**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To use Cloth, you must enable the NVIDIA Cloth gem. For more information, see the NVIDIA Cloth gem (p. 1182) documentation.

You can create cloth assets for entities with Actor components in the content creation application of your choice and import them into Lumberyard from an .fbx file. The actor asset should have the following:
Actor mesh

One or more meshes that visually represent the actor, skinned to a skeleton, that will not be simulated as cloth.

Cloth mesh

One or more meshes that will be simulated and rendered as cloth.
- The cloth mesh must be skinned to bones. The bones do not have to be exclusive to the cloth mesh. The bones must be part of the actor's skeletal hierarchy. Because simulation will drive the cloth mesh, we recommend you use few additional bones for the cloth mesh.
- Cloth data can be added to define per vertex mass and constraint properties using the vertex color tool in your content creation application. For more information see Per vertex properties for cloth (p. 2866).

Skeleton

A skeleton to drive the actor and cloth meshes. Cloth meshes may be skinned to their own bones or any bones in the hierarchy. Bones that drive the cloth meshes must be part of the skeleton's hierarchy.

Animation

A Motion set and Anim graph based on the actor's skeleton. Keyframe animated cloth can be blended with simulated cloth using Motion constraints.

Note

Sample Actor component cloth assets are located in the NVIDIA Cloth gem directory, which is located at /dev/Gems/NvCloth/Assets/Objects/cloth/Chicken/.

For information on exporting actor assets, see FBX Settings actor export (p. 437)

Add Cloth to Actor components

Create cloth by adding the Cloth component to an entity that has an Actor component, and then setting the properties of the Cloth component.

1. In Lumberyard Editor, add a new entity to the level.
2. Add an Actor component to the entity, and reference the actor asset and material.
3. Add an Anim Graph component and reference the actor anim graph asset and motion set.
4. Add a Cloth component to the entity.
5. Set the cloth data of the actor asset.
   a. Click the button beside the Mesh node property to open the FBX Settings window.
b. In the FBX Settings window, on the Actors tab, and choose Add Modifier, Cloth.

c. In the Cloth modifier area:

i. Select the cloth mesh from the drop-down list.

ii. When applicable, select the vertex color stream and channel that includes the Inverse Masses data. If data is not provided, then cloth defaults to an inverse mass value of 1.0 for all vertices.

iii. When applicable, select the vertex color stream and channel that include the Motion Constraints data. If data is not provided, then cloth defaults to a motion constraint value of 1.0 for all vertices.

iv. When applicable, select the vertex color streams and channels that includes the Backstop Offset and Backstop Radius data. If data is not provided, then no backstop constraints will be applied in the simulation.
d. Choose the **Update** button. **Asset Processor** then updates the asset and includes the cloth data.

6. Configure the cloth component.
   a. Select the cloth mesh node from the drop-down list.
b. Adjust cloth properties to obtain the desired cloth behavior. For more information, see Cloth Component (p. 575).

c. You can use the Motion constraints properties Max Distance and Scale to blend between cloth simulation and keyframe animation.

Add cloth colliders to an actor

You can add cloth colliders to an actor to prevent the cloth form penetrating the actor's mesh during simulation. Cloth colliders are added to actors in Animation Editor. For information on adding cloth colliders to an actor, see Add Cloth Colliders to actors (p. 1489).

View the Cloth Simulation

In Lumberyard Editor, press Ctrl+G or press the Play button to run your project.
Per vertex properties for cloth

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Cloth properties can be set per cloth particle using the vertex color tools in your content creation application. In the Cloth modifier, in FBX Settings, you can choose which vertex color stream and which color channel in the stream represents each property. You can use a different stream for each property, or combine multiple properties into a single vertex color stream by storing the properties in different color channels.

Inverse Mass

Inverse Mass calculates a per cloth particle mass value. If no vertex color stream is provided, then the Inverse Mass value of all vertices will be 1.0 by default. The value range for Inverse Mass is 0.0 to 1.0.

An Inverse Mass value of 0.0 excludes the vertex from the cloth simulation. Vertices with a 0.0 Inverse Mass value will be static.
Per cloth particle mass is calculated as \( \text{VertexMass} = \frac{1.0}{\text{InverseMass}} \). For example, if the Inverse Mass value in the color channel is 0.3, then the resulting cloth particle mass value is 3.33. The smaller the Inverse Mass value, the greater the cloth particle mass.

**Motion Constraints**

Motion constraints limit the movement of a simulated cloth particle to an area defined by a sphere. The sphere's position is relative to the corresponding unsimulated vertex position. For a detailed explanation of Motion Constraints, see Cloth simulation constraints (p. 2867).

The Motion Constraints per vertex property calculates the radius of the sphere. Motion Constraints have a value range of 0.0 to 1.0.

A Motion Constraints value of 0.0 constrains the cloth particle to the corresponding unsimulated vertex.

**Backstop**

Backstop prevents a simulated cloth particle from entering an area defined by a sphere. The sphere's position is relative to the corresponding unsimulated vertex position. There are two Backstop properties that you can define per vertex, Backstop Offset and Backstop Radius. For a detailed explanation of Backstop, see Cloth simulation constraints (p. 2867).

**Backstop Offset**

Backstop Offset defines the backstop sphere's offset along the normal of the corresponding unsimulated vertex. The Backstop Offset value range, 0.0 to 1.0, is remapped to a range between -1.0 and 1.0.

A Backstop Offset value of 0.0 is remapped to -1.0 and places the backstop sphere in front of the unsimulated vertex.

A Backstop Offset value of 1.0 places the backstop sphere behind the unsimulated vertex.

A Backstop Offset value of 0.5 is remapped to 0.0 and places the backstop sphere on the unsimulated vertex.

**Backstop Radius**

Backstop Radius calculates the radius of the backstop sphere. Backstop Radius has a value range of 0.0 to 1.0.

A Backstop Radius value of 0.0 disables the backstop for the corresponding vertex.

**Cloth simulation constraints**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Constraints limit the movement of cloth particles to prevent mesh penetration and create more predictable results from cloth simulation. Amazon Lumberyard has two types of cloth constraints: Motion constraints and Backstop.
**Motion constraints** - Constrains a simulated cloth particle within an area defined by a sphere. The sphere's position is relative to the corresponding unsimulated vertex position.

**Backstop** - Prevents a simulated cloth particle from entering an area defined by a sphere. The sphere's position is relative to the corresponding unsimulated vertex position.

Motion constraints and Backstop properties are set by creating vertex color streams for the mesh in a content creation application such as Maya. When exporting a mesh through FBX Settings, you can specify which vertex color streams and color channels define the properties in the Cloth modifier.

Motion constraints and Backstop properties are per vertex and can be used with Actor and Mesh components.

### Motion constraints

Motion constraints limit the movement of a simulated cloth particle to an area defined by a sphere. The sphere is centered on the corresponding vertex of the unsimulated mesh. The radius of the sphere is calculated using the Motion Constraints value from the vertex color stream and the Max Distance, Scale and Bias properties in the Motion constraints property group of the Cloth component.

If no vertex color stream is present, then a default value of 1.0 is used for the Motion constraints of each vertex. Motion Constraints vertex color stream values range from 0.0 to 1.0. The simulated cloth particles are fully constrained to the unsimulated mesh vertices if the vertex color stream has a value of 0.0.

The diagram below visualizes Motion constraints.

### Backstop

Because cloth colliders are simple primitives, you may encounter scenarios where cloth colliders aren't sufficient to prevent the simulated cloth particles from penetrating other meshes. You can use Backstop to fine tune the behavior of simulated cloth particles to address these scenarios.

Backstop prevents a simulated cloth particle from entering an area defined by a sphere. The sphere is positioned along the normal of the corresponding unsimulated mesh vertex through an offset property.
Backstop requires color channels from a vertex color stream to define both the radius of the sphere and the sphere's offset. The Backstop Radius and Backstop Offset values in the vertex color stream are scaled by the Radius and Offset values in the Cloth component Backstop properties.

Because a vertex color channel can only contain values between 0.0 and 1.0, the value in the color channel representing the Backstop Offset property will be remapped to a range between -1.0 and 1.0.

A Backstop Offset vertex color value of 1.0 is scaled by the Back Offset property of the Cloth component. The backstop sphere is placed behind the unsimulated mesh vertex.

A Backstop Offset vertex color value of 0.0 is remapped to -1.0 and scaled by the Front Offset property of the Cloth component. The backstop sphere is placed in front of the unsimulated mesh vertex.

A Backstop Offset vertex color value of 0.5 is remapped to 0.0 and scaled by the Back Offset property of the Cloth component. The backstop sphere is placed on the corresponding unsimulated vertex.

The Backstop Radius vertex color channel has values in the range of 0.0 to 1.0. A value of 0.0 in the Backstop Radius vertex color channel disables the backstop for the corresponding vertex.

The diagram below visualizes Backstop.

\[
\begin{align*}
\text{Cloth vertex position } C_p & \text{ will be constrained during simulation to remain outside the sphere with position } S_p \text{ and radius } S_r \\
S_r & = Vbr \ast Radius \\
S_p & = \begin{cases} 
Vp - Vn \ast (S_r + Vbo \ast \text{BackOffset}) & \text{when } Vbo \geq 0 \\
Vp + Vn \ast (S_r - Vbo \ast \text{FrontOffset}) & \text{when } Vbo < 0 
\end{cases}
\end{align*}
\]

**Cloth Component - Backstop properties**

- Backstop
  - Radius: 0.3 m
  - Back offset: 0.0 m
  - Front offset: 0.0 m

**Cloth visual debugger**

This feature is in preview release and is subject to change.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To enable debug cloth visualization, use the following console variables (CVARs) in the editor console.

**cloth_DebugDraw <value>**
- Draw the cloth mesh wireframe.
  - 0: Disable wireframe display.
  - 1: Enable wireframe display.

**cloth_DebugDrawNormals <value>**
- Draw the cloth mesh normals.
  - 0: Disable normals display.
  - 1: Enable normals display.
  - 2: Enable normals, tangents and bitangents display.

**cloth_DebugDrawColliders <value>**
- Draw the cloth colliders.
  - 0: Disable collider display.
  - 1: Enable collider display.

**cloth_DebugDrawMotionConstraints <value>**
- Draw the cloth motion constraints.
0: Disable motion constraint display.

1: Enable motion constraint display.

cloth_DebugDrawBackstop <value>

Draw the cloth backstop.

0: Disable backstop display.

1: Enable backstop display.

GPU cloth simulation with NVIDIA CUDA

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

NVIDIA Cloth gem supports NVIDIA CUDA on Windows 10. With NVIDIA CUDA enabled for cloth, the simulation is computed on the GPU instead of the CPU. This allows you to use all the computational power of the GPU to run more complex cloth instances, in larger numbers, leaving the CPU free to do other tasks.

For more information about NVIDIA CUDA, visit the NVIDIA CUDA portal.

Contents

- GPU cloth simulation requirements (p. 2871)
- Installing NVIDIA CUDA Toolkit with Setup Assistant (p. 2871)
- Enable NVIDIA CUDA for cloth simulation (p. 2872)
- Releasing your project with NVIDIA CUDA (p. 2873)

GPU cloth simulation requirements

- Microsoft Windows 10
- NVIDIA CUDA Toolkit 10.1.168 or newer
- NVIDIA graphics card with CUDA support - Visit the NVIDIA CUDA GPU support portal for information.
- NVIDIA driver version 418.96 or newer - The latest driver version is recommended.

Installing NVIDIA CUDA Toolkit with Setup Assistant

NVIDIA CUDA Toolkit can be installed through Setup Assistant. The install link is located on the Install Software page, in the Optional software group.

1. Run Setup Assistant.
2. Choose Install Software and scroll down to the Optional software group.
3. Choose Get it to the right of NVIDIA CUDA Toolkit.
4. A browser opens on the NVIDIA CUDA Toolkit Download page. Use the prompts on the page to download the correct version of the toolkit for your system.

5. Run the NVIDIA CUDA Toolkit installer and follow its prompts for Express installation.

   **Note**
   If NVIDIA CUDA Express installation fails, then try these remedies:
   - Run the installation again and choose a **Custom Installation** this time, only selecting the following elements: CUDA Development Compiler and CUDA Runtime Libraries.
   - Update the graphics card driver to the latest version and retry installation.
   - If you are using a laptop, then the manufacturer's drivers for the graphics card might not be compatible with CUDA. Check the manufacturer's website for the latest drivers.

6. Click the **refresh** button at the top-right corner of Lumberyard Setup Assistant. If the NVIDIA CUDA Toolkit is detected, then it appears as **Installed**.

---

**Enable NVIDIA CUDA for cloth simulation**

To use NVIDIA CUDA for cloth simulation on the GPU, you must configure and rebuild your project, and enable NVIDIA CUDA in your PC configuration file.

1. Use Project Configurator to add the **NVIDIA Cloth Gem** to your project.

2. Configure your project. Use the following command.

   **Note**
   Open a new command prompt and navigate to `lumberyard_version\dev\` to run the commands below. Do not use an existing command prompt.

   ```
   lmbr_waf configure
   ```

3. Check in the output that it has detected NVIDIA CUDA.

   ```
   [INFO] Detected NVIDIA CUDA SDK at: C:\Program Files\NVIDIA GPU Computing Toolkit\CUDA\v10.1
   ```
4. Build your project. Use the following command.

```bash
lmbr_waf build_win_x64_vs2019_profile -p all --progress
```

5. Add the following line to the system_windows_pc.cfg file located in `lumberyard_version\dev`.

```
cloth_EnableCUDA = 1
```

6. Run Lumberyard Editor. This also runs the Asset Processor in the background.

7. Verify that the NVIDIA Cloth Gem is running cloth simulation on the GPU by looking for the following line in the game log or in the editor console output:

```
NVIDIA NvCloth Gem using GPU (CUDA) for cloth simulation
```

**Releasing your project with NVIDIA CUDA**

End users do not require the NVIDIA CUDA Toolkit to be installed on their PC in order to run your release builds.

Cloth simulations automatically run on the GPU, if a GPU that is compatible with CUDA is present. If an NVIDIA CUDA compatible GPU is not available, then the simulation defaults to running on the CPU.

For more information about release builds, see Building Lumberyard projects (p. 61).
Creating and Customizing Project User Interfaces

You can use the **UI Editor** to create and customize various parts of the game user interface, such as images, text, buttons, menus, scroll boxes, and heads-up displays (HUDs). For a tutorial about UI creation for games, see Lumberyard Tutorials.

**Topics**
- Using the UI Editor (p. 2874)
- Working with UI Canvases (p. 2888)
- Defining Game and Level Load Screens (p. 2910)
- Working with UI Slices (p. 2912)
- UI Elements (p. 2916)
- UI Components (p. 2923)
- Implementing New Fonts (p. 2999)
- TrueType Fonts (p. 3009)
- Animating the UI (p. 3011)
- UI Lua Reference (p. 3032)

**Using the UI Editor**

You can use the **UI Editor** to create, customize, and animate various game user interface elements and components such as menus, buttons, and heads-up displays (HUDs).

The **UI Editor** consists of the following:

1. **Toolbar** – Commonly used tools and settings
2. **Hierarchy pane** – List of UI elements that you create
3. **UI canvas tab bar** – Tabbed display of open canvases
4. **Viewport** – Display of the UI elements on the current UI canvas
5. **Properties pane** – Component properties for the selected element
6. **Animation Editor** – Tool for animating UI elements

**Note**
You can tear away and redock the **Hierarchy pane**, the **Properties pane**, the **Animation Editor**, and sections of the toolbar to customize the **UI Editor**.
To open the UI Editor

- In Lumberyard Editor, choose **Tools** and then **UI Editor**.

Topics

- Toolbar (p. 2875)
- Rulers and Guides (p. 2878)
- Asset Drag and Drop (p. 2881)
- Sprite Editor (p. 2882)

## Toolbar

### Interaction Modes

The **UI Editor** toolbar features interaction modes. The selected interaction mode determines how you can interact with the UI elements in your canvas.

#### Interaction modes

**Select**

Select elements in your canvas. In this mode, selecting is the only action that you can use on your UI elements.
Move
Select and move UI elements. Moving a UI element modifies its offset. In the Move mode, you can view but not interact with the anchor widget, which is disabled.

You can move UI elements in the following ways:
- Select an element and drag it to a new position.
- Select a particular axis (X, Y, or Z) on the axis gizmo and drag the element by only one axis at a time.
- Nudge your selected element using keyboard arrows.
- Select multiple elements and align them using the Alignment Tool (p. 2876).

Rotate
Select and rotate UI elements.

Resize
Select and resize UI elements. Resizing modifies the UI element’s offsets.

Anchor
Select and move UI elements by their anchors. If you select one element, the anchor widget appears in blue, and you can interact directly with that element. If you select multiple elements, the anchor widget is disabled.

In Anchor mode, you can interact with UI elements in the same ways as in the Move mode.

Alignment Tool
The alignment tool is a set of buttons on the UI Editor’s toolbar.

The alignment tools are enabled when your interaction mode is Move or Anchor and you have selected two or more movable elements.

Note
One type of element that you can’t moved is one that a parent layout element controls.

With these tools, you can align elements by lining up their:
- Top edges
- Elements’ horizontal centers
- Bottom edges
- Left edges
- Elements’ vertical centers
- Right edges

To align objects
1. Select one of the following interaction modes:
   - Move
• **Anchor**

2. On your canvas, select two or more movable elements.

   The alignment tools on the toolbar are now enabled.

3. Select an alignment button.

The method that the alignment tool uses to move the elements depends on the interaction mode you're using. If the mode is in **Move**, elements are moved using their offsets. If the mode is **Anchor**, the elements are moved by their anchors.

A bounding rectangle is a useful graphic for understanding how the alignment tool determines how it aligns elements.

Imagine a gray bounding rectangle that encompasses the elements in it.

![Diagram](image)

If you align vertically by the elements' centers, the elements are centered at the bounding rectangle's center, which remains in its original position.
If you align vertically by the elements' right edges, the elements' right edges are aligned to the bounding rectangle's right edge.

**Rulers and Guides**

Use **Rulers** and **Guides** to visually guide the placement of your UI elements on your UI canvas.

**To show or hide Rulers**

- Do one of the following:
  - Press **Ctrl+R**
  - Choose **View** and then **Rulers**
The ruler's units are measured in pixels in the canvas space. Magenta lines on the rulers mark the current location of your cursor.

Guides appear as green lines and act as a visual aid for positioning UI elements.

**To show or hide Guides**

- Do one of the following:
  - Press Ctrl+; (semicolon)
  - Choose View and then Guides

You place the guides at a specific pixel offset on a canvas. The UI Editor displays guides as green lines, which you can position UI elements around or along.

**To create a guide**

1. Ensure that the Rulers appear.
2. Click on the top or side ruler and drag into the canvas.
   
   If you start in the top ruler, you create a horizontal line. Starting in the side ruler creates a vertical line.
3. Release at the position that you want to place the guide.
4. To adjust the position of the guide, click the guide and drag it to a new position.

![Guide adjustment](image)

**Note**
You must be in **Move** or **Anchor** mode to adjust a guide's position.

You can lock guides to protect against unintentionally moving them. Locking the guides also makes it easier to move UI elements across and around the guides.

**To lock guides**

- Choose **View** and then **Lock Guides**.

**To delete one guide**

- Click on the guide and drag it off of the canvas.
To delete all guides

- Choose View and then Clear Guides.

You can change the color of all guides.

To change guide color

1. Click in an empty area on the viewport or hierarchy pane so that no UI elements are selected, and you see the UI Canvas component in the Properties pane.
2. In the UI Canvas component, under Editor settings, click the Guide color and select a new color.

Asset Drag and Drop

You can drag and drop existing assets from the Asset Browser (p. 296) into the UI Editor’s viewport, hierarchy pane, properties pane, or a specific property field. This can be a convenient way to create new entities and assets to work with in the UI Editor.

Dragging assets associated with components

- You can drop any asset that is associated with a component, such as a Script Canvas file or a Lua script file, into the UI Editor viewport or hierarchy pane.

When you drag an asset from the Asset Browser into the viewport, the UI Editor does the following:

- Creates a new entity at the cursor's location.
- Adds the associated component, which is indicated by the icon next to the asset in the Asset Browser.
- Assigns the asset for that component's property.

When you drag an asset from the Asset Browser into the hierarchy pane, the UI Editor does the following:

- Creates a new entity and places it as a child of an existing parent, unless the drop location is directly on an entity. In this case, the associated component is added to that existing entity without creating a new one. To override this behavior, press the Shift key down while you drop the asset. This creates a new entity and places it as a child of the existing entity.
- Adds the associated component, which is indicated by the icon next to the asset in the Asset Browser.
- Assigns the asset for that component's property.

When you drag an asset from the Asset Browser into the properties pane, the UI Editor does the following to all selected entities:

- Adds the associated component, which is indicated by the icon next to the asset in the Asset Browser.
- Assigns the asset for that component's property.

Dragging UI slice assets

- You can drop any slice asset that consists of only UI entities into the UI Editor viewport or hierarchy pane.
When you drag a UI slice asset from the Asset Browser into the viewport, the UI Editor does the following:

- Instantiates a new entity from the dragged slice at the cursor's location.

When you drag a UI slice asset from the Asset Browser into the hierarchy pane, the UI Editor does the following:

- Instantiates a new entity from the dragged slice and places it as a child of an existing parent, according to the drop location in the hierarchy.

### Dragging UI Canvas assets

- Drag UI Canvas assets from the Asset Browser into the UI Editor to open them for editing.

### Dragging assets to property fields

- Drag an asset from the Asset Browser onto an asset property field in the properties pane to assign that asset to a component's property.

## Sprite Editor

The Sprite Editor configures the following sprite configurations:

- Border values for sliced image types (p. 2883)
- Sprite sheets (p. 2886)

You open the Sprite Editor from the Image component's properties.

### To open the Sprite Editor

1. Open the UI Editor as explained in the preceding section.
2. Choose the ellipsis button next Sprite path and select the sprite file.
3. To the right of Sprite path, click the arrow icon.

The Sprite Editor has the following features:
• **Sprite viewport** – Displays sprite image.

• **Border manipulators** – Sets border properties for sliced image types. To adjust the borders, drag the dotted lines, which are called manipulator positions. Changing these positions updates the corresponding **Border Properties** values.

• **Properties**
  
  • **Image resolution** – The size of the image.
  
  • **Alias** – A short description of what the cell represents. Use this setting to improve the readability of sprite-sheet index values. You can use the same alias string for multiple sprite sheet cells.
  
  • **Top, Bottom, Left, Right** – The number of pixels from the respective edge of the image where the sliced region is situated.

• **Configure Spritesheet** – Available only for sprites that are not currently configured as a sprite sheet. For more information, see Configuring Sprite Sheets (p. 2886).

### Sliced Image Type

Lumberyard uses slice resizing to resize certain images intelligently. For example, using regular resizing to widen the following image results in distortion of the corners and edges.
Slice resizing divides an image into nine sections that scale in such a way as to preserve border and corner details. This technique avoids the distortion that occurs with typical image scaling.

Each area is resized as follows:

- The center is resized both horizontally and vertically
- The corners aren't resized at all
- The top and bottom edges are resized horizontally only
- The right and left edges are resized vertically only

Slice resizing is useful for images with borders and corner details, such as buttons with rounded corners.
Using the Sprite Editor (p. 2882), you can manipulate where the sections are by dragging the dotted lines on the preview image.

**Tip**
You can see your changes in real time. To do this, before you open the Sprite Editor, change the Image component's ImageType property to Sliced.
Sprite Sheets

You can configure an image as a sprite sheet.

A sprite sheet is a collection of separate images—such as icons, buttons, and other UI assets—that are stored in a single image. Although you can keep all of your images in separate files, using a sprite sheet has several advantages:

- Faster performance – For that collection of assets, Lumberyard can load just one image from disk instead of many separate images. Loading multiple images requires many hard drive seeks and is performance expensive.
- Workflow improvements – When your animation contains multiple frames, for example, it's easier to manage just one image that contains all of the animation frames rather than separate files. This makes editing and other workflows easier.

Other workflow improvements include easier management of your assets. For example, you could have one image called `mainmenu_ui_assets_spritesheet.png` that contains all of your buttons rather than a series of files such as `mainmenu_button1.png`, `mainmenu_button2.png`, and so on.

Example

The following image contains 12 walking images in a single row.

In the following procedure, you can divide the image into 12 columns when configuring the sprite sheet. You can then select the piece of the image that you want to display for your Image component.
To configure an image as a sprite sheet

1. In the Sprite Editor (p. 2882), click Configure Spritesheet in the lower-left corner.

   The Configure Spritesheet view displays two new sections, Configure Spritesheet and Select cell.

   ![](image.png)

   - Configure Spritesheet
     - Rows: 1
     - Columns: 12

   - Select cell
     - Multiple walking images are displayed, with one highlighted.

   - Border Properties
     - Cell size is 218 x 218
     - Alias: 
     - Top: 0.0 px
     - Bottom: 0.0 px
     - Left: 0.0 px
     - Right: 0.0 px

   - Save, Cancel

2. Enter the number of rows and columns. The walking images example has 12 columns and 1 row. These values divide the sprite into a uniform grid and assume that each cell of the sprite sheet is of the same (uniform) size.

3. In the Select cell section, click a cell to select it and display its properties.

4. To configure individual cells with slices scaling, drag the dotted lines to the preferred positions. The Top, Bottom, Left, and Right properties are updated automatically to reflect the current positions.

   For more information about slice scaling, see Sliced Image Type (p. 2883).
5. Click **Save** to save your changes and close the **Sprite Editor**. Or click **Cancel** to revert your changes and close the **Sprite Editor**.

6. To select the specific cell of the sprite sheet that you want to use, in the **Image** component properties, select the appropriate **Index** number.

   The **Sprite Editor** assigns index numbers in the rows and columns of the sprite sheet, from left to right and then top to bottom, starting with 0 (zero).

   If you defined an **Alias** in the **Sprite Editor** properties, that also appears next to the index numbers.

![Image properties](image.png)

   The cell that you selected appears in the **UI Editor** viewport.

---

**Working with UI Canvases**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/blogs/gaming/3d-engine/) or visit the [AWS Game Tech blog](https://aws.amazon.com/blogs/gaming/) to learn more.

The **UI Editor** uses the concept of a canvas as an invisible backdrop for your game user interface elements. Once you create a canvas, you can add elements such as images, text, and buttons.

**To create a UI canvas**

1. In Lumberyard Editor, click **Tools, UI Editor**.

   The **UI Editor** automatically creates an empty canvas.

2. In the **UI Editor**, add elements (p. 2916), components (p. 2923), slices (p. 2912), and prefabs (p. 2920).

3. Click **File, Save As**. Name the canvas with a `.uicanvas` file extension, and then click **Save**.

**Topics**

- [Navigating the Viewport](p. 2889)
- [Changing the Canvas Size](p. 2890)
- [Previewing Canvases](p. 2891)
- [Configuring Canvas Properties](p. 2894)
- [Loading Canvases in Lua](p. 2897)
- [Placing UI Canvases in the 3D World](p. 2897)
• Using Texture Atlases (p. 2900)
• Debugging UI Canvases (p. 2906)

You can open multiple canvases in the UI Editor. For each open canvas, a tab appears in the tab bar. The active canvas is highlighted in the tab bar. Its content is displayed in the viewport and its elements and properties are displayed in the hierarchy and properties panes.

From the UI Editor's File menu, in addition to the basic open, close, and save functionality, you can also do the following:

• Save all open canvases
• Close all open canvases
• Close all but the active canvas

Navigating the Viewport

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. **Download O3DE** or visit the **AWS Game Tech blog** to learn more.

The UI Editor features a rectangle with a checkerboard pattern on a dark gray background.
The checkerboard pattern represents empty space within the UI canvas, and the dark gray represents the space outside of the canvas. Anything within the UI canvas space is visible when the canvas is loaded.

**To zoom in or out on a UI canvas**

Do one of the following:

- Mouse – Scroll the mouse wheel.
- Keyboard – Press Ctrl + or Ctrl -.
- Menu – Click View, then click Zoom In or Zoom Out.
- Toolbar – In the Zoom box, enter a percentage value or click the up and down arrows.

**To pan the view on a UI canvas while dragging the canvas with the left mouse button**

- With the mouse on the UI canvas, drag using the middle mouse button.
- Press and hold the space bar while dragging the canvas.

**To toggle common zoom settings**

Do one of the following:

- Fit canvas to current view (default) – Press Ctrl+0, or click View, Fit Canvas.
- View canvas at actual size – Press Ctrl+1, or click View, Actual Size.

---

**Changing the Canvas Size**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Previewing Canvases

Change your game UI canvas size to visualize how your canvas might look on other displays and devices of varying resolutions. The size at which you save your canvas is the reference size that is used when you perform the Scale to Device action.

**To change the canvas size**

1. On the toolbar, click the arrow beside the resolution to see a list of commonly used canvas sizes for various platforms.

2. Select the size you want or click **Other** to enter a custom canvas size.

---

**Tip**

You can customize the list of canvas sizes that appear in the list by modifying a JSON file stored locally on your machine. In Windows, the canvas size presets file is located in the following directory:

`C:\Users\<UserName>\AppData\Local\Amazon\Lumberyard\size_presets.json`

---

**Previewing Canvases**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

You can preview your game UI canvas to visualize how it might look at different screen resolutions and to see how the interactive elements change states.

**Topics**
• Setting Canvas Size in Preview (p. 2893)
• Previewing Canvas Behavior (p. 2893)

The UI Editor Preview consists of the following:

1. **Toolbar** – Tools to view the current **Viewport size**, **Preview canvas size** (selectable), and **Canvas scale**.
2. **Viewport** – Display of the UI canvas as it would appear at the selected resolution.
3. **Animation List (p. 2893)** – List of the animation sequences in the canvas, which you can control using the playback toolbar. Close this pane to increase the viewport size. Use the **View** menu to restore it.
4. **Action Log (p. 2893)** – Record of actions triggered by the canvas's interactable elements. Close this pane to increase the viewport size. Use the **View** menu to restore it.

To open UI canvas Preview

Do one of the following:

• From the **UI Editor** toolbar, click **Preview**.
• From the **UI Editor** menu, click **Preview, Preview**.
• Press **Ctrl+P**.

To exit the canvas preview, click **End Preview**.
Setting Canvas Size in Preview

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Change your game UI canvas size in **UI Editor Preview** to visualize how your canvas might look at different screen resolutions and to see how the interactive elements change state. Changing your canvas size in **Preview** does not affect the canvas size at which you are authoring the UI canvas—that is controlled in the **UI Editor** (p. 2890).

Setting your canvas size in **Preview** is useful when designing games that run on devices that have multiple resolutions. You can see at different resolutions how an element's size and position changes based on the settings of its **Transform2D** properties, such as anchors, offsets, and the **Scale to Device** settings. For more information on the **Transform2D** properties, see **Transform2D Component** (p. 2926).

The **Canvas scale** in the toolbar shows the scale at which the canvas is displayed. If the **Preview canvas size** selected is larger than the viewport size, the canvas you are previewing is drawn at a reduced scale.

Previewing Canvas Behavior

In **UI Editor Preview**, the UI elements in your canvas perform as they would when the game is running.

Try these examples:

- Pause on an interactive element to show its hover state.
- Press (click) an interactive element to show its pressed state.
- Adjust sliders.
- Input and edit text.
- Use keyboard, mouse, or gamepad to interact with the UI.

**Note**

If the interactive component's **Input enabled** setting is deselected (unchecked), that element is drawn in its disabled state and does not respond to hover or click actions.

Animation List

The **Animation List** pane lists all the UI animation sequences found on the canvas that you are previewing. Select an animation to use the reset, play, pause, and set-to-end controls. Hold **Ctrl** or **Shift** to select and control multiple animations at once. You can also control animations independently and simultaneously so that one may be playing, for example, while you pause another.

Action Log

The **Action Log** pane shows the actions generated by interacting with interactive elements in the UI canvas while in **Preview**. These logged actions help the canvas designer ensure that correct actions are being triggered.
To use this feature, you must type text strings in the **Actions** section of the interactive element's properties.

**To enable Action Log entries**

1. In the **UI Editor** viewport or **Hierarchy** pane, select the element to which the interactive component is attached.
2. In the **Properties** pane, under the **Actions** category, enter a text string for each action for which you want to trigger an action log entry.

   The text strings are fully customizable; you can enter any string that helps you ensure that the correct actions are being triggered.

For example, in the picture below, **EnablerChanged** is displayed whenever the **Enable Input** check box changes state (from off to on, or on to off). **EnablerOn** is displayed when the check box is selected, and **EnablerOff** is displayed when it is deselected.

![Example of Action Log entries](image)

During **Preview**, Script Canvas and Lua scripts aren't active. Actions taken in UI canvas **Preview** have no effect on anything outside of the canvas.

**Configuring Canvas Properties**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/developer-preview/) or visit the [AWS Game Tech blog](https://aws.amazon.com/game-tech/) to learn more.

The canvas properties are displayed in the **UI Editor Properties** pane when no elements are selected.
Rendering Properties

The following properties define how a canvas is rendered:

- **Draw order** – The value of this property determines the order that this canvas draws relative to other canvases. Higher numbers draw on top of lower numbers. When canvases have the same draw order, Lumberyard draws them in the order that they are loaded.

- **Is pixel aligned** – Selected by default. This property makes textures look sharper by rounding the position of the elements' corners to the nearest exact pixel. For example, if the position of a corner of an element rectangle is at 123.45, 678.90, then it is rounded to 123.00, 679.00.

- **Is text pixel aligned** – Selected by default. This property makes text look crisper by rounding text positions down to the nearest pixel. An exception to this rule occurs when fonts have been scaled down, in which case the text position is rounded to the nearest pixel. If the property is not checked, the text position is not rounded. You might consider unchecking this property if, for example, a text element will animate or move.

- **Render to texture** – Cleared by default. When this property is selected, the canvas is drawn to a texture rather than to the screen. When you select this property, you are prompted to enter a **Render target name** for the texture. You can enter any name, but the convention is to prefix the name with the `$` symbol to distinguish it from texture assets.

Input Properties

The following properties define how a canvas handles inputs:

- **Handle positional** – Selected by default. This property causes an automatic response to positional input such as mouse movement, mouse button clicks, and touch screen input. Keyboard inputs also cause an automatic response when an interactive UI element is active (such as an elemental with a **Text Input** component on it).
Configuring Canvas Properties

Common reasons to de-select this property are if the canvas doesn't require input, or if you configure your game to handle all inputs and pass selected inputs to the UI system.

- **Consume all input** – Cleared by default. When this property is selected, this canvas consumes *all* input events while it's enabled, regardless of whether the canvas handles a specific input event. For example, if you have canvas A covering canvas B, you probably don't want canvas B handling any input while canvas A is obstructing it, so you would select this property on canvas A. Modal dialog boxes are another example of a canvas that should have this property selected.

Note that anytime a canvas is loaded, if it's set to consume all input, then it steals the inputs from any other loaded canvas. This includes canvases that are set to consume all inputs themselves.

- **Handle multi-touch** – Cleared by default. When this property is selected, it enables elements on the canvas to handle multi-touch input. This is useful for handling input from touch-based screens, such as mobile devices.

- **Handle navigation** – Cleared by default. When this property is selected, it causes an automatic response to navigation input. For example, on a PC, pressing arrow keys moves focus from one interactive UI element to the next, and pressing Enter activates an interactive UI element. We recommend de-selecting this property for canvases that are placed in the game world.

- **Navigation threshold** – The analog input value, from a thumbstick, for example, that must be exceeded before a navigation command is processed. Valid ranges are decimal values between 0 and 1, and the default is 0.4. Adjust this value based on the input sensitivity needs of your UI.

- **Navigation repeat delay** – The delay, in milliseconds, before a held navigation command begins repeating. The default is 300 ms. Adjust this value based on the needs of your UI.

- **Navigation repeat period** – The delay, in milliseconds, after the initial repeat delay, before a held navigation command repeats again. The default is 150 ms. Adjust this value based on the needs of your UI.

For example, if you had a menu list where you hold a button to navigate to the next item in the list, the navigation property settings are used as follows:

1. Hold down the button past the *navigation threshold* to navigate to the next item.
2. Continue holding for an amount of time equal to the *navigation repeat delay* to navigate a second time.
3. Continue holding for an amount of time equal to the *navigation repeat period* to navigate a third time. Thereafter, as you continue holding the button, you will navigate again, every time an amount of time equal to the navigation period elapses.

- **First focus element** – Displayed when **Handle navigation** is selected. First focus element specifies which element gains focus when a canvas is first loaded and a mouse is not detected. For more information about element navigation, see First Focus Element (p. 2952).

### Tooltips Properties

The following property defines how a canvas displays tooltips:

- **Tooltip display element** – Controls which element the game displays when your users hover over an interactive element. Select an element from the drop-down list. This list is composed of the elements on your current canvas that contain the TooltipDisplay component. For more information about the Tooltips components, see Tooltip Components (p. 2985).

### Editor Settings Properties

The following properties define UI Editor behavior:
**Snap distance** – The distance between positions on the grid when **Snap to grid** is selected in the toolbar.

**Snap rotation** – The number of degrees between each step of rotation when you use the rotation gizmo to rotate an element in the viewport when **Snap to grid** is selected in the toolbar.

**Guide color** – The color of the guide lines on this canvas. For more information about using guides in UI Editor, see Rulers and Guides (p. 2878).

**Texture atlases** – The texture atlas that this canvas loads. Using a texture atlas can reduce the number of draw calls in certain situations, resulting in better performance for your UI. For more information about texture atlases, see Using Texture Atlases (p. 2900).

## Loading Canvases in Lua

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Lua scripting language to load and unload UI canvases. For more information, see Loading Canvases in Lua in the Amazon Lumberyard Legacy Reference.

## Placing UI Canvases in the 3D World

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can place a UI canvas directly on an object in the 3D world, as opposed to showing it in screen space. To do this, you render a UI canvas to a texture, and then use that texture in a material on a 3D mesh.

You can use any material on any type of entity to display a texture rendered by a UI canvas. However, if players are to interact with the UI canvas in the 3D world—by clicking with the mouse, for example—you must use a component entity.

To see an example of a UI canvas on an object in a 3D world, open the *UiIn3DWorld* level in the Samples Project.

Follow all the steps in the following procedure if you need to create a canvas that players can interact with. If the canvas is not to be interactive, then you only need steps 1 through 5.

### To place a UI canvas on an object in the 3D world

1. Create your UI canvas file (p. 2888). In the canvas properties (p. 2894), select **Render to texture** and enter a name in the **Render target** text box. You can enter any name, but the convention is to prefix the name with the * character to distinguish it from other texture assets.

2. In the level, create a component entity (p. 463).

3. In the **Entity Inspector**, add to this component entity (p. 480) a **UI Canvas Asset Ref** to specify the UI canvas and optionally to load it automatically when the level loads.

4. In the **Material Editor** (p. 1721), create a material that uses the render target texture that is rendered by your canvas. Under **Texture Maps**, for **Diffuse**, specify the texture file name.

5. Add a **Mesh** (p. 684) component to the component entity and choose the mesh asset onto which you want to map your canvas. Use the **Material override property** to select the material that you created.
6. Add a **Mesh Collider** and a **Static Physics** component. Physics is required on this entity because a ray cast is used to translate a mouse or touch input into a position on the UI canvas that is at that point in the world.

7. Add a **UI Canvas on Mesh** component. Type a canvas name in the **Render target override** property if you want to load several instances of the UI canvas on different meshes and have them display different states. Otherwise, leave this property blank.
### Placing UI Canvases in the 3D World

In the Entity Inspector, you can see the settings for placing a UI Canvas in the 3D world.

- **Name**: `UICanvas_WidgetTestNotLit`
- **Status**: `Start active`

#### Transform
- **Parent entity**: 
- **Translate**: 
  - X: 66.0 m
  - Y: 73.0 m
  - Z: 32.5 m
- **Rotate**: 
  - X: 40.0 deg
  - Y: 0.0 deg
  - Z: 0.0 deg
- **Scale**: 
  - X: 1.0
  - Y: 1.0
  - Z: 1.0
- **Parent activation**: `Original relative transform`
- **Static**: 
- **Network Sync**: 
  - Sync to replicas: 
  - Position Interpolation: `None`
  - Rotation Interpolation: `None`

#### UI Canvas Asset Ref
- **Canvas pathname**: `WidgetTest`
- **Load automatically**: 

#### Mesh
- **Visible**: 
- **Mesh asset**: `plane_proxy_001`
- **Material override**: `uiCanvasMaterial_WidgetTestNotLit`

#### Mesh Collider

#### Static Physics
- **Enabled initially**: 

#### UI Canvas on Mesh
- **Render target override**: `$UIWidgetTestNotLit`

#### Lua Script - LoadCanvasIntoEntity
- **Bind To network**: 
- **Properties**: 
- **Script**: `LoadCanvasIntoEntity`
Using Texture Atlases

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To reduce draw calls, you can add individual textures to a texture atlas and then add one or more texture atlases to a UI canvas.

Characteristics

UI canvases and texture atlases have the following characteristics:

- Each UI canvas contains a list of texture atlases to be loaded.
- Texture atlases are loaded when the UI canvas loads. They're unloaded when the UI canvas unloads.
- If multiple UI canvases load the same texture atlas, the texture atlas is loaded only once.
- UI elements that render textures preferentially use textures from a loaded texture atlas, if available.
- The texture atlas is only unloaded when all UI canvases that loaded it are unloaded.

Advantages

The principle advantages of texture atlases are the following:

- Draw calls are significantly reduced.
- Enhanced compression. Although source textures whose dimensions aren't multiples of four aren't compressed, texture atlases are always compressed.
- Forced preloading of texture groups. When the canvas loads, it also loads its texture atlases.

To see examples of texture atlases, open the UI_TextureAtlasSample level in the Lumberyard SamplesProject.

Topics

- Creating a Texture Atlas (p. 2900)
- Adding Texture Atlases to a UI Canvas (p. 2902)
- Using Texture Atlases to Reduce UI Draw Calls (p. 2904)

Creating a Texture Atlas

To create a texture atlas, you create a texture atlas (.texatlas) file. A texture atlas file is a text file that specifies the image files to be added to the texture atlas. The Asset Processor automatically builds files that have the .texatlas extension.

Texture Atlas File Format

Each line of the .texatlas file represents a command that is executed sequentially. Empty lines are ignored.

Comments

Any line that starts with // denotes a comment.
Example

```
// This is a comment that is ignored.
```

Properties

A line that has an equals (=) sign is considered a property value assignment. Properties not specified use their default values.

The following table shows the list of configurable properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Default Value</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxdimension</td>
<td>4096</td>
<td>The maximum width and height of the output texture atlas.</td>
</tr>
<tr>
<td>padding</td>
<td>1</td>
<td>The minimum number of extra pixels around each texture in the texture atlas. For compression purposes, the edge pixels of each texture are duplicated. The amount of duplication is determined by the calculation <code>image_size + padding</code> rounded up to the nearest compression unit of four.</td>
</tr>
<tr>
<td>poweroftwo</td>
<td>false</td>
<td>Whether the width and height of the output texture atlas is a power of two. If PVRTC compression is used for iOS, the output texture is a power of two regardless of this setting.</td>
</tr>
<tr>
<td>square</td>
<td>false</td>
<td>Whether the width and height of the output texture atlas is the same. If PVRTC compression is used for iOS, the output texture is a square regardless of this setting.</td>
</tr>
<tr>
<td>unusedcolor</td>
<td>#3CB371FF</td>
<td>The color for the unused space in the output texture atlas.</td>
</tr>
<tr>
<td>whitetexture</td>
<td>true</td>
<td>Whether to include a white texture with a path name of WhiteTexture in the output texture atlas.</td>
</tr>
<tr>
<td>presetname</td>
<td>TextureAtlas</td>
<td>The preset to use for image processing. If TextureAtlas is used as the presetname, either explicitly or by default, images will be compressed. This compression can lead to loss of image quality.</td>
</tr>
</tbody>
</table>

When you assign property values, note the following:

- Whitespace is allowed.
- Properties and values aren’t case sensitive.
- If a property value is assigned twice, only the last assignment is accepted.
- The following entries report an error to the Asset Processor and fail the asset processing job:
  - Unrecognized properties
  - Properties with incorrect values
  - Lines with more than one equal (=) symbol

File Paths
If a line specifies a path to an image file, the image is included in the texture atlas. Image file paths can be relative to any watch folder that the Asset Processor monitors for assets. If a line refers to a file that can't be loaded, an error is reported to the Asset Processor and the asset processing job fails. Lines that are neither comments nor properties are assumed to be image file paths.

**Example**

```
UI/Textures/LyShineExamples/button.tif
```

**Updating a Texture Atlas**

The Asset Processor automatically rebuilds the texture atlas if a texture in the atlas changes or if an existing source `.texatlas` file changes.

**Texture Atlas Output Files**

The Asset Processor outputs two files that represent a texture atlas: a `.dds` file and a `.texatlasidx` file. The `.dds` file is a texture that contains all the images specified in the `.texatlas` file. The `.texatlasidx` file stores coordinate and other image information.

**Adding Texture Atlases to a UI Canvas**

You can use the UI Editor to add texture atlases to a UI canvas.

**To add texture atlas references to a UI canvas**

1. Ensure that no elements are selected in the UI Editor and that the **Properties** pane displays the properties for **UI Canvas**.
2. Under **Editor settings**, note the **Texture atlases** property. The **Texture atlases** property lists the texture atlases that the UI canvas loads.

3. For **Texture atlases**, click the plus (+) sign to add one or more texture atlas child elements. One child element is required for each texture atlas to add to the UI canvas.
4. Click the **Browse (…)** button for an element that you added.

5. Choose the texture atlas for the element and then click **OK**.
Using Texture Atlases

The texture atlas that you added appears in the list.

6. To remove an element, click its (X) icon.

7. To remove all elements from the Texture atlases property, click the Remove all elements (☐) icon.

Using Texture Atlases to Reduce UI Draw Calls

The UI shader can combine draw calls that use up to a maximum of 16 textures. If this limit is exceeded, you can use texture atlases to reduce the number of draw calls.

Deciding which textures to add to a texture atlas is a two-part process:

1. Find out which canvases have draw calls that might be reduced by using texture atlases.
2. Determine which textures to place in specific texture atlases.
Using Texture Atlases

To gather data to make these determinations, you can use the Lumberyard Editor console.

To determine the textures to add to a texture atlas

1. In the Lumberyard Editor console, set the `ui_DisplayDrawCallData` console variable to `1` to display the draw call information for each loaded canvas, as in the following example.

   ```plaintext
   ui_DisplayDrawCallData 1
   ```

2. In the last column in the display of draw call information, note the values under `XTex`. The `XTex` column shows the number of draw calls when the shader supported maximum of 16 textures is reached. To reduce the number of draw calls, use a texture atlas.

3. In the Lumberyard Editor console, enter the `ui_ReportDrawCalls` console command. This command outputs a report of the draw calls for all active canvases into a text file.

4. Open the `lumberyard_version\dev\Cache\your_project_name\pc\user\log\LyShine\drawcallreport.txt` log file.

5. At the end of the report, examine the following two sections to identify the textures to put into texture atlases.

   ```plaintext
   Textures used on multiple canvases that are causing extra draw calls
   ```

   ```plaintext
   Per canvas report of textures used on only that canvas that are causing extra draw calls
   ```

6. When deciding which textures to put into a texture atlas, consider the following points:

   - A texture atlas reduces draw calls only if the textures in the atlas are used on screen at the same time. Therefore, to reduce draw calls, put textures that are going to be on screen at the same time into the same texture atlas.

   For example, suppose you have texture sets A and B. The textures in A appear in one screen state, and the textures in B appear in a different screen state. In this situation, put the textures in A into one texture atlas and the textures in B into a different texture atlas.

   - The default maximum size of a texture atlas is `4096x4096`.

   Because this limits the number of textures in a texture atlas, having the UI load multiple separate texture atlases is a good practice.

For more information on the `ui_DisplayDrawCallData` and `ui_ReportDrawCalls` commands, see [Debugging UI Canvases](p. 2906).
Debugging UI Canvases

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the following console commands and console variables to display debug information for the UI when your game is running.

- **ui_DisplayCanvasData** (p. 2906)
- **ui_DisplayDrawCallData** (p. 2907)
- **ui_DisplayElemBounds** (p. 2908)
- **ui_DisplayTextureData** (p. 2909)
- **ui_ReportDrawCalls** (p. 2909)

### ui_DisplayCanvasData

Displays canvas data for enabled or loaded canvases.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Off.</td>
</tr>
<tr>
<td>1</td>
<td>Displays a line of information for each loaded canvas.</td>
</tr>
<tr>
<td>2</td>
<td>Displays information only for canvases that are enabled.</td>
</tr>
</tbody>
</table>

The following example displays data for five loaded UI canvases.

<table>
<thead>
<tr>
<th>NN</th>
<th>Name</th>
<th>En</th>
<th>Po</th>
<th>Na</th>
<th>DO</th>
<th>nElem</th>
<th>nGrab</th>
<th>nMenu</th>
<th>nTitle</th>
<th>nText</th>
<th>nMask</th>
<th>nInput</th>
<th>nNotify</th>
<th>nActive</th>
<th>nHover</th>
<th>nClick</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Connects</td>
<td>Y</td>
<td>Y</td>
<td>Y</td>
<td>6</td>
<td>10</td>
<td>14</td>
<td>12</td>
<td>0</td>
<td>6</td>
<td>0</td>
<td>0</td>
<td>2</td>
<td>0</td>
<td>0</td>
<td>None</td>
</tr>

<td>0</td>
<td>36</td>
<td>15</td>
<td>8</td>
<td></td>
</tr>
</tbody>
</table>

The following table describes each column.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NN</td>
<td>The index number of the canvas in the list. The canvases are listed in the order that they're drawn in.</td>
</tr>
<tr>
<td>Name</td>
<td>The leaf canvas name.</td>
</tr>
<tr>
<td>En</td>
<td>Whether the canvas is enabled.</td>
</tr>
<tr>
<td>Po</td>
<td>Whether the canvas accepts positional inputs (for example, mouse input).</td>
</tr>
<tr>
<td>Na</td>
<td>Whether the canvas has navigation enabled.</td>
</tr>
<tr>
<td>DO</td>
<td>The draw order, which is used to sort the list of loaded canvases.</td>
</tr>
<tr>
<td>nElem</td>
<td>The number of UI elements in the canvas.</td>
</tr>
</tbody>
</table>
### Debugging UI Canvases

#### Column Description

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nEnab</td>
<td>The number of enabled UI elements in the canvas. If a parent isn't enabled, the element isn't counted.</td>
</tr>
<tr>
<td>nRend</td>
<td>The number of enabled renderable elements in the canvas (how many images, text and particle effects are being rendered).</td>
</tr>
<tr>
<td>nRCtrl</td>
<td>The number of enabled &quot;render control&quot; elements in THE canvas (masks and faders).</td>
</tr>
<tr>
<td>nImg</td>
<td>The number of enabled UI elements with UiImageComponents.</td>
</tr>
<tr>
<td>nText</td>
<td>The number of enabled UI elements with UiTextComponents.</td>
</tr>
<tr>
<td>nMask</td>
<td>The number of enabled UI elements with UiMaskComponents.</td>
</tr>
<tr>
<td>nFadr</td>
<td>The number of enabled UI elements with UiFaderComponents.</td>
</tr>
<tr>
<td>nIntr</td>
<td>The number of enabled UI elements with interactable components (Button, Slider, TextInput, and so on).</td>
</tr>
<tr>
<td>nUpdt</td>
<td>Number of enabled UI elements with components that listen for updates (that is, that potentially do something every frame).</td>
</tr>
<tr>
<td>ActiveInt</td>
<td>The name of the active interactable on this canvas (if any).</td>
</tr>
<tr>
<td>HoverInt</td>
<td>The name of the current hover interactable on this canvas (if any).</td>
</tr>
</tbody>
</table>

#### ui_DisplayDrawCallData

Displays the number of draw calls used to render UI canvases. This variable is useful for performance tuning and debugging.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Turns off the display.</td>
</tr>
<tr>
<td>1</td>
<td>Turns on the display.</td>
</tr>
</tbody>
</table>

The following example data shows draw call information for four UI canvases.

<table>
<thead>
<tr>
<th>NN</th>
<th>Canvas name</th>
<th>nDraw</th>
<th>nPrim</th>
<th>nTris</th>
<th>nRTs</th>
<th>nUTex</th>
<th>nMask</th>
<th>XRT</th>
<th>XEInc</th>
<th>XSRgb</th>
<th>XPexV</th>
<th>XTex</th>
</tr>
</thead>
<tbody>

<td>The leaf canvas name.</td>
</tr>
</tbody>
</table>
### _Debugging UI Canvases_

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nDraw</td>
<td>The number of draw calls.</td>
</tr>
<tr>
<td>nPrim</td>
<td>The number of primitives (for example, images and text strings).</td>
</tr>
<tr>
<td>nTris</td>
<td>The number of triangles rendered for the UI.</td>
</tr>
<tr>
<td>nMask</td>
<td>The number of mask render nodes in the render graph.</td>
</tr>
<tr>
<td>nRTs</td>
<td>The number of render target render nodes in the render graph.</td>
</tr>
<tr>
<td>nUTex</td>
<td>The number of unique textures being rendered in the canvas in this frame.</td>
</tr>
<tr>
<td>XMask</td>
<td>The number of draw calls caused by the use of masks. <strong>Note</strong> One mask can cause up to four extra draw calls.</td>
</tr>
<tr>
<td>XRT</td>
<td>The number of draw calls caused by render targets.</td>
</tr>
<tr>
<td>XBlnd</td>
<td>The number of draw calls caused by a change in blend mode.</td>
</tr>
<tr>
<td>XSrgb</td>
<td>The number of draw calls caused by a change in Srgb write. This data point appears only for render targets (for example, playing video).</td>
</tr>
<tr>
<td>XMaxV</td>
<td>The number of draw calls caused by a render node that requires more than 65536 vertices or 16384 quads. This case is uncommon. For example, more than 16000 characters of text would be required for a value to appear.</td>
</tr>
<tr>
<td>XTex</td>
<td>The number of draw calls that occur when the shader supported maximum of 16 textures is reached. To reduce the number of these calls, you can use a texture atlas. For more information, see <em>Using Texture Atlases</em> (p. 2900).</td>
</tr>
</tbody>
</table>

**ui_DisplayElemBounds**

This console command displays an overlay on the screen that shows the rectangles of elements. By default, it shows the rectangular bounds of every UI element for each enabled UI canvas.

If you have several enabled UI canvases and want to see the rectangular bounds for only one canvas, use the `ui_DisplayElemBoundsCanvasIndex` console variable. To use the `ui_DisplayElemBoundsCanvasIndex` console variable, specify the index of the canvas whose bounds you want to display. To find the index for an enabled canvas, use the `ui_DisplayCanvasData 2` setting.

The following example shows the rectangular bounds of nested scrollboxes.
ui_DisplayTextureData

Displays the textures that the UI is using.

The display shows the dimensions, data size, texture format, and pathname of each texture that the UI system is using in the current frame. The textures are sorted in descending order by the amount of memory that they use.

The following example shows data for 13 unique textures in the current frame.

<table>
<thead>
<tr>
<th>Dimensions</th>
<th>Data Size</th>
<th>Format</th>
<th>Texture Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>512 x 256</td>
<td>133072 B</td>
<td>RGBA</td>
<td>AB_button_2B</td>
</tr>
<tr>
<td>136 x 113</td>
<td>25000 B</td>
<td>RGBA</td>
<td>lyshoneexamples/outline.dos</td>
</tr>
<tr>
<td>38 x 38</td>
<td>577 b</td>
<td>RGBA</td>
<td>ui/textures/lyshoneexamples/panelbgd.dos</td>
</tr>
<tr>
<td>38 x 38</td>
<td>577 b</td>
<td>RGBA</td>
<td>ui/textures/prefab/button normal.dds</td>
</tr>
<tr>
<td>38 x 38</td>
<td>577 b</td>
<td>RGBA</td>
<td>ui/textures/prefab/dropdown_button.dds</td>
</tr>
<tr>
<td>64 x 64</td>
<td>1536 b</td>
<td>RGBA</td>
<td>ui/textures/lyshoneexamples/Button.dds</td>
</tr>
<tr>
<td>36 x 36</td>
<td>1536 b</td>
<td>RGBA</td>
<td>ui/textures/prefab/dropdown_arrow.dds</td>

<td>1536 b</td>
<td>RGBA</td>
<td>ui/textures/prefab/slider_track_normal.dds</td>
</tr>
<tr>
<td>32 x 32</td>
<td>1909 b</td>
<td>RGBA</td>
<td>ui/textures/prefab/radiobutton_background_normal.dds</td>
</tr>
<tr>
<td>19 x 16</td>
<td>1296 b</td>
<td>RGBA</td>
<td>ui/textures/prefab/cellbutton_over.dds</td>
</tr>
<tr>
<td>8 x 8</td>
<td>8 b</td>
<td>RGBA</td>
<td>lyshoneexamples/Textures/White.dds</td>
</tr>
</tbody>
</table>

ui_ReportDrawCalls

Writes a report of draw calls to a log file.

The command output displays the location of the log file, as in the following example.

```
ui_ReportDrawCalls (Command)
ui ReportDrawCalls
[CONSOLE] Executing console command 'ui_ReportDrawCalls' (UI) - Wrote Draw Call Report to @log@/LyShine/DrawCallReport.txt
```
Defining Game and Level Load Screens

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can create a game or level loading screen with the UI Editor. The game loading screen is displayed while the game loads. The level loading screen is displayed while a level loads. You can create and define a loading screen for each level.

Load screens were refactored in Lumberyard v1.24 to support more than just UI canvases when using RAD Game Tools' Bink video files. You can specify a path to either a UI canvas or a Bink video file. Additionally, multi-threaded load screens are supported for Bink videos, enabling a load screen to render hitch-free while levels load.

To define the game and level loading screens, you set the file paths as parameters in game.cfg and level.cfg.

Defining a Game Loading Screen

To define a game loading screen, first do one of the following:

• Create the loading screen canvas in the UI Editor and save it in your Lumberyard project directory.
• Save a Bink video file in your Lumberyard project directory.

You then add or modify parameters in game.cfg, which is at the root of your project directory.

To add game loading screen parameters to game.cfg

1. In a text editor, open game.cfg at the root of your project directory.
2. Add or modify the following parameters in game.cfg:

   • game_load_screen_uicanvas_path – File path to the .uicanvas game load screen file relative to your project path. Use this if you are using a UI canvas for your loading screen.
   
   Example

   If your game load canvas is at lumberyard_version\dev\SamplesProject\UI\Canvases\UiAnimMultiSequence.uicanvas, you would specify the following path:

   \UI\Canvases\UiAnimMultiSequence.uicanvas

   • game_load_screen_bink_path – File path to the .bk2 game load screen file relative to your project path. Use this if you are using a Bink video for your loading screen.

   • game_load_screen_minimum_time – Minimum amount of time to show the game load screen, in seconds. Important to prevent short loads from flashing the load screen. 0 means there is no minimum. The default is 0.
Defining a Level Loading Screen

To define a level loading screen, first do one of the following:

- Create the loading screen canvas in the UI Editor and save it in your level's directory.
- Save a Bink video file in your level's directory.

You then add or modify parameters in level.cfg, which is at the root of your level directory.

To add level loading screen parameters to level.cfg

1. In a text editor, open level.cfg at the root of your level directory.
2. Add or modify the following parameters in level.cfg:

   - **level_load_screen_uicanvas_path** – File path to the .uicanvas level load screen file relative to your project path. Use this if you are using a UI canvas for your loading screen.

   **Example**

   If your level load canvas is at \lumberyard_version\dev\StarterGame\Levels\StarterGame\UiAnimMultiSequence.uicanvas (root of the level directory, which is the same as level.cfg), specify the following path:

   Levels\StarterGame\UiAnimMultiSequence.uicanvas

   - **level_load_screen_bink_path** – File path to the .bk2 level load screen file relative to your project path. Use this if you are using a Bink video for your loading screen.

   - **level_load_screen_minimum_time** – Minimum amount of time to show the level load screen, in seconds. Important to prevent short loads from flashing the load screen. 0 means there is no minimum. The default is 0.

   - **level_load_screen_sequence_to_auto_play** – The name of the level load screen animation sequence to play on load.

   - **level_load_screen_sequence_fix_fps** – A fixed frame rate for the level load screen animation to play on load. Default is 60. To ignore this setting and use the real time-delta, specify -1.
• ly_EnableLoadingThread – Experimental. Set to 1 to enable fully threaded loading where the load screen is drawn on a thread that isn't loading data. Currently only supported for Bink load screens.

The following are examples of these parameters in a level.cfg file:

```plaintext
level_load_screen_uicanvas_path="Levels\StarterGame\UiAnimMultiSequence.uicanvas"
level_load_screen_minimum_time=3
level_load_screen_sequence_to_auto_play="TopRowMove"
level_load_screen_sequence_fix_fps=4.0

level_load_screen_bink_path="Videos\IntroLevelLoadingScreen.bk2"
level_load_screen_minimum_time=3
```

## Working with UI Slices

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The UI system uses the slices technology, which is a cascaded data management system for entities. This slice technology is similar to what the main Lumberyard Editor uses, but the user interface and some of the requirements are slightly different for the UI system.

For more information about component entity system slices, see Working with Slices (p. 510).

### Topics

- Creating a UI Slice (p. 2912)
- Instantiating a UI Slice (p. 2913)
- Creating a Cascaded UI Slice (p. 2913)
- Creating a Detached UI Slice (p. 2914)
- Modifying a UI Slice and Pushing Changes (p. 2914)
- Editing Slices in a New Tab (p. 2915)
- Flagging Dynamic Slices (p. 2916)

## Creating a UI Slice

A slice can contain any number of UI elements. However, all UI elements in a slice must be contained within one parent element.

You don't need to select all of the elements to go into the new slice. If you just select one element, all of its child elements are included in the slice.

**To create a UI slice**

1. In the **UI Editor**, in the **Hierarchy** pane or in the viewport, select the top-level parent entity to include in the slice.
Instantiating a UI Slice

You can create an instance of a slice in your UI canvas.

To instantiate a slice

In the UI Editor, do one of the following:

1. Choose New, Element from Slice Browser. This displays a file browser to select your slice file.
2. Choose New, Element from Slice Library. This displays a hierarchical menu of all the slices under \UI\Slices\Library.

Creating a Cascaded UI Slice

A cascaded slice is a slice that contains instances of other slices. Cascaded slices can store their own overrides for component and entity properties and can also contain their own entities.

When you create a cascaded slice, the UI system maintains references to the slices that are child entities. This means, for example, that you can instantiate an image slice as a parent and a text slice as a child. You can then select them both and make a cascaded slice called Button. If you then create instances of the Button slice, they all contain a reference to the image slice and the text slice. If you then push a font change to the text slice, this affects all instances of the Button slice as well as any other instances of the text slice.
To create a cascaded slice

1. Select the root of a set of elements. The child entities within that root can be individual elements, slices, or a combination of both.

   **Note**
   If your root is not already in a slice, and you want to maintain child slice references, you must also select the child slices in this step. If you select only the root, only one option appears: **Make New Slice from Selection**. This creates a detached UI slice (flattens child references).

2. Right-click the selection and then choose **Make Cascaded Slice from Selected Slices & Entities**.

3. Save the cascaded slice with a descriptive name.

Creating a Detached UI Slice

You can create a detached UI slice from an existing UI slice instance. When you create a detached UI slice, the UI system removes, or flattens, all references to child slices. Using the button example from the previous section, let's say you saved the image slice instance and its child text slice instance as a detached slice and called it `Button2`. The detached `Button2` would not reference any other slices; it is a slice that contains two entities. If you pushed a change to the text slice, it would not affect the text within any instances of the `Button2` slice.

To create a detached UI slice

1. Select the root of a set of elements, or a root and one or more child entities. The child entities within that root can be individual elements, slices, or a combination of both.

2. Right-click the selection and choose **Make Detached Slice from Selected Entities**.

   **Note**
   If the any of the elements that you selected are slice instances, two options appear: **Make Detached Slice from Selected Entities** and **Make Cascaded Slice from Selected Slices & Entities**.

3. Save the slice with a descriptive name.

Modifying a UI Slice and Pushing Changes

In the **UI Editor**, you modify UI slices and push changes similarly to the way that you do in the main Lumberyard Editor. For more information on pushing changes in Lumberyard's component entity system, see **Working with Slices** (p. 510).

The following conventions apply when working with slices in the **UI Editor**:

- If you select an entity that is part of a slice instance, the **Properties** pane highlights in orange any properties that are different between the selected entity and the slice to which it belongs.
- A UI slice can't contain references to any entities not within the slice. A UI slice can only contain reference to entities within the slice.

In the **Hierarchy** pane, elements that are part of a slice appear in blue. Elements that appear in bold blue indicate that the element is the root of the slice. Within the slice's root, elements that appear in italic indicate a child slice.

**Example**

- The element `Background` is not in a slice.
• **FontRenderingButton** is a root element and its child element, **Text**, is an element within submenubutton.slice.

You can locally change an instantiated slice's name, which obscures the name of the slice from which it instantiated.

**To determine the slice that the element instantiated from**

• Pause on the element. The slice name and its path appears in a tooltip.

**To push local changes to the slice**

1. Right-click in the **Properties** pane or on selected UI elements in the **Hierarchy** pane.
2. In the context menu, choose **Push to Slice**.

**Editing Slices in a New Tab**

When you edit an instance of a UI slice in a UI canvas, you can use the context menu to **Push to Slice**. This pushes the local changes that you select. For simplicity, you can instead make changes to the slice in its own context. To do this, you can create a blank UI canvas and instantiate the slice there to edit. The **UI Editor** automates this process with the **Edit slice in new tab** feature.

**To edit a slice in a new tab**

1. In the **Hierarchy** pane, right-click a slice element.
2. Choose **Edit slice in new tab** and then choose the slice you want to edit. Multiple choices appear only if the selected element is an instance of a cascaded slice.
The selected slice appears in a new tab labeled **Slice: slice name**.

3. Edit the slice in the new tab.

   **Note**
   
   If you add elements to the slice, the elements must be children of the slice instance. Any elements outside of the slice instance will not be saved, as this is a temporary canvas for editing the slice.

4. When finished, choose **File, Save Slice** to save your changes to the slice.

## Flagging Dynamic Slices

A slice flagged as a dynamic slice can be used like any other slice, but it can also be instantiated at runtime.

You can flag a slice as dynamic in the **Asset Browser**.

**To flag a slice as dynamic**

- Right-click the `.slice` file and choose **Set Dynamic Slice**.

To instantiate a UI slice at runtime, use the **UiSpawner** component on a UI element. This causes the system to automatically spawn a dynamic slice on activation. It also exposes a bus to Lua and C++ that allows the slice to be instantiated whenever needed.

## UI Elements

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the [AWS Game Tech blog](https://aws.amazon.com), to learn more.
UI elements are entities that you can attach multiple components to. You can start with an empty element and add components to it, such as a button, image, slider, text, and so on. Or you can add an existing pre-fabricated (prefab) element (p. 2920), such as a scroll box, which is an element with components already attached. You can also create your own prefab elements (p. 2920).

Every UI element has the following two required components that are added automatically:

- The **Element** component identifies the element **Id** and presents the option to start in a disabled state.

  The **Start enabled** option is selected by default. To start the element as disabled in the game, clear this option. When starting the element as disabled in the game, the player can't see or interact with that element or its children. This setting has no effect on how the element appears in the **UI Editor**'s viewport.

- The **Transform2D** component defines the positioning, spacing, and size of the element relative to its parent (whether its parent is the canvas or another element). For more information, see **Transform2D Component** (p. 2926).

When you select the **Editor Only** option, that element and its children exist only in the context of the **UI Editor**. For example, when the launcher, the game, or **Preview** mode in the **UI Editor** displays a UI canvas, elements marked **Editor Only** and its children don't appear.
You can use **Editor Only** elements when you author a UI canvas and you want to display additional info or visuals that appear only when editing. For example, you can add a UI mockup image of the intended final canvas and mark it as **Editor Only** so that it's visible only when editing the canvas. Those authoring the canvas can use the image as a guide to placing and configuring elements.

**Note**
Runtime references to the **Editor Only** element, such as from script or code, are invalid. You can reference **Editor Only** elements from other **Editor Only** elements. References to **Editor Only** elements from elements that aren't **Editor Only** cause an error and possibly undefined behavior.

Each UI element can also have one visual component (p. 2936) (image or text), one interactive component (p. 2947) (button, check box, scroll box, slider, or text input), and one layout component (p. 2972) (layout column, layout row, or layout grid). The remaining components (p. 2994) are the mask and fader, either or both of which UI elements can attach.

For each of the following procedures, use the **UI Editor** to manage UI elements.

### Managing UI Elements in the UI Editor

<table>
<thead>
<tr>
<th>Task</th>
<th>Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td>To find an element</td>
<td>In the <strong>UI Editor</strong> menu, choose <strong>Edit</strong> and then <strong>Find Elements</strong> or press <strong>Ctrl+F</strong>. For more information, see the section called “Searching for UI Elements” (p. 2921).</td>
</tr>
<tr>
<td>To create an element</td>
<td>In the <strong>UI Editor</strong> toolbar, click <strong>New</strong> and then <strong>Empty element</strong>. The element appears in the <strong>Hierarchy</strong> pane and viewport.</td>
</tr>
<tr>
<td>To move, rotate, or resize an element</td>
<td>Select the element and then click the <strong>Move</strong>, <strong>Rotate</strong>, or <strong>Resize</strong> tool in the toolbar. Select <strong>Snap to grid</strong> to modify elements in increments.</td>
</tr>
<tr>
<td>To copy an element</td>
<td>Right-click the element in the <strong>Hierarchy</strong> pane or viewport and choose <strong>Copy</strong>.</td>
</tr>
<tr>
<td>To nudge an element</td>
<td>To nudge, or move, an element one pixel at a time, select the element and click the <strong>Move</strong> tool. Use arrow keys to nudge elements in the selected direction. Press and hold the <strong>Shift</strong> key while pressing the arrow keys to nudge elements 10 pixels at a time.</td>
</tr>
<tr>
<td>To paste a copied element</td>
<td>Right-click anywhere in the <strong>Hierarchy</strong> pane or viewport and choose <strong>Paste</strong>. If an element is selected, the <strong>Paste as sibling</strong> and <strong>Paste as child</strong> options appear.</td>
</tr>
<tr>
<td>To delete an element</td>
<td>Right-click the element in the <strong>Hierarchy</strong> pane or viewport and choose <strong>Delete</strong>.</td>
</tr>
<tr>
<td>To hide an element</td>
<td>Click the eye icon (to the right of the element name) in the <strong>Hierarchy</strong> pane or viewport. Click again to show the element. When hiding or unhiding (showing) an element, the following behaviors apply:</td>
</tr>
<tr>
<td></td>
<td>• If you hide an element, that element and all of its descendants are hidden in the viewport.</td>
</tr>
<tr>
<td></td>
<td>• If all of the element's parents or ancestors are showing (not hidden), clicking that element's eye icon toggles only that element's visibility.</td>
</tr>
</tbody>
</table>
### Configuring UI Anchors and Offsets

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Each UI element's position is determined by the `Transform2D` component. The `Transform2D` component sets a UI element's position and size relative to its parent's edges. The parent may be another element (if the elements are nested), or the canvas.

For more information about the `Transform2D` component, see Managing UI Anchors and Offsets (p. 2926).

### Scaling to Device Resolutions

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
You can use the **Scale to Device** property on the **Transform2D** component with the anchoring system to build UIs that display on multiple screen resolutions. The **Scale to Device** property applies an element scale that's based on the ratio of the authored canvas size to the target canvas size.

To view the effects of this computation, open the **Preview** canvas in the UI Editor.

For more information about the **Transform2D** component's **Scale to Device** property, see **Scale to Device (p. 2930)**.

**Using and Creating UI Prefabs**

This system has been deprecated and will be removed in a future release.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In the **UI Editor**, prefabs are preconfigured UI elements and compound elements that you can add to a canvas. You can also create custom prefabs.

**To add a prefab element**

1. In the **UI Editor** toolbar, click **New, Element from prefab**.
2. Select from:
   - Button
   - Checkbox
   - Image
   - LayoutColumn
   - LayoutGrid
   - LayoutRow
   - ScrollBox
   - ScrollBarHorizontal
   - ScrollBarVertical
   - Slider
   - Text
   - TextInput

   The new element appears in the **Hierarchy** pane and viewport.

If you have created your own element or modified an existing prefab, you can save it as a custom prefab.

**To save a custom prefab element**

1. In the **UI Editor**, right-click an element that you have created or modified in the **Hierarchy** pane or viewport.
2. Click **(Deprecated) Save as Prefab**.
3. In the **Save As** dialog box, do the following:
a. Navigate to any location in the project folder where you want to save your prefab.
b. Name your prefab with a `.uiprefab` file extension.
c. Click Save.

Your prefab now appears in the **New, (Deprecated) Element from prefab** menu.

## Searching for UI Elements

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can find UI elements by filtering by their name or their attached components. The **Find Element** tool hierarchically displays UI elements for the active UI canvas.

To open the **Find Element** tool

- In the **UI Editor**, do one of the following:
  - From the menu, choose **Edit** and then **Find Elements**.
  - Press **Ctrl+F**.

Initially, all UI elements in the currently active UI canvas appear in a tree view.
Searching for UI Elements

To filter by UI element name

- Enter the name in the search filter box.

  UI element names that contain the entered text remain visible. All other UI elements are hidden.

To filter by component

1. Select the filter button next to the search filter box.
2. In the menu that appears, select one or more components.

  UI elements that contain the selected components are visible. All other UI elements are hidden.

  **Note**
  The Find Element tool displays for selection only the components used by the UI elements in the active UI canvas.

UI elements that don't match the search criteria are typically hidden. However, a parent element that doesn't match the search criteria remains visible if one of its children meets the search criteria. This maintains the tree structure used to display the UI elements. Displayed UI elements that meet search criteria appear as white text. Displayed UI elements that don't meet the criteria but are visible to maintain tree structure appear in gray text.
After you select one or more UI elements, you can choose to select them in your UI Editor hierarchy.

To transfer your selections to the Hierarchy panel

1. In the Find Elements tool, select one or more UI elements. Press Ctrl to select multiple elements.
2. Choose Select in Hierarchy.

The Hierarchy panel appears, with the same UI elements selected.

UI Components

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

UI components define the properties of a UI element. For example, every element has a Transform2D component that defines its position, rotation, size, and scale. You can give an element additional properties by adding components, such as adding the image component to give an element color or texture. Each UI element can have one visual component (image or text), one interactive component (button, check box, scroll box, slider, or text input), and one layout component (layout column, layout row, or layout grid). You can attach any or all of the remaining components: dynamic components, tooltips, tooltips display, mask, and fader.

Topics
- Working with UI Components (p. 2924)
- Transform2D Component (p. 2926)
- Visual Components (p. 2936)
- Interactive Components (p. 2947)
- Layout Components (p. 2972)
- Tooltip Components (p. 2985)
• Dynamic Components (p. 2987)
• UISpawner Component (p. 2990)
• Other Components (p. 2994)

Working with UI Components

You can use the UI Editor to add and delete components, create references to UI elements for component properties, and manage components.

Topics
• Adding or Deleting Components (p. 2924)
• Referencing UI Elements (p. 2924)
• Managing UI Components (p. 2925)

Adding or Deleting Components

You can add or delete components in the UI Editor (p. 2874).

To add a component to an element

1. In the UI Editor, select an element in the Hierarchy pane or in the Viewport.
   
   To add components to multiple elements at once, use Ctrl to select multiple elements.
2. Do one of the following:
   • At the top of the Properties panel, click Add Component.
   • In the Properties panel, right-click and choose Add Component.
3. Select the component to add to the element: image, text, button, check box, slider, text input, scroll box, fader, mask, layout column, layout row, or layout grid.
4. See the instructions for the specific component that you're adding.

To delete a component from an element

1. In the UI Editor, select an element in the Hierarchy pane.
2. In the Properties panel, right-click the component and click Remove.

Referencing UI Elements

You can specify a UI element for some properties on components. For example, you can specify UI elements for Lua Script properties.
Working with UI Components

You can specify elements as properties either by dragging the element into the property field or by using the pick object button.

**To drag a UI element into a property**
- In the **UI Editor**'s **Hierarchy** panel, select an element and drag it to the component property in the **Properties** panel.

**To use the pick object button to reference a UI element**
1. In the **Properties** panel, next to the property to specify an element for, click the pick object button.
2. Select the element that you want from either the viewport or the **Hierarchy** panel.
   The property populates with the UI element name.

**To clear the element name from the property**
- In the **Properties** panel, next to the property name, click x.

After you specify a UI element as a property, you can select that element from the **Properties** panel.

**To select a UI element from the Properties panel**
- In the **Properties** panel, double-click the element name.

**Managing UI Components**

You can use the context menu in the **Properties** panel to add, remove, cut, copy, and paste components.

**To manage components from the context menu**
1. In the **Hierarchy** panel, select the UI element.
2. In the **Properties** panel, either right-click the component or click the menu button in the header. Then choose one of the following:
   - **Add component** – Add a component to the element
   - **Delete component** – Remove a component from the element
   - **Cut component** – Cut a component from one UI element to be pasted onto a different UI element
   - **Copy component** – Copy a component from one UI element to be pasted onto a different UI element
• **Paste component** – Paste a component copied from one UI element onto a different UI element

You can also use the context menu to act on multiple components at once.

**To perform actions on multiple components**

1. Press **Ctrl** to select multiple components and then right-click to open the context menu.
2. Choose an action.

**Note**

- The **Element** and **Transform2D** components are automatically added to a UI element and can't be removed from the component list.

- Some actions are disabled, depending on the context. For example, you can't paste a component if you haven't copied one.

**Transform2D Component**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **Transform2D** component is automatically added to every UI element you create. This component defines the element's position, rotation, size, and scale.

**Topics**

- Managing UI Anchors and Offsets (p. 2926)
- Scale to Device (p. 2930)

**Managing UI Anchors and Offsets**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use anchors and offset settings in the **Transform2D** component to set a UI element's position and size relative to its parent's edges. The **Transform2D** component is a required component in every element.

Anchor values are always 0.00% to 100.00% as defined by the parent's edges. Offsets are expressed in pixels and are relative to the anchors.

Anchors and offsets are useful in a variety of situations:

- Ensuring that an element maintains a specific padding within its parent's edges, regardless of changes to the parent's size
- Anchoring an element to a corner of its parent, regardless of changes to the parent's size or position
- Building resolution-independent UI elements
For example, you can ensure an element remains full screen regardless of the screen's resolution.

**To configure an element's anchors**

1. In the **Hierarchy** pane of the **UI Editor** (p. 2874), select the element whose anchors you want to modify.
2. In the **Properties** pane, under **Transform2D**, choose from the selection of commonly used anchor placements.
   1. Anchor to the parent's center, corner, or midway along an edge without changing size.
   2. Anchor to the left edge, middle, or right edge; vertical size adjusts to parent.
   3. Anchor to the top edge, middle, or bottom edge; horizontal size adjusts to parent.
   4. Anchor all of the element's edges to the parent. The horizontal and vertical size adjusts to parent. You can use this anchor preset to place an element that remains full screen, regardless of a change in resolution. This applies if the canvas is its parent.

**To further edit (fine tune) an element's anchors**

In the **Properties** pane, under **Transform2D**, do the following for **Anchors**, as appropriate:

- For **Left**, enter a value between 0.00% and 100.00%.
- For **Right**, enter a value between 0.00% and 100.00%.
- For **Top**, enter a value between 0.00% and 100.00%.
- For **Bottom**, enter a value between 0.00% and 100.00%.

The anchors' positions can be visualized as points on a grid, plotted in percentages by the length of its parent's edges from left to right and top to bottom. If you want to keep the element's size absolute (so that it doesn't change size when the parent changes size) but want to anchor it a particular vertical or horizontal point relative to the parent's size, make sure the top and bottom (or left and right) anchors have the same number. In this case, the anchors are said to be together.
But if, for example, you want the element's left and right edges to each remain at a fixed percentage relative to its parent and to change size as its parent changes size, then make the numbers different. In this case, the anchors are called split.

To edit an element's position and size

In the Properties pane, under Transform2D, modify the Offsets, as appropriate:

If the element's anchors are together, do the following:
- For X Pos, enter a negative or positive value in pixels. This adjusts the horizontal offset relative to the left-right anchor position.
- For Y Pos, enter a negative or positive value in pixels. This adjusts the vertical offset relative to the top-bottom anchor position.

When the element's anchors are together, only its position adjusts with the parent's size. The element's size is not adjusted. Therefore, you can manually adjust the element's size, which remains consistent when anchors are together.
- For Width, enter a value in pixels.
- For Height, enter a value in pixels.

If the element's anchors are split, do the following:
- For Left, enter a negative or positive value in pixels. This adjusts the size offset relative to the element's left anchor.
- For Right, enter a negative or positive value in pixels. This adjusts the size offset relative to the element's right anchor.
- For Top, enter a negative or positive value in pixels. This adjusts the size offset relative to the element's top anchor.
- For Bottom, enter a negative or positive value in pixels. This adjusts the size offset relative to the element's bottom anchor.
To edit an element's pivot, rotation, and scale

In the Properties pane, under Transform2D, do the following for Pivot, Rotation, and Scale, as appropriate:

- For Pivot, select a pivot preset or enter values for X and Y where 0 and 1 represent the element's edges.
- For Rotation, enter a value in degrees.
- For X Scale, enter a value to use as a multiplier for the element's width.
- For Y Scale, enter a value to use as a multiplier for the element's height.
- Select Scale to Device if you want the UI element and its child elements to scale with the device resolution.

Note
The element rotates around, resizes from, and calculates position from its pivot point. The pivot point is not limited by the element's borders. You can place the pivot outside of the element.

Example: Using Anchors to Resize an Element Relative to its Parent

In the following example, anchors are used to resize the element relative to its parent. The layout column of buttons is resized as needed to stay on the screen. Because the layout column of buttons does not use the Scale to Device setting, the button text does not change size along with its parent button.

Note
You can configure the text element (p. 2943) separately.

The layout column of buttons has the following settings.

<table>
<thead>
<tr>
<th>Layout Column element settings</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property</strong></td>
</tr>
<tr>
<td>Anchors</td>
</tr>
<tr>
<td>Pivot</td>
</tr>
<tr>
<td>Scale to device</td>
</tr>
</tbody>
</table>
Scale to Device

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Scale to Device property helps build game UIs that can display on multiple screen resolutions. You can preview your canvas at different resolutions in the UI Editor in Preview Mode.

A device scale is computed by using the ratio of the authored canvas size to the runtime canvas size. The device scale is then adjusted based on the selected Scale to Device setting. When you select any Scale to Device setting other than None, the device scale is multiplied with the Transform2D component's Scale property to get the final local scale for the element.

The following Scale to Device settings are available:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Does not scale with the device resolution.</td>
</tr>
<tr>
<td>Scale to fit (uniformly)</td>
<td>Scales to fit while maintaining the aspect ratio.</td>
</tr>
<tr>
<td></td>
<td>The final device scale for both X and Y is the minimum of the width and height ratios between the authored canvas size to the viewport size.</td>
</tr>
<tr>
<td>Scale to fill (uniformly)</td>
<td>Scales to fill while maintaining the aspect ratio.</td>
</tr>
<tr>
<td></td>
<td>The final device scale for both X and Y is the maximum of the width and height ratios between the authored canvas size to the viewport size.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Scale to fit X (uniformly)</td>
<td>Scales to fit horizontally while maintaining the aspect ratio. The final device scale for both X and Y is the ratio between the authored canvas width to the viewport width.</td>
</tr>
<tr>
<td>Scale to fit Y (uniformly)</td>
<td>Scales to fit vertically while maintaining the aspect ratio. The final device scale for both X and Y is the ratio between the authored canvas height to the viewport height.</td>
</tr>
<tr>
<td>Stretch to fill (non-uniformly)</td>
<td>Stretches to fill horizontally and vertically without maintaining the aspect ratio. The final device scale is the ratio between the authored canvas size to the viewport size.</td>
</tr>
<tr>
<td>Stretch to fit X (non-uniformly)</td>
<td>Stretches to fit horizontally, but doesn't stretch vertically. The final device scale for X is the ratio between the authored canvas width to the viewport width. Y doesn't scale with the device resolution.</td>
</tr>
<tr>
<td>Stretch to fit Y (non-uniformly)</td>
<td>Stretches to fit vertically, but doesn't stretch horizontally. The final device scale for Y is the ratio between the authored canvas height to the viewport height. X doesn't scale with the device resolution.</td>
</tr>
</tbody>
</table>

When using the *Scale to Device* setting, note the following:

- Scaling is performed about the element's pivot.
- Scaling an element doesn't affect the value of its offsets from its anchors.
- The element's final scale includes any scale inherited from its parents. Set the *Scale to Device* property on a UI element whose child elements that you also want to scale with the device resolution.
- Setting *Scale to Device* on a UI element and a descendant element results in double scaling on the descendant element.
- Avoid setting *Scale to Device* on a UI element that doesn't have its anchors together. Doing so can result in undesired behavior. This is because the anchors affect the size of the element relative to its parent, and the *Scale to Device* scale is applied on top of that.

**Example**

The element's size matches the viewport's size if you set the anchors to the following values:

- Left = 0%
- Top = 0%
- Right = 100%
- Bottom = 100%

However, if you then add a scale on top of these anchor values, the element size no longer matches the viewport size.
Scale to Device Examples

Each of the following examples demonstrates a different Scale to Device setting.

In each example, the background image covers the whole screen and uses the following settings:

- Anchors (apart): Left = 0%, Top = 0%, Right = 100%, Bottom = 100%
- Image type: Tiled
- Scale to Device: None

Uniform Scaling

In this uniform scaling example, the UI parent element has a fixed aspect ratio and is centered and fitted to the screen that it's displayed on.

The background image is a texture with simple settings (p. 2932).

The elements that make up the UI are all contained in a parent element and has the following settings.

Parent UI element settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anchor</td>
<td>Left = 50%, Top = 50%, Right = 50%, Bottom = 50%</td>
</tr>
<tr>
<td>Pivot</td>
<td>Default settings: X = 0.5, Y = 0.5</td>
</tr>
<tr>
<td>Width and Height</td>
<td>Matches the authored canvas size (for example, 1280x720)</td>
</tr>
<tr>
<td>Scale to device</td>
<td>Scale to fit (uniformly)</td>
</tr>
</tbody>
</table>
Scale to Fit Y

In this uniform scale to fit Y example, the layout column and its buttons are uniformly scaled so that they fit vertically on the screen regardless of its resolution.

The background image is a texture with simple settings (p. 2932).

The elements that make up the buttons are contained in a layout column element. The layout column element contains the UI buttons and has the following settings.

### Layout Column element settings for uniform scaling to fit Y

<table>
<thead>
<tr>
<th>Property</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anchors</td>
<td>Left = 50%, Top = 50%, Right = 50%, Bottom = 50%</td>
</tr>
<tr>
<td>Pivot</td>
<td>Default settings: X = 0.5, Y = 0.5</td>
</tr>
<tr>
<td>Scale to device</td>
<td>Scale to fit Y (uniformly)</td>
</tr>
</tbody>
</table>

Uniform Scaling While Maintaining Relative Position

In this example, the **Scale to Device** setting scales the health bar and speed indicator depending on the screen resolution. Anchor settings maintain their positions so that the health bar always appears in the right corner and the speed indicator always appears in the center.

The background image is a texture with simple settings (p. 2932).

The health bar element has the following settings. The anchor values keep it on the upper right corner of the screen.
Health bar element settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anchors</td>
<td>Left = 100%, Top = 0%, Right = 100%, Bottom = 0%</td>
</tr>
<tr>
<td>Pivot</td>
<td>X = 1.0, Y = 0.0</td>
</tr>
<tr>
<td>Scale to device</td>
<td>Scale to fit (uniformly)</td>
</tr>
</tbody>
</table>

The speed indicator element has the following settings. The anchor values keep it in the top center of the screen.

Health bar element settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anchors</td>
<td>Left = 50%, Top = 0%, Right = 50%, Bottom = 0%</td>
</tr>
<tr>
<td>Pivot</td>
<td>X = 0.5, Y = 0.0</td>
</tr>
<tr>
<td>Scale to device</td>
<td>Scale to fit (uniformly)</td>
</tr>
</tbody>
</table>

The following images show how the health bar and speed indicator scales based on the screen resolution while maintaining their position on the screen.

**Note**

The indicated resolutions are not shown to scale.
Visual Components

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add one visual component to an element: Image, Particle Emitter, or Text.

Topics
- Image (p. 2936)
- Particle Emitter (p. 2938)
- Text (p. 2943)

Image

You can use an Image component to add a color tint or texture to an element.

To see in-game examples of completed canvases with Image components

1. In Lumberyard Editor, in the Samples Project (p. 146), open the UiFeatures level.
2. Press Ctrl+G to play the game and then choose fComponents, and then Visual Components, and then Image.

You can view examples of image types such as sliced, stretched, fixed, tiled, stretched to fit, and stretched to fill.
3. Press Esc to exit the game.

To view these same canvases in the UI Editor, navigate to the lumberyard_version\dev\Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\Image directory.

You can open the following canvases:
- ColorTest.uicanvas
- ImageTypes.uicanvas

Use the Properties pane of the UI Editor to configure the following settings for the Image component.

Image Settings

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SpriteType</td>
<td>Select one of the following:</td>
</tr>
<tr>
<td>Sprite/Texture asset</td>
<td>Image displays the asset specified for Sprite path</td>
</tr>
<tr>
<td>Render target</td>
<td>Image displays the render target specified in Render target name</td>
</tr>
<tr>
<td>Sprite path</td>
<td>Click the browse (...) icon and select a suitable file.</td>
</tr>
<tr>
<td></td>
<td>Click the open-in (arrow) icon next to Sprite path to open the Sprite Editor (p. 2882).</td>
</tr>
<tr>
<td>Render target name</td>
<td>Enter a name of a render target and press Enter.</td>
</tr>
</tbody>
</table>

</tbody>
</table>

**Particle Emitter**

You can use a **Particle Emitter** component to emit two-dimensional particles from an element.

**To see in-game examples of completed canvases with a Particle Emitter component**

1. In Lumberyard Editor, in the **Samples Project** (p. 146), open the UiFeatures level.
2. Press **Ctrl+G** to play the game and then choose in order **Components**, **Visual Components**, and **Particle Emitter**.

   You can view particle emitter examples that create a variety of spark effects and trail effects.
3. Press **Esc** to exit the game.

To view these same canvases in the **UI Editor**, navigate to the `lumberyard_version\dev\Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\ParticleEmitter` directory.

You can open the following canvases:

- **ParticleEmitter.uicanvas**
- **ParticleEmitterSparks.uicanvas**
- **ParticleEmitterTrails.uicanvas**

Use the **Properties** pane of the **UI Editor** to configure the following settings for the **Particle Emitter** component.
Emitters Settings

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Emit on activate</td>
<td>Start emitting when the component is activated.</td>
</tr>
<tr>
<td>Hit particle count on activate</td>
<td>Emit and process the average number of particles when the emitter starts emitting.</td>
</tr>
<tr>
<td>Infinite life time</td>
<td>Make the lifetime of the emitter infinite.</td>
</tr>
<tr>
<td>Emitter life time</td>
<td>Enter the number of seconds that the emitter is active during. When the end of the lifetime is reached, the emitter stops emitting. This option is available when Infinite life time isn't set.</td>
</tr>
<tr>
<td>Emit rate</td>
<td>Enter the number of particles to emit per second.</td>
</tr>
<tr>
<td>Emitter shape</td>
<td>Select one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Point – Particles are emitted from the emitter position</td>
</tr>
<tr>
<td></td>
<td>• Circle – Particles are emitted from within the circle that is contained by the element area</td>
</tr>
<tr>
<td></td>
<td>• Quad – Particles are emitted from within the quad that is contained by the element area</td>
</tr>
<tr>
<td>Particle count limit</td>
<td>Use the Active particle limit value to limit the number of active particles.</td>
</tr>
<tr>
<td>Active particles limit</td>
<td>This option is available when Particle Count Limit is set. Type the maximum number of active particles. When the maximum number is reached, additional particles are emitted only after existing particles are removed. The maximum value is 9999.</td>
</tr>
<tr>
<td>Fixed random seed</td>
<td>Specify a fixed random seed for the emitter. When not selected, a random seed is generated each time the emitter starts emitting.</td>
</tr>
<tr>
<td>Random seed</td>
<td>This option is available when Fixed random seed is set. Enter the numerical seed to use for the particle emitter when Fixed random seed is selected. The field accepts a maximum nine-digit negative or positive integer.</td>
</tr>
<tr>
<td>Emit on edge</td>
<td>This option is available when Emitter shape is Circle or Quad. Emit particles on the edge of the specified shape.</td>
</tr>
<tr>
<td>Emit inside distance</td>
<td>This option is available when Emit on Edge is set. Enter the distance inside the edge that the particles are emitted from.</td>
</tr>

</tbody>
</table>

### Text

You can use a **Text** component to add a text string to an element.

#### To see in-game examples of completed canvases with text components

1. In Lumberyard Editor, in the **Samples Project** (p. 146), open the **UiFeatures level**.
2. Press **Ctrl+G** to play the game and then choose in order **Components, Visual Components**, and **Text**. The level has examples of text alignment, color and alpha, styling markup, overflow and wrapping, and character and line spacing.
3. Press Esc to exit the game.

To view the same canvases in the UI Editor, navigate to the `lumberyard_version\dev\Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\Text` directory.

You can open the following canvases:

- **Alignment.uicanvas** – Examples of aligning the text in its element rectangle
- **ColorAlpha.uicanvas** – Examples of setting different colors and transparency levels
- **StylingMarkup.uicanvas** – Examples of customizing the appearance of text using different styles, colors, and font in a single string
- **ImageMarkup.uicanvas** – Example of embedding images in text
- **OverflowWrap.uicanvas** – Examples of different wrap and overflow options

Use the **Properties** pane of the UI Editor to configure the following settings for the **Text** component.

**Text Settings**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text</td>
<td>Enter the preferred text string and press Enter. You can also apply text styling markup (p. 2945).</td>
</tr>
<tr>
<td>Enable markup</td>
<td>If selected, the text string is parsed for markup tags. For more information, see Text Markup (p. 2945).</td>
</tr>
<tr>
<td>Color</td>
<td>Click the color swatch to select a different color.</td>
</tr>
<tr>
<td>Alpha</td>
<td>Use the slider to choose an alpha value between 0 and 1.</td>
</tr>
<tr>
<td>Font path</td>
<td>Click the button and select a font .font file. For more information, see Adding New Fonts (p. 3000).</td>
</tr>
<tr>
<td>Font size</td>
<td>Enter a font size and press Enter.</td>
</tr>
<tr>
<td>Font effect</td>
<td>Select an effect from the list. The available font effects are dictated by the font .font file.</td>
</tr>
<tr>
<td>Horizontal text alignment</td>
<td>Select Left, Center, or Right to align the text with the element's left and right borders.</td>
</tr>
<tr>
<td>Vertical text alignment</td>
<td>Select Top, Center, or Bottom to align the text with the element's top and bottom borders.</td>
</tr>
<tr>
<td>Overflow mode</td>
<td>Select Overflow to allow the text to display beyond the edges of the element. Select Clip text to hide, or clip, any text that flows beyond the element's edges.</td>
</tr>
<tr>
<td>Wrap text</td>
<td>Select No wrap to prevent text from wrapping to subsequent lines. Select Wrap text to allow text to be broken into separate lines.</td>
</tr>
</tbody>
</table>
**Text Markup**

You can customize the appearance of the text in your game UI with bold and italic styling, multiple text colors, and multiple fonts in a single text string. You can also embed images in the text.

To do this, enter specific tags directly into the Text box, along with your string. The simple markup language is loosely based on HTML.

To use the text styling markup feature, you must use a font family `*.fontfamily` asset file in the Font path setting (rather than an individual `.font` asset file). For more information about adding font families to your projects, see Implementing New Fonts (p. 2999).

**To use text styling markup**

1. In the UI Editor (p. 2874), add a Text component to an element on your canvas (or modify an existing component).
2. With the element selected, in the Properties pane, set the Font path property to a `*.fontfamily` file.
3. Enter a string with markup styling in the Text box. See the next section for examples.

**Styling Tags and Attributes**

**Example**

You can use the following tags and attributes when styling text with markup:

**Bold** tag: `<b>`

![This text is bold]

**Italic** tag: `<i>`

![This text is italic]
**Font color** tag: `<font color>`

![Image showing text color change](image)

This text is red

**Font face** tag: `<font face>`

![Image showing font face change](image)

This text uses notosans font

---

**Image Tag and Attributes**

Use the `<img>` tag to embed an image in text.

**Example**

```html
<img src="images/icons/button" vAlign="center" height="fontHeight" scale="1.5" yOffset="5" xPadding="6"/>

<img src="images/icons/button" vAlign="bottom" height="100" scale="0.8" yOffset="-3" lPadding="2" rPadding="6"/>
```

Use the following attributes to customize your image. Only the `src` attribute is required. All other attributes are optional.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>src</code></td>
<td><code>src=&quot;images/icons/button&quot;</code></td>
<td>Asset path of the texture to display.</td>
</tr>
<tr>
<td><code>vAlign</code></td>
<td><code>vAlign=&quot;center&quot;</code></td>
<td>Alignment of image in the text area. The text area refers to the total height of the largest glyph in the font. If you don't specify this attribute, the default alignment is baseline.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &quot;top&quot; – Aligns top of image to top of text area</td>
</tr>
</tbody>
</table>
## Interactive Components

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>height</strong></td>
<td>height=&quot;100&quot;</td>
<td>Sets the image height and adjusts its width to preserve the aspect ratio. If you don't specify this attribute, the default alignment is fontAscent.</td>
</tr>
<tr>
<td><strong>scale</strong></td>
<td>scale=&quot;0.8&quot;</td>
<td>Scales the image by the specified scale factor. If not specified, this attribute defaults to 1.0.</td>
</tr>
<tr>
<td><strong>yOffset</strong></td>
<td>yOffset=&quot;-3&quot;</td>
<td>Offsets the image vertically by the specified float value in pixels. If not specified, this attribute defaults to 0.</td>
</tr>
<tr>
<td><strong>xPadding</strong></td>
<td>xPadding=&quot;6&quot;</td>
<td>Adds equal spacing before and after the image by the specified float value in pixels. If not specified, this attribute defaults to 0.0.</td>
</tr>
<tr>
<td><strong>lPadding</strong></td>
<td>lPadding=&quot;10&quot;</td>
<td>Adds spacing to the left of the image by the specified float value in pixels. If not specified, this attribute defaults to 0.0.</td>
</tr>
<tr>
<td><strong>rPadding</strong></td>
<td>rPadding=&quot;2&quot;</td>
<td>Adds spacing to the right of the image by the specified float value in pixels. If not specified, this attribute defaults to 0.0.</td>
</tr>
</tbody>
</table>

- "center" – Aligns center of image to center of text area
- "bottom" – Aligns bottom of image to bottom of text area
- "baseline" – Aligns bottom of image to baseline of text area
- "fontHeight" – Sets image height to height of total text area
- "fontAscent" – Sets image height to the font's ascent
- "<float value>" – Sets image height to specified float value in pixels
Interactive components respond to user input. For example, the user can click a button or drag a slider. You can use Lua scripts (p. 2897) or Script Canvas graphs to link the component response to an action.

An interactive element is defined as an element that has an interactive component applied.

**Topics**
- Properties for Interactive Components (p. 2948)
- Button (p. 2953)
- Checkbox (p. 2954)
- RadioButton (p. 2955)
- RadioButtonGroup (p. 2956)
- Slider (p. 2957)
- TextInput (p. 2958)
- ScrollBar (p. 2960)
- ScrollBox (p. 2962)
- Draggable (p. 2966)
- DropTarget (p. 2968)
- Dropdown (p. 2969)
- DropdownOption (p. 2971)

**Properties for Interactive Components**

All of the interactive components share a common set of properties. These properties are grouped into the following categories:

- **Input Enabled** (p. 2949) – Check box or flag that determines whether the element can be interacted with.
- **Multi-Touch Input Enabled** (p. 2949) – Check box or flag that determines whether the element will handle multi-touch events. Requires multi-touch to be enabled on the parent UI canvas (enabled by default).
- **States** (p. 2950) – Settings that determine the appearance of the element when in the Hover, Pressed, or Disabled states.
- **Navigation** (p. 2951) – Settings that determine how the gamepad or arrow keys navigate between interactive elements (p. 2952).
- **Auto Activate** (p. 2952) – Check box or flag that determines whether the element is automatically activated when the player pauses on the element.
- **Actions** (p. 2953) – Events that are caused by the listed action.
Input Enabled

The **Input Enabled** setting, selected by default, determines whether the component can be interacted with.

To visualize how the interactive element looks in its disabled state, deselect the **Input Enabled** setting, and then use Preview mode (p. 2891) to preview your canvas.

Multi-Touch Input Enabled

The **Multi-Touch Input Enabled** check box is selected by default. This setting determines whether the component will handle all multi-touch events it receives. When the check box is unchecked, this interactable will handle only primary touch input events.

Lumberyard ignores this setting if **Handle multi-touch** is not enabled in the parent UI Canvas component.
States

The States group of properties defines the appearance of the interactive element and its child UI elements when the element is in the Hover, Pressed, and Disabled states.

The normal appearance of a visual element (defined as an element with a visual component, such as image or text) is defined by the properties of that visual component. Some of the visual component's properties, however, can be overridden by an interactive component that is in the Hover, Pressed, and Disabled states.

The Hover, Pressed, and Disabled states have a list of state actions, which define the appearance of that state, and which override the corresponding property of the visual component:

- **Color** – RGB color tint
- **Alpha** – Opacity
- **Sprite** – Texture
- **Font** – Text font and font effect (of a text component, for example)

The state actions—Color, Alpha, Sprite, and Font—each have a Target property that specifies which visual element is to be affected. The elements from which you can choose include the current element—listed as <This element>, its child elements, and the descendants of its child elements. Using the Target property, you can pick exactly which visual element to override.

For example, the button prefab (p. 2920) has a top element named Button that has a visual component to define its color. It also has a child element with a text component to define the text (and its color) of the button. The top element (Button) also has the Interactable component. The Target for the color state action can override either the Button element's color or the Text element's color, depending on what you select from the list.
When you first add an interactive component to an element, no state actions are added by default. You must add state actions to the states that you want to use and modify.

To add a state action to a state

In the UI Editor (p. 2874), in the Properties pane, under the interactive component's name (for example, Button), do the following:

1. Under Interactable, States, click Add new element (green +).
2. From the list, choose one of the following: Color, Font, Sprite, Alpha.

To delete a state action

- Click Remove element (red x) next to the state action that you want to delete.

To clear all state actions from a state

- Click Clear container (box icon) next to the state from which you want to clear all the state actions.

Navigation

You can use the Navigation group of properties to specify how the arrow keys or gamepad navigates between interactive elements.

For each interactive element, you can set navigation to one of the following:

- Automatic – Algorithm determines which interactive elements become focused when up, down, left, or right is pressed.
Interactive Components

- **Custom** – You manually specify the interactive elements that become focused when up, down, left, or right is pressed.
- **None** – This option removes navigation capability; using the keyboard or gamepad, the player cannot focus on this element.

**First Focus Element**

To determine which element receives first focus when a canvas is first loaded, set the **First Focus Element** in the Canvas Properties (p. 2894). The **First Focus Element** receives focus upon canvas load when no mouse is detected. If you do not set a **First Focus Element**, or if a mouse is detected, no element has focus until the user provides direction input from a keyboard or mouse. At that point, the element closest to the top left corner of the canvas receives focus.

Once an element has focus, navigation to other elements is controlled by the navigation properties (p. 2951) defined for each interactive component.

**Interactive Element Controls**

To interact with a focused element, press **Enter** on the keyboard.

When an element is interactive, use the following controls:

- **Button** and **Checkbox** – **Enter** presses the button or selects or clears the check box, and then returns to navigation automatically. The control does not remain active after action.

- **Slider** and **Scrollbox** – Use arrow keys or joystick to move the slider or scroll box. Press **Enter** to return to navigation.

- **TextInput** – While active, use the following (press **Enter** to return to navigation):
  - Arrow keys move the text cursor.
  - **Shift**+arrow keys selects text.
  - Alphanumeric keys type text at the cursor position.
  - **Ctrl+A** selects the entire text string.
  - **Backspace** deletes the character to the left of the cursor.
  - **Delete** deletes the character to the right of the cursor.

**Auto Activate**

The **Auto Activate** setting applies to interactive elements that remain active after they are pressed. These include the slider, scroll bar, scroll box, and text input.

When Auto Activate is set, an element automatically activates when navigated to with the directional keys, and deactivates when navigated away from with the directional keys. The user does not need to press the **Enter** and **Back** keys to activate or deactivate the element.
Interactive Components

The UI must be designed so that a user cannot get stuck on an activated element. For example, a horizontal slider that is set to automatically activate should not have another interactive element to the left or right of it. This is because pressing the left or right key on an active slider moves the slider handle.

Actions

You can use the Actions properties to trigger a particular event when one of the listed actions occur. Type a string for one of the actions. When the listed action occurs (for example, when a game player starts to pause on the element), the listed string is sent as an action.

You can enter strings for the following actions:

- Hover start
- Hover end
- Pressed
- Release

Button

You can use a Button component to make an element behave like a button.

To see an in-game example of a completed canvas with the Button component, open the level UiFeatures in the project SamplesProject. Press Ctrl+G to play the game, and then choose Components, Interactable Components, Button. You can view the different types of buttons you can create. Press Esc to exit the game.

To view this same canvas in the UI Editor, open \Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\Button\Styles.uicanvas.

Note the following:

- This component is typically applied to an element with an image component; if no visual or image component is present, many of the button's properties have no effect.

- If you want to add a text label to a button, add a child element with a text component.

- To define borders for a sliced image type, open the Sprite Editor. To do this, click the arrow (open-in) next to Sprite path.
You can add a prebuilt **Button** element from the slice library. When you do this, a basic button with the text string "Button" is automatically created in your **Hierarchy** pane.

**To add a Button element from the slice library**

- In the **UI Editor (p. 2874)**, choose **New, Element from Slice Library, Button**.

**To edit a button component**

In the **UI Editor (p. 2874) Properties** pane, expand **Button** and do the following, as appropriate:

  **Interactable**

  See **Properties (p. 2948)** to edit the common interactive component settings.

  **Actions, Click**

  Enter a text string. This string is sent as an action on the UI canvas when the button is clicked.

---

**Checkbox**

You can use the **Checkbox** component to make an element behave like a check box. This component is typically applied to an element with two visual child elements: One element appears when the check box is selected and another appears when the check box is cleared.

To see in-game examples of completed canvases with the **Checkbox** component, open the level **UiFeatures** in the project **SamplesProject**. Press **Ctrl+G** to play the game, and then choose **Components, Interactable Components, Checkbox**. You can view examples of color targets, check box interaction areas, and on and off elements. Press **Esc** to exit the game.

To view these same canvases in the **UI Editor**, navigate to the `\Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\CheckBox` directory. You can open the following canvases:

- **Area.uicanvas** – Examples of different check box interaction areas
- **ColorTargets.uicanvas** – Examples of different color targets when interacting with the check box
- **OnOff.uicanvas** – Examples of different check box on and off elements

You can add a prebuilt **Checkbox** element from the slice library. When you do this, a basic check box with the text string "Checkbox" and a check image for the box is automatically created in your **Hierarchy** pane.

**To add a Checkbox element from the slice library**

- In the **UI Editor (p. 2874)**, choose **New, Element from Slice Library, Checkbox**.

**To edit a check box component**

In the **Properties** pane of the **UI Editor (p. 2874)**, expand **Checkbox** and do the following, as appropriate:

  **Interactable**

  See **Properties (p. 2948)** to edit the common interactive component settings.
Elements, On

Select an element from the list to specify the entity that appears when the check box state is on (selected).

Elements, Off

Select an element from the list to specify the entity that appears when the check box state is off (cleared).

Value, Checked

Select the box to change the initial state of the check box.

Actions, Change

Enter a text string. This string is sent as an action on the UI canvas when the check box has any state changes.

Actions, On

Enter a text string. This string is sent as an action on the UI canvas when the check box state changes to on (selected).

Actions, Off

Enter a text string. This string is sent as an action on the UI canvas when the check box state changes to off (cleared).

RadioButton

You can use the RadioButton component to make an element behave like a radio button. This component is typically used on an element with two visual child elements—one to display when the radio button is selected and another to display when the radio button is cleared.

Use this component in conjunction with the RadioButtonGroup component. The RadioButtonGroup component handles selecting and clearing the radio buttons in the group and makes sure that only one radio button is ever selected.

To see in-game examples of completed canvases with the RadioButton component, open the level UiFeatures in the project SamplesProject. Press Ctrl+G to play the game, and then choose Components, Interactable Components, RadioButton. You can view examples of different behaviors, default settings, and groups for radio buttons Press Esc to exit the game.

To view these same canvases in the UI Editor, navigate to the \Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\RadioButton directory. You can open the following canvases:

- Groups.uicanvas – Examples of different radio button groupings
- RadioButton.uicanvas – Examples of different behaviors and default settings

To edit a radio button component

In the Properties pane of the UI Editor (p. 2874), expand RadioButton and do the following, as appropriate:
Interactable

See Properties (p. 2948) to edit the common interactive component settings.

Elements, On

Select an element from the list to specify the entity that appears when the radio button state is on (selected).

Elements, Off

Select an element from the list to specify the entity that appears when the radio button state is off (cleared).

Elements, Group

Select an element from the list to specify the group the radio button belongs to.

Value, Checked

Select the box to change the initial state of the radio button.

Actions, Change

Enter a text string. This string is sent as an action on the UI canvas when the radio button has any state changes.

Actions, On

Enter a text string. This string is sent as an action on the UI canvas when the radio button state changes to on (selected).

Actions, Off

Enter a text string. This string is sent as an action on the UI canvas when the radio button state changes to off (cleared).

RadioButtonGroup

You can use the RadioButtonGroup component to manage radio buttons. This component handles selecting and clearing the radio buttons in the group when appropriate. It also ensures that only one radio button is selected at one time. You typically use this component on an element with children radio buttons, which are part of the radio button group.

To see in-game examples of completed canvases with the RadioButtonGroup component, open the level UiFeatures in the project SamplesProject. Press Ctrl+G to play the game, and then choose Components, Interactable Components, RadioButton. You can view examples of different behaviors, default settings, and groups for radio buttons Press Esc to exit the game.
To view these same canvases in the **UI Editor**, navigate to the \Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\RadioButton directory. You can open the following canvases:

- Groups.uicanvas – Examples of different radio button groupings
- RadioButton.uicanvas – Examples of different behaviors and default settings

You can add a prebuilt **RadioButtonGroup** element from the slice library. When you do this, a group of three radio buttons is automatically created in your **Hierarchy** pane.

**To add a RadioButtonGroup element from the slice library**

- In the **UI Editor** (p. 2874), choose **New, Element from Slice Library, RadioButtonGroup**.

**To edit a RadioButtonGroup component**

In the **Properties** pane of the **UI Editor** (p. 2874), expand **RadioButtonGroup** and do the following, as appropriate:

**Settings, Allow uncheck**

Select to enable the clearing or unchecking of selected radio buttons.

**Actions, Change**

Enter a text string. This string is sent as an action on the UI canvas when the radio button group has any state changes.

---

**Slider**

You can use the **Slider** component to make an element behave like a slider. This component is typically applied to an element with three visual child elements: one immediate child, called **Track**, and two child elements of the track, called **Fill** and **Handle**.

To see in-game examples of completed canvases with the **Slider** component, open the level UiFeatures in the project SamplesProject. Press Ctrl+G to play the game, and then choose **Components, Interactable Components, Slider**. You can view examples of different slider behavior and positioning. Press Esc to exit the game.

To view these same canvases in the **UI Editor**, navigate to the \Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\Slider directory. You can open the following canvases:

- Behavior.uicanvas – Examples of slider behaviors such as fill type, handles, and buttons to control the slider
- Rotation.uicanvas – Example of slider positioning

You can add a prebuilt **Slider** element from the slice library. When you do this, the slider's track, fill, and handle are automatically created in your **Hierarchy** pane.

**To add a Slider element from the slice library**

- In the **UI Editor** (p. 2874), choose **New, Element from Slice Library, Slider**.
To edit a slider component

In the Properties pane of the UI Editor (p. 2874), expand Slider and do the following, as appropriate:

**Interactable**

See Properties (p. 2948) to edit the common interactive component settings.

**Elements, Track**

Select an element from the list to provide the background of the slider and to limit the movement of the manipulator.

**Elements, Fill**

Select an element from the list to provide the background of the slider, from the lower limit to the center of the manipulator position.

**Elements, Manipulator**

Select an element from the list to provide the movable knob of the slider.

**Value, Value**

Enter the initial value of the slider.

**Value, Min**

Enter the lower limit of the slider.

**Value, Max**

Enter the upper limit of the slider.

**Value, Stepping**

Enter the step value. For example, use 1 to only permit whole integer values.

**Actions, Change**

Enter a text string. This string is sent as an action on the UI canvas when the slider has finished changing values.

**Actions, End Change**

Enter a text string. This string is sent as an action on the UI canvas when the slider has changing values.

---

**TextInput**

You can use a TextInput component to make an element offer player input. This component is typically applied to an element with an image component and two child elements with text components (one for placeholder text and one for input text).

To see in-game examples of completed canvases with the TextInput component, open the level UiFeatures in the project SamplesProject. Press Ctrl+G to play the game, and then choose Components,
Interactable Components, TextInput. You can view examples of different types of text input behavior on single lines and on multiple lines. Press Esc to exit the game.

To view these same canvases in the UI Editor, navigate to the \Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\TextInput directory. You can open the following canvases:

- Multiline.uicanvas – Examples of editing multiline text strings
- SingleLine.uicanvas – Example of editing single-line text strings

You can add a prebuilt TextInput element from the slice library. When you do this, a text input box, pause-on state, and placeholder text "Type here..." are automatically created in your Hierarchy pane.

To add a TextInput element from the slice library

- In the UI Editor (p. 2874), choose New, Element from Slice Library, TextInput.

To edit a text input component

In the Properties pane of the UI Editor (p. 2874), expand TextInput and do the following, as appropriate:

Interactable

See Properties (p. 2948) to edit the common interactive component settings.

Elements, Text

Select an element from the list to provide the text component for the input text. The list shows child elements that have text components.

Elements, Placeholder text element

Select an element from the list to provide the text component for the placeholder text. The list shows child elements that have text components.

Text editing, Selection color

Click the color swatch to select a different color for the selected text.

Text editing, Cursor color

Click the color swatch to select a different color for the cursor.

Text editing, Max char count

Enter the maximum number of characters allowed in the text input box. Type -1 for no character limit.

Text editing, Cursor blink time

Enter a value in seconds. Use 0 for no blink, 1 to blink once every second, 2 to blink once every two seconds, etc.

Text editing, Is password field

Select the box and specify the replacement character.

Text editing, Clip input text

Sets the Overflow mode of the text element to Clip text at runtime.

Actions, Change

Enter a text string. This string is sent as an action on the UI canvas whenever a change occurs in the text input, such as typing or deleting a character.
Actions, End edit

Enter a text string. This string is sent as an action on the UI canvas whenever the player clicks off the text input or presses Enter.

Actions, Enter

Enter a text string. This string is sent as an action on the UI canvas when the player presses Enter.

ScrollBar

You can use a ScrollBar component to add a scrollable bar, or handle, for manipulating settings or scrolling within a scroll box.

To see in-game examples of completed canvases with the ScrollBar component, open the level UiFeatures in the project SamplesProject. Press Ctrl+G to play the game, and then choose Components, Interactable Components, ScrollBar. You can view examples of different types of scroll bar positioning and handles, scroll bars paired with scroll boxes, and visibility options. Press Esc to exit the game.

To view these same canvases in the UI Editor, navigate to the \Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\ScrollBar directory. You can open the following canvases:

- ScrollBoxes.uicanvas – Examples of scroll bars paired with scroll boxes
- Simple.uicanvas – Examples of scroll bar with simple logic
- Visibility.uicanvas – Examples of scroll bar visibility options when paired with scroll boxes

This is a horizontal scroll bar:

This is an image within a scroll box with both a horizontal and a vertical scroll bar:

In Lumberyard version 1.24 and later, the scroll bar can also fade automatically when not in use:
You can add a prefabricated horizontal or vertical scroll bar element. When you do this, a handle is automatically created and nested in your Hierarchy pane.

You can add a prebuilt ScrollBarHorizontal or ScrollBarVertical element from the slice library. When you do this, the scroll bar and its handle is automatically created in your Hierarchy pane.

**To add a ScrollBar element from the slice library**

- In the UI Editor (p. 2874), choose New, Element from Slice Library, ScrollBarHorizontal or ScrollBarVertical.

**To edit a scroll bar component**

In the Properties pane of the UI Editor (p. 2874), expand ScrollBar and do the following, as appropriate:

- **Interactable**

  See Properties (p. 2948) to edit the common interactive component settings.
Elements, Handle

Select an element from the list to provide the movable handle of the scroll bar.

Values, Orientation

Select the scroll bar's orientation:
- **Horizontal** – Scrollbar's handle moves left and right.
- **Vertical** – Scrollbar's handle moves up and down.

Values, Value

Enter the initial value of the scroll bar (0.0 to 1.0).

Values, Handle size

Enter the size of the handle relative to the scroll bar (0.0 to 1.0).

Values, Min handle size

Enter the minimum size of the handle in pixels.

Actions, Change

Enter a text string. This string is sent as an action on the UI canvas when the scroll bar changes values.

Actions, End Change

Enter a text string. This string is sent as an action on the UI canvas when the scroll bar has finished changing values.

Fade, Auto Fade When Not In Use (v1.24 and later)

Select the check box to enable the scrollbar to fade to transparency after it is not used for a set amount of time. Specify the delay time in **Fade Delay**.

Fade, Fade Delay (v1.24 and later)

Enter the delay in seconds before the scrollbar begins fading to transparency. Requires **Auto Fade When Not In Use** to be checked.

Fade, Fade Speed (v1.24 and later)

Enter the time in seconds that it will take for the scrollbar to completely fade to transparency. Requires **Auto Fade When Not In Use** to be checked.

**ScrollBox**

You can use a **ScrollBox** component to present content, such as images or text, within a scrollable area.

This component is typically used with a mask component, which hides the content outside of the masked area.
To see in-game examples of completed canvases with the `ScrollBox` component, open the level `UiFeatures` in the project `SamplesProject`. Press `Ctrl+G` to play the game, and then choose `Components, Interactable Components, ScrollBox`. You can view examples of different scrolling options, snapping options, interactions between scroll boxes and other components, and nested scroll boxes. Press `Esc` to exit the game.

To view these same canvases in the `UI Editor`, navigate to the `\Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\ScrollBox` directory. You can open the following canvases:

- `Interactions.uicanvas` – Examples of interactions between scroll boxes and other interactive components
- `Nested.uicanvas` – Examples of nesting scroll boxes
- `Scrolling.uicanvas` – Examples of different scrolling options such as horizontal, vertical, 2D, and unconstrained
- `Snapping.uicanvas` – Examples of different snapping options

You can add a prebuilt `ScrollBox` element from the slice library. When you do this, a mask, content, and image elements are automatically created and nested in your `Hierarchy` pane.

**To add a ScrollBox element from the slice library**

- In the `UI Editor` (p. 2874), choose `New, Element from Slice Library, Scrollbox`.

The element named `ScrollBox` (1) has the `ScrollBox` component (2) applied to it. You can add an image to the `ScrollBox` element's `Image` component (3), which acts as the visual frame for the scroll box. Because the mask element and its child elements are drawn in front of the scroll box element, you see only the edges of the image on the `ScrollBox` component. To increase or decrease the viewable area of this image, adjust the offsets in the mask element's `Transform2D` (p. 2926) component.
The element named Mask has a Mask component applied to it, which acts as the viewport through which you can see the content. To specify a custom mask, you can add an image to the Mask element’s Image component. The contents are drawn to the visible area of the mask; the transparent area of the mask hides content.

To edit a scroll box component

In the Properties pane of the UI Editor, expand ScrollBox and do the following, as appropriate:

**Interactable**

See Properties to edit the common interactive component settings.

**Content, Content element**

Select an element from the list to provide the content to be displayed within the scroll box.

**Content, Initial scroll offset**

Enter the initial offset value of the content element's pivot point from the parent element's pivot point.

**Content, Constrain scrolling**

Select the check box to prevent content from scrolling beyond its edges.

**Content, Snap**

Select a snapping mode:

- **None** – No snapping.
- **To children** – When a drag motion is released, the content element moves in such a way that the closest child element's pivot point is snapped to the parent element's pivot point. You can use this, for example, to center a child element in the scroll box when the dragging stops.
• **To grid** – When a drag motion is released, the content element's pivot point is snapped to a multiple of the grid spacing from the parent element's pivot point.

**Horizontal scrolling, Enabled**

Select the check box to enable content to scroll horizontally. If the element, or its parent, is rotated, then the axis of scrolling is also rotated. You can enable horizontal scrolling simultaneously with vertical scrolling to scroll in both directions.

**Horizontal scrolling, Scrollbar element**

Select an element from the list to provide the horizontal scroll bar associated with the scroll box.

**Horizontal scrolling, Scrollbar visibility**

Select the visibility behavior of the horizontal scroll bar:

- **Always visible** – Scroll bar is always visible.
- **Auto hide** – Scroll bar is automatically hidden when not needed. Scroll bar is resized according to visibility of the vertical scroll bar.
- **Auto hide and resize view area** – Same as Auto hide, but the view area is also resized smaller when the scroll bar is visible and larger when the scroll bar is hidden.

**Vertical scrolling, Enabled**

Select the check box to enable content to scroll vertically. If the element, or its parent, is rotated, then the axis of scrolling is also rotated. You can enable vertical scrolling simultaneously with horizontal scrolling to scroll in both directions.

**Vertical scrolling, Scrollbar element**

Select an element from the list to provide the vertical scroll bar associated with the scroll box.

**Vertical scrolling, Scrollbar visibility**

Select the visibility behavior of the vertical scroll bar:

- **Always visible** – Scroll bar is always visible.
- **Auto hide** – Scroll bar is automatically hidden when not needed. Scroll bar is resized according to visibility of the vertical scroll bar.
- **Auto hide and resize view area** – Same as auto hide, but the view area is also resized smaller when the scroll bar is visible and larger when the scroll bar is hidden.

**Actions, Change**

Set the action that is triggered during dragging each time the position changes.

**Actions, End change**

Set the action that is triggered when a drag motion is completed.
Draggable

You can use the Draggable component to make a UI element movable from one location to another on screen. Use the Draggable component in combination with the DropTarget component so that dragging can start on the draggable element and end on the drop target element. Drag-and-drop is a common operation in UI screens, such as an inventory system.

Because drag-and-drop behavior is game specific, the Draggable and DropTarget components are designed to be used with scripting or C++ to define actions that result from the drag and the drop.

To add the draggable component to a UI element, use the Add Component menu in the Properties pane.

The following picture shows an example of a Draggable component, where color has been added to the state actions for Drag States.
The **Draggable** component is an interactive component. It has the standard interactive properties (p. 2948).

**To edit a Draggable component**

In the **Properties** pane of the **UI Editor** (p. 2874), expand **Draggable** and do the following, as appropriate:

**Interactable**

See **Properties** (p. 2948) to edit the common interactive component settings.

**Drag States**

Define the color, alpha, sprite, or font of this element and its child elements for a particular drag state.

When it is not being dragged, an element with a draggable component uses the interactable states (pause on, pressed, and disabled).

When being dragged, however, the draggable component has an additional three states:

- **Normal** – Automatic state when a drag state begins.

- **Valid** – Typically the state used when the draggable component pauses on a valid drop target. This state is determined by a script that you write or C++ code that connects to the **UiDropTargetNotificationBus** and listens for the **OnDropHoverStart** method.
**Invalid** — Typically the state used when a draggable component pauses over an invalid drop target. This state is determined by a script that you write or C++ code. When a valid drag state is triggered, a notification is automatically sent using the `UiDropTargetNotificationBus`.

The script or C++ can use the `UiDraggableBus` to set the drag state of the `Draggable` component. It can also set the drop state of the `DropTarget` to indicate valid drop targets to the user.

To see an example of simple drag Lua script, open `DraggableElement.lua` in `LyShineExamples\Assets\UI\Scripts\LyShineExamples\DragAndDrop`.

---

**DropTarget**

You can use the `DropTarget` component to implement drag-and-drop behavior with the `Draggable` component.

Because drag-and-drop behavior is game specific, the `Draggable` and `DropTarget` components are designed to be used with scripting or C++ to define actions that result from the drag and the drop.

To add the `DropTarget` component to a UI element, use the Add Component menu in the Properties pane.

The following picture shows an example of a `DropTarget` component, where color has been added to the state actions for Drop States.

The `DropTarget` component shares properties with interactive components, such as state actions and navigation settings.

**To edit a DropTarget component**

In the Properties pane of the UI Editor (p. 2874), expand `DropTarget` and do the following, as appropriate:

**Drop States**

Define the color, alpha, sprite, or font of this element and its child elements in a valid or invalid drop state. By default, the drop state of a drop target is normal, which means that there are no visual overrides.
During a drop, the drop target component can be **Valid** or **Invalid**. Because the drop target component has no knowledge of what is a valid drag-and-drop operation, you use a script or C++ to switch the drop target into the **Normal**, **Valid**, and **Invalid** states. This is usually accomplished by connecting to the `UiDropTargetNotifications` bus and listening for the `OnDropHoverStart` and `OnDropHoverEnd` notifications.

**Navigation**

Navigation settings control how keyboard or gamepad navigation works during a drag-and-drop operation. When using the keyboard, you can press **Enter** on a draggable element to enter drag mode. Then you can use the arrow keys to move the element from one drop target to another using the navigation settings specified here.

**Actions, On Drop**

Enter a text string. This string is sent as an action on the UI canvas whenever a draggable is dropped on this drop target. For better control, we recommend that you use the `UiDropTargetNotifications` bus instead.

To see an example of simple drop target Lua script, open `DropTarget.lua` in Gems \LyShineExamples\Assets\UI\Scripts\LyShineExamples\DragAndDrop.

**Dropdown**

You can use the **Dropdown** component to make an element behave like a drop-down menu. Use this component with child elements that contain content. The child elements provide the contents of the drop-down menu.

You can use the **Dropdown** component with the **DropdownOption** component. With the **DropdownOption** component, you can configure options to change the menu text and its icon after it is selected.

To see in-game examples of completed canvases with the **Dropdown** component, open the level UiFeatures in the project SamplesProject. Press **Ctrl+G** to play the game, and then choose **Components**, **Interactable Components**, **Dropdown**. You can view **Simple Dropdowns**, **Nested Dropdowns**, **Multiple Select & Functionality**, and **Using UI Components and Dropdowns**. Press **Esc** to exit the game.

To view these same canvases in the **UI Editor**, navigate to the \Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\Dropdown directory. You can open the following canvases:

- **MultipleFunc.uicanvas** – Multiple selection drop-down menu and functional drop-down menu (perform actions on a ball such as create, destroy, move, and change color)
- **Nested.uicanvas** – Two levels and multilevel with siblings submenus
- **Simple.uicanvas** – Simple selection drop-down menu, selection drop-down menu with icons, expand on pause drop-down menu, and expand on pause with icons
- **UsingUi.uicanvas** – Drop-down menus with a scroll box, image, check box, slider, and radio buttons

You can add a prebuilt **Dropdown** element from the slice library. When you do this, a drop-down menu, three options, and their image elements are automatically created in your **Hierarchy** pane.
To add a Dropdown element from the slice library

- In the UI Editor (p. 2874), choose New, Element from Slice Library, Dropdown.

To edit a Dropdown component

In the Properties pane of the UI Editor (p. 2874), expand Dropdown and do the following, as appropriate:

**Interactable**

See Properties (p. 2948) to edit the common interactive component settings.

**Elements, Content**

Select an element from the list. This specifies the entity that appears when the drop-down menu is expanded.

**Elements, Expanded Parent**

Drag an element onto the Expanded Parent box. This specifies the entity that serves as the parent when the drop-down menu is expanded. This is used to layer drop-down menus.

**Elements, Text Element**

Select an element from the list to specify the entity to display the text corresponding to the selected option.

**Elements, Icon Element**

Select an element from the list to specify the entity to display the icon corresponding to which option is selected.

**Options, Expand on Hover**

Select to enable drop-down behavior upon pause and collapse upon exit.
Options, Wait Time

Enter a number of seconds that the drop-down menu waits before expanding on pause or collapsing on exit.

Options, Collapse on Outside Click

Select to enable drop-down menu collapse upon clicking outside the menu.

Dropdown States, Expanded

Click plus to add states to the drop-down menu when it is expanded.

Actions, Expanded

Enter a text string to be sent as an action on the UI canvas when the drop-down menu is expanded.

Actions, Collapsed

Enter a text string to be sent as an action on the UI canvas when the drop-down menu is collapsed.

Actions, Option Selected

Enter a text string to be sent as an action on the UI canvas when a drop-down option is selected.

DropdownOption

You can use the DropdownOption component to make an element an option in a drop-down menu. When using the DropdownOption component, note the following:

- The DropdownOption is used along with the Dropdown component on an element.
- The DropdownOption requires an interactive component, typically a RadioButton component so that only one option can be selected at any time in the drop-down menu.
- Its child elements typically contain the Text component, which appears when the option is selected.

To see an in-game example of a completed canvas with the DropdownOption component, open the level UiFeatures in the project SamplesProject. Press Ctrl+G to play the game, and then choose Components, Interactable Components, Dropdown, Using UI Components and Dropdowns. Press Esc to exit the game.

To view this same canvas in the UI Editor, navigate to the \Gems\LyShineExamples\Assets\UI \Canvases\LyShineExamples\Comp\Dropdown directory and open the UsingUi.uicanvas file. This canvas features a drop-down menu with a scroll box, image, check box, slider, and radio buttons.

To edit a DropdownOption component

In the Properties pane of the UI Editor (p. 2874), expand DropdownOption and do the following, as appropriate:

Interactable

See Properties (p. 2948) to edit the common interactive component settings.

Elements, Owning Dropdown

Select an element from the list that has the Dropdown component. This is the element to be modified when this option is selected.
Elements, Text Element

Select an element from the list that displays the text corresponding to this option. This text is displayed on the owning drop-down menu when this option is selected (as long as the drop-down menu has a Text Element configured).

Elements, Icon Element

Select an element from the list that displays the icon corresponding to this option. This icon is displayed on the owning drop-down menu when this option is selected (as long as the drop-down menu has an Icon Element configured).

Layout Components

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Like other UI components, layout components define the layout properties of your game's interface. The UI system features four layout components to organize your elements: LayoutColumn, LayoutRow, LayoutGrid, and LayoutCell. You can also nest layout components.

Topics

- LayoutColumn (p. 2973)
- LayoutRow (p. 2975)
- LayoutGrid (p. 2976)
- LayoutCell (p. 2978)
- LayoutFitter (p. 2982)
- Nesting Layout Components (p. 2983)

LayoutColumn

Add the LayoutColumn component to an element to make it a layout column. When you add child elements to the layout column, the layout column assigns each child element a layout cell. The layout column adjusts the size of the layout cells depending on how many child elements you add as well as the values provided by the child elements’ layout cells.

LayoutRow

Add the LayoutRow component to an element to make it a layout row. Like the layout column, the layout row assigns each child elements a layout cell. The layout row adjusts the size of the layout cells depending on how many child elements you add and the values provided by the child elements’ layout cells.

LayoutGrid

Add the LayoutGrid component to an element to make it a layout grid. The layout grid places child elements into a grid. Unlike the layout row and layout column, however, the layout grid does not use layout cells. The LayoutGrid component’s properties determine the size of its children.

LayoutCell

Add the LayoutCell component to a layout row or layout column's children to customize how a layout cell's size is determined. A layout cell is a programmatic concept whose properties define the area of a child element. Anytime that you add a child element to a layout row or layout column, that child element receives layout cell properties (not visible in the UI Editor), which determine the size
of the child's space. You can override the layout cell's calculated properties by adding the LayoutCell component to the child. For more information, see LayoutCell (p. 2978).

**LayoutFitter**

Add the LayoutFitter component to an element to make the element resize itself to fit its content. Use the layout fitter component with other components that provide cell sizing information, such as text, image (with ImageType set to Fixed), or layout components (cell, row, column, grid). For more information, see LayoutFitter (p. 2982).

**LayoutColumn**

You can use a LayoutColumn component to organize child elements into a column. To use this feature, add the LayoutColumn component to an element and then add child elements. The UI system positions the child elements within the column, from top to bottom or bottom to top, depending on the order you choose in the component properties. The child elements can contain a texture or image, a button, a check box, text, columns, rows, grids, and so on.

To see an in-game example of a completed canvas with the Layout Column component, open the level UiFeatures in the project SamplesProject. Press Ctrl+G to play the game, and then choose Components, Layout Components, Layout Column. You can view examples of different child sizes within a column. Press Esc to exit the game.

To view this same canvas in the UI Editor, navigate to the \Gems\LyShineExamples\Assets\UI \Canvases\LyShineExamples\Comp\Layout directory and open the SimpleColumn.uicanvas file.

You can add a prebuilt Layout Column element from the slice library. When you do this, a simple layout column is automatically created and nested in your Hierarchy pane.

**To add a Layout Column element from the slice library**

- In the UI Editor (p. 2874), choose New, Element from Slice Library, LayoutColumn.

By default, the layout column gives every child the same amount of space, regardless of its content. You can, however, manipulate the sizes of each child by adding the layout cell (p. 2978) component to each or specific children.

The layout column can also give varying space to each child depending on its content. To enable the layout column to do this, clear the Ignore Default Cell option in the LayoutColumn component's properties.

In the first image, Ignore Default Cells is selected. The layout column gives each child the same amount of space regardless of their contents.
In the second image, **Ignore Default Cells** is cleared. The layout column calculates its children's space based on their contents.

To see an example of a completed canvas with the layout column component, open `SimpleColumn.uicanvas` in the LyShineExamples Gem (`\dev\Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\`).

**To edit a layout column component**

In the **Properties** pane of the [UI Editor](p. 2874), expand **LayoutColumn** and do the following, as appropriate:
Padding

Type values in pixels, relative to the element's borders.

Spacing

Type values in pixels to adjust spacing between elements.

Order

Select Top-to-Bottom or Bottom-to-Top to specify the order in which the child elements appear in the column.

Child Alignment

If the layout's children don't occupy all the available layout space, use this setting to determine how the children are aligned.

For Horizontal, select Left, Center, or Right to determine how the children are aligned horizontally.

For Vertical, select Top, Center, or Bottom to determine how the children are aligned vertically.

Ignore Default Cell

Selected by default, this property causes the layout column to give each child an equal amount of space regardless of their contents (unless the child has a LayoutCell (p. 2978) component). The layout column ignores the layout cell's content-based default calculations.

When you clear this option, the layout column uses the children's layout cell calculated values to determine how much space to give each child based on its contents. For more information, see LayoutCell (p. 2978).

LayoutRow

You can use a LayoutRow component to organize child elements into a row. To use this feature, you add the LayoutRow component to an element and then add child elements. The UI system positions the child elements within the row, from left to right or right to left, depending on the order you choose. The child elements can contain a texture or image, a piece of text, a button, a check box, more columns, rows, grids, and so on. To control the sizes of specific, or all, children, add the layout cell (p. 2978) component to those children.

Similar to the LayoutColumn component, the LayoutRow component has an Ignore Default Cell property. For more information, see LayoutColumn (p. 2973).
To see an in-game example of a completed canvas with the **Layout Row** component, open the level **UiFeatures** in the project **SamplesProject**. Press **Ctrl+G** to play the game, and then choose **Components, Layout Components, Layout Row**. You can view examples of different child sizes within a row. Press **Esc** to exit the game.

To view this same canvas in the **UI Editor**, navigate to the \Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\Layout directory and open the **SimpleRow.uicanvas** file.

You can add a prebuilt **Layout Row** element from the slice library. When you do this, a simple layout row is automatically created and nested in your **Hierarchy** pane.

**To add a Layout Row element from the slice library**

- In the **UI Editor** (p. 2874), choose **New, Element from Slice Library, LayoutRow**.

**To edit a layout row component**

In the **Properties** pane of the **UI Editor** (p. 2874), expand **LayoutRow** and do the following, as appropriate:

- **Padding**
  
  Type values in pixels, relative to the element's borders.

- **Spacing**
  
  Type values in pixels to adjust spacing between elements.

- **Order**
  
  Select **Left-to-Right** or **Right-to-Left** to specify the order in which the child elements appear in the row.

- **Child Alignment**
  
  If the layout's children don't occupy all the available layout space, use this setting to determine how the children are aligned.

    - For **Horizontal**, select **Left**, **Center**, or **Right** to determine how the children are aligned horizontally.

    - For **Vertical**, select **Top**, **Center**, or **Bottom** to determine how the children are aligned vertically.

- **Ignore Default Cell**
  
  Selected by default, this property causes the layout row to give each child an equal amount of space regardless of their contents (unless the child has a **LayoutCell** (p. 2978) component). The layout row ignores the layout cell's content-based default calculations.

  When you clear this option, the layout row uses the children's layout cell calculated values to determine how much space to give each child based on its contents. For more information, see **LayoutCell** (p. 2978).

---

**LayoutGrid**

You can use a layout grid component to organize child elements into a uniform grid. To use this feature, you add the layout grid component to an element and then add child elements. The UI system positions the child elements in a grid pattern. You can choose whether the child elements are positioned left to right or right to left, and bottom to top or top to bottom. The child elements can contain a texture or image, a piece of text, a button, a check box, more columns, rows, grids, and so on. The size of each child is determined by the **Cell Size** property and is independent of each child's content.
To see an in-game example of a completed canvas with the LayoutGrid component, open the level UiFeatures in the project SamplesProject. Press Ctrl+G to play the game, and then choose Components, Layout Components, Layout Grid. You can view examples of different fill patterns. Press Esc to exit the game.

To view this same canvas in the UI Editor, navigate to the \Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\Layout directory and open the SimpleGrid.uicanvas file.

You can add a prebuilt Layout Grid element from the slice library. When you do this, a simple layout grid is automatically created and nested in your Hierarchy pane.

**To add a Layout Grid element from the slice library**

- In the UI Editor (p. 2874), choose New, Element from Slice Library, LayoutGrid.

**To edit a layout grid component**

In the Properties pane of the UI Editor (p. 2874), expand LayoutGrid and do the following, as appropriate:

**Padding**

Type values in pixels, relative to the element's borders.

**Spacing**

Type values in pixels to adjust spacing among elements.

**Cell size**

Type values in pixels to specify the size of the child elements.

**Order**

Do the following as appropriate:

- For Horizontal, select Left-to-Right or Right-to-Left to determine the order in which elements appear horizontally.
• For **Vertical**, select **Top-to-Bottom** or **Bottom-to-Top** to determine the order in which elements appear vertically.

• For **Starting With**, select **Horizontal** or **Vertical** to determine whether elements appear horizontally or vertically first.

**Child Alignment**

If the layout’s children don’t occupy all the available layout space, this setting determines how the children are aligned.

For **Horizontal**, select **Left**, **Center**, or **Right** to determine how the children are aligned horizontally.

For **Vertical**, select **Top**, **Center**, or **Bottom** to determine how the children are aligned vertically.

**LayoutCell**

When working with cell contents, it’s important to understand the difference between a layout cell and the **LayoutCell** component. A layout cell represents a set of values that determine the space or area allocated to a child in a layout row or column. The **LayoutCell** component, on the other hand, manipulates the way a layout cell is sized. A layout cell exists on a child of a layout row or layout column whether or not it has a **LayoutCell** component. The **LayoutCell** component simply provides a way to manipulate and override the default calculations of a layout cell.

A layout cell’s properties consist of a minimum size, a target size, and an extra size ratio. These properties are not directly modifiable in the UI Editor, but are determined in several ways:

• Components – The following components can affect the layout cell size:

  • Image or text – The image’s default size is the layout cell’s target size. The length and size of a string in a text component is the layout cell’s target size.

  • Layout row or layout column (added or nested as children) – The default values of a layout row or layout column, added as a child, determines the layout cell’s minimum and target size. The default value is calculated by the sum of its own children plus padding and spacing.

  **Note**
  
  The **LayoutColumn** and **LayoutRow** components contain a property called **Ignore Default Cells**. Selecting this property causes the above calculations to be ignored and simply allocate equal space to all children regardless of content. Clear this property to calculate layout cell values by components. For more information, see **LayoutColumn** (p. 2973).

• Fixed default layout cell values – If the child doesn’t have any components that calculate their own layout cell values, then the layout cell is assigned a minimum and target size of 0 and an extra size ratio of 1. This typically means equal spacing for the children that do not have a component affecting the layout cell’s size. Each layout cell grows at the same rate to fill the available space (hence the extra size ratio of 1).

• **LayoutCell** component – Add the **LayoutCell** component to specify values for the minimum and target sizes, and the extra size ratio. Any values you specify here override the values calculated by all other methods.

After layout cell values are calculated, layout cell space is allocated by the following:

1. First, each child receives its minimum size (**Min Height** or **Min Width**).
2. If space is available, each child receives its target size (**Target Height** or **Target Width**).
3. If space is still available after that, then the **Extra Size Ratio** value is used to determine how to allocate the remaining space. This ratio is relative to the child’s siblings. For example, if one child’s extra size ratio is 1, and another child’s is 2, then the second child gains twice as much extra space as
the first child. An extra size ratio of 0 means that no more space is allocated once the target size is reached.

Using the LayoutCell Component

You can apply the LayoutCell component to the children of a layout row or column to override the layout cell's default calculations.

In the following example, the layout column has three images as its children. The images each occupy equal space in the column.

If you add a LayoutCell component to the first image, and then select Min Height and assign a value of 100, then the UI system overrides that child's default calculated value, and gives the top image more height than its siblings, whose values are recalculated to adjust to the remaining column space.

In the next example, a layout grid was added as a child. Its calculated size is the same as its two siblings above it.
However, when you add a **LayoutCell** component to the grid, and then specify a **Min Height** of 100, then the grid, as a whole is granted that amount of space. If you add the **LayoutCell** component to the children of a layout grid, however, it has no effect. That's because individual grid spaces are always uniform and are controlled by the grid parent.
To edit a LayoutCell component

In the Properties pane of the UI Editor (p. 2874), expand LayoutCell and do the following, as appropriate:

**Min Width**

Select to define the layout cell's minimum width. Type a value in the box that appears.

**Min Height**

Select to define the layout cell's minimum height. Type a value in the box that appears.

**Target Width**

Select to define the layout cell's target width. Type a value in the box that appears. If space is available, this target width is allocated to the layout cell.

**Target Height**

Select to define the target height. Type a value in the box that appears. If space is available, this target height is allocated to the layout cell.
Extra Width Ratio

Select to define the layout cell's extra width ratio. Type a value in the box that appears. This value is a ratio that is relative to the other elements. If space remains after the layout cell reaches its target size, the Extra Size Ratio value is used to allocate the rest of the space.

Because this Extra Size Ratio value is relative to the other children, if one child's extra size ratio is 1, and another child's is 2, then the second child gains twice as much extra space as the first child. An extra size ratio of 0 means that no more space is allocated once the target size is reached.

Extra Height Ratio

Select to define the layout cell's extra height ratio. Type a value in the box that appears.

LayoutFitter

You can use the LayoutFitter component to make an element resize itself to fit its content. Use this component with other components that provide cell sizing information, such as the Text component, the Image component (with ImageType set to Fixed), or the Layout components (Cell, Row, Column, Grid).

To see an in-game example of a completed canvas with the LayoutFitter component, open the level UFeatures in the project SamplesProject. Press Ctrl+G to play the game, and then choose Components, Layout Components, Layout Fitter. Press Esc to exit the game.

To view that same canvas in the UI Editor, navigate to the \Gems\LyShineExamples\Assets\UI \Canvases\LyShineExamples\Comp\Layout directory and open the \fitter.uicanvas file.

To edit a layout fitter component

In the Properties pane of the UI Editor (p. 2874), expand LayoutFitter and do the following, as appropriate:
Horizontal Fit

Select the check box to resize an element's width to fit its content.

Vertical Fit

Select the check box to resize an element's height to fit its content.

Nesting Layout Components

You can nest layout components within other layout components.

To see an in-game example of a completed canvas with a nested layout, open the level UiFeatures in the project SamplesProject. Press Ctrl+G to play the game, and then choose Components, Layout Components, Nested Layout. Press Esc to exit the game.

To view that same canvas in the UI Editor, navigate to the \Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\Layout directory and open the \NestedLayout.uicanvas.

The following examples shows one large layout row.

Within the layout row are four columns.
Within column A, there are three layout rows. Column B has two layout grids. Column C has three images. Column D has one large image consisting of a color.

The first image in column C has a layout cell component with a minimum height set at 120. This gives it a larger space than its two siblings below it, which do not have LayoutCell components. Layout column D also has a LayoutCell component, with a minimum width of 110, giving it more space than the other three columns, which do not have LayoutCell components.
Tooltip Components

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add either a **Tooltip** component or a **TooltipDisplay** component to an element. With these components, you can display a tooltip when hovering over an interactive element.

To see in-game examples of completed canvases with Tooltip components, open the level UiFeatures in the project SamplesProject. Press Ctrl+G to play the game, and then choose Components, Other Components, Tooltips. You can view examples of tooltip text options and display styles. Press Esc to exit the game.

To view these same canvases in the UI Editor, navigate to the \Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\Tooltips directory.

You can open the following canvases:

- TextOptions.uicanvas
- Tooltips.uicanvas

**Tooltip**

You can use a **Tooltip** component to provide the text of the tooltip. Add a tooltip component to any interactive element that is to display a tooltip in the pause state.

**To edit a tooltip component**

1. In the Properties pane of the UI Editor (p. 2874), expand Tooltip.
2. Enter a text string.
TooltipDisplay

The **TooltipDisplay** component defines the tooltip's display behavior. Add a **TooltipDisplay** component to the element that is to visually represent the tooltip. You must also set the **Tooltip display element** (p. 2896) property of the canvas to this element. For more information, see **Configuring Canvas Properties** (p. 2894).

To edit a **TooltipDisplay** component

- In the **Properties** pane of the **UI Editor** (p. 2874), expand **TooltipDisplay** and use the following settings, as appropriate:

  **Trigger Mode (v1.24 and later)**

  Select a tooltip trigger condition:
  - **On Hover** – The tooltip appears when the pointer hovers over the interactive element, and disappears when the pointer moves off of the interactive element.
  - **On Press** – The tooltip appears when the interactive element is pressed and held, and disappears when the press is released. Note that the pointer might have moved elsewhere on the canvas by the time the release action has occurred.
  - **On Click** – The tooltip appears when a pointer click, which includes a press and a release, occurs on the interactive element. The tooltip disappears when the next pointer click occurs anywhere on the canvas. Note that if the pointer clicks on the same entity, the tooltip disappears, but then reappears after the specified **Delay time**.

  **Tip**
  On mobile devices, you might want to use **On Press** or **On Click** instead of **On Hover**.

  **Note**
  In all cases, the appearance of the tooltip is delayed by the amount of time specified in **Delay time**. Furthermore, in all cases, the tooltip will disappear after a fixed amount of time set by Lumberyard, regardless of other criteria specified in the trigger conditions.

  **Auto position**

  Automatically positions the element based on the positioning mode. The positioning mode is specified in the **Positioning** property.

  **Positioning**

  Select a positioning mode:
  - **Offset from mouse** – Position the element so that its pivot is a certain distance from the pointer. The distance is specified in the **Offset** property.
  - **Offset from element** – Position the element so that its pivot is a certain distance from the pivot of the element that triggered the tooltip display.

  **Offset**

  The offset to use when automatically positioning the element.

  **Auto size**

  Automatically resizes the element to match the tooltip string's size. The text element is a child of the element, and its text is specified in the **Text** property. If **Auto size** is selected, then the text element's anchors should be apart so that the text element can grow and shrink with its parent.

  **Text**

  The child element that is to display a tooltip string.
Dynamic Components

Delay time
The amount of time to wait before displaying the element.

Display time
The amount of time the element is to be displayed.

Show sequence
The animation sequence to be played when the element is about to appear.

Hide sequence
The animation sequence to be played when the element is about to disappear.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Dynamic components work together with Layout (p. 2972) components and the Scroll Box (p. 2962) component to display dynamic content in the user interface.

To see in-game examples of completed canvases with dynamic components, open the level UiFeatures in the project SamplesProject. Press Ctrl+G to play the game, and then choose Components, Dynamic Components. You can view examples of different types of dynamic layouts and scroll boxes. Press Esc to exit the game.

DynamicLayout

To use the DynamicLayout component, you place it on an element that also has a LayoutColumn (p. 2973), LayoutRow (p. 2975), or LayoutGrid (p. 2976) component. With the DynamicLayout component, you can change the number of children of the layout element at run time.

The layout element (1) dynamically resizes to fit its child elements. The first child (2) of the layout element acts as the prototype element. At run time, the UI system clones the prototype element to achieve the specified number of children in the layout.
The automatic resizing of the layout element depends on the layout type.

For **LayoutColumn** (p. 2973) and **LayoutRow** (p. 2975) elements, the layout element resizes in order to keep all of the child elements the same size as the prototype element.

For a **LayoutGrid** (p. 2976) element, the cell size of the **LayoutGrid** component determines the size of the child elements. The **LayoutGrid** element's initial size determines the number of children that can fit in each row or each column, depending on fill direction or **Order** settings. If the **Starting with** fill direction is **horizontal**, the UI system uses the **LayoutGrid** element's initial width to determine how many children fit in each row. If set to **vertical**, the initial height is used to determine how many children fit in each column.

![Layout Grid Component Settings](image)

**To use a dynamic layout component**

1. In the **UI Editor** (p. 2874), add a **LayoutRow**, **LayoutColumn**, or **LayoutGrid** prefab. To do this, choose **New, Element from Prefab**. Then select one of the layout elements.

   This serves as the structure or framework to hold your dynamic content.

2. Add a **DynamicLayout** component to your layout component. To do this, in the **Properties** pane choose **Add Component, DynamicLayout**.

   For **Num Cloned Elements**, enter the initial number of children to be created.

3. Create a child entity that has an **Image** component. To do this, right-click your layout component in the **Hierarchy** pane and choose **New, Element from Prefab, Image**.

   This image serves as the prototype element that will be cloned and filled with dynamic content.

**DynamicScrollBox**

To use the **DynamicScrollBox** component, you place it on an element that also has a **ScrollBox** component. With the **DynamicScrollBox** component, you can change the number of children of the scroll box's element at run time.

The content element dynamically resizes to fit its child elements. The first child of the content element acts as the prototype element. At run time, the UI system clones the prototype element to achieve the specified number of children in the layout.

With the **DynamicScrollBox** component, only the minimum number of child elements are actually created for display. This is different from the **DynamicLayout** component, where all child elements are created at run time and can consume a large amount of resources. The **DynamicScrollBox**'s elements are reused as the user scrolls; therefore, a scroll box can simulate a large number of children while maintaining good performance.
The **DynamicScrollBox** component automatically positions its children and resizes the content element to match the bounding box of its children. Each child's size is the same as the prototype element. By default, the children are positioned in a row from left to right. If vertical scrolling is enabled, the children are positioned in a column from top to bottom.

**To use a dynamic scroll box component**

1. In the **UI Editor (p. 2874)**, add a Scrollbox prefab. To do this, click **New, Element from Prefab, ScrollBox**. This serves as the structure or framework to hold your dynamic content.

2. Add a **DynamicScrollbox** component to your scroll box component. To do this, in the **Properties** pane choose **Add Component, DynamicScrollbox**. For **Default Num Elements**, enter the initial number of children to be created. This is mainly for previewing a canvas in **Preview** mode since the number of children ultimately comes from a custom component that implements the **UiDynamicScrollBoxDataBus**.

3. Create a child entity that has an **Image** component. To do this, right-click on your scroll box component in the **Hierarchy** pane, choose **New, Element from Prefab, Image**. This image serves as the prototype element that will be cloned and filled with dynamic content.

The **DynamicScrollBox** component uses a bus called **UiDynamicScrollBoxDataBus** to retrieve the number of children that the content element should have. It also uses a bus called **UiDynamicScrollBoxElementNotificationBus** to notify when a child element is about to become visible. This is where you set up the child element with dynamic content. To do this, you must create and add to the scroll box element a custom component that implements these two buses.

**EBus Interface**

Use the following notification functions with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

**UiDynamicScrollBoxDataBus:GetNumElements**

Implement this bus to provide a dynamic scroll box the number of children it should clone.

Returns the number of children that the dynamic scroll box should clone.

**Parameters**

None

**Return**

Number of children to clone.

**Ui DynamicScrollBoxElementNotificationBus:OnElementBecomingVisible**

Implement this bus to receive notifications when elements of a dynamic scroll box are about to become visible.

Sends a signal when an element of a dynamic scroll box is about to become visible.
Parameters

entityID – The entity ID of the element that is about to become visible.

index – The index of the element that is about to become visible.

Return

None

UISpawner Component

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the **UISpawner** component to spawn a runtime dynamic slice (**dynamicslice**) at an entity's location with an optional offset. In combination with scripting, you can use the **UISpawner** component to spawn any dynamic slice at any time and to spawn multiple instances of the same dynamic slice.

Contents

- Example UISpawner Component (p. 2990)
- UISpawner Component Properties (p. 2991)
- EBus Request Bus Interface (p. 2991)
  - Spawn (p. 2991)
  - SpawnRelative (p. 2991)
  - SpawnViewport (p. 2992)
  - SpawnSlice (p. 2992)
  - SpawnSliceRelative (p. 2992)
  - SpawnSliceViewport (p. 2992)
- EBus Notification Bus Interface (p. 2993)
  - OnSpawnBegin (p. 2993)
  - OnSpawnEnd (p. 2993)
  - OnEntitySpawned (p. 2993)
  - OnEntitiesSpawned (p. 2994)
  - OnTopLevelEntitiesSpawned (p. 2994)
  - OnSpawnFailed (p. 2994)

Example UISpawner Component

You can view a canvas with the **UISpawner** component in Samples Project. For more information, see Samples Project (p. 146).

To view an example canvas with a UISpawner component

1. For Samples Project, choose **File, Open, UI, UiFeatures**.
2. To start the game, press Ctrl+G.
3. Choose Components, Dynamic Components, Spawner. You can see an example of a simple button spawner and a more complex radio button spawner.
4. To exit the game, press Esc.

You can also view the example canvases in the UI Editor.

To view the canvases
1. In Lumberyard Editor, choose Tools, UI Editor.
2. Navigate to the lumberyard_version\dev\Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\Spawner directory.
3. Select a file and click Open.

UISpawner Component Properties

The UISpawner component has the following properties:

Dynamic Slice
- Select the slice asset to spawn.

Spawn on Activate
- If selected, spawns the selected slice upon activation.

EBus Request Bus Interface

Use the following request functions with the UISpawnerBus EBus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

Spawn

Spawns the UI slice specified in the component at the entity’s location.

Parameters
- None

Return
- The slice instantiation ticket for this spawn.

Scriptable
- Yes

SpawnRelative

Spawns the UI slice specified in the component at the entity’s location with the specified relative offset.

Parameters
- Relative – The offset position from the entity with the spawner component.
**UISpawner Component**

**Return**

The slice instantiation ticket for this spawn.

**Scriptable**

Yes

**SpawnViewport**

Spawns the slice specified in the component at the specified viewport position.

**Parameters**

- **Pos** – The viewport position at which to spawn the slice.

**Return**

The slice instantiation ticket for this spawn.

**Scriptable**

Yes

**SpawnSlice**

Spawns the specified slice at the entity's location.

**Parameters**

- **slice** – Specifies the slice asset to be spawned.

**Return**

The slice instantiation ticket for this spawn.

**Scriptable**

No

**SpawnSliceRelative**

Spawns the given slice at the entity's location with the relative offset.

**Parameters**

- **slice** – Specifies the slice asset to be spawned.

  - **relative** – The offset position from the entity with the spawner component.

**Return**

The slice instantiation ticket for this spawn.

**Scriptable**

No

**SpawnSliceViewport**

Spawns the specified slice at the specified viewport position.
**Parameters**

- **slice** – Specifies the slice asset to be spawned.
- **pos** – The viewport position at which to spawn the slice.

**Return**

The slice instantiation ticket for this spawn.

**Scriptable**

Yes

**EBus Notification Bus Interface**

Use the following notification functions with the UiSpawnerNotificationBus EBus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

**OnSpawnBegin**

Announces that the slice has been spawned, but entities have not yet been activated. **OnEntitySpawned** (p. 2993) events are about to be dispatched.

**Parameters**

- **ticket** – The slice instantiation ticket that is returned by the spawn function. These can be compared in order to know which spawn request it relates to.

**Scriptable**

Yes

**OnSpawnEnd**

Announces that a slice has been spawned. This function is called once for each spawn request. All **OnEntitySpawned** (p. 2993) events have been dispatched.

**Parameters**

- **ticket** – The slice instantiation ticket that is returned by the spawn function. These can be compared in order to know which spawn request it relates to.

**Scriptable**

Yes

**OnEntitySpawned**

Announces that an entity has been created during a spawn. This function is called once for each entity created while spawning a slice.

**Parameters**

- **ticket** – The slice instantiation ticket that is returned by the spawn function. These can be compared in order to know which spawn request it relates to.
- **spawnedEntity** – Specifies the ID of the spawned entity.
Other Components

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
You can add either or both of the fader and mask components to an element.

**Topics**
- Fader (p. 2995)
- Mask (p. 2995)
- Flipbook Animation (p. 2997)

**Fader**

You can use a Fader component to simultaneously adjust the transparency of an element and its children.

**To see in-game examples of completed canvases with a Fader component**

1. Open the Samples Project (p. 47).
2. When Lumberyard Editor has started, choose File, Open and open the UiFeatures level.
3. Press Ctrl+G to play the game.
4. Choose Components, Other Components, Fader. You can view an example of a direct fade and an animated fade.
5. Press Esc to exit the game.

**To view these same canvases in the UI Editor**

- Navigate to the \Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp\Fader directory.

You can open the following canvases:
- AnimFade.uicanvas
- DirectFade.uicanvas

**To edit a fader component**

1. In the Properties pane of the UI Editor (p. 2874), expand Fader.
2. For the Fade multiplier, use the slider to select a number between 0 (invisible) and 1 (opaque) and press Enter.

**Mask**

You can add a Mask component to an element to reveal only those parts of the child elements (for example, image or text) that are within the mask visual. In other words, the opaque region of the mask visual defines a shape that acts like a window through which you view the descendant elements.

**To see in-game examples of completed canvases with a Mask component**

1. Open the Samples Project (p. 47).
2. When Lumberyard Editor opens, expand the UI directory and open the level UiFeatures.
3. Press Ctrl+G to play the game.
4. Choose Components, Other Components, Mask.
5. Press Esc to exit the game.

To view these same canvases in the UI Editor

- Navigate to the `lumberyard_version/dev/Gems/LyShineExamples/Assets/UI/Canvases/LyShineExamples/Comp/Mask` directory.

You can open the following canvases:

- `AlphaMask.uicanvas` – Example of using a texture with alpha as a mask.
- `Basic.uicanvas` – Basic mask example.
- `ChildMaskElement.uicanvas` – Example of using a child element to draw the mask.
- `ImageMode.uicanvas` – Examples of using different image modes on the image used for the mask.
- `MaskingInteractables.uicanvas` – Example of how masks interact with components.
- `NestedMasks.uicanvas` – Example of nesting masks.
- `TextMask.uicanvas` – Example of using text as the visual component of the mask.

When you add a Mask component, the default mask is the visual component on that element, usually an Image component. If you want to use a nonrectangular mask, you must set this Image component to use a texture that contains an alpha channel (p. 3281), which specifies transparent and opaque areas. The child elements are masked by the mask visual. This means that the only parts of the child elements that are visible are the parts that are in the mask visual. In other words, the visible areas of the mask show the child elements, and the transparent areas of the mask visual hide the child elements. You can use other visual components, such as a Text component or Particle Emitter component to specify the mask visual.

You can make the mask movable to use in an animation. To do so without moving all of its children, you can use a special child element as a mask visual in addition to the visual component on the mask element. This child mask element can have as many children as you need to draw your mask visual.

Masks are commonly used with a ScrollBox prefab element (p. 2962).

To add simple mask with an Image component as the visual

1. In the UI Editor (p. 2874) toolbar, choose New, Empty Element. This is the parent element.
2. In the Properties pane, choose Add Component, Image to add an Image component.
3. Choose Add Component, Mask.
4. Right-click the parent element and then choose New, Empty Element to add a child element.
5. Select the child element and add to it an Image component.
6. In the Properties pane, click the folder icon next to Image, Sprite Path to select an image for the child element.
7. Open an image file in your current project directory.
8. On the parent element, in the Properties pane, click the folder icon next to the Image, Sprite Path to select the texture or image to use as a mask.
9. Open an image file in your current project directory. The image that you use as a mask should have opaque areas (which shows the content in child elements) and transparent areas (which hides the content in child elements).
10. In the Properties pane, under Mask, select Use alpha test.

To edit a Mask component

In the Properties pane of the UI Editor (p. 2874), expand Mask and specify the following parameters, as appropriate:
### Other Components

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Masking</td>
<td>If set, only the parts of the child elements that are revealed by the mask are visible. This parameter is enabled by default.</td>
</tr>
<tr>
<td>Draw behind</td>
<td>Draws the mask visual behind the child elements. This is useful for debugging.</td>
</tr>
<tr>
<td>Draw in front</td>
<td>Draws the mask visual in front of the child elements. This is useful for debugging.</td>
</tr>
<tr>
<td>Use alpha test</td>
<td>Uses the alpha channel in the masks visual's texture to define the mask. You must enable this parameter for masks that are anything other than a rectangle.</td>
</tr>
<tr>
<td>Mask interaction</td>
<td>Prevents input events from being sent to elements that are outside of the mask.</td>
</tr>
<tr>
<td>Child Mask Element</td>
<td>Specifies one of the child elements as a special element that is drawn as part of the mask visual. This parameter helps mask the remaining children.</td>
</tr>
</tbody>
</table>

### Flipbook Animation

You can use the `FlipbookAnimation` component to create simple image-based animations by animating the frames or cells of a sprite sheet (p. 2886).

**To see in-game examples of completed canvases with a FlipbookAnimation component**

1. Open the Samples Project (p. 47).  
2. When Lumberyard Editor has started, choose File, Open and open the UiFeatures level.  
3. Press Ctrl+G to play the game.  
4. Then choose Components, Other Components, Flipbook Animation.  
5. Choose None, Linear, or PingPong. Then click Start.  
6. Click Stop to stop the animation. Press Esc to exit.

**To view this canvas in the UI Editor**

1. Navigate to the \Gems\LyShineExamples\Assets\UI\Canvases\LyShineExamples\Comp \Flipbook directory.  
2. Open Flipbook.uicanvas.

You can add the `FlipbookAnimation` component to elements that also have an `Image` (p. 2936) component. You must also set that `Image` component to use a sprite file that has been configured as a sprite sheet (p. 2886).
To add and configure a FlipbookAnimation component

1. If you have not already done so, create a sprite sheet (p. 2886) for your animation image.
2. Add an **Image (p. 2936)** component.

   For the **SpriteType**, choose **Sprite/Texture asset**.

   In the **Sprite path**, click **Browse (…)** and navigate to the directory that contains the sprite sheet asset that you created. Select the sprite sheet.

3. Add a **FlipbookAnimation** component.

4. Configure the **FlipbookAnimation** properties:

   **Start Frame**
   
   The index of the sprite sheet cell that is to be the first frame in the animation. The value must be equal to or less than the **End Frame** value.

   **End Frame**
   
   The index of the sprite sheet cell that is to be the last frame in the animation. The value must be equal to or greater than the **Start Frame** value.

   **Loop start frame**
   
   The index of the sprite sheet cell that is to be the first frame in the looped portion of an animation. This value must be equal to or greater than **Start Frame** value and less than **End Frame** value. This setting has no effect if **Loop Type** is set to **None**.

   **Tip**
   
   To loop the entire animation, specify a value that is equal to the **Start Frame** value. To create an intro sequence that appears before the looping animation, specify a value greater than the **Start Frame**.

   **Loop Type**
   
   Includes the following options:
   
   - **None** – No looping behavior. The animation starts between the **Start Frame** and **End Frame** and then stops.
   - **Linear** – When the animation reaches **End Frame**, it loops by next playing the **Start Frame** and continues until the **End Frame**. This continues until the player stops it manually.
   - **PingPong** – Reverses the direction of the animation. After animation reaches the **End Frame** or the **Start Frame**, it reverses direction. The loop goes back and forth between the two frames until the player stops it.

   **Frame delay**
   
   Number of seconds to delay before displaying the next frame.

   **Auto Play**
   
   If enabled, automatically starts playing the flipbook animation when the canvas is loaded.

---

**Implementing New Fonts**

---

**Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.**

You can add fonts to your game UI in Lumberyard by saving the font asset to your game project and creating an .xml file that contains specifics for that font, such as the path to the font file and parameters that affect the font's appearance. You can combine multiple font assets into a single font family and further customize text appearance using **Text Markup (p. 2945)**.
Using the procedures in this section, you can:

- Add new fonts to your game UI (p. 3000)
- Create font families (p. 3000)
- Configure font rendering quality (p. 3002)

## Adding New Fonts

For each new font to add, you need the following files:

- A font asset – True Type Font (.ttf) or Open Type Font (.otf) file
- A font .font file describing the asset

### To add a new font to your UI

1. Save the font asset (.ttf or .otf file) to your game project directory, such as dev\SamplesProject\Font.
2. Copy an existing font .font file into your game project Font directory. The following directories (included in the Lumberyard project) contain font .font files for reference:
   - dev\Engine\Fonts\n   - dev\SamplesProject\Fonts\n3. Change the .font file name (leave the .font extension unchanged). Use any file name that is descriptive and appropriate for your purposes.
4. Open the .font file and edit the following line to point to your font asset file name.

```xml
<font path="yourFont.ttf" w="512" h="256"/>
```

After the Asset Processor has processed your font assets, you can select your font by loading the font .font file (p. 2943) in the **UI Editor** for any text component.

## Creating Font Families

You can combine multiple font assets into a single font family group.

The following is an example of a .fontfamily file.

```xml
<fontfamily name="MyFontFamily">
  <font>
    <file path="myfontfamily-regular.xml" />
    <file path="myfontfamily-bold.xml" tags="b" />
    <file path="myfontfamily-italic.xml" tags="i" />
    <file path="myfontfamily-bolditalic.xml" tags="b,i" />
  </font>
</fontfamily>
```

The UI system uses the font family definitions to determine which font asset to apply when styling text. You can combine the following types of assets:

- **Unstyled** – Font representing text with no styling applied. In the preceding example, this is myfontfamily-regular.xml.
- **Bold** – Font representing text with bold styling.
- **Italic** – Font representing text with italic styling.
• **Bold-Italic** – Font representing text with both bold and italic styling.

## Font Family File XML

To create a new font family file, you can create a new, empty plain text file and enter the contents, or you can modify an existing font family file.

### To add a new font family file to your UI

1. To create a new font family file, do one of the following:
   - Open Notepad (or similar program) and save an empty text file with a `.fontfamily` file extension.
   - Copy an existing `.fontfamily` file into your game project's Fonts directory.
2. Name your `.fontfamily` file appropriately (leave the `.fontfamily` extension).
3. Open your `.fontfamily` file and edit the contents to configure the font family.

   For example:

   ```xml
   <fontfamily name="MyFontFamily">
     <font>
       <file path="myfontfamily-regular.xml" />
       <file path="myfontfamily-bold.xml" tags="b" />
       <file path="myfontfamily-italic.xml" tags="i" />
       <file path="myfontfamily-bolditalic.xml" tags="b,i" />
     </font>
   </fontfamily>
   ```

   After the Asset Processor has processed your font assets, you can select your font family by selecting the *.fontfamily file in the UI Editor as the font for any text component. To apply custom styling to text using the font family, see Text Styling Markup (p. 2945).

The `.fontfamily` file uses XML. The UI system supports the following tags and attributes for the `.fontfamily` file:

**Tag:** `fontfamily`

**Attribute:** `name`

The unique name of the font family. Each font family name in a project must be unique, and only one `fontfamily` tag may be specified per `.fontfamily` file. You can, however, reuse the same font XML files (defined by the file tag) in multiple font families.

**Tag:** `font`

Container tag for the `file` tag.

**Attribute:** `lang`

The language that the font files should be associated with. The font files are loaded only if the listed language is being used. This enables a single font family to use different fonts and styling depending on the language being used.

**Tag:** `file`

**Attribute:** `path`

The path to the font XML, a TTF or OTF file. The path is relative to the font family file. The same font asset can be referenced multiple times for a given font family and across multiple font families.
**Attribute: tags**

This tag is optional. If omitted, this font file is used when no styling is applied.

Values:
- **b** – indicates `<b>` bold tag
- **i** – indicates `<i>` italic tag
- **b,i** – indicates when both `<b>` bold and `<i>` italic tags are applied

## Configuring Font Rendering Quality

Lumberyard's built-in UI system, **LyShine**, renders text using font textures. The quality of the on-screen text is affected by the font texture size, the number of character slots in the font texture, and the size of the text itself when rendered on the screen.

Use the procedures in this section to configure font size and texture to achieve quality text rendering.

### Font Texture Width and Height Attributes

Fonts are defined in XML by `.font` files. The XML in a `.font` file defines various parameters, such as the path to the source TTF/OTF asset and important rendering properties. The font file `Engine/Fonts/default-ui.font` included in the Lumberyard project has the following content.

```xml
<fontshader>
  <font path="Vera.ttf" w="512" h="256"/>
  <effect name="default">  
    <pass>
      </pass>
  </effect>
  <effect name="drop_shadow">  
    <pass>
      </pass>
    <pass>
      <color r="0" g="0" b="0" a="1"/>
      <pos x="1" y="1"/>
    </pass>
  </effect>
</fontshader>
```

The font texture resolution is controlled by the following line.

```xml
<font path="Vera.ttf" w="512" h="256"/>
```

In this example, the font texture has a resolution of 512x256. This resolution size (along with the number of character slots) is an important value for determining font rendering quality.

### Character Slots

In Lumberyard, a font texture is logically divided into equally sized slots. In each slot, there is a uniform amount of space for each character (glyph). By default (without additional configuration), there are 128 unique characters (16 rows * 8 columns).

If you support a language with many unique characters, such as Chinese, Japanese, or Korean, the default number of slots (128) might not be adequate for your needs, requiring further configuration. Otherwise, 128 unique characters might be adequate for most languages. The following information about character slots describes in further detail the font rendering pipeline in Lumberyard.
When rendering a string of characters, the number of unique characters in a string is different from the number of characters in a string (its length). The number of character slots in a font texture imposes a limitation only on the number of unique characters that can be rendered in a single frame.

For example, the following is a font definition which defines a font texture with 1 (1x1) texture slot.

```xml
<font path="Vera.ttf" w="512" h="512" widthslots="1" heightslots="1"/>
```

The default values for `widthslots` and `heightslots` is 16 and 8, respectively. However, as shown in the previous example, you can configure the number of character slots (1). This font can render a single unique character to the screen, any number of times, such as the following string.

AAAA

The number of unique characters in `AAAA` is 1, and the length of the string is 4. This font texture configuration can render this character an unlimited number of times (that is, a string of variable length) as long as the string contains only a single character. However, this font can't render the following string.

AABB

Because only one character slot exists in the texture, it can't store both the glyphs for upper-case 'A' and upper-case 'B' and render them both in a frame. To render this string, you need to increase the number of slots using the `widthslots` and `heightslots` parameters.

Here is another example.

```xml
<font path="NotoSansSC-Regular.otf" w="4096" h="4096" widthslots="128" heightslots="128"/>
```

In this example, the font texture size is 4096x4096, and there are a total number of 128x128 (16,384) character slots. To determine the available size for each character, divide the texture size (4096x4096) by the number of slots (128x128) to yield a 32x32 pixel space per character. This configuration enables you to render over 16,000 unique characters at a 32-pixel size in a single frame.

**Font Size**

Because a font texture is divided into a logical grid, a simple calculation determines how much real estate each character in the font can use:

- Font texture width / `widthslots` = slot width
- Font texture height / `heightslots` = slot height

Where `widthslots` is the number of character slots across the width (x-axis) of the font texture and `heightslots` is the number of character slots across the height (y-axis) of the font texture.

In the `default-ui.font` example in the previous section, the font texture size was 512x256. Assuming the character slots are at their default values (16x8):

- 512 / 16 = 32 (slot width)
- 256 / 8 = 32 (slot height)

For a 512x256 sized font texture, you can render pixel-perfect characters at 32x32 pixels.

Knowing these calculations helps you determine the right font texture size for the purposes of your game UI.

**To determine the right font texture size for your game UI**

1. Create the font `.font` file (p. 3000) for the font to use.
2. Choose an arbitrary font texture size to start with, such as 512x256 as used in the previous example.
3. Use the UI Editor to mock up a canvas with elements that have text components that use your font.
4. In the UI Editor’s Properties pane, under Text and then Font Size, experiment with the font size to find the ideal size for your use case.
5. After you have determined the appropriate font size for your purposes, use the following formula to determine the font texture width and height:
   - Texture width = Font size * widthslots
   - Texture height = Font size * heightslots

   **Note**
   The default value for widthslots and heightslots is **16** and **8**, respectively, which gives 128 total character slots. If you need to render more than 128 unique characters to the screen in a single frame—for example, if your game supports Chinese, Japanese, or Korean text—adjust these values accordingly.
6. Edit your font .font to use the calculated font texture size.

   **Note**
   - Font texture sizes don’t necessarily need to be a power of 2: 128, 256, 512, 1024, 2048, and so on. However, the width must be a multiple of widthslots (the default value is 16), and the height must be a multiple of heightslots (the default value is 8).
   - You can have multiple font .font files that reference the same TTF/OTF file but have different font texture sizes.

   For example, you might have some caption text that needs to appear only at a small font size, but you have other screens (perhaps a menu screen) where you want the same look and feel by using the same font. However, it needs to be larger and therefore needs a higher resolution font texture. You can achieve this with separate .font files for each use case, with font texture settings adjusted for ideal rendering quality.

### Configuring Font Properties

You can define the appearance of your UI font by configuring various properties that affect the font’s appearance and usage.

You define your font’s properties in the .font file, which is an XML file. The following example shows the default UI font XML file, located in Engine/Fonts/default-ui.font.
The default UI font XML uses the Vera font. It defines a font texture that can hold 128 unique character or glyphs that are 32x32 pixels. The font includes two representations that are defined with the `effect` tags `default` and `drop_shadow`. For the `default` effect, the font is rendered as is. For the `drop_shadow` effect, the font is first rendered as is. A second render pass produces the font in black with a 1-pixel offset from the first pass. This creates a basic shadowing effect of the characters.

**Note**

Fonts can be part of a font family (with a `.fontfamily` extension), though you can use a standalone font that isn't in a font family. For more information on font families, see [Creating Font Families](p. 3000).

Use the following tags, attributes, and values to define key features of your font.

<table>
<thead>
<tr>
<th>Tag</th>
<th>Description</th>
<th>Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>font</code></td>
<td>Contains critical attributes that define the path to the asset, size, and other font qualities.</td>
<td>See the section called “Font Tag Attributes” (p. 3006).</td>
</tr>
<tr>
<td><code>effect</code></td>
<td>Acts as a parent tag to <code>pass</code> children tags. Groups the <code>pass</code> tags that comprises the effect.</td>
<td><code>name</code> – Name of the effect.</td>
</tr>
<tr>
<td><code>effectfile</code></td>
<td>Specifies the path to an XML file that contains effect tags.</td>
<td><code>path</code> – String that specifies the path to an XML file containing effect tags.</td>
</tr>
<tr>
<td><code>pass</code></td>
<td>A child tag of an <code>effect</code> tag. You can add multiple <code>pass</code> tags as the children of a single <code>effect</code> tag.</td>
<td>Doesn't have attributes. Parents the following child tags that define text effects.</td>
</tr>
<tr>
<td></td>
<td>Defines a render pass of the text with various parameters that affect the text's rendering.</td>
<td>• <code>color</code> &lt;br&gt; • <code>pos</code> or <code>offset</code> &lt;br&gt; • <code>blend</code> or <code>blending</code></td>
</tr>
<tr>
<td></td>
<td>The <code>pass</code> tags can be layered on top of each other, giving the effect a unique look.</td>
<td></td>
</tr>
<tr>
<td><code>color</code></td>
<td>A text effect that is a child tag of the <code>pass</code> tag. Defines the text color.</td>
<td>Uses the following attributes to define the effect's intensity with float point values.</td>
</tr>
<tr>
<td></td>
<td>Minimum: 0.0 &lt;br&gt; Maximum: 1.0f &lt;br&gt; • <code>r</code> – Red. &lt;br&gt; • <code>g</code> – Green. &lt;br&gt; • <code>b</code> – Blue. &lt;br&gt; • <code>a</code> – Alpha. 0 is transparent. 1.0f is opaque.</td>
<td></td>
</tr>
<tr>
<td><code>pos</code> or <code>offset</code></td>
<td>A text effect that is a child tag of the <code>pass</code> tag. Sets the position of the text.</td>
<td>Uses the following attributes to set text position with integer values:</td>
</tr>
<tr>
<td>Tag</td>
<td>Description</td>
<td>Attributes</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------</td>

<td>• additive – src_alpha and one (for destination) blending</td>
</tr>
</tbody>
</table>

**Font Tag Attributes**

Font tag attributes define critical attributes for a font, such as the path to the TTF/OTF asset used to display the font, and other attributes affecting font render quality.
### Note
Most of these attributes have a direct impact on font rendering quality. For more information, see Configuring Font Rendering Quality (p. 3002).

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
</table>
| path        | `<font path="Vera.ttf" ... />`             | Type: String  
Path to TTF or OTF font file asset.                                                                                                                        |
| fontsize    | `< ... fontsize="32"/>`                    | Type: Integer  
Defines in pixels the square size of the slots used to store glyphs (characters) in the font texture. For pixel-perfect render quality, this size should match the size specified when rendering the font. |
| w           | `< ... w="512" h="256" />`                 | Type: Integer  
Defines in pixels the width of the font texture.                                                                                                      |
| h           | `< ... w="512" h="256" />`                 | Type: Integer  
Defines in pixels the width of the font texture.                                                                                                      |
| widthslots  | `<font path="Vera.ttf" w="512" h="512" widthslots="8" heightslots="8" />` | Type: Integer  
Default: 16  
Defines the number of character or glyph slots along the X axis of the font texture.  
In the example, the font texture is 512x512. The width and height slots are set to 8. This gives a space of 64x64 for each character. |
| heightslots | `< ... widthslots="8" heightslots="8" />`  | Type: Integer  
Default: 8  
Defines the number of character or glyph slots along the y-axis of the font texture. |
| sizeratio   | `< ... sizeratio="0.6" />`                 | Type: Float  
Default: 0.8  
Applies uniform scaling to characters or glyphs when rendered into the font texture. |
### Configuring Font Properties

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sizebehavior</td>
<td><code>&lt;... sizebehavior=&quot;rerender&quot; /&gt;</code></td>
<td>The default scaling is usually ideal. You can adjust this value for fonts with unusual proportions, such as very long or wide fonts.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Type: String</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Value: rerender</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Renders text again at its new size. Improves font appearance quality when the text's rendered size differs from the font texture's glyph slot size. When text size changes, a simple transformation scale is applied. Quality degrades noticeably when text becomes larger or smaller. Rerendered text can improve that quality, depending on the font. Because rerendering takes time, it's not ideal for some cases, such as for animated text that changes sizes often.</td>
</tr>
<tr>
<td>hintbehavior</td>
<td><code>&lt;... hintbehavior=&quot;nohinting&quot; /&gt;</code></td>
<td>Type: String</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Configures hinting properties for the font.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>* default – Hinting behavior as provided by the font. You can also omit the hintbehavior tag to use the default hinting.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>* nohinting – Disable hinting.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>* autohint – Hinting behavior procedurally derived from the font.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Example</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>hintstyle</td>
<td><code>&lt; ... hintstyle=&quot;light&quot; /&gt;</code></td>
<td>Configures hinted text’s appearance. Possible values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• normal – Appearance as provided by the font. You can also omit the hintstyle tag to use the default hinting.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• light – Fuzzier appearance that might more accurately represent the shape of the glyphs in the font.</td>
</tr>
<tr>
<td>smooth</td>
<td><code>&lt; ... smooth=&quot;blur&quot; smooth_amount=&quot;3&quot; /&gt;</code></td>
<td>Configures smoothing applied to the font. Possible values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• blur – Applies a simple blurring effect to characters or glyphs stored in the font texture. Use smooth_amount to set the number of iterations to use for blurring.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• supersample – Super samples characters or glyphs in the font texture by smooth_amount: 1 for 2x, and 2 for 4x.</td>
</tr>
<tr>
<td>smooth_amount</td>
<td><code>&lt; ... smooth=&quot;supersample&quot; smooth_amount=&quot;1&quot; /&gt;</code></td>
<td>Defines the amount of smoothing applied to the font. Possible values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• none – Default. No smoothing applied.</td>
</tr>
</tbody>
</table>

**TrueType Fonts**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
CryFont is used to generate font textures that are required to render text on the screen. The various features of font rendering can be seen by using the \texttt{r\_DebugFontRendering} console variable. For more information, see Configuring Console Variables (p. 212).

The output is not only to test the functionality but also to document how the features can be used.

## Supported Features

CryFont supports the following features:

- **Font shaders** – Used to configure the appearance of fonts. Multiple passes with configurable offset and color are supported to enable generation of shadows or outlines. A sample font shader is shown in the following XML example.

  ```xml
  <fontshader>
  <font path="VeraMono.ttf" w="288" h="416"/>
  <effect name="default">
    <pass>
      <color r="0" g="0" b="0" a="1"/>
      <pos x="1" y="1"/>
    </pass>
  </effect>
  <effect name="console">
    <pass>
      <color r="0" g="0" b="0" a="0.5"/>
      <pos x="2" y="2"/>
    </pass>
  </effect>
  </fontshader>
  ``

  The attributes \texttt{w} and \texttt{h} of the XML font element specify the width and height of the font texture. The order of the passes in XML defines the order in which the passes are rendered. A \texttt{<pass>} element without child elements means that the pass is rendered with the default settings. The \texttt{<pos>} tag is used to offset the font, while the \texttt{<color>} tag is used to set font color and define the transparency (with the alpha channel \texttt{a}).

- Unicode – The default font used does not support all Unicode characters (to save memory), but other fonts can be used.

- TrueType fonts as source – Cached in a small texture. Common characters are pre-cached, but runtime updates are possible and supported.

- Colored text rendering

- Adjustable transparency

- Color variations within a string – Use a value of \texttt{0..9} to set one of the 10 available colors. Use \texttt{$$} to print the $ symbol, and \texttt{$o} to switch off the feature.

- Returns and tabs within a string

- Text alignment

- Computation of a string’s width and height – Used internally to handle center and right alignment.

- Font size variations – Bilinear filtering allows some blurring, but no mipmaps are used so this feature has limitations in minification.

- Proportional and monospace fonts

- Pixel-perfect rendering with exact texel-to-pixel mapping for best quality.
Useful Console Commands

The following console commands provide information about font rendering. For more information, see Configuring Console Variables (p. 212).

r_DebugFontRendering

Provides information on various font rendering features, useful for verifying function and documenting usage.
- 0=off
- 1=display

r_DumpFontNames

Logs a list of fonts currently loaded.

r_DumpFontTexture

Dumps the texture of a specified font to a bitmap file. You can use r_DumpFontTexture to get the loaded font names.

Animating the UI

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can animate your game's UI using one of the following tools:

Scripted Entity Tweener System (p. 3011)

Installed as a gem, this system uses custom Lua scripts to create powerful and flexible animations.

UI Animation Editor (p. 3023)

Embedded as a GUI in the UI Editor, this tool can create complex animations. You activate your animation sequences by using Script Canvas, with the UiAnimationBus eBus, or through C++ scripting.

Scripted Tweener Entity System

Lumberyard's Scripted Tweener Entity system is a script-driven animation system that creates powerful and flexible animations. To use this system, enable (p. 1064) the Scripted Tweener Entity (p. 1202) gem. In the Samples Project (p. 146), this gem is enabled by default.

The Scripted Tweener Entity system primarily animates entities in the UI Editor, and also supports the following Lumberyard component entities.
• Particle (p. 702)
• Lights – Point Light (p. 706), Area Light (p. 546), and Projector Light (p. 723).
• Mesh (p. 684)
• Transform (p. 878)

For a complete list, see Tweener Supported Components (p. 3018).

Topics
• Understanding Tweeners (p. 3012)
• Tweener Sample Level (p. 3017)
• Tweener Supported Components (p. 3018)
• Tweener Lua Script (p. 3020)
• Tweener Parameters (p. 3021)
• Tweener Timeline (p. 3022)

Understanding Tweeners

A tweener generates the transition between two images, giving the appearance of a smooth evolution between two frames. At its simplest, a tweener creates a linear transition. For example, a circle that starts at the top of the screen and ends at the bottom of the screen travels at a steady, unchanging pace between the two points. This is similar to an object moving on a conveyer belt. To simulate gravity, you can use a quadratic tweener, which accelerates slowly at first and then steeply increases towards the end. This simulates dropping an object that does not bounce.

Bounce and elastic tweeners offer flexibility when you want to simulate bounce or elasticity. The following animation shows a bouncing tweener. The ball starts offscreen and ends at the bottom of the screen. Between the start and end frames, the ball appears to bounce.
Properties other than location can also use tweens. The following animation shows a linear tweener for opacity, and a bouncing tweener for scale.
Tweeners are highly customizable. You can specify parameters to change properties such as duration, delay before starting, number of times to play, whether to go from the specified value to the current value or vice versa, and so on.

For available parameters and how to use them, see Tweener Supported Components (p. 3018). You can also create a timeline (p. 3022) to chain animations together with different tween types.

**Supported Tweener Easing Types**

The easiest way to visualize the concept of Scripted Entity Tweener easing types is to see it on a graph that depicts a change in position over time. The resulting line can be thought of as speed, though it isn't necessarily so.

The movement of objects in the natural world is rarely uniform. A rocket ship blasting off from the ground accelerates slowly as it first gains momentum, and then rapidly accelerates as it shoots toward the sky. If you viewed this motion on a position and time graph, it might look like a quartic or quintic easing in function. A bouncy ball dropped from a height accelerates toward the ground and hits it at a certain velocity. The ball bounces back up at that velocity and decelerates as it nears the top of its arc, and gravity pulls it back down for another bounce. Viewed on a position and time graph, looks like the bounce easing out function.

Lumberyard supports the following tweener ease methods (p. 3021) as easing in, easing out, and easing in-out (p. 3021) functions (ease type).

**Note**

The following images are referenced from http://easings.net.

**Linear**

Does not ease in or out. No acceleration or deceleration. Constant movement, such as a conveyor belt in motion.
**Quadratic**

Easing in function starts at a zero velocity, then accelerates.

Easing out function begins at a certain velocity and decelerates to zero.

Easing in-out function starts at zero velocity, accelerates until the halfway point, and then decelerates to zero.

The following graphs show quadratic ease in, quadratic ease out, and quadratic ease in-out functions.

---

**Cubic**

Similar to quadratic, but with a steeper curve, which indicates a slower rate of acceleration or deceleration at first, followed by a rapid acceleration or deceleration.

The following graphs show cubic ease in, cubic ease out, and cubic ease in-out functions.

---

**Quart**

Similar to cubic, but with an even slower rate of acceleration or deceleration followed by an even faster rate of acceleration or deceleration.

The following graphs show quartic ease in, quartic ease out, and quartic ease in-out functions.

---

**Quint**

Similar to quart, but with an even slower rate of acceleration or deceleration followed by an even faster rate of acceleration or deceleration.

The following graphs show quintic ease in, quintic ease out, and quintic ease in-out functions.

---

**Sine**

Based on a sine or cosine function. Gentle easing in or easing out, with an almost constant speed like the linear function.

The following graphs show sinusoidal ease in, sinusoidal ease out, and sinusoidal ease in-out functions.
Exponential

Similar to cubic.

The following graphs show exponential ease in, exponential ease out, and exponential ease in-out functions.

![Graphs of exponential ease in, ease out, and ease in-out functions.]

Circular

Based on the equation for half of a circle. The graph in the following image is stretched vertically so that you can see how the graph looks like a part of a circle.

The following graphs show circular ease in, circular ease out, and circular ease in-out functions.

![Graphs of circular ease in, ease out, and ease in-out functions.]

Elastic

An example of an elastic easting out function is a plucked guitar string. The string moves up and down with decreasing frequency until it comes to a rest. Easing in is the same motion but in reverse.

The following graphs show elastic ease in, elastic ease out, and elastic ease in-out functions.

![Graphs of elastic ease in, ease out, and ease in-out functions.]

Back

An example of a back easing in function is a toy car pulled backward to wind the springs, and then released.

The following graphs show back ease in, back ease out, and back ease in-out functions.

![Graphs of back ease in, ease out, and ease in-out functions.]

Bounce

Depicts a bouncing motion. For example, a rubber ball dropped from a height displays a bounce ease out function as it bounces and eventually comes to rest.

The following graphs show bounce ease in, bounce ease out, and bounce ease in-out functions.

![Graphs of bounce ease in, ease out, and ease in-out functions.]

Version 1.28
3016
Tweener Sample Level

You can use the Samples Project (p. 146) to see an example level that uses tweener.

To see example Scripted Entity Tweeners in action

1. In Lumberyard Editor, in the Samples Project (p. 146), open the level Samples \ScriptedEntityTweenerSample\SampleFullscreenAnimation.

2. To switch to gameplay mode, press Ctrl+G. The header, list items, earth, stars, and spaceship use tweener for their animation.

3. Press Esc to exit.
To view the sample UI canvas
1. Open the UI Editor (p. 2874).
2. Choose File, Open Canvas.
3. Navigate to the `lumberyard_version\dev\SamplesProject\UI\Canvases\ScriptedEntityTweenerSample` directory and then select `MenuAnimateInSample.uicanvas`.

To view the sample Lua Script with the tweener code
1. In the Hierarchy pane, select MenuSample.
2. In the Properties pane, under the Lua Script component, for Script, click the {} icon. This opens the samplescreenanimation script in the Lua Editor.

3. See how the script uses the listed parameters. For a complete list of parameters, see Tweener Parameters (p. 3021).

Try the following:
- Modify the value of the easeMethod (p. 3021) parameter, especially on the blocks that include `id = self.Properties.CharacterImage`, which represent the spaceship.
- Increase or decrease the duration parameter.
- Change the starting position ["x"] and ["y"].
4. Save your changes and close the Lua Editor.
5. In the UI Editor, click Preview in the upper right to see how your changes affect the game UI.

Tweener Supported Components

You can use the Scripted Entity Tweener system for any entity parameter currently recognized by the tweener system.

You can see the list of supported entity parameters in the `lumberyard_version\dev\Gems\ScriptedEntityTweener\Assets\Scripts\ScriptedEntityTweener\ScriptedEntityTweener.lua` file in the table `self.animationParameterShortcuts`.

The following example shows the `self.animationParameterShortcuts` table that is inside of the `ScriptedEntityTweener.lua` file.

```lua
self.animationParameterShortcuts =
{
  --UI Related
  ["opacity"] = {"UiFaderComponent", "Fade"},
  ["imgColor"] = {"UiImageComponent", "Color"},
```

["] = {"LightComponent", "ProbeBoxProjected" },
Tweener Lua Script

You must have a minimum set of code to play an animation in the Scripted Entity Tweener system. As described in Tweener Sample Level (p. 3017), you add this code to a Lua script. You can copy and paste the code into a text file, and then change the file name extension to .lua. You use this script as part of a Lua script component. For more information about Lua script components, see Adding Lua Scripts to Component Entities (p. 2684).

In the following example, the entity's opacity is linearly tweened to 0.5 over 5 seconds.

```lua
local AnimateUiEntity =
{
    Properties =
    {
        ToAnimate = {default = EntityId()},
    },
}

function AnimateUiEntity:OnActivate()
    self.tickBusHandler = TickBus.Connect(self)
    self.ScriptedEntityTweener =
        require("Scripts.ScriptedEntityTweener.ScriptedEntityTweener")
end

function AnimateUiEntity:OnTick(deltaTime, timePoint)
    self.tickBusHandler:Disconnect()
    self.ScriptedEntityTweener:StartAnimation
    {
        id = self.Properties.ToAnimate,
        duration = 5.0,
        ["opacity"] = 0.5,
    }
end

function AnimateUiEntity:OnDeactivate()
    self.ScriptedEntityTweener:OnDeactivate()
end

return AnimateUiEntity
```

The following example shows a full call with all the default parameters. In this example, the entity moves to the ["x"] and ["y"] positions indicated in the code over the duration of 5 seconds.

```lua
self.ScriptedEntityTweener:StartAnimation
{
    id = self.Properties.ToAnimate,
    duration = 5.0,
```
Scripted Tweener Entity System

```
{["x"] = 150, ["y"] = 200,
 timeIntoTween = 0, -- Start tween some seconds in
 easeMethod = ScriptedEntityTweenerEasingMethod_Linear,
 easeType = ScriptedEntityTweenerEasingType_In,
 delay = 0,
 timesToPlay = 1,
 isFrom = false,
 isPlayingBackward = false,
 uuid = Uuid.Create(),
 --onComplete = function() Debug.Log("Called when this animation is done") end
 --onUpdate = function(currentValue, currentProgressPercent) Debug.Log("Called when this
 animation updates") end
 --onLoop = function() Debug.Log("Looped animation") end
}
```

For the parameter descriptions, see Tweener Supported Components (p. 3018).

**Tweener Parameters**

Scripted Entity Tweener parameters provide flexibility and allow you to customize your tweener animations. Use the parameters with a timeline (p. 3022) for a variety of possibilities.

Use the following tweener parameters to customize your animation.

**duration**

Specifies the time in seconds for the animation to go from the start value to its final value.

**["x"] and ["y"]**

Shortcuts for the x and y values of a UiTransform2dComponent, which is automatically attached to every UI entity. For a full list of shortcuts, see `lumberyard_version\dev \Gems\ScriptedEntityTweener\Assets\Scripts\ScriptedEntityTweener \ScriptedEntityTweener.lua`.

**timeIntoTween**

Specifies a tween to begin at a specified point (in seconds). For example, if the duration is set to 6, and timeIntoTween is set to 3, then the tween begins immediately at its halfway point and finishes in three more seconds.

**easeMethod**

Specifies the easing type (p. 3014) to apply to the tween.

- ScriptedEntityTweenerEasingMethod_Linear
- ScriptedEntityTweenerEasingMethod_Quad
- ScriptedEntityTweenerEasingMethod_Cubic
- ScriptedEntityTweenerEasingMethod_Quart
- ScriptedEntityTweenerEasingMethod_Quint
- ScriptedEntityTweenerEasingMethod_Sine
- ScriptedEntityTweenerEasingMethod_Expo
- ScriptedEntityTweenerEasingMethod_Circ
- ScriptedEntityTweenerEasingMethod_Elastic
- ScriptedEntityTweenerEasingMethod_Back
- ScriptedEntityTweenerEasingMethod_Bounce

**easeType**

Modifies easeMethod.
- `ScriptedEntityTweenerEasingType_In`
- `ScriptedEntityTweenerEasingType_Out`
- `ScriptedEntityTweenerEasingType_InOut`

**delay**

Specifies an amount of time in seconds to delay the start of the animation.

**timesToPlay**

Number of times to play the animation. Specify -1 to play the animation indefinitely.

**isFrom**

If false, the animation starts at the value specified in the component and ends at the value specified in the script.

If true, the animation starts at the value specified in the script and ends at the value specified in the component.

**isPlayingBackward**

If true, the animation plays backwards. To play an animation backward, you must specify a value for `timeIntoTween`. If a value is not specified for `timeIntoTween`, this parameter is ignored.

**uuid**

ID generated by the Scripted Entity Tweener system and used for debugging purposes. You do not need to modify or specify a value.

**onComplete, onUpdate, and onLoop**

Use these parameters to specify a callback function when the animation completes, updates, or loops. `onUpdate` also passes back the animation’s current completion state percentage and the current value of the animated parameter.

**Tweener Timeline**

In the Scripted Entity Tweener system, you can create a timeline for granular control over your animations. You can chain and group animations. You can pause, resume, seek, play backward, label, and even dynamically control the playback speed of the animations.

To create a timeline, you can customize the following Lua script.

In this example, the script first animates the entity specified by `ToAnimate`, increasing its size from its original value to a width `"w"` and height `"h"` of 600. The script then animates the entity by shrinking it to a width `"w"` and height `"h"` of 200.

```lua
local AnimateUiEntity = 
{ 
    Properties = 
    { 
        ToAnimate = {default = EntityId()}, 
    },
}

function AnimateUiEntity:OnActivate() 
    self.tickBusHandler = TickBus.Connect(self) 
    self.ScriptedEntityTweener = 
        require("Scripts.ScriptedEntityTweener.ScriptedEntityTweener") 
end
```
function AnimateUiEntity:OnTick(deltaTime, timePoint)
    self.tickBusHandler:Disconnect()

    self.timeline = self.ScriptedEntityTweener:TimelineCreate()

    self.timeline:Add(
        {
            id = self.Properties.ToAnimate,
            easeMethod = ScriptedEntityTweenerEasingMethod_Bounce,
            easeType = ScriptedEntityTweenerEasingType_In,
            duration = 3.0,
            ["w"] = 600, ["h"] = 600,
        }
    )

    self.timeline:Add(
        {
            id = self.Properties.ToAnimate,
            easeMethod = ScriptedEntityTweenerEasingMethod_Sine,
            easeType = ScriptedEntityTweenerEasingType_in-out,
            duration = 3.0,
            ["w"] = 200, ["h"] = 200,
        }
    )

    self.timeline:Play()
end

function AnimateUiEntity:OnDeactivate()
    self.ScriptedEntityTweener:OnDeactivate()
end

return AnimateUiEntity

The following example shows all of the supported timeline operations.

-- Chained animations
self.timeline = self.ScriptedEntityTweener:TimelineCreate()
self.timeline:Add(...)  
self.timeline:Add(...)  
self.timeline:Play()

--Labels
self.timeline:AddLabel("Label", 0.5) -- Add label that specifies 0.5 seconds into animation
self.timeline:Play("Label") -- Play from label

--General timeline operations
local animationParameters = { id = self.Properties.ToAnimate, duration = 3, ["opacity"] = 0.5 }
self.timeline:Add(animationParameters), {["label"] = "LabelName"}, {["offset"] = 2} -- Start animation 2 seconds after LabelName
self.timeline:Add(animationParameters), {["initialStartTime"] = 2}, {["offset"] = -1} -- Start animation at second 1

self.timeline:Play()
self.timeline:Play(2) -- Play timeline starting at 2 seconds
self.timeline:Pause() -- Pause timeline
self.timeline:Resume() -- Resumes timeline, Play() also resumes
self.timeline:Seek(3) -- Play timeline starting at 3 seconds
self.timeline:PlayBackwards() -- Start playing animation backwards
self.timeline:PlayBackwards(3) -- Start playing animation backwards starting from second 3

UI Animation Editor

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
You can use animation sequences to animate UI elements in your game's UI. A UI canvas can contain many named animation sequences.

The UI Animation Editor has the following features:

- **Menu** – Operations for creating new animation sequences and switching between the Track Editor and Curve Editor.
- **Toolbar** – Tools for the editing and playback of animations. The Curve Editor displays an additional toolbar at the top of the pane.
- **Node pane** – Area for showing the active sequence and all of the elements that it is animating. A track for each animated property appears underneath the related element.
- **Editor pane** – Area for either the Track Editor, the Curve Editor, or both.

**To show the Animation Editor if it is not already visible**

- From the UI Editor (p. 2874) menu, choose View, Animation Editor.

To create an animation sequence, you first create a new sequence, assign one or more UI elements to it, and then record changes you make to the UI element(s)—this becomes the animation sequence. You can then edit the animation sequence(s) using the Animation Editor. These processes are described in greater detail in the following sections.

**Recording Animation Data**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Recording animation typically involves three steps:

1. Create a new animation sequence.
2. Add a UI element to that sequence.
3. Turn on animation recording to capture changes in the element properties.

Adding a UI element also adds a node to the sequence. After that any time that you enter record mode, a track is automatically added to your animation for any change you make to this UI element. You do not need to manually add tracks. For more information, see Using the Node Pane (p. 3026).

You can create an animation sequence from the Animation Editor menu or toolbar.

To create a new animation sequence

In the Animation Editor (p. 3023), do one of the following:

• From the Sequence menu, choose New Sequence.
• Click the Add Sequence icon on the toolbar.

To add a UI element to the sequence

1. In the UI Editor (p. 2874), select the UI element that you want to animate.
2. In the Animation Editor, right-click the sequence that you created and click Add Selected UI Element(s).

To record an animation sequence

1. In the Animation Editor toolbar, click the Record icon.
2. In the UI Editor, use either the Properties pane or viewport pane to make changes to the selected UI element.
3. After making all changes, click the Stop icon in the Animation Editor toolbar.

Note

In the current release, not all component properties can be recorded. For example, enumerated values, such as the image type of an image component, cannot be animated.

After you record a track, it appears beneath its UI element. The node pane lists your current animation sequences. For more information on the Node Pane, see Using the Node Pane (p. 3026)

Playing Animation Sequences

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can play back the animation in the Animation Editor to preview what it will look like in your game. Playing the animation sequence animates the UI elements in the UI Editor.

To control playback of animation in the UI Editor

• In the Play toolbar of the Animation Editor, use the Play, Pause, Stop, Go to start of sequence, and Go to end of sequence buttons.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

After you create your sequence(s) and record animation data to them, you can use the Node Pane, Track Editor, and Curve Editor in the Animation Editor to modify your sequences.

- In the Node Pane, you can add or remove UI elements from an animation sequence, edit sequences, and work with keys. For more information, see Using the Node Pane (p. 3026).
- In the Track Editor, you can limit your animation preview, manipulate keys, and change your animation's timeline. For more information, see Using the Track Editor (p. 3028).
- In the Curve Editor, you can manipulate splines to change the behavior of the transitions between keys. For more information, see Using the Curve Editor in the UI Animation Editor. (p. 3031).

Topics
- Using the Node Pane (p. 3026)
- Using the Track Editor (p. 3028)
- Using the Curve Editor in the UI Animation Editor. (p. 3031)

Using the Node Pane

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Node Pane in the Animation Editor (p. 3023) displays all the nodes in the selected animation sequence. Each item listed in the Node Pane is considered a node, though they represent different parts of the sequence. You can use the Node Pane to add or delete UI element nodes. Track nodes appear beneath its UI element when you record a track.

The animation sequence node, at the top level, contains a list of its UI elements nodes. Each UI element node contains a list of its track nodes.

1. Animation Sequence node
2. **UI Element** nodes

3. **Track** nodes

To add a new UI element node

1. In the **UI Editor** (p. 2874), select one or more elements.
2. In the **Animation Editor**, right-click anywhere in the node pane and select **Add Selected UI Element(s)**.

To remove a UI element node

- In the **Animation Editor**, in the node pane, right-click an element node and click **Delete**.

To edit a track

1. In the **Animation Editor**, in the node pane, select a track node.
2. Right-click the track node and choose any of the following:
   - Copy Keys
   - Copy Selected Keys
   - Paste Keys
   - Disable the track

You can also use the **Edit Sequence** tool to edit the properties of the sequence directly. You can set various properties, such as the start and end time, whether the sequence loops, and so on.

To open the **Edit Sequence** tool

- In the **Animation Editor**, click the **Edit Sequence** icon.
Using the Track Editor

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Track Editor displays all the tracks in your current animation sequence. The Track Editor enables you to do the following:

- Move, delete, copy, and paste keys
- Change the timeline of the animation
- Control the animation preview range
To display the Track Editor

- In the Animation Editor (p. 3023), choose View, Track Editor or View, Both.

To zoom in or out

- Scroll the mouse wheel

To pan the view

- With the mouse in the Track Editor, drag using the middle mouse button

Topics

- Working with Keys in the Track Editor (p. 3029)
- Moving the Play or Record Point in the Track Editor (p. 3030)
- Previewing in the Track Editor (p. 3030)

Working with Keys in the Track Editor

When you create an animation, key values are automatically recorded. Using the Track Editor, you can move, delete, copy, and paste keys. Keys are represented by a green circle on the timeline of each track.

To move a key

- Click a key and drag it to a new time on the timeline.

To constrain movement to time only

- Hold Shift as you drag the key to a new time on the timeline.

To scale the selected keyframes while moving a key

- Hold Alt as you drag the key to a new time on the timeline.

To delete a key

- Right-click a key and click Delete.

To copy a key

- Right-click a key and click Copy.

To paste a key

- Right-click in the timeline and click Paste. Move the key to the desired point on the timeline, then click to place.

The Track Editor's toolbar features a variety of tools to improve your workflow efficiency when editing tracks. Pause over each icon to reveal the tooltips.

Some of the toolbar functions require you to select multiple keys.
To select multiple keys

- In the Track Editor, drag to select multiple keys. The selected keys appear as white circles.

You can also use the Track Editor toolbar to select, move, and snap keys. When moving keys, you can choose to snap them to other keys, to frames, or to second ticks.

Working with Keys in the Track Editor Toolbar

<table>
<thead>
<tr>
<th>Toolbar icon</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Go to previous key</td>
<td>Selects the key directly before the currently selected key.</td>
</tr>
<tr>
<td>Go to next key</td>
<td>Selects the key directly after the currently selected key.</td>
</tr>
<tr>
<td>Slide keys</td>
<td>Moves the currently selected key and slides all the keys after it to the new point on the timeline while maintaining the original spacing.</td>
</tr>
<tr>
<td>Move keys</td>
<td>Moves the currently selected key(s) to the new point on the timeline without affecting other keys.</td>
</tr>
<tr>
<td>Scale keys</td>
<td>Functions only with multiple keys selected to increase or decrease the space between the selected keys proportionally.</td>
</tr>
<tr>
<td>Magnet Snapping</td>
<td>Snaps to keys in other tracks as you get close to them; allows you to place the key anywhere but indicates a red circle on the key you want to snap to.</td>
</tr>
<tr>
<td>Frame Snapping</td>
<td>Snaps to frames.</td>
</tr>
<tr>
<td>Tick Snapping</td>
<td>Snaps to second ticks.</td>
</tr>
</tbody>
</table>

Moving the Play or Record Point in the Track Editor

The play or record point of the animation sequence is shown as a vertical magenta slider on the timeline. Move the play or record point, and the properties of the UI elements in the Animation Editor (p. 3023) change to the values specified by the animation tracks.

To move the play or record point in the Track Editor

- Click or drag the vertical magenta slider in the timeline.

Previewing in the Track Editor

The Track Editor features a timeline along its top edge. To preview your entire animation, simply click the Play button to play your animation at its normal speed. You can also change the speed of preview by clicking the arrow beside the play button and selecting 2, 1, ½, ¼, or ⅛. You can also limit your animation preview, as it plays, to a specific time frame.

To limit play preview in the Track Editor

1. In the timeline, at the start of your preferred preview time, right-click to mark the time with a red triangle.
2. In the timeline, at the end of your preferred preview time, right-click again to mark the end time with a red triangle.
3. Click the Play button to preview your animation in the time frame specified.
**Note**
When you preview an animation or move the playback position on the timeline, it moves the UI elements in the **UI Editor**. This means that, if you then save the canvas, these UI elements will be saved in this position.
Reposition the timeline or preview a different sequence to position the UI elements at the positions in which you want them to load before you save the canvas.

**Using the Curve Editor in the UI Animation Editor.**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **Curve Editor** displays animations as function curves. Each track's curves represent an animation of a property value (such as anchor, offset, color, or any property of a UI element).

**The elements of a curve**
1. Curve or spline
2. Spline key
3. Tangent handles

The path of the curve represents the transition of the value between the keyframes. If the value changes in a straight line between each keyframe (linear), transitions between keyframes will not be smooth. The default curve causes the value to smoothly ease in and ease out. Each key has an in tangent and an out tangent. Depending on the preferred effect, you can use the toolbar icons to switch the tangents to auto, zero, step, or linear. You can also manually drag the tangent handles.
By default, animation tracks are recorded with a smooth transition. You can use the buttons in the toolbar at the top of the Curve Editor to change how the curves behave on either side of the selected key. You can also drag spline keys to a different point in the timeline.

**To display the Curve Editor**

- In the UI Animation editor, choose View, Curve Editor or View, Both.

**To zoom in or out**

- Scroll the mouse wheel

**To pan the view**

- With the mouse in the Curve Editor, drag using the middle mouse button

**To adjust a spline key**

1. In the Node Pane, select a track. The curves for that track appear in the Curve Editor.
2. In the Curve Editor, select a spline key.
3. Do one or more of the following:
   - Drag the spline key to a different point on the timeline.
   - Use the toolbar buttons to select a preset: auto, zero, step, or linear.

You can select multiple spline keys to modify at once. Once selected, you can move them all together, set their in and out tangents, and so on.

**To select multiple spline keys**

- In the Curve Editor, drag a selection box over all the spline keys you want to select.

**To edit multiple elements at once**

1. In the Animation Editor's node pane, select the track that contains the subtracks that you want to edit.
2. Drag a selection box over the spline keys that you want to select.
3. Drag spline keys to edit their position.

---

**UI Lua Reference**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the following Lua scripting functions when you work with UI canvases in Lumberyard Editor. For non-UI component entity Lua scripting functions, see the Component Entity Lua API Reference (p. 2705).

**Topics**
LyShineLua.ShowMouseCursor

- Controls the visibility of the mouse cursor. 1 specifies that the mouse cursor is displayed; 0 specifies that it is hidden.
UIButtonComponent

Syntax

void ShowMouseCursor(bool visible)

Services messages for the UIButtonComponent.

GetOnClickActionName

Returns the action triggered when the button is released.

Syntax

AZStd::string UIButtonBus::GetOnClickActionName()

SetOnClickActionName

Sets the action triggered when the button is released.

Syntax

void UIButtonBus::SetOnClickActionName(const AZStd::string& actionName)

UIButtonNotificationBus

Services notifications for the UIButtonComponent.

OnButtonClick

Occurs when a button has been clicked.

Syntax

void OnButtonClick()

UICanvasComponent

Contains buses and notification buses for UI canvas and animation.
UiCanvasBus

Services messages for the UiCanvasComponent.

FindObjectByName

Returns the entity ID of the first UI element in this canvas that has the specified name.

Syntax

```
AZ::EntityId FindElementByName(const AZStd::string& name)
```

ForceEnterInputEventOnInteractable

Forces a specified interactive element to receive an Enter press/release navigation event. This is useful for automated testing using script, such as simulating a button click.

Syntax

```
void ForceEnterInputEventOnInteractable(AZ::EntityId entityId)
```

ForceHoverInteractable

Forces a specified interactive element to receive the hover.

Syntax

```
void ForceHoverInteractable(AZ::EntityId entityId)
```

GetChildElement

Returns the entity ID of the child element that has the specified index.

Syntax

```
AZ::EntityId GetChildElement(int index)
```

GetChildElements

Returns a list of entity IDs of the child elements of the canvas.

Syntax

```
AZStd::vector<AZ::EntityId> GetChildElements()
```

GetDrawOrder

Returns the draw order on the canvas.

Syntax

```
int GetDrawOrder()
```
GetEnabled
Returns the enabled flag of the canvas. True if the canvas is enabled; false otherwise. Enabled canvases are updated and rendered for each frame.

Syntax
```cpp
bool GetEnabled()
```

GetHoverInteractable
Returns the entity ID of the interactive element that has the hover.

Syntax
```cpp
AZ::EntityId GetHoverInteractable()
```

GetIsNavigationSupported
Returns true if the canvas accepts navigation input; false otherwise.

Syntax
```cpp
bool GetIsNavigationSupported()
```

GetIsPixelAligned
Returns true if pixel alignment is enabled for this canvas; false otherwise. If pixel alignment is enabled, then all corners of all elements are rounded to the nearest pixel when they are rendered.

Syntax
```cpp
bool GetIsPixelAligned()
```

GetIsRenderToTexture
Returns true if the canvas is rendered to a texture instead of the full screen; false otherwise.

Syntax
```cpp
bool GetIsRenderToTexture()
```

GetKeepLoadedOnLevelUnload
Returns true if the canvas stays loaded when the level is unloaded; false otherwise.

Syntax
```cpp
bool GetKeepLoadedOnLevelUnload()
```

GetNumChildElements
Returns the number of child elements that the canvas has.

Syntax
int GetNumChildElements()

**GetRenderTargetName**

Returns the name of the texture that is created when this canvas is rendered to a texture.

**Syntax**

```c++
AZStd::string GetRenderTargetName()
```

**GetTooltipDisplayElement**

Returns the entity ID of the tooltip element that is to be displayed when the pointer pauses on an interactable element.

**Syntax**

```c++
AZ::EntityId GetTooltipDisplayElement()
```

**RecomputeChangedLayouts**

Tells the layout manager for the canvas to recompute the layout. This happens automatically every frame. Occasionally a script modifies something that affects the layout (such as the reparenting of an element) and tries to query positions in the same frame. In this case you can call `RecomputeChangedLayouts` to force an immediate recalculation of all layouts on the canvas that have been flagged for recomputing.

**Syntax**

```c++
void RecomputeChangedLayouts()
```

**SetDrawOrder**

Sets the draw order on the canvas.

**Syntax**

```c++
void SetDrawOrder(int drawOrder)
```

**SetEnabled**

Sets whether the canvas is enabled. Enabled canvases are updated and rendered for each frame. Specify true to enable the canvas, false to disable.

**Syntax**

```c++
void SetEnabled(bool enabled)
```

**SetHoverInteractable**

Sets the interactable element on the canvas on which the pointer has been paused.

**Note**

This action is done automatically, but in unusual situations it can be useful to call this function from a script.
### Syntax

```cpp
void SetHoverInteractable(AZ::EntityId entityId)
```

**SetIsNavigationSupported**

Specify true to make the canvas accept navigation input; false otherwise.

**Syntax**

```cpp
void setIsNavigationSupported(bool isSupported)
```

**SetIsPixelAligned**

Specify true to enable pixel alignment for this canvas; false otherwise.

**Syntax**

```cpp
void setIsPixelAligned(bool isPixelAligned)
```

**SetIsRenderToTexture**

Sets whether the canvas is rendered to a texture instead of the full screen. Specify true to render the canvas to a texture; false otherwise.

**Syntax**

```cpp
void setIsRenderToTexture(bool isRenderToTexture)
```

**SetKeepLoadedOnLevelUnload**

Sets whether the canvas stays loaded when the level is unloaded. Specify true to keep the canvas loaded on level unload; false otherwise.

**Syntax**

```cpp
void setKeepLoadedOnLevelUnload(bool keepLoaded)
```

**SetRenderTargetName**

Sets the name of the texture that is created when this canvas is rendered to a texture.

**Syntax**

```cpp
void setRenderTargetName(const AZStd::string& name)
```

**SetTooltipDisplayElement**

Sets the element that is to be displayed when the pointer pauses over an interactable element.

**Syntax**

```cpp
void setTooltipDisplayElement(AZ::EntityId entityId)
```
UiCanvasInputNotifications

Services notifications for the UiCanvasComponent.

OnCanvasEnterPressed

Called when the “enter” key is pressed. Sends the entity that was pressed or an invalid entity id if no element was pressed.

Syntax

```cpp
OnCanvasEnterPressed(AZ::EntityId entityId)
```

OnCanvasEnterReleased

Called when the enter key is released. Sends the entity that was pressed or an invalid entity id if no element was pressed.

Syntax

```cpp
OnCanvasEnterReleased(AZ::EntityId entityId)
```

OnCanvasHoverEnd

Called when an element ends being hovered.

Syntax

```cpp
OnCanvasHoverEnd(AZ::EntityId entityId)
```

OnCanvasHoverStart

Called when an element starts being hovered.

Syntax

```cpp
OnCanvasHoverStart(AZ::EntityId entityId)
```

OnCanvasPrimaryPressed

Called on a positional input press. Sends the entity that was pressed or an invalid entity id if no element was pressed.

Syntax

```cpp
void OnCanvasPrimaryPressed(AZ::EntityId entityId)
```

OnCanvasPrimaryReleased

Called on a positional input release. Sends the entity that was pressed or an invalid entity id if no element was pressed.

Syntax
OnCanvasPrimaryReleased(AZ::EntityId entityId)

UiCanvasNotificationBus
Services notifications for the UiCanvasComponent.

OnAction
Maps the name of an action to the entity ID of a canvas component that triggers the action.

Syntax

void OnAction(AZ::EntityId entityId, const AZStd::string& actionName)

UiAnimationBus
Animation messages serviced by the UiCanvasComponent.

AbortSequence
Aborts the specified sequence.

Syntax

void AbortSequence(const AZStd::string& sequenceName)

GetSequencePlayingSpeed
Returns the current playing speed of the specified sequence.

Syntax

float GetSequencePlayingSpeed(const AZStd::string& sequenceName)

GetSequencePlayingTime
Returns the current playing time of the specified sequence.

Syntax

float GetSequencePlayingTime(const AZStd::string& sequenceName)

IsSequencePlaying
Returns true if the specified sequence is playing; false otherwise.

Syntax

bool IsSequencePlaying(const AZStd::string& sequenceName)

PauseSequence
Pauses the specified sequence.
**Syntax**

```c
void PauseSequence (const AZStd::string& sequenceName)
```

**ResetSequence**

Resets the specified sequence to the start.

**Syntax**

```c
void ResetSequence (const AZStd::string& sequenceName)
```

**ResumeSequence**

Causes the specified sequence to resume.

**Syntax**

```c
void ResumeSequence (const AZStd::string& sequenceName)
```

**SetSequencePlayingSpeed**

Sets the current playing speed of the specified sequence.

**Syntax**

```c
void SetSequencePlayingSpeed(const AZStd::string& sequenceName, float speed)
```

**StartSequence**

Starts playing the specified sequence.

**Syntax**

```c
void StartSequence(const AZStd::string& sequenceName)
```

**StopSequence**

Stops playing the specified sequence.

**Syntax**

```c
void StopSequence (const AZStd::string& sequenceName)
```

**UiAnimationNotificationBus**

Services animation notifications for the UICanvasComponent.

**OnUiAnimationEvent**

Specifies the animation event for the specified sequence.

**Syntax**
void OnUiAnimationEvent(eUiAnimationEvent uiAnimationEvent, AZStd::string animSequenceName)

Following are possible values for the eUiAnimationEvent flag.

enum eUiAnimationEvent
{
    eUiAnimationEvent_Started,
    eUiAnimationEvent_Stopped,
    eUiAnimationEvent_Aborted,
    eUiAnimationEvent_Updated
};

UICanvasManager

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Contains functions for loading, unloading, and finding UI canvases.

UICanvasManagerBus

Services messages for the UiCanvasManager component.

FindLoadedCanvasByPathName

Returns the entity ID of the loaded canvas that has the specified canvas pathname.

Syntax

AZ::EntityId FindLoadedCanvasByPathName(const AZStd::string& canvasPathname)

LoadCanvas

 Loads a canvas and returns the entity ID of the loaded canvas.

Syntax

AZ::EntityId LoadCanvas(const AZStd::string& canvasPathname)

UnloadCanvas

 Unloads a UI canvas.

Syntax

void UnloadCanvas(AZ::EntityId canvasEntityId)

UICheckboxComponent

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
You can use this component to implement a UI check box in Amazon Lumberyard.

**UiCheckboxBus**

Services messages for the UiCheckboxComponent.

**GetChangedActionName**

Returns the action triggered when the check box value changes.

**Syntax**

```cpp
AZStd::string & GetChangedActionName()
```

**GetCheckedEntity**

Returns the child element that is shown when the check box is selected.

**Syntax**

```cpp
AZ::EntityId GetCheckedEntity()
```

**GetState**

Returns the state of the check box. True if selected; false otherwise.

**Syntax**

```cpp
bool GetState()
```

**GetTurnOffActionName**

Returns the action triggered when the check box is cleared.

**Syntax**

```cpp
const AZStd::string & GetTurnOffActionName()
```

**GetTurnOnActionName**

Returns the name of the action that is triggered when the check box is selected.

**Syntax**

```cpp
const AZStd::string& GetTurnOnActionName()
```

**GetUncheckedEntity**

Returns the child element that is shown when the check box is cleared.

**Syntax**

```cpp
AZ::EntityId GetUncheckedEntity()
```
**SetChangedActionName**
Sets the action triggered when the check box value changes.

**Syntax**

```cpp
void SetChangedActionName(const AZStd::string& actionName)
```

**SetCheckedEntity**
Sets the child element to show when the check box is selected.

**Syntax**

```cpp
void SetCheckedEntity(AZ::EntityId entityId)
```

**SetState**
Sets the state of the check box. True if selected; false otherwise.

**Syntax**

```cpp
void SetState(bool checked)
```

**SetTurnOffActionName**
Sets the action triggered when the check box is cleared.

**Syntax**

```cpp
void SetTurnOffActionName(const AZStd::string & actionName)
```

**SetTurnOnActionName**
Sets the action triggered when the check box is selected.

**Syntax**

```cpp
void SetTurnOnActionName(const AZStd::string & actionName)
```

**SetUncheckedEntity**
Sets the child element to show when the check box is cleared.

**Syntax**

```cpp
void SetUncheckedEntity(AZ::EntityId entityId)
```

**ToggleState**
Toggles the state of the check box.

**Syntax**
**UiCursorBus**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The `UiCursorBus` contains functions for manipulating the cursor in the game UI.

**IncrementVisibleCounter**

Increments the UI cursor visible counter. Should be paired with a call to `DecrementVisibleCounter`.

**Syntax**

```c
void IncrementVisibleCounter()
```

**DecrementVisibleCounter**

Decrements the UI cursor visible counter. Should be paired with a call to `IncrementVisibleCounter`.

**Syntax**

```c
void DecrementVisibleCounter()
```

**IsUiCursorVisible**

Queries whether the UI cursor is currently visible.

**Syntax**

```c
bool IsUiCursorVisible()
```

**SetUiCursor**

Sets the UI cursor image.

**Syntax**

```c
```
void SetUiCursor(const char* cursorImagePath)

**GetUiCursorPosition**

Returns the UI cursor position (in pixels) relative to the top left corner of the UI overlay viewport.

**Syntax**

```
AZ::Vector2 GetUiCursorPosition()
```

**UIDraggableComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use a draggable component to make an element draggable for drag-and-drop behavior.

**UiDraggableBus**

Services messages for the UiDraggableComponent.

**GetCanDropOnAnyCanvas**

Gets the flag that indicates whether this draggable can be dropped on this canvas or any loaded canvas.

**Syntax**

```
bool GetCanDropOnAnyCanvas()
```

**GetDragState**

Returns the current drag state of the draggable component.

**Syntax**

```
eUiDragState GetDragState()
```

Following are possible values for eUiDragState.

```
enum eUiDragState
{
    eUiDragState_Normal,
    eUiDragState_Valid,
    eUiDragState_Invalid
};
```

**GetOriginalFromProxy**

Gets the original draggable component from a draggable component that is acting as a proxy.

**Syntax**
**IsProxy**

Checks whether a draggable component is acting as a proxy for another draggable component.

**Syntax**

```cpp
bool IsProxy()
```

**ProxyDragEnd**

Concludes the drag of a proxy. Call `ProxyDragEnd` at the end of a drag if `SetAsProxy` was used for the drag. Call `ProxyDragEnd` from the `OnDragEnd` handler of the proxy element. This results in a call to `OnDragEnd` for the original draggable component.

**Syntax**

```cpp
void ProxyDragEnd(AZ::Vector2 point)
```

**RedoDrag**

Causes the draggable component to redetect the drop targets that are underneath the pointer and resend `OnDropHoverStart` or `OnDropHoverEnd` messages if needed. You can call `RedoDrag` from a script after the script has caused drop targets to change positions. This function is most useful for keyboard or gamepad navigation.

**Syntax**

```cpp
void RedoDrag(AZ::Vector2 point)
```

**SetAsProxy**

Sets a draggable component to act as a proxy for another draggable component and starts dragging the draggable component at the specified point. A proxy is useful if you want the visible element being dragged to be on a canvas other than the one on which the original draggable component is selected. It is also useful if you want to avoid moving the original draggable component.

**Syntax**

```cpp
void SetAsProxy(AZ::EntityId originalDraggableId, AZ::Vector2 point)
```

**SetCanDropOnAnyCanvas**

Sets the flag that indicates whether a draggable can be dropped on this canvas or any loaded canvas.

**Syntax**

```cpp
void SetCanDropOnAnyCanvas(bool anyCanvas)
```

**SetDragState**

Sets the current drag state of the draggable component.
Syntax

```csharp
void SetDragState(eUiDragState dragState)
```

For possible values for `eUiDragState`, see `GetDragState (p. 3046).

**UiDraggableNotificationBus**

Services notifications for the `UiDraggableComponent`.

**OnDrag**

Occurs each time the drag position changes during dragging. `OnDrag` events happen only between `OnDragStart` and `OnDragEnd` events.

**Syntax**

```csharp
void OnDrag(AZ::Vector2 position)
```

**OnDragEnd**

Occurs at the end of dragging when the release input event occurs. The `OnDragEnd` notification is sent before the `OnDrop` drop target notification.

**Syntax**

```csharp
void OnDragEnd(AZ::Vector2 position)
```

**OnDragStart**

Occurs when dragging is detected on the draggable component. For mouse or touch input, this occurs when movement has been detected after the press or touch.

**Syntax**

```csharp
void OnDragStart(AZ::Vector2 position)
```

**UiDropdownComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use `UiDropdownComponent` to implement a UI dropdown menu in Amazon Lumberyard.

**UiDropdownBus**

Services messages for the `UiDropdownComponent`.

**GetValue**

Returns the value of the dropdown. The value is the last option that was selected.

**Syntax**
UiDropdownComponent

**GetValue**

Sets the value of the dropdown manually.

**Syntax**

```cpp
AZ::EntityId GetValue()
```

**SetValue**

Returns the content element that this dropdown expands.

**Syntax**

```cpp
AZ::EntityId GetContent()
```

**GetContent**

Sets the content element that this dropdown expands.

**Syntax**

```cpp
void SetContent(AZ::EntityId content)
```

**GetExpandOnHover**

Returns whether this dropdown should expand automatically on hover.

**Syntax**

```cpp
bool GetExpandOnHover()
```

**SetExpandOnHover**

Sets whether this dropdown expands automatically on hover.

**Syntax**

```cpp
void SetExpandOnHover(bool expandOnHover)
```

**GetWaitTime**

Returns how long to wait before expanding upon hover and collapsing upon exit.

**Syntax**

```cpp
float GetWaitTime()
```

**SetWaitTime**

Sets how long to wait before expanding upon hover and collapsing upon exit.
**Syntax**

```cpp
void SetWaitTime(float waitTime)
```

**GetCollapseOnOutsideClick**

Returns whether this dropdown collapses when the user clicks outside.

**Syntax**

```cpp
bool GetCollapseOnOutsideClick()
```

**SetCollapseOnOutsideClick**

Sets whether this dropdown collapses when the user clicks outside.

**Syntax**

```cpp
void SetCollapseOnOutsideClick(bool collapseOnOutsideClick)
```

**GetExpandedParentId**

Returns the element that the dropdown content parents to when expanded (the root element by default).

**Syntax**

```cpp
AZ::EntityId GetExpandedParentId()
```

**SetExpandedParentId**

Sets the element that the dropdown content parents to when expanded.

**Syntax**

```cpp
void SetExpandedParentId(AZ::EntityId expandedParentId)
```

**GetTextElement**

Returns the text element that displays the text of the currently selected option.

**Syntax**

```cpp
bool GetCollapseOnOutsideClick()
```

**SetTextElement**

Sets the text element that displays the text of the currently selected option.

**Syntax**

```cpp
voidSetTextElement(AZ::EntityId textElement)
```
GetIconElement

Returns the icon element that displays the icon of the currently selected option.

**Syntax**

```cpp
AZ::EntityId GetIconElement()
```

SetIconElement

Sets the icon element that displays the icon of the currently selected option.

**Syntax**

```cpp
void SetIconElement(AZ::EntityId iconElement)
```

Expand

Expands the dropdown menu.

**Syntax**

```cpp
void Expand()
```

Collapse

Collapses the dropdown menu.

**Syntax**

```cpp
void Collapse()
```

GetExpandedActionName

Returns the name of the action that is sent when the dropdown is expanded.

**Syntax**

```cpp
const LyShine::ActionName& GetExpandedActionName()
```

SetExpandedActionName

Sets the name of the action that is sent when the dropdown is expanded.

**Syntax**

```cpp
void SetExpandedActionName(const LyShine::ActionName& actionName)
```

GetCollapsedActionName

Returns the name of the action that is sent when the dropdown is collapsed.

**Syntax**

```cpp
```
const LyShine::ActionName& GetCollapsedActionName()

SetCollapsedActionName
Sets the name of the action that is sent when the dropdown is collapsed.

Syntax

void SetCollapsedActionName(const LyShine::ActionName& actionName)

GetOptionSelectedActionName
Returns the name of the action that is sent when the dropdown value is changed.

Syntax

const LyShine::ActionName& GetOptionSelectedActionName()

SetOptionSelectedActionName
Sets the name of the action that is sent when the dropdown value is changed.

Syntax

void SetOptionSelectedActionName(const LyShine::ActionName& actionName)

UiDropdownNotificationBus
Services notifications for the UiDropdownComponent.

OnDropdownExpanded
Notifies that the dropdown was expanded.

Syntax

void OnDropdownExpanded()

OnDropdownCollapsed
Notifies that the dropdown was collapsed.

Syntax

void OnDropdownCollapsed()

OnDropdownValueChanged
Notifies that an option was selected.

Syntax

void OnDropdownValueChanged(AZ::EntityId option)
UiDropdownOptionComponent

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use `UiDropdownOptionComponent` to implement a dropdown options for a UI element in Amazon Lumberyard.

UiDropdownOptionBus

Services messages for the `UiDropdownOptionComponent`.

GetOwningDropdown

Returns the owning dropdown to be modified when this dropdown option is selected.

Syntax

```plaintext
AZ::EntityId GetOwningDropdown()
```

SetOwningDropdown

Sets the owning dropdown to be modified when this dropdown option is selected.

Syntax

```plaintext
void SetOwningDropdown(AZ::EntityId owningDropdown)
```

GetTextElement

Returns the text element that is used to display this dropdown option’s text.

Syntax

```plaintext
AZ::EntityId GetTextElement()
```

SetTextElement

Sets the text element that is used to display this dropdown option’s text.

Syntax

```plaintext
void SetTextElement(AZ::EntityId textElement)
```

GetIconElement

Returns the icon element that is used to display this dropdown option’s icon.

Syntax

```plaintext
AZ::EntityId GetIconElement()
```
**SetIconElement**

Sets the icon element that is used to display this dropdown option's icon.

**Syntax**

```cpp
void SetIconElement(AZ::EntityId iconElement)
```

**UiDropdownOptionNotificationBus**

Services notifications for the `UiDropdownOptionComponent`.

**OnDropdownOptionSelected**

Notifies that this dropdown option was selected.

**Syntax**

```cpp
void OnDropdownOptionSelected()
```

**UiDropTargetComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use a drop target component to make an element a target for drag-and-drop behavior.

**UiDropTargetBus**

Services messages for the `UiDropTargetComponent`.

**GetDropState**

Returns the current drop state of the drop target component.

**Syntax**

```cpp
eUiDropState GetDropState()
```

Following are possible values for `eUiDropState`.

```cpp
enum eUiDropState
{
    eUiDropState_Normal,
    eUiDropState_Valid,
    eUiDropState_Invalid
};
```

**GetOnDropAction**

Returns the action triggered when a draggable component is dropped on this drop target.
Syntax

```cpp
const AZStd::string& GetOnDropAction()
```

**SetDropState**

Sets the current drop state of the drop target component.

**Syntax**

```cpp
Void SetDropState(eUiDropState dragState)
```

For possible values for `eUiDropState`, see GetDropState (p. 3054).

**SetOnDropAction**

Sets the action triggered when a draggable component is dropped on this drop target.

**Syntax**

```cpp
void SetOnDropAction(const AZStd::string& actionName)
```

**Tip**

A more flexible way to be notified when a drop occurs is to use the `UiDropTargetNotificationBus (p. 3055).`

**UiDropTargetNotificationBus**

Services notifications for the `UiDropTargetComponent`.

**OnDrop**

Occurs when a draggable component is dropped on this drop target. The draggable component is passed in. Implement the game logic of what should happen on drag and drop here.

**Syntax**

```cpp
void OnDrop(AZ::EntityId draggable)
```

**OnDropHoverEnd**

Occurs when the focus stops being on this drop target during dragging. The draggable component that is being dragged is passed into this function.

**Syntax**

```cpp
void OnDropHoverEnd(AZ::EntityId draggable)
```

**OnDropHoverStart**

Occurs when the focus starts to be on this drop target during dragging. The draggable component that is being dragged is passed into this function.

**Syntax**
void OnDropHoverStart(AZ::EntityId draggable)

**UIDynamicLayoutComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Clones a prototype element to achieve the specified number of child elements.

**UiDynamicLayoutBus**

Services messages for the UiDynamicLayoutComponent.

**SetNumChildElements**

Specifies the number of child elements to be created dynamically.

**Syntax**

```c
void SetNumChildElements(int numChildren)
```

**UIDynamicScrollViewComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Dynamically sets up scrollbox content as a horizontal or vertical list of elements that are cloned from a prototype element. For efficient scrolling, only the minimum number of elements are created.

**UiDynamicScrollViewBus**

Services messages for the UiDynamicScrollViewComponent.

**GetChildElementAtLocationIndex**

Returns the child element at the specified location index.

**Syntax**

```c
AZ::EntityId GetChildElementAtLocationIndex(int index)
```

**GetLocationIndexOfChild**

Returns the location index of the specified child element. Returns -1 if not found.

**Syntax**

```c
int GetLocationIndexOfChild(AZ::EntityId childElement)
```
**RefreshContent**
Refreshes the content. You should call this when the list size or element content has changed.

**Syntax**

```csharp
void RefreshContent()
```

**UiDynamicScrollBoxDataBus**
Create this handler to provide a dynamic scrollbox with the number of elements to display.

**GetNumElements**
Returns the total number of elements that the dynamic scrollbox is to display.

**Syntax**

```csharp
int GetNumElements()
```

**UiDynamicScrollBoxElementNotificationBus**
Create this handler to receive notifications of dynamic scrollbox element state changes, such as when an element is about to scroll into view.

**OnElementBecomingVisible**
An element is about to become visible. Use this event to populate the element with data for display. Specifies the entity ID of the element that is about to become visible and its location index.

**Syntax**

```csharp
void OnElementBecomingVisible(AZ::EntityId entityId, int index)
```

**UIElementComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Provides functionality for UI elements.

**UiElementBus**
Services messages for the UIElementComponent.

**DestroyElement**
Deletes this element and removes it from its parent element.

**Syntax**

```csharp
void DestroyElement()
```
**FindChildByName**

Returns the first immediate child with the specified name. Returns `AZ::InvalidEntityId` if no match is found.

**Syntax**

```
AZ::EntityId FindChildByName(const AZStd::string & name)
```

**FindDescendantByName**

Returns the first descendent entity with the specified name. Returns `AZ::InvalidEntityId` if no match is found.

**Syntax**

```
AZ::EntityId FindDescendantByName(const AZStd::string & name)
```

**GetCanvas**

Returns the canvas that contains this element. Returns `AZ::InvalidEntityId` if the element has no canvas.

**Syntax**

```
AZ::EntityId GetCanvas()
```

**GetChild**

Returns the child entity ID at the specified index. The specified index must be less than `GetNumChildElements()`.

**Syntax**

```
AZ::EntityId GetChild(int index)
```

**GetChildren**

Returns the child entity IDs of this element.

**Syntax**

```
AZStd::vector<AZ::EntityId> GetChildren()
```

**GetIndexOfChildByEntityId**

Returns the index of the specified child element.

**Syntax**

```
int GetIndexOfChildByEntityId(AZ::EntityId childId)
```

**GetName**

Returns the name of this element.
Syntax

AZStd::string GetName()

**GetNumChildElements**

Returns the number of child elements of this element.

Syntax

```cpp
int GetNumChildElements()
```

**GetParent**

Returns the parent entity ID of this element. Returns an invalid entity ID if the element has no parent.

Syntax

```cpp
AZ::EntityId GetParent()
```

**IsAncestor**

Returns whether a specified element is an ancestor of this element.

Syntax

```cpp
bool IsAncestor(AZ::EntityId id)
```

**IsEnabled**

Returns true if the element is enabled; false otherwise.

Syntax

```cpp
bool IsEnabled()
```

**Reparent**

Makes this element the child of a different parent. The element is removed from its current parent and added as a child of the parent specified by `newParent`.

Syntax

```cpp
void Reparent(AZ::EntityId newParent, AZ::EntityId insertBefore)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>newParent</code></td>
<td>Specifies the entity ID of the new parent element. If <code>newParent</code> is invalid, the element becomes a top-level element (that is, the canvas becomes the parent).</td>
</tr>
<tr>
<td><code>insertBefore</code></td>
<td>Child element of the new parent before which to insert this element. If null, the element is put at the end of the child list.</td>
</tr>
</tbody>
</table>
**SetIsEnabled**

Sets the enabled state of the element.

**Syntax**

```csharp
void SetIsEnabled(bool isEnabled)
```

**UIFaderComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/opendesign/) or visit the AWS Game Tech blog to learn more.

You can use a fader component to simultaneously adjust the transparency of an element and its children.

**UiFaderBus**

Services messages for the UiFaderComponent.

**Fade**

Triggers a fade animation.

**Syntax**

```csharp
void Fade(float targetValue, float speed)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>targetValue</td>
<td>The value at which to end the fade [0,1].</td>
</tr>
<tr>
<td>speed</td>
<td>The speed of the fade animation in full fade amount per second; 0 means instant.</td>
</tr>
</tbody>
</table>

**GetFadeValue**

Returns the fade value. The fade value is a float between zero and one. One means no fade; zero means complete fade to invisible.

**Syntax**

```csharp
float GetFadeValue()
```

**IsFading**

Returns whether a fade animation is taking place.

**Syntax**

```csharp
bool IsFading()
```
SetFadeValue
Sets the fade value.

**Syntax**

```csharp
void SetFadeValue(float fade)
```

**UiFaderNotificationBus**
Services notifications for the *UiFaderComponent*.

**OnDestroyed**
The fader component has been destroyed.

**Syntax**

```csharp
void OnFaderDestroyed()
```

**OnFadeComplete**
The fade animation is done.

**Syntax**

```csharp
void OnFadeComplete()
```

**OnFadeInterrupted**
The fade animation has been interrupted.

**Syntax**

```csharp
void OnFadeInterrupted()
```

**UIFlipbookAnimationComponent**
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **UIFlipbookAnimationComponent** animates the display of a range of cells in a sprite sheet image. You must use an *Image* component along with the **UIFlipbookAnimationComponent** component.

**UIFlipbookAnimationBus**
Services messages for the **UIFlipbookAnimationComponent**.

**Start**
 Begins playing the flipbook animation.

**Syntax**

```csharp
```
void Start()

**Stop**

Ends the animation.

**Syntax**

```cpp
void End()
```

**IsPlaying**

Returns true if the animation is currently playing. Otherwise, false.

**Syntax**

```cpp
void IsPlaying()
```

**GetStartFrame**

Returns the first frame to display when starting the animation.

**Syntax**

```cpp
AZ::u32 GetStartFrame()
```

**SetStartFrame**

Sets the first frame to display when starting the animation.

**Syntax**

```cpp
void SetStartFrame(AZ::u32 startFrame)
```

**GetEndFrame**

Returns the last frame to display for the animation.

**Syntax**

```cpp
AZ::u32 GetEndFrame()
```

**SetEndFrame**

Sets the last frame to display for the animation.

**Syntax**

```cpp
void SetEndFrame(AZ::u32 endFrame)
```

**GetCurrentFrame**

Returns the frame of the animation currently displayed.
Syntax

AZ::u32 GetCurrentFrame()

**GetCurrentFrame**

Sets the frame to immediately display for the animation.

**Syntax**

void SetCurrentFrame(AZ::u32 currentFrame)

**GetLoopStartFrame**

Returns the first frame that is displayed within an animation loop.

Applicable only when the **Loop Type** is set to anything other than **None**.

**Syntax**

AZ::u32 GetLoopStartFrame()

**SetLoopStartFrame**

Sets the first frame that is displayed within an animation loop.

Applicable only when the **Loop Type** is set to anything other than **None**.

**Syntax**

void SetLoopStartFrame(AZ::u32 loopStartFrame)

**GetLoopType**

Returns the type of looping behavior for this animation.

**Syntax**

eUiFlipbookAnimationLoopType GetLoopType()

See **SetLoopType** for a list of possible loop type values.

**SetLoopType**

Sets the type of looping behavior for this animation.

**Syntax**

void SetLoopType(eUiFlipbookAnimationLoopType loopType)

Possible loop types are as follows:

```cpp
eUiFlipbookAnimationLoopType
{
...
Each type performs a different looping action:

- **None** – Animation ends when end frame is reached.
- **Linear** – The frame displayed after the end frame is always the Loop Start Frame.
- **PingPong** – The direction of the animation loop goes back and forth between the start frame and the end frame.

**GetFrameDelay**

Returns the number of seconds to wait before displaying the next frame.

**Syntax**

```cpp
float GetFrameDelay()
```

**SetFrameDelay**

Sets the number of seconds to wait before displaying the next frame.

**Syntax**

```cpp
void SetFrameDelay(float delay)
```

**GetIsAutoPlay**

Returns true if the animation will begin playing as soon as the element is activated. Otherwise, false.

**Syntax**

```cpp
bool GetIsAutoPlay()
```

**SetIsAutoPlay**

Sets whether the animation will begin playing as soon as the element is activated.

**Syntax**

```cpp
void SetIsAutoPlay(bool isAutoPlay)
```

**UiFlipbookAnimationNotificationBus**

Notifies listeners of important events concerning the UiFlipbookAnimationComponent.

**OnAnimationStarted**

The flipbook animation has begun playing.

**Syntax**
void OnAnimationStarted()

**OnAnimationStopped**

The flipbook animation has stopped playing.

**Syntax**

```c++
void OnAnimationStopped()
```

**OnLoopSequenceCompleted**

The flipbook animation has completed one loop iteration. This triggers only when the Loop Type of the flipbook animation is configured to anything other than None.

For **Linear** loops, this triggers when End Frame is displayed.

For **Ping Pong** loops, this triggers when either Start Frame or End Frame is displayed (depending on the current loop direction of the loop).

**Syntax**

```c++
void OnLoopSequenceCompleted()
```

**UIImageComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Controls sprites, images, and textures.

**UIImageBus**

Services messages for the UiImageComponent.

**GetColor**

Returns the color tint for the image.

**Syntax**

```c++
AZ::Color GetColor()
```

**SetColor**

Sets the color tint for the image.

**Syntax**

```c++
void SetColor(const AZ::Color& color)
```
GetSpritePathname

Returns the source location of the image to be displayed by the element.

Syntax

```azstd::string GetSpritePathname()```

SetSpritePathname

Sets the source location of the image to be displayed by the element.

Syntax

```void SetSpritePathname(AZStd::string spritePath)```

GetRenderTargetName

Returns the name of the render target associated with the sprite.

Syntax

```azstd::string GetRenderTargetName()```

SetRenderTargetName

Sets the name of the render target associated with the sprite.

Syntax

```void SetRenderTargetName(AZStd::string renderTargetName)```

GetSpriteType

Returns the type of the sprite.

Syntax

```eUiSpriteType GetSpriteType()```

Possible sprite types are as follows.

```enum eUiSpriteType
    {
        eUiSpriteType_SpriteAsset,
        eUiSpriteType_RenderTarget
    }```

SetSpriteType

Sets the type of the sprite.

Syntax
void SetSpriteType(eUiSpriteType spriteType)

For possible sprite types, see GetSpriteType (p. 3066).

**GetImageType**

Returns the type of the image. Affects how the texture or sprite is mapped to the image rectangle.

**Syntax**

```cpp
eUiImageType GetImageType()
```

Possible values for `eUiImageType` are as follows.

```cpp
enum eUiImageType
{
    eUiImageType_Stretched,
    eUiImageType_Sliced,
    eUiImageType_Fixed,
    eUiImageType_Tiled,
    eUiImageType_StretchedToFit,
    eUiImageType_StretchedToFill
};
```

**SetImageType**

Sets the type of the image. Affects how the texture or sprite is mapped to the image rectangle.

**Syntax**

```cpp
void SetImageType(eUiImageType imageType)
```

For possible values for `eUiImageType`, see GetImageType (p. 3067).

**GetFillType**

Returns the Fill Type of the image. Fill Type determines how the image component is filled.

**Syntax**

```cpp
eUiFillType GetFillType()
```

Possible values for `eUiFillType` are as follows.

```cpp
enum eUiFillType
{
    eUiFillType_None,
    eUiFillType_Linear,
    eUiFillType_Radial,
    eUiFillType_RadialCorner,
    eUiFillType_RadialEdge
};
```

**SetFillType**

Sets the Fill Type of the image. Fill Type determines how the image component is filled.
Syntax

```
void SetFillType(eUiFillType fillType)
```

For possible values for `eUiFillType`, see `GetFillType` (p. 3067).

**GetFillAmount**

Returns the **Fill Amount**. The **Fill Amount** is a float between zero and one. 1.00 indicates that the image is completely filled. 0.00 means no part of the image is filled.

Syntax

```
float GetFillAmount()
```

**SetFillAmount**

Sets the **Fill Amount**.

Syntax

```
void SetFillAmount(float fillAmount)
```

**GetRadialFillStartAngle**

Returns the starting angle of the **Radial Fill** in degrees clockwise. A value of 0 indicates the top center of the image.

Syntax

```
float GetRadialFillStartAngle()
```

**SetRadialFillStartAngle**

Sets the starting angle of the **Radial Fill**.

Syntax

```
void SetRadialFillStartAngle(float radialFillStartAngle)
```

**GetCornerFillOrigin**

Returns the **Corner Fill** origin of the image.

Syntax

```
eUiFillCornerOrigin GetCornerFillOrigin()
```

Possible values for `eUiFillCornerOrigin` are as follows.

```
enum eUiFillCornerOrigin
{
    eUiFillCornerOrigin_TopLeft,
    eUiFillCornerOrigin_TopRight,
    // other values...
}
```
SetCornerFillOrigin

Sets the **Corner Fill** origin of the image.

**Syntax**

```c
void SetCornerFillOrigin(eUiFillCornerOrigin cornerFillOrigin)
```

For possible values for `eUiFillCornerOrigin`, see [GetCornerFillOrigin](#) (p. 3068).

GetEdgeFillOrigin

Returns the **Edge Fill** origin of the image.

**Syntax**

```c
enum eUiFillEdgeOrigin GetEdgeFillOrigin()
```

Possible values for `eUiFillEdgeOrigin` are as follows.

```c
enum eUiFillEdgeOrigin
{
    eUiFillEdgeOrigin_Left,
    eUiFillEdgeOrigin_Top,
    eUiFillEdgeOrigin_Right,
    eUiFillEdgeOrigin_Bottom
};
```

SetEdgeFillOrigin

Sets the **Edge Fill** origin of the image.

**Syntax**

```c
void SetEdgeFillOrigin(eUiFillEdgeOrigin edgeFillOrigin)
```

For possible values for `eUiFillEdgeOrigin`, see [GetEdgeOrigin](#) (p. 3069).

GetFillClockwise

Returns whether the image is radially filled clockwise.

**Syntax**

```c
bool GetFillClockwise()
```

SetFillClockwise

Sets whether the image is radially filled clockwise.

**Syntax**

```c
```
void SetFillClockwise(bool fillClockwise)

**GetFillCenter**

Returns whether the center of a sliced image is filled.

**Syntax**

```cpp
bool GetFillCenter()
```

**SetFillCenter**

Sets whether the center of a sliced image is filled.

**Syntax**

```cpp
void SetFillCenter(bool fillCenter)
```

**SetSpriteSheetCellIndex**

Sets the sprite sheet cell index for the image component to display.

**Syntax**

```cpp
void SetSpriteSheetCellIndex(AZ::u32 index)
```

**GetSpriteSheetCellIndex**

Returns the sprite sheet cell index currently displayed by the image component.

**Syntax**

```cpp
AZ::u32 GetSpriteSheetCellIndex()
```

**GetSpriteSheetCellCount**

Returns the number of cells in the sprite sheet.

If no image file is associated with this component, returns 0.

If an image file is associated but not configured as a sprite sheet, returns 1.

**Syntax**

```cpp
AZ::u32 GetSpriteSheetCellCount()
```

**GetSpriteSheetCellAlias**

Returns the string alias associated with the given sprite sheet cell index.

Returns an empty string if an alias is not configured or is unavailable.

**Syntax**
AZStd::string GetSpriteSheetCellAlias(AZ::u32 index)

**SetSpriteSheetCellAlias**

Given a cell index that is valid for the sprite sheet image associated with the image component, assign the alias string for that cell.

**Syntax**

```cpp
void SetSpriteSheetCellAlias(AZ::u32 index, AZStd::string alias)
```

**GetSpriteSheetCellIndexFromAlias**

Given a string alias that corresponds to an alias of a cell within the sprite sheet image of the component, return that cells index value.

**Note**

This returns only the first matching cell in the sprite sheet that matches the given string. Other cells in the sprite sheet that have the same alias are not considered after the first match is found.

**Syntax**

```cpp
AZ::u32 GetSpriteSheetCellIndexFromAlias(AZStd::string alias)
```

**UIInteractableComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Controls elements that respond to user input.

**UIInteractableBus**

Services messages for the UIInteractableComponent.

**GetIsAutoActivationEnabled**

Returns true if automatic activation is enabled; false otherwise.

**Syntax**

```cpp
bool GetIsAutoActivationEnabled()
```

**IsHandlingEvents**

Returns true if event handling is enabled; false otherwise.

**Syntax**

```cpp
bool IsHandlingEvents()
```
**SetIsAutoActivationEnabled**
Sets whether automatic activation is enabled.

**Syntax**

```cpp
void SetIsAutoActivationEnabled (bool isEnabled)
```

**SetIsHandlingEvents**
Sets whether event handling is enabled.

**Syntax**

```cpp
void SetIsHandlingEvents (bool isHandlingEvents)
```

**UiInteractableActionsBus**
Services actions for the UiInteractableComponent.

**GetHoverEndActionName**
Returns the current hover end action name.

**Syntax**

```cpp
AZStd::string& GetHoverEndActionName()
```

**GetHoverStartActionName**
Returns the current hover start action name.

**Syntax**

```cpp
AZStd::string& GetHoverStartActionName()
```

**GetPressedActionName**
Returns the pressed action name.

**Syntax**

```cpp
AZStd::string& GetPressedActionName()
```

**GetReleasedActionName**
Returns the released action name.

**Syntax**

```cpp
AZStd::string& GetReleasedActionName()
```

**SetHoverEndActionName**
Sets the hover end action name.
Syntax

SetHoverEndActionName(const AZStd::string& actionName)

**SetHoverStartActionName**
Sets the hover start action name.

**Syntax**

SetHoverStartActionName(const AZStd::string& actionName)

**SetPressedActionName**
Sets the pressed action name.

**Syntax**

SetPressedActionName(const AZStd::string& actionName)

**SetReleasedActionName**
Sets the released action name.

**Syntax**

SetReleasedActionName(const AZStd::string& actionName)

**UiInteractableStatesBus**
Services states for the UiInteractableComponent.

**GetStateAlpha**
Returns the alpha to be used for the specified target when the interactable element is in the specified state.

**Syntax**

float GetStateAlpha(eUiInteractableState state, AZ::EntityId target)

**GetStateColor**
Returns the color to be used for the specified target when the interactable element is in the specified state.

**Syntax**

AZ::Color GetStateColor(eUiInteractableState state, AZ::EntityId target)

Possible values for eUiInteractableState are as follows.

```cpp
gen eUiInteractableState
```
UIInteractableComponent

```cpp
{
    eUiInteractableState_Normal,
    eUiInteractableState_Hover,
    eUiInteractableState_Pressed,
    eUiInteractableState_Disabled
};
```

**GetStateFontEffectIndex**

Returns the font effect to be used for the specified target when the interactable element is in the specified state.

**Syntax**

```cpp
unsigned int GetStateFontEffectIndex(eUiInteractableState state, AZ::EntityId target)
```

**GetStateFontPathname**

Returns the font path to be used for the specified target when the interactable element is in the specified state.

**Syntax**

```cpp
AZStd::string GetStateFontPathname(eUiInteractableState state, AZ::EntityId target)
```

**GetStateSpritePathname**

Returns the sprite path to be used for the specified target when the interactable element is in the specified state.

**Syntax**

```cpp
AZStd::string GetStateSpritePathname(eUiInteractableState state, AZ::EntityId target)
```

**HasStateAlpha**

Returns true if the interactable element has an alpha action for the specified state and target combination.

**Syntax**

```cpp
bool HasStateAlpha(eUiInteractableState state, AZ::EntityId target)
```

**HasStateColor**

Returns true if the interactable element has a color action for the specified state and target combination.

**Syntax**

```cpp
bool HasStateColor(eUiInteractableState state, AZ::EntityId target)
```

**HasStateFont**

Returns true if the interactable element has a font action for the specified state and target combination.
UIInteractableComponent

Syntax

```cpp
bool HasStateFont(eUiInteractableState state, AZ::EntityId target)
```

**HasStateSprite**

Returns true if the interactable element has a sprite action for the specified state and target combination.

Syntax

```cpp
bool HasStateSprite(eUiInteractableState state, AZ::EntityId target)
```

**SetStateAlpha**

Sets the alpha to be used for the specified target when the interactable element is in the specified state. If the interactable element already has an alpha action for this state and target combination, then SetStateAlpha replaces the alpha action.

Syntax

```cpp
void SetStateAlpha(eUiInteractableState state, AZ::EntityId target, float alpha)
```

**SetStateColor**

Sets the color to be used for the specified target when the interactable element is in the specified state. If the interactable element already has a color action for the current state and target combination, then SetStateColor replaces the color action.

Syntax

```cpp
void SetStateColor(eUiInteractableState state, AZ::EntityId target, const AZ::Color& color)
```

**SetStateFont**

Sets the font to be used for the specified target when the interactable element is in the specified state. If the interactable element already has a font action for the specified state and target combination, then SetStateFont replaces the font action.

Syntax

```cpp
void SetStateFont(eUiInteractableState state, AZ::EntityId target, const AZStd::string& fontPathname, unsigned int fontEffectIndex)
```

**SetStateSpritePathname**

Sets the sprite path to be used for the specified target when the interactable element is in the specified state. If the interactable element already has a sprite action for the specified state and target combination, then SetStateSpritePathname replaces the sprite action.

Syntax

```cpp
void SetStateSpritePathname(eUiInteractableState state, AZ::EntityId target, const AZStd::string& spritePath)
```
UiInteractableNotificationBus
Services notifications for the UIInteractableComponent.

OnHoverEnd
Called on hover end.
Syntax

void OnHoverEnd()

OnHoverStart
Called on hover start.
Syntax

void OnHoverStart()

OnPressed
Called when an element has been pressed.
Syntax

void OnPressed()

OnReleased
Called when an element has been released.
Syntax

void OnReleased()

OnReceivedHoverByNavigatingFromDescendant
Called when the element receives the hover by being navigated to from a descendant.
Syntax

void OnReceivedHoverByNavigatingFromDescendant(AZ::EntityId descendantEntityId)

UiNavigationBus
Services navigation for the UIInteractableComponent.

GetNavigationMode
Returns the navigation mode.
Syntax
eUiNavigationMode GetNavigationMode()

Possible values for eUiNavigationMode are as follows.

enum eUiNavigationMode
{
    eUiNavigationMode_Automatic,
    eUiNavigationMode_Custom,
    eUiNavigationMode_None
};

GetOnDownEntity

Returns the ID of the entity that receives focus when down is pressed.

Syntax

AZ::EntityId GetOnDownEntity()

GetOnLeftEntity

Returns the ID of the entity to receive focus when left is pressed.

Syntax

AZ::EntityId GetOnLeftEntity()

GetOnRightEntity

Returns the ID of the entity to receive focus when right is pressed.

Syntax

AZ::EntityId GetOnRightEntity()

GetOnUpEntity

Returns the ID of the entity that receives focus when up is pressed.

Syntax

AZ::EntityId GetOnUpEntity()

SetNavigationMode

Sets the navigation mode.

Syntax

void SetNavigationMode(eUiNavigationMode navigationMode)

SetOnDownEntity

Sets the entity to receive focus when down is pressed.
Syntax

```cpp
void SetOnDownEntity(AZ::EntityId entityId)
```

### SetOnLeftEntity

Sets the entity to receive focus when left is pressed.

**Syntax**

```cpp
void SetOnLeftEntity(AZ::EntityId entityId)
```

### SetOnRightEntity

Sets the entity to receive focus when right is pressed.

**Syntax**

```cpp
void SetOnRightEntity(AZ::EntityId entityId)
```

### SetOnUpEntity

Sets the entity to receive focus when up is pressed.

**Syntax**

```cpp
void SetOnUpEntity(AZ::EntityId entityId)
```

## UILayout

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Provides common functionality for row, column, and grid layouts.

### UILayoutBus

Services messages for the UILayout components.

### GetHorizontalChildAlignment

Returns the horizontal child alignment.

**Syntax**

```cpp
eUiHAlign GetHorizontalChildAlignment()
```

Following are possible values for `eUiHAlign`.

```cpp
enum eUiHAlign
{
    eUiHAlign_Left,
    eUiHAlign_Center,
}```
GetIgnoreDefaultLayoutCells

Returns whether default layout cell values calculated by other components on the child are ignored.

Syntax

```cpp
bool GetIgnoreDefaultLayoutCells()
```

GetVerticalChildAlignment

Returns the vertical child alignment.

Syntax

```cpp
eUiVAlign GetVerticalChildAlignment()
```

Following are possible values for `eUiVAlign`.

```cpp
class enum eUiVAlign
{
    eUiVAlign_Top,
    eUiVAlign_Center,
    eUiVAlign_Bottom
};
```

SetHorizontalChildAlignment

Sets the horizontal child alignment.

Syntax

```cpp
void SetHorizontalChildAlignment(eUiHAlign hAlign)
```

For possible values for `eUiHAlign`, see `GetHorizontalChildAlignment (p. 3078)`.

SetIgnoreDefaultLayoutCells

Sets whether default layout cell values calculated by other components on the child are ignored.

Syntax

```cpp
void SetIgnoreDefaultLayoutCells (bool ignore)
```

SetVerticalChildAlignment

Sets the vertical child alignment.

Syntax

```cpp
void SetVerticalChildAlignment(eUiVAlign vAlign)
```

For possible values for `eUiVAlign`, see `GetVerticalChildAlignment (p. 3079)`. 
UiLayoutCellComponent

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Overrides default layout cell values.

UiLayoutCellBus

Services messages for the UiLayoutCellComponent.

GetExtraHeightRatio

Returns the overridden extra height ratio for the element. A value of –1 means that the ratio has not been overridden.

Syntax

```c
float GetExtraHeightRatio()
```

GetExtraWidthRatio

Returns the overridden extra width ratio for the element. A value of –1 means that the ratio has not been overridden.

Syntax

```c
float GetExtraWidthRatio()
```

GetMinHeight

Returns the overridden minimum height for the element. A value of –1 means that the height has not been overridden.

Syntax

```c
float GetMinHeight()
```

GetMinWidth

Returns the overridden minimum width for the element. A value of –1 means it has not been overridden.

Syntax

```c
float GetMinWidth()
```

GetTargetHeight

Returns the overridden target height for the element. A value of –1 means that the height has not been overridden.

Syntax

```c
```
float GetTargetHeight()

**GetTargetWidth**

Returns the overridden target width for the element. -1 means it has not been overridden.

**Syntax**

```c
float GetTargetWidth()
```

**SetExtraHeightRatio**

Sets the overridden extra height ratio for the element. A value of -1 means don’t override.

**Syntax**

```c
void SetExtraHeightRatio(float height)
```

**SetExtraWidthRatio**

Sets the overridden extra width ratio for the element. A value of -1 means don’t override.

**Syntax**

```c
void SetExtraWidthRatio(float width)
```

**SetMinHeight**

Sets the overridden minimum height for the element. A value of -1 means don’t override.

**Syntax**

```c
void SetMinHeight(float height)
```

**SetMinWidth**

Sets the overridden minimum width for the element. A value of -1 means don’t override.

**Syntax**

```c
void SetMinWidth(float width)
```

**SetTargetHeight**

Sets the overridden target height for the element. A value of -1 means don’t override.

**Syntax**

```c
void SetTargetHeight(float height)
```

**SetTargetWidth**

Sets the overridden target width for the element. A value of -1 means don’t override.
Syntax

```c
void SetTargetWidth(float width)
```

**UILayoutColumnComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Controls column layout.

**UILayoutColumnBus**

Services messages for the **UILayoutColumnComponent**.

**GetOrder**

Returns the vertical order for this layout.

**Syntax**

```c
eUiVerticalOrder GetOrder()
```

Following are the possible values for **eUiVerticalOrder**.

```c
enum eUiVerticalOrder
{
    eUiVerticalOrder_TopToBottom,
    eUiVerticalOrder_BottomToTop
};
```

**GetPadding**

Returns, in pixels, the padding inside the edges of the element.

**Syntax**

```c
UiPadding GetPadding()
```

Following are the possible values for **UiPadding**.

```c
class UiPadding
{
    int left;
    int right;
    int top;
    int bottom;
};
```

**GetSpacing**

Returns, in pixels, the spacing between child elements.
Syntax

```plaintext
float GetSpacing()
```

**SetOrder**

Sets the vertical order for this layout.

**Syntax**

```plaintext
void SetOrder(eUiVerticalOrder order)
```

For possible values for `eUiVerticalOrder`, see `GetOrder (p. 3082)`.

**SetPadding**

Sets the padding inside the edges of the element to the pixel value specified.

**Syntax**

```plaintext
void SetPadding(UiPadding padding)
```

For the possible values for `UiPadding`, see `GetPadding (p. 3082)`.

**SetSpacing**

Sets the spacing between child elements to the pixel value specified.

**Syntax**

```plaintext
void SetSpacing(float spacing)
```

**UILayoutFitterComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use this component to implement a UI Layout Fitter in Amazon Lumberyard.

**UILayoutFitterBus**

Services messages for the `UILayoutFitterComponent`.

**GetHorizontalFit**

Returns whether to resize the element horizontally.

**Syntax**

```plaintext
bool GetHorizontalFit()
```
SetHorizontalFit
Sets whether to resize the element horizontally.

Syntax

```csharp
void SetHorizontalFit(bool horizontalFit)
```

GetVerticalFit
Returns whether to resize the element vertically.

Syntax

```csharp
bool GetVerticalFit()
```

SetVerticalFit
Sets whether to resize the element vertically.

Syntax

```csharp
void SetVerticalFit(bool verticalFit)
```

UILayoutGridComponent
Controls grid layout characteristics.

UiLayoutGridBus
Services messages for the UiLayoutGridComponent.

GetCellSize
Returns, in pixels, the size of a child element.

Syntax

```csharp
AZ::Vector2 GetCellSize()
```

GetHorizontalOrder
Returns the horizontal order for the layout.

Syntax

```csharp
eUiHorizontalOrder GetHorizontalOrder()
```
Following are possible values for `eUiHorizontalOrder`.

```csharp
enum eUiHorizontalOrder
{
    eUiHorizontalOrder_LeftToRight,
    eUiHorizontalOrder_RightToLeft
};
```

**GetPadding**

Returns, in pixels, the padding inside the edges of the element.

**Syntax**

```csharp
UiPadding GetPadding()
```

Following are the attributes for `UiPadding`.

```csharp
class UiPadding
{
    int left;
    int right;
    int top;
    int bottom;
};
```

**GetSpacing**

Returns, in pixels, the spacing between child elements.

**Syntax**

```csharp
AZ::Vector2 GetSpacing()
```

**GetStartingDirection**

Returns the starting direction for the layout.

**Syntax**

```csharp
eUiLayoutGridStartingDirection GetStartingDirection()
```

Following are possible values for `eUiLayoutGridStartingDirection`.

```csharp
enum eUiLayoutGridStartingDirection
{
    eUiLayoutGridStartingDirection_HorizontalOrder,
    eUiLayoutGridStartingDirection_VerticalOrder
};
```

**GetVerticalOrder**

Returns the vertical order for the layout.

**Syntax**
eUiVerticalOrder GetVerticalOrder()

Following are possible values for eUiVerticalOrder.

enum eUiVerticalOrder

{ eUiVerticalOrder_TopToBottom,
  eUiVerticalOrder_BottomToTop
};

**SetCellSize**

Sets the size of a child element to the specified number of pixels.

**Syntax**

```c
void SetCellSize(AZ::Vector2 size)
```

**SetHorizontalOrder**

Sets the horizontal order for the layout.

**Syntax**

```c
void SetHorizontalOrder(eUiHorizontalOrder order)
```

For possible values for eUiHorizontalOrder, see GetHorizontalOrder (p. 3084).

**SetPadding**

Sets the padding inside the edges of the element to the specified number of pixels.

**Syntax**

```c
void SetPadding(UiPadding padding)
```

For possible values for UiPadding, see GetPadding (p. 3085).

**SetSpacing**

Sets the spacing between child elements to the specified number of pixels.

**Syntax**

```c
void SetSpacing(AZ::Vector2 spacing)
```

**SetStartingDirection**

Sets the starting direction for the layout.

**Syntax**

```c
void SetStartingDirection(eUiLayoutGridStartingDirection direction)
```
For possible values for `eUiLayoutGridStartingDirection`, see `GetStartingDirection (p. 3085)`.

**SetVerticalOrder**

Sets the vertical order for the layout.

**Syntax**

```cpp
void SetVerticalOrder(eUiVerticalOrder order)
```

For possible values for `eUiVerticalOrder`, see `GetVerticalOrder (p. 3085)`.

**UILayoutRowComponent**

Controls the grid layout of rows.

**UILayoutRowBus**

Messages serviced by the `UILayoutRowComponent`.

**GetOrder**

Returns the horizontal order for this layout.

**Syntax**

```cpp
eUiHorizontalOrder GetOrder()
```

Following are possible values for `eUiHorizontalOrder`.

```cpp
eUiHorizontalOrder
{
    eUiHorizontalOrder_LeftToRight,
    eUiHorizontalOrder_RightToLeft
};
```

**GetPadding**

Returns, in pixels, the padding inside the edges of the element.

**Syntax**

```cpp
UiPadding GetPadding()
```

Following are possible values for `UiPadding`.

```cpp
class UiPadding
{
    int left;
};
```
int right;
int top;
int bottom;
);

GetSpacing

Returns, in pixels, the spacing between child elements.

Syntax

float GetSpacing()

SetOrder

Sets the horizontal order for this layout.

Syntax

void SetOrder(eUiHorizontalOrder order)

For possible values for eUiHorizontalOrder, see GetOrder (p. 3087).

SetPadding

Sets the padding inside the edges of the element to the specified number of pixels.

Syntax

void SetPadding(UiPadding padding)

For possible values for UiPadding, see GetPadding (p. 3087).

SetSpacing

Sets the spacing between child elements to the specified number of pixels.

Syntax

void SetSpacing(float spacing)

UIMaskComponent

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add a mask component to an element to show only a part of the content of its child elements (for example, example, image or text).

UIMaskBus

Services messages for the UIMaskComponent.
GetDrawBehind
Returns whether the mask is drawn behind the child elements.

Syntax

```cpp
bool GetDrawBehind()
```

GetDrawInFront
Returns whether the mask is drawn in front of child elements.

Syntax

```cpp
bool GetDrawInFront()
```

GetIsMaskingEnabled
Returns whether masking is enabled.

Syntax

```cpp
bool GetIsMaskingEnabled()
```

GetUseAlphaTest
Returns whether to use the alpha channel in the mask visual's texture to define the mask.

Syntax

```cpp
bool GetUseAlphaTest()
```

SetDrawBehind
Sets whether the mask is drawn behind the child elements.

Syntax

```cpp
void SetDrawBehind(bool drawMaskVisualBehindChildren)
```

SetDrawInFront
Sets whether the mask is drawn in front of child elements.

Syntax

```cpp
void SetDrawInFront(bool drawMaskVisualInFrontOfChildren)
```

SetIsMaskingEnabled
Sets whether masking is enabled.

Syntax

```cpp
```
void SetIsMaskingEnabled(bool enableMasking)

**SetUseAlphaTest**

Sets whether to use the alpha channel in the mask visual's texture to define the mask.

**Syntax**

void SetUseAlphaTest(bool useAlphaTest)

**UIParticleEmitterComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Controls the emission of two dimensional particles. The source code location is `\dev\Gems\LyShine\Code\Source\UiParticleEmitterComponent.*`.

**UIParticleEmitterBus**

Services messages for the `UIParticleEmitterComponent`.

**GetIsEmitting**

Returns whether the emitter is currently emitting.

**Syntax**

bool GetIsEmittingColor()

**SetIsEmitting**

Sets whether the emitter is currently emitting.

**Syntax**

void SetIsEmitting(bool isEmitting)

**GetIsRandomSeedFixed**

Returns whether the emitter uses a fixed random seed.

**Syntax**

bool GetIsRandomSeedFixed()

**SetIsRandomSeedFixed**

Sets whether the emitter uses a fixed random seed.

**Syntax**
void SetRandomSeed(bool randomSeedFixed)

**GetRandomSeed**

Returns the current random seed.

**Syntax**

```c
int GetRandomSeed()
```

**SetRandomSeed**

Sets the random seed used by the emitter.

**Syntax**

```c
void SetRandomSeed(int randomSeed)
```

**GetIsParticlePositionRelativeToEmitter**

Returns whether the emitted particles move relative to the emitter.

**Syntax**

```c
bool GetIsParticlePositionRelativeToEmitter()
```

**SetIsParticlePositionRelativeToEmitter**

Sets whether the emitted particles move relative to the emitter.

**Syntax**

```c
void SetIsParticlePositionRelativeToEmitter(bool relativeToEmitter)
```

**GetParticleEmitRate**

Returns, in particles per second, the current particle emitter emit rate.

**Syntax**

```c
float GetParticleEmitRate()
```

**SetParticleEmitRate**

Sets, in particles per second, the current particle emitter emit rate.

**Syntax**

```c
void SetParticleEmitRate(float particleEmitRate)
```

**GetIsEmitOnActivate**

Returns whether the particle emitter starts emitting when the component is activated.
Syntax

bool GetIsEmitOnActivate()

**SetIsEmitOnActivate**

Sets whether the particle emitter starts emitting when the component is activated.

Syntax

void SetIsEmitOnActivate(bool emitOnActivate)

**GetIsHitParticleCountOnActivate**

Returns whether the average amount of particles are emitted and processed when the emitter starts emitting.

Syntax

bool GetIsHitParticleCountOnActivate()

**SetIsHitParticleCountOnActivate**

Sets whether the average amount of particles are emitted and processed when the emitter starts emitting.

Syntax

void SetIsHitParticleCountOnActivate(bool hitParticleCountOnActivate)

**GetIsEmitterLifetimeInfinite**

Returns whether the emitter lifetime is infinite.

Syntax

bool GetIsEmitterLifetimeInfinite()

**SetIsEmitterLifetimeInfinite**

Sets whether the emitter lifetime is infinite.

Syntax

void SetIsEmitterLifetimeInfinite(bool emitterLifetimeInfinite)

**GetEmitterLifetime**

Returns the total emitter lifetime in seconds. When the lifetime is reached, the emitter stops emitting.

Syntax

float GetEmitterLifetime()
**SetEmitterLifetime**

Sets the total emitter lifetime in seconds. When the lifetime is reached, the emitter stops emitting.

**Syntax**

```c
void SetEmitterLifetime(float emitterLifetime)
```

**GetIsParticleCountLimited**

Returns whether there is a limit to the number of active particles.

**Syntax**

```c
bool GetIsParticleCountLimited()
```

**SetIsParticleCountLimited**

Sets whether there is a limit to the number of active particles.

**Syntax**

```c
void SetIsParticleCountLimited(bool particleCountLimited)
```

**GetMaxParticles**

Returns the numerical limit of active particles.

**Syntax**

```c
AZ::u32 GetMaxParticles()
```

**SetMaxParticles**

Sets the numerical limit of active particles.

**Syntax**

```c
void SetMaxParticles(AZ::u32 maxParticles)
```

**GetEmitterShape**

Returns the current emitter shape.

**Syntax**

```c
eUiEmitShape GetEmitterShape()
```

Possible emitter shapes are as follows.

```c
enum eUiEmitShape
{
    eUiEmitShape_Point,
    // Other shapes...
}
```
SetEmitterShape

Sets the current emitter shape.

Syntax

```c
void SetVariable(eUiEmitShape emitShape)
```

For possible emitter shapes, see GetEmitterShape (p. 3093).

GetIsEmitOnEdge

Returns whether the particles are emitted on the edge of the selected shape.

Syntax

```c
bool GetIsEmitOnEdge()
```

SetIsEmitOnEdge

Sets whether the particles are emitted on the edge of the selected shape.

Syntax

```c
void SetIsEmitOnEdge(bool emitOnEdge)
```

GetInsideEmitDistance

Returns the distance that particles are emitted inside the emitter shape edge.

Syntax

```c
float GetInsideEmitDistance()
```

SetInsideEmitDistance

Sets the distance that particles are emitted inside the emitter shape edge.

Syntax

```c
void SetInsideEmitDistance(float insideEmitDistance)
```

GetOutsideEmitDistance

Returns the distance that particles are emitted outside the emitter shape edge.

Syntax

```c
float GetOutsideEmitDistance()
```
**SetOutsideEmitDistance**

Sets the distance that particles are emitted outside the emitter shape edge.

**Syntax**

```cpp
void SetOutsideEmitDistance(float outsideEmitDistance)
```

**GetParticleInitialDirectionType**

Returns how the initial direction of the emitted particles are calculated.

**Syntax**

```cpp
eUiParticleInitialDirectionType GetParticleInitialDirectionType()
```

Possible values are as follows.

```cpp
enum eUiParticleInitialDirectionType
{
    eUiParticleInitialDirectionType_RelativeToEmitAngle,
    eUiParticleInitialDirectionType_RelativeToEmitterCenter
};
```

**SetParticleInitialDirectionType**

Sets how the initial direction of the emitted particles is calculated.

**Syntax**

```cpp
void SetVariable(eUiEmitShape emitShape)
```

For possible direction types, see [GetParticleInitialDirectionType](#) (p. 3095).

**GetEmitAngle**

Returns, in degrees clockwise from straight up, the angle along which particles are emitted.

**Syntax**

```cpp
float GetEmitAngle()
```

**SetEmitAngle**

Sets, in degrees clockwise from straight up, the angle along which particles are emitted.

**Syntax**

```cpp
void SetEmitAngle(float emitAngle)
```

**GetEmitAngleVariation**

Returns, in degrees, the variation in the emit angle. For example, a variation value of 10 designates a range of plus or minus 10 degrees on each side of the current emit angle.
Syntax

float GetEmitAngleVariation()

SetEmitAngleVariation

Sets, in degrees, the variation in the emit angle. For example, a variation value of 10 designates a range of plus or minus 10 degrees on each side of the current emit angle.

Syntax

void SetEmitAngleVariation(float emitAngleVariation)

GetIsParticleLifetimeInfinite

Returns whether the emitted particles have an infinite lifetime.

Syntax

bool GetIsParticleLifetimeInfinite()

SetIsParticleLifetimeInfinite

Sets whether the emitted particles have an infinite lifetime.

Syntax

void SetIsParticleLifetimeInfinite(bool infiniteLifetime)

GetParticleLifetime

Returns, in seconds, the lifetime of the emitted particles.

Syntax

float GetParticleLifetime()

SetParticleLifetime

Sets, in seconds, the initial lifetime of the emitted particles.

Syntax

void SetParticleLifetime(float lifetime)

GetParticleLifetimeVariation

Returns the variation in lifetime of the emitted particles. For example, a variation of 5 seconds designates a range of 5 seconds on either side of the chosen initial lifetime.

Syntax

float GetParticleLifetimeVariation()
**SetParticleLifetimeVariation**

Sets the variation in lifetime of the emitted particles. For example, a variation of 5 seconds designates a range of 5 seconds on either side of the chosen initial lifetime.

**Syntax**

```cpp
void SetParticleLifetimeVariation(float lifetimeVariation)
```

**GetSpritePathname**

Returns the source location of the image to be used by the emitted particles.

**Syntax**

```cpp
AZStd::string GetSpritePathname()
```

**SetSpritePathname**

Sets the source location of the image to be used by the emitted particles.

**Syntax**

```cpp
void SetSpritePathname(AZStd::string spritePath)
```

**GetIsSpriteSheetAnimated**

Returns whether the sprite sheet cell index changes over time on each particle.

**Syntax**

```cpp
bool GetIsSpriteSheetAnimated()
```

**SetIsSpriteSheetAnimated**

Sets whether the sprite sheet cell index changes over time on each particle.

**Syntax**

```cpp
void SetIsSpriteSheetAnimated(bool spriteSheetAnimated)
```

**GetIsSpriteSheetAnimationLooped**

Returns whether the sprite sheet cell animation is looped.

**Syntax**

```cpp
bool GetIsSpriteSheetAnimationLooped()
```

**SetIsSpriteSheetAnimationLooped**

Sets whether the sprite sheet cell animation is looped.
Syntax

```c
void SetIsSpriteSheetAnimationLooped(bool spriteSheetAnimationLooped)
```

**GetIsSpriteSheetIndexRandom**

Returns whether the initial sprite-sheet index is randomly chosen.

Syntax

```c
bool GetIsSpriteSheetIndexRandom()
```

**SetIsSpriteSheetIndexRandom**

Sets whether the initial sprite-sheet index is randomly chosen.

Syntax

```c
void SetIsSpriteSheetIndexRandom(bool spriteSheetIndexRandom)
```

**GetSpriteSheetCellIndex**

Returns the sprite-sheet index to be used for emitted particles.

Syntax

```c
int GetSpriteSheetCellIndex()
```

**SetSpriteSheetCellIndex**

Sets the sprite-sheet index to be used for emitted particles.

Syntax

```c
void SetSpriteSheetCellIndex(int spriteSheetIndex)
```

**GetSpriteSheetCellEndIndex**

Returns the end index of the sprite-sheet cell range that is used for sprite-sheet animation or random index selection.

Syntax

```c
int GetSpriteSheetCellEndIndex()
```

**SetSpriteSheetCellEndIndex**

Sets the end index of the sprite-sheet cell range that is used for sprite-sheet animation or random index selection.

Syntax

```c
void SetSpriteSheetCellEndIndex(int spriteSheetEndIndex)
```
**GetSpriteSheetFrameDelay**

Returns, in seconds, the delay between each sprite-sheet frame.

**Syntax**

```
float GetSpriteSheetFrameDelay()
```

**SetSpriteSheetFrameDelay**

Sets, in seconds, the delay between each sprite-sheet frame.

**Syntax**

```
void SetSpriteSheetFrameDelay(float spriteSheetFrameDelay)
```

**GetIsParticleAspectRatioLocked**

Returns whether the width and height of the emitted particles are locked into the current aspect ratio.

**Syntax**

```
bool GetIsParticleAspectRatioLocked()
```

**SetIsParticleAspectRatioLocked**

Sets whether the width and height of the emitted particles are locked into the current aspect ratio.

**Syntax**

```
void SetIsParticleAspectRatioLocked(bool aspectRatioLocked)
```

**GetParticlePivot**

Returns the pivot for the particles in a range from (0,0) at the top left to (1,1) at the bottom right.

**Syntax**

```
AZ::Vector2 GetParticlePivot()
```

**SetParticlePivot**

Sets the pivot for the particles in a range from (0,0) at the top left to (1,1) at the bottom right.

**Syntax**

```
void SetParticlePivot(AZ::Vector2 particlePivot)
```

**GetParticleSize**

Returns the size of the emitted particles.

**Syntax**
AZ::Vector2 GetParticleSize()

**SetParticleSize**

Sets the size of the emitted particles.

**Syntax**

```cpp
void SetParticleSize(AZ::Vector2 particleSize)
```

**GetParticleWidth**

Returns the width of the emitted particles.

**Syntax**

```cpp
float GetParticleWidth()
```

**SetParticleWidth**

Sets the width of the emitted particles.

**Syntax**

```cpp
void SetParticleWidth(float particleWidth)
```

**GetParticleWidthVariation**

Returns the variation in width of the emitted particles.

**Syntax**

```cpp
float GetParticleWidthVariation()
```

**SetParticleWidthVariation**

Sets the variation in width of the emitted particles.

**Syntax**

```cpp
void SetParticleWidthVariation(float particleWidthVariation)
```

**GetParticleHeight**

Returns the height of the emitted particles.

**Syntax**

```cpp
float GetParticleHeight()
```

**SetParticleHeight**

Sets the height of the emitted particles.
**void SetParticleHeight(float particleHeight)**

### GetParticleHeightVariation

Returns the variation in height of the emitted particles.

**Syntax**

```c
float GetParticleHeightVariation()
```

### SetParticleHeightVariation

Sets the variation in height of the emitted particles.

**Syntax**

```c
void SetParticleHeightVariation(float particleHeightVariation)
```

### GetParticleMovementCoordinateType

Returns the co-ordinate system used for the movement of the emitted particles.

**Syntax**

```c
eUiParticleCoordinateType GetParticleMovementCoordinateType()
```

Possible values for the movement space are as follows.

```c
enum eUiParticleCoordinateType
{
    eUiParticleCoordinateType_Cartesian,
    eUiParticleCoordinateType_Polar
};
```

### SetParticleMovementCoordinateType

Sets the coordinate system that is used for the movement of the emitted particles.

**Syntax**

```c
void SetParticleMovementCoordinateType(eUiParticleCoordinateType movementCoordinateType)
```

For possible values for the coordinate type, see **GetParticleMovementCoordinateType (p. 3101)**.

### GetParticleAccelerationMovementSpace

Returns the coordinate system that is used for the acceleration of particles.

**Syntax**

```c
eUiParticleCoordinateType GetParticleAccelerationMovementSpace()
```

For possible values for the movement space, see **GetParticleMovementCoordinateType (p. 3101)**.
**SetParticleAccelerationMovementSpace**

Sets the coordinate system that is used for the acceleration of particles.

**Syntax**

```cpp
void SetParticleAccelerationMovementSpace(eUiParticleCoordinateType accelerationMovementSpace)
```

For possible values for the movement space, see `GetParticleMovementCoordinateType` (p. 3101).

**GetParticleInitialVelocity**

Returns the initial velocity of the emitted particles. Applicable only when the emitter doesn't control the emit direction.

**Syntax**

```cpp
AZ::Vector2 GetParticleInitialVelocity()
```

**SetParticleInitialVelocity**

Sets the initial velocity of the emitted particles. Applicable only when the emitter doesn't control the emit direction.

**Syntax**

```cpp
void SetParticleInitialVelocity(AZ::Vector2 particleInitialVelocity)
```

**GetParticleInitialVelocityVariation**

Returns the variation in the particle initial velocity. Applicable only when the emitter doesn't control the emit direction.

**Syntax**

```cpp
AZ::Vector2 GetParticleInitialVelocityVariation()
```

**SetParticleInitialVelocityVariation**

Sets the variation in the particle initial velocity. Applicable only when the emitter doesn't control the emit direction.

**Syntax**

```cpp
void SetParticleInitialVelocityVariation(AZ::Vector2 initialVelocityVariation)
```

**GetParticleSpeed**

Returns the initial particle speed. Applicable only when the emitter doesn't control the emit direction.

**Syntax**

```cpp
float GetParticleSpeed()
```
**SetParticleSpeed**

Sets the initial particle speed. Applicable only when the emitter doesn't control the emit direction.

**Syntax**

```c
void SetParticleSpeed(float particleSpeed)
```

**GetParticleSpeedVariation**

Returns the variation in initial particle speed. Applicable only when the emitter doesn't control the emit direction.

**Syntax**

```c
float GetParticleSpeedVariation()
```

**SetParticleSpeedVariation**

Sets the variation in initial particle speed. Applicable only when the emitter doesn't control the emit direction.

**Syntax**

```c
void SetParticleSpeedVariation(float particleSpeedVariation)
```

**GetParticleAcceleration**

Returns the acceleration of the emitted particles.

**Syntax**

```c
AZ::Vector2 GetParticleAcceleration()
```

**SetParticleAcceleration**

Sets the acceleration of the emitted particles.

**Syntax**

```c
void SetParticleAcceleration(AZ::Vector2 particleAcceleration)
```

**GetIsParticleRotationFromVelocity**

Returns whether the particle is oriented so that its top points towards the current velocity vector.

**Syntax**

```c
bool GetIsParticleRotationFromVelocity()
```

**SetIsParticleRotationFromVelocity**

Sets whether the particle is oriented so that its top points towards the current velocity vector.

**Syntax**
void SetIsParticleRotationFromVelocity(bool rotationFromVelocity)

GetIsParticleInitialRotationFromInitialVelocity
Returns whether the particle is initially oriented so that its top points towards the initial velocity vector.

Syntax
bool GetIsParticleInitialRotationFromInitialVelocity()

SetIsParticleInitialRotationFromInitialVelocity
Sets whether the particle is initially oriented so that its top points towards the initial velocity vector.

Syntax
void SetIsParticleInitialRotationFromInitialVelocity(bool initialRotationFromVelocity)

GetParticleInitialRotation
Returns, in degrees clockwise measured from straight up, the initial rotation.

Syntax
float GetParticleInitialRotation()

SetParticleInitialRotation
Sets, in degrees clockwise measured from straight up, the initial rotation.

Syntax
void SetParticleInitialRotation(float particleInitialRotation)

GetParticleInitialRotationVariation
Returns, in degrees clockwise measured from straight up, the variation of the initial rotation.

Syntax
float GetParticleInitialRotationVariation()

SetParticleInitialRotationVariation
Sets, in degrees clockwise measured from straight up, the variation of the initial rotation.

Syntax
void SetParticleInitialRotation(float particleInitialRotationVariation)

GetParticleRotationSpeed
Returns, in degrees clockwise per second, the rotation speed of the emitted particles.
Syntax

```csharp
float GetParticleRotationSpeed()
```

**SetParticleRotationSpeed**

Sets, in degrees clockwise per second, the rotation speed of the emitted particles.

Syntax

```csharp
void SetParticleRotationSpeed(float rotationSpeed)
```

**GetParticleRotationSpeedVariation**

Returns, in degrees clockwise per second, the variation in rotation speed of the emitted particles.

Syntax

```csharp
float GetParticleRotationSpeedVariation()
```

**SetParticleRotationSpeedVariation**

Sets, in degrees clockwise per second, the variation in rotation speed of the emitted particles.

Syntax

```csharp
void SetParticleRotationSpeedVariation(float rotationSpeedVariation)
```

**GetParticleColor**

Returns the color of the emitted particles.

Syntax

```csharp
AZ::Color GetParticleColor()
```

**SetParticleColor**

Sets the color of the emitted particles.

Syntax

```csharp
void SetParticleColor(AZ::Color particleColor)
```

**GetParticleColorBrightnessVariation**

Returns, in the range [0,1], the variation in color brightness of the emitted particles.

Syntax

```csharp
float GetParticleColorBrightnessVariation()
```

**SetParticleColorBrightnessVariation**

Sets, in the range [0,1], the variation in color brightness of the emitted particles.
### Syntax

```c
void SetParticleColorBrightnessVariation(float brightnessVariation)
```

**GetParticleColorTintVariation**

Returns, in the range [0,1], the variation in color tint of the emitted particles.

### Syntax

```c
float GetParticleColorTintVariation()
```

**SetParticleColorTintVariation**

Sets, in the range [0,1], the variation in color tint of the emitted particles.

### Syntax

```c
void SetParticleColorTintVariation(float tintVariation)
```

**GetParticleAlpha**

Returns, in the range [0,1], the alpha of the emitted particles.

### Syntax

```c
float GetParticleAlpha()
```

**SetParticleAlpha**

Sets, in the range [0,1], the alpha of the emitted particles.

### Syntax

```c
void SetParticleAlpha(float particleAlpha)
```

### UiRadioButtonComponent

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use **UiRadioButtonComponent** to implement a UI radio button in Amazon Lumberyard.

### UiRadioButtonBus

Services messages for the **UiRadioButtonComponent**.

**GetState**

Returns the state of the radio button. True if selected; false otherwise.

### Syntax
bool GetState()

**GetGroup**

Returns the group of the radio button.

**Syntax**

```cpp
AZ::EntityId GetGroup()
```

**GetCheckedEntity**

Returns the child element that is shown when the radio button is selected.

**Syntax**

```cpp
AZ::EntityId GetCheckedEntity()
```

**SetCheckedEntity**

Sets the child element to show when the radio button is selected.

**Syntax**

```cpp
void SetCheckedEntity(AZ::EntityId entityId)
```

**GetUncheckedEntity**

Returns the child element that is shown when the radio button is cleared.

**Syntax**

```cpp
AZ::EntityId GetUncheckedEntity()
```

**SetUncheckedEntity**

Sets the child element to show when the radio button is cleared.

**Syntax**

```cpp
void SetUncheckedEntity(AZ::EntityId entityId)
```

**GetTurnOnActionName**

Returns the name of the action that is triggered when the radio button is selected.

**Syntax**

```cpp
const AZStd::string& GetTurnOnActionName()
```

**SetTurnOnActionName**

Sets the action triggered when the radio button is selected.
UiRadioButtonComponent

Syntax

void SetTurnOnActionName(const AZStd::string & actionName)

GetTurnOffActionName

Returns the action triggered when the radio button is cleared.

Syntax

const AZStd::string & GetTurnOffActionName()

SetTurnOffActionName

Sets the action triggered when the radio button is cleared.

Syntax

void SetTurnOffActionName(const AZStd::string & actionName)

GetChangedActionName

Returns the action triggered when the radio button value changes.

Syntax

AZStd::string & GetChangedActionName()

SetChangedActionName

Sets the action triggered when the radio button value changes.

Syntax

void SetChangedActionName(const AZStd::string & actionName)

UiRadioButtonCommunicationBus

Allows communication between the radio button group and a radio button.

SetState

Sets the state of the radio button. True if selected; false otherwise.

Syntax

void SetState(bool checked)

SetGroup

Sets the group of the radio button.

Syntax
void SetGroup(AZ::EntityId group)

**UiRadioButtonNotificationBus**

Services notifications for the UiRadioButtonComponent.

**OnRadioButtonStateChanged**

Notifies that the radio button state has changed.

**Syntax**

```cpp
void OnRadioButtonStateChanged(bool checked)
```

**UIScrollBarComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.

[Download O3DE](https://aws.amazon.com) or visit the [AWS Game Tech blog](https://aws.amazon.com) to learn more.

Controls scroll bar characteristics.

**UIScrollBarBus**

Services messages for the UiScrollBarComponent.

**GetAutoFadeDelay**

Returns the fade delay in seconds.

**Minimum Lumberyard Version:** 1.24

**Syntax**

```cpp
float GetAutoFadeDelay()
```

**GetAutoFadeSpeed**

Returns the fade speed in seconds.

**Minimum Lumberyard Version:** 1.24

**Syntax**

```cpp
float GetAutoFadeSpeed()
```

**GetHandleEntity**

Returns the handle entity.

**Syntax**

```cpp
AZ::EntityId GetHandleEntity()
```
GetHandleSize
Returns the size of the handle relative to the scroll bar (0 - 1).

Syntax
float GetHandleSize()

GetMinHandlePixelSize
Returns the minimum size of the handle in pixels.

Syntax
float GetMinHandlePixelSize()

IsAutoFadeEnabled
Returns whether auto fade is enabled.

Minimum Lumberyard Version: 1.24

Syntax
bool IsAutoFadeEnabled()

SetAutoFadeDelay
Sets the fade delay in seconds.

Minimum Lumberyard Version: 1.24

Syntax
void SetAutoFadeDelay(float delay)

SetAutoFadeEnabled
Sets whether auto fade is enabled.

Minimum Lumberyard Version: 1.24

Syntax
void SetAutoFadeEnabled(bool isEnabled)

SetAutoFadeSpeed
Sets the fade speed in seconds.

Minimum Lumberyard Version: 1.24

Syntax
void SetAutoFadeSpeed(float speed)
SetHandleEntity
Sets the handle entity.

Syntax

```c
void SetHandleEntity(AZ::EntityId entityId)
```

SetHandleSize
Sets the size of the handle relative to the scroll bar (0 - 1).

Syntax

```c
void SetHandleSize(float size)
```

SetMinHandlePixelSize
Sets the minimum size of the handle in pixels.

Syntax

```c
void SetMinHandlePixelSize(float size)
```

UiScrollerBus
Services scrolling for the UIScrollBarComponent.

GetOrientation
Returns the orientation of the scroller.

Syntax

```c
eUiScrollerOrientation GetOrientation()
```

Following are possible values for eUiScrollerOrientation.

```c
enum eUiScrollerOrientation
{
  eUiScrollerOrientation_Horizontal,
  eUiScrollerOrientation_Vertical
};
```

GetValue
Returns the current value for the scroller (0 - 1).

Syntax

```c
float GetValue()
```

GetValueChangedActionName
Returns the name of the action triggered when the value has changed.
GetValueChangingActionName
Returns the name of the action triggered while the value is changing.

Syntax

```cpp
const AZStd::string& GetValueChangingActionName()
```

SetOrientation
Sets the orientation of the scroller.

Syntax

```cpp
void SetOrientation(eUiScrollerOrientation orientation)
```

For possible values for `eUiScrollerOrientation`, see `GetOrientation (p. 3111)`.

SetValue
Sets the value of the scroller (0 - 1).

Syntax

```cpp
void SetValue(float value)
```

SetValueChangedActionName
Sets the action triggered when the value has changed.

Syntax

```cpp
void SetValueChangedActionName(const AZStd::string& actionName)
```

SetValueChangingActionName
Sets the name of the action triggered while the value is changing.

Syntax

```cpp
void SetValueChangingActionName(const AZStd::string& actionName)
```

UIScrollBoxComponent
Controls the characteristics of a scroll box.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
UiScrollBoxBus

Services messages for the UiScrollBoxComponent.

FindClosestContentChildElement

Finds the child of the content element that is closest to the content anchors at the current scroll offset (the currently selected child).

Syntax

```
AZ::EntityId FindClosestContentChildElement()
```

GetContentEntity

Returns the content element for the scroll box.

Syntax

```
AZ::EntityId GetContentEntity()
```

GetHorizontalScrollBarEntity

Returns the horizontal scroll bar element for the scroll box.

Syntax

```
AZ::EntityId GetHorizontalScrollBarEntity()
```

GetHorizontalScrollBarVisibility

Returns the visibility behavior for the horizontal scroll bar of the scroll box.

Syntax

```
eUiScrollBoxScrollBarVisibility GetHorizontalScrollBarVisibility()
```

Following are possible values for eUiScrollBoxScrollBarVisibility.

```
enum eUiScrollBoxScrollBarVisibility
{
    eUiScrollBoxScrollBarVisibility_AlwaysShow,
    eUiScrollBoxScrollBarVisibility_AutoHide,
    eUiScrollBoxScrollBarVisibility_AutoHideAndResizeViewport
};
```

GetIsHorizontalScrollingEnabled

Returns whether the scroll box allows horizontal scrolling.

Syntax

```
bool GetIsHorizontalScrollingEnabled()
```
GetIsScrollingConstrained
Returns whether the scroll box restricts scrolling to the content area.

Syntax

```cpp
bool GetIsScrollingConstrained()
```

GetIsVerticalScrollingEnabled
Returns whether the scroll box allows vertical scrolling.

Syntax

```cpp
bool GetIsVerticalScrollingEnabled()
```

GetNormalizedScrollValue
Returns the scroll value from 0 – 1.

Syntax

```cpp
AZ::Vector2 GetNormalizedScrollValue()
```

GetScrollOffset
Returns the scroll offset of the scroll box. The scroll offset is the offset from the content element's anchor point to the content element's pivot.

Syntax

```cpp
AZ::Vector2 GetScrollOffset()
```

GetScrollOffsetChangedActionName
Returns the action triggered when the scroll box drag is completed.

Syntax

```cpp
const AZStd::string& GetScrollOffsetChangedActionName()
```

GetScrollOffsetChangingActionName
Returns the action triggered while the scroll box is being dragged.

Syntax

```cpp
AZStd::string& GetScrollOffsetChangingActionName()
```

GetSnapGrid
Returns the snapping grid of the scroll box.

Syntax
GetSnapMode

Returns the snap mode for the scroll box.

Syntax

```cpp
AZ::Vector2 GetSnapGrid()
```

Following are possible values for `eUiScrollBoxSnapMode`.

```cpp
eUiScrollBoxSnapMode
{
    eUiScrollBoxSnapMode_None,
    eUiScrollBoxSnapMode_Children,
    eUiScrollBoxSnapMode_Grid
};
```

GetVerticalScrollBarEntity

Returns the vertical scroll bar element for the scroll box.

Syntax

```cpp
AZ::EntityId GetVerticalScrollBarEntity()
```

GetVerticalScrollBarVisibility

Returns the visibility behavior for the vertical scroll bar of the scroll box.

Syntax

```cpp
eUiScrollBoxScrollBarVisibility GetVerticalScrollBarVisibility()
```

HasHorizontalContentToScroll

Returns whether there is content to scroll horizontally.

Syntax

```cpp
bool HasHorizontalContentToScroll()
```

HasVerticalContentToScroll

Returns whether there is content to scroll vertically.

Syntax

```cpp
bool HasVerticalContentToScroll()
```

SetContentEntity

Sets the content element for the scroll box.
**Syntax**

```cpp
void SetContentEntity(AZ::EntityId entityId)
```

**SetHorizontalScrollBarEntity**

Sets the horizontal scroll bar element for the scroll box.

**Syntax**

```cpp
void SetHorizontalScrollBarEntity(AZ::EntityId entityId)
```

**SetHorizontalScrollBarVisibility**

Sets the visibility behavior for the horizontal scroll bar of the scroll box.

**Syntax**

```cpp
void SetHorizontalScrollBarVisibility(eUiScrollBoxScrollBarVisibility visibility)
```

For possible values for `eUiScrollBoxScrollBarVisibility`, see `GetHorizontalScrollBarVisibility (p. 3113)`.

**SetIsHorizontalScrollingEnabled**

Sets whether the scroll box allows horizontal scrolling.

**Syntax**

```cpp
void setIsHorizontalScrollingEnabled(bool isEnabled)
```

**SetIsScrollingConstrained**

Sets whether the scroll box restricts scrolling to the content area.

**Syntax**

```cpp
void SetIsScrollingConstrained(bool isConstrained)
```

**SetIsVerticalScrollingEnabled**

Sets whether the scroll box allows vertical scrolling.

**Syntax**

```cpp
void setIsVerticalScrollingEnabled(bool isEnabled)
```

**SetScrollOffset**

Sets the scroll offset of the scroll box.

**Syntax**

```cpp
void SetScrollOffset(AZ::Vector2 scrollOffset)
```
**SetScrollOffsetChangedActionName**

Sets the action triggered when the scroll box drag is completed.

**Syntax**

```c
void SetScrollOffsetChangedActionName(const AZStd::string& actionName)
```

**SetScrollOffsetChangingActionName**

Sets the action triggered while the scroll box is being dragged.

**Syntax**

```c
void SetScrollOffsetChangingActionName(const AZStd::string& actionName)
```

**SetSnapGrid**

Sets the snapping grid of the scroll box.

**Syntax**

```c
void SetSnapGrid(AZ::Vector2 snapGrid)
```

**SetSnapMode**

Sets the snap mode for the scroll box.

**Syntax**

```c
void SetSnapMode(eUiScrollBoxSnapMode snapMode)
```

For possible values for `eUiScrollBoxSnapMode`, see [GetSnapMode](p. 3115).

**SetVerticalScrollBarEntity**

Sets the vertical scroll bar element for the scroll box.

**Syntax**

```c
void SetVerticalScrollBarEntity(AZ::EntityId entityId)
```

**SetVerticalScrollBarVisibility**

Sets the visibility behavior for the vertical scroll bar of the scroll box.

**Syntax**

```c
void SetVerticalScrollBarVisibility(eUiScrollBoxScrollBarVisibility visibility)
```

**UiScrollBoxNotificationBus**

Services scroll offset change notifications for the `UiScrollBoxComponent`. 
**OnScrollOffsetChanged**
Called when the scroll offset has changed.

**Syntax**

```csharp
void OnScrollOffsetChanged(AZ::Vector2 newScrollOffset)
```

**OnScrollOffsetChanging**
Called when the scroll offset is changing.

**Syntax**

```csharp
void OnScrollOffsetChanging(AZ::Vector2 newScrollOffset)
```

**UiScrollableNotificationBus**
Services scrollable value change notifications for the **UiScrollBoxComponent**.

**OnScrollableValueChanged**
Called when the scroll value (0 - 1) has changed.

**Syntax**

```csharp
void OnScrollableValueChanged(AZ::Vector2 value)
```

**OnScrollableValueChanging**
Called when the scroll value (0 - 1) is changing.

**Syntax**

```csharp
void OnScrollableValueChanging(AZ::Vector2 value)
```

**UISliderComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Controls the values of a slider.

**UISliderBus**
Services messages for the **UISliderComponent**.

**GetFillEntity**
Returns the fill element.

**Syntax**
**GetManipulatorEntity**

Returns the entity ID of the manipulator element.

**Syntax**

```cpp
AZ::EntityId GetManipulatorEntity()
```

**GetMaxValue**

Returns the maximum value of the slider.

**Syntax**

```cpp
float GetMaxValue()
```

**GetMinValue**

Returns the minimum value of the slider.

**Syntax**

```cpp
float GetMinValue()
```

**GetStepValue**

Returns the smallest increment allowed between values. Zero means no restriction.

**Syntax**

```cpp
float GetStepValue()
```

**GetTrackEntity**

Returns the track element.

**Syntax**

```cpp
AZ::EntityId GetTrackEntity()
```

**GetValue**

Returns the value of the slider.

**Syntax**

```cpp
float GetValue()
```

**GetValueChangedActionName**

Returns the action triggered when the value has finished changing.
**Syntax**

```cpp
const AZStd::string& GetValueChangedActionName()
```

**GetValueChangingActionName**

Returns the name of the action triggered while the value is changing.

**Syntax**

```cpp
const AZStd::string& GetValueChangingActionName()
```

**SetFillEntity**

Sets the fill element.

**Syntax**

```cpp
void SetFillEntity(AZ::EntityId entityId)
```

**SetManipulatorEntity**

Sets the manipulator element.

**Syntax**

```cpp
void SetManipulatorEntity(AZ::EntityId entityId)
```

**SetMaxValue**

Sets the maximum value of the slider.

**Syntax**

```cpp
void SetMaxValue(float value)
```

**SetMinValue**

Sets the minimum value of the slider.

**Syntax**

```cpp
void SetMinValue(float value)
```

**SetStepValue**

Sets the smallest increment allowed between values. Use zero for no restriction.

**Syntax**

```cpp
void SetStepValue(float step)
```

**SetTrackEntity**

Sets the track element.
Syntax

```cpp
void SetTrackEntity(AZ::EntityId entityId)
```

**SetValue**

Sets the value of the slider.

**Syntax**

```cpp
void SetValue(float value)
```

**SetValueChangedActionName**

Sets the action triggered when the value is done changing.

**Syntax**

```cpp
void SetValueChangedActionName(const AZStd::string& actionName)
```

**SetValueChangingActionName**

Sets the action triggered while the value is changing.

**Syntax**

```cpp
void SetValueChangingActionName(const AZStd::string& actionName)
```

**UiSliderNotificationBus**

Services notifications for the `UiSliderComponent`.

**OnSliderValueChanged**

The slider value has finished changing.

**Syntax**

```cpp
void OnSliderValueChanged(float value)
```

**OnSliderValueChanging**

The slider value is changing.

**Syntax**

```cpp
void OnSliderValueChanging(float value)
```

**UITextComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Controls the text and formatting of a text element.

**UiTextBus**

Services messages for the UiTextComponent.

**GetColor**

Returns the color to draw the text string.

**Syntax**

```cpp
AZ::Color GetColor()
```

**GetFont**

Returns the pathname to the font.

**Syntax**

```cpp
AZStd::string GetFont()
```

**GetFontEffect**

Returns the font effect.

**Syntax**

```cpp
int GetFontEffect()
```

**GetFontSize**

Returns the size of the font in points.

**Syntax**

```cpp
float GetFontSize()
```

**GetHorizontalAlignment**

Returns the horizontal text alignment.

**Syntax**

```cpp
eUiHAlign GetHorizontalAlignment()
```

Following are possible values for eUiHAlign.

```cpp
enum eUiHAlign
{
   eUiHAlign_Left,
   eUiHAlign_Center,
   eUiHAlign_Right
};
```
**GetOverflowMode**

Returns the overflow behavior of the text.

**Syntax**

```cpp
eUiTextOverflowMode GetOverflowMode()
```

Following are possible values for `eUiTextOverflowMode`.

```cpp
enum eUiTextOverflowMode
{
    eUiTextOverflowMode_OverflowText,
    eUiTextOverflowMode_ClipText
};
```

**GetText**

Returns the text string being displayed by the element.

**Syntax**

```cpp
AZStd::string GetText()
```

**GetVerticalTextAlignment**

Returns the vertical text alignment.

**Syntax**

```cpp
eUiVAlign GetVerticalTextAlignment()
```

Following are possible values for `eUiVAlign`.

```cpp
enum eUiVAlign
{
    eUiVAlign_Top,
    eUiVAlign_Center,
    eUiVAlign_Bottom
};
```

**GetWrapText**

Returns whether text is wrapped.

**Syntax**

```cpp
eUiTextWrapTextSetting GetWrapText()
```

Following are possible values for `eUiTextWrapTextSetting`.

```cpp
enum eUiTextWrapTextSetting
{
    eUiTextWrapTextSetting_NoWrap,
    eUiTextWrapTextSetting_Wrap
};
```
**SetColor**
Sets the color to draw the text string.

**Syntax**
```cpp
void SetColor(const AZ::Color& color)
```

**SetFont**
Sets the pathname to the font.

**Syntax**
```cpp
void SetFont(const AZStd::string& fontPath)
```

**SetFontEffect**
Sets the font effect.

**Syntax**
```cpp
void SetFontEffect(int effectIndex)
```

**SetFontSize**
Sets the size of the font in points.

**Syntax**
```cpp
void SetFontSize(float size)
```

**SetHorizontalTextAlignment**
Sets the horizontal text alignment.

**Syntax**
```cpp
void SetHorizontalTextAlignment(eUiHAlign alignment)
```

For possible values for `eUiHAlign`, see `GetHorizontalTextAlignment (p. 3122)`.

**SetOverflowMode**
Sets the overflow behavior of the text.

**Syntax**
```cpp
void SetOverflowMode(eUiTextOverflowMode overflowMode)
```

For possible values for `eUiTextOverflowMode`, see `GetOverflowMode (p. 3123)`.

**SetText**
Sets the text string being displayed by the element.
You can use a text input component to provide player text input capability.

**UiTextInputBus**

Services messages for the UiTextInputComponent.

**GetChangeAction**

Returns the action triggered when the text is changed.

**Syntax**

```cpp
const AZStd::string& GetChangeAction()
```

**GetCursorBlinkInterval**

Returns the cursor blink interval of the text input.

**Syntax**

```cpp
float GetCursorBlinkInterval()
```
**GetEndEditAction**

Returns the action triggered when the editing of text is finished.

**Syntax**

```cpp
const AZStd::string& GetEndEditAction()
```

**GetEnterAction**

Returns the action triggered when enter is pressed.

**Syntax**

```cpp
const AZStd::string& GetEnterAction()
```

**GetIsPasswordField**

Returns whether the text input is configured as a password field.

**Syntax**

```cpp
bool GetIsPasswordField()
```

**GetMaxStringLength**

Returns the maximum number of characters that can be entered.

**Syntax**

```cpp
int GetMaxStringLength()
```

**GetPlaceHolderTextEntity**

Returns the placeholder text element.

**Syntax**

```cpp
AZ::EntityId GetPlaceHolderTextEntity()
```

**GetReplacementCharacter**

Returns the replacement character used to hide password text.

**Syntax**

```cpp
char GetReplacementCharacter()
```

**GetText**

Returns the text string being displayed or edited by the element.

**Syntax**

```cpp
AZStd::string GetText()
```
**GetTextCursorColor**
Returns the color to be used for the text cursor.

**Syntax**

```cpp
AZ::Color GetTextCursorColor()
```

**GetTextEntity**
Returns the text element.

**Syntax**

```cpp
AZ::EntityId GetTextEntity()
```

**GetTextSelectionColor**
Returns the color to be used for the text background when it is selected.

**Syntax**

```cpp
AZ::Color GetTextSelectionColor()
```

**SetChangeAction**
Sets the action triggered when the text is changed.

**Syntax**

```cpp
void SetChangeAction(const AZStd::string& actionName)
```

**SetCursorBlinkInterval**
Sets the cursor blink interval of the text input.

**Syntax**

```cpp
void SetCursorBlinkInterval(float interval)
```

**SetEndEditAction**
Sets the action triggered when the editing of text is finished.

**Syntax**

```cpp
void SetEndEditAction(const AZStd::string& actionName)
```

**SetEnterAction**
Sets the action triggered when enter is pressed.

**Syntax**

```cpp
void SetEnterAction(const AZStd::string& actionName)
```
**SetIsPasswordField**
Sets whether the text input is configured as a password field.

**Syntax**

```cpp
void SetIsPasswordField(bool passwordField)
```

**SetMaxStringLength**
Sets the maximum number of characters that can be entered.

**Syntax**

```cpp
void SetMaxStringLength(int maxCharacters)
```

**SetPlaceHolderTextEntity**
Sets the placeholder text element.

**Syntax**

```cpp
void SetPlaceHolderTextEntity(AZ::EntityId textEntity)
```

**SetReplacementCharacter**
Sets the replacement character used to hide password text.

**Syntax**

```cpp
void SetReplacementCharacter(char replacementChar)
```

**SetText**
Sets the text string being displayed or edited by the element.

**Syntax**

```cpp
void SetText(const AZStd::string& text)
```

**SetTextCursorColor**
Sets the color to be used for the text cursor.

**Syntax**

```cpp
void SetTextCursorColor(const AZ::Color& color)
```

**SetTextEntity**
Sets the text element.

**Syntax**

```cpp
void SetTextEntity
```
void SetTextEntity(AZ::EntityId textEntity)

SetTextSelectionColor

Sets the color to be used for the text background when it is selected.

Syntax

void SetTextSelectionColor(const AZ::Color& color)

UiTextInputNotificationBus

Services notifications for the UiTextInputComponent.

OnTextInputChange

Called when a character is added, removed, or changed.

Syntax

void OnTextInputChange(const AZStd::string& textString)

OnTextInputEndEdit

Called when edit of text is completed.

Syntax

void OnTextInputEndEdit(const AZStd::string& textString)

OnTextInputEnter

Called when Enter is pressed on the keyboard.

Syntax

void OnTextInputEnter(const AZStd::string& textString)

UiTooltipComponent

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use a tooltip component to provide the text of a tooltip.

UiTooltipBus

Services messages for the UiTooltipComponent.

GetText

Returns the tooltip text.
### Syntax

```
AZStd::string GetText()
```

### SetText

Sets the tooltip text.

### Syntax

```
void SetText(const AZStd::string& text)
```

## UITooltipDisplayComponent

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Controls the display behavior of a tooltip.

## UiTooltipDisplayBus

Services messages for the UiTooltipDisplayComponent.

### GetAutoPosition

Returns whether the tooltip display element is auto positioned.

### Syntax

```
bool GetAutoPosition()
```

### GetAutoPositionMode

Returns the auto position mode.

### Syntax

```
AutoPositionMode GetAutoPositionMode()
```

Following are possible values for `AutoPositionMode`.

```
enum AutoPositionMode
{
    OffsetFromMouse,
    OffsetFromElement
};
```

### GetAutoSize

Returns whether the tooltip display element should be resized so that the text element size matches the size of the string.

### Syntax
bool GetAutoSize()

GetDelayTime
Returns the amount of time to wait before showing the tooltip display element after the trigger condition has occurred.

Syntax
float GetDelayTime()

GetDisplayTime
Returns the amount of time the tooltip display element is to remain visible.

Syntax
float GetDisplayTime()

GetOffset
Returns the offset from the tooltip display element's pivot to the mouse position.

Syntax
const AZ::Vector2& GetOffset()

GetTextEntity
Returns the entity ID of the text element that is used for resizing.

Syntax
AZ::EntityId GetTextEntity()

GetTriggerMode
Returns the trigger mode describing the condition under which the tooltip will be displayed.

Minimum Lumberyard Version: 1.24

Syntax
TriggerMode GetTriggerMode()

Following are possible values for TriggerMode.

enum TriggerMode
{
    OnHover,
    OnPress,
    OnClick
};
**SetAutoPosition**

Sets whether the tooltip display element is auto positioned.

**Syntax**

```csharp
void SetAutoPosition(bool autoPosition)
```

**SetAutoPositionMode**

Sets the auto position mode.

**Syntax**

```csharp
void SetAutoPositionMode(AutoPositionMode autoPositionMode)
```

Following are possible values for `AutoPositionMode`.

```csharp
enum AutoPositionMode
{
    OffsetFromMouse,
    OffsetFromElement
};
```

**SetAutoSize**

Sets whether the tooltip display element should be resized so that the text element size matches the size of the string.

**Syntax**

```csharp
void SetAutoSize(bool autoSize)
```

**SetDelayTime**

Sets the amount of time to wait before showing the tooltip display element after the trigger condition has occurred.

**Syntax**

```csharp
void SetDelayTime(float delayTime)
```

**SetDisplayTime**

Sets the amount of time the tooltip display element is to remain visible.

**Syntax**

```csharp
void SetDisplayTime(float displayTime)
```

**SetOffset**

Sets the offset from the tooltip display element's pivot to the mouse position.

**Syntax**
void SetOffset(const AZ::Vector2& offset)

**SetTextEntity**

Sets the entity ID of the text element that is used for resizing. The text element must be a child of this entity.

**Syntax**

void SetTextEntity(AZ::EntityId textEntity)

**SetTriggerMode**

Sets the trigger condition for displaying the tooltip after the set amount of delay time has elapsed.

**Minimum Lumberyard Version:** 1.24

**Syntax**

void SetTriggerMode(TriggerMode triggerMode)

Following are possible values for TriggerMode.

```cpp
template
{
    OnHover,
    OnPress,
    OnClick
};
```

**UITransform2dComponent**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Controls positioning, scaling, rotation, anchor, and offset settings for UI elements.

**UiTransformBus**

Services messages for the UiTransform2dComponent.

**GetCanvasPosition**

Returns the position for this element in the canvas space.

**Syntax**

AZ::Vector2 GetCanvasPosition()

**GetLocalPosition**

Returns the position for this element relative to the center of the element's anchors.
UITransform2dComponent

Syntax

```
AZ::Vector2 GetLocalPosition()
```

GetPivot

Returns the pivot point.

Syntax

```
AZ::Vector2 GetPivot()
```

GetScale

Returns the scale.

Syntax

```
AZ::Vector2 GetScale()
```

GetScaleToDeviceMode

Returns how this element and all of the child elements are scaled to allow for the difference between the authored canvas size and the actual viewport size.

Syntax

```
ScaleToDeviceMode GetScaleToDeviceMode()
```

Following are possible values for ScaleToDeviceMode.

```
enum ScaleToDeviceMode
{
    None,
    UniformScaleToFit,
    UniformScaleToFill,
    UniformScaleToFitX,
    UniformScaleToFitY,
    NonUniformScale,
    ScaleXOnly,
    ScaleYOnly
};
```

GetViewportPosition

Returns the position for this element in the viewport space.

Syntax

```
AZ::Vector2 GetViewportPosition()
```

GetZRotation

Returns the rotation about the z-axis.

Syntax
```csharp
float GetZRotation()

**MoveCanvasPositionBy**

Moves this element in the canvas space.

**Syntax**

```csharp
void MoveCanvasPositionBy(const AZ::Vector2& offset)
```

**MoveLocalPositionBy**

Moves this element relative to the center of the element's anchors.

**Syntax**

```csharp
void MoveLocalPositionBy(const AZ::Vector2& offset)
```

**MoveViewportPositionBy**

Moves this element in the viewport space.

**Syntax**

```csharp
void MoveViewportPositionBy(const AZ::Vector2& offset)
```

**SetCanvasPosition**

Sets the position for this element in the canvas space.

**Syntax**

```csharp
void SetCanvasPosition(const AZ::Vector2& position)
```

**SetLocalPosition**

Sets the position for this element relative to the center of the element's anchors.

**Syntax**

```csharp
void SetLocalPosition(const AZ::Vector2& position)
```

**SetPivot**

Sets the pivot point.

**Syntax**

```csharp
void SetPivot(AZ::Vector2 pivot)
```

**SetScale**

Sets the scale.
Syntax

```cpp
void SetScale(AZ::Vector2 scale)
```

**SetScaleToDeviceMode**

Sets how the element and all of its child elements are scaled to allow for the difference between the authored canvas size and the actual viewport size.

**Syntax**

```cpp
void SetScaleToDeviceMode(ScaleToDeviceMode scaleToDeviceMode)
```

Following are possible values for `scaleToDeviceMode`.

```cpp
enum ScaleToDeviceMode {
    None,
    UniformScaleToFit,
    UniformScaleToFill,
    UniformScaleToFitX,
    UniformScaleToFitY,
    NonUniformScale,
    ScaleXOnly,
    ScaleYOnly
};
```

**SetViewportPosition**

Sets the position for this element in the viewport space.

**Syntax**

```cpp
void SetViewportPosition(const AZ::Vector2& position)
```

**SetZRotation**

Sets the rotation about the z-axis.

**Syntax**

```cpp
void SetZRotation(float rotation)
```

**UiTransform2dBus**

Services anchors and offsets for the UiTransform2dComponent.

**GetAnchors**

Returns the UI anchors.

**Syntax**

```cpp
UiAnchors GetAnchors()
```
Following are possible values for `UiAnchors`.

```cpp
class UiAnchors {
    float left;
    float top;
    float right;
    float bottom;
};
```

**GetOffsets**

Returns the UI offsets.

**Syntax**

```cpp
UiOffsets GetOffsets()
```

The following are possible values for `UiOffsets`.

```cpp
class UiOffsets {
    float left;
    float top;
    float right;
    float bottom;
};
```

**SetAnchors**

Sets the anchors.

**Syntax**

```cpp
void SetAnchors(UiAnchors anchors, bool adjustOffsets, bool allowPush)
```

For possible values for `UiAnchors`, see [GetAnchors (p. 3136)](#).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>adjustOffsets</td>
<td>If true, the offsets are adjusted to keep the rectangle in the same position.</td>
</tr>
<tr>
<td>allowPush</td>
<td>Only takes effect if the anchors are invalid. If true, when an anchor is changed to overlap the anchor opposite it, the opposite anchor moves.</td>
</tr>
</tbody>
</table>

**SetOffsets**

Sets UI offsets.

**Syntax**

```cpp
void SetOffsets(UiOffsets offsets)
```

For possible values for `UiOffsets`, see [GetOffsets (p. 3137)](#).
SetPivotAndAdjustOffsets
Sets the pivot and adjusts the offsets so that this element stays in the same place.

Syntax

```cpp
void SetPivotAndAdjustOffsets(AZ::Vector2 pivot)
```

UI World Components

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Controls the loading and unloading of UI canvases.

UiCanvasAssetRefBus
Services messages for the UiCanvasAssetRefComponent.

LoadCanvas
Loads the UI canvas using the stored asset reference. Returns the entity ID of the loaded canvas.

Syntax

```cpp
AZ::EntityId LoadCanvas()
```

UnloadCanvas
Unloads the UI canvas using the stored asset reference.

Syntax

```cpp
void UnloadCanvas()
```

UiCanvasAssetRefNotificationBus
Handles events sent by the UiCanvasAssetRefComponent.

OnCanvasLoadedIntoEntity
Called when the canvas asset reference loads a UI canvas.

Syntax

```cpp
void OnCanvasLoadedIntoEntity(AZ::EntityId uiCanvasEntity)
```

UiCanvasProxyRefBus
Services messages for the UiCanvasProxyRefComponent.
SetCanvasRefEntity

Sets the entity that manages the UI canvas for this proxy.

Syntax

```cpp
void SetCanvasRefEntity(AZ::EntityId canvasAssetRefEntity)
```

UiCanvasRefBus

Services messages for the UiCanvasAssetRefComponent and UiCanvasProxyRefComponent.

GetCanvas

Returns the UI canvas associated with this entity

Syntax

```cpp
AZ::EntityId GetCanvas()
```

UiCanvasRefNotificationBus

Provides notifications of when the UI canvas reference changes.

OnCanvasRefChanged

Called when the canvas referenced by a UiCanvasAssetRefComponent has changed. This can happen when LoadCanvas (p. 3138), UnloadCanvas (p. 3138), or SetCanvasRefEntity (p. 3139) is called.

Syntax

```cpp
void OnCanvasRefChanged(AZ::EntityId uiCanvasRefEntity, AZ::EntityId uiCanvasEntity)
```
Adding Audio and Sound Effects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard uses an audio translation layer (ATL) to interface between Lumberyard and third-party audio middleware, so you can develop and change your audio implementation without affecting the game logic. The game logic interacts with ATL controls, which map to their audio middleware equivalents through the Audio Controls Editor. For example, to play a sound, the game executes an ATL trigger, which is mapped to a 'Play' event in the audio middleware.

Lumberyard supports Audiokinetic Wave Works Interactive Sound Engine (Wwise), an audio pipeline solution with which you can create compelling soundscapes for your game. Lumberyard comes pre-configured with Wwise LTX, a free, compact version of Wwise.

For more information, see Setting up Wwise LTX (p. 3150).

Wwise is an industry standard audio middleware, but the full-featured software is not free. For licensing and pricing details, see http://www.audiokinetic.com/pricing.

Audio System Overview

The Lumberyard audio system consists of Gems, components, and content.

Gems

Lumberyard provides two audio Gems:

- AudioSystem
- AudioEngineWwise

AudioEngineWwise is an audio engine implementation provided by Lumberyard for Audiokinetic Wwise. An audio engine implementation translates generic Audio Translation Layer (ATL) state requests into real calls to the audio middleware API. It also implements low-level hooks for file I/O and memory allocation as needed for the audio middleware.

The AudioEngineWwise Gem depends on the AudioSystem Gem. It is recommended that you enable both Gems to enable audio, but the AudioSystem Gem has no dependencies and can be enabled by itself.
This leaves open the possibility of other audio middleware Gems to be developed and used instead of AudioEngineWwise.

Lumberyard audio Gems feature the following modules:

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audio System</td>
<td>Part of the Audio System Gem. Contains the audio translation layer (ATL) code and manages the state of the audio system in Lumberyard. Most of this module runs on the audio thread, but it also synchronizes with the main thread.</td>
</tr>
<tr>
<td>Audio System Editor</td>
<td>A Lumberyard Editor plugin, and part of the Audio System Gem. Contains the Audio Controls Editor (ACE) to create and manage ATL controls.</td>
</tr>
<tr>
<td>Audio Engine Wwise</td>
<td>Part of the Audio Engine Wwise Gem. Contains the implementation of AudioSystemImplementation interfaces for Wwise. Contains all Audiokinetic APIs. This is the only module that links with Wwise SDK. Can be configured to use Wwise LTX or the full version of Wwise.</td>
</tr>
<tr>
<td>Audio Engine Wwise Editor</td>
<td>A Lumberyard Editor plugin, and part of the Audio Engine Wwise Gem. This is an additional module that the Audio Controls Editor loads when Lumberyard uses Wwise.</td>
</tr>
</tbody>
</table>

**Components**

Core audio components available in Lumberyard Editor enable you to trigger sound effects, play ambient music, change sound variables using RTPC, apply environmental effects, place listeners to act as virtual microphones, and more. For a complete list, see Audio Components (p. 3162).

**Content**

Lumberyard audio features the following content:

<table>
<thead>
<tr>
<th>Content</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Media</td>
<td>Lumberyard loads soundbanks and loose media at runtime. The audio middleware authoring tools compiles and generates the media files.</td>
</tr>
<tr>
<td>Project</td>
<td>The audio middleware authoring tools use a project to manage source audio files, adjust sounds and settings, and generate runtime ready media. The Audio Controls Editor also uses the project to help map ATL controls to the audio middleware equivalents.</td>
</tr>
<tr>
<td>ATL Libraries</td>
<td>When the audio system maps ATL controls to their audio middleware equivalents, it creates ATL libraries, which are saved as XML files.</td>
</tr>
</tbody>
</table>
Audio Translation Layer

Audio Controls Editor

Using the Audio Controls Editor
A. **ATL Controls Pane (p. 3143)** – Hierarchical view of controls that exist in your project. The displayed icon designates the type of control.

B. **Inspector Pane (p. 3144)** – Properties for the control selected in the ATL Controls pane.

C. **Wwise Controls Pane (p. 3146)** – Controls created in the audio middleware authoring application, such as Wwise or Wwise LTX Authoring Tool.

---

### ATL Controls Pane

The ATL Control pane has the following control types. The associated icon designates the type of control. You can customize the name of the control.

#### Audio Controls

<table>
<thead>
<tr>
<th>Audio Control Type</th>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
</table>
| Trigger            | ![Icon] | Containers that connects to events in the audio middleware. You can author events to complete actions such as play or stop sounds, mute or unmute buses, and so on.  
To preview a trigger, right-click and choose **Execute Trigger**, or press the spacebar. |
<p>| RTPC               | ![Icon] | Real-Time Parameter Control (RTPC) is a floating-point variable that is updated over time by the game logic. RTPCs connect to parameters in the audio middleware that drive and modulate sound characteristics. |
| Switch             | ![Icon] | A variable that can be in one of several states, called switch states, that the game logic can set. For example, a <strong>SurfaceType</strong> switch can have values of Rock, Sand, or Grass. |</p>
<table>
<thead>
<tr>
<th>Audio Control Type</th>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment</td>
<td><img src="image" alt="Environment Icon" /></td>
<td>Environments can be set on audio objects, which control the amount of environmental effect, such as reverb and echo.</td>
</tr>
<tr>
<td>Preload</td>
<td><img src="image" alt="Preload Icon" /></td>
<td>Preloads are connected to sound banks, which are audio files that include packaged audio data. This audio data contains both signal content and metadata.</td>
</tr>
</tbody>
</table>

**To display a limited subset of control types**

1. In the **Audio Controls Editor**, click **Filters**.
2. Select or clear control types.

![Filters](image)

**To add a new control**

1. Click **Add**.
2. Select the type of control that you want to add.

![Add](image)

**Inspector Pane**

In the **Inspector** pane, you can edit the properties of the control that you selected in the **ATL Controls** pane. You can modify the control's **Name**, select a **Scope**, and modify the **Connected Controls**.
The following table describes the properties that you can modify in the Inspector pane.

### Inspector Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Name of the control. You can customize the name in the ATL Controls pane.</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Controls can exist for a global or on a per-level scope. A control with a global scope exists as long as the game is running and regardless of whether the control is used in the current level. When a specific level is defined as the scope, the controls exist only when that level is loaded. This setting is useful in low-memory systems because controls are loaded only in levels in which they are needed.</td>
</tr>
<tr>
<td><strong>Auto Load</strong></td>
<td>Available only for preloads. If you select Auto Load, the elements preloaded with this control will be reference counted; only one copy of them is created that is shared between all users.</td>
</tr>
<tr>
<td><strong>Preloaded Soundbanks</strong></td>
<td>Available only for preloads. The soundbanks connected with a preload can be different for different platforms. Different soundbanks can be added to different groups, and then in the Platforms field, you can choose which group to load for each platform that you are targeting.</td>
</tr>
<tr>
<td><strong>Platforms</strong></td>
<td>Available only for preloads. You can specify which group of soundbanks to load for each platform. You can share a group between several platforms.</td>
</tr>
<tr>
<td><strong>Connected Controls</strong></td>
<td>Contains the middleware controls connected to your control.</td>
</tr>
</tbody>
</table>

**Note**

The Auto Load, Preloaded Soundbanks, and Platforms properties appear only when the control is a Preload.
Wwise Controls Pane

The controls in the Wwise Controls pane are middleware-specific.

To filter displayed controls

- In the Audio Controls Editor, for Wwise Controls, enter your search term into the Search bar.

To hide controls that are already assigned

- Select Hide Assigned. The unassigned controls appear in orange text.

To create connections between ATL controls and middleware-specific controls

- In the Wwise Controls pane, select and drag a control to the Connected Controls area of the Inspector pane.
To create a control

1. In the Wwise Controls pane, select and drag a middleware control to the ATL Controls pane.

   This creates a new control, which shares the same name of the middleware control. The middleware control and the ATL control are also automatically connected.

2. To preview the control, choose File, Save All.

ATL Controls

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The game uses Audio Translation Layer (ATL) controls to communicate with the audio middleware. ATL controls are mapped to various data authored in the middleware's authoring tool. This abstraction layer provides you the flexibility to change mappings quickly without updating the game's integration of controls.

To see the list of audio control types, see ATL Controls Pane (p. 3143).

ATL Default Controls

The Audio Controls Editor automatically creates the following ATL controls by default. You can find the controls in the default_controls folder.
# Default ATL Controls

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>do_nothing</strong></td>
<td>Trigger that is used as a blank event where play/stop trigger pairs can be assigned. If you set do_nothing on the stop trigger, the play trigger does not stop automatically.</td>
</tr>
<tr>
<td><strong>get_focus</strong></td>
<td>Trigger that is called when the application window in Lumberyard Editor gains focus.</td>
</tr>
<tr>
<td><strong>lose_focus</strong></td>
<td>Trigger that is called when the application window in Lumberyard Editor loses focus.</td>
</tr>
</tbody>
</table>

**Note**
To disable the `get_focus` and `lose_focus` triggers, use the console command `s_IgnoreWindowFocus = 1`. This is useful when remote connecting Wwise Profiler so that audio continues to play while the Wwise Authoring Tool application has focus.
### Name | Description
--- | ---
mute_all | Trigger that is called when you click **Mute Audio**, which is located on the lower menu bar of Lumberyard Editor.
unmute_all | Trigger that is called when you click **Mute Audio**, which is located on the lower menu bar of Lumberyard Editor.

**object_speed** | RTPC control that is updated according to the speed of the associated entity in the level. You can enable the calculation of speed on a per entity basis with the **object_velocity_tracking** control.

**object_velocity_tracking** | Switch that is used to enable or disable the calculation of the **object_speed** value on a per entity basis. You do not need to connect this switch to the audio middleware because it communicates Lumberyard-specific data.

**ObstructionOcclusionCalculationType** | Switch that is used to set the obstruction and occlusion calculation method of an entity. The switch state values are **Ignore**, **SingleRay**, and **MultiRay**. You do not need to connect this switch to the audio middleware because it communicates Lumberyard-specific data.

---

**Audiokinetic Wwise**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard supports two flavors of Audiokinetic's Wwise audio middleware technology:

- **Wwise** – The full product contains advanced features, supports third-party plugins, has full surround capabilities, and more. Wwise must be purchased separately.
  
  For information, see https://www.audiokinetic.com/pricing/ and https://www.audiokinetic.com/licensing/faq/.

- **Wwise LTX** – An exclusive, free version of Wwise is included with Lumberyard. Wwise LTX has a simplified authoring workflow and is a great starting point for new users.
  
  For a comparison of features, see Comparing Wwise Full to Wwise LTX (p. 3154).

Wwise software consists of the SDK and the Authoring Tool. The SDK contains the headers and libraries that are linked with the Lumberyard engine code. The Authoring Tool is the application software for editing, tweaking, testing, and profiling sounds for your project.

**Topics**

- Setting up Wwise LTX (p. 3150)
- Setting up a Wwise Project (p. 3151)
Setting up Wwise LTX

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard includes Audiokinetic Wwise LTX, which is an exclusive, free version of the Audiokinetic Wwise audio middleware. Sound designers and composers can use Wwise LTX to work independently from the engineering team and author rich soundscapes for your games.

If your game requires advanced features, you can upgrade to the full version of Wwise. For more information, see Upgrading Wwise LTX to the Full Version (p. 3158).

Topics
- Installing Wwise LTX Authoring Tool (p. 3150)
- Running the Wwise LTX Authoring Tool (p. 3151)
- Accessing Wwise LTX Documentation (p. 3151)

Installing Wwise LTX Authoring Tool

To author sounds with Wwise LTX for your game, you must first install Wwise LTX Authoring Tool.

To install Audiokinetic Wwise LTX Authoring Tool

1. Run Lumberyard Setup Assistant (p. 16).
2. Choose Install software.
3. Locate Audiokinetic Wwise LTX Authoring Tool entry under Optional software and choose Install it. This runs the Wwise Launcher.
4. If prompted to sign in to your Audiokinetic account, provide the requested information and choose Log in, or choose Sign up now to create an account.
5. Select the desired installation components and settings for Wwise LTX or accept the default, and then choose Next.

   Note
   The Wwise LTX SDK is already included in Lumberyard's 3rdParty directory. If you prefer a lightweight install, you can clear the SDK component and all the deployment platforms.

6. Review and update the installation Target Directory as needed, then choose Install.
7. Review the license terms, then choose Accept if you wish to proceed with installation.
8. Once the installation successfully completes, close the Wwise Launcher and return to Lumberyard Setup Assistant. It should now show that Wwise LTX is installed. You can now close Lumberyard Setup Assistant.

   Note
   Lumberyard does not require installation of the new version of Wwise listed in the Wwise Launcher.
Running the Wwise LTX Authoring Tool

To run the Wwise LTX Authoring Tool, you must first open or create a project. The Samples Project and Starter Game both include a Wwise LTX audio project that you can use.

**To run the Wwise LTX Authoring Tool from Wwise Launcher**

1. Run **Wwise Launcher**.
2. Choose the **Wwise** tab, locate the LTX installation and choose **Launch Wwise (64-bit)**. If preferred, choose the wrench icon to open a menu and choose **Create Desktop Shortcut** for quicker launch of the authoring tool next time.
3. If this is your first time running Wwise LTX, you are prompted again to review and accept the End-User License Agreement (EULA). After accepting the EULA, choose **Open Other** in the **Project Launcher** dialog box. With successive use of the Wwise Launcher, you will be able to select from recently opened Wwise projects and choose **Open Selection**.
4. Browse to one of the following directories, select the `.wproj` file that you find there, and choose **Open**:
   - `lumberyard_version\dev\SamplesProject\Sounds\wwise_project`
   - `lumberyard_version\dev\StarterGame\Sounds\wwise_project`
5. Alternatively, if you are not using the Samples Project or the Starter Game project, you can choose **New** in the **Project Launcher** dialog box to create a Wwise LTX project.

For more information about setting up Wwise for your game project, see **Setting up a Wwise Project** (p. 3151).

Accessing Wwise LTX Documentation

You can access the Wwise LTX documentation in the Wwise Authoring Tool.

**To access Wwise LTX documentation**

1. Run the **Wwise LTX Authoring Tool**.
2. On the **Help** menu, choose **Wwise Help**.

Setting up a Wwise Project

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **Audio Controls Editor** looks for Wwise project files in the `lumberyard_version\dev \game_project\Sounds\wwise_project\` directory.

Lumberyard looks for the Wwise Soundbanks in the `lumberyard_version\dev \game_project\Sounds\wwise\` directory.

Creating a Wwise Project

**To create a Wwise project**

1. From the Start menu, open **Wwise Launcher**.
2. On the WWISE tab, click **Launch Wwise (64-bit)**.

   **Note**  
   If you have multiple versions of Wwise installed, open the version that you installed for Lumberyard.

3. In the **Project Launcher** dialog, click **New**.

4. In the **New Project** dialog, enter a **Name** for the project.

   **Note**  
   Wwise uses the name of your project to create a directory with the same name. However, you later rename the directory `wwise_project`.

5. For the **Location**, select the `lumberyard_version\dev\game_project\Sounds` directory. If this directory doesn't exist, create it.

6. Review and adjust the remainder of the options and then click **OK**.

7. If you are using the full version of Wwise, the **License Manager** dialog appears. Paste or import your license key if you have one and click **Save**.

   If you don't have your license key, click **Close**.

8. Exit Wwise.

9. In a file explorer, navigate to the `lumberyard_version\dev\game_project\Sounds` directory.

10. Rename the project directory you created in step 4 to `wwise_project`.

11. Create another directory next to `wwise_project` called `wwise`, if it doesn't exist already. This is where your Wwise soundbanks will be generated.

12. Open Wwise again.

13. Click **Open Other**.

14. Navigate to the `lumberyard_version\dev\game_project\Sounds\wwise_project` directory.

15. Select the `.wproj` file and click **Open**.

---

**Generating New Soundbanks**

**To generate new soundbanks**

1. If the Wwise project is not currently open, open it.

2. Choose **Project, Project Settings**.

3. On **SoundBanks** tab, in the **SoundBank Paths** section, edit the **SoundBank Folder** and select the `wwise` directory that you created in Creating a Wwise Project (p. 3151) and then click **OK**.

4. If you are using Wwise LTX, click **Generate Soundbank**.

   If you are using the Wwise full version:

   a. Press F7 to open the **SoundBank Manager Layout**.

   b. If no soundbanks exist, you must create one.

   To create a soundbank, select all **SoundBanks, Platforms**, and **Languages**.

   c. Click **Generate**.

5. Ensure that the soundbank generation succeeded. To do this, navigate to the `lumberyard_version\dev\game_project\Sounds\wwise` directory and verify that you have an `Init.bnk` file and other `.bnk` or `.wem` files.

For information on how to map soundbanks to ATL preloads so that Lumberyard can load them, see Using the Audio Controls Editor (p. 3142).
Creating Wwise Events for the Default ATL Controls

To create Wwise events for the default ATL controls

1. If the Wwise project is not currently open, open it.
2. Select the Events tab.
3. Under the Default Work Unit, select or create a directory to contain default ATL controls.
4. Right-click the directory to display the context menu and choose New Child, Empty Event.
5. Create five empty events named the following:
   - do_nothing
   - get_focus
   - lose_focus
   - mute_all
   - unmute_all

   **Note**
   - The get_focus and unmute_all events unmute the Master Audio Bus.
   - The lose_focus and mute_all events mute the Master Audio Bus.
6. Save the project.
8. In Lumberyard Editor, open the Audio Controls Editor.
9. Map these Wwise events to the default ATL controls.
10. Click File, Save All.

Connecting Wwise to the Editor and Game

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can establish a remote connection between Wwise and Lumberyard for your project's debug and profile builds of Lumberyard. By default, this feature is disabled. Remote connecting is not supported for performance and release builds.

**To enable remote connection**

1. In a text editor, create a file in the lumberyard_version\dev directory and name it user.cfg.
2. Open the file and enter the following parameter and value: s_WwiseEnableCommSystem=1.
3. Save the file.
4. Open your game or Lumberyard Editor.
   **Note**
   If your game or Lumberyard Editor is already running, close and reopen it.
5. Open the Wwise Authoring Tool and open the Wwise project associated with your game.
6. In the Wwise Authoring Tool, click the Connect to Remote Platform icon in the toolbar: 

   The Remote Connections dialog displays a list of computers to which you can connect.
7. Select the **Localhost** entry and click **Connect**. To verify a successful connection, look for the "Connected to" text in the Wwise toolbar.

**Note**

Localhost is the running instance of the game or Lumberyard Editor on your computer with remote connection enabled.

8. You can live edit parameters, mute or solo objects or sounds, and tweak effects in the Wwise project. Because remote connection is engaged, you can hear the changes instantly. Remote connecting is useful not only for profiling but also for debugging.

For additional information and useful tips on using the remote connection, refer to the documentation included with Wwise.

### Comparing Wwise Full to Wwise LTX

### Upgrading Wwise LTX to the Full Version

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To upgrade Wwise LTX to the full version of Wwise, follow the procedures in this topic.

**Topics**
- Upgrading the SDK (p. 3158)
- Upgrading Your Project (p. 3159)
- Upgrading Your Soundbanks (p. 3160)

After you upgrade the SDK, project, and soundbanks, you can open your game in Lumberyard to test your sounds.

**Upgrading the SDK**

**To upgrade the SDK**

1. Open **Wwise Launcher**. If you don't have it, install it from https://www.audiokinetic.com/download.
2. On the **WWISE** tab, under **Install New Version**, click the dropdown menu, and select **Wwise 2018.1.4.6807**, which is the version supported by Lumberyard.
3. Click **Install**.
4. For **Packages**, select **SDK (C++)**.
5. For **Deployment Platforms**, select the platforms required for your project.

Some platform components are available only after you purchase them from Audiokinetic. For more information about licensing, see https://www.audiokinetic.com/pricing.

---

</table>
6. Enter the installation directory and click **Next**.
7. Select the plugins to install, and click **Install**.
8. After installation completes, navigate to the \lumberyard_version\3rdParty\Wwise directory.
9. Create a directory named **2018.1.4.6807**.
10. Navigate to the Wwise installation directory that you specified in step 6, and copy the SDK directory into the \lumberyard_version\3rdParty\Wwise\2018.1.4.6807 directory.
11. To verify that Lumberyard recognizes the Wwise installation and configuration:
   a. Run Lumberyard Setup Assistant.
   b. On the **Install optional SDKs** page, verify that a green checkmark appears next to **Audiokinetic Wwise**.
12. Navigate to the \lumberyard_version\dev\Gems\AudioEngineWwise\Code directory.
13. In a text editor, open the *wscript* file.
14. Edit the *wwise_flavor* parameter from **WWISELTX** to **WWISE** and save the file.
   This instructs the WAF build system to use Wwise instead of Wwise LTX.
15. Configure WAF and build the project. For more information, see the section called “Build a project” (p. 61).

**Upgrading Your Project**

After you successfully configure and build Lumberyard, you can upgrade the content in your project. This assumes that you already have a Wwise LTX project set up for your game project.

Follow this procedure to upgrade an existing Wwise LTX project to use the full version of Wwise.

**Prerequisites**

If your Wwise LTX project and soundbanks are under source control, you must check them out. Check out the entire \lumberyard_version\dev\game_project\Sounds directory. After you upgrade your project, select the files that were created, and then revert any unmodified files before you submit them.

**Important**

During the upgrade process, read each message that Wwise displays.

**To upgrade your project**

1. Open **Wwise Launcher**.
2. On the **WWISE** tab, in the **Versions Installed** list, find **2018.1.4.6807**. Verify that the full revision is listed.
3. Click **Launch Wwise (64-bit)**.
4. If this is the first time running Wwise Authoring Tool for this version, an End-User License Agreement (EULA) dialog appears. Review and accept the EULA.
5. In the **Project Launcher** dialog, click **Open Other**, and open the *file_name*.wproj file for your game project.

   You can find this file in the \lumberyard_version\dev\game_project\Sounds \wwise_project directory.
   • If a message appears stating that you are upgrading from an earlier version of Wwise, you must upgrade the Wwise project XML schema. The message lists the files to be updated and highlights any files that are read-only.
• The message also states that this action is a one-way project upgrade. This means that the
upgraded project no longer loads with Wwise LTX. You can back up of your Wwise LTX project
before you click Yes in this message.
• The Project Load Log message displays all the changes made. You might see information about
default work units that were missing and created when you upgraded.
• If your Wwise project is under source control, ensure that you add these .wwu files to your depot.
6. Close the message and save the Wwise project.

Wwise LTX uses a single generic platform. After upgrading to Wwise, you can edit the platforms for your
project.

Upgrading Your Soundbanks

After you upgrade the SDK and your project, you can rebuild your soundbanks.

Note
Wwise LTX uses a single Generic platform. You can edit the platforms by going to Project,
Platform Manager. If you change the platforms, you must reopen your project.

To upgrade your soundbanks
1. Open your project in Wwise.
2. Click Project, License Manager.
3. Choose to either import your license or paste it from the clipboard.
4. Click Save.
5. Navigate to Project. Click Project Settings or press Shift+K, and select the SoundBanks tab.
6. For each platform in your project, click the ellipsis to open the Post-Generation Step editor.
   a. In the Post-Generation Step editor, click Load, From Last Location.
   b. Navigate to the lumberyard_version\dev\Tools\WwiseAuthoringScripts directory,
      select the ly_copy_output_and_generate_metadata.wcmdline file, and click Open.
   c. Click OK in the Post-Generation Step editor.
7. Click OK in the Project Settings window.
8. Open the SoundBank Layout. Press F7 or click Layouts, Soundbank.
10. Click Generate. The Generating SoundBanks dialog displays the progress.

The most common errors encountered during the generate process are caused by read-only files or
by not having a license applied to the project.

Lumberyard is now using the full version of Wwise. You can now run Lumberyard Editor and your game
to test your sounds.

Using a Different Wwise Version

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.
Download O3DE or visit the AWS Game Tech blog to learn more.

You can also use an older or newer version of Wwise. However, Lumberyard no longer supports versions 2016 and earlier.

**Configuring an Earlier Version of Wwise for Lumberyard**

Follow this procedure to use the 2017 version of Wwise.

**To configure Lumberyard for the 2017 version of Wwise**

1. Navigate to the `{lumberyard_version}/dev/Gems\AudioEngine\Wwise\Code` directory.
2. In a text editor, open the `wwise_backwards_compatibility.README.txt` file.
3. Follow the instructions in the file. The following is an overview of the instructions.
   a. Download a 2017 version of Wwise.
   b. Copy the `{Wwise_version}/SDK` directory from the Wwise install directory to the `{lumberyard_version}/3rdParty/Wwise` directory.
   c. In a text editor, open the `{lumberyard_version}/dev\SetupAssistantConfig.json` file and modify the version of Wwise in the file.

   This configures Lumberyard Setup Assistant to look for that specific version instead.
   d. Add a `.json` file that defines the Wwise 2017 SDK for WAF.
4. After you complete these steps, run Lumberyard Setup Assistant and the `lmbr_waf configure` command to check for errors.

   If no errors occur, build Lumberyard Editor and Engine for Wwise 2017.

**Configuring a Later Version of Wwise for Lumberyard**

Audiokinetic frequently releases new versions of Wwise. Later versions might be compatible with the current version supported by Lumberyard without requiring major code changes. However, minor revisions can contain API updates that require code changes in Lumberyard. Major revisions can require code changes and deeper migration.

If you want to switch to later versions of Wwise, use the following procedure.

**To configure Lumberyard for a later version of Wwise**

1. Download the version of Wwise that you want.
2. Copy the `{Wwise_version}/SDK` directory from the Wwise install directory to the `{lumberyard_version}/3rdParty/Wwise/your_new_wwise_version` directory.
3. In a text editor, open the `{lumberyard_version}/dev\SetupAssistantConfig.json` file and replace all occurrences of `2018.1.4.6807` with the version that you downloaded.

   This configures Lumberyard Setup Assistant to look for the version that you specify.

   `SetupAssistantConfig.json` contains a section for `Wwise` and a separate section for `Wwise LTX`. Modify only the `Wwise` section.
4. Save and close the `SetupAssistantConfig.json` file.
5. Run Lumberyard Setup Assistant. Then verify that the new Wwise SDK version is configured correctly on the Install optional SDKs page.

   You’ll notice that the setup instructions Lumberyard Setup Assistant still mention Wwise 2018.1.4.6807. You can ignore this text.
6. Complete the steps to upgrade Wwise (p. 3158).
Audio Components

Use the following audio components to add and configure sounds in your level:

- **Audio Area Environment** (p. 551) – Enables entities that are moving around and throughout a shape to have environment effects applied to any sounds that they trigger. You must also add a shape component to use the audio area environment component.
- **Audio Environment** (p. 552) – Provides access to features of the Audio Translation Layer (ATL) environments. Environments are used to apply environmental effects such as reverb or echo.
- **Audio Listener** (p. 553) – Places a virtual microphone in the environment. An audio listener acts as a sink for sound sources in the virtual world, and 3D audio rendering is processed with respect to the listener's world transform. You can specify the audio listener's position and rotation independently.
- **Audio Preload** (p. 555) – Loads and unloads ATL preloads, which contain references to soundbanks.
- **Audio Proxy** (p. 557) Required dependency if you add multiple audio components to an entity. It acts as a proxy audio object wrapped in a component. For example, if you have an audio trigger component and an audio rtpc component on the same entity, they communicate to the same audio object using this audio proxy component.
- **Audio RTPC** (p. 557) Provides basic Real-Time Parameter Control (RTPC) functionality. An RTPC is a named variable that the audio system can interpret in many different ways. It allows game developers to set the value from the game at run time to produce real-time tweaking of sounds.
- **Audio Switch** (p. 558) – Provides basic Audio Translation Layer (ATL) switch functionality. With switches (and switch states), you can specify the state of an entity. The audio middleware interprets states, modifies the behavior of sounds, and plays the appropriate sounds.
- **Audio Trigger** (p. 559) – Provides basic play and stop features so that you can set up Audio Translation Layer (ATL) play and stop triggers that can be executed on demand. With an audio trigger, you can also enable the player to run or stop audio triggers by name on entities.

- Text to Speech Cloud Gem (Using Amazon Polly) (p. 2203)
- Speech Recognition Cloud Gem (p. 2203)

Audio Console Variables

The following console variables can be used with the Lumberyard Audio system.

**s_ATLPoolSize**

Specifies in KB the size of the memory pool to be used by the audio translation layer (ATL).
**Audio Console Variables**

Default values: PC = 8192, Mac = 8192, Linux = 8192, iOS = 8192, Android = 4096

**s_AudioEventPoolSize**

Sets the number of preallocated audio events.

Default values: PC = 512, Mac = 512, iOS = 128, Android = 128

**s_AudioLoggingOptions**

Toggles the logging of audio-related messages.

Default values: 0 (disabled), a = Errors, b = Warnings, c = Comments

**s_AudioObjectsDebugFilter**

Allows for filtered display of audio objects by a search string.

Default value: "" (all)

**s_AudioObjectPoolSize**

Sets the number of preallocated audio objects and corresponding audio proxies.

Default values: PC = 2048, Mac = 2048, iOS = 256, Android = 256

**s_AudioProxiesInitType**

Can override on a global scale. If set, it determines whether AudioProxies initialize synchronously or asynchronously. This is a performance variable, as asynchronously initializing AudioProxies has a greatly reduced impact on the calling thread. When set to initialize asynchronously, audio playback is delayed.

Values: 0 = AudioProxy-specific initialization; 1 = Initialize synchronously; 2 = Initialize asynchronously.

Default value: 0 (all platforms)

**s_AudioTriggersDebugFilter**

Allows for filtered display of audio triggers by a search string.

Default value: "" (all)

**s_DrawAudioDebug**

Draws AudioTranslationLayer related debug data to the screen.

Values:
- 0: No audio debug info on the screen
- a: Draw spheres around active audio objects
- b: Show text labels for active audio objects
- c: Show trigger names for active audio objects
- d: Show current states for active audio objects
- e: Show RTPC values for active audio objects
- f: Show Environment amounts for active audio objects
- g: Draw occlusion rays
- h: Show occlusion ray labels
- i: Draw sphere around active audio listener
- v: List active Events
- w: List active Audio Objects
- x: Show FileCache Manager debug info
Audio Console Variables

- `y`: Show memory pool usage info for the audio impl

**s_ExecuteTrigger**

Executes an Audio Trigger. The first argument is the name of the audio trigger to be executed, the second argument is an optional audio object ID. If the second argument is provided, the audio trigger is executed on the audio object with the given ID; otherwise, the audio trigger is executed on the global audio object.

**s_FileCacheManagerDebugFilter**

Allows for filtered display of the different AFCM entries such as Globals, Level Specifics, and Volatiles.

Values: Default = 0 (all); a = Globals; b = Level Specifics; c = Volatiles

**s_FileCacheManagerSize**

Sets the size in KB that the AFCM allocates on the heap.

Default values: PC = 393216, Mac = 393216, Linux = 393216, iOS = 2048, Android = 73728

**s_FullObstructionMaxDistance**

For sounds whose distance to the listener is greater than this value, the obstruction value is attenuated with distance.

Default value: 5 m

**s_IgnoreWindowFocus**

If set to 1, the sound system continues to play when the Editor or Game window loses focus.

Default value: 0 (off)

**s_OcclusionMaxDistance**

Obstruction/Occlusion is not calculated for the sounds whose distance to the listener is greater than this value. Set this value to 0 to disable obstruction/occlusion calculations.

Default value: 500 m

**s_OcclusionMaxSyncDistance**

Physics rays are processed synchronously for the sounds that are closer to the listener than this value, and asynchronously for the rest (possible performance optimization).

Default value: 10 m

**s_PositionUpdateThreshold**

An audio object has to move by at least this amount to issue a position update request to the audio system.

Default: 0.1 (10 cm)

**s_SetRtpc**

Sets an Audio Rtpc value. The first argument is the name of the audio RTPC, the second argument is the float value to be set, the third argument is an optional audio object ID. If the third argument is provided, the RTPC is set on the audio object with the given ID. Otherwise, the RTPC is set on the global audio object.

**s_SetSwitchState**

Sets an audio switch to a provided state. The first argument is the name of the audio switch, the second argument is the name of the switch state to be set, the third argument is an optional audio
object ID. If the third argument is provided, the audio switch is set on the audio object with the given ID; otherwise, the audio switch is set on the global audio object.

**s_ShowActiveAudioObjectsOnly**

When drawing audio object names on the screen, this variable is used to choose between all registered audio objects or only those that reference active audio triggers.

Default value: 1 (active only)

**s_StopTrigger**

Stops an audio trigger. The first argument is the name of the audio trigger to be stopped, the second argument is an optional audio object ID. If the second argument is provided, the audio trigger is stopped on the audio object with the given ID; otherwise, the audio trigger is stopped on the global audio object.

**s_VelocityTrackingThreshold**

An audio object has to change its velocity by at least this amount to issue an `object_speed` RTPC update request to the audio system.

Default value: 0.1 (10 cm/s)
Platform development in Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Learn about the platforms supported by Lumberyard, their specific requirements, and how to test, build, and ship your project. In addition to Windows support, Lumberyard runs on the iOS and Android mobile platforms, macOS, and as dedicated Linux servers. This section also covers building for and running on virtual reality headsets. This documentation covers design considerations for all of these platforms, how to build and deploy, and debugging and troubleshooting advice. Each platform also has documentation specific to its own requirements.

Topics
- Developing for Android and iOS with Lumberyard (p. 3166)
- Create virtual reality projects in Lumberyard (p. 3248)
- Create macOS projects in Lumberyard (p. 3263)
- Creating Lumberyard Executables for Linux (p. 3269)

Developing for Android and iOS with Lumberyard

Amazon Lumberyard comes with support for building and deploying your game to Android and iOS devices. In this section of the guide, you'll learn how to get your projects up and running on mobile, what are some of the important design considerations for these platforms, and which unique workflows are required. You'll also learn how to use the Virtual File System (VFS) server to serve assets on-demand to your game that's running on a physical device, and how to get started using Device Farm for large-scale testing of your mobile project.

Take a deep dive into the Android and iOS documentation to learn about the requirements and configuration to get started with these platforms. When you're up and running, look through the rest of the topics in this section to finish generic setup and take the next steps to make your Lumberyard project a great experience on mobile.

Topics
- Lumberyard Android support (p. 3167)
- iOS Support (p. 3195)
- Design Considerations for Creating Mobile Games Using Lumberyard (p. 3214)
- Lumberyard Performance Tuning Guidelines for Mobile Devices (p. 3215)
- Modifying Project Settings for Mobile Device Games (p. 3224)
- Updating Graphics Settings for Android and iOS (p. 3234)
Lumberyard Android support

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In this section, you'll learn about the system requirements for Android. You will also learn how to set up your Amazon Lumberyard installation for Android builds, configure your project for Android support, and build and deploy to devices. When you finish your development cycle and are ready to release, that's covered here too. Along the way, you'll want to use the troubleshooting guide and reference materials to help resolve any issues you might find.

Topics
- Minimum device requirements (p. 3167)
- Prerequisites (p. 3167)
- Video tutorial (p. 3168)
- Set up your environment to develop for Android with Lumberyard (p. 3168)
- Configure Lumberyard projects for Android (p. 3172)
- Build and deploy your project for Android (p. 3175)
- Releasing Lumberyard projects for Android (p. 3180)
- Troubleshooting Lumberyard issues on Android (p. 3185)
- Reference for Android (p. 3187)

Minimum device requirements

Lumberyard has the following minimum requirements to deploy to Android. These are only minimum device specs. Newer devices offer better performance and require fewer optimizations. Most devices released in 2017 or later meet these criteria.

<table>
<thead>
<tr>
<th>CPU</th>
<th>ARMv8 quad-core</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPU</td>
<td>OpenGL ES 3.0 or 3.1 support</td>
</tr>
<tr>
<td>OS</td>
<td>Android 5.0 (API level 21)</td>
</tr>
</tbody>
</table>

If your Lumberyard project requires higher minimum specifications than these to achieve what you consider acceptable performance, you can set your own device and capability requirements through the Google Play Store. See the Android documentation for more information.

Prerequisites

To get started with your Lumberyard project on Android, you need the following software installed, in addition to Lumberyard. If you need to, download Lumberyard now (p. 10). Lumberyard can be configured for Android development either when you install it, or after you set up your Android tools. See Set up your environment to develop for Android with Lumberyard (p. 3168) for more information.
• An Android development environment. This can be either Android Studio or the standalone command line tools. For developers not already familiar with working with Android, we recommend Android Studio, which includes the command-line tools. Download Android developer tools.

• The required minimum development SDKs:
  • Android NDK r21
  • Android SDK API level 28 (Android 9.0 – Pie). The following libraries and tools are required as part of the SDK installation.
    • Google Play APK Expansion Library
    • Google Play Licensing Library
    • Android SDK Tools
    • Android SDK Platform-Tools
    • Build Tools 26.x.x or later

Important
Google requires that new apps submitted to the Google Play Store are built against an SDK version that is no more than one year old. To make sure that you meet this requirement, build against the latest available Android SDK and check for updated versions before any submission to the Google Play Store.

For instructions on installing the Android SDK and NDK, see the Android Studio SDK Manager or Command-line sdkmanager documentation on the Android developer site. For information on the packages required as part of the Android SDK install, see Set up your environment to develop for Android with Lumberyard (p. 3168).

Video tutorial

To help you get up and running quickly with Android, we have a video tutorial (10:10) that walks through the process of getting Android Studio installed, configuring your Lumberyard project, and running the project on an Android device.

Watch the video on YouTube: Setup Lumberyard to Build Android Games and Projects

Set up your environment to develop for Android with Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This section walks you through the steps needed to get your development environment and Amazon Lumberyard projects ready for build and deployment to Android. To get started, make sure that you have the Prerequisites (p. 3167). To learn about the platform-specific steps involved in project configuration and building, see Configure Lumberyard projects for Android (p. 3172) and Build and deploy your project for Android (p. 3175).

Topics
• Lumberyard environment setup (p. 3169)
• Add Android tools to PATH (p. 3171)
• Build system setup (p. 3171)
• Next steps (p. 3172)
Lumberyard environment setup

After you've installed the prerequisites (p. 3167), configure your Lumberyard installation to allow Android builds.

To allow Android builds

1. Start the Lumberyard Setup Assistant. If you're installing Lumberyard for the first time, Setup Assistant starts automatically. Otherwise, launch it from `lumberyard_install_dir\dev\Tools\LmbrSetup\Win\SetupAssistant.exe`.

2. Using Setup Assistant, select the following capabilities for your Lumberyard configuration:
   - Create, Modify and Build projects
   - Compile for Android Devices

   After selecting these capabilities, select Next to continue with configuration in the Setup Assistant.

3. Provide the paths to the Android Studio installation, and the `ndk-build.cmd` and `adb.exe` Android tools commands. These paths are used to determine the location of all of the Android build tools that Lumberyard uses. If you performed a default install of Android Studio and its tools, Setup Assistant should have already detected the installation paths.

   If you used another install location, or Setup Assistant couldn't find your Android install, provide the paths to the appropriate tools. You can also select the Browse button to use Windows Explorer to navigate to the required files.

   By default, the tools are located at the following paths.
   - Android Studio installation — `C:\Program Files\Android\Android Studio`
   - `ndk-build.cmd` — `C:\Users\username\AppData\Local\Android\Sdk\ndk\version\ndk-build.cmd`
   - `adb.exe` — `C:\Users\username\AppData\Local\Android\Sdk\platform-tools\adb.exe`

   **Tip**

   If you can't find your Android SDK install in `C:\Users\username\AppData\Local\Android\Sdk`, the SDK location might have been changed in Android Studio. To find out the location for your Android SDKs, follow these steps in Android Studio 4.0.x:
   - Open the Settings pane in Android Studio, either by navigating to the File > Settings menu from an open project, or by selecting Settings from the startup window.
   - In the left navigation pane of the Settings window, select Appearance & Behavior > System Settings > Android SDK.
• Note the path displayed as the **Android SDK Location**. Use this as the base path for locating the Android tools.

![Android SDK Location](image)

When each Android tool is marked with a green checkmark icon, you can close the Setup Assistant.

4. Check that the API level for the Android SDK you're using is correctly set in the Lumberyard build settings.
   a. Open the file `lumberyard_install_dir\dev\_WAF\_android\android_settings.json` in a text editor.
   b. Change the value of `SDK_VERSION` to `android-apilevel`, and `NDK_VERSION` to `android-ndk-version`. Use the API level of your development SDK for `apilevel`, and the API version of the NDK for `ndk-version`.

   For example, for Android Q (API level 29) and NDK API version 21, your configuration file will be similar to the following.

   ```json
   {
     "DEV_KEYSTORE_ALIAS" : "development_keystore",
     "DEV_KEYSTORE" : "_WAF_/android/dev.keystore",
     "DISTRO_KEYSTORE_ALIAS" : "distribution_keystore",
     "DISTRO_KEYSTORE" : "_WAF_/android/distro.keystore",
     "BUILD_TOOLS_VER" : "latest",
     "SDK_VERSION" : "android-29",
     "NDK_PLATFORM" : "android-21",
     "BUILD_ENVIRONMENT" : "Development"
   }
   ```

5. Configure the Lumberyard build system.
   a. Open a Windows command prompt and navigate to `lumberyard_install_dir\dev`.
   b. Run `lmbr_waf configure`.

At this point, if you're missing any of the required packages or tools, or if Lumberyard needs additional configuration, `lmbr_waf configure` will report an error telling you what you need to install or edit to get your build working. Use either **Android Studio SDK Manager** or **sdkmanager** to install any missing packages or SDKs.

**Important**
At this point, **don't** rebuild your game or engine. Wait until after you configure your project for Android, so that the Lumberyard tools will pick up those changes.
Add Android tools to PATH

When working with Android, it's useful to have access to the SDK tools directly from the command line. If you're working with build infrastructure or on a development team for your project, we recommend that you add the Android build tools to your PATH environment variable. To set an environment variable on Windows, follow these steps.

1. Open the Windows Control Panel and select System > Advanced system settings.
2. In the System Properties dialog box, select Environment Variables.
3. Under User variables, edit the PATH variable to add the directories containing the Android tools. Select the New button to add a new value to PATH. The values that you add are the directories containing the adb.exe and ndk-build.cmd files.

Build system setup

Now that you have Android support enabled in Lumberyard, you need to configure the build system to recognize your project and produce Android (es3) assets.

1. Open the file lumberyard_install_dir\dev\WAF\user_settings.options in a text editor.
2. In the [Game Projects] section of the configuration file, change the value of enabled_game_projects to include the project that you want to build for Android. This value setting is a comma-separated list of the projects to generate Android targets for during configuration. Either remove the existing values, or add your project name to the list. For example, to enable SamplesProject, MultiplayerSample, and your project:

   [Game Projects]
   enabled_game_projects = SamplesProject, MultiplayerSample, your-project-name

3. Save and close the file.
4. Open the file lumberyard_install_dir\dev\AssetProcessorPlatformConfig.ini in a text editor.
5. Remove the semicolon to uncomment es3=enabled.

   [Platforms]
   ;pc=enabled
   es3=enabled
   ;ios=enabled
   ;osx_gl=enabled

6. Save and close the file.
7. Start the Asset Processor to compile any existing assets for use on Android.
   a. Check to see if the Asset Processor is running. Open the Windows system tray and look for the Asset Processor icon.
b. If the Asset Processor is running, double-click the icon in the tray to bring up the Asset Processor window.

c. If the Asset Processor isn't running, launch it from `lumberyard_install_dir\dev\Bin64\vc142\AssetProcessor.exe`.

8. Wait until the Asset Processor finishes building all of your assets for use with Android. When assets are finished processing, the Asset Processor status line indicates that the Asset Processor is **Idle**.

**Next steps**

Now that you have your Lumberyard environment configured for Android, configure, build, and deploy your project to a device to test.

- Configure Lumberyard projects for Android (p. 3172)
- Build and deploy your project for Android (p. 3175)

**Configure Lumberyard projects for Android**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

In addition to the system-wide configuration requirements (p. 3168) to build for Android, Amazon Lumberyard requires some project-specific settings as well. These settings not only include things like supplying values to the Android Manifest, they also control the application's ability to connect to the shader compiler and how assets are loaded onto the device. With the Virtual File System (VFS) offered by the Asset Processor, you can even live-reload assets on the device as they change.

This section covers the basics of configuring your project so that you can work with Android. For all of the available settings, see Reference for Android (p. 3187).

**Important**
Because project settings impact how your application communicates with some services on the Asset Processor host and modify the Android manifest, changing any settings for your project will require a rebuild.

**Topics**
- Handling assets on Android (p. 3172)
- Serving assets over the Virtual File System (VFS) (p. 3174)
- Custom Android manifests (p. 3174)

**Handling assets on Android**

Working with Android in Lumberyard can be complicated because of the restrictions of the Android platform, which affects how Android application packages (APKs) are built and deployed. Different asset deployment configurations can greatly affect performance during your development process, so make sure that you select the one that's right for your use case. This section helps break down what options are available, when they're most appropriate, and how you configure your Lumberyard project in order to support each.

These are the asset modes that are available modes for asset deployment to devices:

- `configuration_default` — assets are packed according to the build configuration:
  - The **debug** and **profile** configurations use `loose_files` mode.
• The release and performance configurations use the project_settings mode to determine how to build assets, the APK, and any OBB files.
• loose_files and loose_paks — assets are loose, which means that they are copied to storage media. For more information about loose files, see Loose modes (p. 3173).
• apk_files and apk_paks — assets are packed, which means that they are bundled as part of your APK. For more information about packed files, see Packed modes (p. 3173).
• project_settings — assets are packed according to the configuration.

To configure which asset mode your deployments use, open lumberyard_install_dir\dev\WAF_\user_settings.options in a text editor and modify the [Android Options] section.

[Android Options]
android_asset_mode = [ configuration_default | loose_files | loose_paks | apk_files | apk_paks | project_settings ]

Loose modes

In loose files mode (loose_files or loose_paks), none of your assets are included into the APK. Instead, assets are copied directly to the storage media on the Android device and loaded by the Lumberyard engine at runtime. When using loose_paks, assets are first placed into a .pak file and then pushed to the device.

A loose files mode is probably what you want to be using for day-to-day development and to rapidly iterate on assets and deploy updates to the device.

When using loose assets, we recommend the loose_files mode to make manual inspection of the device's SD card easier and on-demand asset deployments faster, at the cost of a small performance hit when making the initial asset load. To configure your deployments to use loose files mode, open lumberyard_install_dir\dev\WAF_\user_settings.options in a text editor and modify the [Android Options] section.

[Android Options]
android_asset_mode = loose_files

Packed modes

Unlike many Lumberyard scenarios in which packed assets refer to .pak files, the packed assets (apk_files and apk_paks) modes bundle your assets as part of the deployed APK, with the option of putting them into a .pak first. This APK is sometimes referred to as a packed APK, which refers to the fact that assets are packed into the APK and not distributed separately.

Bundling your assets in an APK allows for deployment of a single artifact, making these modes ideal for building APKs to distribute for testing or previews.

When using packed assets, we recommend the apk_paks mode, which offers some performance improvements. To configure your deployments to use packed assets mode, open lumberyard_install_dir\dev\WAF_\user_settings.options in a text editor and modify the [Android Options] section.

[Android Options]
android_asset_mode = apk_paks

Tip
If you want to do large-scale automated testing across multiple devices, you can build packed APKs and distribute them to AWS Device Farm.
Serving assets over the Virtual File System (VFS)

During the early stages of development with Lumberyard, and for users rapidly iterating on assets in a way that requires live reloading, you can use the Virtual File System (VFS) to stream assets to a device from your development machine. The VFS uses the Asset Processor as a proxy that your Android device connects to in order to receive updated assets. Whenever the Asset Processor rebuilds a product asset, that asset is copied to the device and reloaded. The VFS doesn't do initial asset deployments — your build configuration's asset mode is respected — only reloads.

To turn on VFS

1. Open the file `lumberyard_install_dir\dev\bootstrap.cfg` in a text editor.
2. Turn on the Asset Processor VFS support by changing the `remote_filesystem` value to 1.

   ```
   remote_filesystem=1
   ```

3. Configure the connection information for the VFS by changing the values of `remote_ip`, `remote_port`, and `white_list`. For an Asset Processor running locally, both the remote IP address and allow list should be `127.0.0.1`. The default port of the Asset Processor is `45643`.

   ```
   remote_ip=127.0.0.1
   remote_port=asset_processor_port
   white_list=127.0.0.1
   ```

4. Configure the Lumberyard engine to connect to the VFS and boot without some assets preloaded.

   ```
   connect_to_remote=1
   wait_for_connect=0
   ```

5. Configure the connection from the device to the shader compiler. You can either do this by starting the Shader Compiler yourself, or by passing traffic to the Shader Compiler through the Asset Processor.

   - **Connect directly to shader compiler** – See Connect to the Shader Compiler (p. 3176) for instructions.
   - **Connect to Asset Processor** – Edit the Android configuration to use the Asset Processor's shader compiler process.

     a. Open the file `lumberyard_install_dir\dev\system_android_es3.cfg` in a text editor.

     b. Change the value of `r_AssetProcessorShaderCompiler` to 1.

       ```
       r_AssetProcessorShaderCompiler=1
       ```

6. Set up port forwarding from the device to the Asset Processor.

   ```
   adb reverse tcp:45643 tcp:45643
   ```

7. Rebuild your Lumberyard project for Android and deploy it to the device.

Now when you launch your Lumberyard project, it will connect to the Asset Processor host to do live asset reloads over the VFS.

Custom Android manifests

As part of each Android application, Google requires a list of activities that will be performed by the application, and which device capabilities are required. For example, if your project uses live location data
on an Android device, you'll need to ensure that your project has the appropriate permissions to collect
data at the right intervals and with the appropriate location precision. Because Lumberyard projects are
made up of many components, during the build process, the build tools pick up multiple manifests and
merge them together.

If you're using a gem or other component that requires special device access, or that runs its own Android
Activity or Intent, the gem requires an Android manifest file. This file needs to meet the following criteria
to be picked up by the build system:

- The file must be named `AndroidManifest.xml` and conform to the Android manifest format.
- The gem or module's `wscript` build file must include `android_manifest_path` as a key in the gem
  definition that's passed to the build system. The value of this key should be the absolute path to the
directory containing the manifest.

For example, the microphone gem (p. 1171) uses an Android manifest to give your project
access to the microphone. Below is a portion of the microphone gem's `wscript` that defines
how to locate the Android manifest file. This snippet sets up the gem to use the manifest
at `lumberyard_install_dir\dev\Gems\Microphone\Code\Source\Android
\AndroidManifest.xml`.

```python
def build(bld):
    manifest_src_root = bld.path.make_node(os.path.join('Source', 'Android'))

    kw_dict = dict(
        # ...
        android_manifest_path = [ manifest_src_root.abspath() ],
        # ...
    )

    bld.DefineGem(**kw_dict)
```

To learn more about the gem building system and using `wscript` files, see Gem Structure (p. 1073) and
Waf Module Files (wscript) (p. 76). For more information on Android manifests, their purpose, and how to
structure their contents, see the official Android documentation.

**Build and deploy your project for Android**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.
Download O3DE or visit the AWS Game Tech blog to learn more.

Once you've set up your environment and configured your project, it's time to build your Amazon
Lumberyard project for Android and get it running on a device. In this section, you'll set up an attached
device to use the Shader Compiler, build your project with `lmbr_waf` or Android Studio, and deploy
to a device. You'll also learn how to configure the Lumberyard build system to activate or deactivate
automatically deploying to a device whenever you build.

**Topics**
- Connect to the Shader Compiler (p. 3176)
- Build your project (p. 3177)
- Deployment prerequisites (p. 3177)
- Deploy with Lumberyard Editor (p. 3177)
- Deploy from command line (p. 3178)
Connect to the Shader Compiler

During development, your Lumberyard project connects to the Shader Compiler to generate the shaders for your device. To do this, by set up a reverse proxy between the Android device and the host machine, in order to connect to the Asset Processor. Note that through the VFS you can connect to a remote Asset Processor, which will handle shader compilation. Follow the steps in Serving assets over the Virtual File System (VFS) (p. 3174) to configure VFS.

Important
The Shader Compiler only runs on Windows PCs. If you're using another environment to develop your Android game, you'll need access to a server with the Shader Compiler running and accessible through a firewall. One option is to run a Windows GPU-based EC2 instance. For more information on running a dedicated Shader Compiler service, see Remote Shader Compiler (p. 1645).

To connect to the Shader Compiler

1. Open the lumberyard_install_dir\dev\system_android_es3.cfg file in a text editor.
2. Change the value of r_AssetProcessorShaderCompiler to 1.
   
   ```
   r_AssetProcessorShaderCompiler=1
   ```
3. Change the value of r_ShaderCompilerServer to the IPv4 address of the machine that's running the Shader Compiler. Unless you're running the Shader Compiler in a dedicated environment, use 127.0.0.1.
   
   ```
   r_ShaderCompilerServer=server-ip
   ```

   Important
   Make sure that the IPv4 address of the Android device is in the allow list for your Shader Compiler. Connections to the compiler are made from the device, not proxied through the host.

4. Change the value of r_ShaderCompilerPort to the port that's used by the Shader Compiler. By default, the port for the Shader Compiler is 61453. To see if you're using another port, examine the Remote Shader Compiler Configuration (p. 1646) on the Shader Compiler host.
   
   ```
   r_ShaderCompilerPort=shader-port
   ```
5. Save the file.
6. If running the Shader Compiler locally: Open a command prompt and use adb to redirect traffic at the Shader Compiler port on the device to the Shader Compiler port on your development machine. By default, the port for the Shader Compiler is 61453.
   
   ```
   adb reverse tcp:shader-port tcp:shader-port
   ```

   Important
   This step relies on the adb command being in the PATH environment variable. Follow the instructions in Set up your environment to develop for Android with Lumberyard (p. 3168) to add Android tools to your PATH.

Whether or not you need to manually start the Shader Compiler is dependent upon whether you use the deployment tool. If you're using the Deployment Tool, the Asset Processor automatically starts a Shader
Compiler in the background for you. Otherwise, you need to start the Shader Compiler manually for a deployment. See Running the Remote Shader Compiler (p. 1646) to learn more.

**Build your project**

With asset loading and the shader compiler configured, you're ready to build your Lumberyard project for Android! You can build from the command line, or load the projects created by `lmbr_waf configure` into Android Studio. This section covers how to build your project from the command line, including information on the available Android targets and build system configuration options that are explicitly for use with Android.

**Important**

If you've enabled Incredibuild (p. 118), turn the feature off to be able to compile for Android. Lumberyard doesn't take advantage of the Incredibuild hooks for Android.

**Build with lmbr_waf**

When using `lmbr_waf`, Android builds use the `android_armv8_clang` platform. When building for Android, all of the usual tasks, options, build configurations, and specs are available with `lmbr_waf`. For example, to build the game and engine for Android in profiling mode, use the command `lmbr_waf build_android_armv8_clang_profile -p game_and_engine`.

For more information about the Lumberyard build system, see Using the Waf Build System (p. 63). For information on the Android-specific build settings and `lmbr_waf` command-line options, see the Reference for Android (p. 3187).

**Build with Android Studio**

The Gradle project created by `lmbr_waf configure` can be directly imported into Android Studio without any changes. Follow the instructions from Android Studio - Import Gradle project to import this project, located at `lumberyard_install_dir\dev\Solutions\LumberyardAndroidSDK`.

For further instructions, including how to select targets and configure for debugging, read the Android Studio documentation.

Targets in Android Studio are called *Build Variants* and are named `project-nameLauncher`. Each build variant produces the bootstrap executable that loads the assets and code for the named project, and the Lumberyard engine.

If you're comfortable using the Android build tools from the command line, you can also build any Lumberyard targets using the Android build tools or Gradle. Keep in mind that this only builds your executable and doesn't recompile the assets.

**Deployment prerequisites**

In order to deploy to an Android device, you need the following:

- An Android device that meets the minimum requirements (p. 3167) for Lumberyard. Lumberyard projects won't deploy to an Android emulator.
- The device has developer mode and USB debugging enabled. See Configure developer options in the official Android documentation for instructions on how to enable these features.
- The device is accessible from an Android debug bridge (`adb`) server on the host running the deployment tools.

**Deploy with Lumberyard Editor**

The Lumberyard Editor offers a way to deploy to a mobile device: the Lumberyard Deployment Tool. If you're a content creator who rapidly iterates on their work, this is an ideal way to get on-device testing.
and validation. Using the Deployment Tool requires that you have the Lumberyard Editor and Asset Processor, and an Android device connected to the machine that's running both.

To use the Deployment Tool

1. From the Editor main menu, select File > Project Settings > Deploy to device.
2. In the Deployment Tool UI, select Android ARMv8 for the Target platform value.
3. Select your build configuration, and set the option toggles for Build game and Load current level. It's only necessary to rebuild your game if you're testing updates to the code itself, and not just asset changes.
4. In the Deploy section, select the Local Device tab.
5. Under Deployment Settings, select your target device. Unless you have multiple Android devices connected, there's no need to change this value. Make sure the value for Device IP address is 127.0.0.1. For Android, the Deployment Tool automatically manages port forwarding and connections through the Android debug bridge.
6. Check the Clean device box to remove any files for your project that are copied to the device, including any installed APKs. This is recommended if you're doing a large asset update.
7. Under Asset Options, select your asset mode (p. 3172). Unless you're running the Asset Processor remotely, make sure that the value for Asset Processor IP address is 127.0.0.1 (localhost). If you'll be building shaders through the Shader Compiler, uncheck the Use Asset Processor for shaders checkbox.
8. Select the Deploy to local device button.

Note
If you're using source control for your project, you might see a warning that some files are not writable when you try to deploy the project. Either check these files out in your source control system, or select the Continue button to overwrite them.

Deploy from command line

If you need to deploy less frequently, or can't meet the requirements of the Deployment Tool, deploy-on-build is another option. Deployments during build can be performed automatically, or controlled through a command-line option passed to lmbr_waf. You can also deploy directly from Android Studio if you're using it as your build environment. For more information on using Android Studio for Lumberyard builds, see Build with Android Studio (p. 3177) and the Android Studio documentation.

Important
As part of using deploy-on-build, you'll want to make sure that your assets are properly updated first. This will always involve running the Asset Processor and the shader compiler before a build.

Automatic deploy during build

At the start of development, and for anyone working on the Lumberyard engine or gems that contain code, deploy to a device every time you rebuild. This keeps the APK on the device up to date and ready to test, at a minimal cost of deployment time to the device. As your project grows in size and assets are added, you might choose to turn this feature off – copying assets to the device is what takes the longest amount of time in a deployment.

To modify the build configuration to automatically deploy

1. Open the lumberyard_install_dir\dev\_WAF\_user_settings.options file in a text editor.
2. Edit the [Android Deploy] section of the file to the following:

```plaintext
[Android Deploy]
```
deploy_android = True
deploy_android_clean_device = True
deploy_android_executable = True
deploy_android_replace_apk = True

Command-line options still take precedence over anything in the configuration file. When building for Android and you don't want to deploy, you can add the arguments shown in the next command to keep the current on-device APK installed:

```
lmbr_waf build_android_armv8_clang_profile -p all ^
  --deploy-android-executable=False ^
  --deploy-android-clean-device=False ^
  --deploy-android-replace-apk=False
```

Using this feature with the `deploy_android_armv8_clang_profile` build command is useful when you don't want to replace the executable on the device, but do need to deploy changed assets.

For a full description of all of the available Android deployment options and their effects, see the Reference for Android (p. 3187).

Manual deploy during build

When working from the command line with `lmbr_waf`, you can control deployments by adding arguments. When you're ready to build for deployment, add the arguments `--deploy-android-executable=True` `--deploy-android-clean-device=True` `--deploy-android-replace-apk=True` to your invocation. The following command is used to deploy during a build:

```
lmbr_waf build_android_armv8_clang_profile -p game_and_engine ^
  --deploy-android-executable=True ^
  --deploy-android-clean-device=True ^
  --deploy-android-replace-apk=True
```

During early testing and development, you'll want to always push to a device only when you've confirmed that all of your asset settings, device network configuration, and other build configurations are appropriate for your project. You only need to push new APKs when updating configurations, making code changes, or adding gems.

For a full description of all of the available Android deployment options and their effects, see the Reference for Android (p. 3187).

Deploy with `lmbr_waf`

If your game and engine are already built and up to date, you can run a deployment without doing a build. By running a deploy-only operation, you can update the assets on a device to test and preview them without the cost of a full rebuild. You can even switch the asset deployment type before doing a manual deployment.

Deployments are performed with the `deploy_android_armv8_clang_profile` command. When you're running deployments in this way, make sure to use the `--deploy-android-*` arguments to specify exactly what should be cleaned and which assets or binaries will be deployed to the device. In general, when you're only updating assets, make sure to avoid cleaning assets from the device and don't re-deploy the binaries. The following command shows how to do an asset-only update:

```
lmbr_waf deploy_android_armv8_clang_profile -p all ^
  --deploy-android-executable=False ^
  --deploy-android-clean-device=False ^
```
--deploy-android-replace-apk=False

For a full description of all of the available Android deployment options and their effects, see the Reference for Android (p. 3187).

Next steps

Now that you have your Lumberyard project building and running on an Android device, learn more about mobile-specific design considerations and releasing to the Google Play Store.

- Design Considerations for Creating Mobile Games Using Lumberyard (p. 3214)
- Lumberyard Performance Tuning Guidelines for Mobile Devices (p. 3215)
- Updating Graphics Settings for Android and iOS (p. 3234)
- Releasing Lumberyard projects for Android (p. 3180)

Releasing Lumberyard projects for Android

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Setting up to release for Android can be a complicated process because of the number of steps involved, and the restrictions that are required for publishing on the Google Play Store. For the full and up to date list of requirements, see the Play Store publishing documentation. In this topic you'll walk through additional steps needed for distribution, configure to submit an application larger than 100Mb to the Google Play Store, and build your release binaries.

Topics
- Configure your signing key (p. 3180)
- Create expansion files (OBBs) (p. 3181)
- Release process (p. 3183)

Configure your signing key

As part of submission to the Google Play Store, you’re required to sign your application. The Android signing documentation discusses setting up your key signing in detail, as well as steps involved in uploading your signing key and signed application to Google Play. As part of building your APK, the Lumberyard build system takes care of doing the signing for you.

In order to set up key signing, you’ll need to generate an upload key.

1. Open the file lumberyard_install_dir/dev/_WAF_/android/android_settings.json in a text editor.
2. Make the following edits.
   a. Change the value for DISTRO_KEYSTORE_ALIAS to the alias of your distribution keystore.
   b. Change the value for DISTRO_KEYSTORE to the path to your distribution keystore. This path must be relative to lumberyard_install_dir/dev.
   c. Change BUILD_ENVIRONMENT to Distribution.
"DEV_KEYSTORE_ALIAS" : "development_keystore",
"DEV_KEYSTORE" : "_WAF_/android/dev.keystore",

"DISTRO_KEYSTORE_ALIAS" : "your-keystore-alias",
"DISTRO_KEYSTORE" : "your-keystore-path",

"BUILD_TOOLS_VER" : "latest",
"SDK_VERSION" : "android-28",
"NDK_PLATFORM" : "android-21",

"BUILD_ENVIRONMENT" : "Distribution"
}

Now when building your project, you're required to include the --distro-store-pass and --distro-key-pass arguments. These are respectively the password to the keystore itself and the password to your upload key for the Google Play Store.

This enables your ability to produce release builds. In order to switch back to performing development builds, change BUILD_ENVIRONMENT back to Development.

Create expansion files (OBBs)

Warning
In Lumberyard version v1.21 and later, the resource compiler job which builds OBB files does not ship with the Lumberyard installer. Download the Android_MakeObb job file and place it in the lumberyard_install_dir/dev/Code/Tools/RC/Config/rc directory before continuing.

The MakeObb job uses the old Lumberyard asset management system, where the project-specific resources you include and exclude from the OBB expansions are defined as part of the job.

The Google Play Store has limitations on how applications can be distributed. Android application packages (APKs) are limited to 100MB in size. To ship larger applications, you should use either dynamic content delivery (p. 2155) or Android expansion files. The Lumberyard engine has support for downloading, checking, and extracting expansion files - all you have to do is create them. Google Play allows for uploading two separate OBB files, main and patch, which have a size limit of 2.0Gb each.

How you package your application is an important part of releasing to the Google Play Store. Before continuing in this section, we recommend that you read the Android Developer documentation for APK expansions.

Note
It's important to remember that these restrictions apply only to the Google Play Store. If you're shipping your application to another Android storefront or service that will install it, read the appropriate documentation and understand your distribution channel's requirements.

If you've decided that APK expansions are the right way to distribute your application, follow these steps to configure your project to build OBBs and modify the engine code so that your project will prefer to load loose files extracted from the OBB over searching for assets within pak files.

1. In Windows Command Prompt or Windows Explorer, navigate to the lumberyard_install_dir/dev\Code\Tools\RC\Config\rc folder.
2. Copy the file RCJob_Generic_Android_MakeObb.xml to a new file named RCJob_project-name_Android_MakeObb.xml.
3. Open the file lumberyard_install_dir\dev\project-name\project.json in a text editor.
4. Make the following edits to the file:

   a. If you haven't, set the value of app_obfuscator_salt to a random Base64 string.
b. To enable building main OBB files, set `use_main_obb` to "true".
c. To enable building patch OBB files, set `use_patch_obb` to "true".
d. Set the value of `rc_obb_job` to `RCJob_project-name_Android_MakeObb.xml`.

```
{
    ...
    "android_settings": {
        "package_name": "com.examples.project-name",
        "version_number": 1,
        "version_name": "1.0.0",
        "orientation": "landscape",
        "app_obfuscator_salt": "MY_OBFUSCATOR_SALT_BASE_64",
        "use_main_obb": "(true | false)",
        "use_patch_obb": "(true | false)",
        "rc_obb_job": "RCJob_project-name_Android_MakeObb.xml"
    }
}
```

5. Save and close `project.json`.
6. Open the file `lumberyard_install_dir\dev\Code\Tools\RC\Config\rc\RCJob_project-name_Android_MakeObb.xml` in a text editor.
7. Edit the file to create the OBBs that you wish to build.
   - **If building only a main OBB:** Edit the values of `<Properties>` to properly reference the files that you wish to include and exclude from the main OBB. The default settings include everything in the cache and exclude everything which is pulled into the main APK to launch the engine.
   - **If building only a patch OBB:**
     a. Edit the `zip` attribute on the `PakAssets` and `PakUnpackedAssets` jobs to change references from `${obb_pak}` to `${obb_patch_pak}`.

```
<PakAssets>
  <Job sourceroot="${src_game}" input="${assets_files}"
      zip="${obb_patch_pak}" exclude="${assets_files_excludes}"/>
</PakAssets>

<PakUnpackedAssets>
  <Job sourceroot="${tmp_folder}" input="*." zip="${obb_patch_pak}" exclude=""/>
</PakUnpackedAssets>
```

b. Edit the values of `<Properties>` to properly reference the files that you wish to include and exclude from the patch OBB. The default settings include everything in the cache and exclude everything which is pulled into the main APK to launch the engine.

- **If building both patch and main OBBs:**
  a. Copy the existing `PakAssets` job to a new job, `PakPatchAssets`. Change the values of this new job's attributes as follows.
    - Change the `input` value to `${patch_files}`.
    - Change the `zip` value to `${obb_patch_pak}`.
    - Change the `exclude` value to `${patch_files_excludes}`.

```
<PakPatchAssets>
  <Job sourceroot="${src_game}" input="${patch_files}"
      zip="${obb_patch_pak}" exclude="${patch_files_excludes}"/>
```
b. Add the following new attributes to <Properties>.

- **patch_files** – The files to include in the patch OBB. This **shouldn't** include any files from the APK and should only include files from the main OBB that are being patched. If you're only patching files in your APK, upload a new version to the Google Play Store and require users to update the main distributable instead.

  This value is formatted as a semicolon (;)-separated list of file paths relative to the asset cache. Globbing is supported.

- **patch_files_excludes** – Everything in the cache you wish to exclude from the patch OBB. Unless explicitly including assets from the APK or the main OBB in your patch, this value should include the string #{assets_files};#{assets_files_excludes}.

  This value is formatted as a semicolon (;)-separated list of file paths relative to the asset cache. Globbing is supported.

  **Tip**

  To maintain the default assets_files_excludes list, we suggest renaming it to engine_files_excludes and including this property as part of both your patch_files_excludes and assets_files_excludes.

```xml
<Properties>
  assets_files="main-obb-assets"
  patch_files="patch-obb-assets"

  engine_files_excludes="*cmakelists.*;editor\.*;${levels_pak_excludes};
  ${game_data_pak_excludes};${engine_pak_types};${engine_pak_excludes};
  ${basic_types}"
  assets_files_excludes="assets-not-in-main-obb;${engine_files_excludes}"
  patch_files_excludes="assets-not-in-patch-obb;${engine_files_excludes}"
</Properties>
```

The job to create the APK expansion files is only run when building a **release** configuration. You can always run **debug** or **profile** builds without creating new OBBs.

**Release process**

Now that you've set up your signing key and configured either for dynamic content delivery or set up your OBBs containing assets, it's time to build your release!

1. Run `lmbr_waf configure` to regenerate your Android Studio project. This action updates your project's Android configuration information to indicate that it's building a release for public deployment to a store. You're required to include the --distro-key-pass and --distro-store-pass arguments, now that your project is in Distribution mode.

   ```bash
   lmbr_waf configure --distro-key-pass=key-password --distro-store-pass=store-password
   ```

   **Important**

   You can safely ignore the following warning during configuration for Distribution mode. Your project will still be configured to use the appropriate keystores and take required actions to generate a valid APK for upload to the Google Play Store.
[WARN] The Distribution build environment is not currently supported in Android Studio, falling back to the Development build environment.

If you made any manual changes to your imported Android Studio project, review them to make sure that the project regeneration didn’t change anything important for your release.

2. Disable any remote connections to the Shader Compiler and Asset Processor used in development.
   a. Open the file `lumberyard_install_dir\dev\system_android_es3.cfg` in a text editor.
   b. Change the value of `r_AssetProcessorShaderCompiler` to `0`.

   ```
   r_AssetProcessorShaderCompiler=0
   ```
   c. Open the file `lumberyard_install_dir\dev\bootstrap.cfg` in a text editor.
   d. Change the value of `remote_filesystem` to `0`.

   ```
   remote_filesystem=0
   ```
   e. Change the value of `connect_to_remote` to `0`.

   ```
   connect_to_remote=0
   ```
   f. Save and close the file.

3. Make sure that the Shader Compiler is running, at the same network address and port used for building shaders during development. Unlike development builds, release uses the `lumberyard_install_dir\dev\shadercachegen.cfg` configuration file to connect to the Shader Compiler during release builds.
   a. Open `lumberyard_install_dir\dev\shadercachegen.cfg` in a text editor.
   b. Edit the value of `r_ShaderCompilerServer` to set it to the IPv4 address of the shader server used in development.
   c. When using the shader compiler on localhost (127.0.0.1): Start the Shader Compiler server on your machine by launching it from `lumberyard_install_dir\dev\Tools\CrySCompileServer\x64\profile\CrySCompileServer.exe`.

4. With everything configured, it’s time to build your release. Build with `lmbr_waf` and supply your distribution key information on the command line.

   ```
   lmbr_waf build_android_armv8_clang_release ^
   --distro-store-pass=distribution-keystore-password ^
   --distro-key-pass=distribution-key-password ^
   -p game_and_engine
   ```

Now your APK and any configured OBBs are ready for testing and upload to the Google Play Store! Your build products are located in the following places.

- **OBB files**: Located in `lumberyard_install_dir\dev`
- **APK**: `lumberyard_install_dir\dev\BinAndroidArmv8Clang.Release\project-nameLauncher_w_assets.apk`

If you inspect the contents of the APK, you’ll see that the only assets included are those needed for configuration and launching of the engine.
Troubleshooting Lumberyard issues on Android

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Things go wrong during development, and knowing which issues are the most commonly encountered and how to resolve them can be a big help. This topic is a knowledge base of many of the issues that users experience when they’re working with Amazon Lumberyard to develop a project for Android. This section focuses on helping you quickly identify your issue and get it resolved, so that you can get back to work.

For information on how to design assets and configure renderer settings to improve performance, see Lumberyard Performance Tuning Guidelines for Mobile Devices (p. 3215).

All of the advice in this section is specific to issues you’ll encounter when building with the Lumberyard tools, or when you’re running a project on a device and see obvious errors caused by the engine itself. For general advice and instructions on debugging your Lumberyard project for Android, see the Android Studio Debugger documentation.

If you have a question that isn’t answered here, try checking in with the Lumberyard community using one of these resources:

- The Lumberyard forums
- The unofficial Lumberyard Discord server

Topics
- Black screen when launching on a device (p. 3185)
- Maven repository warnings (p. 3186)
- Debug release APKs (p. 3187)

Black screen when launching on a device

Oftentimes, launching a build and seeing a black screen means that either a map failed to load, or shaders are missing. You can diagnose and resolve the problem by trying the following actions:

- Inspect logs from adb. Log messages from the Lumberyard engine include the string LMBR, and you can filter the output from adb logcat to display only these messages. Use the following command in a Windows command prompt to get the current device logs:

  ```
  adb logcat -s LMBR
  ```

  For more information on adb logcat and how to improve filtering and which messages are displayed, see the official Android logcat command-line tool documentation.

- Make sure that a map is being loaded upon the application launch by following these steps:
  1. Open the file lumberyard_install_dir/dev/project-name/autoexec.cfg in a text editor.
  2. Check the file for a map command. If the map is missing, or references an incorrect map name, add the following line or change the map value:

    ```
    map level-to-load
    ```
• Check to make sure that the device is allowed to connect to the shader compiler. Run through the following steps to check your configuration and make sure that everything is correctly enabled:

1. If the Shader Compiler is on a remote host, make sure that inbound traffic to the shader compiler's port on the host is allowed. By default, this port is 61453. See also Remote Shader Compiler (p. 1645) for full information on configuring to connect to a remote shader compiler.

2. If the Shader Compiler is running on the same machine with the Android device connected to it, make sure that port forwarding is set up to send traffic to the host from the Android device. By default, the Shader Compiler's port is 61453. Configure device port forwarding by running the following command in a Windows command prompt.

   ```
   adb reverse tcp:shader-compiler-port tcp:shader-compiler-port
   ```

3. Close the Shader Compiler, delete any produced assets, and restart it. Shader Compiler assets for Android are placed in `lumberyard_install_dir\dev\Cache\project-name\es3\user\cache\shaders`.

4. Delete the application from your device, rebuild, and re-deploy.

To run through the full process of setting up a connection from your device to the Shader Compiler, see Connect to the Shader Compiler (p. 3176) or Serving assets over the Virtual File System (VFS) (p. 3174).

### Maven repository warnings

As part of a Lumberyard build or configure, you might see some warnings similar to the following.

```
[WARN] Failed to connect to https://maven.google.com/androidx/compose/ui/group-index.xml. Access to Google's main Maven repository may be incomplete.
[WARN] Failed to connect to https://maven.google.com/androidx/core/group-index.xml. Access to Google's main Maven repository may be incomplete.
```

Behind the scenes, `lmbr_waf` is invoking the Android build tools, which use the Gradle build system. Gradle pulls up-to-date libraries and does some versioning dependency checks by pulling information from Google's Maven repositories. These warnings aren't fatal and shouldn't prevent you from producing a build, but you can remove them by updating the Gradle version for the Android Studio project generated by `lmbr_waf configure`.

To remove Maven repository errors

1. Import the project located at `lumberyard_install_dir\dev\Solutions/LumberyardAndroidSDK` into Android Studio. See Import a Gradle project to Android Studio.

2. Wait for the project to load and for the initial Gradle configure to complete.

3. At a certain point during the configuration, Android Studio will report that the Gradle plugin is ready to update by displaying a popup notification. Select update in this notification.

   ![Plugin Update Recommended](image)

   **Android Gradle Plugin is ready to update.**

4. Another dialog box will appear, informing you of the version to update to and giving you the option to see release notes. Select the **Update** button in this dialog to update the Gradle plugin and remove build warnings.
Note
If you ever regenerate your Android Studio project, you'll need to perform these steps again. As long as the project isn't overwritten, you can safely run `lmbr_waf configure` without needing to make more changes.

Debug release APKs

As part of building for release, debugging symbols are stripped from the final executable. Whether you're trying to diagnose issues before release or working on something reported by a user in your Google Play Store release, the solution is the same. Android uses special metadata associated with the APK to determine whether or not the Android debugger is allowed to connect to a release binary.

This setting is controlled through the Gradle build system. See the Android Studio documentation on enabling debugging for build variants, and debugging pre-build APKs. This documentation has a full set of instructions on how to use debug symbols generated by earlier builds with release APKs.

Reference for Android

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This section is a reference for commands and build settings used by Lumberyard when working with the Android platform. For general information and system-wide build settings or commands, see the following topics.

- Waf Commands and Options (p. 90)
- Waf Project Settings (p. 96)

Topics

- Build command reference (p. 3187)
- Waf settings (p. 3188)
- Android build configuration file (p. 3190)
- Other command-line arguments (p. 3191)
- Lumberyard project settings for Android (p. 3191)

Build command reference

This section contains information on the available build variants and commands that are used to build and deploy Android projects through `lmbr_waf`. The `lmbr_waf` commands are structured as `command_android_armv8_clang_variant`. For example, you deploy a debug build to a device with the following command:

```
lmbr_waf deploy_android_armv8_clang_debug -p game_and_engine
```

Tip
Since you never need to build the editor or any tools for Android, you can always use the `game_and_engine` project spec with any Android commands.

Valid values for all of these parts of a command are indexed here. You can also display all available Android build commands by using `lmbr_waf --help` from the command line.
**Commands**

**build**
Build the currently selected Lumberyard project.

**deploy**
Manually deploy to a connected device.

**clean**
Clean local build artifacts. This command doesn't perform any device cleanup.

**package**
Package the contents of your project into a single distributable APK.

**Build variants**

**debug**
Enables debugging. Does not change or disable any optimizations during compile time.

**profile**
Enables debugging. Does not change or disable any optimizations during compile time.

**release**
Disables debugging and strips debug symbols in the final build.

**Waf settings**

The Waf build system settings can be controlled by either setting an attribute value in `lumberyard_install_dir/dev/_WAF_/user_settings.options`, or by passing an argument on the command line. The configuration file is written in INI file format. Each of the following reference tables are named after their corresponding INI section header.

For a full reference of all configurable Waf settings, see Waf User Options and Settings (p. 78).

**Android Options**

<table>
<thead>
<tr>
<th>Attribute (config file)</th>
<th>Parameter (command line)</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>android_maven_force_http</td>
<td>--android-maven-force-http-requests</td>
<td>Forces Android Maven library requests to use HTTP instead of HTTPS.</td>
<td>False</td>
</tr>
<tr>
<td>android_asset_mode</td>
<td>--android-asset-mode</td>
<td>Specify one of the following asset packaging modes:</td>
<td>configuration_default</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• configuration_default – Use the current build configuration to determine how to package the assets (for example, loose_files for debug or profile, project_settings for release or performance).</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• loose_files – No additional processing is done on the compiled assets.</td>
<td></td>
</tr>
</tbody>
</table>
### Android Deploy

<table>
<thead>
<tr>
<th>Attribute (config file)</th>
<th>Parameter (command line)</th>
<th>Description</th>
<th>Default</th>
</tr>

<td>Name of the root Android project directory and Android Studio project name.</td>
<td>LumberyardAndroidSDK</td>
</tr>
</tbody>
</table>
Android build configuration file

Lumberyard stores some settings for the Android platform in an independent file, `lumberyard_install_dir\dev\_WAF\android\android_settings.json`. This file contains a JSON dictionary of build setting names and their values.

**Important**

After making any changes to the Android settings, run `lmbr_waf configure`. Taking this action causes your changes to be imported to the generated Android Studio project and its manifest information.

### DEV_KEYSTORE_ALIAS

The keystore alias used in the Development environment by the Android JAR signer. This value is exported to the build command's environment as `KEYSTORE_ALIAS`.

### DEV_KEYSTORE

The path to the keystore used in the Development environment by the Android JAR signer. This path should either be absolute or relative to the `lumberyard_install_dir\dev` directory. This value is exported to the build command's environment as `KEYSTORE`.

### DISTRO_KEYSTORE_ALIAS

The keystore alias used in the Distribution environment by the Android JAR signer. This value is exported to the build command's environment as `KEYSTORE_ALIAS`.

### DISTRO_KEYSTORE

The path to the keystore used in the Distribution environment by the Android JAR signer. This path should either be absolute or relative to the `lumberyard_install_dir\dev` directory. This value is exported to the build command's environment as `KEYSTORE`.

### BUILD_TOOLS_VER

The version of the Android build tools to use. The value can either be `latest` to use the most recent version of the Android build tools, or a specific version identifier.

### SDK_VERSION

The SDK version to use. The value must be in the format `android-apilevel`, where `apilevel` is the API level of the SDK.

### NDK_PLATFORM

The NDK version to use. The value must be in the format `android-version`, where `version` is the major version number of the NDK.

### BUILD_ENVIRONMENT

Selects which environment is being built for. Valid values are Development and Distribution (case-sensitive).

#### Development

The default environment, used for daily development. Building for the Development environment doesn't require a key store or signing key.
Distribution

Build for distribution to the Google Play Store. This environment requires that you use the --distro-key-pass and --distro-store-pass arguments to access the distribution key store and your signing key.

Other command-line arguments

Android builds use some command-line arguments that are not stored in a configuration file because they would contain sensitive data, or are best for one-off use. There are also some arguments that override some settings that are less commonly changed.

--android-sdk-version-override

Override the Android SDK version used in the Java compilation. Only works during configure.

--android-ndk-platform-override

Override the Android NDK platform version used in the native compilation. Only works during configure.

--dev-store-pass

The password for the development keystore. Lumberyard ships with a store with the password Lumberyard by default. This default password is used in the Development environment if this command-line argument is missing.

--dev-key-pass

The password for the development key. Lumberyard ships with a self-signed key with the password Lumberyard in its default key store. This default password is used in the Development environment if this command-line argument is missing.

--distro-store-pass

The password for the distribution keystore. This argument is required when using the Distribution environment.

--distro-key-pass

The password for the distribution key. This argument is required when using the Distribution environment.

--deploy-android-attempt-libs-only

Push only the changed native libraries. If deploy_android_executable is enabled, it takes precedence if the executable was modified. This option is ignored if deploy_android_clean_device is enabled. This argument only works when deploying to a rooted device.

Lumberyard project settings for Android

As part of every Lumberyard project, there is a settings file that describes the application and per-project build settings. This file is located at lumberyard_install_dir/dev/project-name/project.json. Within the JSON dictionary contained in this file is the key android_settings, with a value of a JSON dictionary that contains the settings used by your project when building and deploying for Android.

package_name

Android application package identifier. Used for generating the project-specific Java activity class and as part of AndroidManifest.xml. The identifier must be in reverse domain name format.

For more information, see the Android Application ID documentation.
Type: String

Default: "com.lumberyard.sdk"

**version_number**

Internal application version number. Used to set the "android:versionCode" value of AndroidManifest.xml.

Type: Integer (32-bit)

Default: 1

**version_name**

Human-readable version number, displayed in the Google Play Store. Used to set the "android:versionName" value of AndroidManifest.xml.

Type: String

Default: "1.0.0.0"

**orientation**

The orientation of the Android app. Used to set the "android:screenOrientation" value of AndroidManifest.xml.

For valid values, see the Android Activity documentation.

Type: String

Default: "landscape"

**icons**

A map of icon override paths based on screen DPI. All entries should be paths relative to
lumberyard_install_dir/Code/project-name/Resources or an absolute path.

Available options:
- default – Default image used if a specific DPI is not specified
- mdpi – Medium ~160 DPI
- hdpi – High ~240 DPI
- xhdpi – Extra high ~320 DPI
- xxhdpi – Extra-extra high ~480 DPI
- xxxhdpi – Extra-extra-extra high ~640 DPI

For more information on Android screen DPI settings, see the Android screen compatibility documentation.

**Example**

```json
"icons" : {
  "default" : "AndroidLauncher/icon-xhdpi.png",
  "mdpi" : "AndroidLauncher/icon-mdpi.png",
  "hdpi" : "AndroidLauncher/icon-hdpi.png",
  "xhdpi" : "AndroidLauncher/icon-xhdpi.png",
  "xxhdpi" : "AndroidLauncher/icon-xxhdpi.png",
  "xxxhdpi" : "AndroidLauncher/icon-xxxhdpi.png"
}
```
app_public_key

The app license key that the Google Play store provides. Required for using APK expansion files or other Google Play Services.

Type: String

Default: "NoKey"

app_obfuscator_salt

Salt used in the signing of OBB files.

Type: String (Base64)

Default: ""

use_main_obb

Specify if the "Main" APK Expansion file should be used. This option toggles the APK expansion file mode in release builds.

Type: String ("true" | "false")

Default: "false"

use_patch_obb

Specify if the "Patch" APK expansion file should be used. This option toggles the APK expansion file mode in release builds.

Type: String ("true" | "false")

Default: "false"

enable_key_screen_on

Enable or disable the screen wake lock. If true, the device won't go to sleep while the activity is active.

Type: String ("true" | "false")

Default: "false"

disable_immersive_mode

Disable the hiding of top and bottom system bars.

Type: String ("true" | "false")

Default: "false"

rc_pak_job

Path to the RC job XML file that's used to override the normal APK expansion file generation that's used in release builds.

The path must be relative to lumberyard_install_dir/dev/Bin64/rc.

Type: String (Path)

Default: "RCJob_Generic_Android_MakeObb.xml"

multi_window_options

Information for multi-window support when targeting Android N (API 24) or later.
The keys used in this dictionary for window settings are as follows:

**enabled**

Activate or deactivate multi-window support.

Type: Boolean

Default: false

**default_width**

The preferred density-independent pixel width of the application when launching in multi-window mode. This measurement is in dp, which is always calculated against a 160dpi screen (1dp = 1 pixel on a 160dpi screen).

Type: Integer

Default: None

**default_height**

The preferred density-independent pixel height of the application when launching in multi-window mode. This measurement is in dp, which is always calculated against a 160dpi screen (1dp = 1 pixel on a 160dpi screen).

Type: Integer

Default: None

**min_width**

The minimum density-independent pixel width that your application can run in multi-window mode. Your application is cropped if the window is smaller than this value.

This measurement is in dp, which is always calculated against a 160dpi screen (1dp = 1 pixel on a 160dpi screen).

Type: Integer

Default: None

**min_height**

The minimum density-independent pixel height that your application can run in multi-window mode. Your application will be cropped if the window is smaller than this value.

This measurement is in dp, which is always calculated against a 160dpi screen (1dp = 1 pixel on a 160dpi screen).

Type: Integer

Default: None

**gravity**

The preferred starting location of the window when launched in multi-window mode.

See the Android LinearLayout documentation for valid values.

Type: String

Default: None

Type: Dictionary

Default: Empty
iOS Support

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use Lumberyard to create applications for iOS devices (p. 3166). The topics in this section will teach you how to generate assets that your app can load, and how to build and debug code. You will also learn about the different types of apps that you can generate for development purposes or to release publicly.

Lumberyard includes four iOS-supported sample projects that you can use to learn how to build assets for iOS games using Asset Processor, build shaders using the remote shader compiler, and build and deploy iOS apps using the Lumberyard build tools. For more information, see Using Lumberyard sample projects and levels (p. 142).

Lumberyard has the following minimum requirements for iOS:

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Requirement Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU</td>
<td>ARM v8 or newer</td>
</tr>
<tr>
<td>GPU</td>
<td>A8 or newer</td>
</tr>
<tr>
<td></td>
<td>Supports Metal</td>
</tr>
<tr>
<td>OS</td>
<td>iOS 13 or newer</td>
</tr>
<tr>
<td>Example devices</td>
<td>iPhone 6 and newer</td>
</tr>
</tbody>
</table>

Prerequisites

To build apps for iOS devices, you must have the following:

- Xcode 11 or later
- iOS 13 SDK or later
- Lumberyard Mac Support Files
- Lumberyard installed on a Windows computer
- Lumberyard installed on a macOS computer
- Familiarity with Lumberyard Editor, the Shader Compiler, and Asset Processor
- Ability to build from a command line tool
- Previously built the macOS code and optionally the PC code

To set up your environment, use the Lumberyard Setup Assistant (located in the lumberyard_version\dev\Tools\LmbrSetup\Mac directory) to select the following:

- Create, Modify and Build projects
- Compile for iOS devices

The Setup Assistant will install the required third-party software and SDKs.

Lumberyard Binaries

During installation, Lumberyard creates the following directories for its binaries:
Mac

- BinMac64

PC

- Bin64vc142 (for binaries generated with Visual Studio 2019)

Anatomy of a Lumberyard iOS App

The Lumberyard build system can generate the following types of applications:

- Development app
- VFS app
- Release app

**Note**

Lumberyard Editor is currently supported on Windows only. You must export each level of your game project prior to using Asset Processor for your assets.

Development App

You will use a Development app throughout most of your development cycle. Your app must connect to the Remote Shader Compiler in order to compile the shaders into a format that the iOS device can read. Your app connects to the shader compiler over WiFi or through Asset Processor. Asset Processor generates the Development app executable and its assets, which can be loose files or PAK files.
You can use the VFS app with the Virtual Filing System (VFS). While similar to a Development app, the VFS app also contains the `bootstrap.cfg` and `game.xml` configuration files in your build. After reading these configuration files, the app connects to your macOS or Windows computer and uses the assets from the local Cache directory. This allows you to iterate content and see the changes on your device in real time.

Your app must also connect to the Remote Shader Compiler in order to compile the shaders into a format that the iOS device can read. Your app connects to the shader compiler over WiFi or through Asset Processor on startup. You can optionally choose to direct traffic to and from the Remote Compiler through Asset Processor.
Release App

The Release app contains the executable and all binaries and assets that are required for your app to run. The assets and shaders must be PAK files because the app will not connect to the Remote Shader Compiler or Asset Processor.
Topics

- Quick Start: Running the Samples Project on iOS Devices (p. 3200)
- Building Your iOS App (p. 3201)
- Creating a Release App (p. 3204)
- Using Virtual File System with iOS (p. 3208)
- Universal Remote Console (p. 3209)
- Sharing Assets Between Windows and macOS (p. 3211)
- Add iOS Frameworks to a Lumberyard project (p. 3212)

Quick Start: Running the Samples Project on iOS Devices

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use this quick start to learn how to run the Samples Project (p. 146) on your iOS device from a macOS computer.

This topic assumes that you have:
- Xcode installed on your macOS computer
- Lumberyard installed on your macOS computer
- An iOS device connected to your computer with a USB cable
- Lumberyard installed on a Windows computer
- Remote Shader Compiler running on your Windows or macOS computer

For more information about creating iOS apps, see iOS Support (p. 3195).

To run the Samples Project on an iOS device
1. Use Lumberyard Setup Assistant to install the required third-party software and SDKs for iOS.
   a. On your macOS computer, navigate to the `lumberyard_version\dev\Tools\LmbrSetup\Mac` directory and double-click `SetupAssistant.exe`.
   b. If you see a Custom Install box, click Customize and then verify that the engine root path is correct.
   c. On the Get Started page, select the following:
      - Create, Modify and Build projects
      - Compile for iOS devices
   d. Complete the Lumberyard Setup Assistant wizard. For more information, see Running Lumberyard Setup Assistant (p. 16).
2. Configure Asset Processor for iOS.
   a. Use your preferred text editor to open the `AssetProcessorPlatformConfig.ini` file. You can find this file in the `lumberyard_version\dev\` directory.
   b. Remove the preceding semicolon to uncomment `ios=enabled`.
   c. Save the file.
3. Launch Asset Processor.
   a. Navigate to the following directory and double-click `AssetProcessor.exe`:
      - On Windows: `lumberyard_version\dev\Bin64vc141\`
      - On macOS: `lumberyard_version\dev\BinMac64`
   b. In Asset Processor, verify that the Status is Idle.
4. In a command line or Terminal window, do the following:
   a. Change directory to the `lumberyard_version\dev\` directory.
   b. Type the following:
      • On Windows: `lmbr_waf.bat configure`
      • On macOS: `sh lmbr_waf.sh configure`

5. On your Windows or macOS computer, set the IP address for the remote shader compiler server.
   a. Use your preferred text editor to open the `system_ios_ios.cfg` file. You can find this file in the `lumberyard_version\dev\` directory.
   b. Set `r_ShaderCompilerServer` to the IP address of your Windows computer that runs the shader compiler.
   c. Save the file.

6. Build and deploy the code.
   a. Navigate to the `lumberyard_version\dev\Solutions\` directory and open the `LumberyardiOSSDK.xcodeproj` file.
   b. Click **Run** to build and deploy the code to your iOS device.

**Building Your iOS App**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Set up your build environment and build an app that can run on an iOS device.

You must do the following:

1. Configure a game project (p. 3201).
2. Prepare your assets (p. 3202).
3. Configure the build system (p. 3202).
4. Modify your user settings (p. 3203).
5. Run the Remote Shader Compiler (p. 3203).
6. Build code from the command line (p. 3204).

**Step 1: Configure a Game Project**

You have two options for configuring a game project:

- Use the **Samples Project** (p. 142) in the `lumberyard_version\dev\` directory as a foundation for your own game project.
- Create a new game project. For more information, see Creating and Switching Game Projects (p. 44).
To configure a game project

1. On your Windows computer, navigate to the \lumberyard_version\dev\Tools\LmbrSetup\Mac\ directory and open the Project Configurator.
2. In the Project Configurator, do one of the following:
   - Select SamplesProject and then click Set as default. Follow the instructions for switching game projects (p. 48).
   - Click Create new. Follow the instructions for creating a game project (p. 44).
3. If you created a new game project, do the following:
   - a. In the Project Configurator, select your game project name and then click Set as default.
   - b. In Lumberyard Editor, open your level and then press Ctrl+E. This will export the levels you have created.
4. (Optional) Configure system components and memory settings for your game project. For more information, see Configuring Advanced Settings (p. 49).

Step 2: Prepare Your Assets

You can generate the data for your app on a computer running either Windows or macOS. If you choose to use a Windows computer, you must configure your Windows computer and iOS device to share the same network. For more information, see the Run the Remote Shader Compiler (p. 3203) page.

To prepare your assets

1. Do the following to configure Asset Processor for iOS:
   - a. Navigate to the \lumberyard_version\dev\ directory.
   - b. Use your preferred text editor to open the AssetProcessorPlatformConfig.ini file.
   - c. Remove the preceding semicolon to uncomment ios=enabled.

   ```
   [[Platforms]
   ;pc=enabled
   ;es3=enabled
   ios=enabled
   ;osx_gl=enabled
   ```
   - d. Save the file.
2. Do the following to launch Asset Processor:
   - a. Navigate to the following directory:
     - On a Windows computer: \lumberyard_version\dev\Bin64vc141
     - On a macOS computer: \lumberyard_version\dev\Bin64Mac/
   - b. Double-click AssetProcessor.exe.
   - c. In Asset Processor, verify that the Status is Idle.

Step 3: Configure the Build System

When you build the engine and tools code for macOS or Windows, you initialize the build system and generate project files for Xcode.

To configure the build system

1. In a command line window, type sh \lmbr_waf.sh configure
2. Verify that you see the following in the comments from the build system:

```
mac config
[WAF] 'xcode_ios' finished successfully (3.610s)
[WAF] 'xcode_mac' finished successfully (3.507s)
```

### Step 4: Modify Your User Settings

Update your configuration file to help increase the compilation speed and deployment when you build your game project.

**To modify your user settings**

1. Use your preferred text editor to open the `user_settings.options` file. You can find this file in the `lumberyard_version\dev\WAF\` directory.
2. Under `[Build Options]`, set `use_uber_files` to `True`.
3. Save the file.

### Step 5: Run the Remote Shader Compiler

Lumberyard uses a versatile shader system to achieve high quality, realistic graphics. When you run a game on an iOS device during development, you must connect to a remote shader compiler on your Windows or macOS computer. This compiles the subset of shaders required by your game, on demand.

When a new shader is compiled, the game waits for the remote shader compiler to compile the binary shader permutation and then send it back to your device. Once this occurs, the shader is cached on your device until you delete the app. When you are ready to release your game, you must pack up and include all cached binary shaders.

**Note**

You can also run the remote shader compiler on an Amazon EC2 instance. For information, see [Running the Shader Compiler on Amazon EC2](p. 3239).

**Prerequisites**

To use the remote shader compiler, you must do the following:

- (First time only) Create a `config.ini` file that tells the remote shader compiler the addresses from which to accept connections. For instructions, see the procedure below.
- Connect the remote shader compiler host computer and iOS device to the same network and configure any firewalls to allow traffic through port 61453.
- Set up the system configuration file (`system_ios_ios.cfg`) for the mobile device to connect to the remote shader compiler on your computer.

You can use an allow list to specify the IP addresses that are allowed to connect to your remote shader compiler. For information, see [Creating an allow list for the Remote Shader Compiler](p. 1647).

**Enabling a Connection Between the iOS App and the Remote Shader Compiler**

You must modify certain configuration files to allow your iOS app to connect to the shader compiler.

**To allow your iOS app to connect to the shader compiler**

1. Do the following on your macOS computer:
   
   a. Use your preferred text editor to open the `system_ios_ios.cfg` file. You can find this file in the `lumberyard_version/dev/` directory.
b. Set the r_ShaderCompilerServer console variable to the IP address of the host computer on which you are running the shader compiler.

c. Save the file.

2. Do the following on your computer that runs the shader compiler:

a. If one doesn't yet exist, create a config.ini file in one of the following directories:
   - On Windows: `lumberyard_version\dev\Tools\CrySCompileServer\x64\profile\`
   - On macOS: `lumberyard_version/dev/Tools/CrySCompileServer/osx/profile/`

b. Use your preferred text editor to open the config.ini file.

c. For whitelist= <device_ip_address>, replace <device_ip_address> with the IP address, in CIDR format, of your iOS device.

d. Save the file.

3. On your shader compiler host computer, launch CrySCompileServer from one of the following directories:

   - On Windows: `lumberyard_version\dev\Tools\CrySCompileServer\x64\profile\`
   - On macOS: `lumberyard_version/dev/Tools/CrySCompileServer/osx/profile/`

**Step 6: Build Code from a Command Line**

Configure and build various targets of your app, depending on your mode of development. You can create a debug, profile, or release build.

- **Debug** – Allows you to see your code running under a debugger. This build is slowest to run.
- **Profile** – Allows you to debug your code, though some code may be optimized and difficult to trace. This build runs faster on your iOS device.
- **Release** – Includes all required asset and shader .pak files for a release version of your iOS game. This build runs the fastest; however, special steps are required to generate the build. For more information, see Creating a Release App (p. 3204).

When you build code from a command line, you must take an additional step to run your app on an iOS device. You use Xcode to open the LumberyardiOSSDK.xcodeproj project that is generated in the `lumberyard_version/dev/Solutions/` directory. Then you select your device, follow the standard procedure to build and run on the device, set breakpoints, and inspect variables.

**To build code from a command line**

1. On your macOS computer, in a Terminal window, navigate to the `lumberyard_version/dev/` directory.

2. Build various targets of your game:

   - To build debug, type: `sh lmbr_waf.sh build_ios_debug -p all`
   - To build profile, type: `sh lmbr_waf.sh build_ios_profile -p all`
   - To build release, type: `sh lmbr_waf.sh build_ios_release -p all`

**Creating a Release App**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Once you have finished your Lumberyard iOS game, you can prepare it for the App Store by creating a release app and including the assets and shaders in .pak files. You must do the following:

1. **Prepare your code (p. 3205).**
2. **Modify your settings (p. 3205).**
3. **Create .pak files (p. 3205).**
4. **Configure the App Store settings (p. 3207).**
5. **Generate a build (p. 3207).**

## Preparing Your Code

Modify the code in the IConsole.h file to enable the creation of mobile release builds.

### To modify the IConsole.h file

1. On your macOS computer, navigate to the `lumberyard_version\dev\Code\CryEngine\CryCommon\` directory.
2. Use your preferred text editor to open the `IConsole.h` file.
3. Modify line 41 as follows:

   ```cpp
   //Enable modification of CVARS for mobile release builds
   #if defined(AZ_PLATFORM_APPLE_IOS)
   #define ALLOW_CONST_CVAR_MODIFICATIONS 1
   #else
   #define ALLOW_CONST_CVAR_MODIFICATIONS 0
   #endif
   ```

4. Save the file.

## Modifying Your Settings

Modify the settings in your system configuration file to disable communication between the iOS device and the remote shader compiler. For release builds, Lumberyard packages the shaders directly to the iOS device instead of compiling shaders on demand.

### To modify the system configuration file

1. On your macOS computer, navigate to the `lumberyard_version\dev\` directory.
2. Use your preferred text editor to open the `system_ios_ios.cfg` file.
3. Set the following console variables to 0.

   ```
   • r_AssetProcessorShaderCompiler
   • r_ShadersRemoteCompiler
   • r_ShadersAllowCompilation
   ```

4. Save the file.

## Creating .Pak Files

Lumberyard apps use .pak files to include assets and shaders for your app build. The .pak files are required for release apps and must be created manually.

### Topics

- Building Shader .Pak Files (p. 3206)
- Deploying Shader .Pak Files (p. 3206)
Building Shader .Pak Files

Use the Remote Shader Compiler to generate the shaders that are packed into your app build. You must run your app in profile or debug and view every surface in your game level to capture all shader permutations. Lumberyard supports both GMEM 128 and GMEM 256 and generates shaders on the highest version that a device supports. As a result, you must run your game on two devices, one that supports GMEM 128 and one that supports GMEM 256.

To generate shaders for your iOS app

1. Build, deploy, and run your game in profile or debug mode. For information, see Building Your iOS App (p. 3201).
2. In your game, explore every area in every level to ensure that all shader permutations required for the game are generated. Exit the game when you are finished.

To build a shader .pak file

1. Run the Remote Shader Compiler. For more information, see Running the Remote Shader Compiler (p. 1646).
2. In a command line window, navigate to the \lumberyard_version\dev\ directory and locate the lmbr_pak_shaders.sh file.
3. To use the lmbr_pak_shaders.sh file, enter a command that provides the name of the game project and the platform.

```
lmbr_pak_shaders.sh game_project_name METAL ios
```

Example

To build the shaders for the Samples Project, enter the following command:

```
lmbr_pak_shaders.sh SamplesProject METAL ios
```

Deploying Shader .Pak Files

When the batch file finishes building the shader .pak file for your game project, verify that the following files exist in the \lumberyard_version\dev\Build\ios\game_project_name\ directory:

- ShaderCache.pak – Contains all compiled shaders that are used only when the shader cannot be found in the current level's shader cache.
- ShaderCacheStartup.pak – Contains a subset of compiled shaders that are used to accelerate the startup time of the engine.

To pack assets for your app

1. Navigate to the \lumberyard_version\dev\ directory.
2. Copy the Build<game_project_name>_Paks_PC.bat file and rename it to Build<game_project_name>_Paks_iOS.bat.
3. Use your preferred text editor to open the Build<game_project_name>_Paks_iOS.bat file.
4. Edit the file as follows:
   - Line 20: \%BINFOLDER%\AssetProcessorBatch.exe /gamefolder=game_project_name /platforms=ios
iOS Support

- Line 25: `%BINFOLDER%\rc\rc.exe /job=%BINFOLDER%\rc
\RCJob_Generic_MakePaks.xml /p=ios /game=game_project_name

5. Save the file.
6. Run the `Build<game_project_name>_Paks_iOS.bat` file and wait for the .pak files to finish building.

Using Shader .Pak Files

Add the shader .pak files to your Xcode project.

To use shader .pak files

1. Navigate to the `lumberyard_version\dev\Cache\game_project_name\ios_paks\` directory. The generated .pak files are saved here.
2. Do one of the following to add the .pak files to your Xcode project:
   - If you're sharing the Cache directory between your Windows and macOS computers, reopen your Xcode project. This will add the files to your Resources directory.
   - Copy the `ios_paks` directory and save it in the `lumberyard_version\dev\Cache\game_project_name\` directory on your macOS computer. Then reopen your Xcode project.

Configuring the App Store Settings

Every Lumberyard project includes an Info.plist file that contains the default values for the following settings:

- Display name
- App icon
- Splash screen
- Screen orientation
- Other related settings

You can access the Info.plist file in the `lumberyard_version\dev\Code\game_project_name\Resources\IOSLauncher\` directory. The default app icons and splash screens are in the Images.xcassets directory. For information about using the default app icons and splash screens, see the Lumberyard Logos and Branding Guidelines.

Verify the Info.plist file is writeable and then use Xcode to modify the values for these settings. For information about modifying these settings in Xcode, see Configuring Your Xcode Project for Distribution.

Generating a Build

After generating all required asset and shader .pak files, you can use Xcode to build, deploy, run, and archive the release version of your iOS app. Use the same method that you would use for any Xcode project. For more information, see Prepare for app distribution in the XCode Help.

To generate a build

1. On your macOS computer, open Xcode.
2. In Xcode, navigate to your project and then choose Edit Scheme.
3. On the project page, for Build Configuration, select release.
4. Build your project as you would any Xcode project.
5. In the menu, choose **Product, Archive**.
6. In the dialog box, on the **Archives** page, click **Export**.
7. Generate your iOS app.

**Using Virtual File System with iOS**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

If you frequently change assets, you can configure Asset Processor on your macOS computer to use the virtual file system (VFS) to serve asset files to your iOS app. When you modify an asset, it is automatically reloaded without restarting the app. This method may result in slower load times because assets are sourced directly from your computer instead of the mobile device.

**Prerequisites**

Before you can use the VFS with iOS, you must download the usbmuxconnect package and save to a location on your macOS computer.

**Setting up VFS**

On your macOS computer, set up VFS to enable asset processing for iOS.

**To set up VFS on a macOS computer**

1. Do the following to configure Asset Processor for iOS:
   a. Navigate to the `lumberyard_version\dev\` directory.
   b. Use your preferred text editor to open the `AssetProcessorPlatformConfig.ini` file.
   c. Remove the preceding semicolon to uncomment `ios=enabled`.

   ```ini
   [Platforms]
   pc=enabled
   ;es3=enabled
   ios=enabled
   
   d. Save the file.

2. Do the following to update the bootstrap configuration settings:
   a. Navigate to the `lumberyard_version\dev\` directory.
   b. Use your preferred text editor to open the `bootstrap.cfg` file.
   c. Do the following:
      i. Set `remote_filesystem` to `1`.
      ii. Set `ios_connect_to_remote` to `0`.
      iii. Set `ios_wait_for_connect` to `1`.
      iv. Set `white_list` to the IP address of your macOS computer.

   **Note**
   Be sure to update the existing entries. Do not duplicate the entries.

3. Do the following to modify the system configuration file:
   a. Navigate to the `lumberyard_version\dev\` directory.
b. Use your preferred text editor to open the system_ios_ios.cfg file.
c. Set the r_AssetProcessorShaderCompiler console variable to 1.
d. Save the file.

4. Do the following to connect Asset Processor to the iOS device through the local host:
   a. Navigate to the lumberyard_version\dev\BinMac64 directory and launch Asset Processor.
   b. In Asset Processor, on the Connections tab, click Add Connection.
   c. For the new connection, select the Auto Connect check box. You can leave the default values for IP and Port.

5. In a Terminal window, navigate to the location where you saved the usbmuxconnect package.
6. Type the following: ./itnl --iport 22229 --lport 22229
7. Verify that Asset Processor displays one entry on the Connections tab with a status of Connected.

   Note
   If you receive a bind error message, please restart your macOS computer and try again.

Running the VFS Build

Run the VFS build on your macOS computer.

To run the VFS build

1. Do the following to update the bootstrap configuration settings:
   a. Navigate to the lumberyard_version\dev\ directory.
   b. Use your preferred text editor to open the bootstrap.cfg file.
   c. Do the following:
      i. Set remote_filesystem to 1.
      ii. Set ios_connect_to_remote to 0.
      iii. Set ios_wait_for_connect to 1.

2. Build and launch your game for iOS with Xcode. For instructions, see Creating a Release App (p. 3204).
3. Verify that Asset Processor displays an iOS connection on the Connections tab, and that your game runs on the device.

   Note
   If the device cannot be reached or you don’t see a connection in Asset Processor, stop the game, disconnect and then reconnect the device, and start again from step 1. If remote shader compilation is interrupted, you may see malformed shaders cached to your Windows computer. The malformed shaders can cause issues with subsequent runs using VFS. To resolve this issue, delete the lumberyard_version\dev\Cache\game_project_name \ios\user\ directory on your Windows computer. Then, restart the shader compiler.

Universal Remote Console

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use Console commands to modify and configure the Lumberyard runtime application. On a PC, the Console is available from Lumberyard Editor or the game. But for mobile platforms you must use a separate Windows-based application called the Universal Remote Console. With the Universal
Remote Console you can use the IP address of the machine running the Lumberyard game to connect to a remote instance of Lumberyard.

Universal Remote Console requires the use of a PC and works with both Android and iOS. Your mobile device and the PC will need to be on the same network and your firewall should be configured to allow traffic through port 4600.

To start the Universal Remote Console

1. Run `lumberyard_version\dev\Tools\RemoteConsole\RemoteConsole.exe`

2. To see output from the Lumberyard logging system, click the **Full Log** tab.

To connect to a Lumberyard game on a mobile device

1. In the `system_platform_asset.cfg` file, enter the console variable
   `log_RemoteConsoleAllowedAddresses=[IP address]`, where IP address is the address of the computer that the remote console is running on.

   For Android, use the `system_android_es.cfg` file.

   For iOS, use the `system_ios_ios.cfg` file.

2. Save the file.

3. After you update the `.cfg` file, deploy the game to mobile devices.

   For more information, see [Deploy with Lumberyard Editor (p. 3177)](https://example.com) and [Creating a Release App (p. 3204)](https://example.com).

4. If the game is already running, restart it.

5. In the Universal Remote Console, click **Targets** on the toolbar.

6. Enter the IP address of the device under **Custom IP**.
If your network allows you to assign fixed IP addresses per device, you can edit the `params.xml` file and add the new target devices, as illustrated in the following example. This file is located in the same directory as Universal Remote Console, and you can edit it with the application running.

```xml
<Targets>
  <Target name="PC" ip="localhost" port="4600"/>
  <Target name="Android" ip="192.168.1.247" port="4600"/>
</Targets>
```

This lets you select from a list of devices instead of entering the IP address each time. Once successfully connected, the status indicator in the lower right corner will turn green.

### Issuing Commands

In the **Type a command** box at the bottom of the window, enter a command like the ones that follow. This control features autocomplete and, for certain commands (like `map`), can also detect available options.

Commands include the following:

- `cl_DisableHUDText` – Disables HUD text
- `g_debug_stats` – Enables gameplay events debugging
- `r_DisplayInfo` – Displays rendering information
- `r_ProfileShaders` – Displays profiling information for the shaders

### Sharing Assets Between Windows and macOS

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the AWS Game Tech blog to learn more.

You can build your assets on a Windows computer and then use them in an iOS build. To do so, you must set up sharing between your Windows and macOS computers.

#### To set up your Windows computer for sharing assets

1. On your Windows computer, navigate to the `lumberyard_version\dev\Cache\` directory.
2. Right-click the `Cache` directory and choose **Properties**.
3. In the **Properties** window, on the **Sharing** tab, click **Advanced Sharing**.
4. In the **Advanced Sharing** window, select the **Share this folder** check box.
5. (Optional) Click **Permissions** to set permissions for specific groups or users. Add users who will modify the files on a macOS computer.
6. Click **OK**.

#### To set up your macOS computer for sharing assets

1. On your macOS computer, rename any `Cache` directories. For example, rename to `Cache.old`.
2. In the Finder, choose **Go**, **Connect to Server**.
3. For **Server Address**, type: `smb://<IP address or DNS name of Windows computer>/Cache`
4. Click **Connect**.
5. (Optional) To enable your macOS computer to connect to this shared folder on startup, do the following:
a. Launch **System Preferences** and then choose **Users & Groups, Login Items**.

b. Click the + button to add a login item.

c. In the Finder, under **Shared**, select your Windows computer.

d. Select your shared **Cache** directory and then click **Add**.

e. In a Terminal window, navigate to the **lumberyard_version\dev\** directory.

f. To create a symbolic link to the shared **Cache** directory, type: `sudo ln -s /Volumes/Cache`

g. If prompted, type your macOS password.

---

**Add iOS Frameworks to a Lumberyard project**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

As part of making changes to your core application on iOS, you may need to include bundled libraries for Darwin platforms called **Frameworks**. Frameworks are versioned bundles of libraries and their headers packaged as a single redistributable, and more common to ship for Darwin-based platforms rather than independent `.dylib` libraries and header files. When building for iOS, these frameworks need to be included in your final application bundle and code-signed like the rest of your binary. Because headers ship as part of a Framework, you don't need to explicitly export them so that the build system or your code will see the headers.

**Include frameworks in the launcher's wscript**

This section of the guide walks you through configuring your project launcher's wscript to support linking and including Frameworks, as well as . Before reading the rest of this topic, make sure that you're familiar with the general principles behind Waf build scripts in Lumberyard. For more information, see Waf Module Files (wscript) (p. 76).

1. Open the file *lumberyard_install_dir/dev/Code/LauncherUnified/wscript* in a text editor.

2. Inside the function `package(pkg)`, add the `custom_frameworks` argument when calling `pkg.package_game()`. The value of this argument is an array of paths to the frameworks that you want to include. Paths to frameworks can either be absolute or relative to *lumberyard_install_dir/dev*.  

   ```python
   pkg.package_game(
       target = '{}Launcher'.format(pkg.project),
       task_gen_name = '{}ClientLauncher'.format(pkg.project),
       platforms = ['appletv', 'darwin', 'ios'],
       client_only = True,
       exclude_test = True,
       custom_frameworks = [ path-to-framework-1, path-to-framework-2, ... ],
   )
   ```

3. Save and close the file.

4. Unless you need to also modify your `rpath` as described in the next section due to non-default framework locations, build your project.

During the build process, frameworks are copied to the @executable_path/Frameworks directory within your application bundle.
Add library search paths

If you've placed Frameworks in a location other than @executable_path/Frameworks, you need to add this directory to your project's rpath. iOS uses rpath information to find dynamic libraries to load at runtime, meaning that if your framework isn't included as a subdirectory of an rpath element, your application won't be able to load the framework library and may crash or experience other serious errors.

To add an element to your project's rpath, follow these instructions.

1. Open the file lumberyard_install_dir/dev/Code/LauncherUnified/wscript in a text editor.
2. Inside the function build(bld), add values to the ios_rpath argument when calling bld.CryLauncher(). The value of this argument is an array of rpath values to be used at runtime. rpath values should always start with @executable_path, which resolves to the root of the application bundle.

```python
bld.CryLauncher(
    # Common
target = 'ClientLauncher',
file_list = 'launcher.waf_files',
pch = 'Launcher_precompiled.cpp',
client_only = True,
exclude_test = False,
use = ['AzGameFramework'],
includes = [bld.Path('Code/CryEngine/CryCommon')],

    # Platform Specific
platform_roots = [{'root': 'Platform', 'export_includes': False}],
ios_rpath = [@executable_path/Frameworks, my-framework-directory, ...],
test_file_list = ['launcher_test.waf_files'],
test_use = ['AzTest'],
test_uselib = ['GMOCK'],
test_win_linkflags = ['/SUBSYSTEM:CONSOLE']
)
```

Important

Don't remove any values from this argument that you didn't add yourself! Removing any of the default rpath values will cause your application to crash.

3. Save and close the file.
4. Rebuild your project.

iOS Debugging and Troubleshooting

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard provides full access to the source code, which allows you to debug your iOS application using Xcode without additional Lumberyard-specific steps to follow. For information about debugging and profiling your iOS application, see Debugging in the official Apple developer documentation.

Unable to see activity in the shader compiler window

You must connect to the shader compiler on your PC in order to compile the subset of shaders required by your game, on demand. To verify that your app has connected correctly and obtained all shaders, you can view the output in the shader compiler window. If you still do not see any activity in the window,
please check your setup by following the instructions on the Run the Remote Shader Compiler (p. 3203) page.

**Assets appear out of date on iOS devices**

When you make and save changes to your project in Lumberyard Editor, these changes are automatically reflected on your iOS device the next time you deploy. Ensure you have set up your cache folder to share between your PC and Mac. If you encounter Xcode errors when deploying to your iOS devices or your assets appear out of date on the iOS devices, you can try cleaning your product from Xcode (click **Product, Clean**), which clears the .app package built to BinIos or BinIos.Debug (debug builds) in the directory where you installed Lumberyard.

Cleaning the project does not create a full rebuild of the iOS application

Lumberyard uses a custom build step to generate the final executable and temporary C++ object files, which output to the \BinTemp\ios_debug or \BinTemp\ios_profile directory where you installed Lumberyard. Unlike a regular Xcode project, in order to create a full rebuild of the iOS application, you must manually delete the contents of the output folder or run one of the following Waf commands from a Terminal window:

- To build debug, run the following command: `lmbr_waf.sh clean_ios_debug`
- To build profile, run the following command: `lmbr_waf.sh clean_ios_profile`
- To build release, run the following command: `lmbr_waf.sh clean_ios_release`

**Observed frame rate varies greatly**

While running your iOS application, the observable frame rate can vary depending on the build (debug or profile) you are running, whether you are connected to the Xcode debugger, and whether Metal API validation is enabled. To display the frame rate in the upper right corner of the screen, set the `r_DisplayInfo` configuration variable to 1 or higher. When your Xcode project is generated, the default build scheme is set up for debugging. If you want to test or profile your application's speed, we recommend that you edit your active scheme to run a profile build. Deselect **Debug executable** and disable **Metal API Validation**. Additionally, set the target resolution using the `r_WidthAndHeightAsFractionOfScreenSize` console variable or the `r_width` and `r_height` console variables in the system_ios_ios.cfg file. The default value is 1; however, you can lower the target render resolution to help improve performance. If the target render resolution is lower than the default (native device resolution), Lumberyard uses an anti-aliasing algorithm to help maintain the same level of visual quality as the native resolution.

**Design Considerations for Creating Mobile Games Using Lumberyard**

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard is a cross-platform game engine, which allows you to develop your game with less concern about the release platform(s). However, some mobile development considerations are discussed below, including game logic, input, and application lifecycle.
Application Lifecycle

Lumberyard provides a Process Life Management Gem (in the Project Configurator) that shows how you can respond to various application lifecycle events in order to pause your game, display a modal splash screen, and any other actions that need to occur if your application loses focus. You can access system-specific events in C++ by connecting to the appropriate EBus; however, Lumberyard also generates platform-agnostic events that you can use for all supported platforms.

<table>
<thead>
<tr>
<th>Lumberyard Application Lifecycle Events</th>
<th>iOS</th>
<th>Android</th>
</tr>
</thead>
<tbody>
<tr>
<td>OnApplicationConstrained</td>
<td>applicationWillResignActive</td>
<td>onPause()</td>
</tr>
<tr>
<td>OnApplicationUnconstrained</td>
<td>applicationDidBecomeActive</td>
<td>onResume()</td>
</tr>
<tr>
<td>OnApplicationSuspended</td>
<td>applicationDidEnterBackground</td>
<td>onPause()</td>
</tr>
<tr>
<td>OnApplicationResumed</td>
<td>applicationWillEnterForeground</td>
<td>onResume()</td>
</tr>
<tr>
<td>OnMobileApplicationWillTerminate</td>
<td>applicationWillTerminate</td>
<td>onDestroy()</td>
</tr>
<tr>
<td>OnMobileApplicationLowMemoryWarning</td>
<td>applicationDidReceiveMemoryWarning</td>
<td>onLowMemory()</td>
</tr>
</tbody>
</table>

To receive process lifecycle events in your game

1. Derive your class from AzFramework::ApplicationLifecycleEvents::Bus::Handler (or AzFramework::[Ios|Android|Windows]LifecycleEvents::Bus::Handler for platform-specific events).
2. Override the functions corresponding to the events you wish to override:

```cpp
void OnApplicationConstrained(Event /*lastEvent*/) override;
void OnApplicationUnconstrained(Event /*lastEvent*/) override;
void OnApplicationSuspended(Event /*lastEvent*/) override;
void OnApplicationResumed(Event /*lastEvent*/) override;
```

3. Connect to the event bus when you want to start listening for events (be sure to also disconnect when you no longer wish to receive them):

```cpp
ApplicationLifecycleEvents::Bus::Handler::BusConnect();
???
ApplicationLifecycleEvents::Bus::Handler::BusDisconnect();
```

For a complete example of how to subscribe and respond to application events, see the Gems\ProcessLifeManagement\Code\Source\ProcessLifeManagementGem.h\.cpp directory.

Lumberyard Performance Tuning Guidelines for Mobile Devices

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
See the following guidelines for generating art assets for mobile games with Lumberyard and how to tune Lumberyard performance for mobile devices.

**Topics**
- Art Guidelines (p. 3216)
- Engineering Guidelines (p. 3220)
- GPU Memory (GMEM) (p. 3221)
- Memory and App Size (p. 3223)
- Particle Rendering Features and Performance (p. 3224)

**Art Guidelines**

This section provides guidelines for geometry, lighting, cascade shadow maps, and materials.

**Geometry Guidelines**

Follow these guidelines when creating geometry for your mobile game:

- Use fewer individual objects to significantly reduce the draw calls. We recommend 750 or less draw calls on mobile devices.
- Use instances where appropriate. To do so, create a slice in Lumberyard Editor and then instantiate multiple instances of that slice in the level.
- Add support for geometry level of detail (LOD). Each LOD should be a 50% reduction of geometry.
  - Group the high resolution LOD model under \_lod0\_objectname.
  - Group the next LOD model under \_lod1\_objectname\_group.
  - Name the shadow proxy model as shadowproxy.
  - Export the shadow proxy model with the shadow proxy material.
  - Group the shadow proxy model under the last LOD group.

**Example**

The following is an LOD setup in Maya.
• Do the following to tune the LOD:
  1. In Lumberyard Editor, select an entity in your level that has a Mesh (p. 684) component.
  2. In the Entity Inspector, in the Mesh component, under Options, adjust the slider for LOD distance ratio. The slider adjusts the distance at which the LOD pops in.
  3. Tune each asset to see only the high resolution asset when needed.

• Restrict your poly count as follows for each camera view in the game:
  • For low-end devices, use 300k or below.
  • For higher-end devices, use 700k or below if the CPU is the bottleneck.

  **Note**
  To determine the poly count, set r_DisplayInfo to 1 in the Lumberyard Editor console. The debug data on the top right of the screen will display the poly number for each frame of the scene.

• In the Console pane in Lumberyard Editor, set the console variable r_stats to 1 to print the number of draw calls and polygons that the current camera renders.

**Lighting Guidelines**

Follow these guidelines when adding lighting to your mobile game:

• Carefully consider the amount of lights in your scene that cast shadows.

• Do the following to tune the lights:
  1. In Lumberyard Editor, select an entity in your level that has a Mesh component.
  2. In the Entity Inspector, in the Mesh component, under Options, adjust the value for View distance multiplier. Specify a lower value to fade out the light and stop drawing sooner. This setting is important for performance.

• Add area and projector lights only if needed. Lighting pass is expensive.

• Reduce the light area if possible. Be frugal.

• Avoid overlapping light areas.

• Avoid overlapping environment probe areas.

• Avoid covering large areas with environment probes, which can introduce artifacts on the edge of the large areas. For example, 1,000 x 1,000 is too large for an environment probe to cover. We recommend dividing an area that size into four smaller areas.

• Simulate bounced lighting with lights that don't cast shadows. Global illumination cannot be used on mobile devices.

  **Example**

  The following scene uses non-shadow casting lights to simulate global illumination (GI) bounce.
Cascade Shadow Map Guidelines

Lumberyard uses console variables to specify how to generate cascade shadow maps and to improve performance for the shadow pass. You can also set these variables to impact the engine globally or per level. Edit the level.cfg file to set the variables for a specific level. For more information, see Using the Console Window (p. 210).

- e_ShadowsCascadesDebug – Enables the debug view for the cascade shadow maps. Each cascade in the world renders with a different color to provide visual feedback of the area that is covered by a cascade shadow map.

Example

The following global shadow map (GSM) has the e_ShadowsCascadesDebug console variable set to 1.
Use the following console variables to specify the size and how to generate shadow cascades:

- **e_GsmLodsNum** – Specifies the number of shadow cascades to use. The default value is 5.
- **e_GsmRange** – Specifies the size of the first shadow cascade in square world units. The default value is 3, which covers three square units in the world. In the previous example, the first shadow cascade is drawn in red.
- **e_GsmRangeStep** – Specifies the multiplier to use to calculate the size of the next shadow cascade. The default value is 3.

For example, if you set `e_GsmRange` to 3, the first shadow cascade covers three square units in the world. To calculate the next shadow cascade size, Lumberyard multiplies the first shadow cascade and the value for `e_GsmRangeStep`. If the value for `e_GsmRangeStep` is the default value of 3, the next shadow cascade would cover nine square units in the world. The next shadow cascade would cover 27 square units in the world, and so on.

When you set console variables, try to balance reducing the size and number of cascade shadow maps and maintaining the visual quality of your game. You can set `e_shadows` to 0 to turn off shadows, which may be necessary for low-end devices.

The following images demonstrate how the global shadow map (GSM) console variables affect the shadow cascade size and coverage distance.

---

**Example images for GSM impact on shadow cascade size and coverage distance**

<table>
<thead>
<tr>
<th>Description</th>
<th>Console Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set the <code>e_GsmRange</code> console variable to 1 to reduce the size of the shadow cascade.</td>
<td><code>e_GsmRange</code></td>
<td>1</td>
</tr>
<tr>
<td>Set the <code>e_GsmRangeStep</code> console variable to 1.5 to reduce the area that each consecutive cascade covers.</td>
<td><code>e_GsmRangeStep</code></td>
<td>1.5</td>
</tr>
<tr>
<td>Set the <code>e_GsmLodsNum</code> console variable to 3 to reduce the number of shadow cascades that Lumberyard uses.</td>
<td><code>e_GsmLodsNum</code></td>
<td>3</td>
</tr>
</tbody>
</table>
Material Guidelines

Follow these guidelines when creating materials for your mobile game:

- Use fewer individual objects and materials to significantly reduce the draw calls.
- Use texture atlases to reduce the number of materials or submaterials needed, reduce the draw calls, and increase performance.
- Reduce the texture size to 1024 x 1024 or less.

Engineering Guidelines

Lumberyard provides four levels of configuration files to support enabling and disabling features and functionality based on performance characteristics of the mobile devices. You can find the following files in the `lumberyard_version/dev/Engine/Config/spec` directory:

- `ios_low.cfg`
- `ios_medium.cfg`
- `ios_high.cfg`
- `ios_veryhigh.cfg`
- `android_low.cfg`
- `android_medium.cfg`
- `android_high.cfg`
- `android_veryhigh.cfg`

Each file includes a set of console variables in which you can enable or disable engine features.

You can also edit the configuration files in the Graphics Settings window in Lumberyard Editor.

To edit configuration files in Lumberyard Editor

1. In Lumberyard Editor, choose Edit, Editor Settings, Graphics Settings.
2. In the Graphics Settings window, do the following:
   a. For Platform, select your device such as iOS.
   b. For the preferred configuration file, adjust the values for the various console variables. For example, if you select iOS, console variables and values for each configuration file appear (ios_low.cfg, ios_medium.cfg, ios_high.cfg, and ios_veryhigh.cfg).

When you edit the console variables for the configuration file, the renderer displays onscreen how the level may look on a mobile device.
Using android_models.xml and ios_models.xml Files

Lumberyard uses two .xml files to determine which mobile devices use the low, medium, high, or very high configuration settings files. You can find the android_models.xml and ios_models.xml files in the /lumberyard_version/dev/Engine/Config/gpu directory.

Example android_models.xml file

The Samsung Galaxy S5 line shows that Lumberyard supports the use of regular expressions when you specify the device model number. If a device model is listed more than once, the last instance is read and used with the corresponding configuration file.

```xml
<DeviceList>
  <Config file="android_low.cfg">
    <Device model="KFTHWI"/> <!-- Amazon Kindle Fire HDX -->
    <Device model="Nexus 7"/> <!-- Nexus 7 -->
    <Device model="Nexus 5"/> <!-- Nexus 5 -->
    <Device model="SM-N910H"/> <!-- Samsung Galaxy Note 4 (Asia-Pacific)-->
    <Device model="SM-G900\w{1,2}"/> <!-- Samsung Galaxy S5 -->
  </Config>
  <Config file="android_medium.cfg">
    <Device model="SM-T217S"/> <!-- Samsung Galaxy Tab 3 -->
    <Device model="SM-N920C"/> <!-- Samsung Note 5 -->
  </Config>
  <Config file="android_high.cfg">
    <Device model="Nexus 6"/> <!-- Motorola Nexus 6 -->
    <Device model="Pixel"/> <!-- Google Pixel -->
  </Config>
  <Config file="android_veryhigh.cfg">
  </Config>
</DeviceList>
```

GPU Memory (GMEM)

GPU memory (GMEM) is a class of optimizations that uses local memory on the GPU to reduce the transfer of large textures between the CPU and GPU. GMEM can operate in the following modes, depending on what the mobile device can support:
• 256 bit mode – The engine can store three GBuffer render targets and depth or stencil in the local GPU pixel memory, while doing the preliminary Z pass, generating the GBuffer, deferring decals, and deferring rain and snow passes. This mode also stores the diffuse and specular light accumulation textures in the local GPU pixel memory during the deferred shading passes of the renderer.

• 128 bit mode – This mode stores the diffuse and specular light accumulation textures in the local GPU pixel memory during the deferred shading passes of the renderer. Compared to the 256 bit mode, the 128 bit mode provides less of a performance boost. However, with the 128 bit mode you can enable certain rendering features that are not available if you use the 256 bit mode.

• Disabled – This mode means that GMEM is not supported or has been disabled in the configuration files.

The renderer uses two OpenGL extensions to determine which GMEM mode is supported for Android devices:

• Framebuffer fetch (256 bit mode)
• Pixel Local Storage (128 bit mode)

For the iOS devices that Lumberyard supports, both GMEM 256 bit mode and 128 bit mode are supported.

Setting the GMEM Mode

You can enable or disable GMEM with the r_EnableGMEMPath console variable.

• 0 = Disables GMEM in the renderer.
• 1 = Enables the renderer to use GMEM in 256 bit mode. If the mobile device doesn't support 256 bit mode, the renderer will use 128 bit mode. If the mobile device doesn't support 128 bit mode, the renderer will disable GMEM.
• 2 = Enables the renderer to use GMEM in 128 bit mode.

You can only enable or disable GMEM during engine startup. You must add the r_EnableGMEMPath console variable to one of the following files:

• android_low.cfg
• android_medium.cfg
• android_high.cfg
• android_veryhigh.cfg
• ios_low.cfg
• ios_medium.cfg
• ios_high.cfg
• ios_veryhigh.cfg
• system_android_es3.cfg
• system_ios_ios.cfg

Note
To prevent visual artifacts and performance issues, do not change the value of the r_EnableGMEMPath console variable during runtime.

Rendering Features and GMEM

GMEM offers the flexibility of setting the mode and rendering features to meet the visual quality and performance for a range of mobile devices. More powerful mobile devices may be able to use GMEM
128 bit mode and still meet the necessary performance requirements. You can use the configuration files for your mobile device as well as the `android_models.xml` or `ios_models.xml` files to set your requirements.

If you enable GMEM 256 bit mode, you cannot use the following features:

- Motion blur
- Temporal antialiasing
- Screen space reflections
- Screen space directional occlusion
- Fur
- Deferred subsurface scattering
- Volumetric fog
- Deferred rain or snow occlusion

If you enable GMEM 128 bit mode, you cannot use the following features:

- Fur
- Deferred subsurface scattering
- Volumetric fog
- Deferred rain or snow occlusion

If you want to use a rendering feature that GMEM 128 bit mode supports but not GMEM 256 bit mode, the renderer automatically sets the mode to 128. This is true even if the mode is set to 256 in the configuration files.

To use all available rendering features, disable GMEM.

### Memory and App Size

Because mobile devices have a limited amount of memory, you should take the necessary steps to reduce the size of your app and the amount of memory it requires. Follow these guidelines:

- Include only the resources that your game uses.
  - Enable only the gems that are required for your game. This will prevent unnecessary code and assets from being bundled into your app.
- Include only the assets that your game uses.
  - Check the `Cache` directory for your game project to see which assets the build process will pack into the app bundle.
  - On Windows, use WinDirStat to identify which assets use the most resources, and determine whether to include the assets in the app bundle or host the assets online as a separate download.
  - Remove editor-only assets, which Asset Processor adds to the `Cache` directory. This will reduce the size of the final app bundle.
  - Remove assets in the engine directory. These assets may significantly increase the size of your final app bundle, even if your game doesn't use them. The `defaulttextures.xml` file contains a list of textures that certain game projects might not use. You can find this file in the `/lumberyard_version/dev/Engine/EngineAssets` directory.
- Avoid using static allocations. This will reduce the size of your executable code and allow for safer memory management at runtime.
- Provide downloads for region-specific assets. If your app uses localized content and you plan to deploy to multiple regions, consider dividing up your app and hosting the data for each region on Amazon S3. You can then use the dynamic content system to download region-specific assets.
Android

If you want to reduce the size of a large app, you can use the tools that are included with the Android NDK to examine your executable. For example, you can use objdump or nm. The nm tool can disassemble your binary files and show the size of each code segment. The nm tool can also list symbols and detect if code is unexpectedly linked to your binary.

Particle Rendering Features and Performance

Particles use sun and light volumes to determine how they should be lit in the scene. Because light volumes are expensive on mobile devices, we do not recommend using this feature on medium to low-end devices. To specify how particles are lit, you can use the e_LightVolumes console variable with the following values:

- 0 = Particles are not affected by the sun or light volume lights.
- 1 = Particles are affected by the sun and light volume lights.
- 2 = Particles are affected only by the sun light.

Modifying Project Settings for Mobile Device Games

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Project Settings Tool (PST) to make streamlined changes to project settings across all mobile platforms. The Project Settings Tool shows properties from all of the project settings files so that you can edit and save changes at once.

Note

- Before you can use the Project Settings Tool, you must have Lumberyard Editor installed, and an active project created and set as the default project.
- Currently, only Android and iOS are supported for platform-specific configuration.

Topics

- Settings Files (p. 3224)
- Using the Project Settings Tool (p. 3225)
- Properties (p. 3229)

Settings Files

The Project Settings Tool modifies project settings files which are located in their respective project directories. The main settings file, project.json (p. 69), is located in the root directory of each project and contains cross-platform settings for platforms such as PC and Android. The file also contains platform-specific settings for PC and Android.

You can find the project settings for iOS in project_name\Root\Gem\Resources\PlatformLauncher\Info.plist. Plist files have a special format of XML that use dictionaries to store properties. All plist files have some properties that are common across platforms, yet are stored in each individual file.

For more information about .plist files, see About Info.plist Keys and Values and Core Foundation Keys.
For more information about iOS-specific settings, see iOS Keys.

Using the Project Settings Tool

You can use the Project Settings Tool to set settings related to the current project.

To open the PST

1. In Lumberyard Editor, choose File, Project Settings, Project Settings Tool.
2. In the Project Settings Tool, you can review and change your settings. For more information, pause on a property and review the tooltip. You can also see the section called “Properties” (p. 3229).
   • The Base Settings apply to all platforms.
   • The Platform Settings section has tabs for platform-specific settings.
3. If you haven’t saved your changes, and you want to reload the settings back to the way they are on disk (in your settings files), choose Reload.
Image Previews

For image settings such as Icons and Splashscreens, the Project Settings Tool displays image previews using the image to be used for each dpi or size.
Validation

The Project Settings Tool validates settings as you enter values and provides feedback when a value is invalid with the selected setting.

A red outline appears around the setting to indicate an invalid value. You can also pause on the setting to view the error message that describes the reason that the field is invalid.

Linked Properties

You can link similar properties to each other. When you link properties to one another, modifying one of them makes the same changes to all other linked properties.

To work with link properties

1. In the Project Settings Tool, navigate to the property that you want to link. Properties that you can link have a chain-link icon.
2. Pause on the link icon to see what properties are linked. Properties that you can link are automatically linked when loaded from the settings file if all relevant properties have the same value.
3. You can enable or disable any link. To enable a link, click the icon. All properties that it links to are updated with the current value.

   When a property's link is enabled and linked to a valid property, the link icon appears intact and has an orange outline.

   ![Image 1](image1.jpg)

   When a property's link is broken or disabled, the link icon appears broken and without an orange outline.

   ![Image 2](image2.jpg)

4. To disable a link, click the icon again.

   **Note**
   Some properties are always linked and can't be disabled, such as **Base Settings - Project Name** and **iOS - Bundle Name**. This ensures accuracy for properties that are required to have the same values across platforms. If the **Project Settings Tool** finds discrepancies between settings files for the always-linked properties, the **project.json** values take precedence.

**Reconfiguring the Project**

After you make changes and save, the **Project Settings Tool** prompts you to reconfigure your project.

![Image 3](image3.jpg)

If you choose to run the **configure** command, the output appears at the bottom of the window. Once the results display "Reconfiguration Finished," you can use the **Deployment Tool** to deploy to your device with the new changes.

**Note**
If you want to deploy your changes immediately, choose **Yes**. Lumberyard Editor doesn't automatically run the **configure** command and will not prompt you to do so later.
Properties

See the following properties in the Project Settings Tool.

Base Settings

The Base Settings properties apply to both Android and iOS.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Project Name</td>
<td>Name that Lumberyard uses to identify the selected project. This value should not be changed.</td>
</tr>
<tr>
<td>Product Name</td>
<td>Name to be displayed in titles for the executables or apps.</td>
</tr>
<tr>
<td>Executable Name</td>
<td>File name of the application that runs the project. This value should not be changed.</td>
</tr>
<tr>
<td>Game Folder</td>
<td>Directory name that stores all of the project's code and resources. This value should not be changed.</td>
</tr>
<tr>
<td>Game Dll Name</td>
<td>File name of the DLL used to load the game. This value should not be changed.</td>
</tr>
<tr>
<td>Output Folder</td>
<td>Directory to which the packaged project is exported after being built.</td>
</tr>
<tr>
<td>Code Folder</td>
<td>A legacy setting that specifies the directory that contains code for the project.</td>
</tr>
</tbody>
</table>

Android Settings

You can find the following properties in the Platforms Settings on the Android tab.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Package Name</td>
<td>Android application package identifier. Used for generating the project-specific Java activity class and in the AndroidManifest.xml. Must be in dot-separated format.</td>
</tr>
<tr>
<td>Version Name</td>
<td>Human-readable version number. Used to set the android: versionName tag in the AndroidManifest.xml and is displayed in Google Play.</td>
</tr>
<tr>
<td>Version Number</td>
<td>Internal application version number. Used to set the android:versionCode tag in the AndroidManifest.xml. This value must always be greater than the previously submitted build. Otherwise, submission to Google Play will fail.</td>
</tr>
<tr>
<td>Orientation</td>
<td>Desired orientation of the Android application. Used to set the android:screenOrientation tag in the AndroidManifest.xml.</td>
</tr>
<tr>
<td>Public App Key</td>
<td>Application license key provided by Google Play. Required for using APK expansion files or other Google Play Services.</td>
</tr>
<tr>
<td>App Obfuscation Salt</td>
<td>Application-specific salt value for (un)obfuscation when using APK expansion files.</td>
</tr>
<tr>
<td>Rc Job PAK Override</td>
<td>Path to the RC job XML file used to override the normal PAK files generation used in release builds. Path must be relative to dev\Bin64\rc.</td>
</tr>
<tr>
<td>Rc Job APK Override</td>
<td>Path to the RC job XML file used to override the normal APK Expansion file(s) generation used in release builds. Path must be relative to dev\Bin64\rc.</td>
</tr>
<tr>
<td>Use Main APK</td>
<td>Specifies whether the Main APK Expansion file should be used.</td>
</tr>
<tr>
<td>Use Path PAK</td>
<td>Specifies whether the Patch APK Expansion file should be used.</td>
</tr>
<tr>
<td>Enable Screen Wake Lock</td>
<td>Enables the screen wake lock. If enabled, the device won’t go to sleep while the app is running.</td>
</tr>
<tr>
<td>Disable Immersive Mode</td>
<td>Disables hiding of the top and bottom system bars.</td>
</tr>
<tr>
<td>Icons</td>
<td>All icon overrides for Android. The Default property is used on all overrides that are not explicitly specified. PNG images are required.</td>
</tr>
</tbody>
</table>
### Property | Description
--- | ---
Resolutions | Resolutions must be 48px, 72px, 96px, 144px, and 192px.

**Splashscreens**

All splashscreen (the image shown while the app first loads) overrides for Android. The **Default** property is used on all overrides that are not explicitly specified. PNG images are required.

Resolution values are not strictly enforced but the recommended values are 1024 x 640, 1280 x 800, 1920 x 1200, and 2560 x 1600.

### iOS Settings

You can find the following properties in the **Platforms Settings** on the **iOS** tab.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bundle Name</strong></td>
<td>Internal name of the bundle that iOS uses to identify it. This value should not be changed.</td>
</tr>
<tr>
<td><strong>Display Name</strong></td>
<td>User-visible name of the app that is shown in the app store.</td>
</tr>
<tr>
<td><strong>Executable Name</strong></td>
<td>Name of the bundle's generated XCode project. This value should not be changed.</td>
</tr>
<tr>
<td><strong>Bundle Identifier</strong></td>
<td>Uniquely identifies the bundle on iOS. This value should be in reverse-DNS format.</td>
</tr>
<tr>
<td><strong>Version Name</strong></td>
<td>Release version string for the app that is displayed in the App Store.</td>
</tr>
<tr>
<td><strong>Version Number</strong></td>
<td>Build version number string for the bundle. This value must be greater than the previous submission to the App Store.</td>
</tr>
<tr>
<td><strong>Development Region</strong></td>
<td>Default language and region for the app. Defined by the region in which it was developed and the primary language used during development.</td>
</tr>
<tr>
<td><strong>Requires Fullscreen</strong></td>
<td>Specifies whether the app is required to run in full-screen mode.</td>
</tr>
<tr>
<td><strong>Hide Status Bar</strong></td>
<td>Specifies whether the status bar is initially hidden when the app launches.</td>
</tr>
<tr>
<td><strong>Orientations</strong></td>
<td>Select which orientations to enable on the iOS device:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Landscape (right home button)</strong> – Enable landscape orientation with home button on right side of device.</td>
</tr>
</tbody>
</table>
### Property

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>Landscape (left home button)</strong></td>
<td>Enable landscape orientation with home button on left side of device.</td>
</tr>
<tr>
<td>• <strong>Portrait (bottom home button)</strong></td>
<td>Enable portrait orientation with home button on bottom of device.</td>
</tr>
<tr>
<td>• <strong>Portrait (top home button)</strong></td>
<td>Enable portrait orientation with home button on top of device.</td>
</tr>
<tr>
<td><strong>Icons</strong></td>
<td>All icon overrides for iOS. PNG images are required. All resolutions must be exactly as specified.</td>
</tr>
<tr>
<td><strong>Launchscreens</strong></td>
<td>All launch screen overrides for iOS. PNG images are required. All resolutions must be exactly as specified.</td>
</tr>
</tbody>
</table>

### Override Images

On iOS devices, override images are stored in the `project_root\Gem\Resources \platform\Launcher\Images.xcassets`. Within that directory, the `AppIcon.appiconset` directory contains icons and the `LaunchImage.launchimage` directory contains splashscreens.

### Example

The following image shows the default iOS icons and splashscreens. When you choose an override for one of these images, it overwrites the currently selected one. The overwrite is completed when you choose **Save**. This change can't be undone.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard supports low, medium, high, and very high graphics performance for mobile devices. You can change the graphics settings in Lumberyard Editor to simulate the graphics on Android and iOS devices. This feature helps you visually check your mobile games in Lumberyard Editor during the development process.

Updating Graphics Performance in Lumberyard Editor

Use the Graphics Performance menu in Lumberyard Editor to choose a graphics setting for Android or iOS.

To update graphic settings in Lumberyard Editor

1. In Lumberyard Editor, choose Edit, Editor Settings, Graphics Performance.
2. Choose Android or iOS and then choose a setting. For more information, see Editor Settings (p. 189).
When you choose a graphics performance setting, the `r_GraphicsQuality` console variable automatically updates with a corresponding value:

- Very High: 4
- High: 3
- Medium: 2
- Low: 1

You can change the default value for the `r_GraphicsQuality` console variable in each OS configuration file. You can find the files in the `lumberyard_version\dev\Cache\game_project\pc` directory.

**Example iOS Configuration File**

The following is an example of the `system_ios_ios.cfg` file.
If you set \texttt{r\_GraphicsQuality} to 0, the graphics performance setting is automatically detected based on the mobile device model or total RAM. You can review the mapping for mobile device models and graphics performance settings in the \texttt{android\_models.xml} and \texttt{ios\_models.xml} files, located in the \texttt{lumberyard\_version\dev\Cache\game\_project\pc\game\_project\config} directory.

Example

The following is an example of the \texttt{ios\_models.xml} file.
Modifying Graphics Configuration Files

Use the Graphics Settings window in Lumberyard Editor to modify the graphics settings for each OS configuration file. You can also modify the configuration files for the following graphics settings: low, medium, high, and very high.

To modify a graphics configuration file

1. In Lumberyard Editor, choose Edit, Editor Settings, Graphics Settings.
2. In the Graphics Settings window, for Platform, choose Android or iOS for the configuration file that you want to modify.
3. Modify the graphics settings for each parameter as needed.

4. Click **Save**.

**Note**

The configuration file saves to the `lumberyard_version\dev\game_project\Config` directory. Asset Processor prioritizes the settings in this configuration file above the engine's default configuration file, located in the `lumberyard_version\dev\Engine\Config` directory.
Adding IP Addresses to Allow Access to the Asset Processor and Remote Console

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Asset Processor is a networked application that Lumberyard uses to build source assets into game engine ready assets. To ensure your external device can connect to the Asset Processor, you must add the IP address of the external device (Android or iOS) to the `white_list` in the `bootstrap.cfg` file (located in the `lumberyard_version\dev` directory).

The Universal Remote Console is a networked application that Lumberyard uses to send commands and view output from the running game engine. To ensure remote console access to a running game instance on your external device, you must add the IP address of the computer that will run the remote console to the `log_RemoteConsoleAllowedAddresses` list in the appropriate configuration file (located in the `lumberyard_version\dev` directory):

- Android – `system_android_es3.cfg`
- iOS – `system_ios_ios.cfg`

You must update the configuration file to include the allowed IP addresses before you deploy your game to the external device.

Running the Shader Compiler on Amazon EC2

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Amazon Elastic Compute Cloud (Amazon EC2) provides a GPU instance that you can use to run the Lumberyard shader compiler for mobile (Android and iOS) and macOS development. For example, you can use the AWS device farm to test a build rather than hosting a PC on a public IP address. Amazon EC2 also provides a G2 instance type that supports advanced rendering features such as texturing, shadows, and anti-aliasing. For more information, see Amazon EC2 Instances.

To run the Lumberyard shader compiler, you must do the following:

1. Set up the Amazon EC2 instance.
2. Install virtual network computing (VNC) software.
3. Connect to the shader compiler.

Topics

- Prerequisites (p. 3240)
- Setting Up the Amazon EC2 Instance (p. 3240)
- Installing VNC Software (p. 3240)
- Connecting to the Shader Compiler (p. 3241)
Prerequisites

To run the Lumberyard shader compiler on Amazon EC2, you must have the following:

- AWS account
- Familiarity with the AWS Management Console
- Understanding of Amazon EC2 instances, VNC, security groups, and the Lumberyard tool chain

Setting Up the Amazon EC2 Instance

Before you can set up the Amazon EC2 instance, you must request a GPU instance using the Request to Increase Amazon EC2 Instance Limit link. When you are done, follow the steps below. For information about Windows GPU instances, see Windows Accelerated Computing Instances.

To set up the Amazon EC2 instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the console dashboard, choose Launch Instance.
3. On the Amazon Machine Image (AMI) page, enter GPU.
4. In the search results, select Windows Server 2012 R2 with NVIDIA GRID GPU Driver.
5. On the Choose an Instance Type page, select the g2.2xlarge type.
6. Choose Review and Launch to let the wizard complete the other configuration settings for you.
7. On the Add Storage page, add a drive with sufficient space (512 GB minimum).
8. On the Add Tags page, add a memorable tag for the computer. For example, ShaderCompilerMachine.
9. On the Review Instance Launch page, create a new security group or use an existing one.
10. Open port number 61453 for the shader compiler.
12. When prompted for a key pair, select Choose an existing key pair, and then select the key pair that you created when getting set up.
13. When you are ready, select the acknowledgement check box, and then click Launch Instances.
14. A confirmation page lets you know that your instance is launching. Click View Instances to close the confirmation page and return to the console.

Installing VNC Software

Once the Amazon EC2 instance is set up, you can install virtual network computing (VNC) software to run the shader compiler on the instance.

To install VNC software

1. Using a remote desktop connection, log in to the Amazon EC2 instance.
   
   **Note**
   
   If you are using a Mac, you must download Remote Desktop App from the App Store.
2. Download and install your preferred VNC software.
3. On your Amazon EC2 instance, run the VNC server.
4. Terminate the remote desktop session.
5. On your local PC, install a VNC client.
6. Using the VNC connection, run the shader compiler on the Amazon EC2 instance.
7. Leave the VNC window open and then follow the steps in Connecting to the Shader Compiler (p. 3241).

Connecting to the Shader Compiler

Follow these steps to connect to the shader compiler.

To connect to the shader compiler

1. On your computer, open the platform configuration file:
   - For Android, open the `system_android_es3.cfg` file (located in the `lumberyard_version\dev` directory).
   - For iOS, open the `system_ios_ios.cfg` file (located in the `lumberyard_version\dev` directory).

2. Edit the configuration file to set `r_ShaderCompilerServer` to the public IP address of your Amazon EC2 instance. You can retrieve the IP address from the Amazon EC2 console.

3. Run your game on your device to connect to the EC2 instance and compile the shaders.

Using AWS Device Farm in Lumberyard Editor

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use AWS Device Farm to test your Android or iOS apps on many different types of devices without needing to have any of them present physically. Device Farm can help you find and resolve compatibility issues on a large number of devices. For more information about Device Farm, see the Device Farm Developer Guide.

Starting in Lumberyard version 1.20, you can use the Lumberyard Editor Deployment Tool (p. 3175) to make Device Farm a deployment target.
Prerequisites

To use Device Farm in Lumberyard Editor, you need the following requirements:

- The Cloud Gem Framework gem, enabled for your project in the Project Configurator.

For information about using Project Configurator to enable gems, see Enabling Gems (p. 1064).

- A set of Amazon Web Services (AWS) credentials and access keys.
- If you do not have an AWS account, complete the following steps to create one.
To sign up for an AWS account

2. Follow the online instructions.

   Part of the sign-up procedure involves receiving a phone call and entering a verification code on
   the phone keypad.

   - For more information about access keys, see How do I create an AWS access key?.
   - For information about the AWS Free Tier, see the AWS Free Tier page.
   - Device Farm requires that you have a shader compiler running on an Amazon Elastic Compute
     Cloud (Amazon EC2) instance. For more information, see Running the Shader Compiler on Amazon
     EC2 (p. 3239).

Creating an AWS Profile in Lumberyard Editor

After you have a set of AWS credentials, use them to create a profile in Lumberyard Editor.

To enter your credentials in Lumberyard Editor

1. In Lumberyard Editor, choose AWS, Credentials manager.

2. In the Credentials Manager dialog box, click Add profile.

3. In the Add profile dialog box, enter the required information.
Using AWS Device Farm in Lumberyard Editor

1. For **Profile name**, enter a name for the profile.
2. For **AWS access key** and **AWS secret key**, enter the access key and secret key.

**Important**

Do not share these credentials with anyone, and do not check them into source control. These credentials grant control over your AWS account, and a malicious user could incur charges.

4. Click **Save**.
5. In **Credentials Manager**, click **OK**.

You have now created a profile that is associated with your credentials. It is saved locally on your machine in your AWS credentials file. This file is usually located in your `C:\Users\user_name\.aws` directory.

**Accessing the Device Farm Console from Lumberyard Editor**

After the new profile is selected in the **Credentials Manager**, you can use Lumberyard Editor to access the Device Farm console.

**To access the Device Farm console from Lumberyard Editor**

1. Choose **AWS, Credentials Manager** and ensure that a profile is selected.
2. Choose **AWS, Open AWS Console, Device Farm**. This signs you into AWS and creates a new session.

**Configuring a Deployment for AWS Device Farm**

After you have selected a valid AWS profile in Lumberyard Editor, you can use the **Deployment Tool** to configure a deployment to AWS Device Farm.

**To configure a deployment for AWS Device Farm.**

1. Ensure that a valid AWS profile is selected.
2. In Lumberyard Editor, choose **File, Project Settings, Deploy to device.**
3. In **Deployment Tool**, under **Deploy**, click the **AWS Device Farm** tab.
4. The following options are specific to Device Farm usage.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Load current level</strong></td>
<td>Because the Deployment Tool cannot communicate directly with the actual devices used by Device Farm, this option is not supported. Instead, specify the level that you want to test in your project's <code>autoexec.cfg</code> file as a <code>map levelName</code> command.</td>
</tr>
<tr>
<td><strong>Shader compiler IP address</strong></td>
<td>Set the shader compiler IP address to the IP address of your EC2 instance shader compiler. For more information, see Running the Shader Compiler on Amazon EC2 (p. 3239).</td>
</tr>
<tr>
<td><strong>Project name</strong></td>
<td>Select a Device Farm project, or click Add to create a new project.</td>
</tr>
<tr>
<td><strong>Device pool name</strong></td>
<td>Select a device pool, or click Add to create a device pool. For more information about adding a device pool, see the next step.</td>
</tr>
<tr>
<td><strong>Execution timeout</strong></td>
<td>Specify the maximum amount of time, in minutes, that you want the test to run. Possible values are from 5 to 150.</td>
</tr>
<tr>
<td><strong>Test type</strong></td>
<td>Built-in fuzz, the only option, sets the event throttle to 1000. This means that the test waits one second between random input events. The event count is 600.</td>
</tr>
</tbody>
</table>

5. Adding a device pool opens the **Device Farm Device Pool** dialog box, which retrieves the latest list of supported devices from Device Farm.
6. For **Name**, enter a name for your device pool, and then select the devices that you want to test your application on.

7. Click **Save**.

**Building and Deploying an App to AWS Device Farm**

At this point, you are ready to build and deploy your app to Device Farm.
To build and deploy an app to AWS Device Farm

1. Click **Deploy to Device Farm**. The deployment advances through the following steps:
   a. Process all assets. This can take a long time if this is the first time assets for the target platform are processed.
   b. Run the WAF build command using `--deploy-android=False --android-asset-mode=apk_files`.
   c. Run the WAF package command using `--deploy-android=False --android-asset-mode=apk_files`.
   d. Upload the app that is created to Device Farm.
   e. Schedule the test run on Device Farm.

2. After a test run is scheduled, you can track its status in the **Device Farm Log** section of the Deployment Tool. Information from Device Farm is refreshed every 10 seconds.

![Device Farm Log](image)

**Note**
The Device Farm test fails on some devices if the device does not respond to input quickly enough. If this occurs, set `r.ShadersAsyncCompiling=1` in your `system_android_es3.cfg` file so that the main UI thread is blocked by shader loads and continues to respond.

3. To open a test run in the Device Farm console, right-click the run, and choose **View details in AWS console**.
4. To delete a test run, right-click the run, and choose **Delete**.

Create virtual reality projects in Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Lumberyard's virtual reality (p. 3286) system integrates the use of the Oculus Rift and HTC Vive head-mounted displays (HMD) on PC gaming systems. Before using these head-mounted displays, read each manufacturer's safety guide:

- Oculus Rift Health and Safety Warning
- HTC Vive Safety and Regulatory Guide

To activate Lumberyard's virtual reality support, add the appropriate Virtual Reality Gem(s) (p. 3249) in the Project Configurator and then build your project (p. 61). By enabling the appropriate Virtual Reality Gem(s), your project becomes capable of working with the supported virtual reality device(s), after some additional configuration.

Use console variables (CVARs) (p. 3251) to activate and modify configurable features of the virtual reality system, such as resolution and performance specifications.

You can use Script Canvas for gameplay scripting of the HMD device.

For information on Lua scripting functions for VR, see VR Lua Functions (p. 3260).

Topics
- Configuring your Project for Virtual Reality (p. 3249)
- Configuring Required Console Variables (p. 3251)
- Using the InstantVR Slice (p. 3252)
- Previewing your Virtual Reality Project (p. 3258)
- Debugging your Virtual Reality Project (p. 3258)
- Using EBus Request Bus Interface for Virtual Reality (p. 3259)
- VR Lua Functions (p. 3260)

Configuring your Project for Virtual Reality

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Add one or more Virtual Reality gems available in Lumberyard Editor to enable virtual reality for supported head-mounted displays (HMDs). You can add the gem(s) to new or existing projects. If you add more than one gem, the system automatically detects which HMD is connected, and uses the appropriate gem code to control the specific HMD and any associated virtual reality (VR) controllers.

Supported HMDs include:

- **Oculus** – Oculus Rift HMD
- **OpenVR** – HTC Vive HMD

**Note**

Use the NullVR Gem to run your level through the HMD framework without a connected VR device. This is useful for VR graphics debugging. For more information about this Gem, see NullVR Gem (p. 1180).

To add the Virtual Reality Gem(s)

1. Use the Lumberyard Setup Assistant to open the Project Configurator.
2. Select the project you want to add the Virtual Reality Gem to, or create a new project. Then click **Set as Default**.

3. Click **Enable Gems** below the project name.

4. Type **VR** into the search tool. Enable the **HMD Framework** Gem and one or more of the Virtual Reality gems:
   - **Oculus**
   - **OpenVR**
   - **NullVR**

5. Click **Save**.

6. After you enable the gem(s), you must build your project (p. 61) before they are available in Lumberyard Editor.
Configuring Required Console Variables

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Console variables – Console variables (CVARs) are a type of variable that you can manipulate in Lumberyard’s console interface. For more information, see Using the Console Window (p. 210).

You must set the following console variable to enable your project’s capability to support the head-mounted display.

`output_to_hmd = 1`

Enables output to head-mounted display (HMD). Allows users to toggle stereoscopic output while playing the game. With this variable enabled, the height and width resolution for the connected headset is detected and set automatically.

Set the following console variables to 0 in order to turn them off. These features are either unnecessary for virtual reality or too resource-intensive for a virtual reality environment.

`r_DepthOfField = 0`

Disables the depth of field setting. 0 = disabled; 1 = enabled; 2 = hdr time of day enabled.

`r_MotionBlur = 0`

Disables the motion blur setting. 0 = no motion blur; 1 = camera and object motion blur; 2 = debug mode.

`r_ResolutionScale`  
Float value. Scales the resolution for better performance. For example, set to 0.5 to scale the resolution by 50% in width and height (retains the aspect ratio).

`e_gi = 0`

Disables the global illumination setting. 0 = disabled; 1 = enabled.

Optional Console Variables

The following console variables are optional but strongly recommended. Disabling the following rendering features ensures better performance in a virtual reality environment. If you need certain rendering features that are explicitly disabled by these example variables, you may turn them back on at the cost of performance.

`sys_spec = 2`

Sets the system configuration specification to medium. 0 = custom; 1 = low; 2 = medium; 3 = high; 4 = very high.

`r_ssdoHalfRes = 3`

Applies screen space directional occlusion (SSDO) (p. 3285) bandwidth optimizations to half resolution output. 0 = full resolution; 1 = lower resolution; 2 = low res depth (except for small camera field of views) to avoid artifacts; 3 = half resolution output.
Using the InstantVR Slice

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The instantVR slice is a set of entities, scripts, and assets that provide basic pieces of VR functionality to give you a starting point from which you can build your own VR application.

The VR functionality provided in this slice includes:

- Implementation of models-tracked controllers
- Teleportation using a navigation mesh to define a valid area
- Generation of a starting navigation area

The instantVR slice is part of the Virtual Reality Project sample level. Follow the instructions in VirtualRealityProject (p. 164) to download, install, and select the Virtual Reality Project before performing the following procedure.

To use the instantVR slice

1. In the Asset Browser (p. 296), navigate to dev\VirtualRealityProject\slices\.
2. Drag `instantvr.slice` into the viewport.

   The Lumberyard beaver is the starting location in this slice. Two controllers and a navigation area also appear.

3. Click the **VR Preview** button to enable VR preview, and then press **Ctrl+G** to run your level.

   You can use the trigger buttons on your controllers to teleport around the space.
InstantVR Lua Script Properties

You can view instantVR's assets in the Entity Outliner. The instantVR slice contains a Lua script called instantVR, which includes many of the child entities that add controller tracking and provide teleport support.
The `instantVR` Lua script has the following properties:

**TeleportInputEventNameRight**
- Name of the input event that triggers the right controller teleport.

**ControllerEntityRight**
- Name of the right controller entity.

**TeleportUseNavMesh**
- If selected, teleport function uses the navigation area for validation.

  **Note**
  If you select `TeleportUseNavMesh` without selecting `TeleportUseTerrain`, then teleport ray cast uses only the nav mesh to determine the valid area. If it finds no nav mesh, it displays an 'invalid' indicator on terrain.
  If both are selected, then teleport validation uses a ray cast to the terrain and to the navigation mesh. If both beams hit terrain and nav mesh, then the teleport location is valid, otherwise it is invalid.

**TeleportEntityInvalid**
- Name of the entity that spawns the invalid teleport location entity.

**TeleportEntityValid**
- Name of the entity that spawns the valid teleport location entity.

**TeleportInputEventNameLeft**
- Name of the input event that triggers the left controller teleport.

**TeleportMaxDistance**
- Maximum distance for teleporting.

**CameraEntity**
- Name of the camera entity, which determines the transform of the HMD and controllers.

**TeleportUseTerrain**
- If selected, the teleport function uses the terrain for validation.

  **Note**
  If you select `TeleportUseTerrain` without selecting `TeleportUseNavMesh`, then the teleport ray cast uses the terrain for validation only. Teleport will be valid as long as it is in contact with terrain.
  If both are selected, then teleport validation uses a ray cast to the terrain and to the navigation mesh. If both beams hit terrain and nav mesh, then the teleport location is valid, otherwise it is invalid.

**TeleportBeamSpawner**
- The name of the teleport beam arc entity along which to spawn entities, though this does not follow the ray cast line exactly.

To customize the `instantVR` Lua script, try the following modifications:

- Change the controllers to a different model by changing the *Static asset* of the *Static Mesh* component.
- Change the `TeleportMaxDistance` to a large value.
- Deselect `TeleportUseNavMesh` and climb the walls.
- Open the `InvalidLocationSpawner` and `ValidLocationSpawner` dynamic slices and change the entities they spawn.
InstantVR Known Issue

If you modify the size and position of the navigation area in the Lumberyard Editor, you must manually rebuild by clicking Game, AI, Generate Triangulation. Restarting the Lumberyard Editor or reloading the level also automatically rebuilds the navigation area.

Previewing your Virtual Reality Project

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can preview your virtual reality project for any project that has one or more of the virtual reality head-mounted display gems enabled. As you work in Lumberyard Editor, use your head-mounted display to preview your virtual reality game. The preview display inside of Lumberyard Editor is a preview only; it is not a good indicator of how fast the application will perform outside of the editor.

To gauge the game performance outside of Lumberyard Editor, create a release build (p. 344) to run your game in standalone mode.

To preview your virtual reality project

1. In Lumberyard Editor, click VR Preview on the bottom toolbar.

2. Enter game mode by doing one of the following:
   - Press Ctrl + G
   - On the main menu, click Game, Play Game.

To exit virtual reality preview mode

1. Exit game mode by pressing Esc.
2. Click VR Preview if you want to return to the default PC game preview mode.

Debugging your Virtual Reality Project

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can debug your virtual reality project either through a running instance of the game or through Lumberyard Editor. The head-mounted displays that Lumberyard supports outputs debugging information when debugging is enabled.

To enable debugging

- Enable one or both of the following console variable (p. 3251)s:
• Set `hmd_debug_info` to 1 (enabled) – Enables display of debug information provided by the associated HMD SDK.

• Set `hmd_debug_camera` to 1 (enabled) – Tests an editor-style debug camera at runtime. With this setting, players can use WASD keys to control the camera relative to the camera's facing direction, including the HMD. In regular (non-VR) mode, hold down the right mouse button to manipulate the camera's rotation.

When in debug mode, motion controllers appear as white crosshairs. That is, if you assigned an object or entity to represent the motion controller in the gameplay world, you will see it rendered with white crosshairs. The following picture shows two controllers, one with render geometry assigned, and the other without.

Using EBus Request Bus Interface for Virtual Reality

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the following request function with the StereoRendererBus event bus (EBus) interface to communicate with other components of your game.

For more information about using the EBus interface, see Working with the Event Bus (EBus) system (p. 1851).

```
IsRenderingToHMD
```

Returns true if the renderer is rendering to the HMD.
VR Lua Functions

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use Lua bindings to interact programmatically with head-mounted display (HMD) devices that provide Virtual Reality (VR) experiences.

For general information on configuring your Lumberyard game project for VR, see Create virtual reality projects in Lumberyard (p. 3248).

Global Functions

The following functions provide programming interfaces for HMD devices.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HMDDeviceRequestBusSender</td>
<td>Returns an object that is connected to the specified entity. For more information, see HMDDeviceRequestBus (p. 3260).</td>
</tr>
<tr>
<td>ControllerRequestBusSender</td>
<td>Returns an object that is connected to the specified entity. For more information, see ControllerRequestBus (p. 3261).</td>
</tr>
</tbody>
</table>

HMDDeviceRequestBus

Contains functions that return information about an HMD and control its pose and tracking level.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bool IsInitialized()</td>
<td>Returns true if an HMD has successfully initialized on the bus. Returns false if no HMD is connected or failed to initialize.</td>
</tr>
<tr>
<td>Void RecenterPose()</td>
<td>Causes the direction that the HMD is currently facing to be considered forward'.</td>
</tr>
<tr>
<td>Void OutputHMDInfo()</td>
<td>Outputs the information about the currently connected HMD (contained in the HMDDeviceInfo object) to the console and log file.</td>
</tr>
</tbody>
</table>
### VR Lua Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Void SetTrackingLevel(int)</td>
<td>Sets the tracking level for the HMD. 0 specifies head level tracking (the player is standing); 1 is floor level tracking (the player is seated or on the floor).</td>
</tr>
<tr>
<td>HMDDeviceInfo GetDeviceInfo()</td>
<td>Returns an HMDDeviceInfo object that contains device information about a connected HMD. For more information, see struct HMDDeviceInfo (p. 3261).</td>
</tr>
<tr>
<td>TrackingState GetTrackingState()</td>
<td>Returns a TrackingState object that contains the most recent tracking information about a connected HMD. For more information, see struct TrackingState (p. 3261).</td>
</tr>
</tbody>
</table>

## ControllerRequestBus

Returns status information about an HMD controller.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bool IsConnected(int controllerIndex)</td>
<td>Returns true if the given controller is connected, false if a controller is not connected. Pass 0 for the left controller, pass 1 for the right controller.</td>
</tr>
<tr>
<td>TrackingState GetTrackingState(int controllerIndex)</td>
<td>Returns a TrackingState object that contains tracking info about a connected controller. Pass 0 for the left controller, pass 1 for the right controller. For more information, see struct TrackingState (p. 3261).</td>
</tr>
</tbody>
</table>

## struct HMDDeviceInfo

Contains information about a device that displays on the screen when the device is detected.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String productName</td>
<td>Name of the connected HMD. The default is nullptr.</td>
</tr>
<tr>
<td>String manufacturer</td>
<td>Name of the company that manufactured the connected HMD. The default is nullptr.</td>
</tr>
<tr>
<td>Int renderWidth</td>
<td>The render width for the HMD in pixels. This is normally half the full resolution of the device (rendering is per eye). The default is 0.</td>
</tr>
<tr>
<td>Int renderHeight</td>
<td>The render height in pixels for a single eye of the HMD. The default is 0.</td>
</tr>
<tr>
<td>Float fovH</td>
<td>The horizontal field of view for both eyes in radians. The default is 0.0f.</td>
</tr>
<tr>
<td>Float fovV</td>
<td>The vertical field of view in radians. The default is 0.0f.</td>
</tr>
</tbody>
</table>

## struct TrackingState

Stores position and connection state information about the HMD. When an HMD is in use, certain parts of the device can go offline or online. For example, a controller can be disconnected, or the HMD can
temporarily lose rotational tracking. You can use the TrackingState to determine what part of the pose is currently valid.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PoseState pose</td>
<td>The position and orientation in object space of the HMD. For more information, see struct PoseState (p. 3262).</td>
</tr>
<tr>
<td>DynamicsState dynamics</td>
<td>Contains the current state of the physics dynamics for the current device such as linear velocity, angular velocity, and acceleration. For more information, see struct DynamicsState (p. 3262).</td>
</tr>
<tr>
<td>Int statusFlags</td>
<td>Bit field that describes the current tracking state. For bit flags, see the enum HMDStatus (p. 3262).</td>
</tr>
</tbody>
</table>

**struct PoseState**

A specific pose of the HMD device. Each HMD device has its own way of representing its current pose in three dimensional space. This structure acts as a common data set between a connected device and the rest of the system. All data is in a local coordinate space.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Quaternion orientation</td>
<td>A quaternion representing the current orientation in object space of the HMD.</td>
</tr>
<tr>
<td>Vector3 position</td>
<td>A three dimensional vector representing the current position of the HMD in object space as an offset from the centered pose.</td>
</tr>
</tbody>
</table>

**struct DynamicsState**

Dynamics (accelerations and velocities) of the current HMD. Many HMDs have the ability to track the current movements of VR devices for prediction. Not all devices support velocities and accelerations. All data is in a local coordinate space.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector3 angularVelocity</td>
<td>A three dimensional vector representing angular velocity in object space.</td>
</tr>
<tr>
<td>Vector3 angularAcceleration</td>
<td>A three dimensional vector representing angular acceleration in object space.</td>
</tr>
<tr>
<td>Vector3 linearVelocity</td>
<td>A three dimensional vector representing linear velocity in object space.</td>
</tr>
<tr>
<td>Vector3 linearAcceleration</td>
<td>A three dimensional vector representing linear acceleration in object space.</td>
</tr>
</tbody>
</table>

**enum HMDStatus**

The following code shows the status flags for HMDStatus.

```c
enum HMDStatus
{
```
Create macOS projects in Lumberyard

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use Lumberyard to build macOS applications. Lumberyard includes four macOS-supported sample projects that you can use to learn how to build assets for macOS games using the Asset Processor, build shaders using the remote shader compiler, and build and deploy macOS applications using the Lumberyard build tools.

Topics
- Prerequisites (p. 3263)
- Setting Up Your Mac (p. 3263)
- Building macOS Games (p. 3264)
- Building Game Assets for macOS Games (p. 3265)
- Building Shaders for macOS Games (p. 3265)
- Running macOS Games (p. 3266)
- macOS Debugging and Troubleshooting (p. 3267)
- Creating a Project for Your macOS Games (p. 3268)

Prerequisites

To build games for macOS or iOS, Lumberyard requires the following on your Mac:

- Lumberyard Mac Support Files
- Xcode 11 or later
- macOS Mojave or later

Note
Lumberyard Editor requires Windows 10 to edit levels. You must have access to a PC with Lumberyard installed and be able to navigate and run commands from Terminal on your Mac.

Setting Up Your Mac

After you download and extract Lumberyard on your Mac, you must run Lumberyard Setup Assistant to install the third-party software that is required to run the game and compile the game code, engine, and asset pipeline.
To run Lumberyard Setup Assistant

1. Open the directory where you extracted Lumberyard and navigate to the /dev/Tools/LmbrSetup/Mac directory. Run the SetupAssistant.
2. Verify that the engine root path is correct.
3. On the Get started page, select the following and then click Next:
   - Create, Modify and Build projects
     Note
     Lumberyard Editor is not supported on macOS. Selecting this option enables the ability to build the asset processor and resource compiler only.
   - Compile for iOS devices
   - (Optional) Compile for Android devices
     Note
     Select this option if you are developing for Android devices. You must have the Android SDK installed on your Mac.
4. Follow the instructions onscreen to complete the installations for any third-party software or SDKs that you need. For more information about using Lumberyard Setup Assistant, see Using Lumberyard Setup Assistant to Set Up Your Development Environment (p. 16).
5. Open a command line window and navigate to your Lumberyard dev directory.
6. To initialize the build system, run the following command:
   ```
   sh lmbr_waf.sh configure
   ```
7. In the Finder, open the user_settings.options file (located in the /lumberyard/dev/_WAF_/ directory).
8. Verify that enabled_game_projects is set to your game project. For example, you can set this option to SamplesProject. If enabled_game_projects is not set correctly, edit and save the user_settings.options file and then run the configure command (sh lmbr_waf.sh configure) again.

Building macOS Games

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Before you can run your game on a macOS computer, you must ensure the shader compiler (located in the lumberyard_version\dev\Tools\CrySCompileServer\x64\profile directory) is running on your PC. For more information, see Building Shaders for macOS Games (p. 3265).

To build your game for macOS

1. On your Mac, in a Terminal window, navigate to the root directory of your Lumberyard installation (lumberyard_version/dev).
2. To generate an Xcode project and prepare the Lumberyard build system to build your app, run the following command:
   ```
   sh lmbr_waf.sh configure xcode_mac
   ```
   Note
   Metal is the default renderer.
3. Do one of the following to build your game:
Building Game Assets for macOS Games

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When you build a macOS game using Lumberyard, you must first build the assets that are included with the application. All built assets are located in the cache folder of your Lumberyard installation. For example, when you build the Samples Project, the assets are saved to the lumberyard_version\dev \cache\SamplesProject\osx_gl directory. The initial build of the Samples Project assets may take up to an hour to process, but incremental changes should process almost instantly.

Note
If you make changes to your game in Lumberyard Editor on your PC, you must copy the updated assets to your Mac using your preferred method. For example, you can use source control. For information, see Using the Perforce Plugin with Lumberyard (p. 23).

To build macOS game assets on your Mac
1. On your Mac, close all instances of the Asset Processor.
2. Edit the bootstrap.cfg file (located in the lumberyard_version/dev directory) to set sys_game_folder to SamplesProject (or the project you want to build). Save the file.
3. Edit the AssetProcessorPlatformConfig.ini file (located in the lumberyard_version/dev directory) to uncomment osx_gl=enabled (remove the preceding semicolon) and to comment out pc=enabled (add a preceding semicolon). Save the file.
4. In a command line window, navigate to the lumberyard_version/dev/BinMac64 directory and run Asset Processor (GUI or batch version) to process and build your game assets.

Building Shaders for macOS Games

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Lumberyard uses a versatile shader system to achieve high quality, realistic graphics. Because the shader compilation pipeline depends on the Windows-specific HLSL optimizer, you must connect to a shader compiler on your PC when running a game on macOS during development. This compiles the subset of shaders required by your game, on demand.

**Note**
You must connect your PC and macOS computer to the same network and configure any firewalls to allow traffic through port 61453.

When a new shader is compiled, the game waits for the binary shader permutation to compile on your PC and be sent back to your macOS computer. Once this occurs, the shader is cached locally. When you are ready to release your game, you must pack up and include all cached binary shaders.

You can use an allow list to specify the IP addresses that are allowed to connect to your remote shader compiler. For information, see Creating an allow list for the Remote Shader Compiler (p. 1647).

**To build the shader compiler (if not already done)**

1. On your PC, in a command line window, navigate to the `lumberyard_version\dev` directory.
2. Enter the build command for your version of Visual Studio:

   ```
   lmbr_waf build_win_x64_vs2017_profile -p all --targets=CrySCompileServer
   ```

**To run the shader compiler on your PC**

1. Navigate to the `lumberyard_version\dev` directory.
2. Edit the `system_osx_osx_gx.cfg` file to set the `localhost` for `r_ShaderCompilerServer` to the IP address of the PC on which you will run the shader compiler.
3. Launch Asset Processor if it is not still running.
4. Verify that you are sharing the `cache` folder between your PC and Mac by checking the corresponding cache file (located in the `lumberyard_version\dev\cache\SamplesProject \ios\system_osx_osx_gx.cfg` directory).

**Running macOS Games**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Before you can run your game on a macOS computer, you must ensure the shader compiler (located in the `lumberyard_version\dev\Tools\CrySCompileServer\x64\profile` directory) is running on your PC. For more information, see Building Shaders for macOS Games (p. 3265).

**To run your game on a macOS computer**

1. Open the Xcode solution that you generated (located in the `Solutions` folder in the directory where you installed Lumberyard).
2. Build, run, and debug your application as you would any Xcode project. For information, see Launching Your Mac App.
3. (Optional) Load different levels by doing one of the following:

- Open the console window using the tilde (~) key, and then enter `map <name of map or level to load>`. The console supports tab completion, so you can press Tab after the map command to see the list of supported levels and maps to load.

- Edit the `autoexec.cfg` file for your game to change the map command to load a different map or level. Run the game from Xcode again.

  For example, if you are using the Samples Project, edit the `autoexec.cfg` file located in the `/dev/SamplesProject` directory. macOS supports the Advanced_RinLocomotion level.

4. Use the following controls to navigate around your game:

- Switch between cameras by selecting the buttons in the lower right corner of the screen.
- Move Rin in the Character Controller view by using the mouse or keyboard (WASD).
- Jump in the Character Controller view by pressing the Space key.

---

macOS Debugging and Troubleshooting

This feature is in preview release and is subject to change.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard provides full access to the source code, which allows you to debug your macOS application using Xcode without additional Lumberyard-specific steps to follow. For information about debugging and profiling your macOS application, see Debugging in the official Apple developer documentation.

Unable to see activity in the shader compiler window

You must connect to the shader compiler on your PC in order to compile the subset of shaders required by your game, on demand. To verify that your app has connected correctly and obtained all shaders, you can view the output in the shader compiler window. If you still do not see any activity in the window, please check your setup by following the instructions on the Building Shaders for macOS Games (p. 3265) page.

Cleaning the project does not create a full rebuild of the macOS application

Lumberyard uses a custom build step to generate the final executable and temporary C++ object files, which output to the \BinTemp\darwin_x64_debug or \BinTemp\darwin_x64_profile directory where you installed Lumberyard. Unlike a regular Xcode project, in order to create a full rebuild of the macOS application, you must manually delete the contents of the output folder or run one of the following Waf commands from a Terminal window:

- To build debug, run the following command: lmbr_waf.sh clean_darwin_x64_debug
- To build profile, run the following command: lmbr_waf.sh clean_darwin_x64_profile
- To build release, run the following command: lmbr_waf.sh clean_darwin_x64_release

Observed frame rate varies greatly

While running your application, the observable frame rate can vary depending on the build (debug or profile) you are running and whether you are connected to the Xcode debugger. To display the frame rate in the upper right corner of the screen, set the r_DisplayInfo configuration variable to 1 or higher. When your Xcode project is generated, the default build scheme is set up for debugging. If you want to test or profile your application’s speed, we recommend that you edit your active scheme to run a profile build. Deselect Debug executable.

Creating a Project for Your macOS Games

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The topics in Create macOS projects in Lumberyard (p. 3263) demonstrate how to use the Samples Project that is included with Lumberyard to build game assets, shaders, and macOS applications. You can follow the same instructions to create a project for your own macOS game.

Note

Ensure you have the prerequisites (see Create macOS projects in Lumberyard (p. 3263)) and your Mac is properly set up to compile for macOS computers.
To create a project for your macOS game

1. On your PC, use the Project Configurator to create a new project. For information, see Creating Lumberyard projects (p. 43).
2. Submit the new project into your revision control system and then check out the project onto your Mac.
3. Edit the user_settings.options file (located in the lumberyard_version\dev\_WAF_ directory) to set enabled_game_projects to the name of the project you created:

   ```
   [Game Projects]
   enabled_game_projects = MyProject
   ```

   You can simultaneously build multiple projects by separating each project name with a comma:

   ```
   [Game Projects]
   enabled_game_projects = SamplesProject,MyProject,OtherProject
   ```

4. In a command line window, configure and build your project using the instructions on the Building macOS Games (p. 3264) and Running macOS Games (p. 3266) pages.

   **Note**
   If you enabled multiple projects, you can switch between multiple targets in your Xcode project.

Creating Lumberyard Executables for Linux

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard supports compiling a Windows client for a multiplayer project and connecting to a Linux dedicated server. You must do the following to ensure that the Windows client works properly on a Linux dedicated server:

- Compile the assets on a Windows computer (p. 344)
- Compile the server executable for use on a Linux computer (p. 3270)
- Compile a Windows client to use to connect to the Linux server (p. 61)

When these tasks are complete, you can deploy assets to either a Linux server or Windows client.

Topics

- Prerequisites (p. 3270)
- Deploy a Lumberyard multiplayer project's server on Linux (p. 3270)
- Testing the Windows Client to Linux Server Connection (p. 3272)
- Preparing the Amazon GameLift Package (p. 3274)
Prerequisites

To create Lumberyard executables for Linux, you must have the following:

- A Windows 10 Lumberyard install configured to compile your project and the Lumberyard engine.
- A computer running Ubuntu Bionic (18.04 LTS) where you have superuser access, with at least 50Gb of available hard drive space. This can be a native host, Windows Subsystem for Linux (WSL), or a virtual machine. For instructions on hosting an Ubuntu instance on Amazon Elastic Compute Cloud, see Getting started with Amazon EC2 Linux Instances. When you create an Amazon EC2 instance, pick Ubuntu 18.04 LTS as the image and x86_64 as the architecture to ensure that Lumberyard is supported.

Important

In Lumberyard version 1.23 and later, if you enable the EMotionFX Gem on Linux, then you must install libxmu to run the Linux Dedicated Server. Use the following command to install libxmu:

```
apt install libxmu6
```

Deploy a Lumberyard multiplayer project's server on Linux

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To distribute your Lumberyard project's server onto Linux, you need to have access to a Windows 10 computer to perform your first build, which generates the client executable and assets that the server uses. After your build is complete, bundle up the assets and code for distribution, building, and hosting on your Linux server. This topic walks you through the steps to perform the Windows 10 client build, get the files onto your Linux host, and then build the Linux server application.

Currently, the only officially supported Linux distribution is Ubuntu 18.04 LTS. To verify that you're running the correct distribution on your Linux host, run the `lsb_release -a` command. If you're on the correct distribution, you should see Ubuntu 18.04 in the output.

These instructions are for building the MultiplayerSample project that's included in the Lumberyard distribution. When you build and distribute your project, edit the scripts referenced in this topic where needed to reference your project's name and contents instead.

Bundle the assets and source on Windows

To create a Linux server for your project, you first have to build the assets on Windows and bundle them for distribution to the server. This distribution also includes all of the source code and tools that you need to generate a server build, so you don't need to install Lumberyard on your Linux host.

To package the assets and source on Windows

1. Open a console and navigate to the `lumberyard_install\dev` directory.
2. Open `bootstrap.cfg` and set the value of `sys_game_folder` to MultiplayerSample.
3. Build the project assets for the multiplayer server.

```bash
sys_game_folder=MultiplayerSample
```

4. Bundle the packaged assets together into a tape archive (.tar) file for distribution to a Linux host. This requires Python, which is distributed with Lumberyard:

```bash
Tools\Python\version\windows\python.exe Tools\LmbrSetup\Linux\archiver.py
```

This tool generates a file based on the current timestamp, located at `BinTemp\unix_archives\YYYY-MM-DD_HH-mm-ss.tar`

**Note**
This archive file is uncompressed and is quite large. Before distributing it to a remote Linux host, you might want to compress it with LZMA, bzip2, or gzip.

5. Copy the created archive over to your Linux host. You can use SFTP, SCP, or any other method that you would normally use to achieve this. For instructions on copying to an Amazon EC2 instance using SCP, see Transfer files to your Linux instance using WinSCP.

If you're running Windows 10, you can use the Windows Subsystem for Linux (WSL) to test a deployment. See Microsoft's instructions on installing WSL and initializing a distribution to get set up with WSL. You can access the file directly from the WSL mount points for your Windows drives. The drives are available from within a WSL terminal at `/mnt/drive_letter`. To avoid performance problems when running the dedicated server under WSL, copy the archive into WSL's file system before continuing.

### Compile the dedicated server on Linux

1. When the packaged assets and source are copied to your Linux host, extract them so that you can build the dedicated server.

```bash
cd your_upload_path
tar -xvf YYYY-MM-DD_HH-mm-ss.tar
```

**Note**
If you compressed your archive in an earlier step, add a decompression argument to `tar`:

- Compressed with LZMA: `tar -xJvf YYYY-MM-DD_HH-mm-ss.tar.xz`
- Compressed with bzip2: `tar -xyvf YYYY-MM-DD_HH-mm-ss.tar.bz2`
- Compressed with gzip: `tar -xzvf YYYY-MM-DD_HH-mm-ss.tar.gz`

2. With the archive unpacked, change to the project's `dev` directory:

```bash
cd MultiplayerSample/dev
```

3. Check that your Linux host has the correct dependencies installed and update them if needed:

```bash
sudo ./Tools/LmbrSetup/Linux/setup.sh
```

While setting up your environment, this script might prompt you for input to confirm adding a package repository (PPA) or install a package. If you need to automate server setup, edit this script to make sure there are no user prompts.
4. Configure the Lumberyard build environment that's bundled as part of the distribution:

```
./lmbr_waf.sh configure --3rdpartypath absolute_path_to_unarchive_location/
MultiplayerSample/3rdParty/ 
--bootstrap-tool-param "--enablecapability compileengine --enablecapability
compilegame" 
--update-settings True
```

5. Edit the `MultiplayerSample_pc_Paks_Dedicated/system_linux_pc.cfg` file. Set the `log_RemoteConsoleAllowedAddresses` value to a comma-separated list of the IP addresses that Windows clients will connect from.

6. (For non-release builds only) Build the builder assistant tool binaries.

```
./lmbr_waf.sh --3rdpartypath absolute_path_to_unarchive_location/3rdParty/
build_linux_x64_profile -p host_tools
```

7. Build the dedicated server:

```
./lmbr_waf.sh --3rdpartypath absolute_path_to_unarchive_location/
MultiplayerSample/3rdParty/ 
build_linux_x64_profile_dedicated -p game_and_engine
```

**Note**
To create a different type of build, such as a debug or release, change `profile` to the appropriate build type. For all of the available Linux server build types, see Waf Commands and Options (p. 90).

# Testing the Windows Client to Linux Server Connection

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

After you've built the Windows client and Linux server (p. 3270), you should test the connection to make sure that everything is running smoothly. This topic covers starting your server, getting connection information, running the remote console on Windows to manage your connection, and connecting your game client to the server.

**Prerequisites**
To test your server setup, complete the following tasks.

- Complete the steps in Deploy a Lumberyard multiplayer project's server on Linux (p. 3270).
- Get the public IP address (not DNS name) of your Linux server.
- Get the public IP address of your client machine.
- Allow outbound TCP connections on Windows 10 to your Linux server on port 4600, and outbound UDP connections on port 33435. If you're not familiar with how to configure Windows firewall to allow outbound connections, see the Microsoft Windows Firewall documentation.
• Allow inbound TCP connections on Linux on port 4600, and inbound UDP connections on port 33435. If you’re using an Amazon EC2 instance, follow the instructions for Authorizing inbound traffic on Linux. If you’re running your own independent Linux server or using Windows Subsystem for Linux (WSL), read your distribution’s instructions on configuring your firewall to allow the client connection.

**Important**
There might be other considerations in your network environment that require additional setup – such as a corporate firewall, proxy, or VPN – that you should consult with your system administrator on as part of setting up for testing.

## Start the server

Before starting the client and after configuring the server to accept connections, start the dedicated server.

### To start the server

1. In a terminal, navigate to the `absolute_path_to_unarchive_location/dev/BinLinux64.Dedicated` directory.
2. Copy the resources built on Windows to the build directory. To function properly, the working directory that you launch the server from needs to contain configuration information for the project and the `multiplayersample` directory containing the `.pak` asset bundles.

   ```bash
   cp -r ../MultiplayerSample_pc_Paks_Dedicated/* ./
   ```

3. Make sure that the correct project is bootstrapped. Edit the `absolute_path_to_unarchive_location/dev/BinLinux64.Dedicated/bootstrap.cfg` file to ensure that the value of `sys_game_folder` is set to `MultiplayerSample`.

   ```
   sys_game_folder=MultiplayerSample
   ```

   **Note**
   You might see `^M` characters at the end of every line in the `bootstrap.cfg` file. This indicates that the file uses Windows-style line endings rather than Linux-style ones. This doesn't affect the ability of the Lumberyard dedicated server from loading the bootstrap file correctly, and you don't need to worry about preserving the line ending type when you edit the file.

4. Start the server.

   ```
   ./MultiplayerSampleLauncher_Server
   ```

## Configure the server remotely

When the server is running, launch the remote console and set up the server to start hosting a game session.

1. Launch the Remote Console on your Windows 10 machine, located at `lumberyard_install_dir\dev\Tools\RemoteConsole\RemoteConsole.exe`.
2. In the Remote Console, Select `Targets > PC`, and then edit the `Targets > Custom IP` setting to be the IP address for your Linux server.
If the connection to the dedicated server is successful, you see a green status light and the word **Connected** in the lower right corner of the window. Make sure that the IP address and port, located in the lower left of the window, match up with the location of your server. If you had an instance of the client already running, the remote console will attempt to connect to it first.

3. In the command line located at the bottom of the window, send commands to the server to start the multiplayer session and load a map.

   ```plaintext
   mphost
   map multiplayersample
   ```

4. Close the remote console.

### Connect from the client to the server

Start the game client and connect to the multiplayer session.

1. Edit the `lumberyard_install_dir\dev\bootstrap.cfg` file and set `connect_to_remote` to `1`.

   ```plaintext
   connect_to_remote=1
   ```

2. Launch the client.

   - For Visual Studio 2017: `lumberyard_install_dir\dev\Bin64vc141\`
   - For Visual Studio 2019: `lumberyard_install_dir\dev\Bin64vc142\`

3. In the client, press the `\` (grave) key to open the console and enter the command `mpjoin server_ip_address`.

If the connection to the game server was successful, you now have a game session running in your client. Try out connecting other clients to the server using these same steps to continue testing with multiple players!

### Preparing the Amazon GameLift Package

This feature is in **preview** release and is subject to change.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard has support for bundling and distributing your dedicated Linux servers over Amazon GameLift. To integrate your Lumberyard game with GameLift, enable the GameLift Gem (p. 1130) and use the GameLift C++ SDK API to configure your game server and client to manage server sessions and connections from a client application.

In the rest of this topic, you learn how to set up for creating your GameLift package and make a basic deployment.

Prerequisites

Before packaging and pushing your GameLift server, make sure that you complete the following.

- Set up your AWS account to use the GameLift service. Follow the GameLift - Setting Up instructions.
- Install the AWS CLI on your Linux server. Follow the AWS CLI install instructions for Linux.
- Build and do a test deploy of your game server on a standalone Linux machine (p. 3270).
- (Optional) Test client/server connectivity (p. 3272).

Prepare the GameLift package

The following instructions tell you how to package the MultiplayerSample project for a test deployment to GameLift. When you’re ready to deploy your game, edit the MultiplayerSample_CreateGameLiftPackage.sh script to use your project and its asset bundles.

1. On your Linux server, run the packaging script.

   ```bash
   ./MultiplayerSample_CreateGameLiftPackage.sh
   ```

2. Push your GameLift package to AWS using the AWS CLI.

   ```bash
   aws gamelift upload-build --operating-system AMAZON_LINUX \
   --build-root "./GameLiftPackageLinux" \
   --name "your package name" \
   --build-version "your build version" \
   --region us-west-2
   ```

   **Note**
   If you want your servers to be hosted in a different AWS Region, replace the us-west-2 argument value with the appropriate region identifier.

Next steps

Now that you have your server package uploaded to AWS, take these next steps to get your game deployed over GameLift and do more advanced configuration.

- Set up a deployment fleet
- Configure region-based queuing
- Examine metrics and data
- Secure your GameLift servers
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Amazon Lumberyard engine, integrated development environment, and related assets and tools are licensed as "Lumberyard Materials" under the terms and conditions of the AWS Customer Agreement and the Lumberyard Service Terms. Please see these terms and conditions for details.

Topics
- Lumberyard Redistributables (p. 3276)
- Alternate Web Services (p. 3278)

Lumberyard Redistributables

For purposes of the Lumberyard Service Terms, the Lumberyard materials in the directories listed below are designated as "Lumberyard Redistributables." Unless subdirectories of a directory are specified, all files in the directory listed are deemed Lumberyard Redistributables.

Note
Restrictions on use and distribution of the Lumberyard materials, including in source code form, are specified in the Service Terms.

Alternate Web Services

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

For purposes of the Lumberyard Service Terms, "Alternate Web Service" means any non-AWS compute, database, storage, or container service that is similar to or can act as a replacement for the following services: Amazon EC2, Amazon Lambda, Amazon DynamoDB, Amazon RDS, Amazon S3, Amazon EBS, Amazon EC2 Container Service, or Amazon GameLift.
Lumberyard documentation is available in PDF format for the following versions.

# Glossary

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>actor</td>
<td>A specialized entity (p. 3283) that is the basis for characters in a game.</td>
</tr>
<tr>
<td>additive animation</td>
<td>An animation that can be attached to a base animation to extend its behavior.</td>
</tr>
<tr>
<td>agent</td>
<td>An autonomous entity used in artificial intelligence (AI) that uses sensors to observe its environment and directs its activity towards achieving one or more goals.</td>
</tr>
<tr>
<td>aim pose</td>
<td>Part of a collection of parametric-blended poses for making a character take aim at specified points in the game.</td>
</tr>
<tr>
<td>alpha channel</td>
<td>An extension of RGB color values for specifying the opacity of an object. A value of 0.0 indicates fully transparent while a value of 1.0 indicates fully opaque.</td>
</tr>
<tr>
<td>Amazon GameLift</td>
<td>A fully managed AWS (p. 3281) service for deploying, operating, and scaling session-based multiplayer game servers in the cloud.</td>
</tr>
<tr>
<td>archetype entity</td>
<td>A special type of entity (p. 3283) with linked instances. If a parameter of the archetype entity is changed, all other instances of that entity parameter are automatically updated.</td>
</tr>
<tr>
<td>asset</td>
<td>Any art, texture, 3D model, sound effect, or other digital data that is presented to the user in the game.</td>
</tr>
<tr>
<td>attachment</td>
<td>A hierarchical object that is attached to characters, respond to real-world physics, and can be attached, detached, or replaced at runtime in the game. Character attachments include clothing, weapons, tools, or entire body parts such as heads or hands.</td>
</tr>
<tr>
<td>AWS</td>
<td>Amazon Web Services, an infrastructure web services platform in the cloud for companies of all sizes. See Also <a href="http://aws.amazon.com">http://aws.amazon.com</a>.</td>
</tr>
<tr>
<td>baked</td>
<td>Performs and stores all calculations for a scene element so that the element does not need to be processed or rendered in real time in the game. Often used for lighting or physics. Also referred to as prebaked.</td>
</tr>
<tr>
<td>bind pose</td>
<td>The pose that a character has when you bind the mesh (skin) to the skeleton. The skeleton determines the pose.</td>
</tr>
<tr>
<td>blend shape</td>
<td>Method that stores a deformed version of a mesh as a series of vertex positions. In each keyframe of an animation, the vertices are interpolated between these stored positions. Also known as morph target animation or per-vertex animation.</td>
</tr>
</tbody>
</table>
blend space | Animation blending that is treated as geometry. A character’s kinematic, physical, and other high-level motion-related parameters are mapped onto corresponding features that are stored in animation clips. By storing such motion as parameters, controllable interactive animations are possible. Specifically, an animation is associated with a 1D, 2D, or 3D location in the blend space. Also known as a bspace.

bloom | Effect that reproduces an imaging artifact of real-world cameras. The effect appears as fringes or feathers of illumination bleeding from the border of a bright area in an image, which gives the illusion of a bright light overwhelming the camera.

boids | Entities that mimic living animals and that have simulated group behavior and obstacle avoidance.

brush | A simple 3D shape that is tied to an entity, and that provides a specific appearance. Brushes are used for static objects.

bspace | See blend space.

bump map | A grayscale image that allows more realistic rendering of an object by introducing small displacements of its surface without changing its geometry. This is done by perturbing the surface normals of a rendered object during lighting. The amount of perturbation is specified by the values in the bump map.

Cloud Canvas | A tool for building connected gameplay by using Lumberyard and AWS services, such as Amazon Cognito, Amazon DynamoDB, AWS Lambda, Amazon S3, Amazon SNS, and Amazon SQS.

collision proxy | A simplified geometric shape for approximating a more complex piece of geometry for purposes of a fast first-pass collision detection.

cooking | Pre-processing step that converts data such as mesh geometry into formats that PhysX can use. Cooking also prepares data structures and computes intermediate results that can be performed offline, which saves computation at runtime.

cubemap | A set of six squares that represent reflections from the environment. The six squares form the faces of an imaginary cube that surrounds an object.

cutscene | A noninteractive cinematic game sequence that is typically used to promote plot during gameplay.

damping | The gradual reduction of movement, vibration, or intensity.

DCC | Digital content creation; related to a third-party product such as Autodesk 3ds Max or Autodesk Maya for creating digital assets.

decal | A 2D texture placed on a piece of flat geometry.

detail map | An image for adding up-close surface details to an object.

diffuse map | An image for defining the base color and pattern of an object's surface.

displacement map | A type of heightmap (p. 3283) that modifies the position of vertices of a surface by a specified amount.

DOF | Depth of field. The degree to which distant objects are in focus relative to closer ones.

EBus | A modular message dispatch system that enables components, entities, and other types of objects to communicate with one another with few or no
interdependencies. Because Ebuses are decoupled from each other, you can more easily build high performing and modular game systems. Also known as event bus.

emitter
An entity that specifies the location from which particles are emitted.

entity
A game object with one or more components that provide some behavior or functionality. An entity consists of a unique ID and a container.

environment probe
A technique that uses cube maps to provide a game level or location with realistic ambient lighting.

experimental
A designation for a Lumberyard tool that we recommend that you not use in production yet, as it is still in the early stages of development and we have no current plans to support it. However, it also means that feature is stable enough and functional for specific use cases. You may find the experimental feature helpful as a guideline for implementing your own game-specific features. API operations are subject to change.

gem
A package that contains code and assets to provide a single feature or multiple tightly scoped functions.

gloss map
An image that represents the microscale roughness of a surface. The gloss map is located in the alpha channel of the normal map.

heightmap
A grayscale image used to modify vertex positions of a surface. Lumberyard uses heightmaps to store terrain surface height data. White areas represent the high areas while black areas represent the low areas of the terrain.

HDR tone mapping
The process of converting the tonal values of an image from a high dynamic range (HDR) to a lower range.

helper
Visual icons attached to objects in Lumberyard Editor that provide object-specific functionality.

IK
Inverse kinematics. The use of kinematics equations to calculate the positions and orientations of joints of a character's skeleton so that a specific part of the skeleton (the end effector) reaches a defined target point.

IBL
Image-based lighting. A rendering technique that involves capturing lighting information, storing it in an environment probe, and projecting it onto a scene.

imposter
Procedurally created 2D sprites that are rendered to look like 3D objects. In essence, imposters are 2.5D objects.

k-means clustering
Method for partitioning a set of data points into k separate groups. Each group has a mean calculated from the average of the points it contains and each point is assigned to a group based on which group mean the point is closest to. The method usually works iteratively, alternating between updating point assignments and updating mean values until a stable partition is reached.

keyframe
An animation frame that specifies exact positions and orientations of geometry affected by the animation. Animation frames that exist between keyframes are interpolated based on animation curves.

legacy
A designation for Lumberyard tools that are no longer being advanced and will eventually be removed.

level
A world or map that represents the space or area available to the player during the course of completing a discrete game objective. Most games consist of multiple levels.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>locomotion locator</td>
<td>The Y vector of the character root joint quaternion, which is typically the direction in which the character is facing. The locomotion locator is needed for motions that translate in nonuniform ways, such as stop or start transitions that have changes in acceleration.</td>
</tr>
<tr>
<td>LOD</td>
<td>Level of detail. A technique for increasing performance and reducing draw calls by displaying progressively less-detailed objects the farther they are from the camera.</td>
</tr>
<tr>
<td>look pose</td>
<td>Part of a collection of parametric-blended poses for making a character look at specified points in the game.</td>
</tr>
<tr>
<td>mesh</td>
<td>A collection of vertices that define the surface of an object.</td>
</tr>
<tr>
<td>minimap</td>
<td>A miniature map placed at a screen corner in the game to aid players in orienting themselves in the world.</td>
</tr>
<tr>
<td>mip map</td>
<td>A precalculated, optimized sequence of textures, each of which is a progressively lower resolution representation of the same image. Used in conjunction with LOD (p. 3284) processing.</td>
</tr>
<tr>
<td>morph target</td>
<td>A snapshot of vertex locations for a specific mesh that have been deformed in some way.</td>
</tr>
<tr>
<td>morph target animation</td>
<td>See blend shape.</td>
</tr>
<tr>
<td>navmesh</td>
<td>A navigation mesh, or navmesh, defines the areas of an environment in which a character can move freely without obstructions such as trees, lavas, or other environmental barriers.</td>
</tr>
<tr>
<td>normal</td>
<td>The vector that is orthogonal to a surface defined by a set of vertices.</td>
</tr>
<tr>
<td>normal map</td>
<td>An image whose pixel values are interpreted as the normal vectors for each point on the surface to which the image is mapped.</td>
</tr>
<tr>
<td>null bone</td>
<td>The character bone associated with a null or root object.</td>
</tr>
<tr>
<td>parallax mapping</td>
<td>A technique that is used to create detail in a texture adding the illusion of depth. This depth perception changes based on perspective.</td>
</tr>
<tr>
<td>PBR</td>
<td>Physically based rendering. PBR uses real-world physical rules and properties to define how light interacts with the surface of objects. Used by the Lumberyard rendering system.</td>
</tr>
<tr>
<td>per-vertex animation</td>
<td>See blend shape.</td>
</tr>
<tr>
<td>POM</td>
<td>Parallax occlusion mapping. POM uses a displacement map to encode surface detail information in a texture. In this way self-occlusion and self-shadowing of an object is possible without changing the surface geometry.</td>
</tr>
<tr>
<td>prebaked</td>
<td>See baked.</td>
</tr>
<tr>
<td>prefab</td>
<td>A game object template that stores an asset or a group of assets and all associated properties.</td>
</tr>
<tr>
<td>Preview</td>
<td>A designation for Lumberyard tools that may be missing key features but are still stable and usable. The user experience is high quality, functional, and consistent where it exists but may be unfinished. APIs are subject to change.</td>
</tr>
<tr>
<td>procedural vegetation</td>
<td>A technique used to automatically cover a large area of terrain with vegetation objects using texture layers.</td>
</tr>
<tr>
<td>Term</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>project</td>
<td>The collection of levels, assets, and code that make up a game.</td>
</tr>
<tr>
<td>quaternion</td>
<td>Mathematical notation that represents the orientation and rotation of objects in three dimensions.</td>
</tr>
<tr>
<td>ragdoll</td>
<td>Physical rules used to simulate the realistic movement of a skeletal character.</td>
</tr>
<tr>
<td>rigging</td>
<td>The process of building a skeleton hierarchy of bone joints for a character mesh.</td>
</tr>
<tr>
<td>rope</td>
<td>Used for attaching cloth, hair, or ropes to a character so that the objects can dangle and move realistically against the character.</td>
</tr>
<tr>
<td>retargeting</td>
<td>Applying animations that were created for one model to another.</td>
</tr>
<tr>
<td>scripts</td>
<td>Used for creating logic and behaviors for your game project. You can create scripts with one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Script Canvas is a visual scripting tool that doesn't require you to know how to code. You can use the Script Canvas editor to create Script Canvas graphs. Script Canvas graphs have the file extension, .scriptcanvas, such as myscriptexample.scriptcanvas. You can add your Script Canvas graph to your game entities with the Script Canvas component.</td>
</tr>
<tr>
<td></td>
<td>• Lua is a lightweight and embeddable scripting language. You can use Lua to facilitate quick iteration of your game project. Lua scripts have the file extension .lua or .luac, such as myscriptexample.lua. You can add script functionality to your game entities with the Lua Script component.</td>
</tr>
<tr>
<td>sequence</td>
<td>The content generated from the Track View for cutscenes or other canned animation triggers.</td>
</tr>
<tr>
<td>shadow map</td>
<td>A technique for controlling how shadows are added to a scene. You can use multiple, cascaded shadow maps to control how sun shadows look at varying distances.</td>
</tr>
<tr>
<td>skinning</td>
<td>The process of binding bone joints to a model's mesh (skin).</td>
</tr>
<tr>
<td>skybox</td>
<td>A cube without the bottom side that contains the environment around a scene. Usually viewed from the inside of the cube.</td>
</tr>
<tr>
<td>slices</td>
<td>Cascaded data management system for entities. Similar to the capability of prefabs, slices are reusable component entity templates that you can easily update.</td>
</tr>
<tr>
<td>socket</td>
<td>A pivot point on a character where attachments are connected. Attachments dangle or move according to the properties of the socket.</td>
</tr>
<tr>
<td>specular map</td>
<td>An image that determines the shininess of each area of a surface.</td>
</tr>
<tr>
<td>SPOM</td>
<td>Silhouette parallax occlusion mapping. SPOM is similar to POM (p. 3284), but affects the silhouette of a mesh similar to tessellation, without the object actually being tessellated.</td>
</tr>
<tr>
<td>sprite</td>
<td>A 2D bitmap image. Multiple sprites can be grouped into a single image known as a sprite sheet.</td>
</tr>
<tr>
<td>SSDO</td>
<td>Screen Space Directional Occlusion is a method for approximating real time global illumination (GI).</td>
</tr>
<tr>
<td>SSS index</td>
<td>Subsurface scattering index. SSS is used to simulate the diffusion and scattering of light transmitted through translucent objects.</td>
</tr>
<tr>
<td>Term</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>tessellation</td>
<td>The deformation of a surface using one or more geometric objects with no overlaps or gaps. Tessellation increases the geometry count of the mesh by subdividing polygons into smaller polygons before it gets displaced.</td>
</tr>
<tr>
<td>texture mapping</td>
<td>The application of an image to a surface.</td>
</tr>
<tr>
<td>TOD</td>
<td>The time of day in a level. TOD is used to simulate the changing lighting conditions as the sun crosses the sky.</td>
</tr>
<tr>
<td>UV mapping</td>
<td>The projection of texture coordinates onto a 3D surface.</td>
</tr>
<tr>
<td>vertex color</td>
<td>A method for adding variety, depth, and color variations to an object surface.</td>
</tr>
<tr>
<td>virtual reality</td>
<td>Technology that replicates the gaming environment and simulates a user's presence in it, allowing the player to feel as if they are in the game world as they interact with the environment, characters, and objects.</td>
</tr>
<tr>
<td>voxel</td>
<td>A volumetric point in a 3D space, similar to a pixel in a 2D space.</td>
</tr>
<tr>
<td>Waf</td>
<td>Game build system that allows you to automatically compile a game that targets all supported platforms.</td>
</tr>
<tr>
<td>white point</td>
<td>The reference value used to indicate true white in an image or level.</td>
</tr>
<tr>
<td>z-fighting</td>
<td>Phenomenon in 3D rendering that occurs when two or more primitives have similar or identical values in the z-buffer. Also called stitching.</td>
</tr>
</tbody>
</table>
