   - To merge two roads together, select the end point of one road and the start point of another road. Then click Merge.

Creating Bodies of water

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can create realistic-looking ocean, lakes, rivers, waterfalls, and pools with waves and ripples. Players and objects interacting with water surfaces also generate waves and ripples. Water gets its appearance from reflections on the surface and the interaction of light with particles suspended underneath the surface. You need both to achieve an authentic look.

Lumberyard offers three different shaders for rendering bodies of water:

- Water Shader (p. 1715) – For oceans only
- WaterVolume Shader (p. 1719) – For lakes, rivers, ponds and all other water volumes
- Waterfall Shader (p. 1717) – For waterfalls only

Lumberyard also supports caustics. Caustics are optical properties caused by light refracting through a volume of water, creating light and dark patterns at the bottom. Realistic caustic effects also include water ripples generated from players and other objects interacting with the water surface.
Note
To make caustics visible, you must place water volumes at a height of 1 or greater in your level.

Topics
- Preparing the Terrain (p. 1243)
- Setting Ocean Parameters (p. 1243)
- Creating Rivers (p. 1244)
- Adding Waterfalls (p. 1248)
- Adding Water Puddles (p. 1248)
- Adding Fog Beneath Water (p. 1249)
- Advanced Water Volume Parameters (p. 1250)

Preparing the Terrain

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

For all water volumes such as lakes, ponds, and reservoirs, the terrain must first be lowered and sculpted to contain the body of water. To create the bottom and walls of your body of water, you need to consider the depth, shape, and edges of your landform geography.

For rivers, see Preparing the River Terrain (p. 1244).

To prepare the terrain for bodies of water

1. In the Rollup Bar, on the Terrain tab, click Modify, Rise/Lower.
2. Adjust the Outside Radius value as needed for the widest point of the water volume.
3. Adjust the Height value to a negative value for the depth of the water volume.
4. Adjust the other terrain brush settings as needed to fine-tune the look of the walls. See Terrain Brush Parameters (p. 1239) for more information.
5. In your level, drag to define the shape. Release the mouse button and repeat as needed.

Setting Ocean Parameters

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
When you create a new level, Lumberyard creates an ocean by default, complete with waves and reflections. The ocean uses the Water Shader (p. 1715). You can change the ocean's various properties and effects.

To set ocean parameters

1. In the Rollup Bar, on the Terrain tab, click Environment.
2. Under Ocean, adjust the following parameter values:
   - Material – Click the (...) icon to access Material Editor and select your asset.
   - Caustic depth – Set the depth to which caustic effects are visible.
   - Caustic intensity – Scale the intensity of the caustics for the water surface normals.
   - Caustic tiling – Scale the caustic tiling applied to the water surface normals. You can scale caustics independently of the surface material in cases of strong tiled normals or vice-versa.

Creating Rivers

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add realistic rivers, complete with waterfalls, to your terrain in your environment level.

The following are best practices and guidelines to keep in mind when creating rivers.

- Rivers are 2D objects, which means rivers cannot be made to flow down steep inclines. However, to make a river flow down gentle inclines, you can rotate the river along the z-axis slightly (Z=0.5 to 1.0).
- To create rivers that appear to flow down steep inclines, create multiple rivers and connect them with waterfalls.
- The more points you place for the river geometry, the more control you have for direction and curvature.
- The wider the river, the further apart the points should be to avoid clipping at sharp corners.
- For more realism, paint the bottom of the river a different texture and add vegetation.
- For more realism, add particle effects.

For information on the river entity see River Entity.

Topics

- Preparing the River Terrain (p. 1244)
- Creating the River Entity (p. 1245)
- Applying a River Material (p. 1246)
- Adjusting River Spline Geometry (p. 1247)
- Splitting and Merging Rivers (p. 1247)

Preparing the River Terrain

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.
Rivers need a riverbed and walls, which you implement as a deformation in the terrain. Use the rise/lower terrain brush for this effect.

To create a realistic-looking riverbed and walls, make sure that the walls of the river are above the starting (first) point of the river for the entire length of the river.

**To create the riverbed and walls**

1. In the Rollup Bar, on the Terrain tab, click Modify, Rise/Lower.
2. Adjust the Outside Radius slider as needed for the width of the riverbed.
3. Adjust the Height slider to a negative value for the depth of the riverbed.
4. Adjust the other terrain brush settings as needed to fine-tune the look of the riverbed. See Terrain Brush Parameters (p. 1239) for more information.
5. In your level, position the mouse at the start of river, and then drag to define the direction and course of the river. Release the mouse at the end of the river.

**Creating the River Entity**

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

After you have prepared the riverbed, you next create and place the River entity.

When performing this procedure, you may notice that parts of the river disappear into the terrain. The Align Height Map step resolves this by stretching the terrain height to match the path of the river based on its shape and on BorderWidth parameter. For information on BorderWidth and related settings, see River Entity.
To create and place the River entity

1. In the Rollup Bar, on the Objects tab, click Misc, River.
2. In your level, starting at the beginning of the river bed, click to place a series of points that define the river’s path.
3. When complete, double-click at the end of the river bed.
4. In the Rollup Bar, under River Parameters, click Align Height Map to adjust the terrain height to match the path of the river.

Applying a River Material

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

After you place the river entity, you can apply a material to the river. Rivers use the WaterVolume Shader (p. 1719).

To apply a material to a river

1. In the Rollup Bar, on the Objects tab, click Misc, River.
Creating Terrain

2. Click `<No Custom Material>` to open Material Editor.
3. In the Material Editor, expand the tree and select your asset.
4. Modify material settings and WaterVolume Shader (p. 1719) parameters as needed.
5. When finished, click Assign Item to Selected Objects, and close Material Editor.

Adjusting River Spline Geometry

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can make precise changes to the geometry of a river. You simply adjust the spline points and parameters.

To adjust river spline parameters

1. In the Rollup Bar, on the Objects tab, click Misc, River.
2. Under Spline Parameters, click Edit, and do any of the following for the river in your level:
   - To move a point, drag it.
   - To add a new point, hold down Ctrl while clicking the spline at the desired location.
   - To delete a point, double-click it.
   - To change the angle at a point, select it and adjust the Angle value.
   - To change the width at a point, select it, clear the Default width check box, and adjust the Width value.

Tip
You can also change the positions of any spline point. Just select a point and use the X, Y, Z, and XY axis-lock buttons located at the top of Lumberyard Editor.

Splitting and Merging Rivers

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can split a river apart and merge two rivers together.

To split or merge rivers

1. In the Rollup Bar, on the Objects tab, click Misc, River.
2. Under **Spline Parameters**, click **Edit**, and do either of the following in your level:
   - To split a river apart, select the desired point and click **Split**.
   - To merge two rivers together, select the end point of one river and the start point of another river. Then click **Merge**.

**Adding Waterfalls**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A waterfall is a natural feature to add to cliffs or when a river changes elevation or course. Waterfalls are placed as 2D decals in the terrain.

**To add a waterfall**

1. In Lumberyard Editor, click **Tools, Material Editor**.
2. In the Material Editor, select a suitable texture asset.
3. Under **Material Settings**, select the **Waterfall** shader.
4. Under **Texture Maps**, place the texture in the alpha channel of the **Diffuse** texture map.
5. Expand **Diffuse\Oscillator** and adjust parameter values to produce a realistic animation effect for the texture.
6. Under **Shader Params**, adjust **Foam** parameters as needed.
7. Adjust other material settings and shader parameters as needed.
8. Place the waterfall in your level, clicking to create a simple geometry that follows the terrain.
9. Apply water (rain) particle effects if desired.

**Adding Water Puddles**

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To create realistic water puddles and water rifts, use non-tiling textures that can be placed as decals. While water puddles could be created as a water volume, using decals is less demanding on resources. For more information on decals, see Working with Decals (p. 1752).

For proper blending between the water puddle and the terrain, use an alpha channel with a smooth gradient so it fades into the terrain and the transition won't be noticeable.

**To add a water puddle**

1. In Lumberyard Editor, click **Tools, Material Editor**.
2. In the Material Editor, select a suitable material asset.
3. Under \Lighting Settings\Specular, enter 85, 85, 85
4. In your level, click to place the puddle.
5. In the Rollup Bar, on the Objects tab, click Custom, GameVolume.
7. In your level, click boundary points around the puddle. Double-click the last point to complete the enclosure.

Adding Fog Beneath Water

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add realistic-looking fog beneath water surfaces. For more information about Lumberyard's fog system, see Fog Systems (p. 1822).

To add fog beneath water
1. In your level, click to select the water volume entity in which you want to add fog.
2. In the Rollup Bar, on the Objects tab, click Area, WaterVolume, WaterVolume Params, and modify the following parameters as needed.

   **FogDensity**
   Specifies how dense the fog appears.

   **FogColor**
   Sets the fog color.

   **FogColorMultiplier**
   Defines how bright the fog color is.

   **FogColorAffectedBySun**
   Enables the Setting Sun Parameters and Console Variables (p. 1266) Sun color parameter value to affect fog color.

   **FogShadowing**
   Enables the surface of water to receive shadows. You can control the shadow darkness. Valid values are 0–1.
   - For this parameter to function, the console variable r_FogShadowsWater must be set to 1.
   - **FogShadowing** is only available when the Config Spec setting in Lumberyard Editor is set to Very High.

   In addition, if the VolFogShadows property is enabled in the Terrain\Environment panel in Rollup Bar, shadow darkness is automatically set to full. However, the fog above the water will have volumetric shadowing.
CapFogAtVolumeDepth

If false, continues to render fog below the specified river depth.

Advanced Water Volume Parameters

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The following advanced parameters apply to water volumes.

**To set advanced Water Volume parameters**

1. In the Rollup Bar, on the **Objects** tab, click **Area**.
2. Under **Object Type** click **WaterVolume**.
3. Under **WaterVolume Params\Advanced**, adjust the following parameter values as needed:

   **FixedVolume**
   
   Traces a ray down to find a 'vessel' entity and 'spill' the requested amount of water into it. For static entities, it attempts to boolean-merge any surrounding static that intersects with the first vessel (use the **No Dynamic Water** flag on brushes that do not need that).

   **VolumeAccuracy**
   
   Water level is calculated until the resulting volume is within this (relative) difference from the target volume (if set to 0 it runs up to a hardcoded iteration limit).

   **ExtrudeBorder**
   
   Extrudes the border by this distance. This is particularly useful if wave simulation is enabled as waves can raise the surface and reveal open edges if they lie exactly on the vessel geometry.

   **ConvexBorder**
   
   Takes convex hull of the border. This is useful if the border would otherwise have multiple contours, which areas do not support.

   **ObjectSizeLimit**
   
   Only objects with a volume larger than this number takes part in water displacement (set in fractions of FixedVolume).

   **WaveSimCell**
   
   Size of cell for wave simulation (0 means no waves). Can be enabled regardless of whether FixedVolume is used.

   **WaveSpeed**
   
   Sets how “fast” the water appears.

   **WaveDamping**
   
   Standard damping.
Creating Terrain

WaveTimestep
This setting may need to be decreased to maintain stability if more aggressive values for speed are used.

MinWaveVel
Sleep threshold for the simulation.

DepthCells
Sets the depth of the moving layer of water (in WaveSimCell units). Larger values make waves more dramatic.

HeightLimit
Sets a hard limit on wave height (in WaveSimCell units).

Resistance
Sets how strongly moving objects transfer velocity to the water.

SimAreaGrowth
If changing water level is expected to make the area expand, the wave simulation grid should take it into account from the beginning. This sets the projected growth in fractions of the original size. If wave simulation is not used, this setting has no effect.

Copying and Moving Terrain Areas

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can copy and move areas or sections of terrain, including vegetation, water, and other objects in your level. You can also rotate sections of terrain.

To copy or move a section of terrain

1. In Rollup Bar, on the Terrain tab, click Move Area.
2. Click Select Source and then click in the level to define the volume that is copied or moved.
3. Click Select Target and click in the level to define the target volume location.
4. Adjust the values of the following parameters as needed.

Sync Height
Sets the Z position of the source and target volumes to the same value.

Target Rotation
Rotates the source volume counterclockwise by the selected amount when moved to the target location.

DymX, Y, Z
Changes the dimension of the source volume.
Only Vegetation

Moves or copies only vegetation and other objects and not the terrain itself.

Only Terrain

Moves or copies just the terrain and not vegetation or other objects.

5. Click Copy or Move.

Blending Environment Probes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use an Environment Probe (p. 587) component to achieve the right visual quality for a space. Environment probes help to determine proper reflections, ambient diffuse values, particle diffuse values, and shadow colors.

Each environment probe in a scene represents ambient lighting information. The probe data does not change even when other lights in the scene move or change in brightness. This can result in an unnatural appearance. For example, the sun sets but objects are still brightly lit by an environment probe used for daytime lighting.

To achieve convincing transitions in lighting:

- Create multiple environment probes that represent different lighting conditions.
- Write a script that blends and puts them in sync with the scene's dynamic lights.

For example, as the sun moves from noon to dusk, a script takes brighter environment probes and blends them gradually to darker environment probes. A realistic full day-to-night cycle can require eight or more probes.

Environment probes have a Probe Fade property that fades out the environment probe. You can change the Probe Fade property with Script Canvas, Lua, and the Track View. For this property, you can specify a value between 0.0 and 1.0, which represents a percentage of ambient lighting. For example, in a scenario with two overlapping environment probes, the higher priority probe (Probe A) normally hides the lower priority probe (Probe B). Only Probe A lights objects in that area. However, if you set Probe A’s Probe Fade value to 0.5, then 50% of the ambient lighting comes from Probe A and the rest comes from Probe B.

To add an environment probe to your scene, see Working with Components (p. 479) and Environment Probe (p. 587). You can also find detailed, step-by-step instructions at Lighting the Environment in the Amazon Lumberyard Getting Started Guide.

Topics

- Dimmer and Night Light Example (p. 1252)
- Day to Night Cycle Example (p. 1256)

Dimmer and Night Light Example

The following example scenario demonstrates how to dim a lamp. The room has a dimmer lamp and a night light. As the lamp dimms, the ambient lighting provided by the environment probes must dim as well. The room does not completely darken, because of the night light.
To set up the lights, environment probes, and script

1. In Lumberyard Editor, do the following:
   a. Create an entity (p. 463) named **lamp**.
   b. Add the **Point Light (p. 706)** component to the entity.
   c. To assign a high brightness, specify the following property values:
      - **Cast shadow spec**: Low
      - **Diffuse multiplier**: 4
      - **Max Distance**: 10

2. Create another entity named **nightlight** and do the following:
   a. Add the **Point Light (p. 706)** component to the entity.
   b. To assign a low brightness, specify the following property values:
      - **Cast shadow spec**: Low
• **Diffuse multiplier:** 1
• **Max Distance:** 10

3. Create two environment probes (p. 587). Put them at the same location and make them the same size. Name one `probe_light` and the other `probe_dark`.
   a. For `probe_light`, specify the **Sort Priority** (p. 587) property to 1. This is the environment probe that fades in and out.
   b. For `probe_dark`, keep the default value for **Sort Priority** (p. 587). The value should be 0.

4. In the following step, you need to bake the `probe_light` entity. Baked means to store information about the lighting in the environment probe.

   To bake the `probe_light`, do the following:
   a. Select the `probe_light` entity.
   b. In the **Entity Inspector**, under **Cubemap generation** (p. 589), click **Generate**.
      After the cubemap is generated, the **Add Bounce** button replaces the **Generate** button.
   c. Click **Add Bounce** to rebake the probe with bounced light.
   d. **Hide** (p. 465) the `probe_light` entity. This prevents the `probe_light` entity's lighting from getting baked into the `probe_dark` entity.

5. To bake the `probe_dark` entity, do the following:
   a. Select and **hide** (p. 465) the `lamp` entity. This prevents the `lamp` entity's light from getting baked into the `probe_dark` entity.
   b. Select the `probe_dark` entity.
   c. In the **Entity Inspector**, under **Cubemap generation** (p. 589), click **Generate**.
      After the cubemap is generated, the **Add Bounce** button replaces the **Generate** button.
   d. Click **Add Bounce** to rebake the probe with bounced light.

6. **Show** (unhide) (p. 465) the `probe_light` and `lamp` entities.

7. Create an entity and do the following:
   a. Add the **Lua Script** (p. 683) component to the entity.
   b. In the **Lua Script** component, for the **Script** property, click the (...) icon, and then navigate and select the `RoomLights.lua` file. See `RoomLights.lua` (p. 1255).

   **Note**
   To create the script file, copy and paste the code into a text file. Rename the file extension to `.lua` and save it in your project directory.

8. In the **Lua Script** component, for the **LightEntity** property, click the target icon and in the viewport, select the `lamp` entity. You can also use the **Entity Outliner** to select the `lamp` entity.

   The `lamp` entity appears in the **LightEntity** box.

9. In the **Lua Script** component, for the **ProbeEntity** property, click the target icon and in the viewport, select the `probe_light` entity.

   You can also use the **Entity Outliner** to select the `probe_light` entity.

The **Lua Script** component should look like the following example:
Example

See the following `RoomLights.lua` script.

```lua
local RoomLights = {
    -- Defines properties that are exposed in the Entity Inspector window
    Properties = {
        Speed = 1.0,              -- Use to modify the speed of the light cycle
        LightEntity = EntityId(), -- Set this to a Light component that will have its intensity changed
        ProbeEntity = EntityId(), -- Set this to an Environment Probe component that will be faded out in sync with the Light component
    },
}

function RoomLights:OnActivate()
    -- Subscribes to per-frame tick updates
    self.tickBusHandler = TickBus.Connect(self);

    -- Tracks the total number of seconds that the script has been running
    self.time = 0;

    -- The level at which the light starts is its max value. Light level is reduced periodically to dim the light, and then raised back to its max level.
    self.maxLightLevel = Light.Event.GetDiffuseMultiplier(self.Properties.LightEntity);
end

function RoomLights:OnDeactivate()
    self.tickBusHandler:Disconnect();

    -- Restores entities to their default settings
    Light.Event.SetDiffuseMultiplier(self.Properties.LightEntity, self.maxLightLevel);
    Light.Event.SetProbeAttenuation(self.Properties.ProbeEntity, 1);
end

function RoomLights:OnTick(deltaTime, timePoint)
    self.time = self.time + deltaTime;

    -- Increases and decreases brightness between 0 and 1 as time passes
    local brightness = Math.LerpInverse(-1, 1, Math.Sin(self.time * self.Properties.Speed));

    -- Sets the brightness of the light
    Light.Event.SetDiffuseMultiplier(self.Properties.LightEntity, brightness * self.maxLightLevel);

    -- Sets the fade value of the probe
    Light.Event.SetProbeFade(self.Properties.ProbeEntity, brightness);
end
```
Day to Night Cycle Example

The following scenario is a more complex but commonly used example to develop a full day-to-night cycle. This example uses a concept similar to the dimmer in the Dimmer and Night Light Example (p. 1252), but instead of changing the light bulb intensity, you change the sun's position. This requires a large number of probes blending together. Also, dawn and dusk require more probes than noon and midnight. See the following procedure and script outline to get started.

To set up the day-to-night cycle probes and script

1. Create a set of entities (p. 463) to represent times. Put them in the same location and make them the same size.
2. Name the entities so that they correspond to a time on the 24-hour clock, such as probe1200 to represent noon.
   
   For example, start with 0000, 0550, 0600, 0610, 1200, 1750, 1800, and 1810. You don't need another probe at 2400 because that's the same as 0000. Notice that there are more probes clustered around dawn and dusk than noon and midnight.

   Note
   You can name these probes whatever you like, but they must end with the 4-digit time designation. The script that you apply later in this procedure looks for entities that end with four digits corresponding to the time.

3. Add (p. 479) an Environment Probe (p. 587) component to each entity.
4. Hide (p. 465) the probes so that their outputs are not captured in each other's baked lighting.
5. To bake each probe, do the following:
   
   a. Select an environment probe. You do not need to show (unhide) it for the baking process.
   b. Open the Time Of Day (p. 1270) editor.
   c. Set the Current Time to the time that corresponds to the probe name. Close the Time of Day editor.
   d. With the probe selected, click Generate to generate the cubemap.
   e. (Optional) To simulate additional light bounces, show (unhide) the environment probe and click Add Bounce.
   f. If it's not still hidden, hide (p. 465) the probe and then repeat these steps for the next probe.
6. After you set the time of day and generate (bake) the cubemap for every probe, create another entity named probe_set.
7. Select and move the probes into the probe_set entity.
8. In the **Entity Outliner**, do the following:
   
a. Select the **probe_set** entity.

b. Add the **Lua Script (p. 683)** component to the entity.

c. In the **Lua Script** component, for the **Script** property, click (...) and then navigate and select the `ProbeBlending.lua` file. See *ProbeBlending.lua (p. 1260).*

   **Note**
   
   To create the script file, copy and paste the code into a text file. Rename the file extension to `.lua` and save it in your project directory.

   
9. In the **Lua Script** component, for **Probes**, click + until the number of **EntityId** slots equals the number of probes that you have.
10. Assign each of your probes to one of the script's `EntityId` probe slots. In the **Entity Inspector**, click the target icon 🔄 next to an empty slot. In the **Entity Outliner**, select a probe. Repeat until all slots are filled.

In the following example, all of the empty slots are filled. When they are not yet selected, the `EntityId` boxes are blank.
Example

See the following ProbeBlending.lua script. To use this script, you must be in the StarterGame project.

```lua
-- This script connects a set of probes to the time-of-day cycle and blends between them as time progresses.
-- It supports an arbitrary number of probes. This means that you can use as many or as few as you need.
-- A minimum of two environment probes are required. You likely need more to get convincing results, particularly around dawn and dusk when lighting conditions change dramatically.

-- This script is provided as an example to help you get started. It is not an official feature, and is therefore not guaranteed to address every need or be completely free from defects.
```
local ProbeBlending =
{
    Properties =
    {
        Probes = { default = { EntityId(), EntityId() } }, -- Each probe entity's name must
        end in a 24-hour time code such as "envProbe1830" for a probe at 6:30pm
        ShowDebugOutput = false, -- If true, on every frame the script dumps the blend
        values for all probes to the console output
        Blend = true, -- If false, pops between probes rather than blending between them
        (mostly for demonstration purposes)
        UseToD = true, -- If true, progression is based on Time of Day (ToD). If false, an
        internal timer. Turning this off can be useful for testing purposes.
        CycleTime = 10  -- If UseToD = false, this is the number of seconds in one full
        cycle
    },

Working with Database Libraries

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

With Lumberyard's Database View editor, you can organize and work within the libraries of your game items. You can add new or load existing libraries to your level, or remove libraries from your level. Within a library, you can organize items by customized groups, clone and edit items, assign items to selected objects, and retrieve properties from the current selection.

The Database View editor displays the following categories of libraries on its tabs:

- Entity Library
- Prefabs Library
- Vegetation (p. 1298)
• **Particles (p. 1507)**
• **GameTokens**

Using the **Database View** editor's toolbar, you can load, save, or add new libraries, or remove a library. The drop-down menu features a list of libraries that you've already opened; select an open library from this list. Use the **Add new item** tool (1) to add items to your library, **Clone library item** (2) to create a duplicate of an existing item, and **Remove item** (3) to delete the item from the library. Use **Assign item to selected objects** (4) to assign the selected item to objects currently selected in your viewport. Use **Get properties from selection** (5) to use the properties of the object selected in the viewport and apply those properties to the item selected in the item browser.

The item browser pane (A) shows the groups and items that are available in the current library. The properties pane (B) displays the properties of the item selected in the item browser. Some tabs also feature a preview pane (C).

**Adding Sky Effects**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

**Topics**
• **Creating a Dynamic Daytime Sky (p. 1266)**
• **Creating a Dynamic Night Sky (p. 1268)**
• **Creating Time of Day Sky Effects (p. 1269)**
Creating a Dynamic Daytime Sky

To add a dynamic daytime sky, you adjust various sun parameters, atmospheric properties, sun ray effect, and sun shadows. Dynamic skies use the SkyHDR Shader (p. 1708).

All properties and parameters in the following topics are ignored when you use a static sky (SkyBox), which uses the Sky Shader (p. 1708).

Topics
- Setting Daytime Atmospheric Effects (p. 1266)
- Setting Sun Parameters and Console Variables (p. 1266)
- Adding Sun Rays (p. 1267)
- Setting Sun Shadow Settings (p. 1267)
- Adding Cascaded Sun Shadows (p. 1268)

Setting Daytime Atmospheric Effects

To create dynamic daytime sky atmospheric effects, you modify sun and light-scattering setting that affect the appearance of distant objects, which shift in color due to atmospheric interference. These settings do not directly affect the rendering of objects or environment lighting colors and intensities.

To set daytime atmospheric effects

1. In Lumberyard Editor, choose Tools, Other, Time Of Day.
2. In the Parameters pane, for Sky Light, adjust the Sky Light Parameters (p. 1284) as needed.

Setting Sun Parameters and Console Variables

You can define how the sun appears in the daytime sky.

To set sun parameters

1. In Lumberyard Editor, choose Tools, Other, Time Of Day.
2. In the Parameters pane, for Sun, adjust the Sun Parameters (p. 1277) as needed.
You can define how the sun renders in the daytime sky.

**To set console variables for sun rendering behavior**

1. In Lumberyard Editor, in the Console pane, click the icon in the bottom left.
2. In the Console Variables window, search for and set the following console variables to control the sun's rendering behavior. For more information, see Using the Console Window (p. 210).

<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>e_Sun</td>
<td>Activates or deactivates the sun's light source.</td>
</tr>
<tr>
<td></td>
<td>0 = Deactivate</td>
</tr>
<tr>
<td></td>
<td>1 = Activate</td>
</tr>
<tr>
<td>e_SunAngleSnapDot</td>
<td>Updates the cached sun direction if the dot product (cached sun direction and real-time sun direction) is less than the specified value for this console variable.</td>
</tr>
<tr>
<td>e_SunAngleSnapSec</td>
<td>Determines how often, in seconds, to update the cached sun direction.</td>
</tr>
<tr>
<td>e_SkyUpdateRate</td>
<td>Specifies the percentage of a full dynamic sky update, calculated per frame. This console variable affects how smoothly the sun moves in the sky, if the speed value in the Time of Day Editor is greater than 0. Higher values may impact rendering performance. Valid values: 0 to 100</td>
</tr>
</tbody>
</table>

**Adding Sun Rays**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

You can create a sun rays effect, which simulates the shafts of light that the sun produces under certain atmospheric conditions.

**To add sun rays**

1. In Lumberyard Editor, choose Tools, Other, Time Of Day.
2. In the Parameters pane, for Sun Rays Effect, adjust the Sun Ray Effects Parameters (p. 1287) as needed.
3. Close the Time Of Day editor.

**Setting Sun Shadow Settings**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.
You can define how sun shadows appear in your level.

**To set sun shadow settings**

1. In Lumberyard Editor, choose Tools, Terrain Tool.
2. Choose Environment.
3. Under EnvState, adjust the following parameters as needed:
   - **Sun shadows min spec** – Specifies the minimum system specification for casting sun shadows.
   - **Sun shadows additional cascade min spec** – Specifies the minimum system specification for rendering an additional sun shadow cascade at a larger viewing distance.

**Adding Cascaded Sun Shadows**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can create multiple cascaded shadow maps for your level, which controls how sun shadows look at varying distances. The higher the cascade, the further it is away from the camera (cascade 0 is closest to the camera) and the lower the resolution of the shadows.

**To create cascaded sun shadows**

1. In Lumberyard Editor, choose Tools, Other, Time Of Day.
2. In the Parameters pane, for Shadows, adjust the Shadows Parameters (p. 1288) as needed for each shadow cascade.

**Creating a Dynamic Night Sky**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To add a dynamic nighttime sky, you adjust various horizon, moon, and stars settings. Dynamic skies use the SkyHDR Shader (p. 1708).

All properties and settings in the following topics are ignored when using a static sky (SkyBox).

**Topics**

- Setting Nighttime Atmospheric Effects (p. 1268)
- Setting Moon Parameters (p. 1269)

**Setting Nighttime Atmospheric Effects**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To add dynamic nighttime atmospheric effects, you set various horizon, moon, and star field parameters.
To set nighttime atmospheric parameters

1. In Lumberyard Editor, choose Tools, Other, Time Of Day.
2. In the Parameters pane, for Night Sky and Night Sky Multiplier, adjust the Night Sky Parameters (p. 1285) and Night Sky Multiplier Parameters (p. 1286) as needed.

Setting Moon Parameters

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can define how the moon appears in the nighttime sky.

To set moon parameters

1. In Lumberyard Editor, choose Tools, Terrain Tool.
2. Choose Environment.
3. Under Moon, adjust the following parameters as needed:
   - Latitude – Sets the latitude of the moon.
   - Longitude – Sets the longitude of the moon.
   - Size – Adjusts the size of the moon.
   - Texture – Specifies the asset for creating the moon texture.

Creating Time of Day Sky Effects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use time of day effects to create dynamic skies to simulate the changing lighting effects that are caused by the sun moving across the sky. You can also configure and store a complete day–night cycle of changing environment parameters to add realism to your level.

You can use the Time of Day editor and Sun Trajectory Tool to achieve these effects.

Note
All properties and parameters in the following topics are ignored when using a static sky (SkyBox).

Topics
- Setting Dawn and Dusk Effects (p. 1269)
- Setting a Day-Night Cycle (p. 1270)

Setting Dawn and Dusk Effects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
You can simulate the changing lighting effects that are caused by the sun moving across a dynamic sky. You can set sunrise time, duration of dawn, sunset time, duration of dusk, current time, and the path of the sun.

**To set dawn and dusk effects**

1. In Lumberyard Editor, choose **Tools, Other, Sun Trajectory Tool**.
2. In the **Sun Trajectory Tool**, set the following properties and parameter values as needed.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time of Day</td>
<td>Sets the current time.</td>
</tr>
<tr>
<td>Sun Direction</td>
<td>Specifies the direction where the sun rises.</td>
</tr>
<tr>
<td>Dawn Time</td>
<td>Specifies the time the sun will rise.</td>
</tr>
<tr>
<td>Dawn Duration</td>
<td>Sets the transition duration of moon-to-sun lighting.</td>
</tr>
<tr>
<td>Dusk Time</td>
<td>Specifies the time the sun will set.</td>
</tr>
<tr>
<td>Dusk Duration</td>
<td>Sets the transition duration of sun-to-moon lighting.</td>
</tr>
<tr>
<td>Force sky update</td>
<td>If selected, updates the sky light calculations for each frame. If cleared, distributes calculations over several frames.</td>
</tr>
<tr>
<td>Import</td>
<td>Imports settings from a saved lighting file (.lgt).</td>
</tr>
<tr>
<td>Export</td>
<td>Exports current settings to a lighting file (.lgt).</td>
</tr>
<tr>
<td>Terrain Occlusion</td>
<td>Creates the effect of indirect lighting.</td>
</tr>
<tr>
<td>Super Sampling</td>
<td>Interpolates the pixels of indirect sampling data to eliminate hard transitions.</td>
</tr>
</tbody>
</table>

3. Close the **Sun Trajectory Tool** editor.

**Setting a Day-Night Cycle**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Time of Day Editor to configure changes to environment parameters over time to mimic a day-night lighting cycle. The Time of Day Editor uses a 24-hour timeline graph and a recording function to store changing environment parameter values in an XML file.

Environment parameter values that you change in the **Parameters** panel of the **Time of Day Editor** are set for the currently selected time.

The Time of Day graph shows changes to the selected parameter over time. When a parameter value is changed, the graph curve is updated for the currently selected time. You can also directly change the curve by dragging it up or down between the keyframe points. Keyframe points are displayed as yellow...
dots. You can insert new keyframe points by double-clicking the curve. To remove existing keyframe points, double-click the keyframes (yellow dots) themselves. Lumberyard interpolates parameter values for times that lie between keyframe points.

**Example**

The following is an example graph in the Time of Day Editor.

To configure a day-night cycle

1. In Lumberyard Editor, choose **Tools, Other, Time Of Day**.
2. In the **Parameters** pane, adjust the parameter value for each cycle that you want to create, and then do the following:
   a. Click the red button to start recording.
   b. In the **Time Of Day Tasks** pane, under **Time**, set the **Current Time** to apply the parameter value. The graph reflects the new value at the specified time.
   c. Set a new parameter value and current time value pair. Repeat as many times as needed to get a realistic change over time for the parameter.
   d. Click the red button to stop recording.
3. In the **Time Of Day Tasks** pane, complete the following tasks as needed to export, import, and play a time-of-day (day–night) cycle.
### Parameter | Description
---|---
**Import From File** | Imports cycle settings from an `.xml` file.
**Export To File** | Exports cycle settings to an `.xml` file.
**Reset Values** | Resets all parameters to their default values.
**Expand All** | Expand all parameters.
**Collapse All** | Collapse all parameters.
**Current Time** | Sets the current time in the **Time of Day** editor.
**Start Time** | Sets the time to use when the game starts. This is not the same value as the current time.
**End Time** | Sets the time to use when the game ends. If you set the end time to 23.59, the time loops and starts the next cycle when the day is over.
**Play Speed** | Sets the speed at which time advances in the cycle.
**Play** | Starts or resumes the playback of the cycle in the **Time of Day** editor. If the current time value is not within the start and end times, playback begins at the specified start time.
**Stop** | Stops the playback of the cycle in the **Time of Day** editor.
**Force Sky Update** | Updates the sky lighting calculations in each frame. If deselected, calculations are distributed over several frames. The effect may not be visible for some time.

4. Close the **Time of Day** editor.

### Creating Static Skyboxes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Static skies use the **Sky Shader** (p. 1708) and a skybox, which is a cube that has textures on five sides (excluding the bottom). This allows you to simulate the sky in your level. Static skies cannot use dynamic or animated **Time of Day** effects, HDR settings, and sun or moon parameters.

If you want to create a static sky, create a skybox material and then apply the material to the skybox.

**Topics**
- Creating Skybox Materials (p. 1273)
- Applying Skybox Materials to a Skybox (p. 1274)
- Changing Skybox Parameters (p. 1276)
- Switching Skyboxes with the Script Canvas Editor (p. 1276)
Creating Skybox Materials

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Skyboxes in Lumberyard are 5-sided. Sides 1 through 4 are the sides of the box, and side 5 is the top of the box. Skyboxes in Lumberyard do not have a bottom.

The sides of the box are represented by three textures that follow a specific naming convention:

1. skybox_12.tif
2. skybox_34.tif
3. skybox_5.tif

The suffix in the name indicates which sides of the box that the texture is mapped to.

You can use any image editing software to create a skybox texture. We used Adobe Photoshop to create this example and followed these specifications:

- The source sky image is authored at 8192 x 1024.
- The image uses 16 bits per channel to help preserve smooth gradients in the sky.
- The image is divided into four sections that are 2048 x 1024 each (for illustration purposes).

The numbers represent each side of the skybox that the texture is mapped to. Sides 1 and 2 will become skybox_12.tif and sides 3 and 4 will become skybox_34.tif.

The top of the example sky is a separate texture. The numbers represent which edge of the texture to map to which side. This is important for you to manage texture seams. You must name this 2048 x 2048 texture skybox_5.tif.

When you combine sides 1 and 2 into a single texture (skybox_12.tif), you must flip side 2 horizontally. When you combine sides 3 and 4 into a single texture (skybox_34.tif), you must flip side 4 horizontally. This results in two textures that are 2048 x 2048 each.
To prepare the skybox textures for Lumberyard

1. Navigate to the directory with your newly created textures.
2. Right-click each texture and choose RC Open Image.
   
   **Note**
   
   If you do not see RC Open Image, you must install RC Shell Commands using the Lumberyard Setup Assistant. For more information, see Using Lumberyard Setup Assistant to Set Up Your Development Environment (p. 16).

3. In the texture dialog box, under Preset, choose SkyboxHDR from the drop-down list. Click OK. This will create a text file (imagename.exportsettings) that Lumberyard uses to compile the texture correctly.

4. If you use source control, you must check in all images and .exportsettings files. If you do not check in these files, your scene will not render similarly for each person on your project.

Applying Skybox Materials to a Skybox

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Do the following to apply a skybox material to a skybox.

**To apply a skybox material to a skybox**

1. In Lumberyard Editor, choose Tools, Material Editor.
2. In the Material Editor, select an existing skybox material from the tree pane or create a new material.
4. Under **Texture Maps**, for the **Diffuse** texture, choose one of the three skybox textures that you created.

5. In Lumberyard Editor, choose **Tools, Rollup Bar**.

6. In the **Rollup Bar**, on the **Terrain** tab, click **Environment**.

7. Under **SkyBox**, click the browse (..) button to choose a new material for the **Material** parameter.

8. In the **Material Editor**, choose a material that uses the **Sky** shader.

9. Return to the **SkyBox** settings in the **Rollup Bar**, and click the assign (<) button to apply the selected material to the skybox.

10. (Optional) Configure the following parameters:

    - **Material low spec** – Select the skybox material to display at low resolution.
    - **Angle** – Specify the angle to rotate the skybox.
    - **Stretching** – Specify the amount to stretch the skybox texture to reduce the horizon line.

11. Close the **Material Editor**.
Changing Skybox Parameters

Do the following to modify the parameters of the dynamic sky in your level.

To change dynamic sky parameters
1. In Lumberyard Editor, choose Tools, Other, Time of Day.
2. In the Parameters pane, specify changes to the Advanced Parameters (p. 1288).

Switching Skyboxes with the Script Canvas Editor

You can use the Script Canvas editor to create a script that switches the skybox material.

To switch skyboxes with a script
1. In Lumberyard Editor, choose Tools, Script Canvas.
2. In the Script Canvas editor, choose File, New Script.
3. Right-click the canvas, search and then select the following nodes:
   - On Graph Start
   - Load by Name (p. 2586)
   - Set Skybox Material (p. 2575)
4. For your script, do the following:
   a. Select the Out pin for On Graph Start and drag to connect it to the In pin for Load By Name.
   b. For the Material Name parameter, specify the path to the material to use for the skybox. For more information, see Finding the Material Name (p. 2679).
   c. Select the Out pin for Load By Name and drag to connect it to the In pin for Set Skybox Material.
   d. Select the Material pin for Load By Name and drag to connect it to the Material pin for Set Skybox Material.
Example

5. Save the script and attach it to an entity with the Script Canvas (p. 818) component.
6. Close the Script Canvas editor.

Time of Day Parameters

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Set the following parameters to customize your sun, fog, and shadow settings.

**Topics**
- Sun Parameters (p. 1277)
- Fog Parameters (p. 1278)
- Volumetric Fog Parameters (p. 1281)
- Sky Light Parameters (p. 1284)
- Night Sky Parameters (p. 1285)
- Night Sky Multiplier Parameters (p. 1286)
- Cloud Shading Parameters (p. 1287)
- Sun Ray Effects Parameters (p. 1287)
- Advanced Parameters (p. 1288)
- Filters Parameters (p. 1288)
- Depth of Field Parameters (p. 1288)
- Shadows Parameters (p. 1288)

**Sun Parameters**

<table>
<thead>
<tr>
<th>Sun</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sun color</td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Sets the color (RGB values) of the sun. You can use this parameter along with Sun intensity to provide the preferred scene luminance.</td>
</tr>
</tbody>
</table>
## Sun Parameters

<table>
<thead>
<tr>
<th>Sun</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sun intensity (lux)</td>
<td>float</td>
<td>0.00 to 550000.00</td>
<td>Sets the brightness of the sun. This value is multiplied by the sun color to yield the overall color.</td>
</tr>
<tr>
<td>Sun specular multiplier</td>
<td>float</td>
<td>0.0 to 4.0</td>
<td>Controls the brightness and intensity of the sun on specular materials in your scene.</td>
</tr>
</tbody>
</table>

## Fog Parameters

<table>
<thead>
<tr>
<th>Fog</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Color (bottom)</td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Specifies the bottom color for the fog.</td>
</tr>
<tr>
<td>Color (bottom) multiplier</td>
<td>float</td>
<td>0.0 to 16.0</td>
<td>Specifies the intensity of the bottom fog color. This value is multiplied by the top fog color to set the brightness of the bottom fog color. You can set this value to 3 for midday and add three keys to the timeline with the values set at 0.02. This creates a localized orange bloom around the sun as it descends.</td>
</tr>
<tr>
<td>Height (bottom)</td>
<td>float</td>
<td>-5000 to 30000</td>
<td>Specifies a reference height for the vertical fog gradient. This is the height at which the fog color reaches the specified color at the top. For fog density, this value is the height at which the vertical density falloff reaches the specified density.</td>
</tr>
<tr>
<td>Density (bottom)</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Specifies the fog density at the bottom. Values greater than 0 or less than 1 cause the fog to gradually fall off.</td>
</tr>
<tr>
<td>Color (top)</td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Specifies the color of the fog component that produces halos around the sun and sunlight scatter.</td>
</tr>
<tr>
<td>Color (top) multiplier</td>
<td>float</td>
<td>0.0 to 16.0</td>
<td>Specifies the intensity of the top fog color. This value is multiplied by the bottom fog color to set the brightness of the top fog color.</td>
</tr>
</tbody>
</table>
| Height (top)       | float      | -5000 to 30000    | Sets the reference height for the vertical fog gradient. For fog color, this value is the height at which the specified color reaches at the top. For fog density, this value is the height.
### Adding Sky Effects

#### Fog

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Density (top)</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Specifies the fog density at the top. You can set the top density to a higher value than the bottom density. Doing so would reverse the vertical falloff and produce thick fog in the sky and clear views at the bottom. You can also set the top and bottom density values to be equal. Volumetric fog computations treat a level as a continuous unbound volume. If you specify a density greater than 0 at the specified top height, the fog won't suddenly stop at that height. Instead the fog will continue to fall off gradually. The same action is true for bottom boundary or density values that are less than 1.</td>
</tr>
<tr>
<td>Color height offset</td>
<td>float</td>
<td>-1.0 to 1.0</td>
<td>Offsets the height of the vertical fog gradient between the top and bottom colors.</td>
</tr>
<tr>
<td>Color (radial)</td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Specifies the color of the fog component that produces halos around the sun and sunlight scatter.</td>
</tr>
<tr>
<td>Color (radial) multiplier</td>
<td>float</td>
<td>0.0 to 16.0</td>
<td>Specifies the multiplier of the fog color component. Radial fog is more noticeable as the light intensity decreases, so you can decrease the multiplier towards the end of the timeline. Radial fog is also applied to the moon at night, so you can create two keys on the timeline and set the value to 0.</td>
</tr>
<tr>
<td>Radial size</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Specifies the size of the radial fog glow (bloom around the sun), perpendicular to the camera. This value can also enhance effects such as the colors around the sun at sunrise or sunset.</td>
</tr>
<tr>
<td>Radial lobe</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Specifies the size of the radial fog glow towards the camera or how much the radial fog is affected by distance. Higher values create a foggier scene. Lower values affect only the horizon.</td>
</tr>
</tbody>
</table>
## Adding Sky Effects

### Fog

<table>
<thead>
<tr>
<th>Fog</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Final density</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Sets the maximum density that the fog can reach. This enables the sky, horizon, and other bright, distant objects to be visible through dense fog. Setting this value too low can compromise depth perception and result in implausible visuals and apparent artifacts, especially when moving the camera.</td>
</tr>
<tr>
<td>clamp</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Global density</td>
<td>float</td>
<td>0.0 to 100.0</td>
<td>Sets the density of the global fog. Higher values create denser fog.</td>
</tr>
<tr>
<td>Ramp start</td>
<td>float</td>
<td>0.0 to 30000.0</td>
<td>Specifies the distance from the camera at which the fog starts to render at 0 density. This allows you to remove the fog around the camera and fade in at a specified distance.</td>
</tr>
<tr>
<td>Ramp end</td>
<td>float</td>
<td>0.0 to 30000.0</td>
<td>Specifies the distance from the camera at which the fog ceases to render at 0 density. This allows you to remove the fog around the camera and fade out at a specified distance.</td>
</tr>
<tr>
<td>Ramp influence</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Specifies how much the ramp values affect the rendering of the fog.</td>
</tr>
<tr>
<td>Shadow darkening</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Controls the appearance of the fog in shadow areas. Specifies how much the fog color is darkened per pixel based on the volumetric shadow value per pixel. This value is applied after calculating the darkened fog color using the sun and ambient darkening factor. See the next two parameters.</td>
</tr>
<tr>
<td>Shadow darkening sun</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Specifies how much the sun influences the radial fog color.</td>
</tr>
<tr>
<td>Shadow darkening ambient</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Specifies how much the environment influences the ambient fog color height gradient.</td>
</tr>
</tbody>
</table>
## Fog

<table>
<thead>
<tr>
<th>Fog</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shadow range</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Sets the distance that the volumetric shadows are rendered until 10% (0.1) of the level's clipping plane distance is reached. Lower values produce more accurate results; however, the shadows are not rendered as far as with higher values.</td>
</tr>
</tbody>
</table>

### Volumetric Fog Parameters

<table>
<thead>
<tr>
<th>Volumetric fog</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Height (bottom)</td>
<td>float</td>
<td>-5000.0 to 30000.0</td>
<td>Specifies a reference height for the vertical fog gradient. This is the height at which the fog color reaches the specified color at the top. For fog density, this value is the height at which the vertical density falloff reaches the specified density.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Specifies the fog density at the bottom. Values greater than 0 or less than 1 cause the fog to gradually fall off.</td>
</tr>
<tr>
<td>Height (top)</td>
<td>float</td>
<td>-5000.0 to 30000.0</td>
<td>Sets the reference height for the vertical fog gradient. For fog color, this value is the height at which the specified color reaches the top. For fog density, this value is the height at which the vertical density falloff reaches the specified density.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Specifies the fog density at the top. You can set the top density to a higher value than the bottom density. Doing so would reverse the vertical falloff and produce thick fog in the sky and clear views at the bottom. You can also set the top and bottom density values to be equal. Volumetric fog computations treat a level as a continuous unbound volume.</td>
</tr>
<tr>
<td>Density (top)</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Specifies the fog density at the top. You can set the top density to a higher value than the bottom density. Doing so would reverse the vertical falloff and produce thick fog in the sky and clear views at the bottom. You can also set the top and bottom density values to be equal. Volumetric fog computations treat a level as a continuous unbound volume. If you specify a density greater than 0 at the specified top height, the fog won't suddenly stop at that height. Instead the fog will continue to fall off gradually. The same action is true for bottom boundary or density values that are less than 1.</td>
</tr>
</tbody>
</table>
## Adding Sky Effects

### Volumetric fog

<table>
<thead>
<tr>
<th></th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global density</td>
<td>float</td>
<td>0.0 to 100.0</td>
<td>Sets the density of the global volumetric fog. Higher values create denser fog.</td>
</tr>
<tr>
<td>Ramp start</td>
<td>float</td>
<td>0.0 to 30000.0</td>
<td>Specifies the distance from the camera at which the fog starts to render at 0 density.</td>
</tr>
<tr>
<td>Ramp end</td>
<td>float</td>
<td>0.0 to 30000.0</td>
<td>Specifies the distance from the camera at which the fog ceases to render at 0 density.</td>
</tr>
<tr>
<td>Color (atmosphere)</td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Specifies the fog color for the atmosphere. For example, you can set the fog color to light blue (140, 230, 255) for midday, darker blue (90, 148, 164) for sunset or sunrise, and white for night time.</td>
</tr>
<tr>
<td>Anisotropy (atmosphere)</td>
<td>float</td>
<td>-1.0 to 1.0</td>
<td>Adjusts the anisotropy for sun atmosphere scattering. Valid values: -1 to 1 Values less than 0 will shift the fog in the opposite direction of the sun. Values greater than 0 create a consistent appearance of atmospheric fog.</td>
</tr>
<tr>
<td>Color (sun radial)</td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Specifies the color of the glow around the sun.</td>
</tr>
<tr>
<td>Anisotropy (sun radial)</td>
<td>float</td>
<td>-1.0 to 1.0</td>
<td>Adjusts the anisotropy for sun radial scattering. Values less than 0 will shift the glow effect to the opposite side of the sun. Values greater than 0 make the radial color visible even when looking away from the sun.</td>
</tr>
<tr>
<td>Radial blend factor</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Blends the sun radial color with the atmosphere color. Valid values: 0 to 1. Set the value to 0 to turn off radial fog.</td>
</tr>
<tr>
<td>Volumetric fog</td>
<td>Type</td>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>----------</td>
<td>---------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Radial blend mode</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Adjusts the blend mode for blending between atmosphere fog and radial fog. Set the value to 0 to use additive blending. Set the value to 1 to use linear interpolation.</td>
</tr>
<tr>
<td>Color (entities)</td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Specifies the global fog color for volumetric lights, excluding the sun.</td>
</tr>
<tr>
<td>Anisotropy (entities)</td>
<td>float</td>
<td>-1.0 to 1.0</td>
<td>Adjusts the appearance of volumetric fog entities based on the viewing angle in relation to the sun. 0 = isotropic</td>
</tr>
<tr>
<td>Range</td>
<td>float</td>
<td>0.0 to 8192.0</td>
<td>Adjusts the maximum radius of volumetric fog. The default setting is 64.</td>
</tr>
<tr>
<td>In-scattering</td>
<td>float</td>
<td>0.0 to 100.0</td>
<td>Specifies how much light (including sun) is scattered by fog. Higher values create a foggier scene (fog density remains unchanged) with bigger and brighter glow effects.</td>
</tr>
<tr>
<td>Extinction</td>
<td>float</td>
<td>0.0 to 100.0</td>
<td>Specifies how much light the fog absorbs. Higher values create a thick, atmosphere effect that is tough for sun light to penetrate.</td>
</tr>
<tr>
<td>Analytical fog visibility</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Adjusts the global visibility of analytical fog. Set the value to 0 to hide analytical volumetric fog. Set the value to 1 to display analytical volumetric fog.</td>
</tr>
<tr>
<td>Final density clamp</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Sets the maximum density that the fog can reach. This enables the sky, horizon, and other bright, distant objects to be visible through dense fog. Setting this value too low can compromise depth perception and result in implausible visuals and apparent artifacts, especially when moving the camera.</td>
</tr>
</tbody>
</table>
## Sky Light Parameters

<table>
<thead>
<tr>
<th>Sky Light</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sun intensity</td>
<td>R, G, B</td>
<td>0 to 254</td>
<td>Sets the illuminance of the sun and uses an RGB sun color value to compute the atmosphere color. You can use this parameter in conjunction with Sun color to provide desired scene luminance. For bright sunlight, you can use an average illuminance value of 120000 lux. The intensity of the sun decreases as it nears the horizon, so you can add keys to the timeline to lower the intensity value appropriately. To accurately render shadows at night time, you can add keys to the timeline and set the value to 5.</td>
</tr>
<tr>
<td>Sun intensity multiplier</td>
<td>float</td>
<td>0.0 to 1000.0</td>
<td>Sets the brightness of the sun. The brightness is multiplied by the sun intensity to yield the overall color. You can use this parameter in conjunction with Sun color multiplier to provide desired scene luminance. Higher values result in brighter skies. Lower values simulate an eclipse.</td>
</tr>
<tr>
<td>Mie scattering</td>
<td>float</td>
<td>0.0 to 1000.0</td>
<td>Controls mie scattering, which is caused by pollen, dust, smoke, water droplets, and other particles in the lower portion of the atmosphere. Mie scattering occurs when the particles that cause the scattering are larger than the wavelengths of radiation that are in contact with them. Mie scattering is responsible for the white appearance of clouds. Higher values create a hazy sky. Lower values create a clear sky. For a balanced sky, you can set this value to 4.8.</td>
</tr>
<tr>
<td>Rayleigh scattering</td>
<td>float</td>
<td>0.0 to 1000.0</td>
<td>Controls rayleigh scattering, which is sunlight scattering from atmospheric gases. Rayleigh scattering occurs when the particles that cause the scattering are smaller than the wavelengths of radiation that are in contact with them. As the wavelength decreases, the amount of scattering increases. Rayleigh scattering is responsible for the blue appearance of the sky.</td>
</tr>
</tbody>
</table>
## Adding Sky Effects

### Sky Light

<table>
<thead>
<tr>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Sky Light</strong></td>
<td></td>
<td>Higher values create a red-yellow sky. Lower values create a blue sky. For a blue daytime sky and red-yellow sunset sky, you can use the default value of 2.0.</td>
</tr>
<tr>
<td><strong>Sun anisotropy factor</strong></td>
<td>float</td>
<td>Controls the sun's apparent size. As this value approaches -1.0, the sun's disk becomes sharper and smaller. Higher values create a larger, fuzzier disk. For a balanced size, you can set this value to -0.995.</td>
</tr>
<tr>
<td><strong>Wavelength (R)</strong></td>
<td>float</td>
<td>Sets the hue (RGB values) of the atmosphere. You can create different atmospheres by adjusting the color values and gradients. This can be particularly useful with rayleigh scattering, when you choose a sun intensity of pure, bright white.</td>
</tr>
<tr>
<td><strong>Wavelength (G)</strong></td>
<td>float</td>
<td>Sets the hue (RGB values) of the atmosphere. You can create different atmospheres by adjusting the color values and gradients. This can be particularly useful with rayleigh scattering, when you choose a sun intensity of pure, bright white.</td>
</tr>
<tr>
<td><strong>Wavelength (B)</strong></td>
<td>float</td>
<td>Sets the hue (RGB values) of the atmosphere. You can create different atmospheres by adjusting the color values and gradients. This can be particularly useful with rayleigh scattering, when you choose a sun intensity of pure, bright white.</td>
</tr>
</tbody>
</table>

### Night Sky Parameters

<table>
<thead>
<tr>
<th>Night Sky</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Horizon color</strong></td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Specifies the horizon color of the night sky gradient. The RGB value is scaled by the multiplier. You can make a light pollution effect more pronounced by setting this value to a dark blue color (20, 36, 51).</td>
</tr>
<tr>
<td><strong>Zenith color</strong></td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Specifies the zenith color of the night sky gradient. The RGB value is scaled by the multiplier. You can make the night sky gradually appear darker further</td>
</tr>
</tbody>
</table>
### Adding Sky Effects

<table>
<thead>
<tr>
<th>Night Sky</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Night Sky</td>
<td></td>
<td></td>
<td>from the horizon by setting this value to black.</td>
</tr>
<tr>
<td>Zenith shift</td>
<td>float</td>
<td>0.0 to 16.0</td>
<td>Sets the transition for the two colors in a night sky gradient. Smaller values shift the transition towards the bottom. Larger values shift the transition towards the top. You can create a smooth transition by setting this value to 0.8.</td>
</tr>
<tr>
<td>Star intensity</td>
<td>float</td>
<td>0.0 to 16.0</td>
<td>Sets the overall brightness of the stars. Star flickering is by design and cannot be controlled. You can make the stars bright for night time by setting this value to 0.01 between 00:00 – 06:00 and 18:00 – 23:59.</td>
</tr>
<tr>
<td>Moon color</td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Specifies the moon's emissive color. The RGB value is scaled by the multiplier. You can make the moon a less saturated blue by setting this value to 51, 58, 65. You can create a light blue transition color by creating two keys at 07:00 and 17:00 and setting the value to 200, 228, 255. Setting this value to 0 removes the moon texture.</td>
</tr>
<tr>
<td>Moon inner corona color</td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Specifies the color of the moon's inner corona (glow around the moon). The RGB value is scaled by the multiplier.</td>
</tr>
<tr>
<td>Moon inner corona scale</td>
<td>float</td>
<td>0.0 to 2.0</td>
<td>Specifies the size and blurriness of the moon's inner corona. Smaller values create a bigger, blurry corona. Larger values create a smaller, focused corona.</td>
</tr>
<tr>
<td>Moon outer corona color</td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Specifies the color of the moon's outer corona. The RGB value is scaled by the multiplier.</td>
</tr>
<tr>
<td>Moon outer corona scale</td>
<td>float</td>
<td>0.0 to 2.0</td>
<td>Specifies the size and blurriness of the moon's outer corona. Smaller values create a bigger, blurry corona. Larger values create a smaller, focused corona.</td>
</tr>
</tbody>
</table>

### Night Sky Multiplier Parameters

<table>
<thead>
<tr>
<th>Night Sky Multiplier</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Horizon color</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Specifies the multiplier for the Night Sky's Horizon color.</td>
</tr>
</tbody>
</table>
## Adding Sky Effects

### Night Sky Multiplier

<table>
<thead>
<tr>
<th>Night Sky Multiplier</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zenith color</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Specifies the multiplier for the Night Sky's Zenith color.</td>
</tr>
<tr>
<td>Moon color</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Specifies the multiplier for the Night Sky's Moon.</td>
</tr>
<tr>
<td>Moon inner corona color</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Specifies the multiplier for the Night Sky's Moon inner corona color.</td>
</tr>
<tr>
<td>Moon outer corona color</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Specifies the multiplier for the Night Sky's Moon outer corona color.</td>
</tr>
</tbody>
</table>

### Cloud Shading Parameters

<table>
<thead>
<tr>
<th>Cloud Shading</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sun contribution</td>
<td>float</td>
<td>0.0 to 16.0</td>
<td>Specifies how much the sun affects the cloud brightness.</td>
</tr>
<tr>
<td>Sun custom color</td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Sets the RGB sun color.</td>
</tr>
<tr>
<td>Sun custom color multiplier</td>
<td>float</td>
<td>0.0 to 16.0</td>
<td>Sets the brightness of the sun, which is multiplied by the sun custom color.</td>
</tr>
<tr>
<td>Sun custom color influence</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Sets the degree to which the color of the sun contributes to the color of the clouds.</td>
</tr>
</tbody>
</table>

### Sun Ray Effects Parameters

<table>
<thead>
<tr>
<th>Sun Ray Effects</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sun shafts visibility</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Sets the visibility of the sun shafts. Higher values accentuate the shadow streaks that are caused by the sun light penetrating objects.</td>
</tr>
<tr>
<td>Sun rays visibility</td>
<td>float</td>
<td>0.0 to 10.0</td>
<td>Sets the visibility of the sun rays. Higher values create brighter rays around the sun.</td>
</tr>
<tr>
<td>Sun rays attenuation</td>
<td>float</td>
<td>0.0 to 10.0</td>
<td>Sets the length of the sun rays. Higher values create shorter rays around the sun.</td>
</tr>
<tr>
<td>Sun rays suncolor influence</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Sets the degree to which the color of the sun contributes to the color of the sun rays.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Set this value to 1 to use the color of the sun for the sun rays.</td>
</tr>
</tbody>
</table>
Adding Sky Effects

### Sun Ray Effects

<table>
<thead>
<tr>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sun rays custom color</td>
<td>R,G,B</td>
<td>Specifies a custom color for the sun rays. To use this parameter, you must</td>
</tr>
<tr>
<td></td>
<td>0 to 254</td>
<td>set the Sun rays sun color influence parameter to a value greater than 0.</td>
</tr>
</tbody>
</table>

### Advanced Parameters

<table>
<thead>
<tr>
<th>Advanced</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Skybox multiplier</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Controls the brightness of a static skybox. Does not affect a dynamic sky.</td>
</tr>
</tbody>
</table>

### Filters Parameters

<table>
<thead>
<tr>
<th>Filters</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Grain</td>
<td>float</td>
<td>0.0 to 8.0</td>
<td>Controls the strength of the grain filter to apply to the final image.</td>
</tr>
<tr>
<td>Photofilter color</td>
<td>R,G,B</td>
<td>0 to 254</td>
<td>Sets the RGB of the color filter to apply to the final image.</td>
</tr>
<tr>
<td>Photofilter density</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Controls the strength of the color filter to apply to the final image.</td>
</tr>
</tbody>
</table>

### Depth of Field Parameters

<table>
<thead>
<tr>
<th>Depth of Field</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Focus range</td>
<td>float</td>
<td>0.0 to 10000</td>
<td>Specifies the distance at which the background starts to lose focus and become blurry.</td>
</tr>
<tr>
<td>Blur amount</td>
<td>float</td>
<td>0.0 to 1.0</td>
<td>Controls the strength of blur in areas that are out of focus.</td>
</tr>
</tbody>
</table>

### Shadows Parameters

<table>
<thead>
<tr>
<th>Shadows</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cascade N: Bias</td>
<td>float</td>
<td>0.0 to 10.0</td>
<td>Sets the amount to move the shadow cascade away from the shadow-casting object.</td>
</tr>
</tbody>
</table>
You can create realistic-looking skies by setting sun, moon, atmospheric, and time-of-day effects. You can create two types of skies: dynamic and static.

Dynamic skies use the SkyHDR Shader (p. 1708) to render realistic effects.

The primary tools used to create different sky effects for your level are the Time of Day Editor and the Sun Trajectory Tool, as shown below:

<table>
<thead>
<tr>
<th>Shadows</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cascade N: Slope</td>
<td>float</td>
<td>0.0 to 500.0</td>
<td>Adjusts the gradient (slope-based) bias used to compute the shadow bias. Higher values reduce shadows that are cast from an object with a high light angle. For a more realistic effect, set the value between 32 and 64. Slope bias has little to no impact on performance.</td>
</tr>
<tr>
<td>Shadow jittering</td>
<td>float</td>
<td>0.0 to 10.0</td>
<td>Specifies shadow sharpness. Higher values may impact performance.</td>
</tr>
</tbody>
</table>
Adding Weather Effects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard offers a variety of realistic weather effects for your level environment.

Topics
- Adding Wind Effects (p. 1290)
- Adding Clouds (p. 1293)

Adding Wind Effects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can create realistic wind effects in your level environment.

- Adding Localized Wind (p. 1292)
Adding Global Wind

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Global wind and breezes affect everything in your level, such as all vegetation. Here’s how to set them up:

To set global wind parameters
1. In the Rollup Bar, under Terrain, click Environment.
2. Under the EnvState section, adjust values of the following parameters:
   - Wind vector – Speed and wind direction vector. Positive x values are east; positive y values are north.
   - Breeze generation – Enables breezes.
   - Breeze strength – Controls the intensity of the breeze.
   - Breeze movement speed – Controls the velocity of the breeze. Use it to produce short, rapid gusts of wind.
   - Breeze variation – Varies breeze speed, strength, and size.
   - Breeze life time – Sets the duration of each breeze, in seconds.
   - Breeze count – Sets the number of breezes generated per instance.
   - Breeze spawn radius – Radius of breeze travel.
   - Breeze spread – Determines the degree of variation in breeze direction.
   - Breeze radius – Sets the radius of breeze influence.

Adding Ocean Wind

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can simulate realistic wind and wave effects for the ocean in your level.

To set ocean wind parameters
1. In Lumberyard Editor, choose Tools, Rollup Bar.
2. In the Rollup Bar, on the Terrain tab, under Terrain, click Environment.
3. Under **OceanAnimation**, adjust the following parameters:
   - **Wind Direction** – Specifies the direction to push the water texture crawl in radians. Valid values: 0.0 to 6.28.
   - **Wind Speed** – Specifies how frequently the texture water crawl updates.
   - **Wave Frequency** – Sets the frequency of waves. Smaller values mean fewer, longer waves (deep ocean depth). Larger values mean more, shorter waves (shallow ocean depth).
   - **Wave Height** – Sets wave height in meters by means of vertex displacement.

### Creating Wind Areas

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. **Download O3DE** or visit the AWS Game Tech blog to learn more.

Wind areas define a location within which objects experience wind. If no direction is set, wind moves omnidirectionally from the center of the wind area.

**To create a wind area**

1. In the **Rollup Bar**, under **Objects**, click **Entity**.
2. Under **Browser**, expand **Physics** and double-click **WindArea**.
3. Drag to place the entity in your level. A bounding box with direction areas appears.
4. Under **Entity Properties**, adjust values of the following parameters:
   - **Active** – Enables or disables wind inside the area.
   - **AirDensity** – If greater than 0, causes objects moving through the air to slow down.
   - **AirResistance** – If greater than 0, causes lightweight objects to experience buoyancy.
   - **Ellipsoidal** – Specifies an ellipsoidal drop off in air speed.
   - **FalloffInner** – Sets the distance at which distance-based air speed begins to drop off.
   - **Speed** – Sets the wind speed.
   - **Dir** – Sets the wind direction.
   - **Size** – Sets the size of the wind area.

### Adding Localized Wind

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. **Download O3DE** or visit the AWS Game Tech blog to learn more.
Localized wind is used to simulate wind from a specific object, such as a fan or jet exhaust. You set up localized wind with the wind entity.

**To set localized wind parameters**

1. In the **Rollup Bar**, under **Objects**, click **Entity**.
2. Under **Browser**, expand **Physics** and double-click **Wind**.
3. Drag to place the entity in your level at the desired location.
4. Under **Entity Properties**, adjust the following parameters:
   - **FadeTime** – Enables or disables fade time.
   - **vVelocity** – Sets the wind strength and direction.

### Adding Clouds

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. 
[Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

You can create realistic-looking clouds in your level that move, cast shadows, and that objects can fly through.

To add clouds to your level, you add the **Sky Cloud** component to an entity. With the **Sky Cloud** component, you can define the cloud's shape, its volume, how fast it moves, the dimensions of its loop box, and more.

See the following sections to set other cloud effects, such as cloud shading, cloud shadows, and 2D distance clouds.

**Topics**

- Placing Distance Clouds (p. 1293)
- Adding 3D Cloud Shadows (p. 1295)
- Setting Cloud Shading Parameters (p. 1298)

### Placing Distance Clouds

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. 
[Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

Distance clouds are two-dimensional clouds that are placed at a great distance, such as on the horizon or at high altitudes. Distance clouds are suitable for creating a realistic distant sky scene without causing rendering performance issues. Distance clouds do not move and cannot be flown through.
Example Distance Clouds

To place distance clouds

1. Create an entity. (p. 463)
2. Add (p. 479) the Mesh (p. 684) component to the entity.
3. In the Mesh component, for Mesh asset, click (...).

4. Select a mesh asset file and click OK.
Adding 3D Cloud Shadows

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

3D clouds don't actually cast real-time shadows. Instead a moveable texture is imposed on the entire level, creating the illusion that the clouds cast shadows.
Example 3D Cloud Shadows

To add 3D cloud shadows

1. In the Rollup Bar, under Terrain, click Environment.
2. Under CloudShadows, click Cloud shadow texture and the folder icon.
3. In Preview, select an asset.
4. Drag the shadow to the desired location in your level.

5. Under **CloudShadows**, adjust the following parameters:
   
   - **Cloud shadow speed** – Sets the speed that shadows move across the terrain.
   - **Cloud shadow tiling** – Sets the tiling multiplier of the shadow texture.
   - **Cloud shadow brightness** – Sets the brightness level of the shadow.
   - **Cloud shadow invert** – Enables inverting of the cloud shadow texture.
Setting Cloud Shading Parameters

Cloud shading, unlike cloud shadows, affects the brightness and color of clouds in your level. The environment sky and sun color affect how clouds look.

To set cloud shading parameters

1. In Lumberyard Editor, choose **Tools, Other, Time Of Day**.
2. In the **Time of Day Editor**, under **Parameters**, adjust the following **Cloud Shading** properties.
   - **Sun contribution** – Specifies how much the sun affects the cloud brightness.
   - **Sun custom color** – Sets the RGB sun color.
   - **Sun custom color multiplier** – Sets the brightness of the sun, which is multiplied by the sun custom color.
   - **Sun custom color influence** – Sets the degree to which the color of the sun contributes to the color of the clouds.

Adding Vegetation

You can add realistic trees, bushes, grasses, and other vegetation to your Lumberyard terrain.

Topics

- Vegetation Best Practices (p. 1299)
- Vegetation Recommendations (p. 1299)
- Vegetation Texture Mapping (p. 1299)
- Adding Trees and Bushes (p. 1300)
- Adding Grass (p. 1300)
- Adding Vegetation Bending Effects (p. 1302)
- Vegetation Parameters (p. 1311)
Elephant

Adding Vegetation

- Vegetation Debugging (p. 1313)
- Using SpeedTree 8 for Lumberyard (p. 1313)

Vegetation Best Practices

Keep in mind the following best practices, recommendations, and guidelines when you add vegetation to your terrain level.

- Manually place vegetation to get the most control and best results.
- To save memory, place grass manually.
- Keep the polygon count for grass blades as low as possible.
- Do not exceed a diameter of 8 meters for grass patches. This size provides a balance between performance and coverage.
- Grasses and small plants do not require specular or opacity texture maps. For more information, see Working with Textures (p. 1732).
- Set the Opacity texture at a much lower resolution than the other maps.
- Use a Glossiness value of 8 or above for realistic results.
- Use the automerged method to apply wind bending effects to grass.
- Use a maximum of 72 bones per tree for touch bending.

Vegetation Recommendations

The following settings are recommended when creating vegetation in your DCC tool.

<table>
<thead>
<tr>
<th>Vegetation</th>
<th>Polygon Range</th>
<th>Texture Size</th>
<th>Proxies</th>
<th>Material IDs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Grass</td>
<td>0-300</td>
<td>512x512</td>
<td>Bending</td>
<td>Grass, grass proxy</td>
</tr>
<tr>
<td>Bushes</td>
<td>300-600</td>
<td>1024x1024</td>
<td>Bending, collision</td>
<td>Leaf, leaf proxy</td>
</tr>
<tr>
<td>Small Trees</td>
<td>600-1000</td>
<td>(2) 1024x1024</td>
<td>Bending, collision **</td>
<td>Trunk, leaf, leaf proxy</td>
</tr>
<tr>
<td>Large Trees</td>
<td>(2) 1024x1024</td>
<td>Bending, collision ***</td>
<td>Trunk, leaf, leaf proxy, trunk proxy</td>
<td></td>
</tr>
</tbody>
</table>

** Smaller breakable tree trunks are physicalized.

*** Larger non-breakable tree trunks are not physicalized.

Vegetation Texture Mapping

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Vegetation gets its appearance from texture mapping. Trees use two different sets of textures maps, one for leaves and branches and one for the trunk. Normal and specular maps can have a gloss map in the alpha channel.
The texture map you use depends on the type of vegetation:

**Grass** – Diffuse map only

**Leaves and branches (trees or bushes)** – Diffuse, specular, normal, and opacity maps

**Tree trunks** – Diffuse, specular and normal maps

Vegetation placement on a terrain texture layer is based on the pivot point of the vegetation object. Bigger vegetation objects might overlap with other terrain texture layers. This is most obvious if you have two different materials touching, like grass and mud.

### Adding Trees and Bushes

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add realistic trees and bushes to your terrain in your environment level. You must add trees and bushes manually.

**To add trees or bushes**

1. In the Rollup Bar, on the Objects tab, click Geom Entity.
2. Under Browser, select the desired vegetation.
3. Drag to place the tree or bush in your level.

### Adding Grass

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add realistic grass to your terrain in your environment level. You can drag to place and quickly paint the entire terrain, or manually click clump-by-clump to provide the most control and best results.

**Topics**

- Adding Grass Manually (p. 1300)
- Painting to Add Grass (p. 1301)

### Adding Grass Manually

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Although you can paint in your terrain to add grass quickly, the manual approach saves memory and results in better control and a more realistic effect.

**To manually add grass**

1. In Lumberyard Editor, click **Tools, Material Editor**.
2. Expand the left tree and select a suitable asset.
3. Under **Material Settings**, select the **Vegetation** shader.
4. Under **Shader Generation Params** select **Grass**.
5. Modify other settings and parameter values for the desired effect.
6. Click **Assign Object to Item**. Close Material Editor.
7. If necessary, depending on your terrain, in the **Rollup Bar**, on the **Terrain** tab, select the **AlignToTerrain** check box.
8. Click to place grass in your level and repeat as needed.

**Note**

When you add or move grass, it may sporadically jump around. This happens if you move vegetation to a location that is too dense to accommodate it. When this occurs, the vegetation moves to its last position and is outlined in red. You can then move it elsewhere or delete it.

**Painting to Add Grass**

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

You can drag the mouse to quickly paint all terrain in your level with grass. This method of placing vegetation is controlled by the texture layer that the vegetation object is associated with. Painted vegetation is visible wherever the texture layer appears. This is a quick way to automatically cover a huge area with grass.

**Note**

Painting a level with grass consumes 8 MB of memory cache.

**To add grass by painting**

1. In the **Rollup Bar**, on the **Terrain** tab, click **Vegetation**.
2. Under **Vegetation**, click **Add Vegetation Object**.
3. In **Preview**, select a suitable asset.
4. Click to place the grass in your terrain.
5. Under the **Use on Terrain Layers** parameter, select the check box for your asset. The terrain should now be covered with the grass object.

### Adding Vegetation Bending Effects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard provides three methods for adding realistic bending motions to vegetation:

- **Touch (Collision) Bending** – bending effects for larger vegetation caused by players brushing against or colliding with branches
- **Detail (Wind) Bending** – physically accurate wind effects for larger vegetation defined by using vertex colors and environment wind parameters
- **Automerged (Wind) Bending** – physically accurate wind effects for grass defined by vegetation and environment wind parameters

You can use touch and detail bending effects together. For example, a player can brush against a branch that is also swaying in the breeze. Use automerged bending by itself for objects like grass.

From a performance standpoint, detail bending is the least expensive, touch bending is more expensive, and automerged bending is the most expensive.

**Topics**

- Adding Touch (Collision) Bending Effects (p. 1302)
- Adding Detail Bending Effects (p. 1307)
- Using AutoMerged Wind Bending Effects (p. 1310)

### Adding Touch (Collision) Bending Effects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The touch bending technique simulates a player touching, brushing against, and interacting with vegetation. Use it for bushes, branches, flexible trees, and bigger leaves with stems.

To start implementing touch bending vegetation effects in your game, you must have mesh assets for your vegetative elements in FBX format. FBX files can be exported from most 3D modeling software packages.

For a specific vegetation element, you must have:

- The FBX file representing the vegetation asset as a mesh
- A cube-shaped proxy mesh that represents the "trigger volume" for collisions
- A skeleton (tree of joints) used to define the branches as well as the skinning data

The figure below shows how these 3 components are represented in the Lumberyard user interface after you have imported the main vegetation object mesh (as FBX).
Adding Vegetation

You can see the object's geometry, cube proxy mesh (to determine when collisions occur between the player and the object), and the skeleton used for physical behaviors when a collision occurs. Bending occurs when the player volume intersects with the mesh, and the nature of the bending (within the tree of Joints) is typically based on where the collision occurred with respect to the cube proxy mesh.

- Vegetation FBX Mesh (p. 1303)
- Cube Collision Proxy Mesh (p. 1303)
- Vegetation Skeleton (p. 1304)
- Debugging and Performance Tips (p. 1305)

Vegetation FBX Mesh

An FBX mesh can be exported into Lumberyard from many common digital content creation tools, or from an existing .fbx asset file.

For more details on working with FBX meshes in Lumberyard, read Customize FBX asset export with FBX Settings (p. 409).

Cube Collision Proxy Mesh

The cube proxy mesh is a simple primitive used to determine when a collision (a “touch”) occurs between the vegetation object and some other physical entity. You import it as an FBX mesh, and if you name this...
mesh as *touchbend* (for example, proxy_touchbend) the FBX pipeline will automatically identify this mesh as the trigger volume.

This mesh is cube-shaped and big enough to cover the main mesh, and is used at runtime as a trigger volume. Whenever a physical entity enters this volume during your game's inner loop processing, the Lumberyard engine will trigger the creation of a "skeleton" structure made of dynamic rigid bodies (segments) attached to each other via joints (specifically, D6Joints in PhysX). This structure simulates a terrain-anchored skeleton that passively reacts to the movement of physical entities pushing through it.

**Vegetation Skeleton**

For users of standard digital content creation (DCC) tools like Maya, 3D Studio, or Blender, this part of the asset is nothing more than joints organized in a parent-child relationship. This skeleton is used to skin the main mesh and define a binding pose for it.

**Limitations:**

The skeleton cannot have more than 128 joints.

**Naming Convention Requirements:**

The joints must follow the naming convention "branchN_M", where N and M are positive integers starting from number 1. Here is an example showing joint structure and naming:

![Joint Structure Diagram]

**Note**

The name of the root joint can be postfixed with "_touchbend" (for example, "branch1_touchbend") as a convenience to notify the FBX pipeline that this asset is used for touch bending instead of a traditional animated character.
Debugging and Performance Tips

In the Lumberyard Editor, you can instantiate or paint static touch bendable vegetation using the Rollup Bar (LEGACY) UI.

The steps shown above are no different from painting regular vegetation objects. Just make sure that the chosen CGF file comes from an FBX asset exported as Touch Bendable Geometry.

Alternatively, you can use Dynamic Vegetation planting with help from the Vegetation Gem.

Improving performance

There is a set of CVARs that can be used to fine-tune the performance of touch bendable vegetation.

<table>
<thead>
<tr>
<th>CVAR</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>e_CullVegActivation</td>
<td>Maximum distance, in meters, from the camera for a touch bendable vegetation node to be considered for bending. The default value is 50 meters. In many cases, this value can be reduced to 12m and still provide good results and higher performance. Setting this value to 0 indicates that there is no activation limit.</td>
</tr>
</tbody>
</table>
## Adding Vegetation

<table>
<thead>
<tr>
<th>CVAR</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>e_FoliageBranchesTimeout</td>
<td>Lifetime, in seconds, of touch bending physics simulation after the last time a vegetation object was touched by another physical entity. The default value is 4 seconds.</td>
</tr>
<tr>
<td>physx_Debug</td>
<td>Set this CVAR to 1 to enable the drawing of PhysX rigid bodies and trigger volumes when debugging. This allows you to view the interactions during run time and check for unexpected behaviors during object interactions.</td>
</tr>
</tbody>
</table>

The example pictures below show the trigger volume at the time it is first touched by a spherical collider. In the next frame, a tree of capsules is created dynamically and its realtime movement is fed into the renderer for skinning. This tree of capsules will remain alive in PhysX memory for e_FoliageBranchesTimeout seconds unless another collision occurs during that window, in which case the window will reset.
Adding Detail Bending Effects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Detail bending refers to the procedural movement of larger foliage caused by wind or other similar effects. You control the motion by the use of vertex colors in your DCC tool.

When you use detail bending, make sure the distribution of polygons on foliage geometry is regular and properly tessellated. Otherwise you may see visual artifacts.

Contents
- Defining Vegetation Vertex Colors with a DCC Tool (p. 1307)
- Setting the Detail Bending Parameter (p. 1308)

Defining Vegetation Vertex Colors with a DCC Tool

Vegetation objects use vertex colors to specify detail bending. Lumberyard uses all three RGB channels to control the movement of the geometry. Use your DCC tool to edit and view each channel separately.

When painting the vertices, begin with the blue channel so that you can block in the overall motion of the vegetation object. Next, paint the red channel with the vertex color mode set to additive. Use a low opacity so that you can slowly build up the effect. Finally, edit the green channel with vertex color mode set to additive. Use a low opacity so that you can slowly build up the effect.

<table>
<thead>
<tr>
<th>Color</th>
<th>RGB Values</th>
<th>Bending Influence</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red</td>
<td>255/0/0</td>
<td>Irregular bending at the outsides – movement of smaller shapes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Random sinusoidal noise with a high frequency.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The red channel works only if the surface normals of the vegetation face horizontally. If the leaf is flat and all normals face up, the red channel has no effect.</td>
</tr>
<tr>
<td>Green</td>
<td>0/255/0</td>
<td>Delays the start of the movement – used to create variations.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Random sinusoidal noise with a high frequency.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Values less than 0, 255, 0 delay the start of the sinusoidal noise.</td>
</tr>
<tr>
<td>Blue</td>
<td>0/0/255</td>
<td>Bends the leaves up and down – movement of the big shapes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Random sinusoidal noise with a low frequency.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Values less than 0, 0, 255 introduce a greater amount of the noise. Only the blue channel can stop all movement. You can use the blue channel for the unmoving parts of vegetation, such as the base of a blade of grass or where a leaf attaches to its stem. Also use the blue channel on tree trunks so that they sway in the wind.</td>
</tr>
</tbody>
</table>

Once you have painted all of the channels, export your asset as an .fbx file. Your result might look like the following.
Example

![Image of vegetation with vertex colors]

**Setting the Detail Bending Parameter**

Once you define the vertex colors, you must set the *Bending* parameter for detail bending. This value controls the procedural bending for vegetation. Its value ranges from 0 to 100. A value of 0 means no bending effect. A value of 100 indicates the maximum effect when receiving environmental wind.

For more information, see, *Adding Global Wind (p. 1291).*

**To set the vegetation detail bending parameter**

1. In Lumberyard Editor, choose **Tools**, **Terrain Tool** and then choose **Vegetation**.
2. In the **Vegetation** section, click the first icon to add a vegetation object.
3. In the dialog box, select your vegetation object and click **OK**.
4. In the **Vegetation** section, select the asset that you want to modify, and then set the *Bending* parameter from 0.0 to 100.
5. Select your vegetation object, click **Paint Objects**, and then in the viewport, click to place the vegetation object.

6. To modify the vegetation material, in the **Vegetation** section, right-click the asset and choose **Go To Object Material**.

   This opens the **Material Editor**, where you can edit the material and its **Vegetation Shader** (p. 1712).

7. In the **Material Editor**, select the material that is applied to the asset on which you painted vertex colors in your DCC.

   Under **Shader Generation Params**, select the following options:
   
   - **Detail bending**
   - **Leaves** or **Grass**, depending on your use

   After you check these options, several new **Shader Params** appear.

8. Adjust the following parameters to achieve the effect that you want.
- **Bending branch amplitude** – Affects the amplitude of the vertices painted blue.
- **Bending edges amplitude** – Affects the amplitude of the vertices painted red.
- **Detail bending frequency** – Affects the frequency of the detail bending.

The following example uses the `am_aspen_01_group.cfg` file in Starter Game.

**Example**

<table>
<thead>
<tr>
<th>Bending = 2.0</th>
<th>Bending = 6.0</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1.png" alt="Image 1" /></td>
<td><img src="image2.png" alt="Image 2" /></td>
</tr>
</tbody>
</table>

**Using AutoMerged Wind Bending Effects**

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Automerged vegetation has physically accurate wind motions that are defined by wind environment properties and various vegetation properties. It is recommended for use with grass only.

Automerged vegetation reduces the number of draw calls while still allowing you to add any amount or size of grass patches to the terrain. It merges multiple meshes within several sectors as long as they are using the same material and texture. You can paint single grass blade objects on the terrain as well as on brushes in different heights independently while they get merged into larger chunks in real time.

When AutoMerged is enabled, touch bending, vertex colors, and detail bending settings are all ignored, and vegetation movement is defined solely by the AutoMerged parameters. For more information, see Adding Touch (Collision) Bending Effects (p. 1302) and Adding Detail Bending Effects (p. 1307).

**To enable AutoMerged vegetation and set parameters**

1. In the Rollup Bar, on the Terrain tab, click Vegetation, Add Vegetation Object.
2. Expand Objects tree and select the grass object you want to modify.
3. Select the AutoMerged check box, and adjust the following parameter values:
   - **Stiffness** – Defines the stiffness of the vegetation
   - **Damping** – Specifies the amount of damping on the bending motion
   - **AirResistance** – Specifies the amount of bending similar to the Bending parameter used for Setting the Detail Bending Parameter (p. 1308).

The four AutoMerged parameters together define the amount and type of bending motions the vegetation object displays in reaction to wind and breezes. For more information, see, Adding Global Wind (p. 1291).

**Vegetation Parameters**

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The following vegetation parameters can be accessed in the Terrain, Vegetation panel in the Rollup Bar for a previously selected vegetation object. You can adjust parameters for one or more selected objects.

Unless otherwise noted, parameters apply to newly added and placed vegetation assets only.

**Size**

Changes the size of newly placed vegetation objects. Use this to uniformly scale the vegetation, where 1 represents 100%.

**SizeVar**

Changes the limit of size changes for a set of newly placed vegetation objects of a single kind. Keep Size at 1 and set SizeVar to 0.2 to get a nice variation in sizes.

**RandomRotation**

Randomly rotates objects while you paint new vegetation objects. To create a more natural look and distribution, you can set up a RandomRotation in the vegetation objects when you paint them. This feature works only with the Paint Object tool.
**AlignToTerrainCoefficient**

Points the vegetation object away from the ground. When this effect is applied, vegetation on cliffs points away from the surface instead of growing straight up.

**UseTerrainColor**

Makes the individual object receive the color of the underlying terrain for a better match. Use this option to blend the grass with the underlying terrain color. You can also use this setting on other objects, but it works best with grass. This effect is especially useful for making grass appear to fade in the distance.

**AllowIndoor**

Enables the vegetation to be rendered within vis areas.

**Bending**

This value controls the bending deformation of the vegetation objects. It ranges from 0 to 100, with 0 representing no bending effect and 100 the maximum effect. This effect is based on the amount of environment wind (WindVector) in the level.

**GrowOnBrushes**

Controls the placement of objects on brushes.

**GrowOnTerrain**

Controls the placement of objects on terrain. Useful if you want them placed only on brushes.

**AutoMerged**

Enables AutoMerged system on this object. For more information, see Using AutoMerged Wind Bending Effects (p. 1310).

**Stiffness**

Controls the stiffness of selected vegetation and how much it reacts to physics for AutoMerged vegetation.

**Damping**

Determines how responsive the vegetation is to physics damping for AutoMerged vegetation.

**AirResistance**

Degree that vegetation resists air movement (wind). Similar to the Bending setting but specifically designed for AutoMerged vegetation.

**Pickable**

Allows the player to pick up the object.

**Density**

Adjusts the distance between individual objects that you create while painting new vegetation. The density setting ranges from 0 to 100. If your density setting is bigger than your brush radius, the vegetation will not be created, so always make sure you have a suitable brush radius.

**ElevationMin**

Limits the minimum height at which you can paint vegetation objects. For painting underwater vegetation, set this value to lower than the ocean; 0 is a safe option.

**ElevationMax**

Limits the maximum height at which you can paint vegetation objects.
SlopeMin

Limits the minimum angle of the terrain on which you can paint vegetation objects. 255 equals 90 degrees. When you specify a SlopeMin value higher than 0, you can no longer place objects on flat grounds.

SlopeMax

Limits the maximum angle of the terrain on which you can paint vegetation objects. 255 equals 90 degrees. When you specify a SlopeMax lower than 255, you can no longer place objects on very steep areas.

CastShadow

Makes the object cast a shadow based on the minimum selected Config Spec setting. For example, High won't work on Low or Medium specs.

Vegetation Debugging

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Branches and tree trunks can be broken upon collision.

e_vegetation 1 | 0

Enables and disables rendering of the vegetation. 1 = on, 0 = off.

e_MergedMeshesDebug 1

Displays statistics on global memory consumption of vegetation objects placed in the level.

e_MergedMeshesDebug 2

Displays vegetation in the cells that form the merged meshes. They are color coded over distance. Red boxes should be displayed only around the player (the cell the player is standing in and the surrounding eight cells). Beyond this, all cells should be green.

Displayed above each cell is information about the current LOD step and memory consumption for the cell—this updates as you move closer and further away.

Using SpeedTree 8 for Lumberyard

SpeedTree 8 for Lumberyard is a procedural vegetation modeling program that takes advantage of the native Lumberyard vegetation tools. You can use SpeedTree 8 for Lumberyard to create and quickly iterate on trees, bushes, exotic alien foliage species, and other plant life.

The SpeedTree integration provides a simple workflow to add level of detail (LOD) and preview wind accurately with Lumberyard's wind physics integrated directly into the app.

The SpeedTree modeler exports Lumberyard meshes and materials into your game project. You can then use these meshes and materials the same way you would use any other mesh or vegetation object.
Download SpeedTree 8 for Lumberyard.

**Note**
You will need to create a SpeedTree account and activate your license in order to download SpeedTree 8 for Lumberyard.

View the SpeedTree 8 documentation.

**Dynamic vegetation**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

The dynamic vegetation system uses vegetation components to customize vegetation coverage for worlds of any size. To use the dynamic vegetation system, you must enable the **Vegetation** gem for your game project.

For more information, see [Enabling Gems](#).
Using combinations of components from vegetation and other categories, you can do the following:

- Create layers of background vegetation and specify local vegetation areas around environmental objects and points of interest such as buildings.
- Place vegetation using live WYSIWYG (what you see is what you get) vegetation authoring.
- Reconfigure any aspect of vegetation during any development phase without starting from scratch. All edits are nondestructive and populate rapidly throughout the level.
- Create complex ecological biomes all in one nested slice containing many layers of broad coverage for blending across areas or an entire world.
- Configure vegetation to grow only on certain surfaces. Use components to specify where vegetation can grow such as on a range of ground slope angles or at specified altitudes.

The dynamic vegetation system interacts in several ways with the static vegetation system (p. 1298). For example, you can do the following:

- Use the same assets in both dynamic and static vegetation systems
- Configure static vegetation to block dynamic vegetation

Dynamic vegetation differs from static vegetation in the following ways.

<table>
<thead>
<tr>
<th>Dynamic Vegetation</th>
<th>Static Vegetation</th>
</tr>

<tr>
<td></td>
<td>Not templatable</td>
</tr>
<tr>
<td></td>
<td>Static placement data</td>
</tr>
</tbody>
</table>

You can further modify dynamic vegetation with components from other categories. To use the full capabilities of the dynamic vegetation system, enable the following gems.
Vegetation gem (required)

Provides the dynamic vegetation system and the core vegetation components. These are the foundation for creating areas and registering them with the system.

Gradient Signal gem (dependency)

Provides gradient and gradient modifier components, which are vital to the procedure-driven methodology of dynamic vegetation. The gradient components generate various gradient signals, such as random noise and Perlin noise. The gradient modifier components modify and mix the gradient signals.

Using gradient signals with modifier components (such as positional jitter) or filter components (such as vegetation distribution) produces realistically random expressions of vegetation in the game world.

Surface Data gem (dependency)

Enables surfaces such as terrain or meshes to emit signals, or tags, that communicate its surface type. Using a vegetation surface mask filter, you can choose to grow vegetation on a particular surface by using an inclusion list or block it from growing by using an exclusion list. You could also recapture the tags as a gradient signal by using the Surface Mask Gradient component.

FastNoise gem (optional)

Provides an expressive FastNoise Gradient component that generates many procedural noise variations. In the Lumberyard Entity Inspector, the FastNoise Gradient component appears in the Gradient category. You use it like any other gradient component.

Topics

- Dynamic Vegetation Concepts (p. 1316)
- Dynamic Vegetation Procedures (p. 1319)

Dynamic Vegetation Concepts

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The dynamic vegetation system operates around the following ideas:

- **What** – To specify the type of vegetation that appears, you must have prebuilt vegetation assets, such as .cgf or .fbx files. If you don't have your own, you can use Lumberyard's vegetation assets, which are in the Starter Game project.
- **Where** – You can create small patches of flowers or populate a massive area with convincing varieties of plants and objects. To do this, use local area clusters in the foreground layer or coverage areas in the background layers, respectively.

  Using vegetation filters, you can set up rules that specify the surface angles, altitudes, distances from objects, and surface types where vegetation grows.

  Vegetation blockers block out areas of vegetation. For example, to create a border free of vegetation around a house, use a vegetation blocker that is slightly larger than the base of the house.

- **How** – Pairing vegetation modifiers with an appropriate gradient makes vegetation appear random in position, scale, rotation, and alignment to the slope. Gradients also customize how frequently each vegetation asset appears when you use multiple assets for one area.
• If – You can use surface tag emitters to tag certain types of surfaces, such as roads, rivers, oceans, and meshes. The dynamic vegetation system reads the tags to recognize these surfaces and acts on a set of rules that you create in the form of inclusion and exclusion lists. For example, to make water lilies to appear on all water surfaces, add the water volume surface tag to the inclusion list. To ensure that they never appear on roads, add the road surface tag to the exclusion list.

Example

The following image shows grass excluded from the river and road surfaces, and pebble clusters included only on road surfaces.

You can customize your vegetation in the following ways:

• Assign priorities to your vegetation areas. Priorities determine the order in which the vegetation system fills the areas.

• Use customizable gradients such as the **Perlin Noise Gradient** to mimic the types of vegetation groupings often found in nature.

• Save your customized vegetation areas as slices so that you can easily reuse them in other levels or share them with collaborators. Use slice overrides to make small or large changes to individual instances of the slice.

Dynamic Vegetation Components

The common workflow for creating a new vegetation area starts with creating an entity and adding a **Vegetation Layer Spawner** component to it. Then you add to that entity the two required components, which define the area's shape and the assets to display. From there, you can add optional components such as vegetation filters and modifiers.

Any other components that further modify the vegetation area, such as gradients, blockers, and blenders, must be contained on separate entities. These separate entities can be sibling or child entities of the entity that has the **Vegetation Layer Spawner** component.

The following table summarizes the functions of dynamic vegetation components and the components that they typically interact with. The most commonly used components are at the top of the table. Components that appear in a category, such as vegetation filters, are referenced as such rather than
individually named. The optional and incompatible columns aren't comprehensive of all components from every category, only those related to dynamic vegetation.

<table>
<thead>
<tr>
<th>Primary Component Attached to an Entity</th>

Dynamic Vegetation Procedures

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Creating realistic dynamic vegetation in Lumberyard starts with a few basic procedures that you can follow up with endless customizations.

You can perform these procedures in the order that they appear, which presents a basic workflow. Or you can pick and choose the procedures that you need. The examples in these procedures use assets in the Starter Game project.

The following table summarizes each documented procedure, its purpose, and the components used.
Dynamic Vegetation Procedures

Creating a Vegetation Layer

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Creating a vegetation layer is the first and most basic step in creating your dynamic vegetation. The following procedure uses a simple workflow and assets from the Starter Game project.

To create a vegetation layer

1. Create an entity (p. 463) and name it.
   In this example, the entity is named BasicCoverage.

2. Add (p. 479) the Vegetation Layer Spawner component to your entity.
The **Vegetation Layer Spawner** component is the core component that initializes the engine that spawns vegetation.

3. Click *Add Required Component* and choose *Vegetation Reference Shape*.

The **Vegetation Reference Shape** has no shape on its own. You must next create a child entity and add a *Shape* component, which you will reference in the **Vegetation Reference Shape**.

4. Right-click *BasicCoverage*, select *Create Child Entity*, and name it *TestBox*.
5. Select *TextBox*, click *Add Component*, and select the *Box Shape* component.
6. Adjust the size and position of the shape so that it's large enough for your purposes and intersects with the ground.

7. Select *BasicCoverage* and, in the **Vegetation Reference Shape** component, click the target symbol and select the *TestBox* entity.

8. Click *Add Required Component* and choose *Vegetation Asset List*.

The **Vegetation Asset List** component defines what to plant. This is where you specify vegetation assets.
9. In the **Vegetation Asset List** component, next to **Mesh Asset**, click **Browse (...)**.

10. In the **Search** bar, enter **grass** and select one of the grass assets in the results.
You should have a uniform grassy field with the grass in a grid formation.
Using Gradients to Create Random Distribution

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use gradients in different areas of Lumberyard, such as with audio and AI. Gradients are particularly helpful in dynamic vegetation, where they create a realistically random look in the distribution of your vegetation.

You can achieve the appearance of random distribution by using gradients to create both random selection and random placement.

Before you can complete these procedures, you must first create a vegetation layer (p. 1320).

Random selection means that the vegetation that is selected for each point on the grid is variable. Each asset's chance of being selected depends on the weight that is assigned to it. You create weight-based random selection using the **Vegetation Asset Weight Selector** component.

Random placement means that some points on the grid have vegetation on them and some don't. The **Vegetation Distribution Filter** limits the amount of vegetation that the **Vegetation Layer Spawner** component produces.

**Topics**
- Creating Weight-Based Random Selection (p. 1324)
- Random Placement Using the Vegetation Distribution Filter (p. 1328)

### Creating Weight-Based Random Selection

When you create distribution using random selection, the vegetation asset that is selected for a particular point on the grid varies. The assigned weight of each asset determines its chance of selection. In this procedure, you specify weights and link to the gradient using the **Vegetation Asset Weight Selector** component.

**Preparing the Vegetation Entity**

The vegetation entity, or the entity that contains the **Vegetation Layer Spawner** component, must contain a component that assigns values for selection of the listed assets. This procedure uses the **Vegetation Asset Weight Selector** component for that purpose. It's also helpful, though unnecessary, to add multiple assets if you haven't already. If you have only one asset listed, your one asset and bare ground are used when you link the gradient in Creating a Gradient Entity (p. 1326).

**To prepare the vegetation entity**

1. Ensure that you have three or more vegetation assets on your entity that has the **Vegetation Layer Spawner**.

   To add more vegetation assets, do the following:

   a. In the **Vegetation Asset List** component's properties, next to **Embedded Assets**, click +.

      **Note**
      When specifying your first asset, you don't need to click + because there is an empty asset displayed by default. Specify the mesh.
b. Under the blank asset, listed as `<asset name>`, next to Mesh Asset, click **Browse (…)**.

c. In the search bar, enter a search term, such as `flower`, and select a vegetation asset.

Repeat this step with different assets until you have three or more assets.
Although you have specified multiple assets, only the first asset that you added appears in the Viewport. The next several procedures show you how to distribute the vegetation so that all of them appear.

2. Click **Add Component, Vegetation Asset Weight Selector**.

   In the next step, **Creating a Gradient Entity (p. 1326)**, you link this component to the gradient, which supplies values between 0.0 to 1.0 at a given position. Assets are then mapped based on those values and each asset's weight and order values.

**Creating a Gradient Entity**

The gradient entity provides the noise signal to reference from the vegetation entity.

**To create a gradient entity**

1. **Create a child entity (p. 463)** under your vegetation area entity and select it.
2. Rename your new entity to a descriptive name, such as **Gradient**.

3. **Add (p. 479)** the component **Perlin Noise Gradient**.

   This component generates a type of noise called Perlin noise, which mimics the type of randomness found in nature.

   **Note**
   
   If you don't have the **Gradient** category in your list of components, you must enable the **Gradient** gem.

4. Add the required **Gradient Transform Modifier** component.

   This component controls how the procedural noise is generated in the world space.

5. Click **Add Required Component** and select **Vegetation Reference Shape**.

6. In the **Vegetation Reference Shape** component's properties, next to **Shape Entity Id**, click the target button.

7. In the **Entity Outliner**, select the **TestBox** entity (or the entity that contains your shape if you named it something else).

   The **Shape Entity Id** field populates with the entity name that you selected and uses the shape on that entity as its reference shape.
Linking the Gradient to the Vegetation Area

Before the gradient that you created can have any effect on the vegetation, you must reference the gradient from within the vegetation area. This means the component that you reference the gradient (in this example, the Vegetation Asset Weight Selector) in uses the gradient's information for its selection of values.

You can reference the gradient that you created in any number of components. In the procedure Adding Scale, Rotation, and Position Modifiers (p. 1329), you use the same gradient for the vegetation modifiers.

To link the gradient entity to the vegetation entity

1. Select the entity BasicCoverage.
2. On the Vegetation Asset Weight Selector component's properties, next to Gradient Entity Id, click the target.

3. In the Entity Outliner, select the Gradient entity.

   The Gradient Entity Id field populates with the entity name.

   Your vegetation area should now have variation in its vegetation selection.
Random Placement Using the Vegetation Distribution Filter

The **Vegetation Distribution Filter** component creates the look of random placement by limiting the amount of vegetation that the **Vegetation Layer Spawner** component produces.

Before completing the following procedure, you must have the following:

- At least one asset defined in your vegetation layer.
- An entity that contains a gradient component. For instructions, see the section called "Creating a Gradient Entity" (p. 1326).

**To create random distribution**

1. In the **Entity Outliner**, select the entity that contains the **Vegetation Layer Spawner** component.
2. In the **Entity Inspector**, click **Add Component** and select **Vegetation Distribution Filter**.
3. In the **Vegetation Distribution Filter** component's properties, next to **Gradient Entity Id**, click the target button.
4. In the **Entity Outliner**, select the **Gradient** entity.
5. (Optional) Adjust the values for **Threshold Min** and **Threshold Max** to specify how much of the gradient can appear in the vegetation.
Adding Scale, Rotation, and Position Modifiers

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Before you can complete this procedure, you must first create a vegetation layer (p. 1320).

If you have added a gradient for random selection (p. 1324), the vegetable selection appears random, but still produces a grid-like pattern. This is because each type of vegetation is all the same size, faces the same direction, and is indeed planted on points on a grid.

To remedy this, do the following:

- **Add a scale modifier** – Varies the size of the vegetation. You can specify a range of scale, which sizes vegetation up or down while maintaining original proportions.
- **Add a rotation modifier** – Changes the direction that vegetation faces. In this procedure, you modify only the z-axis rotation.
- **Add a position modifier** – Modifies where on the grid points the plants appear. You can shift them by varying amounts on the x-, y-, and z-axes. Modifying the x- and y-axes moves the plants on the ground plane. Modifying the z-axis changes the height at which a plant sprouts (this procedure doesn't modify the z-axis).

Applying modifiers to your vegetation gives it a realistic, natural look.
Adding a Scale Modifier

A scale modifier varies the size of the vegetation.

**To add a scale modifier**

1. Select the **BasicCoverage** entity.
2. In the **Entity Inspector**, add the **Vegetation Scale Modifier** component.

   By itself, this component has no effect because there is not yet any information that tells it how to distribute the values.

3. In the **Vegetation Scale Modifier** component's properties, under **Gradient**, next to **Gradient Entity Id**, click the target.

4. In the **Entity Outliner**, select **Gradient**.

   The **Gradient Entity Id** field populates with the entity name.

   This component has a **Range Min** and **Range Max** both set at 1.0 by default, so there are no results yet.

5. Adjust the **Range Min** value to 0.4 and the **Range Max** value to 1.25.

   **Range Min** sets the scale size for the gradient signal's lowest values. **Range Max** sets the scale size for the gradient signal's highest values. Because the gradient signal varies in range from black to white, a scale value between the minimum and the maximum is applied to that vegetation instance.
Adding a Rotation Modifier

A rotation modifier varies the rotation of the vegetation.

**To add a rotation modifier**

1. Select the BasicCoverage entity.
2. In the **Entity Inspector**, add the **Vegetation Rotation Modifier** component.

   By itself, this component has no effect because there is not yet any information that tells it how to distribute the values.

3. In the **Vegetation Rotation Modifier** component's properties, under **Rotation Z, Gradient**, next to **Gradient Entity Id**, click the target.

4. In the **Entity Outliner**, select **Gradient**.

   The **Gradient Entity Id** field populates with the entity name.

Adding a Position Modifier

A position modifier shifts each instance of vegetation by an amount that the gradient determines, which removes the grid-like appearance of the vegetation.

**To add a position modifier**

1. Select the BasicCoverage entity.
2. In the **Entity Inspector**, add the **Vegetation Position Modifier** component.

   By itself, this component has no effect because there is not yet any information that tells it how to distribute the values.

3. In the **Vegetation Position Modifier** component's properties, under **Position X, Gradient**, next to **Gradient Entity Id**, click the target.
4. In the **Entity Outliner**, select **Gradient**.

   The **Gradient Entity Id** field populates with the entity name.

   The result is a slight x-axis variation in the ranges specified (the default is -0.3 to 0.3). For greater variation, modify the **Range Min** and **Range Max** values.

5. In the **Vegetation Position Modifier** component's properties, under **Position Y, Gradient**, next to **Gradient Entity Id**, click the target.
6. In the **Entity Outliner**, select **Gradient**.

   The **Gradient Entity Id** field populates with the entity name.

   In this procedure, you pass the same gradient signal to both the x and y modifiers, resulting in the same offset for both. This shifts all the vegetation in a common diagonal direction instead of varying the x from the y.

   You can override this by providing some additional values in the **Position Y** properties.

   **Note**
   You can also overcome this issue by using a gradient modifier on your existing gradient or by creating a separate gradient and linking to it.

7. Under **Position Y**, expand the **Advanced** header and check **Enable Transform**.
8. To produce a swizzling effect on the y-axis, use the following values or a variation on them.

<table>
<thead>
<tr>
<th></th>
<th>X</th>

</table>

**Saving the Vegetation Area as a Slice**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Save your vegetation area as a slice so that you can easily place it in other locations or levels and further customize it.

Slices enable you to place multiple instances of the vegetation for your level. If you make a change to a slice, you can save the override to all other instances of the slice. For example, if you change the vegetation asset type from red to yellow flowers, you can choose to update all instances of the slice so that the vegetation area appears with yellow flowers.

For more information, see Working with Slices (p. 510).

To reference vegetation using slices

1. In the Entity Inspector, select the BasicCoverage entity.
2. Right-click the entity and choose Create slice, enter a name such as BasicCoverage.slice, and save it to a directory.
3. In the **Asset Browser**, navigate to the **BasicCoverage.slice** file.

4. Select and drag the file into the viewport. This creates an instance of the slice.

**Example**

Two slice instances in the viewport have the same vegetation assets and configuration.

5. Select the new instance of the **BasicCoverage** entity.

6. On the **Vegetation Asset List** component, click the **Mesh Asset** and select a yellow flower asset.

**Note**

A property that appears orange has an override. An override is a component change that is different than its source slice. For more information, see **Modifying a Slice and Saving Changes** (p. 519).

7. Right-click the property, choose **Save field override**, and choose **basiccoverage.slice**.

This updates all instances of the slice to use yellow flowers.
Expanding Vegetation Coverage

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

After you create a vegetation patch, you can expand it so that your vegetation covers the entire level.

To expand vegetation coverage

1. Create an entity and name it `WorldBox`.
2. Click Add Component and select the Box Shape component.
3. In the Box Shape component, specify values for the x-, y-, and z-axes to match your level. For example, if you created a level with a texture dimension of 512 x 512, specify similar values such as 512.0, 512.0, and 64.0.
4. Select the BasicCoverage entity.
5. On the Vegetation Reference Shape component, for Shape Entity Id, select the WorldBox entity.

Example

The vegetation appears for the entire level. As you move through the level, the vegetation dynamically appears.
Reusing Vegetation in Multiple Areas

After you create your vegetation entity, you can designate your customized vegetation to appear in another area. You do this by referencing another shape. For example, if you created a forest patch that includes the vegetation assets and arrangement for your level, you can create another entity with a different shape and reference this new shape for your vegetation. With this feature, you can reuse your vegetation in different areas of your level without creating a separate vegetation entity each time.

To reuse vegetation in a new area

1. In the **Entity Inspector**, select the **BasicCoverage** entity.
2. Right-click the entity, choose **Create child entity**, and name it **Cylinder(PlacementTest)**.
3. Click **Add Component** and select the **Cylinder Shape** component.
4. Select the **Cylinder(PlacementTest)** entity and move it away from the vegetation area.
5. Select the **BasicCoverage** entity.
6. On the **Vegetation Reference Shape** component, for **Shape Entity Id**, specify the **Cylinder(PlacementTest)** entity.
Dynamic Vegetation Procedures

Example

The vegetation appears in the cylinder instead of the box shape.

Blocking Vegetation in Select Areas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can create areas in your level to block vegetation from appearing. For example, you can use this feature to create areas around buildings or homes where vegetation shouldn't appear.

To block vegetation in select areas

1. Create an entity and name it Blocker.
2. Click Add Component and select the Vegetation Layer Blocker component.
3. Click Add Required Component and select a shape, such as the Box Shape component.
4. In the Box Shape component properties, for Dimensions, enter values for the x-, y-, and z-axes, such as 6.0, 6.0, and 4.0.
5. Move the **Blocker** entity to the vegetation area. The entity blocks the vegetation from appearing in the specified shape.

**Example**

A box shape vegetation blocker placed in the same area as a **Mesh** component blocks vegetation within and around the tower mesh.
Actor and effects animation in Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Working with animation in Lumberyard

Learn how to animate game characters and other actors in your Lumberyard scenes and cinematics, as well as how to add particle-based animation effects.

Create and animate characters

Most game projects require an animated character to move around in the environment. This may be a character that the player controls, or an AI-driven entity that interacts with the level.

Use the EMotion FX Animation Editor to animate characters in Amazon Lumberyard. To build a character, you associate one or more skinned models with an animation skeleton (built in a digital content creation tool like Maya). You then import the character into the Animation Editor and specify the animations that you want your character to have.

You can then blend animations, so that your character transitions from one animation to another, and specify the conditions when an animation occurs for a character. For example, you can specify that your
character starts in an idle position. After several seconds, the character starts to walk, run, and then slow down again until the character returns to an idle position.

In the **Animation Editor**, you can preview the animations and blends between the animations for your characters.

Lumberyard has the **FBX Settings** tool that converts static .fbx meshes, skeletons, skins, animations, and materials into Lumberyard assets. For more information, see [Customize FBX asset export with FBX Settings](p. 409).

**Note**
If you are using Lumberyard 1.10 or earlier, you can use the legacy animation system (Geppetto and Mannequin) to accomplish these tasks. For more information, see [Animation System](p. 1341) in the **Amazon Lumberyard Legacy Reference**.

**Animation Editor Concepts and Terms**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](p. 1341) or visit the [AWS Game Tech blog](p. 1341) to learn more.

The following concepts and terms are used in the **Animation Editor**:

**Topics**
- About Animation Graphs (p. 1343)
- About Parameters (p. 1345)
- About Motion Sets (p. 1347)
- About State Machines (p. 1348)
Actor

A character with at least one bone is called an actor. An actor consists of a set of nodes in a hierarchy. Each node is a transformation (position, rotation, and scale) and can contain a mesh.

Instances of actors are called actor instances. For example, one soldier that is instanced 100 times can create an army of the same character. You can animate actor instances separately, so that each instance behaves differently. Each actor instance has unique transformations, but shares the same hierarchy as the actor from which it was instanced.

Actor files have the .actor extension (for example, hero.actor).

Motions

Motions are individual animation clips, such as walk loop, an idle motion, and so on. Motions contain transformation animation and/or morph target weight animation. A motion can contain animation data for the skeletal structure and the morph targets.

Motion files have the .motion extension (for example, Walk.motion).

Animation graphs

Animation networks are called animation graphs. Animation graphs contain the state machines, transitions, conditions, blend trees, and other nodes. Animation graphs are hierarchical.

Animation graph files have the .animgraph extension (for example, Main.animgraph).

Motion sets

A motion set contains a list of motions, where each motion has a unique string ID (for example, walk, idle, and so on). Nodes inside an animation graph can reference motions based on their string ID.

Motion sets can be hierarchical. A child set can override specific motions for a character, while sharing the rest of the motions with the parent set.

Motion set files have the .motionset extension (for example, MainSet.motionset).

Motion events

Markings at specific time values inside the motion files are called motion events (also called notifiers or notifications). A motion event has a type string (for example, "SOUND") and parameter string (for example, "Footstep").

Motion events can have a fixed time value or range. Events with a single time value are called tick events. Events with specified start and end times are called ranged events.

You can specify event presets, which are pre-setup types of events that you drag and drop into the event tracks. An event track is a group of events that you enable or disable. For example, you can add all sound effects to an event track specifically for sounds.

Motion event data is stored in the motion FBX's .assetinfo file.

Synchronization

You can use full clip-base sync or sync tracks to synchronize motion clips to keep a character's motions in sync while blending. For example, if your character is running, synchronization helps keep the right and left feet in sync.

Full clip-based sync warps the motions so that there is a constant change in playback time of the child motion.

Sync tracks use motion events, where the events mark specific moments (for example, where the right and left feet are on the floor). This system is also known as phase matching and dynamically controls the playback speed.
Floats

Floats are numbers with decimals (for example 1.35 or 1.0.) Booleans and integers are also floats, so they can be passed as weight float inputs to blending nodes. If floats are rounded, the Animation Editor always rounds them down. For example, 2.99 becomes 2.

Time

All time values and durations are in seconds. For example, you can set the transition time for 0.3 or 300 ms.

About Animation Graphs

Contents

• Animation Graph Nodes (p. 1343)

Animation graphs define the animation behavior for your game characters. Animation graphs contain the states that the character can have and define the transitions between these states. Each transition can have a set of conditions that define the logic behind the transitions.

Animation graphs contain nodes and the connections between them. These connections define how data is passed between the nodes or how transitions occur between nodes.

Animation graphs have two main node types:

• State machines
• Blend trees

Because animation graphs are hierarchical, the nodes can be nested. For example, you can have a state machine inside a state machine inside a blend tree, which contains another blend tree and state machine, and so on. The number of hierarchy levels is limitless, but as a best practice limit your hierarchy to 20 levels or fewer.

Each animation graph has one root node, which is a state machine. This root node is the default and cannot be deleted. A simple animation graph can contain one state inside this root state machine. For example, the single state can be a motion node, which outputs a pose that is applied to the character, such as an idle motion.

Before you can add nodes to an animation graph, you must create a motion set. After you create a motion set, you can create an animation graph and then assign the motion sets to the animation graph using the Resource Management pane in the Anim Graph window.

Animation Graph Nodes

In a state machine, you can add the following nodes from the Sources category:

• Blend Tree
• Entry
• Exit Node
• Hub
• Motion
• State Machine
• Bind Pose
In a blend tree, you can add other nodes from the following six categories

1. **Sources**
   - Float Constant
   - Parameters
   - Blend Tree
   - Entry
   - Motion Frame
   - Exit Node
   - Motion
   - State Machine
   - Bind Pose

2. **Blending**
   - Pose Subtract
   - Morph Target
   - Pose Mask
   - Blend N
   - Blend Two (Legacy)
   - Blend Space 2D
   - Blend Space 1D
   - Blend Two

3. **Controllers**
   - Transform
   - LookAt
   - TwoLink IK
   - AccumTransform

4. **Logic**
   - Pose Switch
   - Float Condition
   - Float Switch
   - Bool Logic

5. **Math**
   - Direction to Weight
   - Range Remapper
   - Vector3 Compose
   - Vector2 Compose
   - Vector4 Decompose
   - Vector4 Compose
   - Vector3 Math1
   - Vector3 Decompose
   - Smoothing
   - Float Math2
   - Vector2 Decompose
   - Vector3 Math2
   - Float Math1

6. **Misc**
About Parameters

Contents

- Adding Parameters to an Animation Graph (p. 1345)
- Adding a Parameter Node to a Blend Tree (p. 1346)

When you create your animation graph, you can use parameters to control how your animations transition between different states.

Each transition can have a set of conditions applied to it. These conditions define the logical rules for the transition and how animations blend together.

Each transition condition is controlled by a set of parameters. Your Lumberyard game setup sends parameter values to the animation graph. The actor reacts to the incoming parameters. The game sends the parameter values to the animation graph, which then responds to the changes automatically. For example, you can specify parameter values such as speed, direction, weapon type, and so on.

You can set this up in a game level by adding an Actor and an Animation component to an entity with the Entity Inspector.

For more information, see Animation Editor Components (p. 1398).

Adding Parameters to an Animation Graph

You can add parameters to an animation graph in the Parameters pane.

To add a parameter to an animation graph

1. In Lumberyard Editor, choose Tools, Animation Editor.
2. In the Parameters pane, click the green + icon.
3. In the Create Parameter dialog box, specify the parameter name, description, and the value type.

You can specify the following value types to provide input into animation graph nodes:

- Float (slider)
- Float (spin box)
- Boolean (checkbox)
- Tag (checkbox)
- Integer (slider)
- Integer (spin box)
- Vector2
- Vector3
- Vector3 gizmo
- Vector4
- String
- Color
- Rotation
- Group
You can name parameter types to identify the purpose of the control. For example, you can name parameters such as movement_speed, movement_direction, jumping and attacking. As an artist and game designer, you can specify the parameters that best control your animation graph.

Adding a Parameter Node to a Blend Tree

After you create your parameters in the Parameter pane, you can add a parameter node to your blend tree.

To add a parameter node to your blend tree

1. In the Animation Editor, right-click the animation graph grid and choose Create Node, Sources, Parameters.
2. In the Attributes pane, click select parameter and specify the parameter that you want.
You can rename parameter nodes and specify them to provide input to other nodes. In the following example, the `speed_parameter` node provides input to the blend tree.

About Motion Sets

A motion set is a collection of motions, where each motion refers to a specific motion file and is identified by a string ID, such as `idle_motion1`. When you create motion nodes, you specify the string ID for the motion, not the motion file itself. You can use different motion sets in combination with the same animation graph. For example, you can create an animation graph to define animation behavior for a controllable human character and apply the same animation graph to a frog. Because frog movements differ from a human character's, you specify different motion sets for the frog. You can share animation graphs for your characters; you don't need to create unique animation graphs for each character type.

A combination of an animation graph with a specified motion set being applied to a given actor instance is called an animation graph instance. Each animation graph instance has a unique set of parameter values. For example, an army of 100 soldiers is controlled by 100 different animation graph instances, which allows you to animate each soldier independently.

Motion sets can also be hierarchical. Child motion sets can override certain motions from their parents. When you apply a child motion set to a character, the character uses all the motions shared by the parent except for the motions that are specified for the child motion set. For example, you can have a
character that shares 90% of the same motions of the parent, but has custom motions specific to that character.

**About State Machines**

State machines contain a set of states that are linked together by transitions. A transition goes from one node to another node and has properties, such as the time it takes to make the transition. A blend between the outputs of both states is performed during the transition, when the animation moves from one state to another.

Transition conditions are conditions that are linked a given transition. For example, they can compare a parameter value against another value to see if the given parameter is bigger than the specified value. If the condition is met, this signals the trigger for the transition. For example, if the speed parameter is greater than 0, a character transitions from an idle to a run state. You can apply multiple conditions to a single transition. The transition occurs only when all conditions are met.

**Animation Editor User Interface**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

**Topics**

- Opening Animation Editor (p. 1348)
- Anim Graph Interface (p. 1349)
- Motion Sets Interface (p. 1350)
- Motions Interface (p. 1351)

**Opening Animation Editor**

You can open the Animation Editor from Lumberyard Editor.

**To open the Animation Editor**

- From Lumberyard Editor, choose Tools, Animation Editor.
On the **Animation Editor**, you can do the following:

A. From the menu bar, you can do the following:
   - Open actor files.
   - Open, create, and save your workspaces.
   - Select and deselect actor instances.
   - Change the layout view of the editor.
   - Display or hide menus for the **Animation Editor**.

B. View your character in the perspective window.

C. **Anim Graph** – View and edit your animation graph to define your character’s behavior.

D. **Anim Graph Palette** – Drag and drop nodes into the animation graph grid.

E. **Anim Graphs Navigation** – View the hierarchy of your nodes.

F. **Parameters** – View, add, edit, or delete parameters for the animation graph.

G. **Attributes** – View, add, edit, or delete attributes for the selected node in the animation graph.

H. **Resource Management** – Add, load, save, and delete animation graphs.

I. **Recorder** – View what triggers the recording and manage the playback options.

J. **Time View** – View recorded debug information and edit event tracks of the selected motion.

---

**Anim Graph Interface**

Use the animation graph to create nodes and specify parameter and values for each node.
On the animation graph, you can do the following:

A. From the menu bar, you can do the following:
   - Open and save your animation graphs.
   - Select and deselect nodes.
   - Change the layout view of the editor.
   - Display or hide windows for animation graph.

B. In the grid, create nodes and connect them with connectors.

**Motion Sets Interface**

Use the **Motion Set** pane to create motion set files and add motion files to it.
In theMotion Setspane, you can do the following:

A. **Motion Sets Management** – Add, open, save, or delete motion sets.

B. **Motion Sets** – Add, open, or delete the motion files in the selected motion set.

**Motions Interface**

Use the motions pane to add and manage motion files in a motion set.

In the**Motions**pane, you can do the following:

A. Add, save, open, or delete motions.

B. **Motion Properties** – Specify how you want the motion to animate and the play speed of the motion.
Lumberyard User Guide

Animation Editor File Types

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When you import .fbx files from your DCC to Lumberyard Editor, Asset Processor creates files that you use in the Animation Editor. The following example shows how the file types are created and modified. For more information about processing files for character and animations, see Customize FBX asset export with FBX Settings (p. 409).

The following are file types used in the Animation Editor:

**Files Types**

When you import .fbx files into Lumberyard, Asset Processor generates the following file types used for the Animation Editor:

- **.actor** files are created when the .fbx file has at least one bone. You want to use your character's skinned mesh as your .actor file. The .actor file is the character that displays the animation.
- **.motion** files are created when the .fbx file with a bone has at least one keyframe. If your .fbx file has animation keyframes, a .motion file is created. Your .motion files contain the animations that are added to your motion set before you build your animation graph.
- **.mtl** files are created when the .fbx file has at least one material, which is the case for most DCC tools. If you make changes to the material in the Material Editor, the .mtl file is no longer a child of the .fbx file and the .mtl file is a sibling in the source directory of the .fbx file. You can make other changes to the .mtl file with a text editor or the Material Editor.

When a .motion file is created, an .actor file is also created. The .actor file that you want to use in the Animation Editor is generally the skinned mesh in the bind pose that you export from your DCC. Keep track of your skinned mesh that you want to use as your .actor file in the Animation Editor. You can go to the FBX Settings tool and delete the actor files that you don't need.
File Types Required for Animation Graphs

When you create your animation graph in the Animation Editor, the animation graph must have the following files:

- .actor
- .motion
- .motionset
- .animgraph

Saving Animation Editor Files

Saving your project in the Animation Editor creates a .workspace file. The workspace saves the actor, motion, motion set and animation graphs that you are using. When you open a workspace, the Animation Editor loads the files so that you can pick up where you last left off.

To save your workspace

- In the Animation Editor, choose File, and then choose one of the following:
  - Save Workspace
  - Save Workspace As

When .actor and .motion files are saved, the Animation Editor creates an .assetinfo file, alongside the source .fbx file. The .assetinfo files stores the configuration and settings for the .actor and .motion files.

Settings saved for .actor files include the actor name, motion extraction node, excluded bounds, collision mesh setup, and mirror setup.

Settings saved for .motion files include the motion extraction capture height option and motion events.

To save .actor and .motion files:

- In the Animation Editor, do one of the following:
  - Click Save All to saves any changes made to the .actor, .motion, .motionset, and .animgraph files. A dialog box prompts you to choose which files to save.
  - Click Save Workspace to saves your current workspace. If you don't have a workspace saved, a dialog box appears so that you can name your workspace and save it to your preferred directory.
  - Click Save Workspace As to saves your workspace with a different name or to another directory.
  - To save motion files individually, click the save icon in the Motions pane.
  - To save actor files individually, click the save icon in the Actor Manager pane.

Getting Started with the Animation Editor

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
See the following procedures to get started with the Animation Editor.

In this procedure, you do the following:

- Import your actor file and create a motion set to specify the motions that you want for your character.
- Create a basic animation graph using nodes.
- Create a blend tree to combine the motions and use a slider to control character movement from idle to walking and then running.

You can use the Samples Project to find the files used in this procedure. For more information, see Samples Project (p. 146).

The files for this procedure are located in the following directory:

`lumberyard_version\dev\SamplesProject\AnimationSamples\Simple_JackLocomotion`

**Topics**

- Step 1: Creating a Motion Set (p. 1354)
- Step 2: Creating an Animation Graph (p. 1356)
- Step 3: Blending the Animations (p. 1357)

### Step 1: Creating a Motion Set

In the following procedure, you import your character, Jack the robot, select the motions that you want, and then add those motions to a motion set.

**To create a motion set**

1. In Lumberyard Editor, choose Tools, Animation Editor.
2. In Animation Editor, choose Layouts, AnimGraph.
3. In the Animation Editor, choose File, Open Actor and navigate to the AnimationSamples\Simple_JackLocomotion directory.
4. Select the JackBind_ZUp.fbx file and then click OK.

Your character Jack appears in the Animation Editor.
5. On the **Motion Sets** tab, under **Motion Set Management**, click the + icon to add a motion set.

6. Select the **MotionSet0** node.

7. In the **Motion Set** pane, click the folder icon to add motions.

8. Navigate to the AnimationSamples/Simple_JackLocomotion directory, and select the following files:
   - Jack_Idle_ZUp.fbx
   - Jack_Strafe_Run_Forwards_ZUp.fbx
   - Jack_Strafe_Walk_Forwards_ZUp.fbx

9. Click **OK**.

10. In the **Motion Set Management** pane, click the **Save** icon.

11. Navigate to the /SamplesProject/AnimationSamples/Simple_JackLocomotion directory. For the file name, type **quickstart** and then click **Save** to save the quickstart.motionset file.
Step 2: Creating an Animation Graph

In the following procedure, create an animation graph and nodes.

To create an animation graph

1. On the **Anim Graph** tab, click the + icon to create an animation graph.
2. Click the **Save** icon.
3. Navigate to the `/SamplesProject/AnimationSamples/Simple_JackLocomotion` directory. For the file name, enter **quickstart** and then click **Save** to save the `quickstart.animgraph` file.
4. On the **Anim Graph** tab, right-click the grid, and then select **Create Node, Sources, Motion**.
5. Select the **Motion0** node and in the **Attributes** pane, click **Select motions**. In the dialog box, select `Jack_Idle_ZUp.fbx` and then choose **OK**.
6. Right-click the grid and then choose **Create Node, Sources, Blend Tree**.
7. From the **Motion0** node, click and drag a line to the **BlendTree0** node. A transition line with an arrow connects the nodes.
8. From the **BlendTree0** node, click and drag a line to the **Motion0** node.

![BlendTree0 and Motion0 nodes](image)

9. In the **Parameters** pane, click the + icon to create a parameter.
   a. Leave the **Value type** parameter to the default, **Float (slider)**.
   b. For **Name**, rename **Parameter0** to **speed**.
   c. Click **Create**.

10. In the animation graph, select the transition line that starts from the **Motion0** node and connects to the **BlendTree0** node.
   a. In the **Attributes** pane, click **Add condition**.
   b. In the **Select a Condition** dialog box, select **Parameter Condition** and then click **Add Condition**.
   c. In the **Attributes** pane, under **Parameter Condition**, click **Select parameter** and select **speed**.
   d. For **Test Function**, leave the default value of **param > testValue**. This means that if the speed is greater than zero, the idle motion transitions to the blend tree, and the character starts to move.

![Parameter Condition](image)

11. In the animation graph, select the transition line that starts from the **BlendTree0** node and connects to the **Motion0** node.
   a. In the **Attributes** pane, click **Add condition**.
   b. In the **Select a Condition** dialog box, select **Parameter Condition** and then click **Add Condition**.
   c. In the **Attributes** pane, under **Parameter Condition**, click **Select parameter**. Select **speed** and then click **OK**.
   d. For **Test Function**, select **param == testValue**. This means that if the speed is equal to zero, the motion transitions back to idle, and the character stops moving.

![Parameter Condition](image)

**Step 3: Blending the Animations**

In the following procedure, you use the blend tree node to build your blend tree, which blends the walk and run animations together.
To blend the animations

1. In the animation graph, double-click the BlendTree0 node.
2. Right-click the grid and choose Create Node, Sources, Motion.
3. Select the Motion1 node.
   a. In the Attributes pane, choose Select motions.
   b. In the Motion Selection Window, select jack_strafe_walk_forwards_zup and then click OK.

   The attributes for the Motion1 node should look like this:

   ![Motion1 Attributes](image)

4. In the animation graph, right-click the grid and choose Create Node, Sources, Motion.
5. Select the Motion2 node.
   a. In the Attributes pane, click Select motions.
   b. In the dialog box, select jack_strafe_run_forwards_zup and then click OK.

   The attributes for the Motion2 node should look like this:

   ![Motion2 Attributes](image)

6. Right-click the grid and choose Create Node, Blending, Blend Two.
7. Select the BlendTwo0 node.
   • In the Attributes pane, for Sync Mode, select Full Clip Based.
8. For Motion1 node, select the Output Pose box and drag the connector to the Pose 1 input of the BlendTwo0 node.
9. For **Motion2** node, select the **Output Pose** box and drag the connector to the **Pose 2** input of the **BlendTwo0** node.

10. For the **BlendTwo0** node, select the **Output Pose** box and drag the connector to the **Input Pose** of the **FinalNode0** node.

Your blend tree should look like the following:

![Blend Tree Diagram]

11. Right-click the grid and choose **Create Node**, **Sources**, **Parameters**.

12. Right-click the grid and choose **Create Node**, **Math**, **Smoothing**.

13. For **Parameters0** node, select the **speed** output box and drag the connector to the **Dest** input box of the **Smoothing0** node.

14. For the **Smoothing0** node, select the **Result** output box and drag the connector to the **Weight** input box of the **BlendTwo0** node.

Your blend tree should look like the following:

![Blend Tree Diagram]

15. In the **Animation Editor**, choose **File**, **Save All**. Then in the dialog box, click **OK**.

16. Navigate to the `/SamplesProject/AnimationSamples/Simple_JackLocomotion` directory. For the file name, enter `quickstart` and then click **Save** to save the workspace.

17. In the **Anim Graph** tab, click the **Play** button. The character should now be animated in the idle mode.

18. In the **Parameters** pane, move the **speed** slide control to the right to make Jack walk. Move the slider further to the right to make Jack run.
Referencing External Anim Graphs

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A node-based animation system that has thousands of nodes can be difficult to manage. Lumberyard's EMotion FX Animation Editor uses hierarchical nodes that help alleviate this problem, but universal-level changes to game logic can still be challenging.

Starting in Lumberyard version 1.18, you can use Animation Editor reference nodes to reference external animation graph (anim graph) files. This helps reduce the scale and complexity of anim graphs and minimize human error. Reference nodes behave as the root state machine of the anim graphs that they reference and always output one pose.

Topics
- Benefits (p. 1361)
- Using External Anim Graphs (p. 1361)
- Best Practices for Using Referenced Anim Graphs (p. 1371)
Benefits

Referencing anim graphs provide the following benefits:

- **Sharing anim graph pieces or snippets** – You can create anim graph pieces or snippets that can be shared in multiple other anim graphs. For example, you might build a locomotion anim graph part to share across all characters while individualizing the rest. When you use referencing, you don't need to copy and paste the same anim graph every time that you use it.

- **Ease of maintenance** – You can maintain a shared anim graph in one place. If you copy and paste anim graphs, each copy must be maintained separately.

  **Note**
  Because a change in a referenced anim graph can break the behavior of another, it is important to keep track of your referencing hierarchy. For more information, see Best Practices for Using Referenced Anim Graphs (p. 1371).

- **Greater ease of collaboration** – By clearly separating anim graphs, multiple people can develop animation for different characters simultaneously.

Using External Anim Graphs

This section shows you how to create reference nodes in the **Animation Editor**, assign external anim graphs to them, and view and manage referenced graphs.

**To create a reference to an external anim graph**

1. In the **Animation Editor**, do one of the following:
   - Right-click the **Anim Graph** grid and choose **Create Node, Sources, Reference**.
• Click the **Anim Graph Palette** tab. From **Sources**, drag and drop the **Reference** node to the grid.
The new reference node appears in purple in the Anim Graph grid.
2. Select the **Reference** node. The node color changes to orange when it is selected.
Referencing External Anim Graphs

The **Reference** section of the **Attributes** tab shows the attributes for the reference node.

<table>
<thead>
<tr>
<th>Name</th>
<th>Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Specifies the name of the reference node.</td>
</tr>
<tr>
<td><strong>Anim graph</strong></td>
<td>Specifies the graph that is referenced. If none is provided, the reference node outputs the bind pose of the actor.</td>
</tr>
</tbody>
</table>
### Referencing External Anim Graphs

<table>
<thead>
<tr>
<th>Name</th>
<th>Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Motion set asset</strong></td>
<td>Specifies the motion set (p. 1413) that the referenced anim graph uses. If a motion set is not specified, the referenced anim graph uses the motion set of the graph that contains the reference node. If a motion set asset is defined, an entry named Active motion set appears. Use this attribute to specify which motion set from the motion set asset to use. The root motion set from the motion set asset is selected by default.</td>
</tr>
</tbody>
</table>
| **Parameter mask**  | Specifies the anim graph parameters that are exposed as input ports on the reference node. When an anim graph is assigned to a reference node, the following occurs:  
  - The Animation Editor compares the names and types of parameters to detect which parameters can be mapped automatically.  
  - The parameters that are mapped successfully are not shown as input ports on the reference node.  
  - The parameters that can't be mapped automatically are added to the parameter mask, become inputs on the reference node, and use their default values.  
  You can change the mask to specify which parameters become input ports. Parameters that are not in the mask are subject to automatic mapping.  
  Even if a parameter is automatically mapped, you can remove it from the mask and manually specify it. This can be useful when the leader graph and referenced graph have parameters with the same name, but have a different range of possible values.  
  For example, a leader graph has a Speed value in the range \([0.0, 1.0]\). You want to reference a locomotion graph created by another team that has a Speed parameter in the range \([0.0, 100.0]\). To use the referenced graph, you can remap the Speed parameter for the leader graph to the correct input range for the referenced graph. You can use a visual connection to the graph to specify the correct value. |

3. On the Attributes tab, for Anim graph, click the (...) icon.
4. In the Pick EMotion FX Anim Graph dialog box, select the `.animgraph` file that you want to assign to the reference node, and then click OK.

5. In the Anim Graph grid, double-click the reference node to see the nodes that the referenced anim graph contains.
6. Continue double-clicking nodes to drill down into the nodes underneath. In this example, the referenced anim graph contains a `StateMachine` node, and the `StateMachine` node contains an `EntryNode` and an `ExitNode`.

When you view a referenced anim graph in this way, the referenced anim graph is read-only.
7. The display above the grid shows your current location in the node hierarchy. To go back to a previous node, click the node name.

8. On the upper right of the Anim Graph grid, click the navigation page icon.
The navigation pane opens up on the right side of the grid to show the hierarchy of nodes. The navigation pane displays all loaded anim graphs. The name of the current node is bold. The color of each node indicates its type. For example, the entry nodes are green and the exit nodes are red.

9. To edit an external anim graph, right-click the reference node that you assigned it to and choose Open 'filename.animgraph' file. The changes that you make to the external anim graph are reflected in all anim graphs that reference it.
Best Practices for Using Referenced Anim Graphs

See the following best practices for using referenced anim graphs:

- **Keep track of your referencing hierarchy** – One way to keep track of your referencing hierarchy is by maintaining a chart of your anim graphs and their references. Such a chart can help developers and testers know which anim graphs are affected by changes that are made. A chart can also help you know if an anim graph that you are working on is referenced by another anim graph.

- **Directory hierarchy** – Make your anim graph directory and file hierarchy the same as your referencing hierarchy. For example, anim graphs in directories higher up in the hierarchy use or reference anim graph assets deeper down the hierarchy, but not vice versa.

- **Minimize parameter count** – Keep the number of parameters in your referenced anim graphs minimal. Using many parameters increases complexity.

- **Manage motion sets effectively** – To manage motion sets when you use referencing anim graphs, consider the following options:
  - Manage separate motion sets. Each motion set contains the motions for one anim graph.
  - Create one large motion set for a leader anim graph. This motion set would hold motions for the leader anim graph and for all motions used in any of the referenced anim graphs.

  **Note**
  Both options allow the referenced anim graph to be tested by itself.

Tips for Working with Referenced Anim Graphs

Avoid the following practices when you work with referenced anim graphs:
• **Changing an anim graph that is referenced by another** – Changing an anim graph that is referenced by another anim graph can break its behavior. For example, if you remove a parameter from the referenced anim graph that another anim graph uses, the parameter reverts to its default value. This can cause unexpected behavior.

• **Renaming, moving, or deleting an anim graph** – When you rename, move, or delete an anim graph, its asset ID changes. Therefore, all anim graphs that refer to the renamed, moved, or deleted anim graph must also be updated. Having a system that keeps track of your referencing hierarchy (as mentioned in Best Practices (p. 1371)) makes it easy to know which anim graphs are affected and which to update.

### Synchronizing Animation Graphs: Example

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use synchronized animation graphs to synchronize animation between actors. For example, the animation of one actor might trigger an animation in another actor. An animation graph can be the primary graph and have multiple secondary graphs. Likewise, an animation graph can be both a secondary graph of one graph and a primary graph for another graph.

This topic describes the following main steps for synchronizing two animation graphs:

1. Add the required components to the entities to be synchronized, including the Anim Graph component.
2. Use Animation Editor to create a motion set and one or more animation graphs.
3. Add a parameter to the secondary graph to receive the change event from the primary graph.
4. Add a parameter to the primary graph.
5. Add a servant parameter action to the primary graph to send change events to the secondary graph.
6. Synchronize the graphs by using Lumberyard's Event Bus (EBus) (p. 1851) system and Lua script.

**Note**

For more information about synchronizing animation in separate clients across the network, see Synchronizing Animations Across a Network (p. 2051).

This topic illustrates this graph synchronization with an example that has two actors, a robot actor ("Jack") and a gun actor. When the player activates the sync mode and uses the keyboard to fire, the robot makes a firing motion and the gun fires. When the player deactivates the sync mode, the robot makes a firing motion, but the gun does not fire.
The robot has a syncFeature_Jack animation graph and the gun uses a syncFeature_Gun graph. The robot graph is the primary graph and the gun graph is the secondary graph.

When the sync mode is on, the gun fires in sync with the robot. When the robot fires, the state of the primary graph's shoot parameter is received by secondary graph's gunTrigger parameter. The secondary graph, which is attached to the gun, receives the parameter change event and fires the gun.
1. Add Required Components

The first step is to add the required components to the entities that you want to synchronize. The robot and gun components that are used by the entities in the example are described in the following sections.

Robot Entity Components

The robot entity uses the following components:

- Transform
- Actor
- Anim Graph
- Input
- Lua Script

The following image shows the configuration of the components for the robot entity in the Entity Inspector.
Gun Entity Components

The gun entity uses the following components:

- Transform
- Actor
- Lua Script
- Anim Graph
- Input

The following image shows the configuration of the components for the gun entity in the Entity Inspector.
2. Create a Motion Set and Animation Graphs

After you set up your entities and components, create a motion set and two animation graphs. The motion set contains the motions that your graphs use, and the secondary and primary animation graphs animate and synchronize the entities.

To create a motion set and two animation graphs

1. Create a motion set. For information about creating a motion set, see Getting Started with the Animation Editor (p. 1353). This example's MotionSet0 contains the motions gunshootanimation, jack_shoot, and jack_idle.

2. Create a secondary animation graph. For information about creating a secondary animation graph, see Getting Started with the Animation Editor (p. 1353). The secondary graph controls one or more entities whose actions are determined by the primary graph.

   This example's syncFeature_Gun secondary graph has a BindPose0 node and a Motion0 node. The Motion0 node contains the gunshootanimation motion.
3. Create a primary graph. The primary graph sends control events to the secondary graph.

This example's syncFeature_Jack primary animation graph has a **Motion1** node and a **Motion0** node. The **Motion1** node contains the jack_idle motion and the **Motion0** node contains the jack_shoot motion.
Synchronizing Animation Graphs

- Motion1
  - Name: Motion1
  - Probability weight: jack_idle 1.0
- Motion2
  - Name: Motion2
  - Probability weight: jack_choose 1.0
3. Add a Parameter to the Secondary Graph

You are now ready to add a parameter to the secondary graph that receives the parameter change event from the primary graph. After you add the parameter, add parameter conditions that specify when the animation transitions from one motion to another.

To add a parameter to the secondary graph to receive the change event from the primary graph

1. On the Parameters tab for the secondary animation graph, click the plus (+) icon, and choose Add parameter.

2. In the Create Parameter dialog box, for Value type, choose the data type that you want to use for the parameter. This example uses the Boolean (checkbox) value type because the gun trigger is either on or off.

3. For Name, enter a name for the parameter. This example uses gunTrigger.
4. Click Create. The Parameters list shows the parameter that you created.
Add Parameter Conditions to the Secondary Graph

In this section, add parameter conditions on the transition lines that specify when the animation changes. In the example, the conditions indicate whether the gun trigger has been pressed.

To add parameter conditions to the secondary graph

1. Click the transition line from the BindPose0 node to the Motion0 node. Then, in the Attributes pane, click Add condition, and choose Parameter Condition.

2. Click Select parameter.

3. In the Parameter Selection Window, choose the parameter that you just created, and click OK.
In the Attributes pane, a Parameter Condition section shows the parameter that you added. On the transition line, a small round node indicates that the line has a parameter condition.

4. For Test Function, use the default value of \( \text{param} > \text{testValue} \). In this example, this means that if the trigger receives a value greater than 0, the gun fires.

5. For Test Value, keep the default value of 0.0.

6. Click the transition line from the Motion0 node to the BindPose0 node. Then, in the Attributes pane, click Add condition, and choose Parameter Condition.
7. Click **Select parameter**.

8. In the **Parameter Selection Window**, choose the parameter that you are using. The example uses the `gunTrigger` parameter.

9. For **Test Function**, use the default value of `param == testValue`. In this example, this means that if the trigger value is equal to zero, the motion transitions back to idle, and the gun no longer fires.

10. For **Test Value**, keep the default value of 0.0.

Now the secondary animation graph is ready to receive signals from the primary graph.

### 4. Add a Parameter and Parameter Conditions to the Primary Graph

You add a parameter and parameter conditions to the primary graph just as you did with the secondary graph. However, you also add secondary ("servant") parameter actions to the primary graph. The actions signal the secondary graph to mimic the animations of the primary graph.

**To add a parameter to the primary graph**

1. On the **Parameters** tab, click the plus (+) icon, and choose **Add parameter**.
2. In the **Create Parameter** dialog box, for **Value type**, choose the data type that you want to use for the parameter. This example uses the **Boolean (checkbox)** value type because the gun trigger is either on or off.

3. For **Name**, enter a name for the parameter. This example uses `shoot`.
4. Click **Create**.

**Add Parameter Conditions to the Primary Graph**

Now you add parameter conditions on the transition lines in the primary graph as you did on the secondary graph.

**To add parameter conditions to the primary graph**

1. Click the transition line from the **Motion1** node to the **Motion0** node. Then, in the **Attributes** pane, click **Add condition**, and choose **Parameter Condition**.

2. Click **Select parameter**.
3. In the **Parameter Selection Window**, choose the parameter that you just created. This example uses `shoot`.

![Parameter Selection Window](image)

4. For **Test Function**, use the default value of `param > testValue`.
5. For **Test Value**, use the default value of `0.0`.
6. Click the transition line from the **Motion0** node to the **Motion1** node. Then, in the **Attributes** pane, click **Add condition**, and choose **Parameter Condition**.

![Add condition](image)

7. Click **Select parameter**.
8. In the **Parameter Selection Window**, choose the parameter that you are using. The example uses `shoot`.
9. For **Test Function**, use the default value of `param == testValue`.
10. For **Test Value**, use the default value of `0.0`.

### 5. Add Servant Parameter Actions to the Primary Graph

Now you are ready to add secondary ("servant") parameter actions to the primary graph. A script uses these actions to synchronize the two graphs.

**To add a servant parameter action to the primary graph**

1. In Animation Editor, click to select the first transition line again. This example selects the line from the **jack_idle** node **Motion1** to the **jack_shoot** node **Motion0**.
2. In the **Attributes** pane for the primary graph, click **Add action, Servant Parameter Action**.
3. For **Servant Parameter Action**, in the **Trigger Mode** box, keep the default **On Enter**. **On Enter** specifies that the action is triggered when the state or transition is entered.

4. In the **Servant anim graph** box, click **Browse (...)** and choose the secondary animation graph that has the parameter that you want to use. This example chooses a secondary animation graph called **syncFeature_Gun**.

5. Click **Select parameter** to choose a parameter from the secondary animation graph that you just chose. This example chooses the **gunTrigger** parameter.
On the transition line, a small square node indicates that the transition line has a parameter action. The small round node next to it represents the parameter condition that you added earlier.

6. For **Trigger value**, specify the value to emit when the action is triggered. Because **Trigger value** is treated as a single float, you can use it for float, Boolean, and integer parameters. This example specifies 1.0, which is the value when the gun fires.
7. Click the line from Motion0 to Motion1 and repeat the steps to add a servant parameter action to the remaining transition line.

8. In the Trigger value box, specify a different value. The example specifies a trigger value of 0.0, which is the value when the gun is idle.

Now that the animation graphs are ready, you can perform the next steps: gathering user input and writing Lua scripts to synchronize the graphs.

6. Synchronize the Primary and Secondary Graphs

Synchronizing the primary and secondary graphs involves the following steps:

1. Getting keyboard input from the player.
2. Placing a Lua script component and Lua script on the secondary entity.
3. Placing a Lua script component and Lua script on the primary entity.

The Lua scripts synchronize the two graphs by handling animation graph events in Lumberyard's Event Bus (EBus) (p. 1851) system.

Getting Input from the Player

In the example, the synchronization state of the primary and secondary graphs and the firing of the gun are controlled by the following keyboard inputs, or keystrokes, from the user. The Event Value Multiplier is the actual value sent to the input system and to Lua script.

<table>
<thead>
<tr>
<th>Keystroke</th>
<th>Description</th>
<th>Event Value Multiplier</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Turns on sync mode.</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>Turns off sync mode (off by default).</td>
<td>-1</td>
</tr>
<tr>
<td>S</td>
<td>Fires the gun.</td>
<td>1</td>
</tr>
<tr>
<td>D</td>
<td>Stops the gun from firing.</td>
<td>-1</td>
</tr>
</tbody>
</table>

To gather these inputs, the example adds Input (p. 642) components to the robot entity and to the gun entity.

To use the Input component, you must enable the Input Management Framework (p. 1150) gem and the Starting Point Input (p. 1206) gem for your project. The Input Management Framework converts input to user-defined gameplay events. The Starting Point Input gem interprets hardware input and converts it into input events such as pressed, released, and held.

Each Input component references an .inputbindings file. An .inputbindings file binds a set of inputs to an event. These inputs can come from sources like a mouse, keyboard, or game controller.
You can use the **Input Bindings Editor** in Lumberyard Editor to create an input bindings file. For more information, see *Working with the Input Component (p. 643).*

**Getting Keyboard Input to Control Graph Synchronization**

In the example, the gun entity has an Input component. The Input component uses a `synctest.inputbindings` asset to bind keyboard inputs 1 and 2 to the `SyncControl` event. The `SyncControl` event controls the sync mode, which determines whether or not the gun fires when the robot fires.

The following image shows the corresponding input bindings in the **Input Bindings Editor**.

![Input Bindings Editor](image)

**Getting Keyboard Input to Control Shooting**

The Input component on the robot uses a `syncgun.inputbindings` asset to bind keyboard inputs S and D to the `ShootControl` event. The `ShootControl` event controls the firing of the gun.

The following image shows the corresponding input bindings in the **Input Bindings Editor**.
Using a Script on the Secondary Graph to Toggle Synchronization

The example uses Lua Script components on both the primary (robot) and secondary (gun) entities. The script on the primary entity controls the firing of the gun. The script on the secondary entity controls the sync mode. To add a Lua script to an entity, add a Lua Script component (p. 2684) to the entity and then attach the script to the component.

The Lua script on the gun entity receives the input from the keyboard to toggle the sync mode. To synchronize the secondary graph to the primary graph, the script uses the \texttt{SyncAnimGraph} EBus event. In the following example, the \texttt{self.entityId} parameter refers to the secondary entity (the gun). The \texttt{self.Properties.PrimaryEntity} parameter refers to the robot.

\begin{verbatim}
AnimGraphComponentRequestBus.Event.SyncAnimGraph(self.entityId,self.Properties.PrimaryEntity);
\end{verbatim}

To desynchronize the secondary graph from the primary graph, the same script uses the \texttt{DesyncAnimGraph} EBus event.

\begin{verbatim}
AnimGraphComponentRequestBus.Event.DesyncAnimGraph(self.entityId,self.Properties.PrimaryEntity);
\end{verbatim}

The full script shows how the \texttt{SyncAnimGraph} and \texttt{DesyncAnimGraph} methods handle the \texttt{SyncControl} input event.

\begin{verbatim}
-- syncSample.lua
local syncSample =
{
    Properties =
    {
        PrimaryEntity = { default = EntityId() }
    },
};
\end{verbatim}
function syncSample:OnActivate()
    self.SyncControlInputBusId = InputEventNotificationId("SyncControl");
    self.SyncControlInputBus = InputEventNotificationBus.Connect(self,
        self.SyncControlInputBusId);
    self.ShootControlInputBusId = InputEventNotificationId("ShootControl");
    self.ShootControlInputBus = InputEventNotificationBus.Connect(self,
        self.ShootControlInputBusId);
    self.SyncControl = false;
    self.Shooting = false;
end

function syncSample:HandleSyncControl(floatValue)
    if (floatValue > 0 and self.SyncControl == false) then
        AnimGraphComponentRequestBus.Event.SyncAnimGraph(self.entityId,
            self.Properties.PrimaryEntity);
        self.SyncControl = true;
    elseif (floatValue < 0 and self.SyncControl == true) then
        AnimGraphComponentRequestBus.Event.DesyncAnimGraph(self.entityId,
            self.Properties.PrimaryEntity);
        self.SyncControl = false;
    end
end

function syncSample:HandleInput(floatValue)
    if (InputEventNotificationBus.GetCurrentBusId() == self.SyncControlInputBusId) then
        self:HandleSyncControl(floatValue);
    end
end

function syncSample:OnPressed(floatValue)
    self:HandleInput(floatValue);
end

function syncSample:OnHeld(floatValue)
    self:HandleInput(floatValue);
end

return syncSample;

Using Script on the Primary Graph to Control Shooting

The example Lua script on the primary entity (the robot) receives the keyboard input that toggles
the firing of the gun. The robot entity's animation graph's shoot parameter uses the Boolean
(checkbox) type. When the gun fires, the shoot parameter is true. Because shoot is a named Boolean
parameter, the Lua script on the primary entity uses the SetNamedParameterBool function on the
AnimGraphComponentBus.

The full script shows how the SetNamedParameterBool function is used to toggle the shooting status.

-- syncGun.lua
local syncGun =

function syncGun:OnActivate()
    self.ShootControlInputBusId = InputEventNotificationId("ShootControl");
    self.ShootControlInputBus = InputEventNotificationBus.Connect(self,
        self.ShootControlInputBusId);
    self.SyncControl = false;
end
function syncGun:HandleShootControl(floatValue)
    if (floatValue > 0 and self.Shooting == false ) then
        AnimGraphComponentRequestBus.Event.SetNamedParameterBool(self.entityId, "shoot", true);
        self.Shooting = true;
    elseif(floatValue < 0 and self.Shooting == true ) then
        AnimGraphComponentRequestBus.Event.SetNamedParameterBool(self.entityId, "shoot", false);
        self.Shooting = false;
    end
end

function syncGun:HandleInput(floatValue)
    if (InputEventNotificationBus.GetCurrentBusId() == self.ShootControlInputBusId) then
        self:HandleShootControl(floatValue);
    end
end

function syncGun:OnPressed(floatValue)
    self:HandleInput(floatValue);
end

function syncGun:OnHeld(floatValue)
    self:HandleInput(floatValue);
end

return syncGun;

The Example in Action

The following animated image shows the finished example in action when the sync mode is turned off. The robot fires, but the gun does not.
The following animated image shows the example when the sync mode is turned on. The gun fires when the robot fires.
Animation Editor Components

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add the following Animation Editor components to an entity. You can then specify the actor file, animation graph file, the motion file, or attachment.

For more information, see the following components:

- Actor (p. 536)
- AnimGraph (p. 545)
• Attachment (p. 550)
• Simple Motion (p. 826)

For more information about adding a component to an entity, see Adding Components to an Entity (p. 479).

Using Morph Targets to Deform Characters

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A morph target is a deformed mesh that is stored as a series of vertex positions. Morph targets are also called blend shapes or vertex-level deformations. You can use morph targets to deform a character's face to animate facial expressions or a character's body part to correct undesired deformation of skinning. You can also simulate deformation of clothing on a character.

In the Animation Editor, you can use morph targets with one of the following nodes:
• Motion node – Plays morph target animations similarly as skeletal animations.
• Morph Target node – Animates morph targets by changing the weight at runtime.

Prerequisites

To use morph targets in the Animation Editor, you must do the following:
• Prepare your asset for .fbx export. For more information, see Customize FBX asset export with FBX Settings (p. 409).
• Create and animate morph targets on your character in your DCC tool (for example, Maya).
• Export the character as a .fbx file.

Topics
• Importing Morph Targets (p. 1399)
• Opening Actor Files (p. 1403)
• Previewing Morph Targets on Actors (p. 1404)
• Creating Motion Nodes with Morph Targets (p. 1405)
• Creating Morph Target Nodes (p. 1408)

Importing Morph Targets

When you import an .fbx file into Lumberyard, all morph targets and morph target motions in that file are imported as part of the actor. This allows you to open your actor file in the Animation Editor without additional steps.

You can also change how morph targets are imported.
To change how morph targets are imported

1. In the Asset Browser, right-click your .fbx file and choose Edit Settings.

2. In the FBX Settings window, click the Actors tab.

   A modifier appears to indicate that morph targets will be imported.

3. Click the button next to the Select morph targets field.
4. In the **Select nodes** window, select the morph targets that you want to import, and then click **Select**.
5. In the **FBX Settings** window, click **Update** to save your changes.

### To change how morph target motions are imported

1. In the **Asset Browser**, right-click your `.fbx` file and choose **Edit Settings**.
2. In the **FBX Settings** window, click the **Motions** tab.

**Note**

If you have morph target animations in your `.fbx` file, a modifier appears to indicate that morph target motions will be imported. You can remove the modifier if you do not want the morph target motions in your `.motion` file.
3. Click **Update** to save your changes.

### Opening Actor Files

When you open your actor file in the *Animation Editor*, all morph targets and morph target motions are imported by default. To change how morph targets are imported, see [Importing Morph Targets](#).  

**To open an actor file**

1. In Lumberyard Editor, choose **Tools, Animation Editor**.
2. In the *Animation Editor*, choose **File, Open Actor**.
3. In the *EMotion FX Actor* window, select an actor to import and then click **OK**.
Previewing Morph Targets on Actors

You can preview the morph targets on an actor.

To preview morph targets

1. In Lumberyard Editor, choose Tools, Animation Editor.
2. In the Animation Editor, choose View, Morph Targets.
3. In the Morph Targets window, preview morph target shapes on your actor by doing the following:
   a. Select the Select All check box.
      If enabled, the morph target sliders will override the morph target motions on your actor.
   b. Move the sliders next to the morph target name to see the actor's mesh deform.
Using Morph Targets to Deform Characters

c. Click **Edit** next to the morph target to adjust the range of the slider as needed. The default range is 0 to 1.

4. When you're done previewing the morph targets, clear the **Select All** check box and close the **Morph Targets** window.

**Creating Motion Nodes with Morph Targets**

Creating a motion node with morph targets is similar to other methods of motion node generation.

**To create a motion node with morph targets**

1. In the **Animation Editor**, on the **Motion Sets** tab, under **Motion Set Management**, do one of the following:
   
   • Click the + icon to create a motion set.
   
   • Click the folder icon to open the **Pick EMotion FX Motion Set** window and select a motion set to import. Click **OK**.
2. In the Anim Graphs pane, click the + icon to create an animation graph.

3. Drag the Motion node from the Sources tab in the Anim Graph Palette to the animation graph.
4. In the animation graph, select the **Motion** node that you added.

5. In the **Attributes** pane, click **Select motions**.
6. In the Motion Selection window, select the motion with the morph targets that you want to import and then click OK.

Creating Morph Target Nodes

As an alternative to creating a motion node with morph targets, you can use a Morph Target node to directly animate morph targets in the animation graph.

To create a morph target node

1. In the Animation Editor, drag the Blend Tree node from the Sources tab in the Anim Graph Palette to the animation graph.
2. In the animation graph, double-click the Blend Tree node. You should see a Final Node node and additional nodes in the Anim Graph Palette.
3. Drag the **Morph Target** node from the **Blending** tab in the **Anim Graph Palette** to the animation graph.

4. Do the following to add a bind pose to use as an input pose:
   a. Drag the **Bind Pose** node from the **Sources** tab in the **Anim Graph Palette** to the animation graph.
   b. Connect the **Output Pose** for the **Bind Pose** node to the **Input Pose** for the **Morph Target** node.

5. Do the following to add a parameter to control the weight of the morph target:
   a. Drag the **Parameters** node from the **Sources** tab in the **Anim Graph Palette** to the animation graph.
   b. In the **Parameters** pane, click the + icon to create a parameter.
   c. In the **Create Parameter** window, do the following:
      i. For **Value Type**, select **FloatSlider**.
      ii. For **Minimum** and **Maximum**, use the default values.
      iii. Click **Create**.
d. In the animation graph, do the following:

i. Connect the Parameter for the Parameter node to the Morph Weight for the Morph Target node.

ii. Connect the Output Pose for the Morph Target node to the Input Pose for the Final Node node.
6. In the animation graph, select the **Morph Target** node if it's not already selected.

7. In the **Attributes** pane, click **select morph targets**.

8. In the **Morph target selection** window, select the morph target that you want to import and then click **OK**.
The morph target is updated in the **Morph Target** node in the animation graph and in the **Attributes** pane.

9. In the **Anim Graphs** pane, activate the animation graph by double-clicking the name.

10. In the **Parameters** pane, move the slider to play the animation.
Customizing State Machine Routing with Sparse Motion Sets

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You might run into a case where you have different characters that don't have the exact same motions as the character for which you created the animation graph. Instead of duplicating large parts or creating new animation graphs for different characters, you can share the same animation graph for all your characters.

You can allow or deny transitions and routes to motion states in a state machine, based on the existence of the given motion entry.

Topics

- Sparse Motion Sets (p. 1413)
- Hierarchical Motion Sets and Overwriting Motion Entries (p. 1414)
- Customizing State Machines Based on Motion Sets (p. 1415)

Sparse Motion Sets

A motion set contains a list of motion entries. Each motion entry has a motion ID that you can define. For example, you can name a motion ID, Walk or Jump. The motion entry maps the custom motion ID like Walk to a specific motion file, such as /SampleProject/Animations/Human_Walk.motion.

You can add motion entries to a motion set with the + icon or the folder icon in the motion set window. The + icon creates a new motion entry where you can specify the motion ID, but does not assign it to
a motion file. You can click the folder icon to select a motion to add. Based on the motion file name, a
default motion ID is generated for you.

A *sparse motion set* is when the motion entries do not have a motion file assigned to them.

When you choose an unassigned motion entry on a motion state in a state machine, the motion shows
a red border around the node. If the motion state is activated, the character goes to a bind pose. In the
following example, the character's animation graph does not transition from idle to jump because the
*Jump* node is using a sparse motion set; no motion file is assigned. The character remains in the *Idle*
node.

### Hierarchical Motion Sets and Overwriting Motion Entries

A motion set can contain child motion sets that are stored in the same file. Child motion sets inherit all
motion entries from the parent.

In the following example, a hierarchical motion set has the *Human* motion at the root level. The *Zombie*
motion set is a child, which inherits from the parent *Human* motion set. The *Zombie* motion set does not
have a motion entry for *Jump*.

**Example : Hierarchical Motion Set**

**Human (motion set)**

- + Idle – GenericIdle.motion
- + Walk – GenericWalk.motion
- + Jump – GenericJump.motion

**Zombie (motion set)**

- + Walk – ZombieWalk.motion

Because the parent motion set defines the *Jump* motion entry with a motion file, the child motion set
inherits that motion. This means that when the *Zombie* motion set is activated, characters with that
motion set play the human *Jump* motion.

If you don't want your zombie characters to jump, you can disable inheritance for that specified motion.
In the child motion set, you can create a new motion entry named *Jump* and then mark it as unassigned.
This way you can override the motion entry from the parent, by not assigning it for the child motion set.

**Example : Child Motion Set with Unassigned Jump Motion**

**Human (motion set)**

- + Idle – GenericIdle.motion
Animation Editor Nodes

- + Walk – GenericWalk.motion
- + Jump – GenericJump.motion

Zombie (motion set)
- + Walk – ZombieWalk.motion
- + Jump – Unassigned

The Zombie motion set uses the Idle motion from the parent motion set, customizes the Walk motion, and disables the Jump motion.

For hierarchical motion sets, you can create a motion entry and unassign it to disable inheritance from the parent motion set. If you are not using hierarchical motion sets, this is the same as not having a motion entry with the specified motion ID.

Customizing State Machines Based on Motion Sets

Animation graphs can be shared across characters. Two different characters that use the same animation graph can operate with two different motion sets. For example, you can have a human character that uses the human motion set, and a zombie character that uses the Zombie motion set. Both characters can use the same animation graph.

You can configure the state machine to avoid motion states that are unassigned. In this example, you don't want the zombie to go into the Jump state, as this motion was unassigned for the zombie motion set.

To configure the state machine to avoid motion sets

1. In the Anim Graph, choose the transition line between your motion nodes. For example, you can select the transition line between the Idle and Jump nodes.
2. On the Attributes pane, click Add Condition and then select Motion Condition.
3. For Motion, select the Jump state.
4. For Test Function, select Is Motion Assigned?

Because the Zombie motion set does not have a motion file assigned for Jump, the character can't transition from the idle to jump state. The condition's traffic light appears red and blocks the transition. This lets you control whether a character is allowed to go to specific motion state or not.

Animation Editor Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
See the following nodes available in the Animation Editor.

**Topics**
- Creating Blend Trees (p. 1416)
- Controller Nodes (p. 1432)
- Simplify Node Groups with Hub Nodes (p. 1435)
- Using Math Nodes (p. 1438)
- Actions (p. 1443)

## Creating Blend Trees

This feature is in *preview* release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

In the **Animation Editor**, an animation graph consists of nodes and connections that define transitions and the way that data is passed between nodes. The **Animation Editor** supports state machines and blend trees. For more information about state machines, see About State Machines (p. 1348).

A blend tree is a collection of nodes with input and output ports that are color coded by data type and read from left to right. Input ports appear on the left side of the nodes and output ports appear on the right. The blend tree outputs the pose that is connected to the **Final Node**, which is included in every blend tree and cannot be deleted. If you choose not to connect a node to **Input Pose**, the **Final Node** outputs a bind pose.

### To create a blend tree

1. In Lumberyard Editor, choose **Tools**, **Animation Editor**.
2. In the **Animation Editor**, on the **Anim Graph** tab, click the + icon to create an animation graph.
3. Click the **Save** icon. Navigate to the directory where you want to save your animation graph. Type a name for your file and then click **Save**.
4. In the center pane, on the **Anim Graph** tab, right-click the grid and then choose **Create Node**, **Sources**, **Blend Tree**.
Alternatively, in the Anim Graph Palette, on the Sources tab, drag Blend Tree into the animation graph.

5. Double-click the blend tree node that you created. When you double-click the node, a new link appears above the animation graph with the node name. The Final Node also appears.
6. Do the following to add nodes and connections:
   a. In the animation graph, right-click the grid and choose Create Node. Choose a node from the following categories:
      - Sources
      - Blending
      - Controllers
      - Logic
      - Math
      - Misc
   b. Repeat step 6a to add more nodes to your blend tree.
   c. Connect the nodes by dragging inputs to outputs. Note the following color cues:
      - Gray – Dashed gray helper lines indicate the ports that you can connect to.
      - Green – The connection curve turns green when it's okay to release the mouse button.
      - Red – The connection curve turns red when the connection is not allowed.
      - Yellow – The connection curve turns yellow in transition states, such as when you drag a connection between ports.

Topics
- Creating and Visualizing Blend Spaces (p. 1419)
- Blending Poses with Blend Nodes (p. 1422)
Creating and Visualizing Blend Spaces

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Blend spaces are a collection of sample motions that are organized spatially according to their coordinates. The visual representation is a graph with xy-axes for the coordinates. The xy-axes can represent values such as move speed, travel direction, turn angle, and so on. Each motion is represented by a point (white dot) in the graph or blend space.

When you pick a point in the blend space (interactively or with parameter controls), your character automatically plays a resulting motion that is computed based on the sample motions and appropriate blend weights.

In a 1D blend space the motions correspond to points along a line. In a 2D blend space the motions correspond to points in a 2D space.

Prerequisites

Before you can add blend space nodes to the animation graph, you must have completed the following:

- Selected an actor
- Selected a motion set
- Created an animation graph

For more information, see Getting Started with the Animation Editor (p. 1353).

Creating Blend Spaces

To create a blend space, you must add a blend tree node and a blend space node, and then specify values for the attributes of the blend space node.

Blend space nodes output a pose from the Output Pose port. You can connect this output to the Input Pose port of the Final Output node or to the input port of any other node that accepts a pose as input.

The Blend Space 1D node has the following ports:

- X – The value for this input port indicates the current position of interest in the 1D blend space.
- Output Pose – The blend space node computes the blended motion that corresponds to the current position of interest and outputs the resulting motion from this port.

The Blend Space 2D node has the following ports:

- X – The value for this input port is the x-coordinate of the current position of interest in the 2D blend space.
- Y – The value for this input port is the y-coordinate of the current position of interest in the 2D blend space.
- Output Pose – The blend space node computes the blended motion that corresponds to the current position of interest and outputs the resulting motion from this port.
To create a blend space and specify attributes

1. In the Animation Editor, on the Anim Graph tab in the top middle pane, right-click the grid and then choose Create Node, Sources, Blend Tree.
2. Double-click the Blend Tree node to go to the blend tree view.
3. Add a blend space node to the blend tree by doing one of the following:
   - On the Anim Graph tab, in the blend tree view, right-click the grid and then choose Create Node, Blending, Blend Space 2D or Blend Space 1D.
   - In the Anim Graph Palette, on the Blending tab, drag the Blend Space 2D or Blend Space 1D icon into the blend tree view.
4. Double-click the blend space node to go to the blend space view. If you are using the Blend Space 2D node, your view should look as follows:

   ![Blend Space 2D view](image)

5. In the Attributes pane, specify values for the attributes of the blend space node. These values are used to set up your blend space.

   **Note**
   You can undock the Attributes pane in order to see the attributes and values without scrolling.
• To use provided values for the xy-axes, do the following:
  1. For Calculation method (X-Axis), select Automatically calculate motion coordinates.
  2. For X-Axis Evaluator, select a common motion characteristic.
  3. For Calculation method (Y-Axis), select Automatically calculate motion coordinates.
  4. For Y-Axis Evaluator, select another common motion characteristic.

• To use custom values for the xy-axes, do the following:
  1. For Calculation method (X-Axis), select Manually enter motion coordinates.
  2. For Calculation method (Y-Axis), select Manually enter motion coordinates.

You can also use a combination of provided and custom values. For example, you can manually enter motion coordinates for the x-axis and automatically calculate motion coordinates for the y-axis using the **Travel distance** evaluator.

6. In the **Attributes** pane, for **Motions**, click the + button to add the source motion assets for your blend space.

7. In the **Motion Selection Window**, choose the motions that you want to add to the blend space, and then click **OK**.

- The coordinate value automatically calculates if you selected **Automatically calculate motion coordinates** for Calculation method and if you selected a motion characteristic for the Evaluator.
- You must enter coordinate values if you selected **Manually enter motion coordinates** for Calculation method.

8. After your motions are added to the blend space and the coordinate values are calculated, verify that your blend space view looks similar to the following:
9. In the blend space view, do the following:
   a. Drag within the blend space to change the point of interest (represented by a red dot).
   b. When the point is highlighted, the corresponding motion is automatically computed by blending the motions represented by the three vertices of the triangle. View the blend weights next to each of the motions.
   c. Notice that the motions that are closer to the point have a higher blend weight than the motions that are farther away.
10. In the Attributes pane, you can do the following:
   - View the coordinate values for each motion
   - Change the values to remap the animations and the blend space graph
   - Remove a motion from the blend space

### Blending Poses with Blend Nodes

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use Blend nodes in animation graphs to create an animation that blends two input poses.

**Animation Editor** has the following types of blend nodes, each of which blend poses in different manners:

- Blend N Node (p. 1423)
- Blend Two Additive Node (p. 1425)
- Pose Subtract Node (p. 1427)
- Blend Two Node (p. 1428)
- Blend Two (Legacy) Node (p. 1430)
Blend N Node

The Blend N node accepts up to ten inputs and uses the Weight parameter to determine which inputs to use and their weights. You can specify any type of parameter into the Weight input of a Blend N node.

To use the Blend N node

1. In Lumberyard Editor, choose Tools, Animation Editor.
2. Create a blend tree (p. 1416).
3. Double-click the blend tree node that you created.
4. Select the Anim Graph Palette tab and then select the Blending tab.
5. Drag the Blend N node into the animation graph.
6. Connect nodes to the following inputs and output:
• **Pose 0 to 9** – Pose inputs. Connect one or more inputs.
• **Weight** – Input that determines which pose inputs to use and their weights.
• **Output Pose** – Result of the blended poses.

7. Select the **Blend N** node.
8. For each pose, enter the **Max weight trigger** in ascending order.

**Example**

If you have three poses, you must specify values in ascending order. The first pose should have the lowest value and the last pose must have the highest.

If you enter a series of values in an invalid order, the value box turns red and displays a warning.
You can use the **Evenly Distribute** feature to automatically calculate an even distribution of weights.

**To distribute weights using the Evenly Distribute feature**

1. In the first input's **Max weight trigger**, enter the lowest value.
2. In the last input's **Max weight trigger**, enter the highest value.
3. Click **Evenly Distribute**. This function calculates and evenly spaces the values.

**Example**

You have four inputs. The lowest input is set to 0.0 and the highest input is set to 1.0. Once you click **Evenly Distribute**, your middle values are automatically calculated to be spaced evenly between 0 and 1. The final values would be 0.0, 0.33, 0.66, and 1.0.

The value of the **Weight** parameter determines which inputs to blend by its value with respect to the **Max weight trigger** values. The **Weight** value naturally falls either before the lowest **Max weight trigger** values, between two values, or after the highest **Max weight trigger** value. If it's lower than the lowest **Max weight trigger** value, then only that pose is used in the calculation. If it's higher than the highest **Max weight trigger** value, then only that pose is used. If it's between two values, then those two poses are used.

**Example**

Input ports **Pose 5**, **Pose 7**, and **Pose 9** are connected, with **Max weight trigger** values of -2.0, 4.0, and 8.0. If the input value is less than or equal to -2.0, then only the port **Pose 5** is used to calculate the output pose. If the input is between -2.0 and 4.0, both ports **Pose 5** and port **Pose 7** are used to calculate the output pose. If the weight is greater than 8.0, then only port **Pose 9** is used.

The weight assigned to each value in a pair depends on where the **Weight** parameter falls with respect to the pose values. It calculates the respective distances and assigns a weight based on its position.

**Example**

The **Weight** input is set to 0.0. **Pose 5** is set to -1.0, and **Pose 7** is set to 3.0, which is a difference of 4.0. Because the value of 0.0 is at the 25% point between -1.0 and 3.0, a weight of 0.25 is assigned to **Pose 5**. The remainder (0.75) is assigned to **Pose 7**.

**Blend Two Additive Node**

The **Blend Two Additive** node blends a pose 2 input additively on top of a pose 1 input.

**Note**

This node functions similarly to the **Blend Two (Legacy)** node with **Additive** enabled. The key difference is that the **Blend Two (Legacy)** node subtracts the bind pose when applying an
additive blend. Furthermore, **Blend Two Additive** expects pose 2 to be an additive pose. This means that if you wanted **Blend Two Additive** to function like the **Blend Two (Legacy)** node, you must first subtract the bind pose from pose 2.

**To use the Blend Two Additive node**

1. In Lumberyard Editor, choose **Tools, Animation Editor**.
2. Create a blend tree (p. 1416).
3. Double-click the blend tree node that you created.
4. Select the **Anim Graph Palette** tab and then select the **Blending** tab.
5. Drag the **Blend Two Additive** node into the animation graph.

6. Connect nodes to the following inputs and output:
   - **Pose 1** – The base pose.
   - **Pose 2** – The pose to be added to **Pose 1**.
   - **Weight** – Weight of additive.

   You can use a **Float Constant** node, for example, to specify a float value between 0.0 and 1.0. A value of 0.0 means **Pose 2** does not affect **Pose 1** at all. A value of 1.0 means that **Pose 2** is fully added on top of **Pose 1**. Other nodes that can specify **Weight** include the **Parameter** node, the **Smoothing** node, and so on.
   - **Output Pose** – The result of the blended poses, which you can visualize as **Pose 1 + (Pose 2 * Weight)**.

**Blend Two Additive Node Attributes**

For attribute settings that are shared among the blend node types, see **Blend Node Attributes** (p. 1430).

The **Extraction Mode** for the **Blend Two Additive** node features masking and additive blending, which adds complexity over **Extraction Mode** for transitions.
The output from motion extraction with the **Blend Two Additive** node is calculated as follows.

- **S** = Source transform delta
- **T** = Target transform delta

**Additive, root included in mask (or no mask provided):**

- **Blend** = **S** + **T** * weight
- **Source** = **S**
- **Target** = **T**

**Additive, root excluded from mask:**

- **Blend** = **S**
- **Source** = **S**
- **Target** = **S**

**Pose Subtract Node**

The **Pose Subtract** node subtracts **Pose 2** from **Pose 1**. The output of a **Pose Subtract** node is the delta between them (**Pose 1** – **Pose 2**).

**Note**

With the **Pose Subtract** node, you can generate an additive pose. You can then supply it to the **Blend Two Additive** node at runtime without manually generating it from a DCC. The output of the **Pose Subtract** node cannot be used as an input to the **Blend Two (Legacy)** node. This is because **Blend Two (Legacy)** does not expect a pose that is already a delta or additive pose, but expects a bind pose.

**To use the Pose Subtract node**

1. In Lumberyard Editor, choose **Tools, Animation Editor**.
2. Create a **blend tree** (p. 1416).
3. Double-click the blend tree node that you created.
4. Select the **Anim Graph Palette** tab and then select the **Blending** tab.
5. Drag the **Pose Subtract** node into the animation graph.
6. Connect nodes to the following inputs and output:

- **Pose 1** – The base pose.
- **Pose 2** – The pose to be subtracted from the base pose.
- **Output Pose** – The result of the pose subtraction (Pose 1 - Pose 2).

**Pose Subtract Node Attributes**

For attribute settings that are shared among the blend node types, see [Blend Node Attributes](p. 1430).

**Blend Two Node**

With the **Blend Two** node, you can blend between two input poses based on a weight value. For example, the **Blend Two** node can blend smoothly between a walk and a run based on the character's speed.

The **Blend Two** is similar to the **Blend Two Additive** node, except that it doesn't support **Additive Blend** mode.

**To use the Blend Two node**

1. In Lumberyard Editor, choose **Tools, Animation Editor**.
2. Create a blend tree (p. 1416).
3. Double-click the blend tree node that you created.
4. Select the **Anim Graph Palette** tab and then select the **Blending** tab.
5. Drag the **Blend Two** node into the animation graph.
Connect nodes to the following inputs and output:

- **Pose 1** – The first pose.
- **Pose 2** – The second pose.
- **Weight** – Blend weight.

You can use a Float Constant node, for example, to specify a float value between 0.0 and 1.0. A value of 0.0 means 100% of Pose 1 and 0% of Pose 2. A value of 0.6 weights 40% of Pose 1 and 60% of Pose 2. Other nodes that can specify Weight include the Parameter node, the Smoothing node, and so on.

- **Output Pose** – The result of the pose blending.

**Blend Two Node Attributes**

For attribute settings that are shared among the blend node types, see Blend Node Attributes (p. 1430).

The **Extraction Mode** for the **Blend Two** node is calculated as follows.

- **S** = Source transform delta
- **T** = Target transform delta

**Root included in mask (or no mask provided):**

- **Blend** = S + (T - S) * weight
- **Source** = S
- **Target** = T

**Additive, root excluded from mask:**

Version 1.28
1429
- **Blend** = S
- **Source** = S
- **Target** = Zero

**Blend Two (Legacy) Node**

The **Blend Two (Legacy)** supports backward compatibility. If you are creating new content, use the **Blend Two** (p. 1428) or **Blend Two Additive** (p. 1425) node.

**Blend Node Attributes**

The blend nodes feature a set of attributes that control different aspects of how the two nodes are blended. Some blend nodes have different attributes, which are described in the sections about that node type.

**Sync Mode**

The **Sync Mode** attribute determines the method of synchronizing motion clips to keep the feet synchronized.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disabled</td>
<td>Synchronization is disabled.</td>
</tr>
<tr>
<td>Event Track Based</td>
<td>Synchronization based on sync event tracks. This method pairs sync events,</td>
</tr>
<tr>
<td></td>
<td>which ensures that the events in each of the inputs activate at the same</td>
</tr>
<tr>
<td></td>
<td>time.</td>
</tr>
<tr>
<td>Full Clip Based</td>
<td>Synchronization based on the full clip duration. Inputs are synchronized</td>
</tr>
<tr>
<td></td>
<td>by the percentage that is complete. For example, when the first input is at</td>
</tr>
<tr>
<td></td>
<td>25% playback of the input's duration, the second input is also at 25%</td>
</tr>
<tr>
<td></td>
<td>playback.</td>
</tr>
</tbody>
</table>

**Event Filter Mode**

The **Event Filter Mode** attribute determines which node's events are emitted.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Leader Node Only</td>
<td>Emits events from the leader node only. The follower node is synchronized to</td>
</tr>
<tr>
<td></td>
<td>this node.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------------------------------------------------------</td>
</tr>
<tr>
<td>Follower Node Only</td>
<td>Emits events from the follower node only. The follower node is synchronized to the leader node.</td>
</tr>
<tr>
<td>Both Nodes</td>
<td>Emits events from both leader and follower nodes.</td>
</tr>
<tr>
<td>Most Active</td>
<td>Emits events from the more active node. Special use case for additive blends.</td>
</tr>
</tbody>
</table>

**Extraction Mode**

The **Extraction Mode** attribute controls how the motion extraction behaves when blending. For example, for transitions inside state machines, you can use this node to ensure that a 180 degree turn completes.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Blend</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blend</td>
<td>Blends between the source and target. This setting helps ensure a proper blending result. For example, when transitioning from idle into a turn, translation and rotation are blended. Some of the turn's rotation can get lost in the blending, which means a 180 degree turn might reach only 160 degrees. Use this blend setting to ensure the completion of the turn.</td>
</tr>
<tr>
<td>Target Only</td>
<td>Extracts the target only. For example, when transitioning from idle into a turn, only the turn animation's translation and rotation is extracted. The nodes inside the skeleton still blend normally. This affects only the character's rotation and translation.</td>
</tr>
<tr>
<td>Source Only</td>
<td>For example, when transitioning from idle into a turn, only the idle pose's translation and rotation is extracted. The nodes inside the skeleton still blend normally. This affects only the character's rotation and translation.</td>
</tr>
</tbody>
</table>
Mask

Use **Mask** to select the skeleton nodes to include in the blend.

Example

A walking motion might be your first input pose and a waving motion your second input pose. If you select as a mask the arm, hand, and fingers, and increase the pose’s weight, the arm would wave while the body walks. In this example, it would blend the arm bones from walk to wave.

Controller Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/) or visit the AWS Game Tech blog to learn more.

See the following controller nodes in the **Animation Editor**.

**Topics**

- Get Transform (p. 1432)
- Set Transform (p. 1434)

**Get Transform**

The **Get Transform** node gets the transform data from a joint that you specify. The transform includes the translation (position), rotation, and scale. You can use this node to return the transform for your animations.

**To create a Get Transform node**

1. In Lumberyard Editor, choose **Tools, Animation Editor**.
2. In the **Animation Editor**, on the **Anim Graph** tab, open an existing animation graph or click the + icon to create one.
3. Right-click the graph and choose **Create Node, Sources, Blend Tree**.
4. Double-click the **Blend Tree** node, right-click the graph, and then choose **Create Node, Controllers, Get Transform**.

![Create Node and Get Transform](image)

The **Get Transform** node appears in your graph.
5. To get the transform from a specific animation, right-click the graph and choose Create Node, Sources, Motion.

6. Connect the Output Pose of the Motion node to the Input Pose of the Get Transform node.

7. For the Get Transform node, in the Attributes tab, click Select node. This selects the joint from which you want to get the transform.

8. In the Node Selection Window, select your preferred joint and click OK.
The **Get Transform** node will output the vector \((x, y, z)\) for **Output Translation** (position), **Output Rotation**, and **Output Scale**.

9. In the right pane, on the **Attributes** tab, specify the **Transform Space**. You can specify the following.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local</td>
<td>The transform relative to the parent.</td>
</tr>
<tr>
<td>World</td>
<td>The transform relative to the world.</td>
</tr>
<tr>
<td>Model</td>
<td>The transform relative to the model's origin.</td>
</tr>
</tbody>
</table>

**Set Transform**

The **Set Transform** node sets the transform from a selected joint, including translation (position), rotation, and scale.

**To create a Set Transform node**

1. In Lumberyard Editor, choose **Tools, Animation Editor**.
2. In the **Animation Editor**, on the **Anim Graph** tab, open an existing animation graph or click the + icon to create one.
3. Right-click the graph and choose **Create Node, Sources, Blend Tree**.
4. Double-click the **Blend Tree** node, right-click the graph, and then choose **Create Node, Controllers, Set Transform**.

Version 1.28

1434
The **Set Transform** node takes **Input Pose**, **Translation** (position), **Rotation**, and **Scale** as inputs, and then outputs **Output Pose** for selected nodes (joints).

5. For the **Set Transform** node, on the **Attributes** tab, click **Select joint**. This specifies the joint from which you want to set the transform.

6. Select your preferred joint and click **OK**. The **Set Transform** node will output the vector \((x, y, z)\) for **Output Pose**.

7. In the right pane, on the **Attributes** tab, specify the **Transform space**. You can specify the following.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local</td>
<td>The transform relative to the parent.</td>
</tr>
<tr>
<td>World</td>
<td>The transform relative to the world.</td>
</tr>
<tr>
<td>Model</td>
<td>The transform relative to the model's origin.</td>
</tr>
</tbody>
</table>

### Simplify Node Groups with Hub Nodes

This feature is in **preview** release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/training/tutorials/open-3d-engine/) or visit the [AWS Game Tech blog](https://aws.amazon.com/blog/game/) to learn more.

The **Hub** node acts as a connection point between groups of nodes in an animation graph. This pass-through node outputs or forwards the pose of the node that entered it. Hub nodes reduce the complexity of transitions by acting as the central point in a state machine. By connecting multiple nodes to hubs, you can combine transition lines that share the same transition conditions and strategically organize nodes to create an easy-to-read state machine.

**Example**

The following animation graph has many groups and transitions.
The same graph with **Hub** nodes simplifies transitions between the groups, which makes the graph cleaner and easier to read.

**To use Hub nodes in your animation graph**

1. Add a **Hub** node in an animation graph by doing one of the following:
   - In the **Anim Graph Palette**, choose the **Sources** tab and drag **Hub** to the graph.
   - In the graph, right-click and choose **Create Node, Sources, Hub**.
2. Repeat to add as many **Hub** nodes as you need.

3. Add multiple like nodes, such as motion nodes or state machines, between the **Hub** nodes and create transitions.

**Example**

Transitions between motions are simplified by placing them between two **Hub** nodes.

In the example, the transition between **attack01** and **Hub0** is a shared transition. If you remove the **Hub0** node, you would then individually add those two conditions from **attack01** to each of the four transitions going into the **attack01** nodes.

4. For all transitions entering a **Hub** node, set its **Transition Time** to 0.0 seconds. This ensures that an extra delay is not added to the transition.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard's Animation Editor features a set of math nodes that perform math operations on various types of input. The math nodes pass on the result(s) of the operation as output.

**Topics**

- Rotation Math 2 Node (p. 1438)
- Rotation Limit Node (p. 1440)
- Vector Decompose Nodes (p. 1441)
- Boolean Logic Node (p. 1442)

**Rotation Math 2 Node**

With the Rotation Math 2 node, you can apply math operations to input rotations, which are represented by quaternions (p. 3285).

This node multiplies the input rotation and the specified Default Value to express an output rotation. The Default Value specifies the rotation of an unconnected input. This rotation value is expressed in Euler angle degrees (rotation about the X, Y, and Z axes).
To use the Rotation Math 2 node

1. Connect the **Output Rotation** output rotation output(s) to the input(s) of the **RotationMath2** node.
2. Select the **RotationMath2** node.
3. In the right pane, on the **Attributes** tab, specify the **Math Function**. You can specify the following:
   - **Rotate**
     
     Multiplies two input quaternions or one input with the **Default Value**.
   - **Inverse rotate**
     
     Multiplies the x input with the inverse of the y input. You can also use this to calculate the relative rotation of X with respect to Y.
4. If only one input rotation exists, specify the unconnected rotation values (X, Y, Z) for the **Default Value**.
Rotation Limit Node

With the Rotation Limit node, you can limit an input rotation. To do this, the node decomposes the rotations of the quaternion along relevant axes and limits their angles to a range. You define the minimum and the maximum possible angle values to remove ambiguity between the shortest or longest path angle defined by two values.

To use the Rotation Limit node

1. Connect a rotation output to the Input Rotation of the RotationLimit node.
2. Select the RotationLimit node.

3. In the right pane, on the Attributes tab for Rotation limits, enter Min angle and Max angle values for X, Y, and Z.

   **Note**
   
   The Min angle can't exceed the Max angle. If it does, the error is displayed in red and the value doesn't commit to the graph.

4. For Twist axis, select the X, Y, or Z Axis.

   The Twist axis specifies which axis the Rotation Limit node is to decompose and apply edited constraints.

---

**Vector Decompose Nodes**

Using Vector Decompose nodes, you can output one or more specific values of a vector.

**Example**

You have a 3D vector XYZ that indicates a position in a 3D world, but you only need its height (Z) for a computation. You would input your vector into a Vector3Decompose node and use only the Z output for your calculation.

You don't need to use Vector Decompose nodes if you are simply adding or subtracting one of the X, Y, Z, or W positions. For typical Vector3 to Vector2 (and vice versa) conversion, or Vector3 to Vector4 (and vice versa) conversion, the Animation Editor automatically converts vectors in the following way:

- Vector2 to Vector3 – Adds the Z component set to 0.
• **Vector3** to **Vector2** – Ignores the Z component from **Vector3**.
• **Vector3** to **Vector4** – Adds the **W** component set to 0.
• **Vector4** to **Vector3** – Ignores the **W** component from **Vector4**.

### Boolean Logic Node

Using the **Boolean Logic** node, you can apply a function to two boolean inputs. Boolean values are always 1 or 0 (true or false), such as a check box item. The **Boolean Logic** node sees any non-zero value as true (1) and any zero value as false (0). For example, values 0.54, 10.43 or -2.25 are all true (1). Only 0.0 values are false (0).

When choosing an output type, you can output from the **Float** output or the **Bool** output. The **Bool** output passes on a 0 or 1. The **Float** output passes on a float value that you specify in the attributes.

### Boolean Logic Node Attributes

The **Boolean Logic** node features a set of attributes that performs operations on boolean values.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Name of the node.</td>
</tr>
<tr>
<td><strong>Logic Function</strong></td>
<td>You can set the following functions on boolean inputs:</td>
</tr>
<tr>
<td></td>
<td>• <strong>AND</strong> – Outputs true (1) if both x and y are true (1).</td>
</tr>
</tbody>
</table>
## Animation Editor Nodes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OR</td>
<td>Outputs true (1) if either x or y are true (1).</td>
</tr>
<tr>
<td>XOR</td>
<td>Means &quot;exclusive or.&quot; Outputs true (1) if x and y have different values. Otherwise, false (0).</td>
</tr>
<tr>
<td>NAND</td>
<td>Means &quot;not and.&quot; Outputs false (0) if both x and y are true (1). Otherwise, true (1).</td>
</tr>
<tr>
<td>NOR</td>
<td>Means &quot;not or.&quot; Outputs true (1) if both x and y are false (0).</td>
</tr>
<tr>
<td>XNOR</td>
<td>Means &quot;exclusive not or.&quot; Outputs true (1) if x and y have the same value. For example, if x and y are true or if x and y are false, outputs true (1).</td>
</tr>
<tr>
<td>Not x</td>
<td>Outputs true (1) if x is false (0).</td>
</tr>
<tr>
<td>Not y</td>
<td>Outputs true (1) if y is false (0).</td>
</tr>
</tbody>
</table>

**Default Value**

Used as a second value when only one input value is specified.

**Float Result When True**

Sets a float value to output when the result of the boolean function is true (1). You must also use the Float output connector to output this value.

**Float Result When False**

Sets a float value to output when the result of the boolean function is false (0). You must also use the Float output connector to output this value.

---

**Actions**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use actions to trigger parameter value changes when an animation graph state or transition reaches a specified state.

You can set the Parameter Action on the following:
State

Set actions to trigger upon:
- Entering a state – Action triggers when the state is fully blended into the node and is no longer in transition
- Exiting a state – Action triggers when the state is fully blended out of the node and the node is no longer active

Transition

Set actions to trigger upon:
- Entering a transition – Action triggers immediately upon starting a transition
- Exiting a state – Action triggers when a transition is fully blended to the target state

Adding Actions to a State

Add an action to a state to achieve a parameter value change that triggers after the state is either fully blended into the node or fully blended out of the node.

To add an action to a state

1. In the Animation Editor, open or create an animation graph.
2. Select a node.
3. In the Attributes panel, click Add action and then Parameter Action.
4. In the Attributes panel, under Parameter Action, select a Trigger Mode. You can select one of the following options:
   - On Enter – Executes a State action when the state is fully blended into the node and is no longer in transition
   - On Exit – Executes a State action when the state is fully blended out of the node and the node is no longer active
5. Choose Select parameter and select your preferred parameter.
   The selected parameter name replaces the text in the Select parameter box.
6. To turn the action on, set the Trigger Value to 1.

Adding Actions to a Transition

Add an action to a transition to achieve a parameter value change that triggers either when the transition starts or when the transition is fully blended to the target state.
To add an action to a transition

1. In the Animation Editor, open or create an animation graph.
2. Select a transition.

3. In the Attributes panel, click Add action and then Parameter Action.

The following options trigger the change on a follower graph but with different inputs to the follower graph's parameter:

- **Follower Parameter Action** – A constant value is provided
- **Symbolic Follower Parameter Action** – A user-selected value is provided

4. In the Attributes panel, under Parameter Action, select a Trigger Mode. You can select one of the following options:

- **On Enter** – Executes the action immediately upon starting a transition
- **On Exit** – Executes the action when a transition is fully blended to the target state
5. Choose **Select parameter** and select your preferred parameter.

   The selected parameter name replaces the text in the **Select parameter** box.

   ![Select parameter and Aim](image)

6. To turn the action on, set the **Trigger Value** to 1.

   **Note**
   When you set a trigger on a transition, a square appears on the transition line, which represents the action.

---

**Using Tags with Animation Graphs**

This feature is in **preview** release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the [AWS Game Tech blog](https://aws.amazon.com/blogs/gaming/) to learn more.

In the **Animation Editor**, you use tags to describe the current state of your character and control the transition between different states. Tags are Boolean flags that are either active (enabled) or inactive (disabled). Some examples of tags are Happy, Holding Sword, and Left Leg Injured.

**Adding Tags**

Tags are represented by animation graph parameters. When you define a parameter, you can specify a different value for each entity that uses the same animation graph and parameter. For example, you
can specify a different value for the Speed parameter for each entity that uses the animation graph. Similarly, you can assign a different tag to each entity. For example, one entity has the Holding Sword tag active and another entity has the Happy tag active. For more information about parameters, see About Parameters (p. 1345).

To create a tag

1. In Lumberyard Editor, choose Tools, Animation Editor.
2. In the Animation Editor, in the Parameters pane, click the + button.

   ![Parameters Pane]

3. In the Create Parameter dialog box, do the following:
   a. For Value type, select Tag.
   b. For Name, enter a name for your tag.
   c. For Description, enter an optional description for your tag.
   d. For Default, select the check box to enable the tag.
4. Click **Create**.

### Adding Conditions to Tags

Use tag conditions to enable the state machine to change the active state. For example, you can choose a specific jump animation based on the active tag. To transition to Awesome Jump, you would enable the Freaky, Awesome, and Happy tags.
You can also use tags in combination with wildcard transitions to choose a specific state that other states can access. Wildcard transitions are transitions that can originate from any node. In the preceding example, the arrow to the left of `Idle` represents the wildcard transition. This means you can transition from any state to the `Idle` state, as long as the condition for the wildcard transition is met.

Tag conditions have two attributes: test function and tags.

**Test Function**

Specifies the tag status to pass the condition.

You can choose from the following options:

- **All tags active** – All tags must be active or the condition blocks the change.
- **One or more tags inactive** – At least one tag must be inactive or the condition blocks the change.
- **One or more tags active** – At least one tag must be active or the condition blocks the change.
- **No tag active** – All tags must be inactive or the condition blocks the change.

**Tags**

Specifies the tags that the condition checks for.

To add a tag to a condition, select the transition line between your nodes. In the Attributes pane, select the values that you want to use.

**Note**

You can only choose from tags that are available in the Parameters pane. For more information, see Adding Tags (p. 1446).

**Customizing EMotion FX Objects**

This feature is in preview release and is subject to change.
The EMotion FX API supports registering custom object types, including state machine nodes, blend tree nodes, transitions, and conditions. You can define custom object types in your game code or a custom gem. This allows you to have granular control of the Lumberyard animation system.

Registering Custom Objects

Before registering custom objects, activate the EMotion FX SystemComponent to ensure the EMotion FX runtime is initialized correctly. Then use an EBus call to the EMotionFXRequestBus::Events::RegisterAnimGraphObjectType method. You can ensure that EMotion FX runtime is activated by registering your custom node from a component that has a dependency on EmotionFXAnimationService. You do not need to manually instantiate the EMotion FX SystemComponent and call Activate; component dependencies handle these tasks.

To register your custom node

1. In your custom gem or game project code, define your subclass of EMotionFX::AnimGraphObject.
2. Create a subclass of AZ::Component.
3. In your component's GetDependentServices() method, add the dependency to EmotionFXAnimationService:

   ```cpp
   dependent.push_back(AZ_CRC("EmotionFXAnimationService", 0x3f8a6369));
   ```

4. In your component's Activate() method, register your node type:

   ```cpp
   EmotionFXAnimation::EMotionFXRequestBus::Broadcast(
       &EmotionFXAnimation::EMotionFXRequestBus::Events::RegisterAnimGraphNodeType,
       MyCustomNode::Create(nullptr)
   );
   ```

Implementing AnimGraphObject Subclasses

AnimGraphObject is the base class for all objects in the animation graph. The constructor on the base class is protected; instead, objects are instantiated with the Create() method. The Lumberyard animation system (EMotion FX) uses an instance of AnimGraphObject to create other instances by calling the Clone() method.

Each AnimGraphObject subclass has a unique type ID that is used to serialize an object to and unserialize an object from an .animgraph file. You use a public anonymous enum with a TYPE_ID member to declare the type ID for an object.

When implementing an AnimGraphObject subclass, you must define the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uint32 GetBaseType() const</td>
<td>Defines the base type of an object. There are three base types: nodes, transitions, and conditions.</td>
</tr>
<tr>
<td>const char* GetTypeString() const</td>
<td>Defines the string version of the object type name.</td>
</tr>
</tbody>
</table>
Creating Custom Motion Events and Parameters Using C++

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can author custom event classes with custom parameters and reflect them to the edit context for use in Animation Editor. By creating predefined motion events with known parameters, you minimize the performance impact of complex parameters and reduce the risk of human error.

In Animation Editor, users can perform the following tasks with the events and parameters that you create:

- Choose the events to add to motions
- Provide their own values for the parameters
- Add additional parameters to an event instead of creating duplicate events when the timing for two events is the same
- Quickly create events with complex parameters
- Tag motion events with colors that they choose and create a color scheme that is meaningful for them
- Save the event and parameter information in an XML file that can be reloaded

Topics
- Creating Motion Events (p. 1451)
- Creating EventData Types (p. 1455)

Creating Motion Events

The EMotionFX::MotionEvent class inherits EMotionFX::Event and describes an event that happens at a specified time or range of time during a motion.

A motion event could be a footstep sound to play, a particle system to spawn, or a script to execute. Because motion events are completely generic, EMotion FX doesn't handle them for you. You must create and handle the events that your game requires.
Each motion event has a list of `EventData` instances that are attached to the event. An event handler uses the `EventData` list to perform the required actions.

All motion events are stored in a motion event table. The motion event table (see `Motion.h`) contains data for the event types and parameters that can be shared between events.

To listen to motion events, connect to the `ActorNotificationBus` and implement `OnMotionEvent()`.

For information on creating `EventData` instances and adding motion events to a motion, see Creating `EventData` Types (p. 1455).

Topics
- MotionEvent Public Member Functions (p. 1452)

MotionEvent Public Member Functions

The `MotionEvent` class includes the following public member functions.

Functions
- `MotionEvent` (p. 1452)
- `SetStartTime` (p. 1453)
- `SetEndTime` (p. 1453)
- `GetStartTime` (p. 1454)
- `GetEndTime` (p. 1454)
- `GetIsTickEvent` (p. 1454)
- `ConvertToTickEvent` (p. 1454)
- `GetIsSyncEvent` (p. 1454)
- `SetIsSyncEvent` (p. 1454)
- `HashForSyncing` (p. 1454)

**MotionEvent**

You can use the `MotionEvent` function to trigger an event at a specific point in time (a tick event) or during a specified time range (a range event). To specify the data that the event emits, you can use pointers or datasets.

**Syntax**

```
MotionEvent (float timeValue, EventDataPtr &&data)
```

Creates a tick event and uses a data pointer.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeValue</td>
<td>The time value, in seconds, when the motion event should occur.</td>
</tr>
<tr>
<td>data</td>
<td>The values to emit when the event is triggered.</td>
</tr>
</tbody>
</table>

**Syntax**

```
MotionEvent (float startTimeValue, float endTimeValue, EventDataPtr &&data)
```
Creating Custom Motion Events and Parameters Using C++

Creates a ranged event and uses a data pointer.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>startTimeValue</td>
<td>The start time value, in seconds, when the motion event should start.</td>
</tr>
<tr>
<td>endTimeValue</td>
<td>The end time value, in seconds, when the motion event should end. When equal to the start time value, a start event is triggered, but no end event occurs.</td>
</tr>
<tr>
<td>data</td>
<td>The values to emit when the event is triggered.</td>
</tr>
</tbody>
</table>

**Syntax**

```
MotionEvent (float timeValue, EventDataSet &&datas)
```

Creates a tick event and uses a dataset.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeValue</td>
<td>The time value, in seconds, when the motion event should occur.</td>
</tr>
<tr>
<td>datas</td>
<td>The values to emit when the event is triggered.</td>
</tr>
</tbody>
</table>

**Syntax**

```
MotionEvent (float startTimeValue, float endTimeValue, EventDataSet &&datas)
```

SetStartTime

Sets the start time value of the event, which is when the event should be processed.

**Syntax**

```
void SetStartTime (float timeValue)
```

SetEndTime

Sets the end time value of the event, which is when the event should be processed.

**Syntax**

```
void SetEndTime (float timeValue)
```
GetStartTime

Gets the start time value of this event, which is when the event should be executed.

**Syntax**

```cpp
float GetStartTime () const
```

GetEndTime

Gets the end time value of this event, which is when the event should stop.

**Syntax**

```cpp
float GetEndTime () const
```

GetIsTickEvent

Checks whether this is a tick event.

**Syntax**

```cpp
bool GetIsTickEvent () const
```

ConvertToTickEvent

Converts this event into a tick event.

**Syntax**

```cpp
void ConvertToTickEvent ()
```

GetIsSyncEvent

Checks whether this event is a sync event.

**Syntax**

```cpp
bool GetIsSyncEvent () const
```

SetIsSyncEvent

Specifies whether this event is a sync event.

**Syntax**

```cpp
void setIsSyncEvent (bool newValue)
```

HashForSyncing

Creates a hash on the sync track of a motion.

**Syntax**

```cpp
size_t HashForSyncing (bool isMirror) const
```

For the MotionEvent class source code, see `lumberyard_version\dev\Gems\EMotionFX\Code\EMotionFX\Source\MotionEvent.*`. 
Creating EventData Types

You can create EventData types in a separate gem or directly in a game project's code. Each parameterized motion event can contain more than one EventData object. This makes it possible for users to attach an arbitrary number of EventData objects to a single event.

The EMotionFX::EventData class describes a set of parameters and values that is sent when an event is dispatched. The EventData class is the base class for all event data types. For full source code, see the lumberyard_version\dev\Gems\EMotionFX\Code\EMotionFX\Source\EventData.* files.

To create an EventData type

1. Using the following criteria, subclass either the EventData class or the EventDataSyncable class:
   - For general-purpose parameters, subclass the EventData type.
   - For parameters for the sync track, use the EventDataSyncable class. These parameters are for synchronizing blended motions.

   The following code snippet subclasses the EventDataSyncable class to create a LeftFootEvent for a left footstep.

   ```cpp
   class LeftFootEvent final
   : public EMotionFX::EventDataSyncable
   {
   public:
       AZ_RTTI(LeftFootEvent, "{117454DC-0675-483E-843E-841C57A4354D}",
       EventDataSyncable);
       LeftFootEvent() = default;
       ...
   }
   
   2. Implement the Equal function in the subclass. The Equal function tests whether two EventData instances are equal and is used for deduplication of EventData instances.

   The following example checks whether the EventData passed in is a LeftFootEvent.

   ```cpp
   bool Equal(const EventData& rhs, const bool /*ignoreEmptyFields*/) const override
   {
       // All LeftFootEvents are equal.
       const LeftFootEvent* rhsEvent = azrtti_cast<const LeftFootEvent*>(&rhs);
       return rhsEvent != nullptr;
   }
   
   For more information about the Equal function, see More About the Equal Function (p. 1457).

   3. Implement the Reflect method to reflect the type to the Serialization Context (p. 1033) and Edit Context (p. 1052) contexts.

   When you reflect the event to the edit context, add the Creatable attribute to ClassElement. This makes the EventData type visible in the Animation Editor's Motion Events tab so that users can select it.

   The following code example reflects the LeftFootEvent to the serialize and edit contexts.

   ```cpp
   static void Reflect(AZ::ReflectContext* context)
   {
       AZ::SerializeContext* serializeContext = azrtti_cast<AZ::SerializeContext*>(context);
   }
   ```
if (!serializeContext) return;

serializeContext->Class<LeftFootEvent, EventDataSyncable>()->Version(1);

AZ::EditContext* editContext = serializeContext->GetEditContext();
if (!editContext) return;

editContext->Class<LeftFootEvent>("LeftFootEvent", "")
->ClassElement(AZ::Edit::ClassElements::EditorData, "")
->Attribute(AZ::Edit::Attributes::AutoExpand, true)
->Attribute(AZ::Edit::Attributes::Visibility,
AZ::Edit::PropertyVisibility::ShowChildrenOnly)
->Attribute(AZ_CRC("Creatable", 0x47bff8c4), true);
}
...

4. To add the event to a motion, use the FindOrCreateEventData template, which accepts any subclass of EventData.

... auto footstepData = GetEMotionFX().GetEventManager()->
>FindOrCreateEventData<LeftFootEvent>();
motion->GetEventTable()->FindTrackByName("Sound")->AddEvent(0.2f, footstepData);
...

Example

The following example shows the completed LeftFootEvent sample EventData subclass and the code to add the event to a motion.

class LeftFootEvent final
 : public EMotionFX::EventDataSyncable
{
public:
    AZ_RTTI(LeftFootEvent, "{117454DC-0675-483E-843E-841C57A4354D}", EventDataSyncable);

    LeftFootEvent() = default;

    static void Reflect(AZ::ReflectContext* context)
    {
        AZ::SerializeContext* serializeContext = azrtti_cast<AZ::SerializeContext*>(context);
        if (!serializeContext) return;

        serializeContext->Class<LeftFootEvent, EventDataSyncable>()->Version(1);

        AZ::EditContext* editContext = serializeContext->GetEditContext();
        if (!editContext) return;

        editContext->Class<LeftFootEvent>("LeftFootEvent", "")
            ->ClassElement(AZ::Edit::ClassElements::EditorData, "")
            ->Attribute(AZ::Edit::Attributes::AutoExpand, true)
            ->Attribute(AZ::Edit::Attributes::Visibility,
            AZ::Edit::PropertyVisibility::ShowChildrenOnly)
            ->Attribute(AZ_CRC("Creatable", 0x47bff8c4), true);
    }

    bool Equal(const EventData& rhs, const bool /*ignoreEmptyFields */) const override
    {
        // all LeftFootEvents are equal
        const LeftFootEvent* rhsEvent = azrtti_cast<const LeftFootEvent*>(&rhs);
        return rhsEvent != nullptr;
    }
}
size_t HashForSyncing(bool isMirror) const override { return isMirror ? 1 : 0; }

protected:
    LeftFootEvent(const size_t /*hash*/) : LeftFootEvent() {}

};

auto footstepData = GetEMotionFX().GetEventManager()-
    >FindOrCreateEventData<LeftFootEvent>();

motion->GetEventTable()->FindTrackByName("Sound")->
AddEvent(0.2f, footstepData);

More About the Equal Function

The **Equal** function tests whether two EventData instances are equal.

**Syntax**

```cpp
virtual bool Equal(const EventData& rhs, bool ignoreEmptyFields = false) const = 0;
```

EMotion FX uses the **Equal** method to deduplicate instances of EventData subclasses. The AnimGraphMotionCondition class also uses it for motion event matching logic.

When Event Manager loads a .motion file and deserializes the motion events on the event tracks, EventManager::FindOrCreateEventData processes each EventData instance.

The EventManager stores a list of the EventData instances in use and attempts to find an EventData instance in which the call to Equal(loadedEventData) returns true. If the EventManager finds an EventData instance that is equal, the duplicate data is discarded.

When a call to AnimGraphMotionCondition tests a motion event, AnimGraphMotionCondition::TestCondition calls the **Equal** method with the ignoreEmptyFields parameter set to true. The ignoreEmptyFields parameter enables partial matching of EventData instances. For example, if one of the fields is a string and the string value is empty in the condition, any value in the field matches.

**Synchronizing Blended Motions**

The **EMotionFX::EventDataSyncable** class extends the functionality of the base EventData class and enables events that drive motion synchronization behavior. Use the **EventDataSyncable** class to specify parameters for synchronizing blended motions. The class calls HashForSyncing on the sync tracks of two different motions, compares the results, and finds events that are equal based on their hash value.

For source code, see `lumberyard_version\dev\Gems\EMotionFX\Code\EMotionFX\Source \EventDataSyncable.*`.

**Mirroring**

You can use EMotionFX to mirror motions programmatically. When a motion is being mirrored, its sync events must also be mirrored. To signal this mirroring, the HashForSyncing method accepts an isMirror parameter.

For example, suppose that you use an EventDataSyncable subclass to mirror the gait of a horse. You use an integer field to represent the feet of the horse with the following convention.

```cpp
0=left rear
1=right rear
2=left front
3=right front
```
Implement `HashForSyncing` as in the following example.

```cpp
size_t HashForSyncing(bool isMirror) const
{
    if (!isMirror)
    {
        return m_footIndex;
    }
    // Translate left foot (an even foot index) to right foot, and vice
    // versa
    return (m_footIndex % 2 == 0) ? m_footIndex + 1 : m_footIndex - 1;
}
```

The default implementation for `HashForSyncing` returns the hash of the type ID of the type and ignores the `isMirror` parameter.

## Creating and Simulating a PhysX Ragdoll

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A ragdoll is a physical representation of a character in the animation system that you can use to simulate behavior, such as hit reactions and character death. The physical representation consists of a hierarchy of rigid bodies with simple shapes that are connected by joints. The animation system and the PhysX system work together to simulate the realistic behaviors. While the ragdoll setup occurs in the animation system, the PhysX system is responsible for how a character moves based on environmental interactions and external forces. For example, you can set up your ragdoll so that the character will rotate as it collapses when you apply force to the character's outer shoulder area.

To use the PhysX Ragdoll (p. 757), add it to an entity in Lumberyard Editor. You can then follow the procedures below to create and control the physical representation of the ragdoll.

**Important**

- You can enable the ragdoll to interact physically with the terrain. To do so, add a PhysX Terrain (p. 767) component to an entity in the level.

- The PhysX Character Controller component currently doesn't support the PhysX Ragdoll component.

This topic will teach you how to do the following:

- Set up a ragdoll. (p. 1458)
- Add the ragdoll to an animation graph. (p. 1465)
- Simulate a ragdoll in Lumberyard Editor. (p. 1468)

## Setting Up a Ragdoll

When you set up a ragdoll, you do the following:
• Define joints for the ragdoll. (p. 1459)
• Add ragdoll colliders. (p. 1461)
• Create joint limits. (p. 1463)

In addition, your actor must have a motion extraction node that is a root node. Your ragdoll must have a root node that is a direct parent of the motion extraction node. For example, the Rin character uses root for its motion extraction node. For the ragdoll root node, the Rin character uses 'C_pelvis_JNT, which is a child node of root.

Step 1: Define Joints for the Ragdoll

Do the following to select the joints for your ragdoll.

To select joints for the ragdoll
1. In Lumberyard Editor, choose Tools, Animation Editor.
2. In the Animation Editor, on the right side of the menu bar, choose Physics from the drop-down list. This changes the layout.
3. Choose File, Open Actor and select your actor.
4. In the Skeleton Outliner, multi-select the joints that you want to include in your ragdoll.
5. Right-click one of the selected joints and then choose Ragdoll, Add to ragdoll.

Note
You can add joints to the ragdoll at any time.

6. Click the filter icon next to the search text box, and select Ragdoll joints and colliders. This shows only the joints in the ragdoll and not the full animation skeleton.
The **Skeleton Outliner** displays icons to indicate that:

- A joint is part of the ragdoll
- A joint holds ragdoll colliders
- A joint holds hit detection colliders

7. In the **OpenGL Render window**, use the render options to show or hide the ragdoll colliders (rendered in orange), ragdoll joint limits, and the hit detection colliders (rendered in blue).

   **Note**
   If your ragdoll colliders and hit detection colliders are the same size, you may need to hide the colliders that you are not working on.

8. On the **Ragdoll** tab, you can view and modify the ragdoll properties for the selected joint. For example, the rigid body mass, sleeping threshold, and colliders.
Step 2: Add Ragdoll Colliders

The ragdoll automatically suppresses collisions between joints that are adjacent in the skeleton. This means that adjacent colliders can overlap, but a pair of colliders that are not adjacent should not intersect. If the pair of colliders intersects, they'll collide when the ragdoll is simulated.

In the following example, the collider for the second spine joint (highlighted) can intersect with the first or third spine joint. The first and third spine joints, however, should not intersect.
To add a ragdoll collider

1. In the Animation Editor, on the Ragdoll tab, click Add ragdoll collider and then choose Add box, Add capsule, or Add sphere.
2. On the **Ragdoll** tab, do the following in the collider properties:

   a. Set the **Offset** and **Rotation** to move the collider to the correct location. The **Offset** and **Rotation** are relative to the joint transform.

   b. Adjust the collider dimensions (for example, set the **Height** and **Radius** for a **Capsule**) to resize the collider.

3. Choose **File**, **Save Selected Actors**. This saves the ragdoll data to the `.assetinfo` file for the character. The Asset Processor then bakes the ragdoll data into the `.actor` file.

**Step 3: Create a Joint Limit**

Joint limits are enabled for every joint in your ragdoll. This allows you to edit the joints and ensure they're set up correctly.

The following image shows joint limits that are set up correctly.
Creating and Simulating a PhysX Ragdoll

To create a joint limit

1. In the Animation Editor, in the OpenGL Render Window, adjust the child local rotation so that the red axis points along the bone.
2. Adjust the parent local rotation so that the red axis appears inside the swing cone.
3. Adjust the twist limit value so that the line appears inside the wedge.
Creating and Simulating a PhysX Ragdoll

Adding Your Ragdoll to an Animation Graph

When you create an animation graph to control the ragdoll simulation of your character, you do the following:

- Prepare the actor asset.
- Adjust the animation graph to enable the ragdoll.
- Preview

The animation graph controls the ragdoll simulation of your character. When your character transitions into a blend tree that has a ragdoll node, the ragdoll automatically activates and simulates in game mode in Lumberyard Editor. When your character transitions out of that state, the ragdoll deactivates. The ragdoll node outputs a bind pose in the Animation Editor.

To create an animation graph to transition from running state to ragdoll state

1. In the Animation Editor, on the right side of the menu bar, choose AnimGraph from the drop-down list. This changes the layout.

2. In the Anim Graph pane, click the + icon to create a new animation graph.

3. Right-click the grid and then choose Create Node, Sources, Motion. Alternatively, in the Anim Graph Palette, on the Sources tab, drag Motion into the animation graph.
4. Select the **Motion** node in the animation graph.

5. In the **Attributes** pane, do the following:
   a. For **Name**, enter a name for your motion. For example, **Run**.
   b. Click **Select motions**. In the **Motion Selection** window, select a motion and then click **OK**.

6. Right-click the grid and then choose **Create Node, Sources, Blend Tree**. Alternatively, in the **Anim Graph Palette**, on the **Sources** tab, drag **Blend Tree** into the animation graph.

7. Select the **Blend Tree** node in the animation graph.
8. In the Attributes pane, enter a name for your blend tree. For example, Ragdoll.

9. In the animation graph, connect the Motion node to the Blend Tree node. For example, connect the Run node to the Ragdoll node.

10. Double-click the Blend Tree node.

11. Right-click the grid and then choose Create Node, Sources, Ragdoll. Alternatively, in the Anim Graph Palette, on the Sources tab, drag Ragdoll into the animation graph.

12. Connect the Output Pose for the Ragdoll node to the Input Pose for the Final Node node.

13. At the root of the animation graph, select the transition line that starts from the Motion node and connects to the Blend Tree node. For example, select the transition line that connects the Run node to the Ragdoll node.

   a. In the Attributes pane, click Add condition and then choose Time Condition.

   b. Under Time Condition, set the Countdown Time.
14. In the animation graph, click the **Motion** node for a preview.

## Simulating Your Ragdoll

Once you've created your ragdoll and animation graph, you can simulate the ragdoll in game mode in Lumberyard Editor.

**To simulate your ragdoll**

1. In Lumberyard Editor, right-click the viewport and choose **Create entity**.
2. In the **Entity Inspector**, for **Name**, enter `Ragdoll`.
3. Add an **Actor** component:
   a. Click **Add Component, Actor**.
   b. In the **Actor** component, for **Actor asset**, click the browse (...) button.
   c. In the **Pick EMotion FX Actor** window, select the actor for which you set up the ragdoll and then click **OK**.
4. Add an Anim Graph component:
   
a. Click Add Component, Anim Graph.
   
b. In the Anim Graph component, for Motion set asset, click the browse (...) button.
   
c. In the Pick EMotion FX Motion Set window, select your motion set and then click OK.
   
d. In the Anim Graph component, for Anim graph, click the browse (...) button.
   
e. In the Pick EMotion FX Anim Graph window, select your animation graph and then click OK.
Creating Additive Animations

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Additive animations are animations that you can add as layers on top of a base animation. They are commonly used to add a partial-body animation to a full-body animation. Because additive animations do not interfere with base animation functionality, you can reuse the same base to create many variations in motion. Reusing the base also has the advantage of greatly reducing the overall asset count.

Because additive animations preserve the underlying animation's style, they are useful for adding poses and animations to a character's upper body. For example, you can use additive animations to make a character breathe, look around, flinch, or change posture. This adds variety to the animations and avoids what might otherwise be a monotonous look.

You can create additive animations in two ways:

- At runtime, use the Blend Two Additive and Pose Subtract nodes. For more information, see Blend Two Additive Node (p. 1425) and Pose Subtract Node (p. 1427).
- At asset processing time, use the Asset Browser and FBX settings motion additive modifier to convert an existing animation into an additive animation. This approach removes the generation of additive animations from runtime processing and improves runtime performance. See the following procedure.

To convert a motion into an additive animation

1. From Lumberyard Editor, choose Tools, Asset Browser.
2. In the Asset Browser, locate the FBX animation file that you want to convert into an additive animation.
3. Right-click the FBX animation file and choose Edit Settings.
4. In the FBX Settings dialog box, on the Motions tab, click Add Modifier, and then choose Additive Motion.
5. In the Motion additive section, for Base frame, specify the number of the frame that contains the reference pose that you want to subtract.

   For example, if you're creating an additive animation for the idle state, the base frame can be the first frame of your idle motion. If you're creating an additive aim blendspace, the base frame can be the frame that contains the center aim.

   **Note**
   The reference pose that you want to subtract must be in the FBX file that you selected.

---

### Retargeting Motions

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Animation Editor to retarget motions from one actor to another actor. This lets you reuse motions that you've created for an actor, and to quickly prototype motions on other actors while you wait for new ones to be created. The retarget feature is also important to ensure that actors are scaled appropriately. Without this feature, the retargeted actor stretches and scales to the size of the original actor for which the motion was recorded. With this feature, the retargeted actor retains its size.

For example, you may have a human character that's six feet tall and your motions are recorded for that actor. You may also have a giant character that's 18 feet tall. If you play the motions for the human character on the giant character without retargeting, the giant character will scale to the size of the human character. When you enable the retarget feature, the giant character retains its height of 18 feet.

**Important**
To retarget motions, your assets **must** meet these requirements:

1. The first frame in every motion must be the actor's bind pose. For example, if you have an animation that contains frames 1-100, the actor's bind pose (skinned mesh and bones) must be added at frame 0.
2. The bone names and hierarchy **must** be identical between the original actor and the retargeted actor. The retargeted actor **may** contain additional leaf bones in its hierarchy, but the areas of the hierarchy that are being retargeted must be identical.

   **Note**
   If your retargeted actor has the same bone names and transforms as the original actor, you do not need to use the retarget motions procedure.

**To retarget motions**

1. In your DCC tool, add the actor's bind pose, which includes skinning and bones, to the first frame of your motion. Then export the file into Lumberyard. For more information, see Importing Assets into Lumberyard (p. 263).
2. Open Lumberyard Editor.
3. In the Asset Browser, right-click the file that you imported, and choose Edit Settings.
4. In the Fbx Settings window, on the Motions tab, choose Add Modifier, Motion range.
   Note
   If you do not see the Motion range modifier, be sure that your .fbx file has keyframes.
5. Under Motion range, do the following:
   a. Set the Start frame to the frame that does not include the bind pose. For example, if the original actor's bind pose is on frame 0, set the Start frame to 1. This ensures that the bind pose does not play in your motion.
   b. Set the End frame to the last frame of your motion. Based on the example in the previous step, the last frame would be 100.
   c. Click Update.
      Note
      If you receive an error, check the number of keyframes in your motion, and update the End frame.

The frame settings are shown in the following example:

6. Repeat steps 1 to 5 for all of the motions that you want to retarget.
7. In Lumberyard Editor, choose Tools, Animation Editor.
8. In the Animation Editor, in the center pane, on the Anim Graph tab, open your animation graph (p. 1349).
9. In the right pane, on the Attributes tab, select the Retarget check box.
Creating Simulated Objects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When you animate a character (actor), your actor might wear objects that move differently from the primary motion. For example, if your actor runs and wears a backpack, the backpack might sway back and forth. To create this dynamic movement, you create a simulated object. A simulated object acts as a container for the bones on your actor. In the Animation Editor, you can specify how loose objects, such as chains, backpacks, or long hair, move in relation to the actor.

**Note**
Simulated objects don't collide with ragdoll colliders or PhysX entities in the level.

In this procedure, you'll do the following:

1. Create a simulated object that's attached to an actor.
2. Add colliders to the skeleton so that the object collides with the actor's body.
3. Adjust your settings so that the animation appears more smooth and realistic.
4. View the simulation in the render window.
Prerequisites

Before you begin, you must do the following:

- Using Project Configurator, enable the Samples Project (p. 146).
- In the Animation Editor, complete the following:
  - Import your actor, such as the rinActor.fbx file
  - Create a motion set
  - Import your motions, such as the rin_Run.fbx

For more information, see Step 1: Creating a Motion Set (p. 1354).

Topics

- Setting Up a Simulated Object (p. 1474)
- Setting Up the Simulated Object Anim Graph Node (p. 1476)
- Setting Up Simulated Object Colliders (p. 1480)
- Using Debug Mode to Refine the Simulation (p. 1483)
- Using Parameters to Adjust the Animation During Runtime (p. 1487)

Setting Up a Simulated Object

In the following procedure, add motion to a tassel attached to the character.

To set up a simulated object

1. In the Animation Editor, choose Layouts and choose SimulatedObjects.
2. In the Skeleton Outliner, select the bones to add to a simulated object. Enter a name in the search bar or filter for results.
3. Select the bones, right-click, and choose Simulated Object, Add selected joints, <New simulated object>.

Example

The L_tassle_01_JNT bone and its children are selected.

4. In the dialog box, enter a name for the simulated object and click OK.
Example

The simulated object appears in the **Simulated Object** panel.

5. In the **Simulated Objects** panel, select an object or joint. The properties that you can customize appear in the **Simulated Object Inspector** panel.

   **Note**
   After you create an anim graph, you can preview the simulation. For now, keep the default values.

Example

The first joint in the simulated object chain (L_tassle_01_JNT) is **Pinned**. Pinned joints follow the original joint. If you have multiple joints, you can pin them if you don't want them to move as a simulated object. The root joint is always pinned.

6. In the render window, view the collider radius of each joint in the simulated object. Select the simulated object to view all colliders or select a joint to see an individual collider.

   **Tip**
   - In the render window, click the icon to toggle the collider.
   - The **Collision radius** is the distance in which the simulated object joint avoids a collider specified in the simulated object. If the value is 0, the joint remains on the surface of the collider.
   - After you complete the next section, you can adjust the **Collider radius** to get your preferred results.
Creating Simulated Objects

Example

7. To save your actor, click the save icon in the Actor Manager.

Example

Setting Up the Simulated Object Anim Graph Node

After you set up the simulated object, create an anim graph to view the simulation. This lets you preview how the tassel moves in relation to the actor's primary motion.

To set up an anim graph node for the simulated object

1. In the Anim Graph panel, click the + icon to create an anim graph.
2. Right-click the graph and choose Create Node, Sources, Blend Tree.
Example

3. Double-click the BlendTree0 node, right-click the anim graph grid, and choose Create Node, Physics, Simulated Object.

Example

4. Connect the Pose output of the SimulatedObject0 node to the Input Pose of the FinalNode0 node.
5. Right-click the anim graph and choose Create Node, Sources, Motion.
6. Connect the Output Pose of the Motion0 node to the Pose input of the Simulated Object0 node.
Example

Your graph should look like the following.

7. Select the **Motion0** node and in the **Attributes** panel, click the + icon to add a motion to the node.
8. In the **Motion Selection Window**, select a motion, such as the *run*, and click **OK**.
9. Save the anim graph and enter a name, such as *simulatedobjects*.animgraph.
10. Select the **SimulatedObject0** node and in the **Attributes** panel, click **Select simulated objects**.

Example

11. In the dialog box, select the simulated object.
12. Save the anim graph.

**Example**

In the Anim Graph panel, click the play icon to run the anim graph. The colliders that you set up for each joint don't collide with other colliders and the tassel goes through the arm and chest of the actor.

In the next procedure, you create another collider attached to the actor's skeleton. This prevents the tassel from moving into the actor's body.
Creating Simulated Objects

Setting Up Simulated Object Colliders

In the following procedure, add a collider to the spine and left arm to reduce the tassel’s movement. This ensures that the tassel has something to collide with, which prevents it from moving through the actor’s body.

To set up simulated object colliders

1. In the Skeleton Outliner, select the joint or joints to add a simulated object collider to. In this example, use the C_spine_04_JNT joint.
2. Right-click your selection and choose Simulated object collider, Add collider, Add capsule. This creates a shape that defines the collider area for the joint.

Example

You can also add a sphere if that shape fits your actor better.
In the **Skeleton Outliner**, a simulated object collider icon appears next to the joint.

3. In the **Simulated Object Inspector**, adjust the capsule so that it's larger than the actor's geometry.

   In this example, change the **Height** to 0.344 and the **Radius** to 0.162.

**Example**

By default, the name of the joint (C_spine_04_JNT) is also the name of the collider.

4. Repeat **Step 1** to add the L_arm_JNT joint. This creates another simulated object collider to the upper-left arm.

5. Repeat **Step 2** and **3** to set up a collider for the arm.

6. Adjust the capsule so that it fits the arm. In this example, enter the following values:

   - **Height** to 0.322
   - **Radius** to 0.081
   - **Rotation**: X to 180
   - **Radius**: Y to 89.99
• **Radius:** Z to 180

**Example**

By default, the name of the joint (`L_arm_JNT`) is also the name of the collider.

![Simulated Object Inspector](image)

7. In the **Skeleton Outliner**, select the joints where the simulated object colliders are attached.

**Tip**

In the render window, deselect the first icon (**Solid**) and select the second (**Wireframe**) to view the capsule colliders.

**Example**

In the render window, the colliders appear purple. If you deselect the joint, the collider appears gray.

Now that you added the simulated objects to the spine and arm, add these colliders to the simulated object.
8. In the **Simulated Objects** panel, select the simulated object.

9. In the **Simulated Object Inspector**, for **Collides with**, select the available colliders. This enables the simulated object joints (the tassel) to collide with the actor's body (the spine and left arm).

**Example**

![Simulated Object Inspector](image)

10. In the **Actor Manager**, save the actor. You might have to wait for Asset Processor to finish processing your changes.

**Using Debug Mode to Refine the Simulation**

In the following procedure, use the debug mode to refine the simulated object's movement.

**To use debug mode for the simulation**

1. In the **Anim Graph** panel, click the play icon to run the anim graph.
Example

Use the speed slider to reduce the speed of the animation. Note that the tassel moves through the neck and arm of the actor.

2. In the SimulatedObject0 node, click the right-corner box. This enables debug rendering for the node.

Example

3. In debug mode, you can do the following.
   a. To turn off the simulated object colliders, click the icon.
b. To turn off joint collision radius, click the icon.

Example

In debug mode, the following appear in the render window:

- Simulated object colliders – The colliders that the simulated object collides with. The colliders appear in light gray.
- Joint angle limit cones – The angle of a joint that simulates. The cones appear in light pink.
- Joint collision radius – The size of the collision radius on a joint. The radius appears in dark gray.

In the render window, you can click the first icon to toggle the actor geometry and see only simulated objects.

4. To fix the simulated object (tassel) movement, do the following.
   a. In the Simulated Object panel, select L_tassle_02_JNT.
   b. In the Simulated Object Inspector, select Pinned. This pins the second part of the tassel and prevents it from moving.
   c. For Joint angle limit, enter 80 to increase the swing of the joint.
   d. In the Simulated Object panel, select L_tassle_03_JNT.
   e. In the Simulated Object Inspector, for Radius, enter 0.065.
5. To fix the simulated joint colliders (chest and arm of the actor), do the following.
a. In the **Skeleton Outliner** panel, select the `C_spine_04_JNT` where you added the simulated joint collider.

b. In the **Simulated Object Inspector**, for **Radius**, enter `0.0.172`.

c. In the **Skeleton Outliner** panel, select the `L_arm_JNT` where you added the simulated joint collider.

d. In the **Simulated Object Inspector**, for **Radius**, enter `0.0.101`.

6. If you're satisfied with the results, save the actor.

7. To disable debugging mode, click the upper-right box again on the `SimulatedObject0` node.

**Example**

The following animation is the finished debugged version of the actor running. Note that the tassel no longer passes through the actor's body.
Using Parameters to Adjust the Animation During Runtime

You can adjust the SimulatedObject node to change its animation during runtime. To do so, create a Parameter node and attach them to the node in the anim graph. If you don't, the SimulatedObject node uses the properties that you entered in the Attributes panel.

To adjust the animation during runtime

1. In the Parameters panel, click the + icon and choose Add parameter.
2. Enter the following values.
   a. For Value type, select the Float (slider).
   b. For Name, enter Stiffness.
   c. For Default, enter 1.0.
   d. For Minimum to 1.0.
   e. For Maximum, enter 100.

Example

Your parameter should look like the following.
3. Click Create.

4. Repeat Steps 2 and 3 but change Name to Gravity, Default to 1.0, Minimum to 0 and Maximum to 5.

5. Repeat Steps 2 and 3 but change Name to Damping, Default to 1.0, Minimum to 1 and Maximum to 100.

6. Repeat Steps 2 and 3 but change Name to Weight, Default to 1, Minimum to 0 and Maximum to 1.

**Example**

Your parameters should look like the following.
7. In the Anim Graph grid, right-click and choose Create Node, Sources, Parameters.
8. On the Parameters node, connect the Stiffness output to the Stiffness factor, the Gravity output to the Gravity factor, and so on.

Example

Your graph should look like the following.

9. Pay the anim graph and adjust the sliders for the Parameters to view your changes.

Note
The simulated object, simulated joints, and parameters on the anim graph share the following properties: Stiffness, Gravity, Damping
When you adjust the properties, the Animation Editor calculates the results of these properties using the following:

- Stiffness factor parameter \( x \) simulated object stiffness \( x \) simulated joint stiffness
- Gravity factor parameter \( x \) simulated object gravity \( x \) simulated joint gravity
- Damping factor parameter \( x \) simulated object damping \( x \) simulated joint damping

Add Cloth Colliders to actors

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Applying cloth simulation to actors adds realism and dynamism in their every movement. Adding cloth colliders greatly enhances the effect. Cloth colliders can prevent cloth from penetrating into the meshes of the actor. To add cloth colliders, you must enable the NVIDIA Cloth Gem.

For more information, see the NVIDIA Cloth Gem documentation (p. 1182).

**Add Cloth Colliders to an actor**

1. In Lumberyard Editor, choose **Tools, Animation Editor**.
2. In the **Animation Editor**, on the right side of the menu bar, choose **Physics** from the drop-down list. This changes the layout.
3. Choose **File, Open Actor**, and select your actor.
4. In the **Skeleton Outliner**, select the joint that you want to add the cloth collider to.
5. Right-click the selected joint, and then choose **Cloth, Add collider**. You can add colliders (capsules or spheres). You can also copy them from Hit Detection, Ragdolls or Simulated Objects.
6. The Cloth Colliders tab shows you the list of cloth colliders of the selected joint.

7. Adjust the dimensions, offset, and rotation of cloth colliders.
8. Choose **File, Save Selected Actors**.

### Best Practices for Working with Skinned Meshes for Animation

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

See the following guidelines when working with skinned meshes for the **Animation Editor**.

**Topics**

- Creating Skinned Meshes for Actors (p. 1492)
- Exporting Actors and Motions (p. 1494)
- Tutorials: Importing FBX Files as Actors and Motions (p. 1497)
- Troubleshooting Skinned Meshes (p. 1497)
- Using Actor LODs to Optimize Game Performance (p. 1498)

### Creating Skinned Meshes for Actors

Use the following best practices when you create your character for the **Animation Editor**. In Lumberyard, a character is a skinned mesh.

#### Setting up the World Coordinate System and Root Joint

If you use the y-up or z-up world coordinate system in your DCC, use the following guidelines to set up your character:
Use a root joint for your skinned mesh. This is required to ensure that motion extraction works properly in the **Animation Editor**.

Do not use transforms, groups, or parent nodes in the hierarchy above your root joint. The root joint must be the top parent of the skeletal hierarchy to ensure that motion extraction works properly.

Set the root joint position at the origin: 0,0,0.

Set the root joint rotation and orientation to 0,0,0.

Orient your character so that the front orthographic camera view shows the front of your character.

When using the Lumberyard **Animation Editor**, ensure that your imported character faces the positive y direction. The Asset Processor automatically adds a *Coordinate system change* modifier in the .fbx settings. The default value for **Facing Direction** is **Rotate 180 degrees around the up axis**. This enables the game entity's forward direction and character to point in the same direction.

If your character faces the negative y direction after you import the character into the **Animation Editor**, in the **Asset Browser** right-click your .fbx file and choose **Edit Settings**. For the **Coordinate system change** modifier, set **Facing Direction** to **Do Nothing**.

Use the same *Coordinate system change* modifier for the actor and each of the actor's motions. This is required to ensure that animations work properly in the **Animation Editor**.

### Setting up Skin Binding

Observe the following best practices when you set up skin binding:

- Delete the geometry history on your mesh before skinning the geometry to joints.
- When skinning your mesh, limit your maximum influences per vertex to four. Lumberyard currently supports only four weight influences per vertex using the .fbx pipeline.
- Skin bind your mesh at the origin and in the same forward direction as the root joint.
- Check the bind pose before exporting your skinned mesh. For example, if the mesh moves after unbinding, you must reskin the mesh in order to prevent any errors in Lumberyard.
- Ensure that your skinned mesh has one bind pose in your DCC before you export to an .fbx file.
- Do not include any static meshes with your skinned meshes. Lumberyard cannot render unskinned meshes that are parented to bones.

Do the following to reskin your mesh:

**To reskin your mesh in Maya**

1. For **Menu Set**, choose **Rigging**.
2. Click **Skin, Unbind Skin**.
3. In the **Detach Skin Options** dialog box, for **History**, choose **Delete history**. Click **Detach** and then click **Close**.
4. Move or rotate your mesh to the appropriate position.
5. Click **Modify, Freeze Transformations**.
6. In the **Freeze Transformations Options** dialog box, select the **Translate, Rotate**, and **Scale** check boxes. Click **Freeze Transform** and then click **Close**.
7. Select your mesh.
8. Choose **Edit, Delete by Type, History**.
9. In the outliner, select the bones that you want skinned. Hold **Ctrl** and select the mesh that you want skinned.
10. Click **Skin, Bind Skin**.
11. In the **Bind Skin Options** dialog box, for **Bind to** choose **Selected joints**. For **Bind method**, choose your preferred bind method. For **Skinning method**, choose **Dual quaternion** or **Linear**. Click **Bind Skin** and then click **Close**.
Note
You must export and save your deformer weights in order to import the weight maps after reskinning.

To reskin your mesh in 3ds Max
1. Select your mesh.
2. On the Modify tab, expand Advanced Parameters. Click Save.
3. Save the mesh envelope (skin).
4. On the Modify tab, select the skin. Right-click the skin and choose Delete.
5. On the Utilities tab, click Reset XForm.
6. Click Reset Selected.
7. Click Collapse.
8. Click Collapse Selected.
10. For Modifier List, choose Skin.
11. Under Advanced Parameters, click Load and choose the mesh envelope (skin) that you saved earlier.
   Note
   You must save your weights in order to load the weights after adding a new skin modifier.
12. In the Load Envelopes dialog box, click Match by Name to preserve the weights that you saved earlier. Close the dialog box.

If you want to add a root joint to a skinned mesh, follow the preceding steps to unbind and reskin your mesh.

Exporting Actors and Motions
Use the following best practices when you export your skinned meshes using the FBX Settings tool.

- If you use the z-up world coordinate system, use the following guidelines:
  - Ensure that your DCC scene is set to z for the up-axis world coordinate system.
  - Set the axis conversion up axis to z when exporting an .fbx file.
- If you use the y-up world coordinate system, use the following guidelines:
  - Ensure that your DCC scene is set to y for the up-axis world coordinate system.
  - Set the axis conversion up axis to y when exporting an .fbx file.
- When you create an .actor file, export your skinned mesh at the bind pose without any keyframes.
- When you create a .motion file, bake animations before you export. Alternatively, bake animations when you use your DCC's .fbx export tools.
- Export only the skeleton and mesh. Do not use transforms, groups, or parent nodes in the hierarchy above your root joint. The root joint must be the top parent of the skeletal hierarchy to ensure that motion extraction works properly.
- Remove unused geometry, bones, vertices, materials, and nodes that are not necessary for the .fbx asset. This reduces the processing time and offers a better chance that the automatic processing works properly without making adjustments later. In your DCC, consider naming nodes with _ignore as a suffix to prevent those nodes from being processed.
- We recommend that you enable the EMotion FX Animation (p. 1124) gem or the CryLegacyAnimation gem, but not both. You can disable the animation gem that you don't use. For more information, see Add modular features and assets with Gems (p. 1064).
Use the following guidelines for vertex count:

**If you enabled the CryLegacyAnimation gem:**

Asset Processor processes your .fbx file to create an .actor file. Occasionally, the number of vertices does not match the original vertex count of the .fbx file. Lumberyard allows a maximum of 65,536 vertices for skinned geometry after asset processing. However, the original vertex count from your DCC tool cannot be up to 65,536 vertices. As a best practice when modeling your geometry, divide 65,536 by 3 for a value of 21,845 vertices. This allows you to import .fbx files that have 21,845 or fewer vertices. After you export the .fbx file, verify that Asset Processor successfully processes the skinned mesh. If Asset Processor does not successfully process the skinned mesh, reduce the number of vertices in the model until the file is successfully processed.

**If you enabled the EMotion FX Animation (p. 1124) gem:**

The theoretical maximum number of vertices for skinned meshes after processing is 4,294,967,295 \((2^{32} – 1)\). Although this limit is exceptionally high, we recommend that you follow best practices when modeling your skinned meshes. Use a reasonable polygon count that's suitable for the game device for which you are developing. Experiment with the number of polygons to get the desired quality while balancing game performance. You may need to adjust the polygon count if your game displays many actors at once. The value range for polygon counts can vary between 1,000 to 30,000. The polygon count that you should use depends on the game device, and the performance and quality of the actor.

The more vertices in an .fbx file, the longer Asset Processor takes to process it. View Asset Processor often and check for errors.

### Using the Maya Game Exporter

The following are typical settings for the Maya Game Exporter when you export your skinned mesh character into Lumberyard.

**Export settings for .actor files**

- Use the **Model** tab to export your .fbx files.

  ![Game Exporter](image)

  - Use the following settings:
    - Select **Export Selection** from the drop-down list.
• Select the **Skinning** check box.
• If you are exporting blendshapes (morph targets), select the **Blendshapes** check box.
• Clear the **Animation** check box. If this is selected, a .motion file is created.
• Select your world coordinate system from the **Up Axis** drop-down list.
• Navigate to a save path and specify the name of your .fbx file.
• When you're done choosing these settings, select all of the bones for the character's skeleton and all of the skinned meshes.
• Click **Export**.

**Export settings for .motion files (Animation Clips tab)**

• Use the **Animation Clips** tab to export your .fbx files.

- Use the following settings:
  - Select **Export Selection** from the drop-down list.
  - Click the + button to add an animation clip.
  - For **Clip Name**, enter a name for the clip.
  - For **Start** and **End**, specify a frame.
  - Select the **Bake Animation** check box.
  - Select your world coordinate system from the **Up Axis** drop-down list.
  - Navigate to a save path and specify the name of your .fbx file.
  - When you're done choosing these settings, select all of the bones for the character's skeleton.
  - If you are exporting blendshapes with your animation, also select the skinned mesh that has the blendshape animations. For example, if your character's face mesh has blendshapes, select the skeleton and the character's face mesh.
• Click **Export**.

**Export Settings for .motion files (Time Editor tab)**

• Use the **Time Editor** tab to export your .fbx files.
Best Practices for Working with Skinned Meshes for Animation

Use the following settings:

- Select **Export Selection** from the drop-down list.
- Select the clip that you want to export from the **Time Editor Clips** drop-down list.
- Click the + button to add an animation clip.
- Select the **Bake Animation** check box.
- Select your world coordinate system from the **Up Axis** drop-down list.
- Navigate to a save path and specify the name of your .fbx file.
- When you're done choosing these settings, select all of the bones for the character's skeleton.
- If you are exporting blendshapes with your animation, also select the skinned mesh that has the blendshape animations. For example, if your character's face mesh has blendshapes, select the skeleton and the character's face mesh.
- Click **Export**.

**Tutorials: Importing FBX Files as Actors and Motions**

To learn about importing FBX files as actors into Lumberyard, watch the following video tutorial.

**Importing Characters into Lumberyard as Actors**

To learn about importing FBX files as motions into Lumberyard, watch the following video tutorial.

**Importing Animations into Lumberyard as Motions**

For more information, see Customize FBX asset export with FBX Settings (p. 409).

**Troubleshooting Skinned Meshes**

If your character's skinning appears visually broken in the **Animation Editor**, the following issues could be why:

- The **Coordinate system change** modifier isn't identical for the .actor and .motion files
- You might need to reset the bind pose
To change the coordinate system modifier

1. In Lumberyard Editor, in the Asset Browser, navigate to your .fbx file.
2. Right-click the .fbx file and choose Edit Settings.
3. In the FBX Settings window, for the Coordinate system change modifier, set Facing Direction to Do Nothing or Rotate 180 degrees around the up axis.
4. Ensure your .actor and .motion files use the same Coordinate system change modifier.

To reset a bind pose in Maya

1. Ensure your character is in the bind pose.
2. In Maya, select the character root bone.
3. In the Rigging menu, click Skin and then select the Go to Bind Pose check box.
4. For the Input box, choose Select by name.
5. Search for all bind poses by entering bindPose* in the search box.
6. Press Enter to select all of the bind poses and then press Delete.
7. Select the root bone of your character.
8. In Maya, in the bottom left corner, enter the following to reset the bind pose for your character:
   `dagPose -bp -save;`

Using Actor LODs to Optimize Game Performance

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use levels of detail (LODs) to optimize the rendering performance of games. This is especially true for large in-game worlds, which are constrained by hardware, frame rate, and the real-time rendering limits. LODs increase performance and reduce draw calls by displaying progressively less detail in objects that are farther from the camera. To further reduce draw calls, lower LODs have multiple textures combined into one texture.

Topics

- Using Actor LODs in Lumberyard (p. 1498)
- Using Digital Content Creation Tools to Create LODs (p. 1499)
- Using the FBX Settings Tool to Check LODs (p. 1501)
- Adding Actor LOD to a Level in Lumberyard (p. 1503)
- Adding the Simple LOD Distance Component (p. 1504)

Using Actor LODs in Lumberyard

In Lumberyard, you can use up to five actor LODs in addition to your actor’s base mesh. An LOD of 1 has the highest level of detail, and an LOD of 5 the least. Each successive LOD typically has its vertices reduced by 50 percent from the previous level and reduces the number of materials used.

Features

In Lumberyard, you can use actor LODs on skinned meshes, skeletons, and materials or textures. Lumberyard performs the following actions:

- Provides a Simple LOD Distance component that supports rendering of different LODs.
• Reads and imports skinned mesh LODs from a single FBX file.
• Auto populates skinned mesh LODs that use a soft naming convention.

Requirements and Limitations

Note the following requirements:

Skinned Meshes
• Each LOD mesh must skin to the same skeleton. However, you can choose which bones to skin to.

Skeletons
• To skin each LOD mesh to a different skeleton, create a separate skeletal hierarchy.
• For each LOD, the skeleton hierarchy must remain the same. Remove leaf bones first and work up the chain.
• In lower LODs, you cannot remove in-between bones. For instance, if you have Spine1, Spine2 and Spine3 for an LOD of 1, you cannot delete Spine2 and leave Spine1 and Spine3.

Materials or Textures
• Each actor requires a separate material group.
• Create a material LOD in the same way that you create a material for static meshes.

Using Digital Content Creation Tools to Create LODs

To author actor LODs in a DCC tool like Autodesk Maya or Autodesk 3ds Max, you can use one of the following two methods:

• Soft naming conventions
• LOD groups

**Important**
Currently, Lumberyard supports skeletons created with LOD groups only.

To use the soft naming convention to create LODs

1. Create an actor with multiple LOD meshes by adding a suffix at the end of the name of each LOD mesh. See the following table for examples.

<table>
<thead>
<tr>
<th>Suffix</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>_lod1</td>
<td>Rin_lod1</td>
</tr>
<tr>
<td>_lod2</td>
<td>Rin_lod2</td>
</tr>
<tr>
<td>_lod3</td>
<td>Rin_lod3</td>
</tr>
<tr>
<td>_lod4</td>
<td>Rin_lod4</td>
</tr>
<tr>
<td>_lod5</td>
<td>Rin_lod5</td>
</tr>
</tbody>
</table>

For more information, see FBX soft naming conventions (p. 443).
2. Follow the instructions in Customize FBX asset export with FBX Settings (p. 409) to export the meshes to FBX format so that you can use them in Lumberyard.

**To use LOD groups to create actor LODs**

- To create an actor with multiple LOD meshes, use an empty LOD group as the parent of the skeleton and the LOD meshes. The following example shows a skeleton created with an LOD group and imported into Lumberyard.
Using the FBX Settings Tool to Check LODs

After you export your .fbx file to Lumberyard, do the following:
To use the FBX Settings to check LODs

1. In Lumberyard Editor, choose **Tools, Asset Browser**.
2. Right click the .fbx file and choose **Edit Settings**. The **FBX Settings** tool shows a **Level of Detail** modifier that lists the additional LOD meshes.
You can use the **FBX Settings** tool to verify that your LODs were imported correctly. Currently, you can also unselect a mesh or skeleton for each LOD, but you can't move a mesh or skeleton across a level or add a new mesh or skeleton to a level.

**Adding Actor LOD to a Level in Lumberyard**

After you import your LODs into Lumberyard Editor, you can add an actor LOD to a level.

**To add an actor LOD to a level in Lumberyard**

1. In Lumberyard Editor, choose **Tools, Asset Browser**.
2. Select and drag the exported `.fbx` file to the viewport. In the **Actor** component that appears in the **Entity Inspector**, a shared material file with multiple materials contains the LOD asset.
3. To preview the LODs, change the number for **LOD Level** in the **Actor** component.

**Example**

![Actor LOD Preview](image)

**Notes**

- Lumberyard supports only one material group for each actor.
- Author the material definition (.mtl) file with all the actor LOD submaterials inside the same .mtl file.
- If you author in Maya, you can assign a different shader for each LOD mesh or use the same shader for all the meshes.
Adding the Simple LOD Distance Component

To enable rendering of levels of detail in Lumberyard, you must add the Simple LOD Distance component to your level. The Simple LOD Distance component performs a simple LOD distance check. The LOD distance is the distance that the current level of detail must reach before it changes to the next LOD. Each distance must be greater than the previous distance.

To add the Simple LOD Distance component to your level

1. In Lumberyard Editor, choose Tools, Entity Inspector.
2. In Entity Inspector, click Add Component.
3. In the Animation section, select the Simple LOD Distance component.
4. Specify an LOD distance or use the default.
5. In the viewport, zoom out. Notice that the actor mesh changes for each level of detail when the specified LOD distance is reached.

Adding particle effects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard includes an advanced particle effects system that you can use to simulate explosions, fire, smoke, sparks, water spray, fog, snow, rain, and other effects. Use the Particle Editor to create and manage particle effects in your game. You can place particle emitters in your level, link them to an object, set up a material to define a custom effect, and control these effects from Script Canvas and the Track View.

Lumberyard uses two shaders for rendering particles:

- Particles Shader (p. 1704) – Render particle effects that are affected by light. These effects can cast shadows and cause reflections.
- ParticleImposter Shader (p. 1704) – Render mesh particle effects that are not affected by light. These effects do not cast shadows or cause reflections.

Topics

- Using the Particle Editor (p. 1504)
- Particle Effects Best Practices (p. 1576)
- Advanced Particle Techniques (p. 1576)
- Particle Debugging with Console Variables (p. 1578)

Using the Particle Editor

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.
Use the **Particle Editor** to create, edit, preview, and save particle libraries and emitters that are used with entities in your levels.

**To open the Particle Editor**

- In Lumberyard Editor, choose **Tools, Particle Editor**. You can also click the particle editor icon in the Lumberyard Editor toolbar.

The **Particle Editor** includes the following UI elements:

- **Libraries** panel – Lists the particle art assets. You can view and interact with multiple libraries simultaneously.

- **Preview** panel – Displays the selected, active particle effect. The preview camera automatically positions to capture the entire particle. Use the W, A, S, and D keys and mouse controls to pan, zoom, and rotate the camera.

- **Attributes** panel – Lists the properties for the selected particle.
Using the Particle Editor

• **Level of Detail** panel – Displays level of detail (LOD) information for added particles. For more information, see Managing Particle Level of Detail (LOD) (p. 1570).

**Adding a Particle Component**

**To add a particle component to your level**

• Do one of the following:
  • Drag a particle emitter from the Particle Editor library and drop it into the Lumberyard Editor viewport.
  • Drag a particle effect asset from the Asset Browser into your scene. Choose the emitter that you want to use from the Entity Inspector properties. For more information, see Entity Inspector (p. 475).
  • Create a Particle component entity and assign the particle effect with the Particle effect library parameter. For more information, see the Particle (p. 702) component and Adding Components to an Entity (p. 479).

**Customizing the Particle Editor UI**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Particle Editor has a customizable interface so you can set up your workspace in different layouts. All panels are moveable. You can undock panels to become floating windows, or you can dock panels in new locations to rearrange the look and feel. Save your custom layouts to access later or to share with others.

You can customize the Particle Editor in the following ways:

- **Floating panels**
  Drag the panel title bar to separate the panel from the editor and make it a floating window.

- **Docking panels**
  Dock panels on the edges of the window or anywhere an orange highlight appears. To dock a floating panel, drag the panel title bar into the Particle Editor window.

- **Tabbing panels**
  You can dock a panel inside another panel to create a tabbed view. Toggle the tabs to display one panel and hide the other. This option minimizes the number of panels that are visible at a time.

- **Showing or hiding panels**
  Customize which panels are visible by clicking View and choosing a panel to show or hide.

- **Resetting the layout**
  To reset the Particle Editor layout, click View, Reset to Default Layout. This positions the Libraries panel on the top left, the Preview panel on the middle left, the Level of detail panel on the bottom left, and the Attributes panel on the right.

- **Exporting a layout**
  You can export and share custom layouts. After you create a layout, click View, Export layout. Navigate to the location where you want to export the layout file.
Importing a layout

To import custom layouts, click View, Import layout. Locate and select the layout file.

Managing Particle Libraries

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Particle libraries are .xml assets that contain the data for all effects in the library. The .xml files are located in the \game_project_name\libs\particles directory.

Use the Particle Editor to add and manage particle libraries. You can rename library assets by duplicating and renaming a library in the Particle Editor. Do not rename the base .xml file; doing so can negatively affect the entities in your levels.

Multiple selection

Press Ctrl or Shift to select multiple emitters. The emitters can be from different libraries. You can do any of the following:

- Copy – Copies the selected item. If you copy multiple items, they become children of the item that you paste them on.
- Delete – Deletes all selected emitters.
- Group – Groups the selected items that share the same parent. Select the emitters that you want to group and press Ctrl+G. Alternatively, you can right-click the selected emitters and choose Group.

If you use hot keys while multiple items are selected, the hot keys apply to all selected items.

Drag and drop

Add emitters from any of the libraries into a specific library. To do this, drag and drop the emitters onto the library name. You can also drag emitters from the library to a new parent in the same library.

Search

Type queries into the Libraries panel search box to instantly view results. Click the arrow icon on the left to display previous search results.

Level library (Deprecated)

The level library is no longer updated. You can import particle data stored in level files that were created in Lumberyard 1.8 and earlier. To do so, open a level and, in the Particle Editor, choose File, Import Level Library. This imports the data to a project particle library in the \game_project_name\libs\particles directory.

We recommended that you update all entities that reference the level library emitters to use this newly created library.

Topics

- Adding Particle Libraries (p. 1508)
- Importing Particle Libraries (p. 1508)
- Saving Particle Libraries (p. 1508)
- Using Particle Libraries (p. 1509)
Adding Particle Libraries

Particle effect data is stored in an XML-based library file.

To add a particle library

1. In the Particle Editor, do one of the following:
   - Choose Create new library.
   - Choose File, Add library.
   - Choose the drop-down arrow in the Libraries panel, and choose Add library.
   - Choose the icon to the right of the search bar.

2. In Libraries, where the default name is highlighted, enter a name for the library.
3. Choose Add Particle or Add Folder and then enter a name for the new particle or folder.

Importing Particle Libraries

Particle effect data is stored in an XML-based library file. You can import a particle library for your game.

To import a particle library

1. In the Particle Editor, choose File, Import.
2. In the Pick Particles dialog box, select a library to load. Choose OK. You can also choose the drop-down arrow to access the menu.

Saving Particle Libraries

You can save your particle library in the Particle Editor.

To save a particle library

- In the Particle Editor, right-click the library name and choose Save. You can also press Ctrl+S to save all libraries that are loaded in the editor.
Your library is now saved to the `\game_project_name\libs\particles` directory. You can nest libraries in any hierarchy in the `\libs\particles` directory.

**Using Particle Libraries**

The **Particle Editor** provides a context menu with the following options for you to manage your particle libraries. Right-click a library name to access the context menu.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add New</td>
<td><strong>Add Particle</strong> – Adds a new emitter to the library. The default keyboard shortcut is <strong>Ctrl+N</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Add Folder</strong> – Adds a new folder to the library. The default keyboard shortcut is <strong>Ctrl+Alt+N</strong>.</td>
</tr>
<tr>
<td>Save</td>
<td>Saves changes to the selected library. Libraries are saved in the <code>\game_project_name\libs\particles</code> directory.</td>
</tr>
<tr>
<td>Duplicate</td>
<td>Duplicates and renames the library.</td>
</tr>
<tr>
<td>Disable/Enable All</td>
<td>Disables or enables all items in the library.</td>
</tr>
<tr>
<td>Expand/Collapse All</td>
<td>Expands or collapses all branches in the library. You can click a library name to collapse or expand the entire library. The contents do not lose their collapsed or expanded state when you do so.</td>
</tr>
<tr>
<td>Remove</td>
<td>Removes the library from the library list. The library list is still available on disk.</td>
</tr>
<tr>
<td>Reload</td>
<td>Reloads the library.</td>
</tr>
</tbody>
</table>
You can access the following toolbar menu items and buttons in the **Particle Editor** and **Libraries** panel.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Add Particle</strong></td>
<td>Adds a particle effect. By default, the particle effect is a child of the selected particle, folder, or library. Set the particle name in the <strong>New Particle Name</strong> window.</td>
</tr>
<tr>
<td><strong>Add Folder</strong></td>
<td>Adds a directory in the library so you can organize your particle effects.</td>
</tr>
<tr>
<td><strong>Add library</strong></td>
<td>Adds a particle library.</td>
</tr>
<tr>
<td><strong>Import</strong></td>
<td>Opens the file browser to import the selected particle libraries.</td>
</tr>
<tr>
<td><strong>Import Level Library</strong></td>
<td>Imports particle data stored in level files that were created in Lumberyard 1.8 or earlier.</td>
</tr>
<tr>
<td><strong>Save All</strong></td>
<td>Saves all modified particle libraries to disk.</td>
</tr>
<tr>
<td><strong>Close</strong></td>
<td>Closes the <strong>Particle Editor</strong>.</td>
</tr>
<tr>
<td><strong>Undo</strong></td>
<td>Clears the last change.</td>
</tr>
<tr>
<td><strong>Redo</strong></td>
<td>Removes the last undo.</td>
</tr>
<tr>
<td><strong>Copy</strong></td>
<td>Copies all of the settings for the selected item to the clipboard.</td>
</tr>
<tr>
<td><strong>Paste</strong></td>
<td>Writes data from the clipboard to the selected item.</td>
</tr>
<tr>
<td><strong>Duplicate</strong></td>
<td>Duplicates the selected particle effect.</td>
</tr>
<tr>
<td><strong>Add LOD</strong></td>
<td>Adds a level of detail (LOD) to the selected emitter.</td>
</tr>
<tr>
<td><strong>Rename</strong></td>
<td>Renames the selected item.</td>
</tr>
<tr>
<td><strong>Delete</strong></td>
<td>Deletes the selected item.</td>
</tr>
<tr>
<td><strong>Reset to default</strong></td>
<td>Resets all properties and parameters for the selected item to the default values and states.</td>
</tr>
<tr>
<td><strong>Edit Hotkeys</strong></td>
<td>Opens the <strong>HotKey Configuration</strong> window for you to edit keyboard shortcuts (hotkeys).</td>
</tr>
</tbody>
</table>

### Using the Preview Panel

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the **Preview** panel in the **Particle Editor** to view the particle effects.
This panel has the following features:

A. Display content in the viewport
B. Display the main menu
C. Choose which emitter hierarchies to display in the viewport
D. Reset the viewport to default settings
E. Toggle time of day visibility to simulate the approximate time of day
F. Toggle the display of the particles wireframe
G. Play back the timeline
H. Play, pause, and step forward
I. Reset emitter playback
J. Loop playback

You can access the following Preview panel options in the main menu and context menu.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Import Mesh</td>
<td>Imports a game mesh to view.</td>
</tr>
<tr>
<td>Play</td>
<td>Toggles playback.</td>
</tr>
<tr>
<td>Pause</td>
<td>Pauses playback.</td>
</tr>
<tr>
<td>Step forward</td>
<td>Steps forward one frame.</td>
</tr>
<tr>
<td>Play loop</td>
<td>Toggles the playback from once to looping.</td>
</tr>
<tr>
<td>Reset</td>
<td>Resets the playback to the beginning.</td>
</tr>
<tr>
<td>Reset camera position</td>
<td>Resets the preview camera to the default position.</td>

</table>

**Particles Attributes Reference**

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In the **Particle Editor**, you can modify how emitters and particles look and behave. You can find all available parameters in the Attributes pane. Except for a parameter's base value, most numeric parameters allow random variation over a particle or emitter lifetime.

Some parameters have additional settings:

- **Random** – Specifies how much a particle's parameter value deviates from the default value of 0 (no variation).
- **Strength Over Emitter Life** – Controls the alpha strength over the lifetime of the particle. This parameter works with finite particles only. This parameter has no effect if set to continuous.
- **Strength Over Particle Life** – Controls the alpha strength over the lifetime of an individual particle. For example, you can use this parameter to make a smoke particle fade to nothing once its lifetime has finished. The particle fades out earlier or later depending on where you reduce the value to zero.

**Topics**

- Using the Curve Editor in the Particle Editor (p. 1514)
Using the Particle Editor

- Advanced Attribute (p. 1514)
- Audio Attribute (p. 1516)

- Rotation Attribute (p. 1540)
- Size Attribute (p. 1541)
- Visibility Attribute (p. 1542)

Using the Curve Editor in the Particle Editor

Use the Curve Editor to edit the attribute values over the emitter and particle lifetimes. Strength Over Emitter Life is active only if you have an emitter lifetime that is greater than zero.

To edit the curves

1. In the Curve Editor, double-click along the curve timeline to add a key.
2. Click and drag the keyframe to the preferred value and shape.

Advanced Attribute

In the Advanced attribute, specify advanced appearance and optimization settings.
### Advanced Attribute Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Force Generation</td>
<td>(CPU only) Adds a force that is generated by the emitter.</td>
</tr>
<tr>
<td></td>
<td>- <strong>None</strong> – Does not add a force.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Wind</strong> – Creates a physical wind force, approximately following the velocity, direction, volume, and timing of the emitter's particles. This wind affects all particles and objects in its region, except particles in the emitter group. Setting the emitter's <strong>Speed</strong> to a negative value creates a wind force in the opposite direction. You can use this to create a vacuum force.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Gravity</strong> – Creates a physical gravity force similar to wind, but creates a gravitational acceleration force instead of wind velocity.</td>
</tr>
<tr>
<td></td>
<td>Default value: <strong>None</strong></td>
</tr>
<tr>
<td>Fill Rate Cost</td>
<td>(CPU only) Multiplies the emitter's contribution to the total fill rate. This affects automatic culling of large particles when the global limit is reached. Set this to a value greater than 1 if the effect is relatively expensive or unimportant. Set this to a value less than or equal to 0 if the effect is important. You should not experience automatic culling.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td>Heat Scale</td>
<td>(CPU only) Multiplies thermal vision.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 to 4</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td>Sort Quality</td>
<td>(CPU only) Specifies more accurate sorting of new particles in the emitter's list. To avoid the popping that results from changing the render particle order, particles are never re-sorted after emission. Instead they are sorted only when emitted, based on the main camera's position.</td>
</tr>
</tbody>
</table>
Using the Particle Editor

<table>

<td>Stop Trigger</td>
<td>Selects the stop trigger sound asset to play with the emitter.</td>
</tr>
<tr>
<td>Sound FXParam</td>
<td>Applies the modulate value to the sound. The effect depends on how you define the particlefx parameter for the individual sound. Depending on the sound, this value might affect volume, pitch, or other attributes. You can set a Random value and Strength Over Emitter Lifetime curve. Valid values: 0+ Default value: 1</td>
</tr>
</tbody>
</table>
| Sound Control Time    | • **EmitterLifeTime** – Plays for the length of the emitter's lifetime.  
• **EmitterExtendedLifeTime** – Plays for the length of the emitter's lifetime plus all particles' lifetimes (until all particles die).  
• **EmitterPulsePeriod** – Plays for the length of the pulse period. |

Collision Attribute

In the **Collision** attribute, specify how to control the particle's physical setup.
## Using the Particle Editor

### CPU Collision Attribute Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Physics Type</strong></td>
<td>Specifies how the particle interacts physically.</td>
</tr>
<tr>
<td></td>
<td>- <strong>None</strong> – No collisions or other physics. This setting is used by default.</td>
</tr>
<tr>
<td></td>
<td>- <strong>SimpleCollision</strong> – Collides the particle with the static environment using simple physics. This is the simplest mode.</td>
</tr>
<tr>
<td></td>
<td>- <strong>SimplePhysics (Geometry particles)</strong> – Creates a particle in the physics system and collides using a spherical particle model. Use <strong>Surface Type</strong> to set the bounciness.</td>
</tr>
<tr>
<td></td>
<td>- <strong>RigidBody (Geometry particles)</strong> – Creates a particle in the physics system and collides using the full collision mesh of the assigned geometry. This is the most expensive mode. Use <strong>Surface Type</strong> to set the bounciness.</td>
</tr>
<tr>
<td><strong>Collide Terrain</strong></td>
<td>Includes terrain in particle collisions.</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
</tr>
<tr>
<td><strong>Collide Static Objects</strong></td>
<td>Includes non-terrain, static objects in particle collisions. This is expensive.</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
</tr>
<tr>
<td><strong>Collide Dynamic Objects</strong></td>
<td>Includes non-terrain, dynamic objects in particle collisions. This is expensive.</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>

</tbody>
</table>
### Using the Particle Editor

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>On Collide</strong></td>
<td>Upon impact with the static environment, the particle dies.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Die</strong> – The particle dies upon colliding with an object.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Bounce</strong> – If you enable <strong>Collide Terrain</strong>, <strong>Collide Static Objects</strong>, or <strong>Collide Dynamic Objects</strong>, the particle bounces off the respective type. If none of these are enabled, the selected particle ignores the object that it collides with and passes through. This is useful with <strong>Spawn Indirection – Parent Collide</strong>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Stop</strong> – The particle stops when it collides with an object.</td>
</tr>
<tr>
<td><strong>Max Collision Events</strong></td>
<td>Limits the number of collisions that the particle can have in its physics simulation. This affects only particles that have <strong>Physics Type</strong> set to <strong>Rigid Body</strong>.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 to 255</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td><strong>Bounciness</strong></td>
<td>Controls the elasticity for collision response. This affects only particles that have <strong>Physics Type</strong> set to <strong>Simple Collision</strong>. You can override this feature by setting <strong>Surface Type</strong>. You can also use a special value of −1 to have the particle die on first collision.</td>
</tr>
<tr>
<td></td>
<td>Valid values: any</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td><strong>Collision Fraction</strong></td>
<td>Determines the fraction of emitted particles that perform collisions.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 to 1</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td><strong>Collision Cutoff Distance</strong></td>
<td>Specifies the maximum distance from the camera at which collisions are performed. A value of 0 means infinite.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td><strong>Surface Type</strong></td>
<td>Selects from a variety of surface material types for the collision behavior. If set, <strong>Surface Type</strong> overrides <strong>Bounciness</strong> and <strong>Dynamic Friction</strong>.</td>
</tr>
<tr>
<td></td>
<td>Default value: none</td>
</tr>
<tr>
<td><strong>Dynamic Friction</strong></td>
<td>The coefficient of dynamic friction. If set, <strong>Surface Type</strong> overrides <strong>Dynamic Friction</strong>. This affects only particles that have <strong>Physics Type</strong> set to <strong>Simple Collision</strong>.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>

</tbody>
</table>

Valid values: any
Default value: 0

**Comment Attribute**

Save or edit comments about an emitter in the **Comment** text box.

**Configuration Attribute**

In the **Configuration** attribute, specify the minimum and maximum specs for your particle emitters.
Configuration Attribute Parameters for CPU Emitters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config Min</td>
<td>Specifies the minimum system configuration level for the effect. If the configuration is lower than the set value, the item will not appear. Choose from Low, Medium, High, or VeryHigh. Default value: Low</td>
</tr>
<tr>
<td>Config Max</td>
<td>Specifies the maximum system configuration level for the effect. If the configuration is higher than the set value, the item will not appear. Choose from Low, Medium, High, or VeryHigh. Default value: VeryHigh</td>
</tr>
<tr>
<td>Platforms</td>
<td>Specifies which platform to use with the effect.</td>
</tr>
<tr>
<td></td>
<td>• PCDX11</td>
</tr>
<tr>
<td></td>
<td>• iOS</td>
</tr>
<tr>
<td></td>
<td>• Android</td>
</tr>
<tr>
<td></td>
<td>• macOS GL</td>
</tr>
<tr>
<td></td>
<td>• macOS Metal</td>
</tr>
<tr>
<td></td>
<td>Default value: all selected (true)</td>
</tr>
</tbody>
</table>

**Emitter Attribute**

In the Emitter attribute, specify how to control the location and spawning attributes of the particle and emitter shape. The parameters are updated based on the type that you select.
Emitter Attribute Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Particle Type</td>
<td>Specifies whether the emitter is a CPU or GPU type.</td>
</tr>
<tr>
<td>Emitter Shape Type</td>
<td>Specifies the emitter shape type.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Angle</strong> – Standard emitter type based on angle parameters. This is the default value.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Point</strong> – Spherical distribution emitter.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Sphere</strong> – Sphere shape emitter with particles controlled along the sphere's circumference coordinates.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Circle</strong> – Circle shape emitter with particles controlled along the circumference and vertical coordinates.</td>
</tr>
</tbody>
</table>
### Name
<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Box</strong> – Box shape emitter with particles controlled along the planes of the box.</td>
</tr>
<tr>
<td><strong>Trail</strong> – Emitter to create trail type effects.</td>
</tr>
<tr>
<td><strong>Beam</strong> – Emitter to create beam type effects.</td>
</tr>
</tbody>
</table>

**Note**
If you change the **Emitter Shape Type**, the attributes will reset to the default settings for the selected emitter. In the confirmation message, you can select **Do not prompt again**. This prompt is reset when you select **Reset to default layout**.

### Relative Particle Movement

Determines the particle motion in the emitter's space. The following is an example of particles that are emitted upward from an emitter:

- **No** – The emitted particles stay in world space and fall behind as the emitter moves away, for example, like smoke from the chimney of a train.
- **Yes** – The emitted particles stay relative to the emitter's local space and won't fall behind as the emitter is moved. An example is a smoke column going straight up from the chimney and staying vertical with the emitter. This excludes tail particles.
- **Yes with Tail** – The emitted particles stay relative to the emitter's local space, including any associated tail particles.

Default value: **No**
### Parameter Inheritance

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter Inheritance</td>
<td>Specifies the source for default (starting) effect parameters.</td>
</tr>
<tr>
<td>• <strong>Standard</strong> (default) – Uses the values set in DefaultParticleEmitters.xml.</td>
<td></td>
</tr>
<tr>
<td>• <strong>System</strong> (deprecated) – Reads the System.Default.xml file to use as defaults for the angle emitter. If this effect does not exist, you can use standard defaults. You can generate the System.Default.xml file by adding a library named System and an emitter named default. Save the library to your <code>&lt;project&gt;/libs/particles</code> directory.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Parent</strong> – Uses the parent particle effect for defaults. This is useful when creating a parent effect with one set of parameters and a variety of subeffects that alter some of the parameters for variation. Subeffects can spawn on their own. Edit the parent effect to update the default values of all subeffects.</td>
<td></td>
</tr>
</tbody>
</table>

The selected source has the following consequences:

• When you create a new effect, default parameters are set from the following file:

  \`lumberyard_version\dev\Editor\Plugins\ParticleEditorPlugin\defaults\DefaultParticleEmitters.xml\`.

• Changing the inheritance source does not change any other parameters. However, different parameters may be highlighted if their defaults have changed.

To reset parameters to the default values that are located in the DefaultParticleEmitters.xml file, right-click the parameter and choose **Reset to default**. You can modify the default values for the project using the same file.

When you save effects to .xml libraries, only non-default values are saved. When you load effects from the .xml libraries, the current default values for the effect's inheritance are used as a base.

When you edit a parent effect's parameters, the non-edited parameters of all children (and descendants) that have **Parent** selected are instantly updated.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Spawn Indirection</strong></td>
<td>This parameter has the following values:</td>
</tr>
<tr>
<td></td>
<td>• Direct – Spawns without relying on the parent's input for timing. This is the default value.</td>
</tr>
<tr>
<td></td>
<td>• ParentStart – Spawns once the parent has spawned.</td>
</tr>
<tr>
<td></td>
<td>• ParentCollide – Spawns a particle with this setting when the parent particle has collided with an object.</td>
</tr>
<tr>
<td></td>
<td>• ParentDeath – Spawns a particle with this setting when the parent particle has lived out its lifetime.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>This parameter is supported only within the same CPU or GPU particle type.</td>
</tr>
<tr>
<td><strong>Attach Type</strong></td>
<td>Specifies the emission location when the parent emitter has geometry.</td>
</tr>
<tr>
<td></td>
<td>• None – Particles ignore geometry and emit from the emitter center as normal.</td>
</tr>
<tr>
<td></td>
<td>• Bounding Box – Particles emit from the object's bounding box.</td>
</tr>
<tr>
<td></td>
<td>• Physics – Particles emit from the geometry of the attached physics object (mesh or simple primitive).</td>
</tr>
<tr>
<td></td>
<td>• Render – Particles emit from the full mesh of the render object (static or animated mesh). This is generally more CPU-intensive than emitting from physics.</td>
</tr>
<tr>
<td>Default value:</td>
<td><strong>None</strong></td>
</tr>
<tr>
<td><strong>Attach Form</strong></td>
<td>Specifies the elements of the geometry from which particles emit.</td>
</tr>
<tr>
<td></td>
<td>• None – Not active.</td>
</tr>
<tr>
<td></td>
<td>• Vertices – Emits randomly from the vertices of the geometry. This is the most efficient form of mesh emission.</td>
</tr>
<tr>
<td></td>
<td>• Edges – Emits randomly from the edges of the geometry. This is useful for effects on breaking element pieces.</td>
</tr>
<tr>
<td></td>
<td>• Surface – Emits randomly from the surfaces (faces) of the geometry.</td>
</tr>
<tr>
<td></td>
<td>• Volume – Emits randomly inside the volume of the geometry.</td>
</tr>
<tr>
<td>Default value:</td>
<td><strong>Vertices</strong></td>
</tr>
<tr>
<td><strong>Count</strong></td>
<td>Specifies the total number of particles that are active at a given time and determines the emission rate (\textit{Count/Particle Lifetime}). You can set a Random value and the Strength Over Emitter Life curve.</td>
</tr>
<tr>
<td>Valid values:</td>
<td>(0^+)</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **Maintain Density**| Increases the emission rate (and particle count) when an emitter moves in order to maintain the same spatial density as when motionless. You can scale the increase from 0 to 1.  
  • **Reduce Alpha** – When **Maintain Density** is active, this reduces particle alpha in order to maintain the same overall emitter alpha.  
  Valid values: 0+                                                                 |
| **Continuous**      | If false, emits all particles at once and then dies. If true, emits particles gradually over the emitter lifetime. If true and **Emitter Lifetime** = 0, emits particles gradually at a rate of **Count/Particle Lifetime** per second, indefinitely.  
  Default value: false                                                                 |
| **Spawn Delay**     | Delays the start of the emitter for the specified time. This is useful to delay subeffects relative to the overall emitter creation time. Can set a Random value.  
  Valid values: 0+  
  Default value: 0                                                                 |
| **Emitter Lifetime**| If **Continuous** = true, specifies the lifetime of the emitter. Emitter lifetime does not apply to noncontinuous effects, which always disappear as soon as they have emitted all of their particles. You can set a Random value.  
  Valid values: 0+  
  Default value: 0 (infinite lifetime)                                                                 |
| **Pulse Period**    | If greater than 0 and **Continuous** = false, restarts the emitter repeatedly at this interval. You can set a Random value.  
  Valid values: any  
  Default value: 0                                                                 |
| **Orient to Velocity** | Forces the particle x-axis to align to the velocity direction. You can use Rotation parameters to rotate the particle further.  
  Default value: false                                                                 |
| **Position Offset** | XYZ values define the spawning position away from the emitter itself in emitter space.  
  Valid values: any  
  Default values: 0, 0, 0                                                                 |
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| Random Offset   | XYZ values define the range of a random spawning box in both directions, away from the position offset.  
                  | Valid values: any                                                           
                  | Default values: 0, 0, 0                                                     |
| Offset Roundness | Specifies the fraction of spawning volume corners to round.                  
                  | Valid values: 0 (box shape) to 1 (ellipsoid shape)                          
                  | Default value: 0                                                           |
| Offset Inner Fraction | Specifies the ratio of inner to outer spawning volume.                    
                  | Valid values: 0 (spawn within entire volume) to 1 (spawn only at surface)   
                  | Default value: 0                                                           |

**Lighting Attribute**

In the **Lighting** attribute, specify how to control the particle lighting.

![Lighting Attribute](image)

**Lighting Attribute Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| Light Source| (CPU only) Causes each particle to create a deferred light, where color is equal to the **Color** value.  
                  | • **Affects This Area Only** – Use with clip volumes. When enabled, the particle lights do not exceed the volume boundary.  
                  | • **Radius** – Radius of the light. You can set a **Random** value and **Strength Over Emitter Lifetime** and **Strength Over Particle Lifetime** curves.  
                  | • **Intensity** – Intensity of the light. You can set a **Random** value and **Strength Over Emitter Lifetime** and **Strength Over Particle Lifetime** curves. |
### Using the Particle Editor

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diffuse Lighting</td>
<td>Multiplies the particle color for dynamic (diffuse) lighting.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: false, 0, 0</td>
</tr>
<tr>
<td>Diffuse Backlighting</td>
<td>Specifies the fraction of diffuse lighting that is applied to unlit particle directions.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 (standard diffuse and normals facing the light are lit the most) to 1 (omnidirectional diffuse and light affects all normals equally).</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td>Emissive Lighting</td>
<td>Multiplies the particle color for constantly emitting light. You can add a value to make a particle appear as if it's glowing.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td>Environment Probe Lighting</td>
<td>(CPU only) Controls the amount of diffuse lighting that is contributed from environment probes.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 to 1</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td>Receive Shadows</td>
<td>(CPU only) Allows shadows to cast on the particles.</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
</tr>
<tr>
<td>Cast Shadows</td>
<td>(GPU and geometry particles only) Allows particles to cast shadows.</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
</tr>
<tr>
<td>Not Affected by Fog</td>
<td>(CPU only) Causes particles to ignore scene fog.</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
</tr>
</tbody>
</table>

**Note**
When there is a single light source, some or all particles can appear unlit (black). To address this:

1. Add an environment probe to the scene to create indirect lighting. For more information, see the [Environment Probe (p. 587)](environmentprobe) component.
2. Specify a value for the **Environment Probe Lighting** parameter to enable environment probe lighting on the particle system. For example, a value of 0.5 applies light from the environment probe at half intensity.

### Movement Attribute

In the **Movement** attribute, specify how to control the particle's movement.
For the Air Resistance, Gravity Scale, Turbulence 3D Speed, Turbulence Size, and Turbulence Speed parameters, you can set a Random value and Strength Over Emitter Lifetime and Strength Over Particle Lifetime curves.

Movement Attribute Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Min visible segment length</td>
<td>Trail Emitter (CPU) (p. 1560) only) Tail particles are visible only when they have moved the specified distance.</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
</tr>
<tr>
<td>Min visible distance</td>
<td>Trail Emitter (CPU) (p. 1560) only) Specifies the minimum distance between the start and end of a trail segment. Segments that are smaller than this value become transparent.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td>Speed</td>
<td>Specifies the initial speed of particles. You can set a Random value and Strength Over Emitter Lifetime curve.</td>
</tr>
<tr>
<td></td>
<td>Valid values: any</td>
</tr>
<tr>
<td></td>
<td>Default value: 5</td>
</tr>
<tr>
<td>Acceleration</td>
<td>XYZ values define the constant acceleration that is applied to particles in world space.</td>
</tr>
<tr>
<td></td>
<td>Valid values: any</td>

</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>Default value: 0, 0, 0</td>
<td></td>
</tr>
<tr>
<td>Inherit Velocity</td>
<td>Specifies the fraction of initial velocity that is inherited from the particle's parent. For indirect particles, the parent particle's velocity is inherited. For direct particles, the emitter's velocity is inherited.</td>
</tr>
<tr>
<td>Valid values: any</td>
<td>Default value: 0</td>
</tr>
<tr>
<td>Bind Emitter to Camera</td>
<td>(CPU only) Forces the emitter to relocate to the main camera's position. This is useful (with Space Loop) for making a rain or snow effect, which the player cannot pass.</td>
</tr>
<tr>
<td>Default value: false</td>
<td></td>
</tr>
<tr>
<td>Space Loop</td>
<td>(CPU only) Loops particles within a region around the camera, as defined by Camera Min/Max Distance (under the Visibility tab). This is useful for making a rain or snow effect, which has an effective infinite spawning area.</td>
</tr>
<tr>
<td>Default value: false</td>
<td></td>
</tr>
<tr>
<td>Air Resistance</td>
<td>Particles behave as if encountering resistance and slow down over time.</td>
</tr>
<tr>
<td>Valid values: 0+</td>
<td>Default value: 0</td>
</tr>
<tr>
<td>Gravity Scale</td>
<td>Applies multiple of world gravity to particles. Set most physicalized particles to 1 (use air resistance to provide drag). Set the parameter to a negative value for buoyant particles such as smoke.</td>
</tr>
<tr>
<td>Valid values: any</td>
<td>Default value: 0, 0, 0</td>
</tr>
<tr>
<td>Turbulence 3D Speed</td>
<td>Adds a 3D, random, turbulent movement to the particle, with the specified average speed.</td>
</tr>
<tr>
<td>Valid values: 0+</td>
<td>Default value: 0                                                                ----------------------------------------------------------------</td>
</tr>
<tr>
<td>Turbulence Size</td>
<td>Adds a spiral movement to the particle, with the specified radius. Set the axis of the spiral from the particle's velocity.</td>
</tr>
<tr>

<td>Default value: 0                                                                ----------------------------------------------------------------</td>
</tr>
</tbody>
</table>
### Name | Description
--- | ---
**Target Attraction** | Specifies how particles behave if the emitter is attached to a target. By default, all particles are attracted to any target to which the emitter is linked. These parameters customize that behavior.

- **Target**
  - **External** – Particles are attracted to a target entity, if the emitter is linked to one (default).
  - **OwnEmitter** – Particles are attracted to their emitter’s origin.
  - **Ignore** – Particles ignore any external attractor.
- **Extend Speed** – Particles speed up to reach the target in their lifetime. Otherwise, they move at a real-world, natural speed toward the target and may not reach it.
- **Shrink** – Particles shrink as they approach the target.
- **Orbit** – Particles orbit around the target when reached. Otherwise, they disappear into the target.
- **Radius** – Distance from the target that particles orbit around or disappear. You can set a Random value and **Strength Over Emitter Lifetime** and **Strength Over Particle Lifetime** curves.

Valid values: any
Default value: 0

**Particles Attribute**

In the **Particles** attribute, specify how to control the particle’s basic appearance.

**Note**
We recommend that you set up the **Particles** attribute first because it includes the **Texture** file, which is used for most particles.
## Particles Attribute Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Particle Life Time</strong></td>
<td>Specifies the lifetime of individual particles. After an emitter's lifetime has expired, spawned particles live out their own lifetime. Valid values: 0+</td>
</tr>
<tr>
<td><strong>Remain While Visible</strong></td>
<td>Indicates that particles do not die until the entire emitter is out of view. This is typically used for emitters that move through space quickly and die to avoid particle pooling and other unintended consequences. Default value: false</td>
</tr>
<tr>
<td><strong>Facing</strong></td>
<td>Determines how the sprite or geometry is oriented in space. You can further modify texture orientation using the following rotational parameters.</td>
</tr>
</tbody>
</table>
## Name

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camera (default)</td>
<td>Faces the viewer, with texture X and Y aligned with screen X and Y. In this mode only, particles are assumed to represent spherical objects and are lit accordingly. In all other modes, particles are lit as flat polygons.</td>
</tr>
<tr>
<td>CameraX</td>
<td>Rotates about the local y-axis only and faces the camera as much as possible.</td>
</tr>
<tr>
<td>Free</td>
<td>Rotates freely in 3D. Be sure to give it some rotation. The default orientation is equal to the emitter's orientation.</td>
</tr>
<tr>
<td>Horizontal</td>
<td>Faces horizontal to the emitter's z-axis.</td>
</tr>
<tr>
<td>Velocity</td>
<td>Faces the direction of movement.</td>
</tr>
<tr>
<td>Water</td>
<td>Faces upward and is moved and aligned to the nearest water plane.</td>
</tr>
<tr>
<td>Terrain</td>
<td>Faces upward and is moved and aligned to the nearest terrain location.</td>
</tr>
<tr>
<td>Decal</td>
<td>Renders the particle as a deferred decal, projected onto the nearest surface along the entity's y-axis. The Thickness parameter under Collision controls the projection depth. This parameter works only with materials and does not work with textures.</td>
</tr>
<tr>
<td>Shape</td>
<td>Faces the nearest edge of the emitter shape boundary. You can use this parameter with the following shape types: Circle, Sphere, and Box Emitter.</td>
</tr>
</tbody>
</table>

Default value: Camera

## Blend Type

Applies to 2D particles only and determines how the sprite blends with the background.

- **Alpha Based** – Final color = Particle color * Particle alpha + Background color * (1 – Particle alpha)
- **Additive** – Final color = Particle color + Background color
- **Multiplicative** – Final color = Particle color * 2 * Background color
- **Opaque** – Final color = Particle color

Default value: Alpha Based

## Material

Opens the Asset Browser for you to assign a material for the 2D sprite particles. Different shaders are uniquely affected by the lighting and environment.

Default value: Empty

## Sorting Method

(GPU only) Enables intra-GPU emitter sorting.

- **None** – No sorting
- **Bitonic** – Sorts using a bitonic sorting algorithm
- **OddEven** – Sorts using an odd even merge sorting

Default value: None
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sorting Convergence</td>
<td>(GPU only) Sorts convergence per frame for an odd to even merge sort.</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td>Texture</td>
<td>Opens the Asset Browser to specify a texture for the 2D sprite particles.</td>
</tr>
<tr>
<td></td>
<td>When you pause on the input box, a preview of the texture appears.</td>
</tr>
<tr>
<td></td>
<td>Default value: /Editor/Plugins/ParticleEditorPlugin/defaultparticle.dds</td>
</tr>
<tr>
<td>Normal Map</td>
<td>(GPU only) Opens the Asset Browser to specify a normal map for the 2D GPU</td>
</tr>
<tr>
<td></td>
<td>particles.</td>
</tr>
<tr>
<td>Glow Map</td>
<td>(GPU only) Opens the Asset Browser to specify a glow map for the 2D GPU</td>
</tr>
<tr>
<td></td>
<td>particles.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>

<td>You must specify a positive value for the Emissive Lighting (p. 1529)</td>
</tr>
<tr>
<td></td>
<td>parameter for the glow map to be visible.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>---------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Texture Tiling</strong></td>
<td>Splits the texture into tiles for variation and animation.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Tiles X, Y</strong> – The number of tiles that the texture is split into.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 1 to 256</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td></td>
<td>• <strong>First Tile</strong> – The first of the range of tiles used by the particle.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 to 255</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td></td>
<td>• <strong>Variant Count</strong> – The number of consecutive tiles in the texture from which the particle randomly selects.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 1 to 256</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td></td>
<td>• <strong>Anims Frame Count</strong> – The number of tiles that compose an animation sequence. You can use <strong>Variant Count</strong> and <strong>Anim Frames Count</strong> together. For example, if <strong>Variant Count</strong> = 2 and <strong>Anim Frames Count</strong> = 8, the particle randomly chooses between tiles 0 to 7 or 8 to 15, as an animated sequence.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 1 to 256</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td></td>
<td>• <strong>Anim Framerate</strong> – The number of frames per second for the animation. If 0, the animation runs through one sequence in the particle lifetime.</td>

<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td></td>
<td>• <strong>Anim Cycle</strong> – This parameter has the following values.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Once</strong> – Animation plays once and holds on the last frame</td>
</tr>
<tr>
<td></td>
<td>• <strong>Loop</strong> – Animation loops indefinitely</td>
</tr>
<tr>
<td></td>
<td>• <strong>Mirror</strong> – Animation alternates cycling forward and backward indefinitely</td>
</tr>
<tr>
<td></td>
<td>Default value: <strong>Once</strong></td>
</tr>
<tr>
<td></td>
<td>• <strong>Anim Blend</strong> – Renders the particle blended between the two adjacent animation frames. This has a performance impact.</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
</tr>
<tr>
<td></td>
<td>• <strong>Horizontal Flip Chance</strong> – Specifies the fraction of particles that are rendered and mirrored in texture X.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Vertical Flip Chance</strong> – Specifies the fraction of particles that are rendered and mirrored in texture Y.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 to 1</td>

</tr>
</tbody>
</table>
### Using the Particle Editor

#### Name: Alpha clip

*(CPU only)* Customizes how the particle **Alpha** value controls opacity or alpha test values. Each parameter has two values that correspond when particle **Alpha** = 0 and 1. They are interpolated for each particle with its **Alpha** value and used in the shader with the following equation:

\[
\text{FinalOpacity} = \text{saturate} \left( \frac{(\text{TextureAlpha} - \text{SourceMin})}{\text{min}(\text{SourceWidth}, 1 - \text{SourceMin})} \right) \cdot \text{Scale}
\]

- **Scale** – Multiplies the final alpha value. When set to the default value (0, 1), the particle **Alpha** directly scales the final opacity.
  - Valid values: 0+

- **Source Min** – Specifies the minimum source (texture) alpha to render (alpha test); values below the minimum become transparent. When set to the default value (0, 0), there is no alpha test.
  - Valid values: 0+

- **Source Width** – Specifies the feathering range of alpha clipping. When set to the default value (1, 1), texture alpha is fully used. A value of 0 specifies hard clipping. A value of 1 specifies soft clipping.
  - Valid values: 0+

  Default value: 0

  - Default – Alpha controls opacity with no alpha clipping: Scale = (0, 1), Source min = (0, 0), Source width = (1, 1).
  - Hard clipping at texture alpha = C, with no feathering: Scale = (1, 1), Source min = (C, C), Source width = (0, 0).
  - Hard clipping controlled by particle alpha: Scale = (1, 1), Source min = (0, 1), Source width = (0, 0).
  - Feathered clipping with width F, controlled by particle alpha: Scale = (1, 1), Source min = (0, 1), Source width = (F, F).
  - Soft clipping with the test value controlled by particle alpha: Scale = (1, 1), Source min = (0, 1), Source width = (1, 1)
  - Clipping and opacity scale controlled by particle alpha: Scale = (0, 1), Source min = (0, 1), Source width = (1, 1)

#### Tessellation

Enables tessellation, rendering more vertices in the sprite. You must have a minimum of DirectX 11. This parameter is useful when **Receive Shadows** is set, increasing the resolution of shadows. It is also useful when **Tail Length** or **Connection** are set, creating smoother curves in connected particles. This produces more accurate lighting when receiving light from point lights.

Default value: false
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| Soft Particles     | Applies rendering that softens the intersection between sprites and nearby objects to prevent unnatural seams. Use sparingly on particles that need it, such as smoke, because this is slightly more expensive. Use the **Softness** parameter to define the amount of rendering to apply.  
| Default value: false |
| Motion Blur        | (GPU only) Simulates motion blur on GPU particles. Use **Blur Strength** to set the strength of the blur effect. |
| Geometry           | (CPU only) Opens the **Asset Browser** window to select a 3D object to use for the particles.  
| Default value: empty |
| Geometry in Pieces | (CPU only) Emits the geometry in pieces, originating at each piece's location in the asset. This applies only if the **Geometry** asset contains multiple subobjects.  
  - **Whole** – Emits the whole geometry asset as one object.  
  - **Random Pieces** – Emits geometry fragments randomly over the emitter lifetime.  
  - **All Pieces** – Emits geometry pieces in order over the emitter lifetime.  
| Default value: **Whole** |

This parameter requires that you provide specific names for the nodes in the Maya outliner. The following show examples of acceptable node names:

In these examples, the groups and individual nodes have a _group suffix. As a result, the Maya exporter assumes there is no geometry. If you receive a "group has no geometry" error, you can safely ignore it.
<table>
<thead>
<tr>
<th>Name</th>

</table>
Size Attribute

In the **Size** attribute, specify how to control the particle’s size and shape.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Lock Aspect Ratio</strong></td>
<td>Maintains the particle aspect ratio.</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
</tr>
<tr>
<td><strong>Size X, Y, Z</strong></td>
<td>Specifies the world particle size.</td>
</tr>
<tr>
<td></td>
<td>For 2D sprite particles, only X and Y are used.</td>
</tr>
<tr>
<td></td>
<td>For geometry particles, X, Y, and Z are used. For more information, see the Geometry (p. 1539) parameter.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td><strong>Pivot X, Y, Z</strong></td>
<td>Moves the sprite's pivot point.</td>
</tr>
<tr>
<td></td>
<td>For 2D sprite particles, only X and Y are used.</td>
</tr>
<tr>
<td></td>
<td>For geometry particles, X, Y, and Z are used. For more information, see the Geometry (p. 1539) parameter.</td>
</tr>
<tr>
<td></td>
<td>Valid values: −1 to +1</td>
</tr>
<tr>
<td></td>
<td>Default value: 0 (texture center)</td>
</tr>
<tr>
<td><strong>Stretch</strong></td>
<td>Specifies the amount of stretch, in seconds, that is applied to the particle in the direction of travel. This is based on the current velocity and stretches in both directions by default.</td>
</tr>
<tr>
<td></td>
<td><strong>Offset Ratio</strong> – Adjusts the center of stretching. 0 = stretch both directions</td>
</tr>
</tbody>
</table>
### Using the Particle Editor

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td><strong>Tail Length</strong></td>
<td>(CPU only) The length of the particle's tail in seconds. The particle texture is stretched through the tail.</td>
</tr>
<tr>
<td></td>
<td><strong>Tail Steps</strong> – The number of segments for the tail. A higher number produces smoother tail curves for nonlinear, moving particles.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td><strong>Min Pixels</strong></td>
<td>(CPU only) Adds the specified number of pixels to the particle's true size when rendering. This is useful for important effects that should be visible even at a distance.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
</tbody>
</table>

### Visibility Attribute

In the **Visibility** attribute, specify how to control the particle's visibility.

![Visibility Attribute](image)

- **Camera Non Facing Fade**
- **Fade Curve**
- **View Distance Adjust**
- **Camera Min Distance**
- **Camera Max Distance**
- **Camera Distance Offset**
- **Sort Offset**
- **Sort Bounds Scale**
- **Draw Near**
- **Draw On Top**
- **Visible Indoors**
- **Visible Underwater**
## Visibility Attribute Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Camera Non Facing Fade** | When enabled, this parameter adjusts the transparency of each particle based on its angle relative to the camera. You can specify this parameter to fade out particles at sharp angles, which hides the appearance of thin polygons. You can adjust the level of fade according to the angle with the **Fade Curve** tool.  
  Default value: false |
| **View Distance Adjust** | Multiplies the automatically computed fade-out camera distance.  
  Valid values: 0+  
  Default value: 1 |
| **Camera Min/Max Distance** | Determines the camera range that particles render in. A default value of 0 indicates an unlimited range.  
  Valid values: 0+  
  Default value: 0 |
| **Camera Distance Offset** | Offsets the emitter away from the camera.  
  Valid values: any  
  Default value: 0 |
| **Fade Strength Min/Max Distance** | (GPU only) Specifies the distance from the camera at which particles fade.  
  - **Fade Strength Min Distance** – Minimum distance from the camera at which particles fade.  
  - **Fade Strength Max Distance** – Maximum distance from the camera at which particles fade.  
  Default value: 0, 0 |
| **Sort Offset** | Bias the distance used for sorting. You can customize the sort order in an emitter tree. By default, subemitters render in the order they are listed in the effect. A bias of 0.01 or greater overrides that order. You can use larger biases to adjust the sorting order, with respect to other transparent objects in the level.  
  Valid values: any  
  Default value: 0 |
| **Sort Bounds Scale** | Specifies the emitter point for sorting.  
  1 = bounds nearest | 0 = origin | -1 = bounds farthest  
  Valid values: any  
  Default value: 0 |
| **Draw Near** | Renders particles in a near first-person space (with weapons). |

Creating and Managing Particle Emitters

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can create, edit, and manage emitters for particle effects in the Particle Editor. For more information about emitter attributes and parameters displayed in the Attributes panel, see Particles Attributes Reference (p. 1513).

Before you can create or edit emitters, you must first set up a particle library. For more information, see Adding Particle Libraries (p. 1508).

Creating Emitters

Do the following to create an emitter. You must have already created a library.

To create new emitters

1. In Lumberyard Editor, choose Tools, Particle Editor.
2. In the Libraries panel, under your selected library, click Add Particle. Alternatively, right-click the library name and then choose Add New, Add Particle.
3. Enter a name for the emitter and press Enter. Do not use special characters in the name.
4. In the Attributes panel, edit the attributes and parameters as needed.

Editing Emitters

Do the following to edit emitter attributes and parameters.
To edit emitter attributes and parameters

1. In Lumberyard Editor, click Tools, Particle Editor.
2. In the Libraries panel, choose an emitter.
3. In the Attributes panel, adjust the attribute and parameter settings and values to achieve the intended effect.

Duplicating Emitters

Do the following to duplicate an emitter. This will also duplicate any associated child emitters.

To duplicate emitters

1. In Lumberyard Editor, click Tools, Particle Editor.
2. In the Libraries panel, select the emitter that you want to duplicate. Right-click the emitter and choose Duplicate. Alternatively, press Ctrl+D.
3. In the dialog box, enter a name for the emitter and click OK.

Topics
- Creating Child Emitters (p. 1545)
- Organizing Emitters in a Library (p. 1546)
- Reverting Changes to Emitter Attributes (p. 1546)

Creating Child Emitters

To create a child emitter, you first set the parent effect and then attach the child emitter to the parent particles. You can attach multiple child emitters to the parent particle. A particle effect can have any number of child effects (also called subeffects), which you can nest in a library by dragging and dropping where needed.

To create child emitters

1. In Lumberyard Editor, choose Tools, Particle Editor.
2. In the Libraries panel, right-click the emitter for which you want to create a child emitter. Choose Add New, Add Particle.
3. Enter a name for the child emitter and then press Enter.

To assign an existing emitter to be a child

- Drag the emitter on top of another emitter. The selected emitter is nested underneath as a child.

To remove a child emitter from a parent

- Drag the child emitter to the preferred location. Alternatively, you can drag the child emitter to the library name to detach it from its parent and make it appear at the bottom of the emitter stack.

Lumberyard has two types of child effects:

- Regular child effects – These effects behave like separate effects, though they are spawned with and attached to their parent effect. Each child effect has its own independent parameters and lifetime, allowing for an overall effect that consists of several parts.
• **Second-generation child effects** – These effects are attached to individual particles of the parent effect. A separate emitter is spawned for each particle of the parent effect, and those emitters move with their parent particles. This allows you to create more complex effects. You can nest second-generation effects multiple times in order to create third-generation (and greater) effects.

An example of a child effect is attaching an emitter to a parent particle and leaving trailing particles behind. You can achieve this effect using the **Spawn Indirection** attribute.

**Organizing Emitters in a Library**

All particle emitters are listed in the Libraries panel. You can organize and create relationships between your emitters. For example, you can have single emitters or emitters with various child hierarchies. You can also create directories and groups in each library to organize your particle effects. This relationship is displayed in a tree hierarchy in the Libraries panel.

A visual indicator shows you the placement of an emitter based on the position of your cursor. For example, if you place an emitter on another emitter or a folder for grouping, the folder row appears highlighted with a blue stroke.

**Reverting Changes to Emitter Attributes**

Emitters have a list of attributes or property types that are categorized for easier identification. You can reorder and rearrange the categories, including combining categories into a tabbed view.

- To reorder categories, drag and drop the category to the preferred position. An orange highlight appears to indicate a valid docking location.
- To combine categories into tabs, drag a category on another category title bar. If you have not expanded the category, the tabs appear collapsed until you click a category title bar.
- To revert changes made to the Attributes panel layout, click the menu in the title bar and choose **Reset to default**.

By default, emitter parameters are set to the attribute as a common starting point. These default attributes have a white text label. When you change the attribute parameter from the default state, the text label changes from white to orange.

- To revert the last change to the emitter attribute, click **Edit, Undo**. Alternatively, you can press Ctrl+Z.
- To revert all changes to the attributes parameter, right-click the attribute name and choose **Reset to default**.

**Working with Emitter Shape Types**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Particle Editor provides emitter shape types that you can use to achieve a variety of effects, such as using the **Beam** emitter to create fire effects.

**To choose the emitter shape type**

1. In Lumberyard Editor, choose **Tools, Particle Editor**.
2. In the Libraries panel, choose an emitter.
3. In the **Attributes** panel, choose **Emitter**.
4. For **Emitter Shape Type**, choose the shape type. The following emitter shape types are supported:
   - **Angle**
   - **Beam**
   - **Box**
   - **Circle**
   - **Point**
   - **Sphere**
   - **Trail**

Most emitters have CPU and GPU particle types. Each emitter's velocity functions on either world or shape axial coordinates, based on type. To view the shape XYZ coordinates, right-click the **Preview** viewport and choose **Show Emitter Shape**.

**Topics**

- **Angle Emitter (CPU and GPU)** (p. 1547)
- **Beam Emitter (CPU)** (p. 1550)
- **Box Emitter (CPU and GPU)** (p. 1553)
- **Circle Emitter (CPU and GPU)** (p. 1554)
- **Point Emitter (CPU and GPU)** (p. 1556)
- **Sphere Emitter (CPU and GPU)** (p. 1558)
- **Trail Emitter (CPU)** (p. 1560)

**Angle Emitter (CPU and GPU)**

The **Angle** emitter spawns particles in a directional pattern based on the parameters. This is done to control the angle of emission from its source.

The following are parameters for the **Angle** emitter (CPU).
## Angle Emitter Parameters for CPU Attributes

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Focus Angle</strong></td>
<td>Specifies the number of degrees to rotate from the y-axis.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 (up) – 180 (down)</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td><strong>Focus Azimuth</strong></td>
<td>Specifies the number of degrees to rotate the new axis about the y-axis.</td>
</tr>
<tr>
<td></td>
<td>Valid values: any (0, 360 = North, 90 = West, 180 = South, 270 = East)</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td><strong>Focus Camera Direction</strong></td>
<td>Sets the focus direction to face the camera. You can set a Random value and the Strength over Emitter Lifetime curve.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 – 1</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td><strong>Focus Gravity Direction</strong></td>
<td>Ignores the emitter rotation and focuses gravity on world Z.</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
</tr>
<tr>
<td><strong>Focus Rotates Emitter</strong></td>
<td>Default value: false</td>
</tr>
<tr>
<td><strong>Emit Offset Direction</strong></td>
<td>If true, changes each particle's emission direction to align with its offset from the origin.</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
</tr>
<tr>
<td><strong>Emit Angle</strong></td>
<td>Sets the angle deviation of an emitted particle from the default focus (+Y) axis. 0 = up, 90 = horizontal, 180 = down. This is the maximum angle from the focus. You can set a Random value (determines minimum angle) and the Strength over Emitter Lifetime curve.</td>
</tr>
<tr>
<td></td>
<td>• To emit in all directions, set Emit Angle = 180, Random = 1.</td>
</tr>
<tr>
<td></td>
<td>• To emit in the top hemisphere, set Emit Angle = 90, Random = 1.</td>
</tr>
<tr>
<td></td>
<td>• To emit in a horizontal circle, set Emit Angle = 90, Random = 0.</td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Curvature** | Sets how far to bend the vertex normals for **Facing=Camera** particles into a spherical shape. This affects lighting.  
Valid values: 0 (flat) – 1 (hemispherical shape)  
Default value: 1 |

### Angle Emitter Parameters for GPU Attributes

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Focus Angle** | Specifies the number of degrees to rotate from the y-axis  
Valid values: 0 (up) – 180 (down)  
Default value: 0 |
| **Focus Azimuth** | Specifies the number of degrees to rotate the new axis about the y-axis.  
Valid values: any (0, 360 = North, 90 = West, 180 = South, 270 = East)  
Default value: 0 |
| **Emit Angle** | Sets the angle deviation of an emitted particle from the default focus (+Y) axis. 0 = up, 90 = horizontal, 180 = down. This is the maximum angle from the focus. You can set a Random value (determines minimum angle) and the Strength over Emitter Lifetime curve  
Valid values: 0 – 180  
Default value: 0 |

- To emit in all directions, set **Emit Angle** = 180, **Random** = 1.  
- To emit in the top hemisphere, set **Emit Angle** = 90, **Random** = 1.  
- To emit in a horizontal circle, set **Emit Angle** = 90, **Random** = 0.
Beam Emitter (CPU)

The **Beam** emitter spawns a length of connected particles at once, based on the origin and specified target position. You can also set wave form attributes to shape or animate the beam.

The following are parameters for the **Beam** emitter (CPU).

### Beam Emitter Parameters for CPU Attributes

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Beam Lifetime</strong></td>
<td>Sets the beam lifetime, in seconds. You must use this in conjunction with particle lifetime.  &lt;br&gt;Valid values: 0+  &lt;br&gt;Default value: 1</td>
</tr>
<tr>
<td><strong>Target Position</strong></td>
<td>Specifies the XYZ position to set the beam target, offset from the origin.  &lt;br&gt;Default value: 0, 0, 15</td>
</tr>
<tr>
<td><strong>Random Target Offset</strong></td>
<td>Randomizes the XYZ beam target, offset from the target position.  &lt;br&gt;Valid values: any  &lt;br&gt;Default value: 0, 0, 0</td>
</tr>
<tr>
<td><strong>Segment Type</strong></td>
<td>Specifies how each segment generates over the length of the beam. Use <strong>Fixed</strong> to set the number of segments over the length. Use <strong>Length</strong> to set the length of each segment over the beam length.  &lt;br&gt;Valid values: <strong>Fixed</strong>, <strong>Length</strong></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>Default value: <strong>Fixed</strong></td>
</tr>
<tr>
<td><strong>Segment Count</strong></td>
<td>Defines the number of segments with the <strong>Fixed</strong> type set.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 10</td>
</tr>
<tr>
<td><strong>Segment Length</strong></td>
<td>Defines the length of each segment with the <strong>Length</strong> type set.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 5</td>
</tr>
<tr>
<td><strong>Texture Shift</strong></td>
<td>Shifts the texture coordinate in the V direction at the specified rate.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td><strong>Up Vector for Waves</strong></td>
<td>Specifies the XYZ vector on which the waveform occurs.</td>
</tr>
<tr>
<td></td>
<td>Valid values: any</td>
</tr>
<tr>
<td></td>
<td>Default value: 0, 0, 0</td>
</tr>
<tr>
<td><strong>Wave Form Source</strong></td>
<td>Specifies the side of the beam from which to generate the waveform.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Origin</strong> – Waveform is calculated from the emitter origin.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Target</strong> – Waveform is calculated from the target specified by the target attributes.</td>
</tr>
<tr>
<td></td>
<td>Default value: <strong>Origin</strong></td>
</tr>
<tr>
<td><strong>Wave Form Type</strong></td>
<td>Sets the behavior for the waveform.</td>
</tr>
<tr>
<td></td>
<td>• <strong>None</strong> – No waveform is used.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Sine</strong> – A periodic waveform generates a smooth, repetitive curve.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Square</strong> – A nonsinusoidal, periodic waveform in which the amplitude alternates.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Noise</strong> – A repetitive waveform with a randomized amplitude.</td>
</tr>
<tr>
<td></td>
<td>Default value: <strong>None</strong></td>
</tr>
</tbody>
</table>
### Using the Particle Editor

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Wave Phase**   | Sets the position of the waveform at the specified source. A value of 360 completes one full cycle of the waveform. You can animate the beam waveform by using **Emitter Lifetime**, **Pulse Period**, and **Strength over Emitter Lifetime** in conjunction.  

**Note**  
The beam animation is updated when a new one is spawned based on the **Beam Lifetime** parameter. A lower lifetime provides a smoother animation.  

The following example demonstrates the wave phase parameter:  
Beam lifetime = .01, Emitter lifetime = 2, Pulse period = 2, Up vector = 1, 0, 0, Wave form type = Sine, wave phase = 180 (with a curve set on **Strength over Emitter Lifetime**), Wave amplitude = 2, Wave frequency = 0.5  
Valid values: 0+  
Default value: 0  

<table>
<thead>
<tr>
<th><strong>Wave Amplitude</strong></th>
<th>Sets the strength of the waveform deformation.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Wave Frequency</strong></th>
<th>Sets the number of wave cycles over the waveform length.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Texture Mapping</strong></th>
<th>Maps the assigned texture to each particle quad or across the trail stream.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Per Particle</strong> – Texture is mapped on each quad.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Per Stream</strong> – Texture is mapped over the length of the beam.</td>
</tr>
<tr>
<td>Default value:</td>
<td><strong>Per Particle</strong></td>
</tr>
</tbody>
</table>

**Note**  
When there is a single light source, some or all particles for **Trail** emitters can appear unlit (black). This is most apparent when the sun is the only light source and the time and day setting is noon. To address this:  

1. Add an Environment Probe to the scene to create indirect lighting. For more information, see **Environment Probe** (p. 587).  
2. Enable Environment Probe Lighting on the particle system by specifying a value for the Environment Probe Lighting parameter. For example, a value of 0.5 applies light from the Environment Probe at half intensity. For more information, see **Lighting Attribute** (p. 1528).
Box Emitter (CPU and GPU)

The **Box** emitter enables spawning of particles along the shapes axial coordinate system. This allows you to create complex planar and rectangular effects.

The following is an example of the **Box** emitter in the **Preview** viewport.

The following are parameters for the **Box** emitter.

### Shape Parameters
- Emitter Size
- Confine X
- Confine Y
- Confine Z
- Spawn Pos XYZ
- Spawn Pos XYZ Random
- Velocity XYZ
- Velocity XYZ Random

### Box Emitter Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Emitter Size XYZ</td>
<td>Sets the size of the box emitter in meters.</td>
</tr>
</tbody>
</table>
### Parameter | Description
--- | ---
**Confine XYZ** | Confines the particles to render within the box size on each axis.  
Valid values: 0+ (radius)  
Default value: 5

**Spawn Pos XYZ** | XYZ values define the spawning position away from the emitter in emitter space. You can set a Random value and Strength over Emitter Lifetime curve.  
Valid values: any  
Default value: 0, 0, 0

**Spawn Pos XYZ Random** | For additional random layering, XYZ values define the range of random spawning in both directions, away from the spawn position. You can set a Random value and Strength over Emitter Lifetime curve.  
Valid values: any  
Default value: 0, 0, 0

**Velocity XYZ** | XYZ values define the velocity applied to particles in world space. The velocity direction also sets the axis in which velocity spread occurs around. You can set a Random value and Strength over Emitter Lifetime curve.  
Valid values: any  
Default values: 0, 0, 0

**Velocity XYZ Random** | For additional random layering, XYZ values define the random velocity applied to particles in world space. You can set a Random value and Strength over Emitter Lifetime curve.  
Valid values: any  
Default value: 0, 0, 0

---

**Circle Emitter (CPU and GPU)**

The Circle emitter enables spawning of particles along the shapes axial coordinate system (see diagram below). This allows you to create complex circular and cylindrical effects.

The following is an example of the Circle emitter in the Preview viewport.
The following are parameters for the Circle emitter.

**Shape Parameters**
- Emitter Size
- Spawn Pos XYZ
- Spawn Pos XYZ Random
- Spawn Pos Increment XYZ
- Spawn Pos Increment XYZ Random
- Velocity XYZ
- Velocity XYZ Random

**Circle Emitter Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>

<td>Valid values: any</td>
</tr>
<tr>
<td></td>
<td>Default value: 0, 0, 0</td>
</tr>
</tbody>
</table>

**Point Emitter (CPU and GPU)**

The Point emitter spawns particles in a spherical distribution from the origin. This allows you to control the spread angle to create complex conical and spherical effects.
The following are parameters for the **Point** emitter.

### Point Emitter Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Spawn Offset</strong></td>
<td>Offsets the spawning of particles spherically at distance from the emitter origin. Valid values: 0+ (radius) Default value: 0</td>
</tr>
<tr>
<td><strong>Spawn Pos XYZ</strong></td>
<td>XYZ values define the spawning position away from the emitter itself in emitter space. You can set a <strong>Random</strong> value and <strong>Strength over Emitter Lifetime</strong> curve. Valid values: any Default value: 0, 0, 0</td>

</tr>
<tr>
<td>Default value: 360</td>
<td></td>
</tr>
</tbody>
</table>

**Sphere Emitter (CPU and GPU)**

The **Sphere** emitter enables spawning of particles along the shapes axial coordinate system (see diagram below). This allows you to create complex spherical effects.

The following is an example of the **Sphere** emitter in the **Preview** viewport.

The following are parameters for the **Sphere** emitter.
**Sphere Emitter Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>

**Trail Emitter (CPU)**

The Trail emitter connects particles together to create a trailing effect as the system moves through space.

The following are parameters for the Trail emitter.

**Trail Emitter Parameters**

<table>
<thead>
<tr>
<th>Parameter Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connect to Origin</td>
<td>Connects a newly spawned particle to the origin.</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
</tr>
<tr>
<td>Texture Mirror</td>
<td>Mirrors alternating texture tiles.</td>
</tr>
<tr>
<td></td>
<td>Default value: true</td>
</tr>
<tr>
<td>Texture Frequency</td>
<td>Specifies the number of texture wraps per trail emitter sequence, based on the Texture Mapping type.</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0+</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
</tbody>
</table>
Using the Particle Editor

Parameter Function | Description
--- | ---
**Lock Anchor Points** | Locks the UV anchor points of the texture to stay in place, rather than follow the emitter location.

- Default value: false

**Texture Mapping** | Maps the assigned texture to each particle quad or across the trail stream.

- **Per Particle** – Texture is mapped on each quad.
- **Per Stream** – Texture is mapped over the length of the beam.

- Default value: **Per Particle**

**Note**

When there is a single light source, some or all particles for Trail emitters can appear unlit (black). This is most apparent when the sun is the only light source and the time and day setting is noon. To address this:

1. Add an Environment Probe to the scene to create indirect lighting. For more information, see Environment Probe (p. 587).
2. Enable Environment Probe Lighting on the particle system by specifying a value for the Environment Probe Lighting parameter. For example, a value of 0.5 applies light from the Environment Probe at half intensity. For more information, see Lighting Attribute (p. 1528).

**Particle Trail Visibility**

Trail segments are drawn when the distance between the start and end of a segment exceed the value for **Min visible distance**. You can choose to automatically disable the drawing of trails that are not moving or are moving too slowly. This is useful if you have particle trail effects that need to be drawn only when the emitter is moving.

The following are movement parameters for the Trail emitter.

**Related Movement Attributes**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Min visible segment length</strong></td>
<td><em>(Trail Emitter (CPU) (p. 1560) only)</em> Tail particles are visible only when they have moved the specified distance.</td>
</tr>
</tbody>
</table>

- Default value: false

| **Min visible distance** | *(Trail Emitter (CPU) (p. 1560) only)* Specifies the minimum distance between the start and end of a trail segment. Segments that are smaller than this value become transparent. |

- Valid values: 0+
Creating Custom Attribute Panels

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Create a custom particle attribute panel so you can quickly access the parameters that you frequently use. You can drag parameters from an existing standard panel to copy the parameters into the custom panel. Or you can drag parameters from a custom panel to move the parameters to the new custom panel. If you want to simultaneously add multiple parameters, press Ctrl while selecting the parameters.

When you move a panel to a new location, an indicator appears so you can preview a valid drop location. If you do not see an indicator, the parameter is inserted at the end of the panel. The following example shows a custom panel with drop indicators.
To create a custom attribute panel

1. In Lumberyard Editor, choose **Tools, Particle Editor**.
2. In the **Particle Editor**, click the menu in the **Attributes** title bar.
3. Do one of the following:
   - Choose Custom attributes, New attribute.
   - Choose Custom attributes, Import attribute.

4. Name your custom attribute or browse to the attribute that you want to import.

5. Once created, you can right-click the attribute title bar to rename, empty, or export custom attribute panels.

Custom Attributes Panel Menu Options

Use the following menu options to modify your custom attribute panel.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>New attribute</td>
<td>Adds an empty, custom panel to the Attributes panel.</td>
</tr>
<tr>
<td>Import attribute</td>
<td>Loads an existing custom attribute panel. The panel is also added to the panel preset list.</td>
</tr>
<tr>
<td>Panel preset list</td>
<td>Lists the custom panel presets.</td>
</tr>
<tr>
<td>Reset list</td>
<td>Resets the preset list.</td>
</tr>
<tr>
<td>Rename</td>
<td>Renames the custom panel.</td>
</tr>
<tr>
<td>Remove all</td>
<td>Removes all attributes in the panel.</td>
</tr>
</tbody>
</table>
Option | Description
---|---
Export | Exports the selected custom panel as a .custom_attribute file. The panel is also added to the panel preset list.
Close | Closes the custom panel.

### Using the Color Picker

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the color picker to apply a color tint and alpha (opacity) to your particles. You can save your palette libraries to share with others.

**To use the Color Picker**

1. In Lumberyard Editor, choose Tools, Particle Editor.
2. In the Libraries panel, select an emitter.
3. In the Attributes panel, under Particles, click the color swatch for the Color parameter.
The **Color Picker** includes the following:

A. **Eye dropper** – Selects a color on your screen with magnification.
B. **Current** and **New color** – Displays your current color selection and the new color selection.
C. HTML and RGB values – Specifies the color value inputs.
D. Color window – View the range of colors to select.
E. Channels – Focuses the hue range based on RGB and CMY color sets.
F. Hue, Saturation, Value, and Alpha – Slides to select a new color.
G. Default Library palette – A list or grid of the currently selected library palette.
H. Help icon – Displays the online help topic for the Color Picker.

Using the Palette Libraries

Create a palette library to save your collection of custom colors. You can create multiple palette libraries.

Use the following actions in the palette library menu.
Using the Particle Editor

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>List</td>
<td>Displays a list view with name or RGBA values.</td>
</tr>
<tr>
<td>Grid</td>
<td>Displays the palette as a grid of color swatches.</td>
</tr>
<tr>
<td>Preset preview size</td>
<td>Changes the palette swatch size.</td>
</tr>
<tr>
<td>Create New Library</td>
<td>Creates a blank palette library.</td>
</tr>
<tr>
<td>Libraries</td>
<td>Displays a list of imported palette libraries.</td>
</tr>
<tr>
<td>Load Library</td>
<td>Imports a saved palette library.</td>
</tr>
<tr>
<td>Export</td>
<td>Exports the current palette library to a file.</td>
</tr>
<tr>
<td>Rename Library</td>
<td>Renames the current palette library.</td>
</tr>
<tr>
<td>Remove Library</td>
<td>Removes the current palette library.</td>
</tr>
<tr>
<td>Reset to default</td>
<td>Resets the current library to the default palette.</td>
</tr>
<tr>
<td>Remove All Libraries</td>
<td>Removes all palette libraries from the libraries list. This does not delete exported library palettes.</td>
</tr>
</tbody>
</table>

Using the Gradient Editor

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the **Gradient Editor** to apply color ranges to an emitter and configure additional subparameters.

**To use the Gradient Editor**

1. In Lumberyard Editor, choose **Tools, Particle Editor**.
2. In the **Libraries** panel, select an emitter.
3. In the **Attributes** panel, under **Particles**, expand **Color**.
4. Click the color swatch for the **Strength Over Emitter Lifetime** or **Strength Over Particle Lifetime** parameter.
Gradient Editor UI Options

The Gradient Editor includes the following:

- **Location** – Sets the location value range from 0% – 100%.
- **Color** – Opens the Color Picker.
- **Gradient box** – Applies the combined gradient and alpha.
- Gradient viewport
  - The x-axis represents the gradient generator of the color change over the full gradient.
  - The y-axis represents 0 – 100% alpha of the gradient color.
- **Default Library**, alpha curve – Provides alpha curves to use as a starting point.
- **Default Library**, gradient – Provides gradients to use as a starting point.

Working with Color Gradients

When you select a gradient from the Default Library, it displays with the alpha curve in the Gradient Editor viewport. You can do the following when selecting a gradient:

**To change the gradient color**

- Click the triangle keyframes and select a new color from the Color Picker.
To add a color to the gradient

- Double-click the X-axis to generate a color keyframe. The color in the color thumbnail is added to the gradient viewport. Any adjustments you make to the gradient is reflected in the gradient viewport.

To display the RGBA values

- Pause on the color keyframe.

To delete a color keyframe

- Select the keyframe and press Delete. The selected keyframe has an orange outline.

To adjust the alpha curve

- Click and drag the circle (alpha keyframe) in the gradient viewport. Move the circle up (towards 100%) or down (towards 0%) to adjust the alpha percentage. Moving the circle left or right adjusts the curve based on the curve endpoints.

To display the alpha curve context menu

- Right-click the alpha curve keyframe. The following options are available: Delete selected keys, Create flat or linear curves, Adjust the in-and-out tangent of the curve to be linear or flat, Add a created curve to the library or preset list, and Reset the curve to defaults.

To add an alpha key

- Double-click the curve in the gradient viewport.

To delete an alpha key

- Select the circle key and press Delete.

To add a generated alpha curve to the preset list

- Click the + button.

To add a generated gradient to the gradient preset list

- Click the + button.

To delete a curve or gradient preset

- Right-click the gradient or curve and click Remove.

Managing Particle Level of Detail (LOD)

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The Level of Detail (LOD) system blends multiple particle emitters based on their distance from the camera. This allows you to use emitters that require less computation and rendering time, rather than computationally heavy particle emitters.

**To add an LOD for a particle emitter**

1. In Lumberyard Editor, choose Tools, Particle Editor.
2. In the Particle Editor, in the Libraries panel, right-click an emitter.
3. Select Add LOD.

The LOD is a copy of the base particle emitter and has the same settings. The LOD also applies to all parent or child particle emitters in the hierarchy that belong to the selected emitter.

**Level of Detail Panel**

The Level of Detail panel appears when you add an LOD. This panel shows the level of detail that you selected from the View menu in the Particle Editor.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blend In</td>
<td>The amount of time, in seconds, for an LOD to blend in.</td>
</tr>
<tr>
<td>Blend Out</td>
<td>The amount of time, in seconds, for an LOD to blend out.</td>
</tr>
<tr>
<td>Overlap</td>
<td>The amount of time, in seconds, that both LODs are shown before the old LOD blends out and the new LOD blends in.</td>
</tr>
</tbody>
</table>
## Using the Particle Editor

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+ Add Level of Detail</td>
<td>Adds an LOD. The new LOD distance is set to 10 additional units from the farthest LOD. The list of added LOD levels appears under + Add Level of Detail.</td>
</tr>
</tbody>
</table>

### Hide or Display Options

Hide or display the **Level of Detail** panel by clicking **View, Hide Level of Detail** in the **Particle Editor**.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hide Level of Detail</td>
<td>Hides the LOD panel if the panel is visible.</td>
</tr>
<tr>
<td>Show Level of Detail</td>
<td>Displays the LOD panel if the panel is hidden.</td>
</tr>
</tbody>
</table>

### Manage LOD Options

Manage your LOD levels in the list by clicking the drop-down menu in the **Level of Detail** title bar.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add level</td>
<td></td>
</tr>
<tr>
<td>Arrange</td>
<td></td>
</tr>
<tr>
<td>Jump to first</td>
<td></td>
</tr>
<tr>
<td>Jump to Last</td>
<td></td>
</tr>
<tr>
<td>Remove</td>
<td></td>
</tr>
<tr>
<td>Remove all</td>
<td></td>
</tr>
<tr>
<td>Close</td>
<td></td>
</tr>
</tbody>
</table>
Using the Particle Editor

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add level</td>
<td>Adds an LOD level to the end of the list.</td>
</tr>
<tr>
<td>Arrange</td>
<td>Shows the Arrange submenu:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Move up</strong> – Moves the selected LOD level one position up in the list.</td>
</tr>
<tr>
<td></td>
<td>This also changes the <strong>Level LOD Distance</strong> to 1.0 lower than the previous level.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Move down</strong> – Moves the selected LOD level one position down in the list.</td>
</tr>
<tr>
<td></td>
<td>This also changes the <strong>Level LOD Distance</strong> to 1.0 higher than the previous level.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Move to top</strong> – Moves the selected LOD level to the top of the list.</td>
</tr>
<tr>
<td></td>
<td>This also changes the <strong>Level LOD Distance</strong> to 1.0 lower than the previous top level.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Move to bottom</strong> – Moves the selected LOD level to the end of the list.</td>
</tr>
<tr>
<td></td>
<td>This also changes the <strong>Level LOD Distance</strong> to 1.0 higher than the previous bottom level.</td>
</tr>
<tr>
<td>Jump to first</td>
<td>Selects the first LOD level in the list.</td>
</tr>
<tr>
<td></td>
<td>This also selects the top particle emitter in the list and loads it in the Attributes panel.</td>
</tr>
<tr>
<td>Jump to last</td>
<td>Selects the last LOD level in the list.</td>
</tr>
<tr>
<td></td>
<td>This also selects the top particle emitter in the list and loads it in the Attributes panel.</td>
</tr>
<tr>
<td>Remove</td>
<td>Removes the selected LOD level.</td>
</tr>
<tr>
<td>Remove All</td>
<td>Removes all LOD levels for the related particle emitters.</td>
</tr>
<tr>
<td>Close</td>
<td>Closes the <strong>Level of Detail</strong> panel.</td>
</tr>
</tbody>
</table>

**LOD Level Panel**

Each LOD level has its own panel in the LOD level list. These panels show all relevant information for each individual level.

**Note**

The base particle emitter is shown if the camera distance is lower than the top LOD level. This makes the base particle the starting LOD level.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top left check box</td>
<td>Turns on/off the entire level.</td>
</tr>
<tr>
<td>LOD distance value</td>
<td>Specifies the camera distance at which the LOD level becomes active. This level, the particle emitter blends toward the LOD level and blends out the previous LOD level.</td>
</tr>
<tr>
<td>Top right button</td>
<td>Deletes the corresponding LOD level.</td>
</tr>
</tbody>
</table>
### Using the Particle Editor

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Particle check box</td>
<td>Turns off the particle emitter at this level. When the emitter is off, nothing is drawn. You can use this to turn off particle emitters based on the LOD level.</td>
</tr>
<tr>
<td>Particle name</td>
<td>Click a particle name to load the LOD level particle emitter for the selected particle emitter in the Attributes panel. You can use this to change the LOD level particle emitter. Right-click a particle name and click Remove to remove the particle from the LOD level. Any child particle emitters are also removed from the LOD level.</td>
</tr>
</tbody>
</table>

#### Using Particle Editor Keyboard Shortcuts

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Most of the commands in the Particle Editor menus have corresponding keyboard shortcuts. You can edit the keyboard shortcuts by clicking Edit, Edit Hotkeys. Modify as needed in the HotKey Configuration window.

**Hotkey Configuration**

**Export**

Exports the keyboard shortcuts (hotkey) list to a file.

**Import**

Imports a keyboard shortcuts (hotkey) list from a file.

**Reset to Default**

Resets all keyboard shortcuts (hotkeys) to the editor default settings.

**Click to assign**

Records a new keyboard shortcut when you click the shortcut. Clears the keyboard shortcut when you right-click the shortcut. Click OK to save your changes.

The Particle Editor uses the following keyboard shortcuts.
Particle Effects Best Practices

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The total number of particles in a scene is not a critical factor when considering best practices for working with particles. Total fill-rate, physics, and (to some extent) spawn rate are more important. Following are some best practices for working with particles:

- Use soft particles only on subemitters that are near the ground and have only small particles. Create similar subemitters higher up that emit particles that never intersect with the ground and don't require soft particles.
- If sharp details are not required, use low-resolution textures and texture compression.
- Use an alpha texture with high or average opacity rather than additive blending.
- Each second-generation effect causes an emitter to be created for each particle in the parent effect. Use this sparingly because it can be expensive.
- Use physicalized particles sparingly because they are expensive. You can split an effect into subeffects, so that only a few large particles have physics enabled for appearance. The rest go through the ground or fade out quickly.
- Instead of multiple overlaid sprites for chaotic glow effects, use only two particles at a time. Carefully tune the lifetime and rotation rate, and set curves for Alpha, Color, and Size to combine in chaotic ways. Or, increase the Emissive Lighting parameter.
- For large, full-screen particles, use a Fill Rate Cost value of 1 or above.
- For small particles, such as sparks, set a maximum distance value to ensure that they aren't rendered as small, single pixel particles. Use the lowest Config spec setting to turn off small particles that are used in collisions.

Advanced Particle Techniques

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the following advanced techniques in the Particle Editor to emit particles from geometry, create a particle effect that explodes, preview your effects on an animated character, or generate particles from surface properties.

Emitting Particles from Geometry

Do the following to emit particles from the parent geometry.

To emit particles from geometry

1. Create a parent emitter with a .cgf mesh asset that is assigned in the Geometry input under Particles. For more information, see Creating and Managing Particle Emitters (p. 1544).
2. Create a new emitter as a child of the first emitter.
3. On the child emitter, in the emitter attributes, set **Spawn Indirection** to **Parent Start**.
4. Set the **AttachType** to **Render**, and the **AttachForm** to **Vertices**.

The child's particles spawn from the mesh of its parent.

![Advanced Particle Techniques](image)

**Note**

Use any **Attach Type** and **AttachForm** for the intended effect.

**Creating Exploding Geometry Particle Effect**

Do the following to create a particle effect that instantly spawns exploding chunks.

**To create an exploding geometry particle effect**

1. Create an emitter. In the **Attributes** panel, under **Particles**, assign a multipart .cgf file to the **Geometry** input.
2. Set **Geometry** in **Pieces** to the option for your use case: **RandomPieces** or **AllPieces**.
3. Set appropriate values for **Gravity**, **Speed**, **Rotation Rate**, and more to create an exploding effect.
4. Optionally set **Collision** parameters for physicalized pieces.

**Attaching Particles to Character Animations for Previewing**

Do the following to preview the effects on an animated character in your level.

**To attach a particle to an animation**

1. In Lumberyard Editor, choose **Tools, Asset Browser**.
2. In the **Asset Browser**, select and drag a .cdf character asset that has animations into the Lumberyard Editor viewport. Close the **Asset Browser**.
3. In the **Entity Inspector**, click **Add Component**. Under **Animation**, choose **Simple Animation**.
4. Under **Simple Animation**, click the + button to add an element. Select an animation to play.
5. Open the **Particle Editor** and drag the effect that you want to preview into your level.
6. In the **Entity Inspector**, click **Add Component**. Under **Animation**, choose **Attachment**.
7. Under **Attachment**, click the target entity picker and select your character in the viewport.
8. In the joint list, select a joint name to which to attach the effect. Select an offset as needed.
9. In the bottom toolbar, click **AI/Physics**. Alternatively, press **Ctrl+G** to start the animation and preview the effect.

### Generating Particles from Surface Properties

Use the properties for an object's material surface to define the event-driven effects that can occur when an object experiences an event. You can specify these events on a render material or on individual pieces or surfaces of a `.cgf` asset.

Many of the properties define the particle effects that are spawned by events such as walking or a bullet hit. To specify the effect that is spawned when a geometry piece breaks off of an object, set the following parameters in a Lua script:

**Name**
- Specifies the name of the particle effect.

**Scale**
- Multiplies the size of the particle.

**Count_scale**
- Multiplies the particle counts.

### Particle Debugging with Console Variables

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the following console variables to monitor and debug particle system issues. For more information, see Using the Console Window (p. 210).

**Particle Console Variables**

<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Description</th>
<th>Valid Values</th>
</tr>

</tr>
<tr>
<td>e_ParticlesPoolSize</td>
<td>Particle system pool memory size in KB.</td>
<td>Default value: 16384</td>
</tr>
<tr>
<td>e_ParticlesPreload</td>
<td>Enables preloading of all particle effects at the beginning.</td>
<td>Default value: 0</td>
</tr>
</tbody>
</table>
### Console Variable Description

<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Description</th>
<th>Valid Values</th>
</tr>
</thead>
</table>
| e_ParticlesProfile | Displays particle information on the screen. | 0 = Off (default)  
1 = Always show the statistics about particle pool usage.  
2 = Disable the warning message when running out of pool memory. |
| e_ParticlesQuality | Specifies the quality of particle detail. | Default value: 4 |
| e_ParticlesShadows | Displays shadows on particles. | 0 = Off  
1 = On (default)  
2 = Force |
| e_ParticlesShowMainThreadUpdates | Renders a list of containers not updated by a job and provides details why. | Default value: 1 |
| e_ParticlesSoftIntersect | Renders appropriate particles with soft intersection. | 0 = Off  
1 = On (default)  
2 = Force |
| e_ParticlesSortQuality | Minimum sort quality for new particle insertion. | 0 = Basic (default)  
1 = Better  
2 = Best |
| e_ParticlesThread | Enables particle threading. | 0 = Off  
1 = On (default) |
| e_ParticlesUseLevelSpecificLibs | Allows searching for level-specific version of effects files. | 0 = Off (default)  
1 = On |
| e_ParticlesVertexPoolSize | Memory size of vertex pool between particle and render thread. | Default value: 256 |
| e_SkipParticleOcclusion | Skips occlusion testing for particles in the occlusion buffer. **Note** The particles may be too small to return reliable results. | 0 = Off  
1 = On (default) |
| gpu_particle_physics | Enables graphics processing unit (GPU) for physics, if available. | 0 = Off (default)  
1 = On |

</tr>
</tbody>
</table>

Specify a number to switch the group of particle console variables. You can find the group number, the specified console variables, and their values in the sys_spec_Particles.cfg file in the lumberyard_version\dev\Engine\Config\CVarGroups directory.

For example, when sys_spec_particles = 1, the console variable uses the settings defined in group 1 in the sys_spec_Particles.cfg file.

---

Create cinematic sequences

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Cinematics, also known as sequences or cutscenes, are interactive movie animations with time-dependent control over objects and events. You can use Lumberyard to add cutscenes to your game.
You can also add scripted events so that a sequence of objects, animations, and sounds are triggered in the game. The player can view these sequences from their own (first person) or another’s (third person) perspective.

Sequences consist of the following elements (listed in hierarchical order), which are created and managed from the Track View:

- **Node** – Each sequence comprises a top-level director (scene) node, one or more camera nodes, image effects nodes, and entity nodes.
- **Track** – Depending on the type, each node consists of multiple tracks, such as position, animation, sound, lighting, text, and events. Tracks are displayed in the track timeline pane.
- **Key** – A key is a setting for a property at a specific time. As the sequence plays, keys are interpolated based on their in and out tangent values set in the Track View.

**Topics**
- Using the Track View Editor (p. 1584)
- Populating a Scene (p. 1608)
- Animating Characters in Scenes (p. 1622)
- Capturing Image Frames (p. 1630)
- Debugging Cinematic Scenes with Console Variables (p. 1632)

**Using the Track View Editor**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Track View is the primary tool to create and manage cinematic sequences. A *sequence* is the content generated from the Track View for cutscenes or other canned animation triggers. When you create a sequence, this creates a component entity in the level. The component entity stores all of the animation key data that you specified in the Track View.

If you want to generate cutscenes for games or create a script to trigger an animation, you can use the Track View to control cameras, component entities, global variables in a level, and so on.

**To create a sequence in the Track View**

1. Do one of the following:
   - In Lumberyard Editor, choose Tools, Track View.
   - Press T.
2. To create a sequence, do one of the following:
   - Choose Sequences, New Sequence.
3. Enter a sequence name, such as Example Sequence and click OK.
4. In the Entity Outliner, a component entity appears with the same name as your sequence. This component entity has a Sequence component that stores your sequence data from the Track View.
After you create a sequence, you can add properties to it. Any part of the sequence is considered a node. Nodes can be a reference to existing component entities or added to a sequence. For example, if you want to include an active camera for your sequence, you can add the Director node. Each node can have one or more tracks, depending on your animation sequence. A track displays animation keys on a timeline in relation to the property that is animated on a node.

To add a node to a sequence

1. In the Track View, right-click the sequence or the node browser and select Add Name Node.
2. Select the node to update its properties.

For more information, see Track View Editor Nodes (p. 1586).

Topics

- Track View Editor Nodes (p. 1586)
- Adding and Removing Animation Keys on Tracks (p. 1601)
- Controlling the Playhead (p. 1602)
- Using Record Mode (p. 1604)
- Using Animation Curves (p. 1607)

Track View Editor Toolbars

See the following main sections of the Track View:

1. Main toolbar – Tools to create and modify sequences and the tracks in a sequence. The main toolbar includes the Sequence/Node, View, Play, Keys, and Tracks toolbars. To add or remove toolbars, right-click the main toolbar and select your preferred options.
2. Node browser – Tree pane of all nodes and associated tracks. Nodes can be in reference to existing component entities or nodes that you can add to a sequence such as a Director Node.
3. Track Editor – Track timeline of all node tracks specified for animation keys. Each row in the timeline corresponds to a track listed in the node browser.
4. Key properties – Pane that shows more information for a selected animation key. It also provides information about the key number on the track and its location in the timeline, in seconds. Common properties are color (RGB) values and floats.
5. Curve Editor – Pane for controlling keys and their interpolation for all sequence nodes. The Curve Editor provides more control over easing in or out of curves, setting some curves to be linear, and so on, depending on your animation requirements.

For more information, see Using Animation Curves (p. 1607).

Note

You can pause over buttons in the Track View to view their descriptions.
Track View Editor Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.
Download O3DE or visit the AWS Game Tech blog to learn more.

The Track View offers a variety of nodes for specific purposes. Anything part of the sequence is considered a node. Nodes can be a reference to existing component entities or added to a sequence. The top-level node in the tree view is the sequence and all other nodes are listed below the sequence.

Topics

- Component Entities and Component Nodes (p. 1586)
- Comment Node (p. 1590)
- Console Variable Node (p. 1590)
- Director (Scene) Node (p. 1591)
- Environment Node (p. 1594)
- Event Node (p. 1595)
- Material Node (p. 1596)
- Shadows Setup Node (p. 1598)
- Full Screen Effect Nodes (p. 1598)

Component Entities and Component Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.
Download O3DE or visit the AWS Game Tech blog to learn more.
Topics

- Naming and Identifying Component Entities (p. 1588)
- Adding or Removing Components from a Component Entity (p. 1589)
- Animating Components on a Component Entity (p. 1589)

In the Track View, component entity nodes function as containers for component nodes.

When you add an animation using the Track View, the animation track is applied to a component node. Component entity nodes don't directly have tracks or key properties.

Example

The component entity GameObject contains Transform, Mesh, and Point Light components. When you add the GameObject component entity to a sequence in the Track View, you can see all the components in the node browser. The component entity node is a reference to which components are animated in the sequence.

Component nodes that can be animated are nested as children under the associated entity node. You can add animation tracks to any of these component nodes.

To add a track to an animation node

1. In the Track View, create or select a sequence.
2. In the node browser, right-click and choose Add Track, then choose the component property.
Not all components can be animated in the Track View. For example, you can add the Visibility track only for the Mesh component. The Point Light component has multiple tracks that you can add to the sequence. In the following example, the Color, DiffuseMultiplier, and Visible tracks are added to the sequence.

For more information about adding node support to the Track View, see Exposing Custom Components to Track View for Animation (p. 1021).

**Naming and Identifying Component Entities**

Lumberyard uses entity IDs to identify component entities, which means that you can name your component entities as you want. This includes reusing the same name for multiple entities. In the Track View, if component entity nodes share the same name, a number is appended to the name. This doesn't change the name of the component entity in the level, but it might be difficult to determine which entity to animate.
Example

If you have component entities with the same name (for example, if they're multiple instances of a slice), you can determine which entity that you're editing. For more information, see Working with Slices and Sequences (p. 1611).

Adding or Removing Components from a Component Entity

When you add a component to a component entity in Lumberyard Editor, the component is automatically added to any component entity nodes in the Track View. When you remove a component, the component and any animation data are also removed from the Track View.

**Important**

Be careful when removing components from component entities because it might affect your existing sequence. For example, if you remove a **Simple Motion** component from an entity that is part of a sequence, the animation no longer references the specified animation.

Animating Components on a Component Entity

Component nodes that can be animated are nested as children under the associated component entity node. You can add animation tracks to any of these component nodes.

**To add an animation track to a component node**

1. In the Track View, select or create a sequence.
2. In the node browser, right-click the component node and choose **Add Track**, then choose the track that you want.
Using the Track View Editor

Note

- Some components support only a limited number of tracks that can be animated in a sequence. For more information for component-specific properties, see the Component Reference (p. 532).
- Not all components can be animated in the Track View. For more information about adding node support to the Track View, see Exposing Custom Components to Track View for Animation (p. 1021).

After you add the component entity nodes to the sequence and specify the tracks to animate, you can then add keyframes to the timeline. In keyframes, you specify where in the timeline you want to animate the property and edit its properties.

For more information, see Adding and Removing Animation Keys on Tracks (p. 1601).

Comment Node

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Comment node to add comments to your track view sequence. This is mostly used for production purposes and is not rendered in the game.

To add a Comment node in the Track View

1. In the Track View, right-click either the sequence (top node) or the Director node in the tree as applicable, and then click Add Comment Node.
2. For each of the keys listed below, click the applicable key listed under the Comment node.
3. To position a key, double-click the preferred location on its highlighted row in the timeline. Double-click the green marker, and then under Key Properties enter a value for Value.

Comment Node Key Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unit Pos X</td>
<td>position of the text horizontally</td>
</tr>
<tr>
<td>Unit Pos Y</td>
<td>position of the text vertically</td>
</tr>
</tbody>
</table>
| Text | • Comment – Text string  
  • Duration – Length of time the node is active  
  • Size – Font size  
  • Color – Font color  
  • Align – Text alignment (Center, Left, Right)  
  • Font – Font type (default, console, hud) |

Console Variable Node

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Use the **Console Variable** node to use and animate console variables in a track view sequence.

**To add a console variable node in Track View**

1. In the Track View, right-click either the sequence (top node) or the **Director** node in the tree as applicable, and then click **Add Console Variable**. Type a name for it and click **OK**.
2. At the bottom of **Lumberyard Editor**, right-click the text box in the **Console** window, which opens up the **Console Variables** window that displays a list of all available console variables.
3. Pause on the desired console variable to get a tool tip that gives a description and valid values to use.
4. In the Track View select the **value** key listed under the console variable node.
5. To position a key, double-click the preferred location on its highlighted row in the timeline. Double-click the green marker, and then under **Key Properties** enter a value for **Value**.

**To animate a console variable**

1. In the Track View click **View, Curve Editor**.
2. Click **Set In Tangent To Step** button (located third button from the left above the timeline window) to set the keyframes for the console variable.

**Director (Scene) Node**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **Director (Scene)** node includes a camera track that specifies the active camera for a track view sequence. You can add sequence-specific nodes (for example, **Depth of Field** or **Comment**) under the **Director** node to override the same nodes that were set at the sequence level.

**To add a Director node in the Track View**

1. In Lumberyard Editor, choose **Tools, Track View**.
2. In the Track View, click the **Add Sequence** icon.
3. In the **Add New Sequence** dialog box, enter a name for your sequence and click **OK**.
4. Right-click your sequence and choose **Add Director (Scene) Node**.
5. Right-click the **Director** node and click **Add Track**.
6. Select the track and double-click to position the key on its highlighted row in the timeline.
7. Double-click the green marker, and under **Key Properties**, enter a value for **Value**.

You can add the following tracks and then set the key properties to the **Director** node.

### Director Node Tracks and Key Properties

<table>
<thead>
<tr>
<th>Track</th>
<th>Key Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Camera</td>
<td>Camera</td>
<td>Specifies the sequence camera. You can optionally override the camera with the <code>mov_overrideCam</code> console variable. Set the console variable to an entity ID (string) of a <strong>Camera</strong> (p. 566) component entity for component entity sequences. For more information, see Using the Console Window (p. 210).</td>
</tr>
<tr>
<td></td>
<td>Blend time</td>
<td>Specifies the blend time, in seconds, between sequential cameras in the track.</td>
</tr>
<tr>
<td>Capture</td>
<td>Duration</td>
<td>Sets the capture duration in seconds.</td>
</tr>
<tr>
<td></td>
<td>Time Step</td>
<td>Forces a fixed frame rate, in seconds, by using a specified time step. Time step = 1/number of frames. Units are in 1 fps (frames per second), so a time step value of .0333 results in a game frame rate of 30 fps.</td>
</tr>
<tr>
<td></td>
<td>Output Format</td>
<td>Specifies the image output file format. Choose from the following options:</td>
</tr>
</tbody>
</table>
## Track View Editor

<table>
<thead>
<tr>
<th>Track</th>
<th>Key Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Output Prefix</strong></td>
<td>Specifies a prefix to apply to the image file names. For best results, use the same prefix as the sequence for clarity.</td>
</tr>
<tr>
<td></td>
<td><strong>Output Folder</strong></td>
<td>Specifies the directory where the image files are stored.</td>
</tr>
<tr>
<td></td>
<td><strong>Buffer(s) to capture</strong></td>
<td>Specifies the image capture format. Choose from the following options:</td>
</tr>
<tr>
<td></td>
<td>Color</td>
<td>RGB pixel information</td>
</tr>
<tr>
<td></td>
<td>Color+Alpha</td>
<td>RGB pixel data and Alpha channel data</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
<td>To capture Alpha channel data, you must set <strong>Output Format to tga.</strong></td>
</tr>
<tr>
<td></td>
<td><strong>Just one frame?</strong></td>
<td>Specifies if you want to capture a single frame.</td>
</tr>
<tr>
<td><strong>Console</strong></td>
<td><strong>Command</strong></td>
<td>Runs the specified console variable command.</td>
</tr>
<tr>
<td><strong>Event</strong></td>
<td><strong>Event</strong></td>
<td>Specifies the event to trigger in the <strong>Director</strong> node Lua script.</td>
</tr>
<tr>
<td></td>
<td><strong>Value</strong></td>
<td>Specifies the custom value that is referenced in the nodes for your Script Canvas graph or code.</td>
</tr>
<tr>
<td></td>
<td><strong>No trigger in scrubbing.</strong></td>
<td>Prevents the event from occurring while you preview the timeline of the track view sequence.</td>
</tr>
<tr>
<td><strong>FixedTimeStep</strong></td>
<td><strong>Value</strong></td>
<td>Sets a fixed time step in order to modify the game speed. Units are in 1 fps, so a fixed time step value of .0333 results in a game frame rate of 30 fps.</td>
</tr>
<tr>
<td><strong>GoTo</strong></td>
<td><strong>Goto Time</strong></td>
<td>Jumps forward or backward in a sequence. Use this track for key framing time shifts and to loop part of a sequence. This key automatically applies animation blending on animations that are currently playing in the sequence.</td>
</tr>
<tr>
<td><strong>Sequence</strong></td>
<td><strong>Sequence</strong></td>
<td>Specifies the track view sequence to play at the specified keyframe.</td>
</tr>
<tr>
<td></td>
<td><strong>Override Start/End Times</strong></td>
<td>Overrides the sequence start and end times.</td>
</tr>
<tr>
<td></td>
<td><strong>Start Time</strong></td>
<td>Specifies the start time to override.</td>
</tr>
<tr>
<td></td>
<td><strong>End Time</strong></td>
<td>Specifies the end time to override.</td>
</tr>
<tr>
<td><strong>Sound</strong></td>
<td><strong>StartTrigger</strong></td>
<td>Specifies the trigger to start the audio.</td>
</tr>
</tbody>
</table>

<th>Track</th>
<th>Key Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>StopTrigger</td>
<td>Specifies the trigger to stop the audio.</td>
</tr>
<tr>
<td></td>
<td>Duration</td>
<td>Specifies the length to play the audio.</td>
</tr>
<tr>
<td></td>
<td>Custom Color</td>
<td>Specifies the color to display for the audio on the timeline.</td>
</tr>
</tbody>
</table>

**Timewarp**

|       | Value | Creates a slow-motion effect using a curve that scales the movie playback speed by the Timewarp value. A value of 1.0 represents normal speed; smaller values slow down time and larger values speed up time. If you set Timewarp to 0, playback will completely stop in your movie. Timewarp applies only to visuals; sounds are not slowed down. |

**Note**

- You can add multiple Director nodes to a scene, but only one Director node can be active.
- To change the active Director node, right-click the node and choose Set as Active Director. When you deactivate a Director node, all child node animations are deactivated. This is useful when you want to enable and disable animation for specific objects within the same track view sequence.

### Environment Node

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Environment node to set the sun's longitude and latitude in a scene.

**To add an Environment node in the Track View**

1. In the Track View, right-click either the sequence (top node) or the Director node in the tree as applicable, and then click Add Environment Node.
2. For each of the keys listed below, click the applicable key listed under the Environment node.
3. To position a key, double-click the preferred location on its highlighted row in the timeline. Double-click the green marker, and then under Key Properties, enter a value for Value.

### Environment Node Key Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sun Longitude</td>
<td>Sets the sun's longitude.</td>
</tr>
<tr>
<td>Sun Latitude</td>
<td>Sets the sun's latitude.</td>
</tr>
</tbody>
</table>
Event Node

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add an Event node to your sequence to trigger and send values to Script Canvas. You create Track Events using the Track View Events window. You then assign the Track Event to an animation key that is added to the track for the Event node. When the key is played during the sequence, the event is triggered. Script Canvas then uses the Track Event to trigger additional script logic.

To add an Event node

1. In the Track View, select or create a sequence.
2. In the node browser, right-click and choose Add Event Node.
3. In the Track Event Name window, enter a name for the track and choose OK.

This creates a Track Event node and a Track Event track is automatically to that node.

To create a Track Event

1. In the node browser, right-click and choose Edit Events. This opens the Track View Events window.
2. In the **Track View Events** window, click **Add** to create an event.

3. Enter an event name and choose **OK**. Your track event appears in the window.

4. When you are done, close the window. You can now specify this track event in Script Canvas.

**Material Node**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

**Material** nodes help you animate commonly used material properties that you would normally set in the **Material Editor**. You can add **Material** nodes through a sequence or from the **Director** node.

**Note**

The name of the **Material** node must be the full path of the material that you want to animate, as shown in the **Material Editor**.
A recommended workflow is to select the material inside the **Material Editor** that you want to animate.

**To add a Material node in the Track View**

1. In Lumberyard Editor, choose **Tools, Material Editor**.
2. Navigate to the material that you want to animate.
3. Right-click the selected material and choose **Copy Path to Clipboard**. If the material is in a material group, select the group and copy the group name to the clipboard.

![Material Editor](image)

4. Choose **Tools, Track View**.
5. Create or select an existing sequence or **Director** node that you want to contain the animation.
6. In the node tree, right-click and choose **Add Material Node** and then in the **Material Name** dialog box, press Ctrl+V to paste the full path to the material that you copied in step 3 and then click **OK**.
7. If the material is in a material group, the text appears red on the **Material** node in the Track View. This means that a submaterial hasn't been selected.

To add a submaterial, do the following:

a. In the Track View, right-click the **Material** node.
b. Select the submaterial that you want to animate.
c. The **Material** node text should no longer appear in red.

8. To add tracks to the **Material** node, right-click the node name and choose **Add Track**. See the following table for the available tracks.

### Material Node Tracks

<table>
<thead>
<tr>
<th>Track</th>
<th>Key Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diffuse</td>
<td>Color (RGB)</td>
<td>RGB values to specify the base color of a material.</td>
</tr>
<tr>
<td>Emissive Color</td>
<td>Color (RGB)</td>
<td>RGB values to enable objects to emit light and be visible in the dark.</td>
</tr>
<tr>
<td>Emissive Intensity</td>
<td>Float (0.00 to 1.0)</td>
<td>Float value that controls the brightness simulating light emitting from the surface that makes an object glow.</td>
</tr>
<tr>
<td>Emittance Map Gamma</td>
<td>Float (1.0 to 2.0)</td>
<td>Float value that expands the lower range of the emittance map. This makes darker colors appear less bright.</td>
</tr>
<tr>
<td>Glossiness</td>
<td>Float (0 to 255)</td>
<td>Acuity or sharpness of the specular reflection. Values of 10 or less create a scattered reflection. Values greater than 10 create a sharp reflection.</td>
</tr>
</tbody>
</table>
## Using the Track View Editor

<table>
<thead>
<tr>
<th>Track</th>
<th>Key Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Indirect Color</td>
<td>Color (RBG)</td>
<td>RGB values to specify that tints the bounce light from global illumination.</td>
</tr>
<tr>
<td>Opacity</td>
<td>Float (0.00 to 1.0)</td>
<td>Degree of transparency. Values less than 50 fall more to the white end of the alpha channel map. Values greater than 50 fall more to the black end of the alpha channel map.</td>
</tr>
</tbody>
</table>
| SSSIndex            | Float (0.00 to 3.99) | Controls subsurface scattering profile and amount.  
For marble, specify a value between 0.01 to 0.99.  
For skin, specify a value between 1.00 to 1.99. |
| Specular            | Color (RGB)  | Reflective brightness and color of a material when light shines on the object. The greater the value, the shinier the material.  
To apply reflections in degrees of black and white, specify the same values for R, G, and B. For colored reflections, specify different values for each. |

### Shadows Setup Node

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.  
Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Shadows Setup node to add or remove sun shadow maps over several frames in a sequence.

**To add a Shadows Setup node in the Track View**

1. In the Track View, right-click the sequence (top node) or the Director node in the tree, and then choose Add Shadows Setup Node.
2. Select the GSMCache key under the ShadowsSetup node.
3. Double-click to position the key on its highlighted row in the timeline.

### Full Screen Effect Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.  
Download O3DE or visit the AWS Game Tech blog to learn more.

Full Screen Effect nodes create post-processing effects for a sequence. They are added by using the context menu for a Sequence or Director node.

**Topics**

- Radial Blur Node (p. 1599)
You can use the Radial Blur node to blur the animation radially outward from a center point.

**To add a Radial Blur node in the Track View**

1. In the Track View, right-click the sequence (top node) or the Director node in the tree as applicable, and then choose Add Radial Blur Node.
2. For each of the keys in the following list, click the applicable key listed under the RadialBlur node.
3. Double-click to position the key on its highlighted row in the timeline.
4. Double-click the green marker, and under Key Properties, enter a value for Value.

**Radial Blur Node Key Properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Amount</strong></td>
<td>Intensity of the blur effect. Range is 0 to 1.</td>
</tr>
<tr>
<td><strong>ScreenPosX</strong></td>
<td>X-axis position of the effect's center. The range is −1 to 1, with 0.5 being the center of the screen.</td>
</tr>
<tr>
<td><strong>ScreenPosY</strong></td>
<td>Y-axis position of the effect's center. The range is −1 to 1, with 0.5 being the center of the screen.</td>
</tr>
<tr>
<td><strong>Blurring Radius</strong></td>
<td>Size of the blur effect. The range is 0 (not visible) to 1 (covers the entire screen).</td>
</tr>
</tbody>
</table>

**Color Correction Node**

You use the Color Correction node to change the CMYK, brightness, contrast, saturation, and hue in a scene. Most color correction properties don't update smoothly. For this reason, you should hide stronger color correction changes should by cuts or fading between scenes.

**To add a Color Correction node in the Track View**

1. In the Track View, right-click either the sequence (top node) or the Director node in the tree as applicable, and then click Add Color Correction Node.
2. Click the applicable key listed under the ColorCorrection node.
3. To position a key, double-click the preferred location on its highlighted row in the timeline. Double-click the green marker, and then under Key Properties enter an applicable value for Value.
**Note**
To have change correction dynamically based on a variable, you can use the **Enable Color Correction** node in the **Script Canvas** editor.

### Adding a Depth of Field Node

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the **Depth of Field** (DOF) node to add realism to scenes to simulate the way a real-world camera works. You can use a broad depth of field to focus on the entire scene, or use a shallow depth of field to have sharp focus only on objects that are a specific distance from the camera.

**To add a Depth of Field node in the Track View**

1. In the Track View, right-click the sequence (top node) or the **Director** node in the tree as applicable, and then choose **Add Depth of Field Node**.
2. For each of the keys listed below, click the applicable key listed under the **DepthOfField** node.
3. Double-click to position the key on its highlighted row in the timeline.
4. Double-click the green marker, and under **Key Properties**, enter a value for **Value**.

**Depth Of Field Node Key Properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable</td>
<td>Enables or disables depth of field effect.</td>
</tr>
<tr>
<td>FocusDistance</td>
<td>Distance the focus is from the camera. Positive values are in front of the camera while negative values are behind the camera.</td>
</tr>
<tr>
<td>FocusRange</td>
<td>Distance toward and away from the camera until maximum blurriness is reached. By default, this value is twice the <strong>FocusDistance</strong> value.</td>
</tr>
<tr>
<td>BlurAmount</td>
<td>Maximum blurriness value.</td>
</tr>
</tbody>
</table>

**Screen Fader Node**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the **Screen Fader** node to fade the screen in and out in a scene.

**To add a Screen Fader node in the Track View**

1. In the Track View, right-click the sequence (top node) or the **Director** node in the tree as applicable, and then choose **Add Screen Fader**.
2. Click the **Fader** key under the **ScreenFader** node.
3. Double-click to position the key on its highlighted row in the timeline.
4. Double-click the green marker, and under **Key Properties**, enter a value for **Value**.
Screen Fader Node Key Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Specifies either FadeIn or FadeOut values.</td>
</tr>
<tr>
<td>ChangeType</td>
<td>For this transition type, you can specify one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Cubic Square</td>
</tr>
<tr>
<td></td>
<td>• Linear</td>
</tr>
<tr>
<td></td>
<td>• Sinus Curve</td>
</tr>
<tr>
<td></td>
<td>• Square</td>
</tr>
<tr>
<td></td>
<td>• Square Root</td>
</tr>
<tr>
<td>Color</td>
<td>Specifies the RGB value used for fading.</td>
</tr>
<tr>
<td>Duration</td>
<td>Specifies how long it takes to fade in or out the screen.</td>
</tr>
<tr>
<td>Texture</td>
<td>Specifies a texture file to use as a screen overlay. An alpha texture is</td>
</tr>
<tr>
<td></td>
<td>commonly used for effects like dirt or blood. The texture is multiplied by</td>
</tr>
<tr>
<td></td>
<td>the color value to allow you to animate the brightness during the fade.</td>
</tr>
<tr>
<td>Use Current Color</td>
<td>Ignores the Color property and uses the color of the previous key instead.</td>
</tr>
</tbody>
</table>

Adding and Removing Animation Keys on Tracks

You can add a keyframe to a track in the timeline with one of the following:

**Double-click the track**

This is the quickest way to add an animation key to the track. This adds a key exactly where you click and stores the data at the exact point in the timeline.

**Add Keys**

In the Keys toolbar, click the Add Keys icon and then click the timeline. This is useful if you need to add many keys to the timeline. To stop adding keys, choose the move, scale, or slide icon.

**Record Mode**

In the Play toolbar, click the Record Mode icon and then makes changes directly to your components.

When you enter record mode, you can update the component entities that are part of the sequence in the viewport. Animation keys are added automatically to the appropriate node tracks in the timeline, based on the current location of the timeline playhead.

For example, if you specify a different value for the Transform component at three seconds, the key for this update appears in the timeline.

To specify an animation to play over time, move the playhead to different places along the timeline. Otherwise, you will overwrite the keys at the same location of the timeline as you update the component entities in the level.
To stop recording, click the **Record Mode** icon again.

For more information, see Using Record Mode (p. 1604).

You can delete individual keys or click and drag to select multiple animation keys.

**To delete keys from your timeline**

1. In the timeline, select a key.
2. Do one of the following:
   - Right-click the key and choose **Delete**.
   - Press **Delete** on your keyboard.
   - In the **Keys** toolbar, click the **Delete Keys** icon.

---

### Controlling the Playhead

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Track View's **Play** toolbar contains the main controls for controlling the playhead for the sequence timeline.

<table>
<thead>
<tr>
<th>Toolbar Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Go to start of sequence</td>
<td>Playhead is moved to the <strong>In</strong> marker of your sequence. For more information, see Setting the In and Out Markers (p. 1603).</td>
</tr>
<tr>
<td>Play</td>
<td>Activates play mode and moves the playhead forward through the sequence timeline. Click the drop-down menu to control the play speed.</td>
</tr>
<tr>
<td></td>
<td>The default is <strong>1x</strong> speed. Other options include <strong>2x</strong>, <strong>1/2x</strong>, <strong>1/4x</strong>, and <strong>1/8x</strong>.</td>
</tr>
<tr>
<td>Stop</td>
<td>Stops the playhead. Click the drop-down menu to specify the default <strong>Stop</strong> or <strong>Stop with Hard Reset</strong>, which returns the playhead to the start of the sequence.</td>
</tr>
<tr>
<td>Pause</td>
<td>During play mode, holds the playhead at the current point in the timeline. When selected again, the sequence resumes playing.</td>
</tr>
<tr>
<td>Go to end of sequence</td>
<td>Playhead is moved to the <strong>Out</strong> marker of the sequence.</td>
</tr>
</tbody>
</table>
Using the Track View Editor

### Toolbar Options

<table>
<thead>
<tr>
<th>Description</th>
<th>For more information, see Setting the In and Out Markers (p. 1603).</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Start Animation Recording</strong></td>
<td>Also known as record mode, you can manipulate objects within the level and the animation keys are automatically added to the sequence. For more information, see Using Record Mode (p. 1604).</td>
</tr>
<tr>
<td><strong>Start Auto Recording</strong></td>
<td>When selected, also activates record mode. The playhead automatically moves in the timeline based on the setting specified in the drop-down menu. The default is 1 sec. Other options include 1/2 sec, 1/5 sec, 1/10 sec, 1/25 sec, 1/50 sec, and 1/100 sec.</td>
</tr>
<tr>
<td><strong>Loop</strong></td>
<td>During play mode, when the playhead reaches the End marker it returns to the In marker of the sequence and continues playing the sequence again.</td>
</tr>
<tr>
<td><strong>Playhead Location</strong></td>
<td>Shows information about the playhead's current location in the timeline and the assigned frame rate.</td>
</tr>
<tr>
<td><strong>Frame Rate</strong></td>
<td>Assigns the frame rate for the sequence. This number is also used for frame snapping.</td>
</tr>
<tr>
<td><strong>Active Camera/Camera Name</strong></td>
<td>Camera name is updated to show which camera is active from the Director Node only if the Editor Viewport Camera is set to Sequence Camera.</td>
</tr>
<tr>
<td><strong>Undo</strong></td>
<td>Reverts the previous action.</td>
</tr>
<tr>
<td><strong>Redo</strong></td>
<td>Applies the previous action.</td>
</tr>
</tbody>
</table>

**Note**
You can also manually adjust the playhead along the timeline. At the top of the sequence timeline, select and drag the playhead to your preferred location.

### Setting the In and Out Markers

The In and Out markers are small red triangles at the top of the sequence timeline. By default, the In and Out markers are set to the beginning and end of the sequence. You can move the markers by right-clicking at the top of the timeline where the frames/seconds are listed. Depending on where you right-click, the Track View identifies which marker is closest to the mouse cursor and moves that one.

For example, if a sequence is 300 frames long, and you right-click at the 50 frame tick, the In marker will move to that spot. If you right-click at the 200 frame tick, the Out marker will move to that spot.
Note
When you move the In and Out markers, this will apply the updated range to the Go to start of sequence, Play, Go to end of Sequence, and Loop settings. For example, if you change the In marker to the two second mark, the Go to start of sequence icon will now move the playhead to the two second mark.

Using Record Mode

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Track View's Play toolbar has the Start Animation Recording icon to enter record mode. In record mode, you can manipulate component entities for a sequence directly in the viewport. Animation keys are automatically placed on the appropriate node tracks in the timeline based on the current location of the timeline playhead.

To use record mode

1. In the Track View, select or create the sequence that you want.
2. In the Play toolbar, click the Start Animation Recording icon.
3. In the viewport, manipulate a component entity that is part of your sequence. Your changes will appear in the timeline as animation keys.
4. To stop recording, click the Start Animation Recording icon again.

Note
You must move the playhead to different locations on the timeline in order to have an animation play over time. Otherwise, you will override the keys at the same timeline location as you manipulate the component entities in the level.

You can also use the Start Auto Recording option. When you choose this option, the playhead automatically moves along the timeline at the specified time. The default is one second. This means that the playhead skips ahead every one second. You can specify a lower value, which means the playhead sets keys more frequently. However, this can result in many keys that you must modify after you are finished recording.

To start auto recording

1. In the Track View, select or create the sequence that you want.
2. In the Play toolbar, click the Start Auto Recording icon. The playhead automatically moves in the timeline based on the setting specified in the drop-down menu.
3. In the viewport, manipulate a component entity that is part of your sequence. As the playhead moves and you make changes to component entities, your changes appear in the timeline as animation keys.
4. To stop auto recording, click the Start Auto Recording icon again.

Example 1: Recording Component Entity Changes

The following example uses the Transform component, but the same idea applies to any component tracks that are specified as animation keys in the sequence. In record mode, you don't need to manually set keys each time you make changes to your component entities.

1. In a level, you have a component entity that is part of a sequence.
2. By default, the Transform component on the component entity already has tracks in the sequence for the Position and Rotation properties.

3. To maintain the current position and rotation of the game object, add animation keys for both tracks at 0 on the timeline.

4. Select and drag the playhead to a different location on the timeline. This example moves the playhead to 1 second.

5. Move the Track View window to the side or dock it so that it's still open but not blocking the viewport for the currently open level.

6. Click the Start Animation Recording icon to enter record mode.

7. In the viewport or the Entity Outliner, select the component entity.

8. Use the Transform tool to move the entity farther back into the level. You can also enter different values in the Transform component properties.

10. Move the playhead to where you want to set another animation key and then adjust the property values again.

11. When finished, click the Start Animation Recording icon again to exit record mode.

Example 2: Recording Camera Movement from Camera View

The following example shows how you can add animation keys automatically in the sequence as you position your camera within the level from the perspective of the specified camera.

1. In a level, you have a component entity with the Camera component that is part of your sequence.
2. By default, the **Transform** component on the component entity has tracks in the sequence for the **Position** and **Rotation** properties.

3. To maintain the current position and rotation of the game object, specify the animation keys on both tracks at 0 on the timeline.

4. Move the playhead to a different location on the timeline.

5. Move the Track View window to the side or dock it so that it's still open but not blocking the viewport for the currently open level.

6. Click the **Start Animation Recording** icon to enter record mode.

7. In the left-corner of the viewport window, right-click **Perspective** and choose **Camera** and then specify the camera that is part of your sequence. The text will change from **Perspective** to **Camera entity: NameOfYourCamera**.

8. While you are viewing from the perspective of the camera, when you move in the level, the camera will move as well. This includes any rotations. In record mode, this adds animation keys at the current playhead location.

9. Move the playhead when you need to set another animation key in the timeline and then move the camera view around in the level.

10. When finished, click the **Start Animation Recording** icon again to exit record mode.
Using Animation Curves

The Curve Editor displays animations as function curves. Each track's curves represent an animation of a property value, such as anchor, offset, color, or any property of a UI element.

To open the Curve Editor

1. Do one of the following:
   - In the Track View, choose View, Curve Editor.
   - In the View toolbar, choose the Curve Editor icon.
2. Select a keyframe in the timeline to view it in the Curve Editor.

Note
You can have the Track View and Curve Editor open simultaneously if you prefer to access both tools.

A curve has the following three parts:

1. Curve or spline.
2. Keys on the curve/spline.
3. Tangent handles for the keys.
To edit elements in a curve

1. Select a key to see the associated tangent handles and then drag the boxes on the keys or the ends of the tangent handles (including unify tangents and automatic tangents) to manipulate them.
2. When moving keyframes, press and hold Shift to constrain the movement to time only.
3. Press and hold Alt to scale the selected keyframes around the playhead location.

The path of the curve represents the transition of the value between the keyframes. If the value changes in a straight line between each keyframe (linear), transitions between keyframes aren’t smooth. The default curve causes the value to smoothly ease in and ease out. Each key has an in tangent and an out tangent. Depending on the preferred effect, you can use the toolbar icons to switch the tangents to auto, zero, step, or linear. You can also manually drag the tangent handles.

By default, animation tracks are recorded with a smooth transition. You can use the buttons in the toolbar at the top of the Curve Editor to change how the curves behave on either side of the selected key. You can also drag spline keys to a different point in the timeline.

See the following tips for working in the Curve Editor:

- To zoom in or out, scroll the mouse wheel
- To pan the view, click and drag the middle mouse wheel
- To select multiple spline keys, click and drag to select the keys

To adjust a spline key

1. In the Node Pane, select a track. The curves for that track appear in the Curve Editor.
2. In the Curve Editor, select a spline key.
3. Do one of the following:
   - Drag the spline key to a different point on the timeline.
   - Use the toolbar buttons to select a preset: auto, zero, step, or linear.

To edit multiple elements at once

1. In the Node browser, select the parent track or sub-track.
2. Drag the spline key to a different point on the timeline.
3. Use the toolbar buttons to select a preset: auto, zero, step, or linear.

Populating a Scene

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Cinematic scenes, also known as sequences, consist of multiple nodes, tracks, and track events. When you create a sequence, the sequence name is always the top (parent) node in the node browser.

For more information, see Using the Track View Editor (p. 1584).

Topics

- Setting Sequence Properties (p. 1609)
- Working with Slices and Sequences (p. 1611)
- Adding Component Entities (p. 1613)
- Moving a Component Entity in a Sequence (p. 1620)
Setting Sequence Properties

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can set properties in the Track View to control how the track view sequence appears. For example, you can specify Autostart so that the track view sequence starts playing as soon as the game starts.

To set sequence properties

1. In the Track View, select the applicable sequence and click the Edit Sequence icon.
2. In the Sequence Properties dialog box, you can specify the following properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>When to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autostart</td>
<td>Plays the scene on game start.</td>
<td>Use for testing purposes only. For scenes that must always play on game start, use triggers instead.</td>
</tr>
<tr>
<td>NoSeek</td>
<td>Disables random seeks in a scene, such as jumping to a certain time.</td>
<td></td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td>When to use</td>
</tr>
<tr>
<td>------------------------------</td>
<td>------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Cut-Scene</strong></td>
<td>Enables various scene toggles. When selected, the following options are available:</td>
<td>This property is required for all scenes that are camera-controlled.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Non-Skippable</strong> – Sets the IAnimSequence::eSeqFlags_NoAbort bit flag to 1. This flag provides a UI to specify whether the sequence can be skipped. Your game code must implement the input and code required to skip a sequence. You can use the IAnimSequence::GetFlags() method in C++ to retrieve the set if bit flags for the sequence.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Disable Player</strong> – Disables the player (required for all camera-controlled scenes).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Disable Sound</strong> – Disables all sounds that are not in the scene.</td>
<td></td>
</tr>
<tr>
<td><strong>Update Movie System First</strong></td>
<td>Reverses the update order. Typically, the movie system updates after the entity system updates.</td>
<td>Fix bone-attached entities that lag behind the parent movement. This problem typically occurs if the parent locator position is animated in the Track View.</td>
</tr>
<tr>
<td><strong>Timing</strong></td>
<td>For <strong>Start Time</strong> and <strong>End Time</strong>, specifies the start and end times of the sequence.</td>
<td></td>
</tr>
<tr>
<td><strong>Display Start/End Time As:</strong></td>
<td>Displays the start and end times. You can specify one of the following:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Frames</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Seconds</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>This is a display-only option; the times are always stored in seconds.</td>
<td></td>
</tr>
<tr>
<td><strong>Out of Range</strong></td>
<td>Changes the movie time behavior when it passes the end of the sequence:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Once</strong> – The movie time continues past the end of the sequence.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Constant</strong> – The movie time is held at the end of the sequence.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Loop</strong> – The movie time loops back to the beginning of the sequence when it reaches the end.</td>
<td></td>
</tr>
</tbody>
</table>
### Property Details

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>When to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Move/Scale Keys</td>
<td>Scales animation curves over the timeline when the start or end times are changed.</td>
<td>Use when you want to lengthen or shorten a sequence, and either slow down or speed up the animations to fill the same relative percentage of the sequence timeline.</td>
</tr>
</tbody>
</table>

3. When you are finished, click **OK**.

## Working with Slices and Sequences

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When you create a track view sequence that has entities contained in slices or add a track view sequence in a slice, the process is the same as creating a track view sequence in a level. The workflow is identical. However, see the following best practices when working with slices and track view sequences.

For more information about slices, see Working with Slices (p. 510).

### Avoid External References

As with any reference in a slice, if you make an external reference from within the slice, that reference will break if you also instantiate the slice in another level.

For example, you have a track view sequence that is in a slice and also animates an entity outside of the slice. When you instantiate that slice in another level, the track view sequence will not be able to find the external animated entity. The animation for that specific entity will not apply to any entity.

To avoid this, ensure that entities that you animate from a track view sequence in a slice is either in the same slice or in a child slice.

### Determine Which Instantiated Slice is in the Active Track View Sequence

If you instantiate a slice that has a track view sequence, this creates another track view sequence with the same name as the original slice.

**Example: Determine which sequence is active**

1. You create a track view sequence named `Seq` that is in a slice and you then instantiate that slice three times in the level.
2. In the Track View, for the **Active Sequence** drop-down menu, you will see `Seq` three times, one for each instantiated slice. Because the slices have the same name, it's unclear which instance of the sequence that you are editing in the Track View.
3. To determine which slice you are editing, in the Track View, in the **Node Browser**, right-click the track view sequence and in the context menu, choose **Select in Viewport**.
4. In the **Entity Outliner**, you can see the selected slice instance and track view sequence that you are editing.

### Avoid Animating the Parent Entity in a Slice

If you instantiate a slice for a track view sequence, ensure that parent entities are not animated. You can animate child entities, but the parent entity cannot be animated in a slice.
Example: Animate Child Entities in a Slice

The Entity Outliner shows two Parent slices, which have two children entities and a track view sequence.

In the Track View, the ExampleSequence animates only the two children entities in the slice. The Parent entity cannot be animated in a slice.

Note
The Transform (p. 878) component is animated in local space relative to its parent. When a slice is instantiated and its root transform is moved, all the child entity animations within also move as well. If you instantiate the slice and move it to a new location, the animations will play at this new location.

Avoid Setting a Director's Camera Track in a Sequence in a Slice

You should assume that multiple slices might be instantiated and playing back the slice sequence at the same time. Therefore, if you have a Director node that sets the camera track in a sequence, that
track may be playing at different local movie times simultaneously. Also, the order of slice animation playback may change between ticks. As a best practice, do not use the Camera track in Director nodes for sequences in slices.

For more information, see Director (Scene) Node (p. 1591).

Adding Component Entities

In the Track View, sequences determine what to animate based on what you add to the sequence. For example, if you want to animate an entity with an Actor or Light component, you can add that component entity to a sequence and then modify its properties.

To add a component entity to a sequence
1. In the viewport or the Entity Outliner, select the entity.
2. In the Track View, select or create the sequence that you want.
3. Do one of the following:
   • In the node browser, right-click and choose Add Selected Entity.
   • On the Sequence/Node toolbar, click the Add Selected Entity icon.

All component entities have the Transform component. This means you can animate the Position and Rotation properties for each component entity that is part of the sequence as needed.

If there are other components attached to the entity, those may also appear in the sequence. However, some components are not available for animating in the Track View.

For components that are available, you can right-click them to see what additional tracks can be added to the sequence. Some component properties can't be added as a track in a sequence and can't be animated.

For more information, see Component Entities and Component Nodes (p. 1586).

See the following topics for working with common component entities in a sequence.

Topics
• Adding Lighting (p. 1613)
• Adding a Camera (p. 1615)

Adding Lighting
You can set up a different lighting scenario in a sequence using light components and/or a time of day settings that are only triggered during the sequence. You can add light components to the sequence and then add the tracks that you want to animate. You can then set the Console Variable Node (p. 1590) to specify the time of day settings.

**Cinematic Lighting Best Practices**

See the following recommended guidelines and best practices for cinematics lighting.

- Lights should be turned on and off while in the Track View. If lights are off by default, they won’t accidentally render in game or interfere with a scene shot. You can animate the Visible track for each light to determine when a light should be turned on or off.
- Disable gameplay and cubemap lights as needed for shots to avoid interference.
- For pre-rendered cinematic scenes, use the console variable `e_timeofday` to trigger the correct time of day.

For more information, see Using the Console Window (p. 210).

- For real-time cinematics, use a track event node to trigger the correct time of day. For more information, see Event Node (p. 1595).
- For pre-rendered cinematic scenes, use the Shadows Setup Node (p. 1598) to enable high quality shadows mode.
- For pre-rendered cinematic scenes, because performance isn't an issue, you should always enable shadow casting and use as many spotlights as needed. Projector textures should be used as much as possible for spotlights. The SpecularMultiplier value should always be 1.
- Shadowmap quality from point lights improves greatly when the ProjectorFOV value is as low as possible. To soften shadows, you can increase the ProjectorFOV value slightly, but this also decreases the accuracy of the shadowmap.
- Don’t use ambient lights as they can weaken contrast and illuminate unwanted areas. Instead, use cubemaps to make the deepest shadow as dark as possible, and then add lights to increase the overall illumination.

**Light Components and Exposed Tracks**

See the following light components and their properties that you can add as tracks to animate in a sequence.

**Area Light (p. 546) component**

- Ambient
- Area FOV
- Area Height
- Area Max Distance
- Area Width
- Color
- Diffuse Multiplier
- Specular Multiplier
- Visible

**Environment Probe (p. 587) component**

Adding a Camera

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add a camera to a sequence so that it presents the sequence from a particular point of view. This helps you control what is being displayed in the animation and how.

Some sequences may require multiple cameras to cut between for different shots. You can use any number of component entity cameras as part of your sequence. The Director (Scene) Node (p. 1591)
helps you determine your active cameras for the sequence as well. You can also set the depth of field (DoF) within the sequence to control the focus view of the camera for the sequence.

See the following topics for working with cameras.

**Topics**
- Adding a Director (Scene) Node (p. 1616)
- Positioning a Camera (p. 1617)
- Animating Depth of Field (p. 1619)

**Adding a Director (Scene) Node**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To determine what camera you want your sequence to use, you must add a Director (Scene) Node (p. 1591).

**To add a Director node in the Track View**

1. In Lumberyard Editor, choose **Tools, Track View**.
2. In the Track View, select or create a sequence.
3. Do one of the following:
   - Right-click your sequence and choose **Add Director (Scene) Node**.
   - Click the **Add Director Node** icon.

By default, the Camera track appears on the Director (Scene) Node to control which camera is active for the sequence. This is the only track that is needed to assign and switch between cameras.

For more information about other tracks that you can add, see the Director (Scene) Node (p. 1591).

When you add an animation key on the Camera track, you can select the key and assign which camera should be active from the Key Properties pane. When a camera is set, you can see the name of the camera on the track.

To create a series of jump cuts from one camera to another camera in a sequence, add animation keys on the Camera track for the Director node. The Director node uses the key properties set for the Camera track to determine which camera to switch.
Positioning a Camera

You can control a camera's position and rotation to manipulate the facing direction during a sequence. These can be animated over time to make the camera dynamic. If you have multiple cameras, you can also control if the cameras switch immediately or if they should blend over time.

Animating the Camera

As a recommended workflow, enter record mode and then animate the camera while viewing from the specific camera's perspective. For more information, see Using Record Mode (p. 1604).

Note
You can still manipulate the component entity camera within the level from the default editor camera. However, this method makes it more difficult to determine where the camera is facing.

Example

1. In a level, you have a component entity with a Camera component attached. This component entity is part of your sequence.
2. By default, the Transform component attached to the entity has the Position and Rotation tracks in the sequence.
3. To maintain the current position and rotation of the game object, add animation keys on both tracks at 0 on the timeline.
4. Select and drag the playhead to a different location on the timeline.
5. Move the Track View window to the side or dock it so that it's open but not blocking the viewport for the currently open level.
6. Click the Start Animation Recording icon to enter record mode.
7. In the left-corner of the viewport window, right-click Perspective and choose Camera and then specify the camera that is part of your sequence. The text will change from Perspective to Camera entity: NameOfYourCamera.
8. While you are viewing from the perspective of the camera, as you move in the level, the camera moves as well. This includes any rotations. In record mode, this adds animation keys at the current playhead location.
9. Move the playhead when you need to add another animation key in the timeline and then move the camera view around in the level.

10. When finished, Click the **Start Animation Recording** icon again to exit record mode.

### Blending Cameras

By default, when you switch between cameras, the change is immediate. However, if you want a smoother transition, you can blend the cameras together. You can blend a camera in and out of the camera-controlled sequence, or blend between cameras that are part of the sequence.

#### Blending from Game Camera to Sequence Camera

**To use the default game camera**

1. Under the **Director** node, for the **Camera** track, add an animation key to the timeline.
2. Double-click the animation key and verify that the **Camera** property is set to **None**.
3. Add another key on the timeline for the **Camera** track. You can add the key at the beginning or end of the sequence, or both.
4. Double-click the animation key before a camera change, and for **Blend time**, specify a value in seconds. This value determines how the current camera will blend into the next.

   **Note**
   
   This creates a blend between the game camera to the sequence camera, or from the sequence camera back to the game camera, depending on where you place the key and adjust the **Blend time**.

#### Blending Cameras within a Sequence

Blended camera keys will blend the position, rotation, and field of view of the current camera into the next camera on the **Camera** track. This allows the cut to appear as a continuous single camera motion rather than an abrupt jump cut.

**To create a blended camera key**

1. Select the key for the first camera of the blend.
2. Double-click the key and do the following:
   
   a. For **Camera**, select the camera that you want to start.
   b. For **Blend time**, specify a value greater than 0. This is the time in seconds over which the blend will occur.
Example

If you add the first camera as a track view node, then you must add at least one animation key for the Position, Rotation, and Field of View tracks when using blended sequence cameras.

In this sequence, the Camera track starts at 0 seconds for CinematicsCamera and will blend into Camera5 at 2 seconds.

Animating Depth of Field

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Camera focus, or depth of field (DoF), is used to add realism to scenes, which simulates the way a real-world camera works. You can use a broad DoF to focus on the entire scene, or use a shallow DoF to have sharp focus only on objects that are a specific distance from the camera.

See the following guidelines and best practices when setting up camera focus:

- Always keep characters in focus.
- Shift focus slowly and deliberately.
- Don't overdo camera focus
- Don't use DoF for scenes that are far away. DoF works best for differentiating between closeups and the background.

- Use your eyes to focus at different distances and see what is sharp and what is blurred. You can use your thumb as a helper. This should give you a sense of how it should look in a scene.

DoF is rendered only for a single view pane layout (the default) in the viewport in Lumberyard Editor. If you are using a multiple view pane layout and the sequence camera is not in the active pane, DoF doesn't render. If you need to set this, do the following.

To set the viewport for a single view pane layout

1. In Lumberyard Editor, right-click the Perspective title bar in the viewport and choose Configure Layout
2. In the Layout Configuration dialog box, select the single view pane and then click OK.
3. Right-click the Perspective title bar again and choose Sequence Camera.

To add a Depth of Field node

1. In the Track View, select or create the sequence that you want.
2. In the node browser, right-click the Director node or any Camera node and choose Add Depth of Field Node.

Camera nodes take precedence over the Director node. Use the Director DoF node if you want the same DoF setup for multiple cameras. In most cases, you want separate, specific DoF setups for each camera for more control.

You can add as many keys as you want, and use the Curve Editor to further adjust DoF settings to change over time.

For more information, see Using Animation Curves (p. 1607).

Moving a Component Entity in a Sequence

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Each component entity has a Transform component. By default, when you add a component entity to a sequence, the Position and Rotation tracks appear automatically. You can manipulate the Position and Rotation properties for the component entity in a sequence. You can also add the Scale track if you want to manipulate the overall size of the component entity.

Each of the tracks has a subtrack for XYZ properties so that you can animate each axis.
You can add any number of keys for each track as needed, and adjust the transitions with the Curve Editor.

For more information, see Using Animation Curves (p. 1607).

When moving component entities, we recommend the following workflows:

- Manipulate the component entity in the level and then manually add your animation keys.
  
  For more information, see Adding and Removing Animation Keys on Tracks (p. 1601)
- Use record mode to set your keys. For more information, see Using Record Mode (p. 1604).

To set transform keys with record mode

1. In the Track View, create or select sequence and add a component entity. See Adding Component Entities (p. 1613).
2. By default, the Transform component attached to the entity automatically adds the Position and Rotation tracks to the sequence.
3. To maintain the current position and rotation of the game object, add an animation key for both tracks at 0 on the timeline.
4. Select and drag the playhead to a different position on the timeline.
5. Move the Track View window to the side or dock it so that it’s still open, but not blocking the viewport for the currently open level.
6. Click the Start Animation Recording icon to enter record mode.
7. In the viewport or the Entity Outliner, select the component entity.
8. Use the translation tool to move the entity farther back into the level. You can also enter values in the Transform component properties.
9. View the timeline for the sequence. New keys appear on the **Position** track at the 1 second position.

10. Move the playhead to where you want to set another animation key and then adjust the property values again.

11. When finished, click the **Start Animation Recording** icon again to exit record mode.

### Animating Characters in Scenes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To create character animations with the Track View, you can add the **Simple Motion** component and the **Actor** component to an entity. This creates a character, which you then add to a track view sequence.

**Topics**
- Creating Character Animations with the Simple Motion Component (p. 1622)
- Moving an Entity in a Scene (p. 1629)

### Creating Character Animations with the Simple Motion Component

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To create character animations with the Track View, you can add the **Simple Motion** component and the **Actor** component to an entity. You then add the entity to a track view sequence and specify the motions that you want your character to animate. When you add a motion track to a track view sequence, the Track View drives animation on the **Simple Motion** component and its properties:

- **Motion**
- **Play speed**
- **Play time**
- **Blend in time**
- **Blend out time**

For more information, see the **Simple Motion** (p. 826) component.
Note

- The Play speed property is always set to 0.0. This is because the Track View will set the Play time value every frame to drive the playback of the motion. This allows scrubbing and playback in the Track View as well as playback in the game.
- When you add the Simple Motion component to a track view sequence, the Preview in Editor property is automatically enabled.

The following procedure uses Starter Game (p. 148).

To add the Simple Motion component in the Track View editor

1. In Lumberyard Editor, right-click in the viewport and choose Create entity.
2. Enter a name for the entity.
3. In the Entity Inspector, click Add Component, and then choose the Simple Motion component.
4. Add the Actor (p. 536) component.
5. In the Actor component, for Actor asset, specify an actor file. For example, you can specify the Jack.fbx file.

Example

Your entity should look like the following.
6. In Lumberyard Editor, choose **Tools, Track View**.

7. Click the **Add Sequence** icon, enter a sequence name, and then click **OK**.

8. Select the entity in the viewport, right-click the sequence, and then choose **Add Selected Entity**.

This adds the entity and its components to the track view sequence.

9. Right-click **Simple Motion**, choose **Add Track**, and then choose the **Motion** option.

10. In the timeline, for **Simple Motion**, double-click to create to a key.

11. Click the key and in the **Key Properties** dialog box, specify the following:
   
   a. For **Motion**, click the folder icon and specify the motion file, such as `jack_idle_to_walk.motion`.
   
   b. Specify the parameters that you want, such as the **Start Time** and **End Time**.

   **Note**
   You can set the **Loop** parameter so that motion continues to play as long as the track view sequence is set.

**Example**

12. Click the play icon to view the animation in the track view sequence. You can also drag the Track View needle across the timeline.
### Example

The following shows the actor animating the idle to walk motion.

![Animation Track View](image)

#### Note

When you update properties in the Track View, the original values for the entity properties are overwritten and are not restored. For example, if you set the **Start time** to 3.0 in the Track View, this updates the **Simple Motion** component properties in the **Entity Inspector**. If you want to reuse an entity with a **Simple Motion** component after a track view sequence is completed, update the **Play speed** parameter; the **Play speed** parameter always resets to zero in the Track View. You can also avoid this issue by not reusing entities in this way.
Blending Motions in the Track View Editor

The **Simple Motion** component supports two motions at a time for blending: the currently playing motion and the previously played motion. For example, you can blend two motions so that your actor smoothly transitions between a walk motion to a run motion.

You can set the **Blend In Time** and **Blend Out Time** properties for simple animation blending.

- **Blend In Time** – Specifies how long it takes for the motion that is set to fully blend in from zero to one second.
- **Blend Out Time** – Specifies how long it will take for a motion to fully blend out from one to zero second.

To blend two motions, overlap two animations and set the **Blend Out Time** of the last motion to 0.33 seconds, and the **Blend In Time** of the next motion by 0.33 seconds. This allows the two motions to smoothly chain together in the track view sequence.

**Note**
- If you want your animation to start when the game starts, click the **Edit Sequence** icon and in the **Edit Sequence** dialog box, select **Autostart**, and then click **OK**. For more information, see Setting Sequence Properties (p. 1609).
- The **Blend In Time** and **Blend Out Time** parameters affect the bone weight that are set in your DCC.

To blend motions in the Track View Editor

1. Double-click the first key and for **Blend Out Time**, enter 0.33. This allows the first motion, `jack_idle_to_walk.motion`, to blend into the next motion.

**Example**

2. Double-click the timeline to create a second key.

3. Double-click the key again and in the **Key Properties** dialog box, specify the following:
   a. For **Motion**, click the folder icon and specify the next motion, such as the `jack_strafe_run_forwards.motion` file.
   b. Specify the parameters that you want, such as the **Start Time** and **End Time**. For **Blend In Time**, enter 0.33. This allows enough time to overlap with the previous motion.

**Example**
4. Select and drag the second key so that overlaps with the first motion track.

5. Repeat steps 2 to 4 to add additional motions. For a motion that is ending, enter 0.33 for **Blend Out Time**. For the motion that starts next, enter 0.33 for **Blend In Time**.

**Example**

The following is a timeline with four motions blended together.

6. Click the play icon to view the track view sequence. You can also drag the Track View needle across the timeline. The motions blend together in the track view sequence.
Moving an Entity in a Scene

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Track View to move or rotate any entity in a scene.

To move a character in a scene

1. In the Track View, add the character to the desired sequence, then click the red record button.
2. In the Lumberyard viewport, click the character, then move or rotate as desired. This automatically updates keys at the current position of the slider in the track view sequence timeline slider.
3. Double-click the key to access Key Properties, then adjust values as needed.
4. Click the Curve Editor button, then select the tracks where the curve needs to be adjusted.
5. Drag a selection box around all the keys you want to change.
6. Click the **Set In/Out Tangents to Auto** button.

## Capturing Image Frames

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can capture image frames using render output, a capture track, or console variables.

**Topics**
- Capturing Image Frames with Render Output (p. 1630)
- Capturing Image Frames using a Capture Track (p. 1630)
- Capturing Image Frames with Console Variables (p. 1631)

### Capturing Image Frames with Render Output

You can use the **Render Output** tool in the Track View to capture image frames.

**To capture image frames using Render Output**

1. In Lumberyard Editor, choose **Tools, Track View**.
2. In the Track View, click **Tools, Render Output**.
3. In **Render Output**, set the input and out properties, and then click **Add**. You will see the capture added under **Batch**.
4. Click **Start** to start the capture.

**Note**

You may need to adjust the aspect ratio for captured image frames.

**To change the aspect ratio for image frame captures**

1. In Lumberyard Editor, choose **Edit, Editor Settings, Global Preferences**.
2. In **Preferences**, click **Viewports**.
3. Under **General Viewport Settings**, change the value for **Perspective View Aspect Ratio**. The default value is 1.3333.

### Capturing Image Frames using a Capture Track

You can capture image frames when a sequence is played in game mode.

**To capture image frames using a capture track**

1. In Lumberyard Editor, choose **Tools, Track View**.
2. In the Track View, right-click the **Director** node and choose **Add Track, Capture**.
3. Double-click the created track to add a capture keyframe. You can set the following key properties:

<table>
<thead>
<tr>
<th>Key Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Duration</strong></td>
<td>Sets the capture duration in seconds.</td>
</tr>
</tbody>
</table>
Capturing Image Frames

### Key Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Time Step</strong></td>
<td>For a fixed frame rate, in seconds, by using a specified time step. Time step = 1/number of frames. Units are in 1 fps (frames per second), so a time step value of 0.0333 results in a game frame rate of 30 fps.</td>
</tr>
<tr>
<td><strong>Output Format</strong></td>
<td>Specifies the image output file format.</td>
</tr>
<tr>
<td><strong>Output Prefix</strong></td>
<td>Specifies a prefix to apply to the image file names. For best results, use the same prefix as the sequence for clarity.</td>
</tr>
<tr>
<td><strong>Output Folder</strong></td>
<td>Specifies the directory where the image files are stored under the following path:</td>
</tr>
<tr>
<td></td>
<td>lumberyard_version\dev\Cache\project_name\pc\project_name\</td>
</tr>
<tr>
<td><strong>Buffer(s) to capture</strong></td>
<td>Specifies the image capture format. Choose from the following options:</td>
</tr>
<tr>
<td></td>
<td>• Color – RGB pixel information</td>
</tr>
<tr>
<td></td>
<td>• Color+Alpha – RGB pixel data and Alpha channel data</td>
</tr>
<tr>
<td></td>
<td>Note: To capture Alpha channel data, you must set Output Format to tga.</td>
</tr>
<tr>
<td><strong>Just 1 Frame</strong></td>
<td>Chooses between single or multi-frame image capture.</td>
</tr>
</tbody>
</table>

4. Set up a Script Canvas graph to play the sequence on game start.

### Capturing Image Frames with Console Variables

Capture image frames with the following console variables. For more information, see Using the Console Window (p. 210).

**Capture Image Frames Console Variables**

<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fixed_time_step</td>
<td>Lowers the game speed to achieve a constant frame rate throughout the sequence. For example, a time step value of 0.04 specifies a 25 fps gameplay speed. Default value: 0.0</td>
</tr>
<tr>
<td>capture_frames</td>
<td>Enables frame capture, if the value is set to 1.</td>
</tr>
<tr>
<td>capture_file_format</td>
<td>Sets the output format for the images. Valid values: .jpg, .tga, .tif</td>
</tr>
<tr>
<td>capture_file_prefix</td>
<td>Sets a file name prefix to use for captured frames.</td>
</tr>
</tbody>
</table>
Debugging Cinematic Scenes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can specify the following console variables when profiling a scene. For more information, see Using the Console Window (p. 210).

**Cinematic Scene Console Variables**

<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Description</th>
<th>Valid Values</th>
</tr>
</thead>
</table>
| e_DisplayInfo    | Displays basic performance information. The console variable also displays a warning if you exceed texture streaming memory. | 0 = Off  
1 = On  
2 = Enhanced  
3 = Compact |
| p_profile_entities | Runs your scene and looks for fluctuations. You can use this console variable to identify which entities are causing large peaks. | 0 = Off (default)  
1 = On |
| r_Stats | Toggles render statistics. Specify a value of 6 to finds assets with large draw calls or excessive materials. For example, this can help you find where shadows can be disabled, and so on. | 0 = Off  
1 = Displays per-frame and global render statistics.  
2 = Displays shaders for selected object.  
3 = Displays the CPU times for render passes and video memory usage.  
4 = Displays CPU times for render passes only.  
5 = Displays occlusion query calls. |
<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Description</th>

Working with shaders and materials

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

There is a close relationship between materials, textures and shaders. For a material, you select a shader and then specify the material's properties and attributes such as color, specularity, and texture that are used by the shader for rendering the object. In this way, the shader entirely defines how the object looks. Lumberyard uses physically-based rendering (PBR) shaders, which use real-world physical rules and properties to describe how light interacts with the surface of objects. This means that game object...
materials look realistic under all lighting conditions. For more information, see Shader Rendering System (p. 1639).

For computer monitors, the sRGB (instead of RGB) color space is used. Using sRGB, you have greater precision for darker colors to which the human eye is more sensitive. sRGB also minimizes any banding artifacts. Always ensure that your monitor is calibrated properly. In sRGB, a 50% mid-gray is not 0.5 or 127 but rather 0.5 raised by the inverse of gamma 2.2, which equals 187 in Adobe Photoshop. For Photoshop, make sure that color management is be set to sRGB and Gray-to-Gray Gamma 2.2. By default, Gray is often set to Dot Gain 20%, which results in a color transformation in the alpha channel. A value of 127 comes into Lumberyard as 104 and cause inconsistencies.

The Material Editor is the primary tool used to create materials, texture mapping, setting opacity and lighting effects, setting shader parameters, vertex deformations, tessellation, and more, as shown below.

Topics

- Concepts (p. 1638)
- Shader Rendering System (p. 1639)
- Shader Reference (p. 1652)
- Selecting Material Surface Type (p. 1721)
- Setting Material Opacity (p. 1721)
- Setting Material Lighting and Color Settings (p. 1722)
- Material ID Mapping in Autodesk 3ds Max (p. 1723)
- Working with Textures (p. 1732)
Materials

A material has a set of properties that determines how its surface (p. 1721) reacts to physical actions, other materials, and its environment. For example, a metal surface is hard, doesn't shatter, reacts to bullets by generating spark particles, and has a unique sound when struck. Contrast this with a grass surface, which is soft, responds to wind, generates grass strands and dirt particles when hit, and sounds different than metal.

Within the definition of a material, you can also change its transparency (opacity (p. 1721)) level, color, specular reflections, glossiness, and glow (p. 1722). Textures (p. 1638) and shaders (p. 1639) are parameters of a material.

Textures

A texture is simply a 2D image. This image file can be a digital photo or other image file created with Photoshop, paint programs, or other applications.

In Lumberyard, these image files can be imported from .tif, .jpg, .png, .bmp, or .tga images. When you browse to select them in the Material Editor, for example, they appear with their original file extensions but are actually processed as .dds texture files.

Lumberyard uses textures to help define what the surface of an object looks like. You can layer textures on top of each other to define different aspects of the material's appearance. Lumberyard uses the following types of texture maps. These are the most common types you'll use with the default Illum (p. 1697) shader.

Diffuse (p. 1748)

Defines the base color of the material. For example, this could be a detailed image of a marble surface or wood grain. Defining a diffuse texture is optional; if you need a uniform color, you can instead define a diffuse color or tint.

Normal (p. 1749)

Simulates bumps on the surface of the material. Using a normal map can make a low-polygon mesh look like it has high-resolution geometry. Normal maps do not change the actual geometry of the surface to which it's mapped but only simulate variances in height. For example, a rock wall with a normal map applied might look like it has holes and projections that respond to light and shadows.
when the viewer faces it directly. But when viewed from the side, its silhouette appears as a flat surface.

**Specular**

Defines a surface's shininess and the color of its reflective highlights. A high value pixel (for example, white or light colors) renders a material as more shiny, such as metal details. A lower value pixel (for example, black, gray, or other dark colors) renders a less reflective surface, such as leather.

**Detail (p. 1751)**

Provides additional detail for close-up viewing. This map is typically a small image that is tiled many times across a larger surface. This level of detail would appear only at a close range; from a distance, the object still retains its normal level of detail. For example, a boulder can gain extra details such as scratches and dents or a porous surface when viewed at close range. Human skin can appear smooth from a distance but show pores and imperfections when viewed up close. To use, enable Detail Mapping under Shader Generation Params.

**Heightmap (p. 1757)**

Specifies height or elevation in a grayscale image that uses 256 shades. Black and white represent the lowest and highest elevations, respectively. High-quality 32-bit heightmaps (p. 1230) are recommended for large terrain areas. An important difference between heightmaps and normal mapping is that a heightmap changes the actual geometry of the surface to which you apply it. This is crucial, for example, if you apply a heightmap to a terrain, as objects and players need to respond to the changes in elevation. In Lumberyard, the heightmap setting in the Material Editor can be applied as offset bump map, POM, silhouette POM, and displacement mapping.

**Emittance Multiplier**

Multiplies the emissive color with RGB texture.

**Decal Opacity (p. 1752)**

Alpha mask used for decal entities. To use, enable Decal under Shader Generation Params.

**Emittance**

Multiplies the emissive color with RGB texture. Emissive alpha mask is contained in alpha channel.

**Shaders**

Shaders (p. 1639) use real-world physical rules and properties to describe how incoming light interacts with objects. This means that object materials look more convincing under different lighting conditions. The two main types of shaders are metallic and nonmetallic. Examples of metallic materials include iron, gold, and copper. Nonmetallic material examples include plastic, stone, wood, skin, and glass. A shader can also mix metal and nonmetal materials.

**Shader Rendering System**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard uses physically-based rendering (PBR) shaders that use real-world physical rules and properties to describe how incoming light interacts with objects. This means that object materials look more convincing under different lighting conditions. A basic understanding of how light interacts with objects in the real world can be very helpful when setting up materials.
Each shader has a unique set of shader parameters (Shader Params) and generation parameters (Shader Generation Params). Some shader parameters become available (are visible) only if an associated shader generation parameter is first enabled. This is also true for certain texture map slots (file paths) under Texture Maps. For a listing of all shaders, see Shader Reference (p. 1652).

There are two categories of materials that are relevant for shader rendering: metals such as like iron, gold, copper, and non-metals such as plastic, stone, wood, skin, glass. Each has different diffuse and specular reflectance characteristics.

**Shading Metallic Materials** - Metal reflects all visible light, hence has specular reflectance. The different types of metal have different specular colors, and should always be above sRGB 180. Metal has no diffuse reflection and thus has a black diffuse color. Rusty metal however needs some diffuse color.

**Shading Nonmetallic Materials** - In contrast, non-metals have diffuse reflection with weak, monochromatic (gray) specular reflections. Most non-metals reflect only 2%-5% of the light as specular. The sRGB color range for most non-metal materials is between 40 and 60 and should never be above 80. A good clean diffuse map is required for non-metals.

As the variation is so little, it is often enough to use a constant specular color instead of a specular texture map.

**Shading Mixed Metal and Nonmetal Materials** - Materials that contain both metals and non-metals require a specular map, as metal has a much brighter specular color than non-metal. If a specular map is used, the specular color should be set to white (255/255/255) - as it gets multiplied with the values from the specular map and would otherwise lower the physical values from the map.

To access a shader

1. In Lumberyard Editor, click **Tools, Material Editor**.
2. In the left tree pane, select a material to work with.
4. Locate shader-specific parameters under **Shader Params** and associated **Shader Generation Params**.

**Topics**

- Image-Based Lighting (p. 1640)
- Environment Probes and Cubemaps (p. 1641)
- Height Map Ambient Occlusion (p. 1641)
- Developing a Custom Shader (p. 1642)

**Image-Based Lighting**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Image-based lighting is a rendering technique where complex lighting is stored in an environment map that is projected onto a scene. In simple words, a light probe or environment map is just an image on a sphere.

If the range of the image colors is within some small defined range (0-255 for monitor displays), the image is LDR (low dynamic range). With HDR (high dynamic range) some rendering effects become more
apparent and correct (DOF, motion blur, bloom, dark materials, global illumination). Depending on the image and compression requirements, various texture formats can be useful.

Diffuse lighting can be approximated very well by diffuse-convolving an environment map, which can be stored as a cube map again. Because of bilinear filtering, the texture can be quite low resolution. Mip maps are not required and the result with mip maps can actually look worse as ordinary mip mapping on the GPU is computed for each 2x2 pixel block and 2x2 block artifacts can become noticeable.

Environment Probes and Cubemaps

Cube mapping uses the six faces of a cube as the texture for a material. The cube map is generated by projecting and then rendering the scene six times from a single viewpoint, one for each cube face. In this way, the local environment can be stored as either six square textures, or unfolded onto six regions of a single texture. This texture is used to store the image of the environment surrounding the object. Cube maps are useful for showing reflections, and are relatively small in size because reflections can be blurry as long as you are not simulating a mirror.

Cube maps control shadow color, ambient diffuse, and particle diffuse as well as reflections. They function as bounce lighting by taking the colors from the surroundings and applying them directly into the diffuse texture of materials inside their specified radius.

For information about using environment probes and cubemaps, see Environment Lighting (p. 1779)

Cube maps use image-based lighting. For more information see Image-Based Lighting (p. 1640).

Height Map Ambient Occlusion

Ambient occlusion (AO) is a technique used to calculate how exposed each point in a scene is to ambient lighting. The lighting at each point is a function of other geometry in the scene. For example, the interior of a building is more occluded and thus appears darker than the outside of the building that is more exposed.

Lumberyard uses height map-based ambient occlusion (AO), which is a high-performance and efficient method of providing ambient occlusion in outdoor environments without the need for prebaking. This make it suitable for PC, consoles, and virtual reality headsets.

In combination with screen space directional occlusion (SSDO), height map AO provides additional shading cues that enhance the depth perception of a scene.

To enable height map ambient occlusion

1. In the Rollup Bar, click the Terrain tab, and then choose Environment.
2. **Under Terrain**, select the **Height map AO** check box.

The influence that height map AO provides can be restricted using clip volumes and vis areas. Both of these object types have a **IgnoreHeightMap AO** check box that will locally disable height map AO inside the volume or area.

By default, evaluation is performed at quarter-display resolution. This can be changed using the **r_HeightMapAO** console variable, as listed below.

Heightmap AO uses the following console variables:

- **r_HeightMapAO** – Sets the resolution that evaluation is performed at. Values are: 0=off, 1=quarter resolution, 2=half resolution, 3=full resolution.
- **r_HeightMapAOAmount** – Sets the strength of the occlusion effect when combined with the scene.
- **r_HeightMapAORange** – Area around the viewer that is affected by height map AO.
- **r_HeightMapAOResolution** – Texture resolution of the height map used for approximating the scene.

### Developing a Custom Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Most visual effects in Lumberyard are produced by shaders, which employ a number of standard and advanced lighting models like Blinn, Cook-Torrance, Oren-Naye, Kajiya-Kay, and some custom models.

There are two types of shaders used: lighting shaders that interact with scene illumination, and regular shaders that don’t calculate any lighting information and are used for post-processing effects. All lighting shaders have a common structure and make use of a unified shading interface. This interface should always be used to ensure proper usage of the lighting pipeline, minimize code duplication and save a lot of work.

Lumberyard uses an ubershader system with compile-time defines to handle the many different shader permutations that are required for combining numerous shader features. The shader format used that is very similar to High-Level Shader Language (HLSL), DirectX FX, and CgFX.

Shader development is a programming discipline onto itself and requires expert knowledge to optimize as shader code can be performance-critical and platform-dependent.

The easiest way to create new shaders is with a text editor.

**To create a new shader**

1. Using a text editor, copy an existing .ext extension file and associated .cfx effect file.
2. Add the shader's file name to the **lumberyard_version/dev/Editor/Materials/ShaderList.xml** file.
3. Restart the Material Editor. The new shader appears and you can assign it to a material.

Shader Development Best Practices

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Shaders add flexibility to the modern rendering effects seen in games today. To save you the trouble of managing multiple shader permutations, the shader compiler automatically creates the permutations for you when it parses the code, hiding the complexity. However, this process requires high memory performance and requires long compile times.

See the following guidelines and best practices when you develop a custom shader for Lumberyard:

- Before creating a new shader, make sure that you can't reuse or parameterize one of the existing shaders.
- Precompute as much as possible. Place the shaders in either textures or in the vertex shader and pass the data to vertex interpolators.
- For performances reasons, try to reduce the usage of sincos (8 ALU), normalize (3 ALU), pow (3–9 ALU), divisions (3 ALU), and smoothstep because of their higher execution cost.
- Pack as much data as possible in each texture instead of doing multiple texture lookups. Texture lookups are expensive on consoles and older hardware.
- Shader code is compiled depending on permutation flags that can come from various sources, such as material and runtime flags. These flags are defined in the following files:
  - `runtime.ext` – This file contains all runtime flags that can be shared by all shaders. You can review the file to better understand how to add flags and apply to any newly added shader that requires an existing runtime flag.
  - `shader_name.ext` – These files define shader-specific flags that are exposed in the Material Editor.
- Having many flags leads to many shader permutations. For best results, try to keep the number of flags relatively small.

Compiling Shaders in Debug Mode

To debug shaders in applications such as RenderDoc, Nsight, or Pix, it's important to enable shader debugging information. By default, shaders are optimized and don't output potentially useful debugging information. You can use the `r_ShadersDebug` console variable to enable debug information when needed.

To enable shader debug compiler options

1. To ensure a clean compile, we recommend that you first delete your `lumberyard_version\dev\Cache\your_game\platform_type\user\cache\shaders` directory.
2. In a text editor, navigate to the `lumberyard_version\dev\system_windows_pc.cfg` file.
3. Add the following console variable to the file.

   `r_ShadersDebug=3`
The console variable will change the DX11 compile flags in order to disable optimizations (/Od) and enable debugging information (/Zi).

4. Save the file. Lumberyard will automatically compile new shaders.

**Note**
You can modify some console variables at runtime. However, we recommend that you add this console variable to the `system_windows_pc.cfg` file. For more information, see Using the Console Window (p. 210).

**Shader Rendering Pipeline**

Lumberyard has a fixed rendering pipeline that is set up in the renderer code. Lumberyard is almost fully deferred and only does forward for hair, eyes, glass, transparencies, and water reflections. Lumberyard makes use of two elements: effects that define parameterized shader code, and materials that customize the shader parameters for a specific mesh.

First, Lumberyard fills the off-screen buffers like reflection buffers and shadow maps. After that, it writes the scene depth to the frame buffer and additionally to a render target. Having access to scene depth is essential for some subsequent rendering steps like screen space ambient occlusion or fog rendering. After the depth is written, Lumberyard does the forward lighting. The shadow contributions are written in a separate step to a texture that combines the shadowing result from several light sources (deferred shadowing). Finally, translucent objects are drawn in a back-to-front order.

When Lumberyard tries to render an object it will first check if a compiled shader is available. If the shader is not available, Lumberyard will try to load it from the global shader cache. If the shader cannot be found in the cache, the rendering thread will issue a request to stream the shader in from disk and will block until the streaming load is complete. This can cause severe stalls due to the relatively long time needed to load data from disk.

**Hot Reloading of Shaders**

Lumberyard supports hot reloading of shaders, so whenever you modify and save a shader file, it will get reloaded automatically and the results can be viewed directly in a test level.

For hot reloading to work, shader files must be copied to the appropriate locations, and the following requirements must also be met:

- Add the following code to the `dev\system.cfg` file:

```plaintext
sys_PakPriority=0 <!--ensures the shader files get loaded from the file system instead of from pak files>

r_ShadersEditing=1 <!--ensures that shader code can be recompiled at runtime-->
```

- In the Console, enter `r_reloadshaders 1`. This is only required in the game executable. In Lumberyard Editor, it will automatically reload a shader when you modify it.
For Lumberyard, copy the shader files to the `dev\Lumberyard\Shaders` directory.

**Remote Shader Compiler**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard's remote shader compiler application provides a convenient way to compile shaders during development. You can install the shader compiler on a PC or Mac local network server that can communicate over TCP. The server receives the shader source file from a computer running Lumberyard, compiles it, and sends back the shader. Almost all renderers require a remote shader compiler. The exception is a PC running DX11, for which a remote shader compiler is optional for local development.

The remote shader compiler is used to store all the shader combinations that have been requested by the game so far. Ideally, during development, you set up a remote shader compiler server for all designers, developers, and testers to connect to while building the game. This builds a comprehensive shader list (`ShaderList.txt`), which you then use to generate the shaders and compress them into `.pak` files for the game to use.

If preferred, you can also set up the shader compiler locally on a PC rather than setting up a central remote shader compile server.

Lumberyard also generates its own `ShaderList.txt`, which records all of the shader combinations requested on that particular instance of Lumberyard. When preparing the game for release, Lumberyard's local `ShaderList.txt` for shader generation is sufficient if the game is developed solely on one instance of Lumberyard. Otherwise, if a team is developing multiple levels or using a very large map, some shaders may be missed by using the `ShaderList.txt` in the Lumberyard application's file system.

On a PC, the remote shader compiler can generate shaders for Lumberyard running on the following systems. For information about the options listed with the systems, see Game Development Configuration (p. 1648).

- PC (DX11) with `r_ShadersRemoteCompiler=1`
- Consoles
- Android OpenGL ES 3.1 mobile device with `r_ShadersUseLLVMDirectXCompiler=0`
- Android OpenGL ES 3.0 mobile device with `r_ShadersUseLLVMDirectXCompiler=0`
- Mac with `r_ShadersUseLLVMDirectXCompiler=0`
- Mac with `r_ShadersUseLLVMDirectXCompiler=1`
- iOS mobile device with `r_ShadersUseLLVMDirectXCompiler=0`
- iOS mobile device with `r_ShadersUseLLVMDirectXCompiler=1`

On a Mac, the remote shader compiler can generate shaders for Lumberyard running on the following:

- Mac with `r_ShadersUseLLVMDirectXCompiler=1`
- iOS mobile device with `r_ShadersUseLLVMDirectXCompiler=1`

**Important**

Ensure the server or computer that is running the remote shader compiler is in a controlled environment that restricts incoming network requests to only authorized and trusted users or devices. Don't run the remote shader compiler with escalated root, admin, or super-user privileges.
Running the Remote Shader Compiler

You can find the remote shader compiler, CrySCompileServer, in the following directories:

- PC – \lumberyard_version\dev\Tools\CrySCompileServer\x64\profile\n- Mac – \lumberyard_version\dev\Tools\CrySCompileServer\osx\profile\

A configuration file (p. 1646) is also available for configuring the TCP port that the server application will listen on.

You can launch the remote shader compiler by starting CrySCompileServer.exe manually. However, usually it makes sense to set it up as a service, so that it always starts with the operating system.

Because requests for shaders are executed in parallel, you may notice significant delays in acquiring shaders at runtime.

Remote Shader Compiler Configuration

You configure the remote shader compiler by creating or editing the config.ini file, which is located in the following directories:

- PC: \lumberyard_version\dev\Tools\CrySCompileServer\x64\profile
- Mac: \lumberyard_version\dev\Tools\CrySCompileServer\osx\profile

To configure the remote shader compiler, edit the following parameters.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MailError</td>
<td>Set to an internal company email address to which notifications about compilation errors will be sent.</td>
</tr>
<tr>
<td>TempDir</td>
<td>The cache directory in which the binary shaders are stored once they are compiled. This parameter must point to a valid absolute path. The default path is C:\SHADER_CACHE.</td>
</tr>
<tr>
<td>port</td>
<td>TCP port, which must match the setting in the game system_platform_shader_version.cfg file. For examples, see the system_windows_pc.cfg, system_osx_metal.cfg, or system_android_es3.cfg file.</td>
</tr>
<tr>
<td>MailServer</td>
<td>Your email server.</td>
</tr>
<tr>
<td>SCMailAddress</td>
<td>Email address used in the From field of the email sent by the remote shader compiler.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PrintCommands</td>
<td>If set to 1 (enabled), the remote shader compiler prints out the commands it uses to generate shaders.</td>
</tr>
<tr>
<td>PrintWarnings</td>
<td>If set to 1 (enabled), the remote shader compiler prints out all the compilation warnings when shaders are generated.</td>
</tr>
<tr>
<td>white_list</td>
<td>If set to 0.0.0.0/0, the remote shader compiler authorizes any IP. Any device can connect to the remote shader compiler. As this can be a security risk, use this parameter with caution.</td>
</tr>
<tr>
<td>DumpShaders</td>
<td>If set to 1 (enabled), dumps the output of HLSL, GLSL, and metal shaders. This outputs shaders into the Shaders/platform-compiler-shader_language directory, where:</td>
</tr>
</tbody>
</table>
|                 | • **platform** = PC, Mac, iOS, or Android  
|                 | • **compiler** = D3D11_FXC, GLSL_HLSL, METAL_HLSLcc, or METAL_LLVM_DXC  
|                 | • **shader_language** = D3D11, GL_4, GLES3_1, GLES3_0, or METAL |

**Example**

The completed `config.ini` file can look like the following.

```
MailError = shadererror@your_company.tld
MailInterval = 1
port = 61453
TempDir = C:\SHADER_CACHE
MailServer = your_email_server
SCMailAddress = RemoteShaderCompiler@your_company.tld
PrintWarnings = 1
```

**Creating an allow list for the Remote Shader Compiler**

You can use an allow list to specify the IP addresses that are allowed to connect to your remote shader compiler. If a computer has an IP address that is not in the allow list, the remote shader compiler provides a message that an invalid computer tried to connect and then closes the connection. This prevents data from being read or sent to an invalid connection.

**To create an allow list for the remote shader compiler**

1. Create or edit the `config.ini` in the same directory as the remote shader compiler executable.
2. Add the following parameter to the file.

   `white_list` – Provide a comma-separated list of IP addresses in CIDR format. The remote shader compiler uses this list to validate incoming connection requests. The remote shader compiler automatically adds the loopback IP address (127.0.0.1) and its own IP address.

   **Note**

   To specify multiple IP addresses, specify a comma-delineated list. Do not include white space or empty lines.
Example

The following allows computers or devices with IP addresses matching the allow list to connect to the remote shader compiler.

```
white_list=10.53.180.37,10.53.104.220
```

The following allows computers or devices with an IP address of `192.168.0.*` to connect to the remote shader compiler. The `/24` specifies a net mask of 24-bits. If you specify `/8`, any address that starts with `192` is allowed, given only an 8-bit net mask.

```
white_list=192.168.0.1/24
```

Location of Specific Shader Compilers

In the root directory of the remote shader compiler, each shader language or render API has its own directory with additional subdirectories for different version numbers. They are located in the following directory:

```
lumberyard_version\Tools\CrySCompileServer\Compiler
```

You can find information about the path used by the remote shader compiler in the `ShaderCache.cpp` file, under the function `mfGetShaderCompileFlags`.

Lumberyard provides all appropriate shader compilers for you that match the code of that version.

Shader Cache Lists

The remote shader compiler contains different text files of all the combinations requested so far by the game. These files are important as the shader `.pak` files cannot be generated without them.

The shader cache list files are located in the following directories:

- **PC** – `lumberyard_version\dev\Tools\CrySCompileServer\x64\profile\Cache\project_name\platform-compiler-shader_language`
- **Mac** – `lumberyard_version\dev\Tools\CrySCompileServer\osx\profile\Cache\project_name\platform-compiler-shader_language`

Where:

- `platform` = PC, Mac, iOS, or Android
- `compiler` = D3D11_FXC, GLSL_HLSL, METAL_HLSLcc, or METAL_LLVM_DXC
- `shader_language` = D3D11, GL_4, GLES3_1, GLES3_0, or METAL

The game submits the requests to the remote shader compiler either during actual gameplay or during loading phases, even when remote shader compiling is disabled. This ensures that all possible shader combinations are collected and that the shader caches, which are generated during the shader cache generation phase, are as complete as possible.

Lumberyard also generates shaders locally. These text files are named `ShaderList_platform.txt` (for example, `ShaderList_DX11.txt`). You can find these files in the `lumberyard_version\dev\cache\project_name\pc\user\cache\shaders` directory.

Game Development Configuration

A remote shader compiler server can provide a performance benefit as it caches the results and sends them to team members instead of having to compile shaders each time. In addition, the server keeps
track of all shaders used by all people, which can be valuable if you want to make a release build that includes all shaders.

You can set the following parameters in the `system_platform_shader_version.cfg` file in Lumberyard's root directory, such as `system_android_es3.cfg` or `system_windows_pc.cfg`.

<table>
<thead>
<tr>
<th>Console Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>r_ShadersUseLLVMDirectXCompiler=1</code></td>
<td>Turn on the shader compiler that generates metal shaders on Windows and Mac.</td>
</tr>
<tr>
<td><code>r_ShadersRemoteCompiler=1</code></td>
<td>Specifies whether the game enables or disables the remote shader compiler.</td>
</tr>
<tr>
<td></td>
<td>If set to 0, Lumberyard does not compile remote shaders and will instead compile local shaders.</td>
</tr>
<tr>
<td><code>r_ShaderCompilerServer=IPv4_of_PC_running_the_RemoteShaderCompiler</code></td>
<td>Specifies the remote shader compiler location. When the remote shader compiler is enabled, the game needs the location of the remote shader compiler.</td>
</tr>
<tr>
<td><code>r_ShaderCompilerServer=localhost</code></td>
<td>If you are running on a PC, specify this console variable to use the remote shader compiler locally.</td>
</tr>
<tr>
<td><code>r_ShaderCompilerServer=10.0.0.10;10.0.0.11</code></td>
<td>Specifies more than one remote shader compiler. Separate multiple IP addresses with semicolons. Note: It is not possible to use the network name of the server instead of the IP address, because name resolving is not performed.</td>
</tr>
<tr>
<td><code>r_ShaderCompilerPort=portnumber</code></td>
<td>If the remote shader compiler server uses a user-defined port number as specified in the <code>config.ini</code> file, you can configure the port number with this console variable.</td>
</tr>
<tr>
<td><code>r_shaderssubmitrequestline=0</code></td>
<td>Disables submit request lines to the remote shader compiler. This is console variable is useful when you are experimenting with shaders and you don't want to add these combinations to the shader cache.</td>
</tr>
<tr>
<td><code>r_AssetProcessorShaderCompiler=1</code></td>
<td>You can use Asset Processor to proxy remote requests to the shader compiler server if a device cannot connect to the shader compiler server. In this case, set <code>r_AssetProcessorShaderCompiler=1</code>. Now, whenever the game would have made a request directly to the shader compiler server, it instead submits the request to Asset Processor (this can also be over a USB connection), which then forwards it to the shader compiler server.</td>
</tr>
<tr>
<td><code>r_shadersAsyncCompiling=3</code></td>
<td>Allows shaders to stream asynchronously and prevents the game from freezing while waiting for the shaders to compile.</td>
</tr>
</tbody>
</table>
Console Variables | Description
--- | ---
r_ShadersAsyncActivation=1 | Allows shaders to stream asynchronously. Set to 0 to prevent the shaders from streaming asynchronously.

Creating Paks for Server Assets

Specify `RC.exe` to build a pak file that contains server assets only. You generate these assets by using the following command:

```
AssetProcessorBatch.exe /gamefolder=my_game /platforms=server /server)
```

You can update `RC.exe` to look for assets in the `lumberyard_version\dev\cache\MyGame\server` directory, instead of using the PC client assets.

Example

To create paks for server assets

1. Navigate to the `lumberyard_version\dev\Bin64vc141\rc` directory.
2. In a text editor, open the `RCJob_Generic_MakePaks.xml` file.
3. Make a copy of the file and name it `RCJob_Generic_MakePaks_Server.xml`.
4. Edit the file so that the `src` points to your server assets, instead of the PC client assets.

   Before

   ```xml
   # <DefaultProperties
   p="pc"
   game="samplesproject"
   src="cache\$(game)\$(p)"
   trg="$(game)_$(p)_paks"
   />
   ```

   After

   ```xml
   # <DefaultProperties
   p="pc"
   game="samplesproject"
   src="cache\$(game)\server"
   trg="$(game)_server_paks"
   />
   ```

5. Save the file.
6. Now when you run `RC.exe`, you can assign the job to the new xml file.

   **Example**

   ```
   rc.exe /job=path\to\RCJob_Generic_MakePaks_Server.xml /p=pc /game=my_game /trg=BinTemp \server_paks
   ```

**Generating Shader Combinations**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Make sure that the Remote Shader Compiler (p. 1645) has been set up successfully first. The remote shader compiler should be accessible by everyone playing the game, especially QA. Try to have everyone who is working on a certain game project share the same remote shader compiler.

Normal game builds should contain shader cache .pak files generated by the shader cache generation phase. At the beginning of a project this could be either completely missing (because no shaders requests have been submitted yet) or the .pak files could still be missing a lot of shaders.

When Lumberyard tries to render an object it will check if the compiled shader is available. When the shader is not available, it will try to load it from the global cache. This can either be loaded directly or through the streaming engine. The direct loading will cause direct disc access from the render thread and this could cause severe stalls due to the streaming thread trying to access the disc at the same time.

By default, when shader compiling is disabled, Lumberyard will stream the shaders from the global cache. The object won't be rendered when shader data is being streamed in. This default behavior can be modified with the following console variable. Note that streaming of shaders is not allowed when shader compiling is enabled, and Lumberyard will automatically disable the following console variable:

```
r_shadersAsyncActivation = 0
```

When the shader is missing from the global cache, a "request line" to store this missing shader is directly sent to the remote shader compiler to be sure that this shader will be available in the next shader cache generation. This happens even when shader compiling is disabled, but the remote shader compiler needs to be active.

When no shader compiler is defined or if the shader compiler is disabled then the request line will be ignored. It is recommended to test the remote shader compiler as much as possible to collect as many shader combinations as possible. The remote shader compiling can be disabled with the following console variable, which is disabled by default in release builds, otherwise is always enabled:

```
r_shadersRemoteCompiler = 0
```

The submission of the shader request lines can be disabled as well:

```
r_shadersSubmitRequestLine = 0
```

When shader compiling is disabled and the shader is missing in the global cache, the object won't be rendered at all. When shader compiling is enabled, and the remote shader compiler is active, an asynchronous request to compile the shader will be sent to the remote shader compiler. If the remote shader compiler is disabled, then the shader will be compiled locally on the PC platform. Other game platforms do not support local compilation.

To keep track of the current shader cache state in game, extra debug information can be enabled using the following console variable:
r_displayinfo = 2

A shader cache information line can be found on the top right of the screen, which reports the amount of Global Cache Misses (GCM) that have been found so far. It also reports if shader compiling is currently enabled or not.

All the shader cache misses also get written to a text file at the following location: \Shaders \ShaderCacheMisses.txt. This information is only used for debugging the current state of the shader cache, and should ideally be empty.

**Shader Reference**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard includes the following physically-based rendering (PBR) shaders, which use real-world physical rules and properties to describe how light interacts with the surface of objects. This means that game object materials look realistic under all lighting conditions.

**To access a shader**

1. In Lumberyard Editor, click **Tools, Material Editor**.
2. In the left tree pane, select a material to work with.
4. Locate shader-specific parameters under **Shader Params** and associated **Shader Generation Params**.

**Note**

Some shader parameters become available (are visible) only if an associated shader generation parameter is first enabled. This is also true for certain texture map slots (file paths) under **Texture Maps**.

</table>

**Common.Cloud Shader**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Common.Cloud shader is used exclusively for common clouds (p. 830). The shader uses per-vertex gradient lighting and takes the sun, cloud, and viewer positions into account. Gradient lighting interpolates between the bright color, which is calculated from the HDR Sun color multiplier, and the
dark color, which is calculated from the HDR Sky color multiplier. In addition, rim lighting is also applied on a per-pixel basis to capture the effects of light scattering when looking at clouds that are lit by the sun from behind.

Common clouds use soft clipping to gradually fade in and out at the near and far clipping plane. This prevents rendering artifacts in the far distance and flickering due to cloud particles entering and leaving the view cone near the camera during a flythrough. Additionally, clouds blend softly against opaque scene geometry.

The default **Diffuse** texture map for this shader is `cumulus_01.dds`, which contains images of cloud particles.
Shader Parameters

CloudAngularAtten

Defines the angular attenuation factor for rim lighting. The smaller the value, the more widespread the rim lighting effect for clouds (partially) covering the sun becomes from the viewer's point of view.

Valid values: 1 to 100

Default value: 30

Example

The following examples show a cloud with angular attenuation set to 20 and 100.

CloudBacklightingScale

Defines how much to scale rim lighting. Higher values increase the glow of cloud edges.

Valid values: 0 to 5

Default value: 1

Example

The following examples show a cloud with backlighting scale set to 0 and 5.
CloudOutlineSlope

Defines the slope of the ramp function used to blend in rim lighting. Higher values create harder transitions.

Valid values: 0 to 20

Default value: 1

Example

The following examples show a cloud with outline slope set to 0 and 20.

CloudOutlineThreshold

Defines the cloud's opacity threshold value below which the rim lighting effect is applied. Higher thresholds cause the rim lighting to grow inward.
Valid values: 0.0 to 1.0

Default value: 0.4

Example

The following examples show a cloud with outline threshold set to 0.0 and 1.0.

HDRBrightnessAdjust

Controls brightness of clouds in high dynamic range (HDR) image format (relative to low dynamic range (LDR) image format).

Default value: 1

DistanceClouds Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The DistanceClouds shader is a dedicated shader used for 2D clouds that are placed at a far distance.

Shader Parameters

Alpha Multiplier

Alpha multiplier for cloud texture.

This parameter requires that the Advance distance clouds shader generation parameter is enabled.

Default value: 1

AlphaSaturation

Controls the alpha saturation of clouds when blending them with the sky. High values make less opaque parts of the cloud texture fade out more.
You can reuse the same texture for slightly different looking clouds by defining several materials with custom \textit{AlphaSaturation} values.

This parameter does not apply if the \textit{Simple distance clouds} shader generation parameter is enabled.

Default value: 2

\textbf{Attenuation}

Controls how strongly sun light is attenuated when traveling through the distance cloud. Light attenuation is computed per pixel.

Use \textbf{Attenuation} to blend between current sun color and sky color. Use higher attenuation values to accentuate cloud self-shadowing (for example, strong cloud layers).

This parameter applies if no Shader Generation parameter is enabled.

Default value: 0.6

\textbf{Cloud Height}

Sets the height of the cloud layer.

This parameter requires that the \textit{Advanced distance clouds} shader generation parameter is enabled.

Default value: 0.3

\textbf{Density Sky}

Sets the cloud density that is used for sky light scattering.

This parameter requires that the \textit{Advanced distance clouds} shader generation parameter is enabled.

Default value: 4.5

\textbf{Density Sun}

Sets the cloud density that is used for sunlight scattering.

This parameter requires that the \textit{Advanced distance clouds} shader generation parameter is enabled.

Default value: 1.5

\textbf{Exposure}

Sets exposure amount to enable HDR on LDR cloud texture.

This parameter requires that the \textit{Simple distance clouds} shader generation parameter is enabled.

Default value: 1

\textbf{Opacity}

Sets opacity modifier for the cloud.

This parameter requires that the \textit{Simple distance clouds} shader generation parameter is enabled.

Default value: 1

\textbf{SkyColorMultiplier}

A value multiplied to the sky color defined for the current time of day.
The result is used in the pixel shader to blend between sun and sky color using the computed light attenuation value.

This parameter applies if no shader generation parameter is enabled.

Default value: 1.5

**StepSize**

Controls how fast to step through the cloud texture (density) to compute per-pixel light attenuation.

This effect determines the appearance of the gradient. Higher values create smoother and less abrupt gradients, but can also produce unnatural gradient changes over time of day.

This parameter applies if no shader generation parameter is enabled.

Default value: 0.004

**SunColorMultiplier**

A value multiplied by the sun color that is defined for the current time of day. The result is used in the pixel shader to blend between sun and sky color using the computed light attenuation value.

This parameter applies if no shader generation parameter is enabled.

Default value: 4

**Shader Generation Parameters**

**Simple distance clouds**

Enables the use of distance clouds with no volumetric shading computations.

**Advanced distance clouds**

Enables the use of distance clouds with more accurate shading computations.

**Eye Shader**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Eye shader is used to render realistic eyes that take sclera, cornea, iris, and eye moisture properties into account.

**Shader Parameters**

**Cornea Refraction**

Controls and optionally animates pupil size.

Default value: 0.01

**Cornea Smoothness**

Controls the glossiness of corneas reflections.
The default creates smaller and sharper highlights that are more lifelike.

Default value: 1

**Indirect bounce color**

Sets the amount of indirectly bounced color. Has no effect when the Physically Based Shading (PBR) model is used.

Default value: 136,136,136

**Iris Color**

Tweaks the iris color without affecting the eye white.

**Iris Color** can be used for eye variation between characters that use the same texture.

Default value: 187,187,187

**Iris Depth**

Simulates the actual form of the iris, since the in-game mesh has the shape of a sphere.

Default value: 0.005

**Iris Shadowing**

Controls iris self-shadowing, which further simulates the actual form of the iris.

*Note*

This effect is only affected by sunlight and not by other light sources.

Default value: 5

**Iris SSS**

Controls the subsurface scattering (SSS) amount of the iris, which blurs the shadows. Higher values blur the shading more.

Default value: 0.6

**Sclera SSS**

Controls the subsurface scattering (SSS) amount of the eye whites, which blurs the shadows. Higher values blur the shading more.

Default value: 0.4

**Depth bias scale**

Sets the depth bias of the overlay mesh to avoid clipping with the eyes.

This parameter requires that the *Specular overlay* shader generation parameter is enabled.

Default value:

**Diffuse occlusion strength**

Controls the strength of the occlusion effect on the eyes.

This parameter requires that the *Ambient occlusion overlay* shader generation parameter is enabled.

Default value: 1
**Specular occlusion strength**

Controls the strength of the occlusion effect on the eyes' specular highlights.

This parameter requires that the Ambient occlusion overlay shader generation parameter is enabled.

Default value: 1

**Shader Generation Parameters**

**Environment map**

Enables environment map as a separate texture.

If the blending cube map feature isn't used, Environment map must be enabled and nearest_cubemap must be assigned for the texture's environment.

**Ambient occlusion overlay**

Enables ambient occlusion overlay rendering.

Must be enabled to use the occlusion mesh that overlays the eye. This mesh gives the eyes a more natural shadowing and integrates them with the head.

**Specular overlay**

Enables the eye water mesh.

---

**Fur Shader**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard's Fur shader renders fur in real time. You can apply this shader to any mesh and adjust its properties to customize the fur's appearance and behavior.

**Topics**

- Fur Combing (p. 1664)
- Fur Features (p. 1665)
- Material Settings (p. 1674)
- Fur Console Variables (p. 1677)
- Maya – Fur Previsualization (p. 1679)
- 3DSMax – Fur Previsualization (p. 1685)

To use the fur shader, create a new material and, from the Shader drop-down, select Fur. Apply this new material to your mesh object.
You set a Fur Heightmap (p. 1674) to define where fur appears, how it clumps together, and to provide non-uniformity of strands across a mesh. A fur heightmap is a grayscale texture, as shown in the following image.

![Fur Heightmap Image]

Brighter values at a UV result in longer fur at that point. Under Shader Params, adjust Fur Length (cm) to modify the length of the fur. The following image shows objects with different fur lengths.
Fur Combing

You can apply fur to any mesh. But by authoring your meshes specifically for fur, you can achieve a more controlled look.
To use fur combing, in Shader Generation Params, enable Fur Color Data. With this parameter enabled, the engine uses the mesh's vertex color to control the fur direction and length. The RGB channels correspond to an XYZ combing direction, and the alpha channel scales the fur length.

For example, a material might have a vertex color of $1, 0.5, 0.5, 0.25$ (X, Y, Z, alpha). These values specify that the fur combs in the positive X direction. The alpha channel, set at $0.25$, defines the fur length at that vertex as one fourth of the value specified in the material's Fur Length (cm).

Lumberyard provides shaders for Maya (p. 1679) and 3DSMax (p. 1685). These shaders simplify the process of specifying the vertex color data on your mesh.

For information on how to use these shaders, see the following topics:

- Maya – Fur Previsualization (p. 1679)
- 3DSMax – Fur Previsualization (p. 1685)

Fur Features

Using various Fur Material Settings (p. 1674) and Fur Console Variables (p. 1677), the fur shader can give your furry entities realistic highlights, dynamic shadows, responsive movement, and much more.

Topics

- Anisotropic Specular Highlights (p. 1665)
- Subsurface Scattering (p. 1667)
- Simulated Self-Shadowing (p. 1668)
- Fur in Shadows (p. 1669)
- Bending (p. 1670)
- Motion Bending (p. 1673)
- Level of Detail (p. 1674)

Anisotropic Specular Highlights

Anisotropic specular highlights are supported when a mesh provides fur combing (p. 1664) data. This feature creates highlights that appear "banded" in the direction perpendicular to the fur strands. Notice the banded highlight from the green light on the bear's fur.
Anisotropic highlights are not applied to areas where fur length is set to 0 in the mesh vertex color. For example, non-furry areas such as a nose, mouth, or claws will display isotropic, or hotspot, highlights rather than banded, or anisotropic highlights.
Subsurface Scattering

The fur shader simulates subsurface scattering around silhouette edges of the fur, where less inscattering and absorption occurs. This results in a glow effect when the fur is backlit. You can tune this feature by adjusting the material parameters **SSS Strength** and **SSS Falloff**.
Simulated Self-Shadowing

To simulate the self-shadowing effect of fur, you can set a blend color or blend layer. To do this, you can enable **Fur Blendlayer** or **Fur Blend color**. If both are enabled, only **Fur Blendlayer** is used. You then set the color using the **Fur Self Shadowing Color** property. This value is interpolated with the default diffuse texture, where self-shadowing is stronger toward the mesh surface.

The following image shows a furry sphere with no self-shadowing (1), the same sphere with fur blend color (2), and again with fur blendlayer (3).
You can adjust the interpolation speed by modifying the material parameter **Fur Self Shadowing Bias**.

**Fur in Shadows**

When fur casts a shadow, it adds definition to the silhouette. If fur is not set to cast a shadow, then you would see a smooth edge of the structure that the fur covers. In the following image, you can see the shadow of the bear's fur on the wall.
Fur can contribute to shadow passes, including bending caused by wind. Fur is alpha-tested in shadow passes.

You can adjust this by modifying the material parameter **Fur Fins Alpha Test**.

You can also turn on fur in shadows by toggling the console variable `r_furfinshadowpass`.

**Bending**

In addition to fur combing by vertex normal, Lumberyard provides three additional types of bending: **Wind Bending**, **Gravity Bending**, and **Motion Bending**. You can control the strength of the bending by adjusting the Material Parameter (p. 1674) **Stiffness**. This parameter specifies the amount to which the fur is resistant to change.

**Wind Bending**

Enable the Shader Generation Parameter (p. 1674) **Wind bending** to see the effects of wind on fur's movement. Adjust the shader parameter (p. 1674) **WindFrequency**, **WindPhase**, and **WindScale** to control how the wind affects the fur. The amount of wind applied to the fur is also dependent on the local wind at the entity position as measured by both global wind and wind areas.
Gravity Bending

Gravity bending is controlled by adjusting the shader parameter (p. 1674) **Fur Maximum Gravity**. Gravity is applied most where the fur sprouts away from the world's surface. It is also applied more strongly to the ends of the fur pieces.

For example, the following image shows a fur ball with a very low gravity applied. The second image shows the same fur ball with a higher maximum gravity applied.
Motion Bending

Motion bending occurs when a furry entity's transform changes, such as its position, rotation, or scale. The fur appears to lag behind the motion slightly, and catches up over a short time. You can tune this globally using the console variable (p. 1677) `r_FurMovementBendingBias`. 
Level of Detail

Fur rendering level of detail uses many of the same mechanics as mesh level of detail.

For fur rendering, the number of shell passes drawn decreases over a distance. You can define the maximum number of passes using the console variable (p. 1677) `r_FurShellPassCount`.

The starting distance for beginning to decrease shell passes is mesh dependent. This distance is determined by the mesh's parameters View distance multiplier and LOD distance ratio. You can find these parameters for the mesh (p. 684) or skinned mesh (p. 684) in the Entity Inspector (p. 475)'s Options section. The ending distance, after which no fur shells are drawn, is determined by the console variable (p. 1677) `r_FurMaxViewDist`.

Material Settings

Using fur material parameters, you can fine-tune the look of the fur.

Fur rendering supports the following textures:

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diffuse</td>
<td>The texture used for the mesh.</td>
</tr>
</tbody>
</table>
### Shader Reference

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal Map</td>
<td>Adjustments for per-vertex normals. Note that a busy normal map may reduce the appearance of anisotropic specular highlights, as the normals do not align across the mesh as well.</td>
</tr>
<tr>
<td>Specular</td>
<td>Specularity of the mesh.</td>
</tr>
<tr>
<td>Fur Heightmap</td>
<td>A grayscale texture that specifies how fur fades out at different frequencies over the mesh. Without this texture, fur appears blurry and without definition to strands.</td>
</tr>
</tbody>
</table>

#### Default fur Shader Params

Default fur **Shader Params** are as follows:

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Value Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fur Fins Alpha Test</td>
<td>[0.0, 1.0]</td>
<td>Alpha test value used for fin and shadow passes, if enabled.</td>
</tr>
<tr>
<td>Fur Length (cm)</td>
<td>[0.0, 100.0]</td>
<td>Maximum length of fur, in centimeters.</td>
</tr>
<tr>
<td>Fur Maximum Gravity</td>
<td>[0.0, 5.0]</td>
<td>Maximum amount of gravity to apply to fur.</td>
</tr>
<tr>
<td>Fur Stiffness</td>
<td>[0.0, 1.0]</td>
<td>Rigidity of the fur. Higher values cause less bending to occur.</td>
</tr>
<tr>
<td>Indirect bounce color</td>
<td>Color</td>
<td>Tint for bounce light from global illumination.</td>
</tr>
<tr>
<td>SSS Falloff</td>
<td>[0.0, 5.0]</td>
<td>Falloff speed for subsurface scattering influence.</td>
</tr>
<tr>
<td>SSS Strength</td>
<td>[0.0, 5.0]</td>
<td>Initial strength of subsurface scattering influence.</td>
</tr>
<tr>
<td>Threshold for writing depth</td>
<td>[0.0, 1.0]</td>
<td>For alpha blended fur, the alpha threshold for writing depth. Using this, alpha blended fur</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Value Range</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>works well with post effects such as depth of field.</td>
</tr>
</tbody>
</table>

When you enable **Fur Color Data** under **Shader Generation Params**, the following additional parameters appear:

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Value Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fur Base Intrusion</td>
<td>[0.0, 1.0]</td>
<td>Percentage of scaled fur length per vertex to move the base mesh in the negative normal direction. With this parameter, a mesh can provide a similar silhouette with or without fur.</td>
</tr>
<tr>
<td>Fur Combing Bias</td>
<td>[0.0, 5.0]</td>
<td>Defines how quickly fur combs from the normal direction to the per-vertex combing direction.</td>
</tr>
<tr>
<td>Wind Scale</td>
<td>[0.0, 1.0]</td>
<td>Scale of local wind speed to apply to the fur.</td>
</tr>
</tbody>
</table>

When you enable **Wind bending** under **Shader Generation Param**, the following additional parameters appear in **Shader Params**:

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Value Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wind Frequency</td>
<td>[0.0, 10.0]</td>
<td>Speed at which the wind moves through a set pattern of amplitudes.</td>
</tr>
<tr>
<td>Wind Phase</td>
<td>[0.0, 10.0]</td>
<td>Phase offset for wind applied to this material.</td>
</tr>
<tr>
<td>Wind Scale</td>
<td>[0.0, 1.0]</td>
<td>Scale of local wind speed to apply to the fur.</td>
</tr>
</tbody>
</table>

When you enable **Fur Blendlayer** or **Fur Blend color** under **Shader Generation Params**, the following additional parameters appear in **Shader Params**:

**Note**

If both **Fur Blendlayer** and **Fur Blend color** are enabled, Lumberyard uses only **Fur Blendlayer**.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Value Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fur Self Shadowing Bias</td>
<td>[0.0, 5.0]</td>
<td>Defines how quickly the blendlayer or blend color fades to the primary diffuse texture color.</td>
</tr>
<tr>
<td>Fur Self Shadowing Color</td>
<td>Color</td>
<td>With <strong>Fur Blend color</strong>, the color to apply at the base of the fur.</td>
</tr>
</tbody>
</table>
### Shader Reference

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Value Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fur Self Shadowing Map</td>
<td>Texture</td>
<td>With <strong>Fur Blendlayer</strong>, the texture to apply at the base of the fur. Uses the same UV set as the diffuse texture.</td>
</tr>
</tbody>
</table>

When you enable **Scale fur length** under **Shader Generation Params**, the entity's scale is factored into the fur length used by the mesh.

When you enable **Model Space Z Up** under **Shader Generation Params**, fur combing is computed as Z-up instead of Y-up.

**Note**
For materials that use the **Fur** shader, Lumberyard ignores settings for **Opacity** (under **Opacity Settings**) and **Emissive Intensity (kcd/m2)** (under **Lighting Settings**).

### Fur Console Variables

<table>
<thead>
<tr>
<th>Console Variable Name</th>
<th>Value Range</th>
<th>Description</th>
</tr>
</thead>
</table>
| r_Fur                         | [0,2]       | Specifies how fur draws:  
  • 0: Fur does not draw; appears similar to Illum  
  • 1: Transparent alpha blended passes  
  • 2: Opaque alpha tested passes |
| r_FurDebug                   | [0,8]       | Toggles various visual debug information for fur rendering:  
  • 1: Base/tip sample validity (red = base valid; green = tip valid; yellow = both valid)  
  • 2: Base/tip selection (red = base chosen; green = tip chosen)  
  • 3: Show offscreen UVs for base deferred sample (gray = onscreen)  
  • 4: Show offscreen UVs for tip deferred sample (gray = onscreen)  
  • 5: Show final lighting with all base lighting selected  
  • 6: Show final lighting with all tip lighting selected  
  • 7: Visualize fur length scaling  
  • 8: Visualize fur animation bending velocity |
<p>| r_FurDebugOneShell            | [0, ∞ )     | If the specified shell number exists, draws only that shell, |</p>
<table>
<thead>
<tr>
<th>Console Variable Name</th>
<th>Value Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>r_FurFinPass</td>
<td>[0,1]</td>
<td>Toggles the drawing of an opaque alpha tested silhouette fin pass for fur rendering.</td>
</tr>
<tr>
<td>r_FurFinShadowPass</td>
<td>[0,1]</td>
<td>Toggles the drawing of alpha tested silhouette fins in shadow passes.</td>
</tr>
<tr>
<td>r_FurMaxViewDist</td>
<td>[0.0, ∞)</td>
<td>Specifies the maximum distance for fur shells to be drawn.</td>
</tr>
<tr>
<td>r_FurMovementBendingBias</td>
<td>[0.0, 1.0]</td>
<td>Specifies motion bending bias for fur. A value closer to 0 causes fur motion bending to be more pronounced.</td>
</tr>
<tr>
<td>r_FurShellPassCount</td>
<td>[0, ∞)</td>
<td>Maximum number of fur shell passes to draw for each object.</td>
</tr>
<tr>
<td>r_FurShowBending</td>
<td>[0, 1]</td>
<td>When enabled, draws debug lines visualizing the normals and fur combing vectors on a mesh.</td>
</tr>
</tbody>
</table>
Maya – Fur Previsualization
To visualize fur on a mesh

1. Verify that the Cgfx Shader is enabled.

   In Maya, navigate to Windows, Settings/Preferences, Plug-in Manager.

   Find cgfxShader.mll in the list, and then verify that both Loaded and Auto load are selected.

   If you made any changes, restart Maya.

   ![Plug-in Manager](image)

2. Open the Hypershade editor by navigating to Rendering Editors, Hypershade.
3. Create a new material. To do this, in the **Hypershade** window, navigate to **Create**, **Materials**, **Cgfx Shader**.
4. In the Property Editor, click the folder icon next to the CgFX File text box.

Note
If the Property Editor is not visible, navigate to Windows, Property Editor.

5. Navigate to your Lumberyard install folder, and then select `dev\Tools\Maya\fx\Fur.cgfx`.

6. In the Fur.cgfx Parameters section, specify the following, at a minimum:
   - Enable Fur Combing (disabled/unselected if you haven't prepared your mesh with vertex colors for fur combing)
   - Use Base Fur Diffuse Map (selected/enabled)
7. Select the mesh or sub-mesh on which you want to visualize fur, and then right-click hold on the CgFX shader material in Hypershade. Select Assign Material to Selection.

8. In the main viewport, press 6 to ensure that Shaded Display (with texture maps) is enabled.

9. Adjust fur settings on the material as preferred.

To apply vertex colors on a mesh

1. Enable fur combing on the material. To do this, on the Fur.cgfx Parameters, select Enable Fur Combing.
2. Open the **Paint Vertex Color Tool**. To do this, click the square box next to **Color, Paint Vertex Color Tool**.

3. Since Maya does not permit painting alpha only on a RGBA color set, begin by painting RGBA to specify fur length scaling:
   a. In the **Color** section of the tool, select **RGBA** for the **Channels**.
   b. Click the color swatch next to **Color value**. Specify **0.5, 0.5, 0.5** as the color using the mode **RGB, 0.0 to 1.0**.
   c. Set the alpha value to your desired fur scaling setting.
   d. Set other tool settings as needed, and apply fur scaling to your mesh.

4. Now paint RGB only to apply combing:
   a. In the **Color** section of the tool, select **RGB** as the **Channels**.
   b. Click the color swatch next to **Color value**. Select the preferred direction.
   c. Set other tool settings as needed, and apply fur scaling to your mesh.
3DSMax – Fur Previsualization

To visualize fur on a mesh

1. Ensure that your renderer is set to Legacy Direct3D:
   a. Open the Preference Settings dialog. To do this, navigate to Customize, Preferences.
   b. Select the Viewports tab. Under Display Drivers, view the currently installed driver.
c. If it does not display Direct3D 9.0, click Choose Driver. From the drop-down menu, choose Legacy Direct3D. Click OK.

2. Open the Material Editor. To do this, navigate to Rendering, Material Editor, Compact Material Editor.

3. Select a material that you want to set for fur, and click the button to the right of the submaterial drop-down menu (the button might display “Standard”).
Choose **DirectX Shader**, and choose to discard the old material.

4. Click in filename box. Navigate to your Lumberyard install folder, and select `dev\Tools\maxscript\fx\Fur.fx`.

5. In the **Fur.cgfx Parameters** section, specify the following, at a minimum:
   - **Enable Fur Combing** (disabled/unselected if you haven't prepared your mesh with vertex colors for fur combing)
   - **Use Base Fur Diffuse Map** (unselected/disabled)
   - **Color Texture**
   - **Fur Heightmap**

6. In the viewport, select your mesh or sub-mesh. In the **Material Editor**, click **Assign Material to Selection**.
To apply vertex colors on a mesh

1. With your object selected, go to the Modify panel. From the Modifier List drop-down menu, select VertexPaint.

2. To adjust fur combing, set the Channel to Vertex Color.
   
   To adjust fur length scaling, set the Channel to Vertex Alpha.

3. For fur combing:
   
   a. Click on the color swatch below the eraser button, and select the preferred direction.
   
   b. Use the Paint or Paint All button to apply the combing direction to the mesh.
Note
The default vertex color for meshes is white, so you may want to begin by using Painting All with RGB(128, 128, 128). This way, you can work from a default “no combing” state.

4. For fur length scaling:
   a. Click on the color swatch below the eraser button, and set the preferred length scale in the red channel.
   b. Use the Paint or Paint All button to apply the length scaling to the mesh.

GeometryBeam Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the GeometryBeam shader to create volumetric light beams that feature dust and turbulence effects.

Shader Parameters

Ambience strength
Controls the general strength of the beam effect.
Default value: 0.12

Base UV scale
Controls the scale or tiling of the object’s base UV mapping.
Default value: 1

Brightness
Controls the overall brightness of the beam effect.
Default value: 1

Dust anim speed
Controls the animation speed for the dust turbulence effect, as defined by the Specular texture map.
This parameter requires that the Dust Turbulence shader generation parameter is enabled.
Default value: 1

Dust UV rotation
Changes the rotation of the dust turbulence effect, as defined by the Specular texture map.
This parameter requires that the Dust Turbulence shader generation parameter is enabled.
Default value: 0

Dust UV scale
Sets the scale or tiling of the UV mapping for the dust turbulence effect, as defined by the Specular texture map.
This parameter requires that the **Dust Turbulence** shader generation parameter is enabled.

**Default value**: 0.6

**End color**

Sets the end color for gradient along the U axis.

**Default value**: 255,255,255

**Soft intersection factor**

Controls softness of surface interaction with other opaque scene geometry.

**Default value**: 1

**Start color**

Sets the start color for gradient along the U axis.

**Default value**: 255,255,255

**Turbulence tiling**

Multiplies turbulence, as defined by the **Bumpmap** texture map.

This parameter requires that the **Dust Turbulence** shader generation parameter is enabled.

**Default value**: 1

**Turbulence visibility**

Controls the visibility level of turbulence, as defined by the bump map texture map.

This parameter requires that the **Dust Turbulence** shader generation parameter is enabled.

**Default value**: 0.55

**UV vignetting**

Applies a vignetting effect to the edges of the UV map.

This parameter requires that the **UV Vignetting** shader generation parameter is enabled.

**Default value**: 4

**Vertex alpha fading**

If you use vertex alpha to fade out the edges, use this slider to control the interpolation curve.

**Default value**: 0.55

**View dependency factor**

Determines how beams blend in and out depending on the camera-facing angle.

**The higher the value, the longer the beam is visible even when at a nearly 90° angle to camera. Smaller values cause the beam to begin to vanish.**

**Default value**: 2

**Volumetric scale**

Controls the volumetric features when shadow receiving is enabled. This also has the effect of changing the soft shadow radius.

This parameter requires that the **Receive Shadows** shader generation parameter is enabled.
Default value: 0.7

**Shader Generation Parameters**

**Dust Turbulence**

Enables dust and turbulence overlay. Specular and Bumpmap texture map slots also become available under Texture Maps to fine-tune appearance.

**Receive Shadows**

Enables sun shadows to be cast on the light beams, creating volumetric shafts.

You can use this parameter for an interesting effect, but it might affect your game's performance.

**UV Vignetting**

Enables vignettes in UV space.

---

**Glass Shader**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Glass shader renders windows and other glass objects, imparting refractive, tint, fog, and cracking effects for both breakable and non-breakable glass objects. Use the Illum Shader (p. 1697) instead if you require non-refractive effects for non-breakable glass objects.

Here are a few things to keep in mind when using the Glass shader:

- Ambient diffuse lighting from cube maps isn't taken into account.
- The shader uses the sky color exclusively for all ambient lighting.
- Except for the sun, all deferred lights don't affect transparent glass objects.
- The shader can't receive sun shadows.

**Shader Parameters**

**Back light scale**

Controls the amount of light that gets through the glass.

Default value: 0.5

**Blur Amount**

Controls the amount of blur.

This parameter requires that the Blur refraction – PC Only shader generation parameter is enabled.

Default value: 0.5

**Bump Map Tiling**

Adjusts tiling of the bump map independently from diffuse.

Default value: 1
**Bump Scale**
Sets the reflection and refraction bump scale.

Default value: 0.005

**Cloudiness Masks Blur**
Applies blur to just cloudy areas.

This parameter requires that the Tint map – Tint/Gloss/Spec shader generation parameter is enabled.

Default value: 0

**Cloudiness Masks Gloss**
Makes cloudy areas less glossy.

This parameter requires that the Tint map – Tint/Gloss/Spec shader generation parameter is enabled.

Default value: 0.5

**Fog color**
Sets fog color.

This parameter requires that the Depth Fog shader generation parameter is enabled.

Default value: 255,255,255

**Fog cutoff end depth**
Sets the distance, in meters, after which fog doesn’t get any stronger.

This parameter requires that the Depth Fog shader generation parameter is enabled.

Default value: 20

**Fog density**
Sets fog density.

This parameter requires that the Depth Fog shader generation parameter is enabled.

Default value: 1

**Indirect bounce color**
Sets the amount of indirectly bounced color.

Not used if the Depth Fog shader generation parameter is enabled.

Default value: 136,136,136

**Tint Cloudiness**
Adjusts the cloudiness of tinted areas.

Default value: 0

**Tint Color**
Applies a tint color to the glass.
Default value: 255,255,255

**Shader Generation Parameters**

**Use Diffuse map**

Enables diffuse map for dirt, and so on. Requires alpha channel.

**Environment map**

Enables environment map as a separate texture.

**Tint map – Tint/Gloss/Spec**

Enables the RGB spec map to control tinting in red channel, cloudiness in green channel, and specular in blue channel.

**Use Tint Color Map**

Enables the Tint Color map. Used for multicolored glass, which goes in the custom Tint Color map slot.

**Blur refraction – PC Only**

Enables the blurring of objects seen through the glass.

**Depth Fog**

Enables depth fog behind the glass surface.

**Disable Lights**

Disables the reflection of lights.

**Hair Shader**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Hair shader is a dedicated shader for rendering hair and fur, imparting different color, stranding, and animation effects. Hair rendering is a relatively difficult task to achieve in real-time with high-quality results due to the very fine geometry and specific lighting behavior. Depending on the hairstyle, either a simple scalp plane or a more complex shape that defines the volume of the hairstyle is needed. In some cases, breaking up a hairstyle into multiple large patches makes more sense.

**Shader Parameters**

**Alpha Blend Multiplier**

Multiplies the alpha map with the result that grayscale values are increased. Useful for the Thin Hair shader generation parameter.

Default value: 1

**Diffuse Wrap**

Allows light to pass through the hair, thus illuminating a wider area.

A tightly woven braid would have a lower Diffuse Wrap value (the hair being very dense), whereas sparse, loose hair would have a high Diffuse Wrap value.
Default value: 0.5

**Indirect bounce color**

Sets the amount of indirectly bounced color.

Default value: 136,136,136

**Secondary Color**

Sets color and intensity of the secondary specular highlight.

Primary highlight color depends on the diffuse color, whereas the secondary highlight usually has a more neutral color.

Default value: 217,217,217

**Secondary Shift**

Allows the secondary highlight to be shifted over the surface of the hair mesh. Make sure it works with the primary highlight, the position of which can't be shifted.

Default value: 0.1

**Secondary Width**

Sets the width of the secondary specular highlight.

Default value: 1.5

**Shift Variation**

Adds variation to the shift of the secondary highlight.

Default value: 0

**Soft Intersection**

Controls the alpha blending of the hair against skin or scalp.

Default value: 0

**Strand Width**

Controls the width of the view aligned hair strands. The mesh you exported utilizing this feature from DCC tools is rather thin. The value functions as a multiplier relative to the meshes V coordinate (width) in UV space, which can be used to control strand thickness. For example, you might want thinner strands around the border areas.

This parameter requires that the **View aligned strands** shader generation parameter is enabled.

Default value: 0.01

**Thin Hair Threshold**

Determines how alpha blending works for screen space effects such as DOF and motion blur. Lower values make the blending harder but can cause artifacts. Higher values soften the blending, but in some cases the hair turns into a blurry mess.

For most gameplay situations, the rather low default value works fine, but in cinematics, manual tweaking might be needed. The value must then be animated throughout the scene.

This parameter requires that the **Thin Hair** shader generation parameter is enabled.

Default value: 0.05
Wind frequency

Sets the speed at which the vertices are deformed.

This parameter requires that the Wind bending shader generation parameter is enabled.

Default value: 0

Wind phase

Sets hair animation phase and randomizes the deformation.

This parameter requires that the Wind bending shader generation parameter is enabled.

Default value: 1

Wind wave0 amp

Sets the amount or amplitude at which the vertices are deformed.

This parameter requires that the Wind bending shader generation parameter is enabled.

Default value: 0

Wind wave2 amp

Sets the amount or amplitude at which the vertices are deformed on a different curve.

This parameter requires that the Wind bending shader generation parameter is enabled.

Default value: 0

Shader Generation Parameters

Vertex Colors

Enables vertex colors.

View Aligned Strands

Enables the hair strands to self-align to the camera.

Because this is a global setting for the material, using view-aligned strands requires an extra draw call. For more information, see the Strand Width shader parameter.

Thin Hair

For information, see the Thin Hair Threshold shader parameter.

Ambient Cubemap

Enables the use of the nearest cube map specified in environment map slot for ambient lighting. Leave this enabled.

Enforce Tiled Shading

Forces hair to be fully affected by tile shading. This effect works as an override for the global tiled shading settings.

With tiled shading off, improper lighting of a scene can cause hair to turn very dark.

Use this effect carefully, as tiled shading for hair is generally quite expensive.

Wind bending

Simulates wind effects. If enabled, various frequency, phase, and amplitude wind options appear under Shader Parameters.
HumanSkin Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The HumanSkin shader is used to render skin and its various physical properties including color, oiliness, pores, stubble, and wrinkles.

Shader Parameters

**Detail bump scale**

Controls the strength of the detail normal map.

This parameter requires that the Detail normal map shader generation parameter is enabled.

Default value: 0

**Displacement bias**

For information, see Tessellation and Displacement.

This parameter requires that the Displacement mapping shader generation parameter is enabled.

Default value: 0.5

**Displacement height scale**

For information, see Tessellation and Displacement.

This parameter requires that the Displacement mapping shader generation parameter is enabled.

Default value: 1

**Indirect bounce color**

Sets the amount of indirectly bounced color.

Default value: 136,136,136

**Melanin**

Controls the amount of pigmentation in the skin.

Default value: 0

**SSS Index**

Changes the index of subsurface scattering (SSS).

Default value: 1.2

**Tessellation face cull**

This parameter requires that the Displacement mapping shader generation parameter is enabled.

Default value: 0.75

**Tessellation factor**

This parameter requires that the Displacement mapping shader generation parameter is enabled.
Default value: 1

**Tessellation factor max**

This parameter requires that the Displacement mapping shader generation parameter is enabled.

Default value: 32

**Tessellation factor min**

This parameter requires that the Displacement mapping shader generation parameter is enabled.

Default value: 1

**Translucency Multiplier**

Controls strength of the SSS feature.

Default value: 0

**Wrinkles blend**

Controls strength of the wrinkle map.

This parameter requires that the Wrinkle blending shader generation parameter is enabled.

Default value: 1.0

---

**Shader Generation Parameters**

**Decal map**

Enables the use of a decal map, which is blended on top of the diffuse map.

**Detail normal map**

Enables the use of a tiled detailed map for pores and tiny details (_ddn).

**Displacement mapping**

Enables the use of displacement mapping, which requires a height map (_displ).

**Phong tessellation**

Enables the use of rough approximation of smooth surface subdivision.

**PN triangles tessellation**

Enables the use of rough approximation of smooth surface subdivision.

**Subsurface Scattering Mask**

Enables the use of diffuse map alpha as an SSS amount multiplier.

**Wrinkle blending**

Enables the use of subsurface map alpha for wrinkle blending.

---

**Illum Shader**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The Illum shader is the most commonly used shader. You can use this shader to create a variety of effects.

**Shader Parameters**

**Blend Factor**
- Controls the visibility of the blended layer.
- To use this parameter, you must enable the **Blendlayer** shader generation parameter.
- Default value: 8

**Blend Falloff**
- Controls blending falloff.
- To use this parameter, you must enable the **Blendlayer** shader generation parameter.
- Default value: 32

**Blend Layer 2 Tiling**
- Controls tiling of the second blend layer.
- To use this parameter, you must enable the **Blendlayer** shader generation parameter.
- Default value: 1

**Blend Layer 2-Diffuse(Tint)**
- Controls the diffuse (tint) of the second blend layer.
- To use this parameter, you must enable the **Blendlayer** shader generation parameter.

**Blend Layer 2-Smoothness**
- Controls the smoothness of the second blend layer.
- To use this parameter, you must enable the **Blendlayer** shader generation parameter.
- Default value: 10

**Blend Layer 2-Specular**
- Controls specular intensity of the second blend layer.
- To use this parameter, you must enable the **Blendlayer** shader generation parameter.
- Default value: 132, 132, 132

**Blend Mask Tiling**
- Controls tiling of the blend mask.
- To use this parameter, you must enable the **Blendlayer** shader generation parameter.
- Default value: 1

**Detail bump scale**
- Sets detail bump scale.
- To use this parameter, you must enable the **Detail mapping** shader generation parameter.
- Default value: 0.5
**Detail diffuse scale**
Sets diffuse detail blend scale.
To use this parameter, you must enable the `Detail mapping` shader generation parameter.
Default value: 0.5

**Detail gloss scale**
Sets gloss detail blend scale.
To use this parameter, you must enable the `Detail mapping` shader generation parameter.
Default value: 0.5

**Dissolve Color**
Determines color of the edge if edge thickness is greater than 0
To use this parameter, you must enable the `Dissolve FX` shader generation parameter.
Default value: 255,255,255

**Dissolve Edge Thickness**
Determines the thickness of a border that is the `Dissolve Color` around the edge of the effect.
To use this parameter, you must enable the `Dissolve FX` shader generation parameter.
Default value: 0
Valid values: 0.000 to 1

**Dissolve Noise Map**
A grayscale map that defines the dissolve pattern. Black areas dissolve first; white areas dissolve last.
Appears under `Texture Maps` after you enable `Dissolve FX` shader generation parameter.

**Dissolve Percentage**
Controls the amount that the texture is dissolved.
To use this parameter, you must enable the `Dissolve FX` shader generation parameter.
Default value: 0
Valid values: 0.000 to 1

**Height bias**
Controls the height bias.
To use this parameter, you must enable the `Parallax occlusion mapping` shader generation parameter.
Default value: 0.5

**Indirect bounce color**
Adds an extra color tint to the reflection.
Default value: 136,136,136

**OBM Displacement**
Controls the amount of displacement for offset bump mapping (OBM).
To use this parameter, you must enable the **Offset bump mapping** shader generation parameter.

Default value: 0.01

**POM Displacement**

Controls the amount of displacement for parallax occlusion mapping (POM).

To use this parameter, you must enable the **Parallax occlusion mapping** shader generation parameter.

Default value: 0.01

**Self shadow strength**

Allows movable objects, such as interactive objects or game characters, to cast shadows on themselves and each other. Without self-shadowing, for example, if a character holds their right arm over the left, the right arm does not cast a shadow on the left arm.

To use this parameter, you must enable the **Parallax occlusion mapping** shader generation parameter.

Default value: 3

**Roughness maximum footprint**

Specifies the maximum allowed area of the projected pixel footprint at any point in the scene.

To use this parameter, you must enable the **Specular Antialiasing** shader generation parameter.

Valid value ranges: 0–10

**SAA Roughness Boost**

Specifies the degree to which the effect should be applied.

To use this parameter, you must enable the **Specular Antialiasing** shader generation parameter.

Valid value ranges: 0–10

**SSS Index**

Controls subsurface scattering profile (SSS) and the amount.

Valid value ranges: 0.01–0.99 for marble; 1.00–1.99 for skin.

Default value: 1.2

---

**Shader Generation Parameters**

**Detail mapping**

Enables detail mapping. This option requires a **Detail** map, which you can select under the **Texture Maps** heading.

**Use UV set 2 for detail map**

Enables a second UV channel, if available, for detail map.

**Offset bump mapping**

Enables offset bump mapping. This option requires a heightmap, which you can select for the **Normal Map** option under the **Texture Maps** heading.
Dissolve FX

Enables dissolve effect. Selecting this parameter enables the Dissolve Noise Map under Texture Maps, and three Shader Parameters: Dissolve Color, Dissolve Edge Thickness, and Dissolve Percentage.

These three parameters work in tandem to determine the dissolve effect.

For example, assume your Dissolve Color is white, Dissolve Edge Thickness is 0.1, and Dissolve Percentage is 0.5. In that case, any area on the surface of the Dissolve Noise Map that is less than 0.5 (the value set for Dissolve Percentage) is completely transparent. Areas from 0.5 to 0.6, which is a difference of 0.1 (the value set for Dissolve Edge Thickness) are white (the value set for Dissolve Color). Areas from 0.6 to 1.0 are unchanged and appear with the original material.

Vertex Colors

Allows the use of fake ambient occlusion. Also adds more depth and contrast to the model.

You must add vertex colors to the geometry in the DCC tool.

Decal

Applies a decal appearance when enabled for a material. Decal planes are normally placed close to other geometry.

Use this parameter to prevent flickering and z-fighting (p. 3286) when faces are close to each other.

Parallax occlusion mapping (p. 1768)

Enables parallax occlusion mapping. This option requires a heightmap, which you can select for the Normal Map option under the Texture Maps heading.

Displacement mapping

Enables displacement mapping. This option requires a heightmap, which you can select for the Normal Map option under the Texture Maps heading.

Phong tessellation

Enables the rough approximation of smooth surface subdivision.

PN triangles tessellation

Enables the rough approximation of smooth surface subdivision.

Blendlayer

Enables the blending of the normal-mapped diffuse layer on top of the base material.

Use UV set 2 for blendlayer (p. 1763) maps

Enables a second UV channel, if available, for blend layer texture maps and blend mask.

Use UV set 2 for emittance map

Enables a second UV channel, if available, for emittance map.

DetailMap mask in Diffuse alpha

Enables diffuse map alpha for masking detail maps. With this option you can use the alpha channel in the RGBA texture map to mask the decal.

Silhouette POM (p. 1767)

Enables parallax occlusion mapping with silhouettes. This option requires a heightmap, which you can select for the Normal Map option under the Texture Maps heading.

Depth Fixup

Enables write depth for depth of field and postprocessing.
Specular Anti-aliasing

Enables specular anti-aliasing. Enable this feature for highly glossy highlights on curved surfaces, which can be challenging to render without specular shimmering and crawling. This anti-aliasing feature estimates the subpixel region of the scene over which the specular normal distribution function should be filtered. The computation of the region is based on the projected size of each pixel. The normal distribution function (NDF) used in the specular bidirectional reflection distribution function (BRDF) is then filtered over this region, minimizing shimmering, crawling, and other specular aliasing artifacts. This method has almost no impact to GPU performance, is temporally stable, and compatible with Lumberyard's deferred shading system. Normal maps and normal map filtering techniques are compatible with this feature.

Occlusion Map

Enables support for a single channel occlusion map. If provided, this map decreases the amount of influence that indirect light has on a surface. When calculating the occlusion for a given pixel, if the occlusion map occludes more than the dynamically calculated occlusion, then that occlusion map is used instead. Otherwise it is ignored.

Dynamic Lighting for Transparency

Transparent materials (defined as having an alpha less than 100) that use this option are rendered using a full lighting pass. The lighting pass renders the object using a forward pass, forcing the object to be fully lit in any type of light. This parameter creates a better visual effect, but is also more GPU demanding.

LightBeam Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The LightBeam shader creates various fog-like volumetric and atmospheric effects for light beams. The shader can only be applied to light entities. To use the LightBeam shader, create a Projector Light component and assign the shader to the material slot.

Shader Parameters

Fade Distance

Defines the distance at which the effect should fade in/out.

This parameter requires that the Use Falloff shader generation parameter is enabled.

Default value: 200

Fade Scale

Scales how much the fading effect occurs at defined distance.

This parameter requires that the Use Falloff shader generation parameter is enabled.

Default value: 100

Global Density

Controls how dense or thick the fog effect is.

Default value: 1
Jitter Scale

Controls shadow jitter amount. Use to soften shadow artifacts at the cost of shadow accuracy.

Default value: 10

Noise Contrast

Defines the contrast level of the noise effect.

This parameter requires that the Noise map shader generation parameter be enabled.

Default value: 1

Noise Coord Scale

Scales noise. Applies to shadow and projector UVs.

This parameter requires that the Noise map shader generation parameter be enabled.

Default value: 0.005

Noise Dir X

Defines noise travel along the x-axis.

This parameter requires that the Noise map shader generation parameter be enabled.

Default value: 1

Noise Dir Y

Defines noise travel along the y-axis.

This parameter requires that the Noise map shader generation parameter be enabled.

Default value: 0

Noise Dir Z

Defines noise travel along the z-axis.

This parameter requires that the Noise map shader generation parameter be enabled.

Default value: 0

Noise Speed

Controls the speed at which noise travels.

This parameter requires that the Noise map shader generation parameter be enabled.

Default value: 5

Shader Generation Parameters

Noise map

Enables the use of a 3D, procedurally-generated noise map.

Use Falloff

Activates the Fade-type shader parameters to tweak visual fall-off settings.

Extra Sampling

Reduces aliasing for slightly more expensive rendering.
ParticleImposter Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The ParticleImposter shader is used to create particle effects that are not affected by light and hence do not cast shadows or cause reflections.

Particles Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Particles shader is used to render particle effects for fire, smoke, lightning, sparks, and fog that are affected by light, and as such cast shadows and cause reflections.

Shader Parameters

Color lookup amplitude

Sets the color lookup brightness and multiplier.

This parameter requires that the Color lookup shader generation parameter is enabled.

Default value: 1

Color lookup color phase

Sets the per-color phase to be used.

This parameter requires that the Color lookup shader generation parameter is enabled.

Default value: 1

Global Illumination Amount

Sets the amount of global illumination.

Default value: 1

Perturbation amount

Controls the amount of deformation that is used.

This parameter requires that the Screen space deformation shader generation parameter is enabled.

Default value: 0.01

Perturbation anim speed

Controls animation translation speed and frequency that is applied to the deformation map.

This parameter requires that the Screen space deformation shader generation parameter is enabled.

Default value: 0.05
Perturbation tiling

Controls the tiling amount of deformation.

This parameter requires that the Screen space deformation shader generation parameter is enabled.

Default value: 0.5

Deform amount

Controls deformation multiplier.

This parameter requires that the Deformation shader generation parameter is enabled.

Default value: 0

Deform anim speed

Controls deformation animation translation speed and frequency.

This parameter requires that the Deformation shader generation parameter is enabled.

Default value: 0

Deform tiling

Controls deformation tiling.

This parameter requires that the Deformation shader generation parameter is enabled.

Default value: 0.1

Refraction Bump Scale

Sets the refraction bump scale.

This parameter requires that the Refraction shader generation parameter is enabled.

Valid value range: 0 - 2.0

Default value: 0.1

Soft particles scale

Controls soft particle intersection softness for sharper or softer intersections.

Default value: 1

Threshold for writing depth

Sets the threshold for writing depth.

This parameter requires that the Depth Fixup shader generation parameter is enabled.

Default value: 0.05

Shader Generation Parameters

Refraction

Enables the use of a bump-map texture as the displacement for refraction.

Refraction Tinting

Enables the use of a color texture to tint refraction.
Screen space deformation

When enabled, the Refraction Normal texture map slot also becomes available under Texture Maps.

Deformation

When enabled, the Deformation Normal texture map slot also becomes available under Texture Maps.

Color lookup

Enables the use of the color lookup map for applying color lookup. When enabled, the Color Lookup Map texture map slot also becomes available under Texture Maps.

Specular Lighting

Enables the calculation of specular lighting in addition to diffuse lighting.

Depth Fixup

Enables writing depth for depth of field and post processing.

Scopes Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Scopes shader is used to render various optical effects for binoculars, telescopes, and weapon sight scopes.

Shader Parameters

Fake glow amount

Sets the amount of fake glow.

This parameter requires that the Reflex sight new shader generation parameter is enabled.

Default value: 0.25

Fresnel Bias

Sets the amount of fresnel bias.

This parameter requires that the Scope zoomed refraction shader generation parameter is enabled.

Default value: 1

Fresnel Scale

Sets the fresnel scaling amount.

This parameter requires that the Scope zoomed refraction shader generation parameter is enabled.

Default value: 1

Hologram depth

Sets the depth of the hologram.

This parameter requires that the Use halo sight depth shader generation parameter is enabled.
Default value: 2

**Holographic noise scale**

Sets the holographic noise scale.

This parameter requires that the Reflex sight new shader generation parameter is enabled.

Default value: 0

**Noise bias**

Sets noise bias.

This parameter requires that the Reflex sight new shader generation parameter is enabled.

Default value: 1

**Noise scale**

Sets noise scale.

Default value: 0.75

**Object space UV usage**

Sets the amount of usage of object space.

Default value: 0

**Refraction Bump Scale**

Sets the amount of scaling for refraction bumpiness.

Default value: 0

**Scope color multiplier**

Sets the scope color multiplier.

Default value: 160

**Scope scale**

Sets scope scale.

Default value: 4

**Shader Generation Parameters**

**Reflex sight**

Use for reflex-style weapon sights. When enabled, the Diffuse texture map slot under Texture Maps also becomes available.

**Reflex sight new**

Use for the newer version reflex-style weapon sights. When enabled, the Diffuse texture map slot under Texture Maps also becomes available.

**Scope zoomed refraction**

Use to produce light refraction effects for zoomed-in scopes.

**Use halo sight depth**

Used for holographic-style weapon sights with a depth-field modifier.
Thermal vision scope

Use to produce thermal color effects for night-use scopes.

Sky Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. 
Download O3DE or visit the AWS Game Tech blog to learn more.

The Sky shader is used to render performance-optimized static sky (SkyBox) effects.

Shader Parameters

Indirect bounce color

Adds an extra color tint to the reflection.

Default value: 136,136,136

SSS Index

Subsurface Scattering Index

Default value: 0

SkyHDR Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. 
Download O3DE or visit the AWS Game Tech blog to learn more.

The SkyHDR shader is used to render realistic dynamic sky effects that change based on the time of day in a level.

Shader Parameters

Indirect bounce color

Adds an extra color tint to the reflection.

Default value: 136,136,136

SSS Index

The Subsurface Scattering Index.

Default value: 0

Shader Generation Parameters

No moon

Removes the moon for the dynamic sky.
No night sky gradient

Removes the entire day night effect gradient for the dynamic sky.

No day sky gradient

Removes the entire day sky effect gradient for the dynamic sky.

TemplBeamProc Shader

The TemplBeamProc shader is used to create inexpensive fog-like light beam effects, enabling control over beam size and blending.

Best Practices

The following are some best practices for using this shader:

- Select the No Shadow property under Advanced.
- Set Opacity to 100%.
- Use a simple grayscale texture with no alpha in the Diffuse texture map slot.
- The shader fades out rendering faces that are at a certain angle to the camera. As such, use different sub-materials for the top plane and the intersecting planes to allow control of the angle of visibility.

Shader Parameters

ColorMultiplier

Increases or decreases brightness and blending.

Default value: 1

EndColor

Sets the end color for the gradient.

Default value: 255,255,255

EndRadius

Sets the radius (in meters) of the effect at the end of the object.

Default value: 2

Length

Adjusts the scaling of the rendered effect.

Default value: 10

OriginalLength

Sets the length scaling factor. If the values of Length and OriginalLength are identical, the object has scale of 100%.

Default value: 10
OriginalWidth

Sets the width scaling factor. If the values of Width and OriginalWidth are identical, the object has scale of 100%.

Default value: 1

Soft intersection factor

Controls softness of surface interaction with other opaque scene geometry.

Default value: 1

StartColor

Sets the start color for the gradient.

Default value: 255,255,255

StartRadius

Sets the radius (in meters) of the effect at the start of the object.

Default value: 1

View dependency factor

Controls the blending in and out depending on the facing angle to the camera.

The higher the value, the longer the effect is visible even when nearly 90° to camera, the smaller the value the earlier the effect starts to vanish.

Default value: 2

Shader Generation Parameters

Noise map

Enables the use of a 3D animated noise map, which enables a nice motion to the beams. However, this motion cannot be controlled by any parameters.

Muzzleflash

Enables use as a muzzle flash effect.

Terrain.Layer Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Terrain.Layer shader is used for painting and blending terrain texture layers in a level. Besides needing a bump map and high-passed diffuse map, the Terrain.Layer shader also requires a height map with either offset bump mapping (OBM) or parallax occlusion mapping (POM) enabled. Blending uses the height map to determine how the materials blend together. For example, if you have pebbles on one material and dirt as another, you may want the pebbles to accurately stand out from the dirt.

Here are a few notes regarding usage of this shader:

- The Detail normals texture is not an external texture, but rather a texture generated by Lumberyard through code.
• The **Decal** parameters don't appear under **Shader Params** unless you put a texture into the **Decal** slot first. The **Decal Bumpmap** slot also appears after this task.
• Flow map textures go in the **Detail** slot.

**Shader Parameters**

**Blend Factor**

Changes the visibility of the blended layer. A height map is required. **OBM** or **OBM** shader generation parameter must be enabled first.

Default value: 0

**Blend Falloff**

Changes the falloff of blending. A height map is required. **OBM** or **OBM** shader generation parameter must be enabled first.

Default value: 1

**Detail bump scale**

**Detail mapping** shader generation parameter must be enabled first.

Default value:

**Detail gloss scale**

**Detail mapping** shader generation parameter must be enabled first.

Default value:

**DetailTextureStrength**

Sets the strength of the diffuse map, which dictates how much detail texture is visible over the layer texture. The higher the value, the more you see only your Diffuse map.

Default value: 1

**Height bias**

**POM** shader generation parameter must be enabled first.

Default value: 0.5

**Indirect bounce color**

Sets the amount of indirectly bounced color

Default value: 136,136,136

Default value:

**OBM Displacement**

**OBM** shader generation parameter must be enabled first.

Default value: 0.01

**POM Displacement**

**POM** shader generation parameter must be enabled first.

Default value: 0.01
Self shadow strength

- **POM** shader generation parameter must be enabled first.
  - Default value: 3

Shader Generation Parameters

**Offset bump mapping (OBM)**

- Uses offset bump mapping. Requires a height map (_displ format).

**Detail mapping**

- Uses detail mapping.

**Parallax occlusion mapping (POM)**

- Uses parallax occlusion mapping. Requires a height map (_displ format).

Vegetation Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Vegetation shader is used to render trees, bushes, grass and other vegetation, as well as imparting various bending motion effects.

See the following guidelines for best results and performance with this shader:

- Use an **AlphaTest** value of 50 for opacity.
- Use a **Diffuse** color value of 128, 128, 128 for lighting.

Shader Parameters

**Bending branch amplitude**

- Defines the movement of blue color in the complex bending setup.
  - Default value: -0.5

**Bending edges amplitude**

- Defines the movement of red color in the complex bending setup.
  - Default value: 0.2

**Blend Factor**

- Changes visibility of blending layer. **Blendlayer** generation parameter must be enabled first.
  - Default value: 0

**Blend Falloff**

- Changes the falloff of blending.
  - Default value: 1
Blend Layer 2 Spec

Changes specular intensity of second blend layer. **Blendlayer** generation parameter must be enabled first.

Default value:

Blend Layer 2 Tiling

Changes tiling of second blend layer. **Blendlayer** generation parameter must be enabled first.

Default value:

Blend Mask Tiling

Changes tiling of blend mask.

Default value: 1

Cap opacity fall off

Controls the fading of alpha test textures when seen at a steep angle (so they look less like a plane). A value of 1 means it's turned off; 0 means it's fully activated.

Default value: 1

Detail bending frequency

Defines the bending speed for complex (wind) bending. Make sure that this value is in the correct proportion to the wind in your level.

Default value: 1

Indirect bounce color

Sets the amount of indirectly bounced color.

Default value: 136, 136, 136

Terrain Color Blend

Controls how much of the terrain color is blended into the diffuse color when up close. **Use Terrain Color** for the selected vegetation object must be enabled first, except when **AutoMerge** is enabled.

Default value: 0

Terrain Color Blend Dist

Controls how much of the terrain color is blended into the diffuse color at a distance. **Use Terrain Color** for the selected vegetation object must be enabled first, except when **AutoMerge** is enabled.

Default value: 0.5

Transmittance Color

Applies color tint for translucency. **Leaves** or **Grass** shader generation parameter must be enabled first.

Default value: 255, 255, 203

Shader Generation Parameters

Leaves

Enables leaf shading and leaves animation. This parameter causes the gaming Lumberyard to use a much more complex (expensive) shading, so activate only for leaves rendering.
Grass

Enables simple and cheap grass rendering. Specular and normal map setting are essentially disabled, so the shading is only diffuse.

Detail bending

Enables detail bending, which simulates wind on vegetation objects. Activate for leaves and grass only. Also, make sure to paint required vertex colors.

Detail mapping

Enables detail mapping.

Blendlayer

Enables normal-mapped diffuse layer blended on top of base material.

Displacement mapping

Enables displacement mapping. Requires a height map (.displ format).

Phong tessellation

Enables rough approximation of smooth surface subdivision.

PN triangles tessellation

Enables rough approximation of smooth surface subdivision.

VolumeObject Shader

Use Amazon Lumberyard's VolumeObject shader to render volumetric clouds with realistic shading and self-shadowing effects.

In addition to the shader parameters, the Time of Day Editor's Cloud Shading parameters (p. 1298) also can affect VolumeObject rendering. To disable this feature, deselect Use TOD Settings in the Shader Generation Parameters (p. 1714).

Shader Parameters

Global Density

Defines how dense the clouds appear.

Default value: 1

Shader Generation Parameters

Soft Intersections

Enhances transparency with opaque scene geometry. Use this parameter sparingly due to increased pixel shading cost.

Back Lighting

Enables back lighting of volume objects. The silhouette slightly glows when viewed against the sun.
Jittering

Enables jittering on volume objects.

Soft Jittering

Softens the jittering effect on volume objects.

Use TOD Settings

Enables time of day (TOD) settings.

Water Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Water shader is a dedicated shader used to render the ocean exclusively, and imparts various reflection, ripple, and foam effects. For lakes, rivers, and other bodies of water, use the VolumeObject Shader (p. 1714) instead.

Shader Parameters

Crest Foam Amount

Sets amount of foam that appears at the crest of a wave. Use for FFT-displaced ocean only on the Very High Spec setting. Foam shader generation parameter must be enabled first.

Default value: 1

Detail Normals scale

Sets normal scale.

Default value: 0.5

Detail Tiling

Sets waves detail bump tiling.

Default value: 2.5

Fake camera speed

Causes the surface of the water to scroll in world-space. This parameter gives the impression that a stationary object in the ocean is actually moving through the ocean. Fake camera movement shader generation parameter must be enabled first.

Default value: 0

Foam Amount

Multiplier for foam. Foam shader generation parameter must be enabled first.

Default value: 1

Foam soft intersection

Very similar to soft intersection, but blends foam on intersection regions. Foam shader generation parameter must be enabled first.

Default value: 0.75
Foam tiling
Sets tiling amount for foam. **Foam** shader generation parameter must be enabled first.
Default value: 12

Fresnel gloss
The gloss of the Fresnel effect.
Default value: 0.9

Gradient scale
Applies a more choppy look to waves.
Default value: 0.1

Height scale
Sets scale for height map, which is used for parallax mapping approximation.
Default value: 0.2

Normals scale
Sets overall scale for normals.
Default value: 1.25

Rain ripples tiling
Sets tiling for rain ripples.
Default value: 1

Reflection bump scale
Reflection map bump scale.
Default value: 0.1

Reflection scale
Sets real-time reflection map multiplier or cube map multiplier for water volumes.
Default value: 1

Ripples normals scale
Sets dynamic ripples normals scale.
Default value: 1

Soft intersection factor
Sets water soft intersection with geometry.
Default value: 1

SSS scale
Sets SSS scale.
Default value: 2

Tiling
Sets waves bump tiling.
Default value: 10
**Watervol flow speed**

Default value:

Sets the flow speed for the water volume flow map. **Water Volume flow** shader generation parameter must be enabled first.

Default value: 10

**Shader Generation Parameters**

**Water Volume flow**

Enables water flow along UVs.

**Water Volume**

Disable this parameter to use the Water shader.

**Sunshine**

Enables sunshine effects on the ocean surface.

**Fake camera movement**

Enables fake camera movement for scenes in the ocean.

**No refraction bump**

Disables refraction bump.

**Foam**

Enables foam on the ocean surface.

**Waterfall Shader**

---

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

---

The Waterfall shader is used for waterfalls exclusively, and provides layering, tiling, and motion effects.

**Shader Parameters**

**Alpha blend multiplier**

Applies a multiplier amount for alpha blending.

Default value: 1

**Foam deform**

Deforms the foam texture with a multiplier, based on the bump map texture. **Foam** shader generation parameter must be enabled first.

Default value: 0.025

**Foam multiplier**

Applies a multiplier amount for foam texture. **Foam** shader generation parameter must be enabled first.
Default value: 1

Fresnel bias

The Fresnel bias.

Default value: 0.25

Layer0 bump scale

Scales the bump map texture for the first layer.

Default value: 2

Layer0 speed

Controls the texture rolling speed for the first layer.

Default value: 1

Layer0 tiling

Sets the texture tiling amount for the first layer.

Default value: 1

Layer1 bump scale

Scales the bump map texture for the second layer.

Default value: 1

Layer1 speed

Controls the texture rolling speed for the second layer.

Default value: 2

Layer1 tiling

Sets the texture tiling amount for the second layer.

Default value: 2

Reflect amount

Controls the reflection amount, which comes from the environment map. Environment map shader generation parameter must be enabled first.

Default value:

Refraction bump scale

Scale the refraction effect inherited by the bump map texture.

Default value: 0.01

Sun multiplier

Applies a multiplier amount for sun shading. Sun shading shader generation parameter must be enabled first.

Default value: 1

Shader Generation Parameters

Environment map

Enables the use of an environment map as a separate texture.
Sun shading

Enables sunlight shading effects.

Foam

Enables foam rendering. Uses diffuse texture.

WaterVolume Shader

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Watervolume shader is used for rendering volumetric bodies of water including lakes, pools, and rivers and imparts various reflection, ripple, and foam effects. For the ocean, use the Water Shader (p. 1715) instead. Here are a few notes regarding usage of this shader:

- The Detail normals texture is not an external texture, but rather a texture generated by Lumberyard through code.
- The Decal parameters don't appear under Shader Params unless you put a texture into the Decal slot first. The Decal Bumpmap slot also appears after this task.
- Flow map textures go in the Detail slot.

Shader Parameters

Detail normals scale

Scales the detail bump normals intensity.

Default value: 0.5

Detail tiling

Sets detail bump tiling.

Default value: 2.5

Env projection scale

Controls the projection scale, or the tiling, of the specified environment map.

Default value: 20

Env reflection amount

Controls the reflection amount of the environment map. Can be offset with Specular Color.

Default value: 1

Flow map scale

Controls the scale, or tiling, of the flow map texture. Enable Water flow map in Shader Generations Params to use this property.

Default value: 0

Flow speed

Specifies the speed of the flow effect. Water flow shader generation parameter must be enabled first.
Default value: 0

**Foam amount**

Controls the amount of foam placed on the water surface. *Foam* shader generation parameter must be enabled first.

Default value: 1

**Foam soft intersection**

Controls how the foam behaves from contact areas. Foam forms around intersecting objects and the terrain after it gets close to the surface. *Foam* shader generation parameter must be enabled first.

Default value: 0.75

**Foam tiling**

Sets the tiling amount of the foam texture. *Foam* shader generation parameter must be enabled first.

Default value: 12

**Normals scale**

Controls the scale of the normals. Don’t confuse this parameter with Detail normals.

Default value: 1.25

**Rain ripples tiling**

Sets the tiling amount for the rain ripples texture.

Default value: 1

**Realtime reflection amount**

Controls the reflection amount for the Realtime Reflection.

Default value: 1

**Soft intersection factor**

Similar to the Foam soft intersection but for the base water surface.

Default value: 1

**Tiling**

Changes the amount of texture map tilling on the water surface.

Default value: 10

**Vertex wave scale**

Sets strength of vertex displaced wave animation.

Default value: 0.125

---

**Shader Generation Parameters**

**Realtime Reflection**

Enables approximate real-time reflections.
Selecting Material Surface Type

Water flow
- Enables water to flow along geometry UVs.

Water flow map
- Enables water flow along a flow map.

Water flow map strength
- Enables additional water flow strength controls, which requires the blue channel for strength.

Sun specular
- Enables water sunshine.

Debug flow map
- Enables visualizing flow map.

Foam
- Enables foam.

Selecting Material Surface Type

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The surface of a material determines the physical effects and how the material reacts to other materials and its environment. For example, a metal surface is hard, doesn't shatter, reacts to bullets by generating spark particles, and has a unique sound when struck. Contrast this with a grass surface, which is soft, responds to wind, generates grass strands and dirt particles when hit, and sounds different than metal.

To select a material surface type
1. In Lumberyard Editor, click Tools, Material Editor.
2. In the left pane, click to select the desired asset.
3. Under Material Settings, make a selection for Surface Type.

Setting Material Opacity

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

An object's opacity refers to its transparency level. Opacity is important when using an alpha channel for transparency.

To set opacity for a material
1. In Lumberyard Editor, choose Tools, Material Editor.
2. In the Material Editor, search for or browse to your asset and then select it.
3. Use the opacity settings to switch between alpha blend and alpha test modes. With the alpha blend mode, you can enable soft and semi-transparent opacity. The alpha test mode is more performant and uses a black and white hard edge from the alpha map.
Under **Opacity Settings**, you can adjust the following parameters:

- **Opacity** – Set the opacity mode and transparency amount of the material. For the alpha blend mode, set the value between 0 to 99. For the alpha test mode, set the value to 100.

  ![Example images for opacity](image)

  - Opacity = 99, AlphaTest = 0
  - Opacity = 99, AlphaTest = 10
  - Opacity = 50, AlphaTest = 0

- **Alpha Test** – Bias the edge of the alpha towards black or white. Set the value below 50 to bias toward the white of the alpha map. Set the value above 50 to bias toward the black of the alpha map.

  ![Example images for alpha test](image)

  - Opacity = 100, AlphaTest = 0
  - Opacity = 100, AlphaTest = 1
  - Opacity = 90, AlphaTest = 50

- **Additive** – Enable to add the material color to the background color. This results in a brighter color for the object.

## Setting Material Lighting and Color Settings

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Material Editor to specify color, specular reflection, and lighting effects such as specularity, glossiness, and glow.
Specify the diffuse, specular, or emissive color values in RGB format, or select the values using the Colors dialog box. Click the color square next to the parameter to open the Colors dialog box. You can then use the color picker to select standard or custom colors for the hue, saturation, and luminance values.

To set lighting and color settings for a material

1. In Lumberyard Editor, click Tools, Material Editor.
2. In the left pane, select the asset that you want to modify.
3. Under Lighting Settings, set values for the following parameters:

### Material Lighting and Color Settings

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diffuse Color</td>
<td>The base color of a material.</td>
</tr>
<tr>
<td>Specular Color</td>
<td>The reflective brightness and color of a material when light shines on the object. The greater the value, the shinier the material. Grayscale values affect reflective brightness levels. To tint the specular color, use the color picker to select the desired tint.</td>
</tr>
<tr>
<td>Smoothness</td>
<td>The acuity or sharpness of a specular reflection. For values of 10 or less, there is a scattered reflection. For values greater than 10, there is a sharp reflection. You cannot have glossiness without specular color (reflection), as glossiness determines the sharpness of the reflection.</td>
</tr>
<tr>
<td>Emissive Color</td>
<td>Enable objects to emit light and be visible in the dark. Use this parameter to add brightness to objects. Unlike glow, this parameter does not emit light onto other objects. It does not work with deferred shading.</td>
</tr>
<tr>
<td>Emissive Intensity</td>
<td>Enable objects to glow, and simulate light that emits from extremely bright surfaces. Use this parameter in dark scenes for computer monitors, lamps, fire, neon lights, and similar objects. Unlike emissive color, this parameter emits light onto other objects. You can use a diffuse texture RGB channel to specify glow color, and a diffuse texture alpha channel to specify glow mapping. This allows you to mask the pixels where you want less (or no) glow. You can use glow with the Cloth, HumanSkin, and Illum shaders. To enable or disable glow, use the r_Glow console variable.</td>
</tr>
</tbody>
</table>

### Material ID Mapping in Autodesk 3ds Max

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A mesh (.cgf file) can have different materials assigned to different faces. When you work in Autodesk 3ds Max, make sure you have enough submaterials to cover the number of material IDs assigned to faces on the mesh object. Otherwise the material IDs won’t get exported correctly to Lumberyard.

The following procedure presents an example that uses a multimaterial cube.
To map multi-material IDs in 3ds Max

1. Open 3ds Max. Then create and place a cube in the viewport.

2. Right-click the cube and click **Convert To, Convert to Editable Mesh**. You can now assign different material IDs to the faces.
3. From the 3ds Max top menu, choose Rendering, Material Editor, Compact Material Editor.
4. From the 3ds Max top menu, choose Rendering, Material/Map Browser.
5. In Material/Map Browser, under Materials, expand Standard. Then double-click Multi/Sub-Object. In the 3ds Max Material Editor, under Multi/Sub-Object Basic Parameters, look for a material ID list to fill in. Select the first entry by clicking None in the Sub-Material column. Select Standard under the Standard material rollout.
6. In the 3Ds Max Material Editor, under Shader Basic Parameters, select Crytek Shader.

7. Under Maps, next to Diffuse Color, select None.

8. In Material/Map Browser, under Maps, double-click Bitmap. Then double-click to select the desired image file. Afterward the image file appears in the 3DS Max Material Editor for the Diffuse Color parameter.
9. While still in Material Editor, choose Navigation, Go to Parent. Then repeat to get back to the material ID list.
10. Create a second subshader by repeating steps 5 through 9 for the second entry in the list. Click Set Number, then enter 2 in the Number of Materials pop-up window. The list shows only two submaterials.

11. In Material Editor, under Name, enter a name.

12. With the object selected in the viewport, go to Material Editor and choose Material, Assign to Selection.

13. Click the hammer icon. Under Utilities, select Lumberyard Export, select the object, and then choose Add Selected to place the object in the Geometry Export list.

14. In the 3ds Max panel on the right, under Modifier List, select Editable Mesh, Polygon.

15. In the viewport, select the top face. Then, under Surface Properties, click Set ID and set the value to 2. This makes the top face use the second material in the final material group.

16. Select the other faces and set their Set ID values to 1. The final face coloring should match the one shown in the following image.
17. Select **Export Nodes** to create a `.cgf` file.
18. Click Create Material to open the Lumberyard Material Editor and display a file dialog box.

19. Navigate to the directory where your .cgf files are located. Then enter the same file name that you specified in 3ds Max. This ensures that the .cgf file can automatically find the correct .mtl file when loaded in the Lumberyard Material Editor.
20. In Lumberyard Editor, create a level and open the `.cgf`. The object should have the correct materials mapped onto its faces.

**Working with Textures**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

Textures can be used to provide color, depth, and details to a surface. For example, a repeating brick-and-mortar texture can be used to simulate a brick wall, rather than creating geometry for each individual brick.

A texture is an image file that consists of a number of pixels, called texels, each occupying a coordinate determined by the width and height of the texture. These coordinates are then mapped into values ranging from 0 to 1 along a U (width) and V (height) axis. This process produces a 2D texture map that is stored in a `.DDS` file.

In turn, the process of mapping the UV coordinates of a texture map to the corresponding UV coordinates at the vertices on a 3D object is called UV mapping. This in effect wraps the 2D texture onto the 3D object.

Textures are dictated by, and applied by, the shader that is selected for a material. There can be multiple textures applied by the shader for a material.

Textures used in Lumberyard are usually created with Adobe Photoshop or other DCC tool.

Topics
Texture Map Types

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Source texture files are converted and compiled in .DDS format by the Resource Compiler (RC). If you do not specify presets for the source file, the Resource Compiler will do the following:

- Files with a file suffix of _ddn or _bump will generate an uncompressed RGBA or U8V8 NormalMap .DDS file with height information in the alpha channel.
- Files with a non-white (less than 255) alpha channel will generate a DXT3-compressed .DDS file.
- Files without an alpha channel will generate DXT1 compressed .DDS file.

<table>
<thead>
<tr>
<th>Texture Map</th>
<th>Filename Suffix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diffuse map</td>
<td>_diff</td>
<td>Defines the main color for an object.</td>
</tr>
<tr>
<td>Normal map</td>
<td>_ddn</td>
<td>Defines the direction of normals on an object surface. The RGB normal map stores the normal direction for each pixel in the texture.</td>
</tr>
<tr>
<td>Normal with Gloss map</td>
<td>_ddna</td>
<td>Achieves physically-correct results. DDNA textures are standard DDN textures with the gloss map stored inside the Alpha channel.</td>
</tr>
<tr>
<td>Environment map</td>
<td>N/A</td>
<td>Makes an object reflective. The environment map stores the image that is reflected off the object.</td>
</tr>
<tr>
<td>Displacement map</td>
<td>_displ</td>
<td>Gives more depth and definition to an object when used in tessellations, parallax occlusion mapping (POM), and offset bump mapping (OBM).</td>
</tr>
<tr>
<td>Detail map</td>
<td>_detail</td>
<td>Adds more detail to a surface. This texture map works like a second material layer and is not affected by the mapping of the object.</td>
</tr>
<tr>
<td>Emittance Multiplier</td>
<td>N/A</td>
<td>Multiplies the emissive color.</td>
</tr>
<tr>
<td>Blend (layer)</td>
<td>N/A</td>
<td>Blends multiple textures using an adjustable mask texture and a vertex alpha.</td>
</tr>
</tbody>
</table>
Texture Settings Editor

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Texture Settings Editor to edit the texture settings for individual images. This is useful if you are customizing your images for different platforms, such as PC and Android. For example, you can specify compression scheme, mipmap generation parameters, alpha map combinations, and so on for images. When you edit your texture settings for an image, the Texture Settings Editor generates a .imagesettings file to save your settings.

The Texture Settings Editor supports the following image formats:

- .bmp
- .gif
- .jpg
- .jpeg
- .png
- .tga
- .tif
- .tiff

Note

- The Texture Settings Editor requires the Image Processing (p. 1147) gem. By default, this gem is enabled.

The Texture Settings Editor can also load the previous Resource Compiler (RC) generated .exportsettings file. If you make any changes to this file, the Texture Settings Editor deletes this file and generates a new .imagesettings file. If you have Perforce enabled, Perforce tracks the new or modified files.

You can find the default settings for the Texture Settings Editor in the ImageBuilderDefaultPresets.settings file. You can modify the default settings file as needed.

To modify the default settings

2. Navigate to the lumberyard_version/dev/game_project/Config/ImageBuilder/ directory.
3. Paste the copied file and rename it to ImageBuilderPresets.settings.
4. In a text editor, make your changes and save.

Note

This file replaces the previous rc.ini file, which contains the predefined presets to generate textures for your game. To migrate your settings from the rc.ini file, see Migrate RC.ini Settings to the Texture Settings Editor (p. 1746).

Topics

- Using the Texture Settings Editor (p. 1735)
Using the Texture Settings Editor

To use the Texture Settings Editor

1. In Lumberyard Editor, choose **Tools, Asset Browser**.
2. In the **Asset Browser**, navigate and select a source file, such as a `.tif` file.

![Asset Browser Screenshot](image)

You can preview the texture, its file size, dimensions, and select the drop-down menu to preview the texture with the following channels:

- **RGB**
- **Alpha**
- **RGBA**

3. To view more information, expand the arrow icon, and select the texture file that appears below the source file.
See the following information about the texture:

- Compiled texture
- File size
- Resolution
- Format
- Mip count
- Memory size
- Color space
- Image flag

4. To open the Texture Settings Editor, right-click the source file, and choose Edit Texture Settings.

5. In the Texture Settings Editor, you can view the following:
   
   A. **Preview (p. 1737)** – Preview of the processed image with the current settings.
   
   B. **Texture Presets (p. 1738)** – List of presets to choose.
C. **Platform (p. 1739)** – Specify the different resolution adjustments on different platforms.

D. **Mipmap Settings (p. 1743)** – Allows the adjustment of mipmap generation.

6. When finished, click **Apply** to save the current properties. This exports a setting file named `imageName.imagesettings` next to the source file.

**Note**

- If there is an existing legacy `.exportsettings` file associated with the texture file, the legacy file will be automatically deleted.
- Click the ? icon to open the texture documentation.

**Preview**

In the preview panel, you can do the following:

A. Click the drop-down menu to preview the texture in the following channels:

- **RGB** – Displays the RGB color channels (default).
- **R** – Previews the red channel in grayscale.
- **G** – Previews the green channel in grayscale.
- **Alpha** – Previews the alpha channel in grayscale.
- **RGBA** – Previews the alpha blended with the background.
B. **Preview tiled** – Preview the texture in a 2x2 tiled layout. By default, the texture appears in a fixed size.

C. Press and hold the following shortcuts to change the preview for the texture:
   - **Shift** – Changes the preview to RGBA mode.
   - **Alt** – Changes the preview to Alpha mode.
   - **Space** – Opens a pop up window that previews the texture in its actual output size.

D. Click the arrow icons to view the different mipmap previews. Mip 0 is the original output image.

E. Click the refresh icon to refresh the preview. You can click the drop-down menu to specify the following:
   - **Always refresh preview** – Refresh automatically when you make a change.
   - **Press to refresh preview** – Manually refresh the preview.

---

**Texture Presets**

In the **Texture presets**, you can do the following:

- **Active preset** – Click the drop-down menu to view the presets that you can assign to a texture. The texture using the preset values automatically appears in the preview panel. Texture properties are also updated.

  **Note**
  The Texture Settings Editor supports different presets that specify the options that are applied when an image asset is compiled. When you open the Texture Settings Editor, it loads the main settings and presets from the game project folder at the following file:
  `lumberyard_version\dev\game_project\Config\ImageBuilder\ImageBuilderPresets.settings`
  If this file doesn't exist, the Texture Settings Editor loads the default settings from the following file:
  `lumberyard_version\dev\Gems\ImageProcessing\Code\Source\ImageBuilderDefaultPresets.settings`

- Click the reset icon to reset all texture properties to the default values of the current preset.
- Click the info icon to display a pop-up window for the current settings.
• **Active file conventions** – Name convention that the current preset setting supports. For more information, see Texture Map Types (p. 1733).

• **Suppress spec reduction** – By default, when Lumberyard Editor switches from high to low specification, textures are automatically scaled down so that they can load into the graphics card memory. However, you can set this setting, which overwrites all resolution reduction settings, so that the texture keep its original size throughout the different quality settings. It's recommended that you set this setting for textures that have text.

  For more information, see Editor Settings (p. 189).

**Platform**

In the **Platform**, you can specify the following.

---

**Setting**

Lumberyard supports the following platforms:

- PC
- Android
- iOS
Setting

- macOS
**Setting**

*Specifies the resolution for each platform.*

You can specify the following values:

- **0**
  - No reduction.
- **1**
  - Reduces the texture resolution by ½. Reduces the memory consumption to ¼ of the original memory.
- **2**
  - Reduces the texture resolution by 1/4. Reduces the memory consumption to 1/16 of the original memory.
### Setting

- **3**  
  Reduces the texture resolution by 1/8. Reduces the memory consumption to 1/64 of the original memory.

- **4**  
  Reduces the texture resolution by 1/16. Reduces the memory consumption to 1/256 of the original memory.

- **5**  
  Reduces the texture resolution by 1/32. Reduces the memory consumption to 1/1024 of the original memory.
**Setting**

**Size**
Compiled texture resolution calculated according to the **DownRes** value.

**Format**
Compiled texture format on the platform.

### Mipmap Settings

In the **Mipmap Settings**, you can specify the following.

![Mipmap Settings](image)

**Enable**

Enable or disables mipmap generation for the current texture.
<table>
<thead>
<tr>
<th>Description Settings</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Maintain Alpha Coverage</strong></td>
</tr>
<tr>
<td>manual adjustment of alpha channel mipmaps is allowed or not.</td>
</tr>
</tbody>
</table>
### Description

**Settings**

**Alpha**

Alpha map's

**Bias**

be multiplied with

a scale based on alpha coverage.

This value will be applied to the final results as an offset.

You can only set this setting if **Maintain Alpha Coverage** is set.

Valid values: 0 to 100
### Mipmap

**Description**

(pixel) is generated when sampling mipmaps.

You can specify the following options:

- **Max**
- **Min**
- **Sum**

**Filter Method**

Specifies the filter method used to process the mipmap.

You can specify the following options:

- **Point**
- **Average**
- **Linear**
- **Bilinear**
- **Gaussian**
- **BlackmanHaris**
- **KaiserSinc**

### Migrate RC.ini Settings to the Texture Settings Editor

The Resource Compiler uses the `rc.ini` file to store your default texture presets. In Lumberyard 1.18, the Texture Settings Editor uses the `ImageBuilderDefaultPresets.settings` instead.

If you want to transfer your settings from the Resource Compiler to the Texture Settings Editor, you must do this manually.
Example

In rc.ini, settings are ordered by preset, which contains the format for all devices. For example, the Albedo preset is stored.

```
[Albedo]
pixelformat=BC1
pixelformat:es3=ETC2
pixelformat:ios=PVRTC4
maxtexturesize:es3=512
rgbweights=ciexyz
powof2=1
colorspace=sRGB,auto
filemasks=_diff*
```

The ImageBuilderDefaultPresets.settings file is in a format that Lumberyard can serialize.

The following example contains the Albedo preset for PC with only the relevant parts that match the settings used in rc.ini. If you modify the PC Albedo preset, you should also make the change to other platforms. This ensures that your changes take effect on all platforms.

```
<ObjectStream version="3">
  ...
  <Class name="AZStd::string" field="value1" value="pc" type="{03AAAB3F-5C47-5A66-9EBC-D5FA4DB353C9}"/>
  ...
  <Class name="PresetSettings" field="value2" version="1" type="{935BCE3F-9E76-494E-9408-47C937D7286B}">

Texture Best Practices

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When creating textures, consider the following best practices and guidelines:

- Use the fewest number of textures that will do the job.
- For road textures, make sure the texture is horizontal.
- Use detail maps to add detail and crispness to lower-resolution textures. Detail maps can be used to add extra grain to wood, extra cracks to a concrete wall, or small scratches to car paint.
- Reuse normal maps and specular maps when possible to save texture memory. Normal maps are twice as expensive memory-wise compared to regular textures. For example, when using several types of floor tiles, brick walls, and concrete walls, create textures so they can use the same normal map and specular map.
- Combine textures for small generic items such as pipes and railings to save on drawcalls. For example, a house can consist of a wall texture, roof texture, and a detail sheet with all windows, frames, and doors. This saves on materials and drawcalls.
- Do not make textures bigger than they appear onscreen. A roof texture on a tall building that neither the player nor the camera can see at close range should be smaller, for example, than a ground texture.
- Use decals to break up and compensate for lack of texture amount. Dirt and stain decals are an easy way to break up tiled textures.
- Use vertex colors to create variety, depth, and color variations. Vertex painting and pre-baked vertex lighting is a relatively cheap way to add depth to objects and make them more interesting.
- Use grayscale textures that can be color-tinted to save on texture memory. Objects that benefit from this technique include cars, fences, barrels, and crates.

Working with Diffuse Maps

When light hits a surface, it splits into two directions: some is reflected immediately off the surface while the rest enters the surface and gets refracted. The refracted light can be absorbed or scattered underneath the surface and exit again at a different angle. This absorbed and refracted light is the diffuse color of an object.

The diffuse color defines how bright a surface is when lit directly by a white light source with an intensity of 100%. Physically speaking, it defines what percentage for each component of the RGB spectrum does not get absorbed when light scatters underneath the surface.

Texture mapping the diffuse color is like applying an image to the surface of the object. For example, if you want a wall object to be made out of brick, you can choose an image file with a photograph of bricks. A diffuse map is always required for objects.

The diffuse map should not contain any lighting, shading or shadowing information, as all this gets added dynamically by Lumberyard. In certain cases, pre-baked ambient occlusion (AO) is required, which is stored in a dedicated AO map in the diffuse channel of the Detail Map. For more information, see Working with Detail Maps (p. 1751).
Diffuse maps can be combined with other texture maps, such as ambient occlusion maps and cavity maps, to create more definition.

**Diffuse Mapping Best Practices**

- Don't use too light or too dark of a texture that will require too much color compensation.
- Metal objects should have a black diffuse color. Rusty metal however needs some diffuse color.
- Paint, or use occlusion mapping, to darken cracks and holes.
- Use crisp colors and contrast to define variations in shapes in order to break up the image.
- Create UV maps so that there is a decent compromise of space utilization and stretching.

**Working with Normal Maps**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The illusion of extra depth and detail to objects is achieved by using normal maps, which are a type of bump map. Bump maps and normal maps both add detail without increasing the number of polygons. As such, they are used to "fake" depth and details such as wrinkles, scratches and beveled edges. Unlike displacement mapping, normal maps affect shading and not the surface itself. The surface remains flat when seen from an angle.

Bump maps store an intensity that represents the relative height (bump) of pixels from the viewpoint of the camera. Traditional normal maps, in addition to storing the height, also store the direction of normals in the RGB values of the texture image. As such, they are more accurate than bump maps.

Lumberyard uses a form of normal mapping, called Tangent Space Normal Mapping, which uses either a height map or is derived from a high-polygon model. In a normal map, a color represents a certain normal vector (surface orientation of a point). For tangent space normal maps the information is relative to the underlying surface.

Tangent space normal maps are independent of the underlying geometry which means the texture can be used on other geometry as well. It will automatically align to the surface regardless of mirroring, rotation, scale or translation. Only the latter two are supported by traditional (object or world) normal maps.

An advantage of tangent space normal maps is that the normals are always pointing outwards, so assuming unit length, the normal z coordinate can be reconstructed from the x and y components. After the coordinate expansion from 0..1 to the -1..1 range, the z component can be computed in the shader with this formula: \( z = \sqrt{1 - x^2 + y^2} \). This makes it possible to use two-channel textures (2 bytes per texel) to store normal maps.

**Topics**

- Normal Mapping Best Practices (p. 1749)
- Using Normals with Gloss Maps (p. 1750)

**Normal Mapping Best Practices**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To get the best results, use the following best practices when creating normal maps.
You can use the following practices in your content creation tool to get the best results from your normal maps:

- Render normal maps using the following swizzle coordinates:
  - +X
  - -Y
  - +Z
- To minimize errors generated by mipmap levels, set the UV padding in your DCC tool to a minimum of 3 pixels.
- When resizing a normal map, use bi-linear interpolation and not bi-cubic.
- When you create mirrored UVs, check the seams and make sure the UVs are facing the same direction on both sides.
- To prevent unexpected lighting issues, make sure the normal map was not altered by the following:
  - Bi-cubic filter
  - Sharpening
  - Alpha blending

Changes to these settings can negatively impact the values in a normal map.

- Preview the normal map in the Material Editor to check for rendering issues.
- For naming conventions:
  - Normal maps with a gloss map in the alpha channel should use the suffix _ddna. For example, road.tif would be road_ddna.tif.
  - Normal maps without a gloss map in the alpha channel should use the suffix _ddn. For example, road.tif would be road_ddn.tif.

Using Normals with Gloss Maps

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Most materials should have a gloss map as well as a normal map as this can impart a lot of variation to the shading. Gloss maps are closely related to normal maps, as high frequency details in a normal map can create some roughness as well. However, gloss is more the microscale roughness of the material while normal represents macro-scale bumpiness. Gloss maps are treated like diffuse maps.

The Gloss map always goes into the Alpha channel of the Normal map, even if you’re using a specular map for metals and metal-embedded surfaces.

If the preset NormalMapWithGlossInAlpha_highQ is selected, the Resource Compiler will automatically adjust the gloss map stored in the alpha channel based on the normal variance and lower the gloss where normals are very bumpy. This can greatly help to reduce shimmering and sparkling highlights artifacts.

Lumberyard uses DDNA textures, which is a standard DDN texture with the addition of a Gloss map in the alpha channel of the normal map. DDNA texture map must use the _ddna.dds filename suffix (instead of _ddn.dds) for the Resource Compiler to recognize the texture correctly.

Working with Gloss Maps

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Gloss defines the roughness of a surface. A low gloss value means that the surface is rough while a high value means the surface is smooth and shiny. The roughness influences the size and the intensity of specular highlights. The smoother and glossier a surface is, the smaller the specular highlight will be. A smaller highlight will at the same time be brighter in order to obey to the rules of energy conservation.

For physically-based shaders, the gloss map is highly important. Most materials should have a gloss map as well as a normal map as this can impart a lot of variation to the shading. Gloss maps are closely related to normal maps, as high frequency details in a normal map can create some roughness as well. However, gloss is more the microscale roughness of the material while normal represents macro-scale bumpiness. Gloss maps are treated like diffuse maps.

The Gloss map always goes into the Alpha channel of the Normal map, even if you're using a specular map for metals and metal-embedded surfaces.

Gloss mapping is more powerful than the traditional specular mask, as gloss influences not only the brightness of a highlight but also its size and the sharpness of reflections.

When working with textures, gloss maps and normal maps are created first, then diffuse maps. Diffuse maps should contain no lighting information.

The gloss map is always stored in the alpha channel of the normal map. If the preset NormalMapWithGlossInAlpha_highQ is selected, the Resource Compiler will automatically adjust the gloss map stored in the alpha channel based on the normal variance and lower the gloss where normals are very bumpy. This can greatly help to reduce shimmering and sparkling highlights artifacts.

**Gloss Map Best Practices**

- Put variation into the gloss map. Not just random noise but really where the object would be less or more rough.
- If an object has the correct physical specular color but does not show specular highlights on top of the diffuse, the gloss is likely set too low. Increase the brightness of the gloss map.
- The Glossiness value must be set to 255, otherwise the gloss map will not work.
- Non-metals should have a specular color value between 53 and 61, based on what looks the best.
- For metals (and for metal parts embedded in non-metals), a dedicated specular texture map is used, with the gloss map going into the alpha channel of the normal map. The gloss map defines the smoothness, reflectivity and tightness of specular highlights. For metals, the shader doesn't control specular color – the specular texture map does. Specular color is physically based. Because of this, set the Specular color value to 255.

**Working with Detail Maps**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Detail mapping is a simple technique to add macro surface detail at relatively low cost, memory and performance wise. The following best practices should be taken into consideration:

- Use as low a resolution as possible for best performance (512x512 or lower).
- Prevent artifacts by using a higher tiling scale.
- Decrease contrast for the detail diffuse and gloss.

Unified detail mapping (UDM) is basically a reversed detail map. Usually the detail map is used for finer details as you get closer. UDM is the opposite. It helps to define big shapes viewed from the distance.
Since close-up detail is provided in tiled textures, larger details are needed to define shapes better when viewed from a distance.

**Setting Up Detail Map Textures**

Detail map parameters are setup in the Material Editor.

**To set Detail Map parameters**

1. In Lumberyard Editor, click **Tools, Material Editor**.
2. In the left tree, select an applicable texture.
3. In the right pane, under **Shader Generation Params**, click the **Detail Mapping** check box.
4. Under **Shader Params**, set values for the following parameters.
   - **Detail bump scale**: Defines how much the normal map is visible. The higher the value, the more the normal map will show through.
   - **Detail diffuse scale**: Defines how much the diffuse map (or AO map) visible. The higher the value, the more the normal map will show through.
   - **Detail gloss scale**: Defines how much the gloss map is visible. The higher the value, the more the gloss map will show through.

**Working with Decals**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Decals are non-repeating images or textures that are applied to the surface of an object or terrain with a specified projection. Common examples of decals are product labels and logos, artwork for walls, signs, and surface cracks.

Decals can break up uninteresting textures and bring together such level elements as brushes and terrain. Good decal placement can also create seamless transitions between many different objects. Decals only work with the **Illum Shader** (p. 1697).

**Note**

If you apply decals to an object that can be moved by a player, the decal will not move with the object.

**Topics**

- Decal Projection Types (p. 1752)
- Placing a Decal (p. 1753)
- Setting Decal Parameters (p. 1754)
- Debugging Decal Mapping Issues (p. 1757)

**Decal Projection Types**

Decals have several different projection types. To change projection type, select the decal and change the **ProjectionType** value.
Planar Projection

Planar projection is the cheapest performance-wise. The decal is displayed in the same location as the center of the object. Use planer projection only on flat surfaces, otherwise the decal may appear to be floating.

Deferred Projection

Deferred projection is a simple method to get decals to follow the contours of objects and is similar to Planar projection, but slower. As such, use Planar projection wherever possible.

Deferred projection is enabled by selecting the Decal Params, Deferred check box.

ProjectOnTerrain Projection

The decal is projected directly onto the terrain, ignoring any objects that might otherwise receive the projection.

ProjectOnStaticObjects Projection

The decal is projected onto the geometry of an object along the opposite direction of the blue z-axis. This method is automatically done as a deferred pass.

ProjectOnTerrainAndStaticObjects Projection

A combination of ProjectOnStaticObjects and ProjectOnTerrain, the decal is displayed on both the terrain and on objects. This method is automatically performed as a deferred pass.

Placing a Decal

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Do the following to place a decal in your level.

Note
If you apply decals to an object that can be moved by a player, the decal will not move with the object.

To place a decal

1. In Lumberyard Editor, click the top Follow Terrain button.
2. In Rollup Bar, click Objects, Misc, Decal.
3. Drag the detail into the level and then click to place it.
4. Using the Edit menu, move, rotate, or scale the decal as needed.
5. To place a decal manually, select the Reorientate check box, and use mouse shortcuts to place the decal as follows. This can speed up placement enormously.
a. Ctrl+Click: Move the decals to the desired position
b. Alt+Click: Scales the decal along the X, Y axes
c. Ctrl+Alt+Click: Rotates the decal around the z-axis

To place a decal on vegetation

1. Enable deferred projection so the decal follows the contours of the vegetation:
   a. In Lumberyard Editor, in the Rollup Bar, under Objects, click Misc, Decal.
   b. Under Decal Params, select the Deferred check box. For information about projection types, see Decal Projection Types (p. 1752).

2. Enable the r_deferredDecalsOnDynamicObjects console variable so the decal appears on the vegetation:
   a. In Lumberyard Editor, click the X icon in the Console section.

   ![Console](image)

   b. In the Console Variables window, search for r_deferredDecalsOnDynamicObjects
   c. Set the value to any positive number, for example 1.
   d. Close the Console Variables window to save the new value.

3. Follow the instructions above for placing a decal.

Setting Decal Parameters

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Complete the following procedures for setting decal mapping parameters.

To set decal parameters in the Rollup Bar

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Most decal parameters are in the Rollup Bar on the Objects tab, under Misc, Decal.
To set decal parameters in the Rollup Bar

1. In the Rollup Bar, under Objects, click Misc, Decal.
2. Under Decal Params, adjust the following parameters:
- **ProjectionType** – Choose the projection type from the drop-down list: Planar, ProjectOnStaticObjects, ProjectOnTerrain, and ProjectOnTerrainAndStaticObjects.
- **Deferred** – Select to enable deferred decal projection.
- **View Distance Multiplier** – Set the distance at which the decal is visible. The default value is 1. A higher number indicates a longer visibility distance.
- **SortPriority** – Specify if the decal will appear on top of another decal.
- **Projection Depth** – Set the projection depth (distance) of the decal from the object. This can also affect blending of decals.

**To set shader decal parameters**

Some decal parameters are set in the Material Editor under **Shader Params**.

1. In Lumberyard Editor, click **Tools**, **Material Editor**.
2. Click the **Add New Item** button.
3. Select a decals folder, select a subfolder, and then click **Save**. The new material will be selected automatically with the default settings.
4. Under **Shader Generation Params**, select **Decal**.
5. Right-click the decal you created and click **Assign to Selected Objects**.
6. Under **Shader Params**, adjust the values of the following parameters:
   a. **Decal Alpha Falloff** – Set the power applied to the decal alpha.
   b. **Decal Alpha Multiplier** – Set the multiplier applied to the decal alpha.
   c. **Decal Diffuse Opacity** – Set the opacity multiplier for the fading out decal diffuse color.
Debugging Decal Mapping Issues

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

See the following ways you can debug decals.

Debugging Deferred Decals

The cost of a deferred decal depends on how many objects the decal projects, how expensive the geometry is, and how many overdraws the decal creates.

You can use the console variable (CVAR) `r_deferredDecalsDebug` to show how expensive it is to render a deferred decal. Specify a value of 1. For more information, see Using the Console Window (p. 210).

Deferred decals in the Lumberyard Editor viewport render in red, green and blue. The colors show you the expense for rendering a deferred decal.

- Red = expensive
- Green = medium
- Blue = cheap

We recommend that you place deferred decals so that they display mostly in blue.

Debugging Decal Flicker

If a placed decal is flickering, follow these guidelines to ensure that the decal is correctly set up.

- In the Material Editor, for the Shader Generation Params pane, verify that the Decal parameter is selected for all submaterials.
- Check for overlapping layers that have the Decal parameter selected. Use the Sort Priority parameter to specify which decal appears on top of the other. Decals with higher Sort Priority values sort on top of decals with lower values. For more information, see the Decal Component Properties (p. 585).
- Other than for decals, the mesh shouldn't have overlapping triangles. Do not offset along the surface normal; this can still break in some situations and introduce floating parallax effects.

Displacement Maps and Tessellation

Displacement mapping allows you to displace the actual surface geometry of an object to give you extra depth and detail than is available using bump mapping, offset bump mapping or parallax occlusion mapping (POM) techniques, which all "fake" surface detail. Displacement mapping results are dependent on how far the camera is from the object.

Displacement mapping uses a texture map, called the height map, which is used to define the value of vertex height displacement. Specifically, this is a scalar displacement that is stored in the alpha channel of a *.displ* texture file.
In order for displacement mapping to work correctly, you need to also apply tessellation to your object, otherwise there wouldn't be enough geometry to displace. Tessellation increases the geometry count by subdividing polygons into smaller polygons before it gets displaced.

**Topics**
- Displacement Mapping Best Practices (p. 1758)
- Setting Displacement Mapping Parameters (p. 1758)
- Tessellation (p. 1759)

**Displacement Mapping Best Practices**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

For best results, use the following best practices when creating displacement maps.

**Content Creation Practices**
- Place the displacement map in the alpha channel of your texture. The RGB values are not used for this map type and can be left empty.
- Use the suffix _displ. For example, road.tif would be road_displ.tif.

**Game Implementation Practices in Lumberyard**
- In Lumberyard Editor, set the performance to High or Very High for your target platform.
  
  **To set the graphics performance for your target platform**
  
  1. In Lumberyard Editor, choose Edit, Editor Settings, Graphics Performance.
  2. Select your platform and then select the performance setting.
- The console variable e_ShadowsTessellateCascades=1 enables shadows for tessellated geometry. Use this console variable sparingly, as this feature increases performance costs.
- Use the Displacement Map preset to store _displ textures. Height maps are converted to A8 textures. If you don't see any displacement, open the texture file in the Material Editor and verify the rendering in preview. If the file isn't in A8 format, fix the preset, save, and reload.
- In the Material Editor, under Shader Generation Params, select the Displacement mapping parameter. Under Texture Maps, for the Height Map parameter, assign the displacement map.

**Setting Displacement Mapping Parameters**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

**To apply displacement mapping to an object**

1. In Lumberyard Editor, click Tools, Material Editor.
2. In the left tree, select the desired asset.
3. In the right pane, under Shader Generation Params, select Displacement mapping.
4. Under **Shader Params**, adjust the values of the following parameters for the desired effect.
   
a. **Displacement bias** – Moves the plane where the displacement is applied. This reduces gaps in meshes, and prevents objects from displacing other objects that are placed above them.

b. **Displacement height scale** – Changes the overall height of the displacement.

**Tessellation**

In order for displacement mapping to work correctly, tessellation is also required, otherwise there wouldn't be enough geometry to displace. Tessellation increases the geometry count by subdividing polygons into smaller polygons before it gets displaced. Phong and PN triangles are the two available tessellation methods.

**Phong tessellation** approximates smoothing based on surface normals. Surfaces with Phong tessellation applied are not perfectly smooth across patch boundaries, causing the object to look inflated.

**PN triangle tessellation** is similar to Phong tessellation and is slower, but with better approximation.

Tessellation is only supported for the Illum Shader (p. 1697) and HumanSkin Shader (p. 1696).

**Topics**

- Setting Tessellation Parameters (p. 1759)
- Fixing Tessellation Seams (p. 1760)

**Setting Tessellation Parameters**

To apply tessellation to an object and set parameter values, complete this procedure.

**To apply tessellation to an object**

1. In Material Editor, click **Tools, Material Editor**.
2. In the left tree, click to select the desired asset.
3. In the right pane, under **Shader Generation Params**, select either **Phong tessellation** or **PN triangles tessellation**.
4. Under **Shader Params**, adjust the values of the following parameters.

**Tessellation Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tessellation face cull</td>
<td>Specifies the extent to which vertices are culled. Because tessellation uses its own face culling, it takes the original (non-tessellated) triangle and checks if it's facing the camera; if not it discards it.</td>
</tr>
</tbody>
</table>
Parameter | Description
--- | ---
| This can also be used for 2-sided sorting of polygons. In this case, the 2 Sided check box must also be selected under Advanced in the Material Editor. An issue may arise when there is displacement that is visible from the camera. For example, a bump on a cube that is rotating is still visible for a while, even though the cube face is no longer facing the camera. Setting this parameter to 0 means no face culling at all, while setting it to 1 will cull anything not facing the camera. |

Tessellation factor | Specifies the density of the mesh triangles
Tessellation factor max | Used for objects that are at a fixed distance or range from the camera to get rid of geometry “popping” artifacts. This is useful for cutscenes.
Tessellation factor min | Setting this value to 1 means that it will be always tessellated at level 1, even if the object is far away from camera.

Fixing Tessellation Seams

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

There are two types of seams or cracks that can become noticeable when using tessellation.

**Border Seams**

Border seams occur when different meshes are placed close to each other, or when a mesh consisting of sub-meshes causes unpleasant cracks because of using different materials with different displacement (or even same displacement maps with slightly different UV mapping).

The solution involves carefully placing meshes or fade-out displacement by modifying the displacement map as needed.

**UV Seams**

UV seams occur when two adjacent triangles share an edge but use separate vertices with different UVs. This shared edge will have a different displacement on each side due to sampling different places in the displacement map. Even tiny differences in UV can cause visible seams. This is automatically fixed by Lumberyard if there is no tiling. Otherwise you must change the UV mapping to hide such artifacts where possible.

Phong tessellation and PN Triangle tessellation do not suffer from UV seams as they do not use UV mapping.

**Working with Substances**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Substances are procedural materials created using Allegorithmic's Substance Designer. Lumberyard has the ability to import Substance .sbsar files using the Substance Editor.

**Creating Substances for Lumberyard**

When creating Substances for Lumberyard using Allegorithmic's Substance Designer, it is recommended to use the PBR Specular/Glossiness substance as the base. This will involve less adjustments to your default outputs for substances. However, you will need to delete the Glossiness output and save the Gloss map into the alpha channel for the Normal map output in Substance Designer.

If you want to use a PBR Metallic/Roughness Substance and convert it for use in Lumberyard, follow these steps:

- Change the BaseColor output node to Diffuse.
- Create a Specular output node in the Substance Graph.
- Create a RGB-A Merge node in the Substance Graph.
  - Connect the node that was originally going into the Normal map into the RGB input.
  - Note that the A (Alpha) input for this node will be connected later on.
  - Connect the output of this merge node into the input for the Normal output node.
- Create a BaseColor/Metallic/Roughness converter node in the Substance Graph.
  - Connect the node that was originally going into the BaseColor/Diffuse map into the BaseColor input for this converter node.
  - Connect the node that was originally going into the Metallic map into the Metallic input for this converter node.
    - Connect the Diffuse output of this converter node into the input for the Diffuse output node.
    - Connect the Specular output of this converter node into the input for the Specular output node.
    - Connect the Glossiness output of this converter node into the A (Alpha) input for the RGB-A Merge node.
- Delete the Roughness output node.
- Delete the Metallic output node.
- Save the changes to your Substance and then publish the .sbs as a .sbsar to be imported into Lumberyard.

**Exporting Substances for Lumberyard**

When using Allegorithmic's Substance Designer to export textures to Lumberyard, take extra care to select the correct file type. The following file types export correctly: .tif, .tga, .bmp. Avoid exporting with the following common file types: .png, .jpg, .psd.

**To export textures in Substance Designer for Lumberyard**

1. In the File menu, click Export Textures.
2. Click the Configuration tab, and then under Presets, select Amazon Lumberyard.
3. Click the Export tab. In the file type drop-down menu (upper right corner), select one of the following file types:
   - .tif
   - .tga
   - .bmp
4. Click **Export**.

**Working with Substance in Lumberyard**

Using Substance Editor, you can edit Substance material properties and visualize substances on objects in real-time. Substance Editor also has the ability to generate and export static textures from Substances.

Here are some things to keep in mind when working with Substances in Substance Editor:

- The Substance Gem needs to be enabled first for the project using *Creating Lumberyard projects* (p. 43). For more information on Gems, see *Add modular features and assets with Gems* (p. 1064).
- When importing substance files, you must restart Lumberyard Editor before substance textures are rendered correctly.
- A `.smtl` (substance material) file and a `.sub` (substance texture) file are generated in the same directory location as the imported `.sbsar` for applying the substance material or substance textures to objects.
- By default, an `.smtl` file will inherit the `.sub` files in the appropriately matching channels based on the outputs in the published `.sbsar` from Substance Designer. For example, a diffuse output texture will map into the diffuse channel for the `.smtl` file.

**To use Substance Editor**

1. Open Lumberyard Editor and select **Tools, Plug-Ins, Substance Editor**. You can also click the Substance icon in the main toolbar of Lumberyard Editor.
2. To update imported `.sbsar` files, click **Edit, Reimport Substance**. Current changes will not be overwritten.
3. To remove a substance, click **File, Delete Substance**.

  **Note**
  This permanently removes the substance and all associated assets from the `.sbsar` project, which cannot be recovered using the Windows Recycle Bin.
Console Variables for Substances

To control how Substances are handled by CPU and memory, you can set the following CVars in your `system_windows_pc.cfg` file or `editor.cfg` file.

**substance_engineLibrary**

Enables substances to run on the GPU instead of the CPU, permitting the output of higher resolution textures. Specifies the engine to load for substance plugin. Possible values are PC: `sse2|d3d10|d3d11`. The default is `sse2`, which specifies CPU.

**substance_commitRenderOptions**

Applies CPU and memory changes immediately, rather than waiting for the next render call.

**substance_coreCount**

Sets how many CPU cores are used for Substance rendering. A value of 32 specifies all cores. This setting is relevant only when using CPU based engines.

**substance_memoryBudget**

Sets, in megabytes, the amount of memory used for Substance rendering. The default is 512.

Working with Blend Layers

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Blend layers can be thought of as a layered material. You can create one material with a second set of per-pixel functions, including texture maps, UV tiling and offset, rotation and oscillation animation, second UV set, diffuse and specular color tinting, smoothness, and blend masking.

Integrate blend layers in the Illum and Vegetation shaders and activate them by setting the blend layer shader generation parameters.
Working with Blend Layers

Topics
- Shader Generation Parameters (p. 1764)
- Blend Layer Textures (p. 1764)
- Blend Layer Parameters (p. 1765)

Shader Generation Parameters

You can set the following parameters for generating shaders.

**Blend layer**
- Activate the texture inputs and parameters for the blend layer.

**Use UV set 2 for blend layers maps**
- Use a second UV channel, if available, for the second layer.

Blend Layer Textures

You can set the following parameters for your blend layer textures.

**Second Height Map**
- Displacement map for the blend layer (grayscale)

**Second Diffuse Map**
- Diffuse map for the blend layer (RGB)

**Second Normal Map**
- Normal map for the blend layer; the second layer gloss map is contained in the alpha (RGBA)
Second Specular Map
Specular map for the blend layer (RGB)

Blend Map
Blending map to blend between the first and second layers (grayscale)

Blend Layer Parameters
You can set the following parameters for your blend layer.

Blend Factor
Control visibility of the blend layer, with a bias toward black or white
Valid values: 0 – 16

Blend Falloff
Control the fall off of the blend range
Valid values: 0.1 – 128

Blend Layer 2 Tiling
Control tiling of the second blend layer
Valid values: 0 – 20
Default: 1

Blend Layer 2 Diffuse (Tint)
Base color tint for the second layer (RGB)
Valid values: 0 – 255

Blend Layer 2 Smoothness
Sharpness of specular reflection for the second layer
Valid values: 0 – 255
Default: 10

Blend Layer 2 Specular
Reflective brightness and color for the second layer (RGB)
Valid values: 0 – 255

Blend Mask Tiling
Control tiling of the blend map
Valid values: 0.05 – 20
Default: 1

Parallax Mapping

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Parallax occlusion mapping (POM) is an enhancement of the traditional parallax mapping technique that creates detail in a texture to add the illusion of depth. This depth perception changes based on perspective.

Parallax occlusion mapping (POM) and offset bump mapping (OBM) are similar to displacement mapping and tessellation, but their computational requirements are not as demanding. However, POM is not suitable in every situation. Use POM only for high-performance computers and OBM for devices such as consoles. When you use POM, you must enable both shader generation parameters. Lumberyard automatically defaults to OBM for setups that cannot run POM.

Topics
- Parallax Mapping Best Practices (p. 1766)
- Applying Parallax Occlusion Mapping (POM) (p. 1767)
- Applying Silhouette Parallax Occlusion Mapping (SPOM) (p. 1767)
- Using Blend Layers for Parallax Mapping (p. 1768)

Parallax Mapping Best Practices

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

For best results, use the following best practices when creating POM or SPOM parallax mapping.

Content Creation Practices
- Place the displacement map in the alpha channel of your texture. The RGB values are not used for this map type and can be left empty.
- Use the suffix _displ. For example, road.tif would be road_displ.tif.
- If your project requires file names other than those listed here, use the Resource Compiler (RC) Open Image tool to specify other conventions for Asset Processor to recognize. For textures not using the _displ suffix, choose the DisplacementMap preset to generate the correct .dds file. Height maps are converted to A8 textures. If you do not see any displacement, preview the file in the Material Editor. If the image isn't in A8 format, you can fix the preset, save, and reload. For textures using non-
standard naming, the tool generates an .exportsetting file that Asset Processor uses to generate the displacement map.

- By default, Asset Processor recognizes the _displ suffix and writes the correct metadata to a .dds file.

**Game Implementation Practices in Lumberyard**

- In Lumberyard Editor, set the performance to **High** or **Very High** for your target platform.

  **To set the graphics performance for your target platform**

  1. In Lumberyard Editor, choose **Edit, Editor Settings, Graphics Performance**.
  2. Select your platform and then select the performance setting.

- In the **Material Editor**, you must first assign textures for both the **Normal Map** and the **Height Map** parameters. Then, under **Shader Generation Params**, select the **Parallax occlusion mapping** parameter.

- You can assign POM maps to the **Height Map** parameter located under **Texture Maps**.

**Applying Parallax Occlusion Mapping (POM)**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To apply POM, complete the following procedure.

**To apply Parallax Occlusion Mapping**

1. In Lumberyard Editor, click **Tools, Material Editor**.
2. In the left tree, select the desired asset.
3. In the right pane, under **Shader Generation Params**, select **Offset bump mapping** and **Parallax occlusion mapping**.
4. Under **Shader Params**, adjust the values of the following parameters.
   a. **Height bias** – Moves the plane where the displacement is applied. This reduces gaps in meshes, and prevents objects from displacing other objects that are placed above them.
   b. **POM Displacement** – Sets the POM depth. A larger value adds more depth.
   c. **Self shadow strength** – Changes the strength of self-shadowing. A larger value imparts more shadowing
5. Under **Texture Maps**, enter the paths to the various textures.

**Applying Silhouette Parallax Occlusion Mapping (SPOM)**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To apply SPOM, complete the following procedure.

**To apply Silhouette Parallax Occlusion Mapping**

1. In Lumberyard Editor, click **Tools, Material Editor**.
2. In the left tree, select the desired asset.
3. In the right pane, under Shader Generation Params, select Parallax occlusion mapping with silhouette.
4. Under Shader Params, adjust the values of the following parameters.
   a. **Height bias** – Moves the plane where the displacement is applied. This reduces gaps in meshes, and prevents objects from displacing other objects that are placed above them.
   b. **Self shadow strength** – Changes the strength of self-shadowing. A larger value imparts more shadowing.
   c. **Silhouette POM Displacement** – Sets the SPOM depth. A larger value adds more depth.
5. Under Texture Maps, enter the paths to the various textures.

### Using Blend Layers for Parallax Mapping

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use blend layers for parallax mapping. For both POM and OBM, set the diffuse and normal map as usual. The \_disp texture will be loaded automatically as long as the Applying Parallax Occlusion Mapping (POM) (p. 1767) procedure is first completed.

When using a second blend layer, the diffuse map is placed in the Custom texture map slot, the normal map is placed in the [1] Custom slot, and the height map is placed in the SubSurface slot.

**To use a blend layer for parallax mapping**

1. Complete the Applying Parallax Occlusion Mapping (POM) (p. 1767) procedure.
2. Under Shader Generation Params, select Parallax occlusion mapping and Blendlayer.
3. Under Texture Maps, place maps as follows:
   a. Place the height map in Second Height Map.
   b. Place the height map in Second Diffuse Map.
   c. Place the height map in Second Bump Map.
4. Under Shader Params, adjust the values of the parameters as needed.

### Using Vertex Colors

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Vertex color, or vcolor, is just a color with RGB and alpha channel values stored for each vertex of a mesh. Vertex color and alpha can be used for multi-texturing, transparency, or fake ambient occlusion.

Vertex color is typically multiplied against the Diffuse color, colorizing or darkening the color map.

When used for non-color effects, typically each color channel is treated as a separate monochrome set of values, so for example vertex color can control three different per-vertex effects.

Vertex Colors is a Shader Generation parameter that can be enabled using the Material Editor, which is part of Lumberyard Editor.
Customizing Post-Processing Effects

For a good application of vertex colors, see Defining Vegetation Vertex Colors with a DCC Tool (p. 1307).

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard includes post-processing effects that can help improve your game's graphics, lighting, and transitions between effects such as color correction, bloom, and depth of field.

Use XML files with Script Canvas editor or Lua scripts to customize effects by setting their parameters, create prioritized groups of effect parameter sand enable or disable them.

You can also use effect groups to specify the following:

- Blend curves to smoothly transition between effects
- Stay enabled until explicitly disabled
- Make effect strength based on distance from the camera

**Note**

Creating a new effect requires modifying Lumberyard, while creating a new effect group does not.

**Topics**

- Post Effect Group XML Files (p. 1769)
- Enabling and Disabling Effect Groups (p. 1770)
- Specifying a Blend Curve for Smooth Effect Transitions (p. 1771)
- Setting Effect Strength Based on Camera Distance (p. 1772)
- Using the Screen Fader Effect (p. 1773)

**Post Effect Group XML Files**

When you open Lumberyard Editor, the effect group located at `lumberyard_version\dev\Engine\Libs\PostEffectGroups\Default.xml` automatically loads. The `Default.xml` file includes all available effects and the default values for each parameter. You can modify the default values and copy and paste sections of the `Default.xml` file into custom effect groups.

**Example**

```xml
<PostEffectGroup priority="1" hold="1">
    <Effect name="Global">
        <Param name="User_Brightness" floatValue="0.5"/>
    </Effect>
</PostEffectGroup>
```
Priority

Non-negative integer used to set priorities. Larger priorities override smaller priorities. If multiple effect groups that are enabled have the same priority value, the effect group that was enabled later has the higher priority.

Default value: 0 (for Time of Day and Script Canvas nodes that set effects)

Valid values: 0 - 999

Hold

Indicates if the effect should stay enabled until explicitly disabled.

Default value: 0

Valid values: 0 = effect is disabled after blending is complete | 1 = effect remains enabled until explicitly disabled

If you create a custom effect groups, create a directory named \PostEffectGroups under /Engine/Libs. You can then load the post effect group XML files from any valid path location.

Enabling and Disabling Effect Groups

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can enable and disable effect groups with the Script Canvas editor or Lua scripting.

To enable or disable effect groups with Script Canvas

1. In Lumberyard Editor, open your level.
2. In the menu bar, choose Tools, Script Canvas.
3. In the Script Canvas editor, choose File, New Script.
4. Right-click the canvas, search and then select the following nodes:
   - On Graph Start
   - Enable Effect Group (p. 2622) or Disable Effect Group (p. 2610)
5. For your script, do the following:
   a. Select the Out pin for On Graph Start and drag to connect it to the In pin for the Enable/Disable Effect Group node.
   b. For the Group Name parameter, enter the file path for the group (for example, Libs \PostEffectGroups\MyEffectGroup.xml).
6. Save the script and attach it to an entity with the **Script Canvas (p. 818)** component.
7. Close the **Script Canvas** editor.

**Note**
You can manually enable or disable an effect group in Lumberyard Editor by running the Lua functions in the **Console** window. To indicate a Lua command, prepend each command with the `#` character.

### Specifying a Blend Curve for Smooth Effect Transitions

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

You can use **BlendIn** and **BlendOut** tags to specify a blend curve that enables smooth transitions between effects.

An example XML file with added **BlendIn** and **BlendOut** tags:

```xml
<PostEffectGroup priority="1" hold="1">
  <Effect name="SunShafts">
    <Param name="RaysAmount" floatValue="0.2"/>
  </Effect>
  <BlendIn curve="smooth">
    <Key time="0" value="0"/>
    <Key time="0.5" value="1"/>
  </BlendIn>
  <BlendOut curve="smooth">
    <Key time="0" value="1"/>
    <Key time="0.5" value="0"/>
  </BlendOut>
</PostEffectGroup>
```

**Priority**

Indicates how much the effects should override the lower priority values.

**Hold**

Determines when the **BlendIn** and **BlendOut** curves play and whether the effect group is enabled or disabled.
Valid values:

0 = Plays the BlendOut curve immediately after the BlendIn curve finishes playing; when the BlendOut curve plays, the effect group is disabled

1 = Plays the BlendIn curve; when the BlendIn curve plays, the effect group fully overrides lower priority values until the effect group is explicitly disabled

Curve

Available curve types are smooth, linear, and step. If a curve attribute value is not specified, the curve type defaults to smooth. You can include as many keyframes in a curve as desired.

Default curve value: smooth

Valid key time values: smooth, linear, step

Key time

Valid values: 0 – 1 (seconds)

Setting Effect Strength Based on Camera Distance

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the fadeDistance attribute to set the effect strength based on the distance from the camera.

Example opening XML tag using the fadeDistance attribute:

```xml
<PostEffectGroup priority="1" fadeDistance="20">
```

fadeDistance – Indicates how the effects are actualized based on the distance of the camera from the entity.

- When the camera is at the position of the entity, the effects are fully overridden.
- When the camera is less than fade distance from the entity, the effects are blended.
- When the camera is at least fade distance from the entity, the effects are set to the lower priority values.

Script Canvas Editor

You need to use a script to apply this effect group at the specified position for each frame. For more information, see the Apply Effect Group At Position (p. 2606) node.

Example

The following script uses the Get World Translation to send the entity's position to the Apply Effect Group At Position node; this node then applies the effect group to that specified position.
Lua
To enable an effect group using Lua, set the position at which to apply the effect by using the following function:

```lua
local pos = TransformBus.Event.GetWorldTranslation(EntityId)
PostEffects.ApplyEffectGroupAtPosition("example.xml", pos)
```

**Note**
This function must be called once per frame while the effect group is enabled. If this function is called multiple times in a single frame, the effect strength increases each time, as if each call applies the effect from a different entity.

Using the Screen Fader Effect
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the screen fader effect to control all screen fade properties, including duration of the fade effect and the color or texture to use for the fade.

You can stack multiple screen fader effects; multiple screen faders are rendered concurrently and in order of post effect group priority. Screen fader effects do not blend the parameters between layers.

The following example demonstrates how to use the screen fader effect in an `.xml` file:

```xml
<PostEffectGroup priority="2" hold="1">
  <Effect name="ScreenFader">
    <Param name="Enable" floatValue="1.0"/>
    <Param name="FadeInTime" floatValue="2.5"/>
    <Param name="FadeOutTime" floatValue="1.0"/>
    <Param name="ScreenCoordinates" vec4Value="0.0,0.0,1.0,1.0"/>
    <Param name="FadeColor" vec4Value="0.2,0.7,0.7,0.5"/>
    <Param name="TextureName" stringValue="textures/StyleTown/_dev_Blue_Light.tif"/>
  </Effect>
</PostEffectGroup>
```

**Parameters**
You can set the following parameters:

**Enable**
Determines whether or not the ScreenFader is active for the post-processing effect group.
Valid values: 0 = Disable | 1 = Enable

**FadeInTime**

Time, in seconds, for the screen fader to fade in, once enabled.

**FadeOutTime**

Time, in seconds, for the screen fader to fade out, once disabled.

**ScreenCoordinates**

Determines the rectangle where the screen fader is rendered. Specify the coordinates in the format (Left, Top, Right, Bottom). For example, a fullscreen quad is specified as (0.0, 0.0, 1.0, 1.0) and a quad that fills half of the screen is specified as (0.0, 0.0, 0.5, 1.0).

Valid values: 0.0 – 1.0

**FadeColor**

Sets the quad color by multiplying the color by the specified texture. If no texture is specified, the quad will be a solid color.

**TextureName**

Path of the texture to use for the screen fader.

---

**Toon Shading (Experimental Feature)**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Toon shading is a feature with which you can simulate cartoon effects for your game. Instead of using a shade gradient, toon shading uses less shading color to make 3D graphics appear flat. You can use toon shading to create a comic book or cartoon style for your game. Lumberyard's toon shading feature projects the scene luminance into a lookup table, which controls the smoothness of shading on the surface to achieve the intended look.

As a best practice for toon shading, use clear textures with fewer patterns when designing game art. Also, create models with fewer features at a lower level of detail (LOD). Otherwise, your models can have darker meshes in the distance due to their feature lines. For example, if you have a high density of polygons for vegetation, the vegetation can appear too dark or have too many black lines.

To enable toon shading, use the console to specify the console variable (CVAR):

r_AlphaBlendLayerCount.

Valid values: 0 – 1

For more information, see Configuring Console Variables (p. 212).

The following example level does not have toon shading enabled (r_AlphaBlendLayerCount=0).
The following example level has toon shading enabled (r_AlphaBlendLayerCount=1).

See additional examples of toon shading enabled:
Order-Independent Transparency

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Order-independent transparency (OIT) corrects the display of transparent objects that are drawn out of order.

OIT is useful when creating the following:

- Concave geometry – When you create concave geometry, such as a glass, wine glass, or glass sculpture, some triangles may cover the same pixels and are drawn on top of each other. OIT solves the out-of-order issues that appear from certain angles.
- Intersecting geometry – When you create intersecting geometry, such as hair planes, some triangles may intersect in separate draws. OIT properly orders the triangles for each pixel.
- Transparent objects inside transparent objects – This includes liquids inside of glasses, holograms, or x-ray style effects.
To further demonstrate, see the following images.

| OIT is not needed in the following example. Drawing object 1, then object 2, and finally object 3 works. | OIT is needed in the following example. Drawing object 1 and then object 2 will not work because certain pixels from object 1 must be in front of pixels from object 2 (and vice versa). | OIT is needed in the following example. Object 2 is long and its center point is in front of object 1, but it must draw behind object 1. | OIT is needed in the following example. Certain parts of object 1 draw behind other parts of the object, and you cannot control which draws first. |

Configuring Order-Independent Transparency for Lumberyard

You can configure OIT with the console or create a level configuration file with this setting.

Specify the value for `r_AlphaBlendLayerCount` to the number of transparency layers that OIT can solve. A value of 1 is sufficient to solve most out-of-order transparency issues.

Valid values: 0 – 4

0 = Disables OIT

- Specify the value for the `r_AlphaBlendLayerCount` console variable
- Specify the value for the `level.cfg` file in the `lumberyard_version\dev\project_name\Levels\level_name` directory.

For more information, see Configuring Console Variables (p. 212).
OIT requires the following:

- Hardware requirements: DirectX 12_1 feature level compatible graphics card (NVIDIA Maxwell & Pascal, 4th generation Intel core processors).
- Software requirements: DirectX 11.3 and 12 runtime on Windows 10 compiled with Windows 10 SDK.

To set the Windows 10 SDK for Lumberyard

1. With a text editor, open the `user_settings.options` file in the `lumberyard_version\dev\_WAF_` directory.
2. Under the `[Windows Options]` section, set `win_vs2017_winkit` to your version of the Windows 10 SDK (for example, `10.1.17134.12`).
3. Build your game project. For more information, see Building Lumberyard projects (p. 61).

Adding lighting and shadows

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard uses physically-based lighting and shading models to implement global illumination and lighting.

For information about the Light entity and the Environment Probe entity used in environment lighting, see Light Entities.

For information about using the Time of Day Editor to simulate the changing lighting effects caused by the sun moving across the sky, see Creating Time of Day Sky Effects (p. 1269).

Topics

- Environment Lighting (p. 1779)
- Environment Shadows (p. 1785)

Environment Lighting

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard uses physically-based lighting and shading models to implement global illumination and environment lighting.

For information about the Light entity and the Environment Probe entity used in environment lighting, see Light Entities.

For information about using the Time of Day Editor to simulate the changing lighting effects caused by the sun moving across the sky, see Creating Time of Day Sky Effects (p. 1269).

Topics

- Illuminance and Auto Exposure Key (p. 1780)
Illuminance and Auto Exposure Key

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Also known as luminous flux density, illuminance is the total amount of visible light falling on a point on a surface from all directions above the surface in a given time. Proper illuminance values ensure the environment lighting in your level closely models real-world values. Besides simply having good ratios between light and dark, accurate illuminance values ensure that tone-mapping, and eye adaptation works optimally.

The following table lists real-world illuminance values, expressed in luminous flux (lux). Lux is the unit of illuminance and luminous emittance, measuring lux per unit area, and equal to one lumen per square meter.

<table>
<thead>
<tr>
<th>Real-world illuminance</th>

</tbody>
</table>

The Auto Exposure Key setting controls the amount of light exposure and determines whether the tone-mapped image appears relatively bright or dark. This setting is calculated automatically from the average scene illuminance, which is why it is important to use standard real-world illuminance levels. For other settings that affect the tone mapping of a scene, see HDR Settings (p. 1781).

Lumberyard's auto-exposure mode works in exposure value (EV) units and can be enabled using the r_HDREyeAdaptationMode console variable.

The following settings are used to achieve the desired illuminance in an environment level. See Setting Daytime Atmospheric Effects (p. 1266) for more information.

- Sun color
- Sun color multiplier
- Sun intensity
• Sun intensity multiplier

**HDR Settings**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

As discussed in Illuminance and Auto Exposure Key (p. 1780), the auto exposure key setting controls the amount of scene exposure and determines whether the tone-mapped image appears relatively bright or dark. Several other settings also affect the tone mapping of scene. These are known collectively as HDR (high dynamic range) in the **Time of Day Editor**.

Film curve parameters in the **Time of Day Editor** correspond to analogous parameters that exist for camera film. A film curve has three distinct regions with different contrast transfer characteristics:

- The lower part of a film curve that is associated with relatively low exposures is designated the toe, and corresponds to the low-density portions of an image. When an image is exposed so that areas fall within the toe region, little or no contrast is transferred to the image.
- The upper part of a film curve that is associated with relatively high exposures is designated the shoulder, and corresponds to the high-density portions of an image. When an image is exposed so that areas fall within the shoulder region, little or no contrast is transferred to the image.
- The middle part of a film curve with the highest level of contrast is produced within a range of exposures falling between the toe and the shoulder, and is designated the midtones region. This portion of the curve is characterized by a relatively straight and steep slope in comparison to the toe and shoulder regions. You should adjust your image so that important areas fall within this region for maximum contrast.

**To set HDR settings parameters**

1. In Lumberyard Editor, choose **Tools, Other, Time Of Day**.
2. Choose **HDR Settings**, and for **HDR**, adjust the values of the following settings.

<table>
<thead>
<tr>
<th>HDR Settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Film curve shoulder scale</td>
<td>Slope at the tip of the HDR curve (modifies bright values).</td>

## Global Environment Lighting

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To implement global lighting for an entire level, you use a global environment probe (also known as a global light probe) and associated generated cubemap.

Environment probes control many aspects of the physically based lighting in Lumberyard, including accurate shadow colors, ambient diffuse values, and specular reflections. They also provide bounce lighting by taking the colors from the surroundings and applying them directly to the diffuse color of materials inside their radius.

When placing environment probes in a level, pay attention to how probes are layered and sorted going from global to local probes.

Every level should have a global environment probe. Global probes provide the entire level with ambient lighting, which is calculated from the probe's location. In addition to a global probe, a level may have one or more local probes. For more information about local probes, see Local Environment Lighting (p. 1784).

As shown in the following table, the probe has several configurable properties, which you can adjust in the Rollup Bar.

### EnvironmentProbe Properties

**Active**

Enables and disables the probe.
**BoxSizeX, BoxSizeY, BoxSizeZ**

Specifies the XYZ dimensions of the probe's area of effect. Probes are projected as cubes in the level. For a global probe, set values large enough to span the entire level.

**Diffuse**

Sets the diffuse color of the light. Set to 255, 255, 255.

**DiffuseMultiplier**

Makes the light brighter. Set to 1.

**SpecularMultiplier**

Multiplies the specular color brightness. Set to 1.

**AffectsThisAreaOnly**

Set parameter to False to make lights cover other vis areas.

**AttenuationFalloffMax**

Controls the falloff amount (0–1) to create smoother transitions or hard edges. A value of 0.8 means that falloff begins at 80% at the boundaries of the box. Set value to 0 for a global probe (no falloff).

**IgnoresVisAreas**

Controls whether the light should respond to vis areas. Set value to True for a global probe.

**SortPriority**

Gives control over which probe has more visual interest and therefore a higher priority. Set the value to 0 for a global probe, then increase the value for local probes, where higher values indicate more localized probes.

**deferred_cubemap**

Specifies the file location of the cubemap texture.

**BoxHeight**

Adjusts the height of cubemap box.

**BoxLength**

Adjusts the length of cubemap box.

**BoxProject**

When enabled, Lumberyard factors in the size of the cubemap box.

**BoxWidth**

Adjusts the width of cubemap box.

---

**To generate a global cubemap**

1. In Rollup Bar, under Objects, click Misc, EnvironmentProbe.
2. Click to place the probe in your level.
3. Under EnvironmentProbe Params, leave cubemap_resolution at the default 256. This is the optimal resolution for best performance.
4. Select the preview_cubemap check box to see the cubemap in your level.
5. Under EnvironmentProbe Properties, adjust the following property values to configure the probe to be global:
   - **BoxSizeX, BoxSizeY, and BoxSizeZ** values: Large enough to span the entire level
   - **Diffuse** color value: 255, 255, 255
• **DiffuseMultiplier** and **SpecularMultiplier** values: 1
• **SortPriority**: 0
• **AttenuationFalloffMax**: 0
• **IgnoreVisAreas**: True (check box selected)

6. Click **Generate Cubemap**. Lumberyard creates three textures in `textures\cubemaps\your_level`— one for the diffuse map, one for the specular map, and one for the source .t.i.f file.

7. To check your cubemap for accuracy, create and then place a smooth, reflective sphere entity near the probe. If its surface looks different from the environment around it, you need to regenerate the cubemap.

8. Click **Generate Cubemap** again. This incorporates object reflections from the originally generated cubemap for added realism.

9. To hide the sphere entity in your level, select its **HiddenInGame** check box, found under **Entity Params** in the **Rollup Bar**.

### Local Environment Lighting

This topic references tools and features that are **legacy**. If you want to use legacy tools in Lumberyard Editor, disable the **CryEntity Removal gem** using the **Project Configurator** or the **command line**. To learn more about legacy features, see the **Lumberyard Legacy Reference**.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. **Download O3DE** or visit the AWS Game Tech blog to learn more.

Lumberyard uses local environment probes and their generated cubemaps to implement local lighting. The purpose of local cubemaps is to light smaller areas more accurately. This ensures that all areas in your level have accurate lighting effects that may not be covered by the global cubemap. Lumberyard automatically gives a local probe higher priority within its defined radius and superimposes its effects on those of the global probe. For more information about global probes, see **Global Environment Lighting** (p. 1782).

When placing environment probes in a level, pay attention to how probes are layered and sorted going from global to local probes.

**To generate a local cubemap**

1. In the **Rollup Bar**, under **Objects**, click **Misc**, **EnvironmentProbe**.
2. Click to place in the probe in your level.
3. Under **EnvironmentProbe Params**, leave the **cubemap_resolution** at 256, the default. This is the optimal resolution for performance.
4. Select the **preview_cubemap** check box to see the cubemap in your level.
5. Under **EnvironmentProbe Params** and under **EnvironmentProbe Properties**, adjust property values for the desired effect. For more information about these properties, see the table in **Global Environment Lighting** (p. 1782).
6. Click **Generate Cubemap**.

Lumberyard creates three textures in `textures\cubemaps\your_level`— one for the diffuse map, one for the specular map, and one for the source .t.i.f file.

7. To check your cubemap for accuracy, create and then place a smooth, reflective sphere entity near the probe. If its surface looks different from the environment around it, you need to regenerate the cubemap.
8. Click **Generate Cubemap** again. This incorporates object reflections from the originally generated cubemap for added realism.

9. To hide the sphere entity in your level, select its **HiddenInGame** check box, found under **Entity Params** in the **Rollup Bar**.

### Environment Shadows

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

---

Lumberyard supports shadow casting from all light sources and shadow receiving on all deferred and most forward-rendered geometry. Traditional shadow mapping is used for shadow generation. Light sources can be directional, such as from the sun and moon, or from point and area light sources.

As shadow generation is resource-intensive, Lumberyard offers the following features to mitigate this:

- You can control the degree to which Lumberyard caches shadows and stops dynamically updating the most distant cascaded sun shadows.
- You can set point and area light sources to be updated in intervals, such as every second frame.
- You can use the `r_MergeShadowDrawcalls` console variable to merge submaterials during shadow generation, resulting in fewer drawcalls.

**Topics**

- Cached Shadows (p. 1785)
- Object Shadows (p. 1786)
- Shadow Proxies (p. 1787)
- Using CVARs to Configure Terrain and Cascade Shadow Maps (p. 1787)

### Cached Shadows

Shadow caching is an effective optimization method to reduce the number of shadow drawcalls and to increase the shadow casting and receiving range.

Starting from a defined cascade number, Lumberyard can render subsequent shadow cascades and then keep them in memory. Once the cached cascade is initialized, no more draw calls are needed for updates. This enables long-range distant shadows with almost no performance cost.

Keep in mind that cached shadows are memory intensive, with the default configuration requiring approximately 130 MB of video memory.

In addition, ensure that all shaders are compiled before triggering an update or all objects may not be rendered into the cached shadow maps.

**Placement and Update**

Cached shadow cascades are centered around the rendering camera by default, and automatically recenter and update once the camera gets close to the cascade border.
You can override this automated placement by using the **Recompute Static Shadows** Script Canvas node, which takes the world space Min and Max input positions of the bounding area for the first cached cascade. Bounding boxes for subsequent cached cascades are scaled versions of the preceding cascades and are based on the **NextCascadeScale** input multiplier. The **Trigger** input causes an update of all cached shadow cascades.

**Note**
To keep you informed, a warning message appears in the console each time a cached shadow cascade is updated.

### Dynamic Distance Shadows

Cached shadows work well with static objects, but dynamic objects don't get their shadows updated while moving. To overcome this, you can selectively exclude dynamic objects from the cache and render them to the standard cascades. The performance overhead of enabling this feature for a limited number of entities is generally low.

**To enable dynamic distance shadows for an object**

- Select the **DynamicDistanceShadows** check box for the entity.

### Console Variables

When Lumberyard is set to place shadows automatically, the selected resolution combined with the desired world space pixel density, which is derived from the approximate logarithmic split scheme, determines the world space area covered by each shadow cascade. Lowering the resolution lowers the shadowed range for each cascade while still maintaining shadow quality.

When you place shadows manually, the resolution is uniformly stretched across the shadow cascade. Consequently, lower resolutions result in lower shadow quality at the same world space coverage.

Use the following console variables to control cached shadows, including setting the placement and resolution for individually cached shadow cascades.

- **r_ShadowsCache** – Caches all sun shadow cascades above the value. 0 = no cached cascades, 1 = cache first cascade and up, 2 = cache second cascade and up.
- **r_ShadowsCacheResolutions** – The resolution of the cached cascades.
- **r_ShadowsCacheFormat** – Storage format for cached shadow maps: 0 = D32: 32 bit float, 1 = D16: 16 bit integer.
- **e_ShadowsCacheUpdate** – Triggers updates of cached shadow maps: 0 = no update, 1 = one update, 2 = continuous updates.
- **e_ShadowsCacheObjectLod** – The level of detail (LOD) used for rendering objects into the cached shadow maps.
- **e_ShadowsCascadesDebug** – Enables debug view mode. 0 = disable, 1 = enable.
- **e_DynamicDistanceShadows** – Toggles support for having selected objects cast dynamic shadows.

### Object Shadows

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

With object shadows, you can assign custom shadow maps to selected objects, resulting in increased shadow quality due to higher world space shadow texel (texture element) density and reduced depth range.
The drawbacks of using object shadows are increased memory consumption of the additional shadow maps and increased shadow filtering cost.

Object shadows only affect sun shadows. For performance reasons they are not sampled on forward geometry such as particles, hair, and eyes.

**Using I3DEngine**

The following I3DEngine interface functions can be called from anywhere in game code.

- **AddPerObjectShadow** – Adds an object shadow.
- **RemovePerObjectShadow** – Removes an object shadow.
- **GetPerObjectShadow** – Retrieves object shadow settings for a given RenderNode. Do not overwrite the RenderNode pointer. Instead use `AddPerObjectShadow\RemovePerObjectShadow`.
- **ShadowMapSize**: Size of the custom shadow map, which is automatically rounded to the next power of two.

**Console Variables**

You can use the `e_ShadowsPerObject` console variable with object shadows. With this variable, 0 = off, 1 = on, and -1 = don't draw object shadows.

**Shadow Proxies**

Shadow proxies are a method of significantly reducing shadow performance costs by creating dedicated low-polygon count geometry to cast an object's shadow with minimal visual differences. You can also use shadow proxies to minimize shadow artifacts by controlling which geometry can cast shadows.

Keep in mind that if the shadow proxy mesh aligns closely with the RenderMesh, you may notice self-shadow artifacts.

No material setup is required in your DCC tool. Instead you use the Material Editor to set up shadow proxies in the material using Material Editor. Place the shadow proxy on its own submaterial, setting **Opacity** to 0 and ensuring that **No Shadow** is not selected (the default).

The shadow proxy must also be linked as a child node of the RenderMesh, and it must be on its own material ID.

For the RenderMesh material, set as you normally would, except under the **Advanced** properties, select the **No Shadow** option. This instructs Lumberyard to use the shadow proxy instead of the RenderMesh to render the shadows.

**Using CVARs to Configure Terrain and Cascade Shadow Maps**

You can use console variables (CVARs) in Amazon Lumberyard to configure terrain and cascade shadow maps (also known as gradient shadow maps, or GSMs). This topic provides a list of key shadow-related console variables and shows you how to save your changes to them. It also shows you how to learn about other related console variables.
Topics

- Some Key Shadow-Related Console Variables (p. 1788)

Some Key Shadow-Related Console Variables

The following table shows some of the console variables that configure shadows, gradient shadow maps, and related debug modes.

<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>e_GsmCastFromTerrain</td>
<td>int</td>
<td>Specifies that shadows are cast from terrain. Off by default.</td>
</tr>
<tr>
<td>e_GsmDepthBoundsDebug</td>
<td>int</td>
<td>Shows bounding volumes related to gradient shadow maps.</td>
</tr>
<tr>
<td>e_GsmLodsNum</td>
<td>int</td>
<td>Specifies the number of gradient shadow map levels of detail (LOD).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values: 0 to 7.</td>
</tr>
<tr>
<td>e_GsmRange</td>
<td>float</td>
<td>Size of the LOD 0 gradient shadow map area in meters.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default value: 3 meters</td>
</tr>
<tr>
<td>e_GsmRangeStep</td>
<td>float</td>
<td>Specifies a step value to multiply the previous range by to determine the range of the next GSM LOD.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>To determine the step size, use the following guidelines:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If e_GsmRange is 3, cascade 0 is 3m.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If e_GsmRangeStep is 3, the following values result.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Cascade 1 is 3m x 3m = 9m</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Cascade 2 is 9m x 3m = 27m</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Cascade 3 is 27m x 3m = 81m</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Cascade 4 is 81m x 3m = 243m</td>
</tr>
<tr>
<td>e_GsmStats</td>
<td>int</td>
<td>When enabled, shows debug information about shadow cascades.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Off (default)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = On</td>
</tr>
<tr>
<td>e_ObjShadowCastSpec</td>
<td>int</td>
<td>Specifies that objects that have a shadow cast spec less than or equal to the specified value cast shadows.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default value: 4</td>
</tr>
</tbody>
</table>
## Environment Shadows

### Console Variable

<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>e_ParticleShadowsNumGSMs</td>
<td>int</td>
<td>Specifies the number of shadow GMSs that are used for particle shadows.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default value: 3</td>
</tr>
<tr>
<td>e_ParticlesShadows</td>
<td>int</td>
<td>Enables shadows on particles.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = On (default)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2 = Force</td>
</tr>
<tr>
<td>e_Shadows</td>
<td>int</td>
<td>Activates the drawing of shadows.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = On (default)</td>
</tr>
<tr>
<td>e_ShadowsBlendCascades</td>
<td>int</td>
<td>Softens the blend between shadow cascade regions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = On (default)</td>
</tr>
<tr>
<td>e_ShadowsBlendCascadesVal</td>
<td>float</td>
<td>Specifies the width of the region across which two cascades blend.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default value: 0.75</td>
</tr>
<tr>
<td>e_ShadowsCascadesDebug</td>
<td>int</td>
<td>For debugging purposes, draws each shadow cascade with a different color on</td>
</tr>
<tr>
<td></td>
<td></td>
<td>screen.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Off (default)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = On</td>
</tr>
<tr>
<td>e_ShadowsCastViewDistRatio</td>
<td>float</td>
<td>Specifies the view distance ratio for shadow maps that cast from objects.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td>e_ShadowsClouds</td>
<td>int</td>
<td>Enables shadows for clouds.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = On (default)</td>
</tr>
<tr>
<td>e_ShadowsConstBias</td>
<td>float</td>
<td>Specifies the shadow slope bias for shadow generation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The shadow bias is the distance from where the shadows are cast to where they</td>
</tr>
<tr>
<td></td>
<td></td>
<td>can be received.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td>Console Variable</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>--------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>e_ShadowsConstBiasHQ</td>
<td>float</td>
<td>Specifies the shadow slope bias for shadow generation in high quality mode. When shadow mode is set to high quality, the value of <code>e_ShadowsConstBiasHQ</code> or <code>e_ShadowsConstBias</code> is used, whichever is smaller. Default value: 0.05</td>
</tr>
<tr>
<td>e_ShadowsDebug</td>
<td>int</td>
<td>Displays a debug viewport for shadow maps.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Off (default)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = On</td>
</tr>
<tr>
<td>e_ShadowsLodBiasFixed</td>
<td>int</td>
<td>Specifies the number of LOD levels that simplify mesh for shadow map generation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td>e_ShadowsMaxTexRes</td>
<td>int</td>
<td>Sets the maximum resolution of the shadow map. Typical values are 256 for faster performance, 512 for a balance of performance and quality, and 1024 for higher quality. Default value: 1024</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Larger values can cause texture thrashing warnings. To compensate, increase the value of <code>r_DynTexMaxSize</code>.</td>
</tr>
<tr>
<td>e_ShadowsPoolSize</td>
<td>int</td>
<td>Uses the formula <code>e_ShadowsPoolSize * e_ShadowsPoolSize</code> to set the size of the shadow pool. The shadow pool is the texture atlas used for rendering shadows from individual light points. Depending on the quality required, each light uses a different sized portion of the shadow map.</td>
</tr>
<tr>
<td>e_ShadowsResScale</td>
<td>float</td>
<td>Specifies the resolution scale for an individual shadow inside the shadow pool for use by point lights. Determines how much of the shadow pool atlas to use when rendering the shadows for a light entity. Default value: 4</td>
</tr>
<tr>
<td>e_ShadowsSlopeBias</td>
<td>float</td>
<td>Specifies the shadow slope bias. The shadow slope bias is the distance from where shadows are cast to where they can be received, scaled by the slope of the geometry. Default value: 1</td>
</tr>
<tr>
<td>Console Variable</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>e_ShadowsSlopeBiasHQ</td>
<td>float</td>
<td>Specifies the shadow slope bias in high quality mode. When shadow mode is set to high quality, the value of e_ShadowsSlopeBiasHQ or e_ShadowsSlopeBias is used, whichever is smaller. Default value: 0.25</td>
</tr>
<tr>
<td>e_ShadowsTessellateCascades</td>
<td>int</td>
<td>Specifies the maximum cascade number to render tessellated shadows. In cascades higher than the specified value, objects render shadows without tessellation. Default value: 1 Note Use this console variable to optimize performance.</td>
</tr>
<tr>
<td>e_ShadowsTessellateDLights</td>
<td>int</td>
<td>Enables or disables tessellation for shadows cast by local lights. 0 = Off (default) 1 = On</td>
</tr>
<tr>
<td>e_ShadowsUpdateViewDistRatio</td>
<td>int</td>
<td>Specifies the view distance ratio for shadow maps that update for the shadow pool. Default: 256</td>
</tr>
<tr>
<td>e_ShadowsOnAlphaBlend</td>
<td>int</td>
<td>Enables shadows on alpha blend. 0 = Off (default) 1 = On</td>
</tr>
<tr>
<td>r_DrawNearShadows</td>
<td>int</td>
<td>Enables shadows for near objects. 0 = Off 1 = On (default)</td>
</tr>
<tr>
<td>r_DynTexMaxSize</td>
<td>int</td>
<td>Specifies the maximum dynamic texture size. Use in conjunction with e_ShadowsMaxTexRes. Default value: 80</td>
</tr>
<tr>
<td>r_FogShadows</td>
<td>int</td>
<td>Enables deferred volumetric fog shadows. 0 = Off 1 = Standard resolution (default) 2 = Reduced resolution</td>
</tr>
<tr>
<td>Console Variable</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>

<td><code>r_fogShadowsWater</code></td>
<td>int</td>
<td>Enables volumetric fog shadows for water volumes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = On (default)</td>
</tr>
<tr>
<td><code>r_ShadowJittering</code></td>
<td>float</td>
<td>Specifies the shadow map jittering radius. Values set by this CVAR are overwritten by ToD animation as soon as the ToD changes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default value: 2.5</td>
</tr>
<tr>
<td><code>r_ShadowPoolMaxFrames</code></td>
<td>int</td>
<td>Specifies the maximum number of frames during which a shadow can exist in the shadow pool.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td><code>r_ShadowPoolMaxTimeslicedUpdatesPerFrame</code></td>
<td>int</td>
<td>Specifies the maximum number of time-sliced shadow pool updates that are allowed per frame.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td><code>r_ShadowsCache</code></td>
<td>int</td>
<td>Replaces all sun cascades above the specified value with a cached (static) shadow map.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = No cached shadows.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = Replace the first and following cascades.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2 = Replace the second and following cascades.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>[...]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default value: 5</td>
</tr>
<tr>
<td><code>r_ShadowsCacheFormat</code></td>
<td>int</td>
<td>Specifies the texture format for shadow cache.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Use D32 texture format.</td>
</tr>
<tr>

### Saving Console Variable Changes

Changes that you make to CVARs within the console do not automatically save in your level or editing session. To save your changes, you can use configuration files or Lua script.

**To save console variable changes**

- Do one of the following:
  - Edit and save one of the console variable configuration files. For more information, see [Configuring Console Variables](#).
  - In a Lua script, use the following syntax to assign a value to the variable at startup:
    ```lua
    ConsoleRequestBus.Broadcast.ExecuteConsoleCommand('r_ConsoleVariable = Value')
    ```

### Finding Other Shadow-Related Console Variables

You can use the Lumberyard Editor console window to search for additional shadow-related console variables.

**To find additional shadow-related console variables**

1. In Lumberyard Editor, choose **Tools, Console**.
2. In the console window, do one of the following to open the **Console Variables** search window.
A. Click the X icon next to the command entry area.
B. Right-click the command entry area.

3. In the **Console Variables** window, for **Search**, enter **shadow** or **gsm**.

4. To learn more about a console variable, pause your pointer on the variable name.

For more information about using the Lumberyard Editor console, see **Using the Console Window** (p. 210).

**Tutorial: Using Console Variables to Tune Cascade Shadows**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This topic shows you how to use console variables (CVARs) to tune the shadows in a scene. The sample is a 2k island test level that was generated with World Machine.

**Topics**
- Prerequisite: Disable Rendering Features (p. 1796)
• Step 1: Enable Cascade Shadows (p. 1796)
• Step 2: Enable Cascades Debug Mode (p. 1798)
• Step 3: Maximize the Number of Cascades (p. 1800)
• Step 4: Change the Size of the Root Cascade (p. 1802)
• Step 5: Change the Step Size (p. 1806)
• Step 6: Enable Shadows Debug Mode (p. 1809)

Prerequisite: Disable Rendering Features

Before you begin, disable rendering features like fog. Rendering features like fog can obscure the view of shadows at a distance. To disable fog, enter the following command:

```
e_Fog=0
```

Step 1: Enable Cascade Shadows

By default, shadow cascades are disabled for terrain, as the following image shows.
To enable cascade shadows from terrain, enter the following command:

```
e_GsmCastFromTerrain=1
```

The left side of the cliff in the foreground now has shadows.
To disable cascade shadows, set `e_GsmCastFromTerrain` to 0.

\[
e_{\text{GsmCastFromTerrain}} = 0
\]

**Step 2: Enable Cascades Debug Mode**

You can use debug mode to better see the cascades and the effects of shadow-related console variables. To enable debug mode, enter the following command:
In debug mode, each cascade is assigned a separate color. In the following example, the nearest cascade is in red and the farthest in pink.

| Cascade 0: Red | Cascade 1: Green | Cascade 2: Blue | Cascade 3: Yellow | Cascade 4: Pink |

This information is displayed in the viewport, as the following image shows. Areas that do not have these special colorings do not have shadows.
Step 3: Maximize the Number of Cascades

To create the highest quality shadows, start by maximizing the number of cascades and then scale back as needed. To maximize the number of cascades, enter the `e_GsmLodsNum` console variable, which specifies the number of gradient shadow map levels of detail (LOD). The default is 5.

**Note**
The default of 5 is true even when the `sys_spec_shadows` group console variable is set to its highest value (8).
To increase the number of cascades to 7, enter the following command:

```
e_GsmLodsNum=7
```

In the example, this command expands the set of debug cascade colors to the following:

- Cascade 0: Red
- Cascade 1: Green
- Cascade 2: Blue
- Cascade 3: Yellow
- Cascade 4: Pink
- Cascade 5: Light Blue
- Cascade 6: Red Orange

**Note**

The additional cascade numbers and corresponding colors are not listed in the upper left of the viewport but do appear on the terrain.

The light blue color shows that the shadow range has been extended much further into the distance.
Step 4: Change the Size of the Root Cascade

In a scene, the terrain scales away from the root cascade 0 in the foreground to higher numbered cascades in the background. To specify the size of the root cascade 0 in meters, use the e_GsmRange console variable. The examples in this section show how e_GsmRange values affect shadows.

The first example sets e_GsmRange to 0.5.

```
e_GsmRange=0.5
```
The resulting image shows that Cascade 0 (red) is not yet visible. Cascades 1 through 6 (green, blue, yellow, pink, light blue, and red-orange) are successively visible the farther one looks into the distance. Beyond the last cascade, the mountain has its usual brownish color.

The following command increases the range of the root cascade to 1 meter.

```
e_GsmRange=1.0
```

At this setting, Cascade 0 is visible in the foreground in red. The range has increased to include the distant mountain in Cascade 6 (red-orange).
The following command changes the range of the root cascade to 3 meters, which is the default.

```
e_GsmRange=3.0
```

In the example, this setting expands the area of the red Cascade 0 in the foreground. The other cascades are pushed farther back. The mountain in the distance, which was Cascade 6 (red-orange) is now Cascade 5 (light blue), and Cascade 6 is no longer visible.
At this point, you can reduce the number of cascades from 7 to 6 with the following command.

```
e_GsmLodsNum=6
```

As the following image shows, the command has no visual impact on the range of shadows.
Step 5: Change the Step Size

The range step size specifies how much the next cascade changes. The following command specifies a range of 3, which is the default.

```
e_GsmRangeStep=3
```

The following command changes the range to 1.5.
The following image shows how this significantly reduces the range. In the example, the number of cascades is still 6 (\texttt{e\_GsmLodsNum=6}) and the root cascade is still at 3 meters (\texttt{e\_GsmRange=3.0}). However, the mountains in the distance no longer have shadows.

The next example maintains the same settings but changes the range step to 2.7.

This scales the cascades out again so that they fall just short of the furthest mountain in the distance.
The following example lowers the number of cascades from 6 to 5 but increases the range step to 3.5.

```plaintext
e_GsmLodsNum=5
e_GsmRange=3.0
e_GsmRangeStep=3.5
```

Because of the increase in range step, the reduced number of cascades covers approximately the same amount of terrain as in the previous example. The area which was previously Cascade 5 (light blue) is now Cascade 4 (pink).
Step 6: Enable Shadows Debug Mode

The `e_ShadowsDebug` debug mode, unlike the `e_ShadowsCascadesDebug` console variable presented earlier, shows you information about each cascade in individual windows in the viewport. To enable shadows debug mode, enter the following command:

```
e_ShadowsDebug=1
```

The following image shows the viewport with shadows debug mode enabled.
The following example in shadows debug mode uses the maximum number of cascades (7) but adjusts their reach by tuning the range step to 2.25.

```plaintext
e_ShadowsDebug=1
e_GsmLodsNum=7
e_GsmRange=3.0
e_GsmRangeStep=2.25
```
Create screen effects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard’s rendering technology starts with a modern, physically-based shading core that renders materials based on real world physical parameters (such as base color, metallicity, smoothness, and specularity), allowing you to achieve realistic results using the same physically-based parameters used in the highest end film rendering pipelines.

The rendering core is supplemented by a rich set of the most frequently used real time lighting, shading, special effects, and post effects features, such as physical lights, global illumination, volumetric fog, procedural weathering, particle systems, dynamic real time shadows, motion blur, bokeh depth of field, post color correction, and more.
Lumberyard's rendering engine is tightly integrated with Lumberyard Editor, so the graphical fidelity and performance achieved in your game is what you see in the editor. Changes made in the editor are instantly reflected in the fully rendered scene, allowing for immediate feedback and rapid iteration.

The Lumberyard rendering technology is designed to take maximum advantage of today's high-end PC and console operating systems, while maintaining compatibility with older hardware by scaling down graphical features and fidelity without compromising the core visual elements of your scene.

Working with camera screen effects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use rendering cameras to define custom views within your level. You can trigger them using the Track View or the Enable Depth Of Field Script Canvas node. Rendering cameras are used frequently for animated sequences.

For more information about how to add and use rendering cameras, see Camera Entity.

Depth of Field

Lumberyard uses an efficient gather-based depth of field (DOF) implementation. Depth of field is used to enhance the realism of a scene by simulating the way a real-world camera works. Use a broad depth of field to focus on all or nearly all of a scene. Use a narrow depth of field to focus on objects that are within a certain distance from the camera.
You can enable depth of field by using the `r_depthOfFieldMode` console variable. To control depth of field use the Track View or the `Enable Depth Of Field` Script Canvas node.

**Motion Blur**

Lumberyard uses a sample-weighted motion blur implementation whose settings mirror real-world camera shutter speed settings.
Temporal Antialiasing and Supersampling

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Supersampling is a method of antialiasing that attempts to reduce jagged, pixelated edges (aliasing) in images. It works by sampling a higher resolution version of the image to get the average color of a pixel before reducing it to the intended size. The averaged color values create smoother transitions along an edge of colors, reducing the jagged look.

Because supersampling is memory intensive, Lumberyard uses temporal antialiasing (TAA) to approximate supersampling. While supersampling analyzes pixels spatially, TAA analyzes frames over time, even when the camera is static. The current frame is projected onto the previous frame and samples are blended into an accumulation buffer. This technique reduces ghosting artifacts in motion and gives you control over the amount of antialiasing needed for your graphics. You can create sharp images or softer, blurred images. You can also use supersampling for very high quality rendering.

TAA is useful for reducing aliasing from the following:

- Specular highlights and bright pixels, especially when combined with convolution filters such as Depth of Field or Bloom.
- Geometric and alpha-tested edges.

You can configure TAA by setting the `r_AntialiasingMode` console variable, editing the platform configuration file, or creating a level configuration file with this setting.

Controlling Antialiasing

The following table lists the antialiasing modes that are available in Lumberyard when you use the `r_AntialiasingMode` console variable.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Console Variable Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>No antialiasing</td>
<td>0</td>
<td>Disables postprocessing-based antialiasing. This is useful for debugging or when the technique is unnecessary. You may also use a higher resolution if you prefer not to spend system resources on antialiasing.</td>
</tr>
<tr>
<td>FXAA</td>
<td>1</td>
<td>Enables fast approximate antialiasing (FXAA), which filters edges using a postprocessing edge detection technique.</td>
</tr>
<tr>
<td>SMAA (1TX)</td>
<td>2</td>
<td>Enables subpixel morphological antialiasing (SMAA), which uses an advanced postprocessing technique to detect edges in order to filter edges. This mode includes a basic temporal antialiasing component but does not address subpixel jitter.</td>
</tr>
<tr>
<td>TAA</td>
<td>3</td>
<td>Enables temporal antialiasing (TAA). This is the default mode.</td>
</tr>
</tbody>
</table>

The following table lists the additional console variables that you can configure for temporal antialiasing.

Version 1.28
1815
<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| r_AntialiasingModeEditor             | Specifies whether to use subpixel jitter in the editor. This can eliminate jiggling artifacts on helper objects at the expense of losing antialiasing on static scenes.  
Valid values: 0 = disables this mode | 1 = enables this mode                                                                                                                                    |
| r_AntialiasingTAAClampingFactor      | Controls the clamping factor in standard deviations. Set the value at which to limit the TAA response. Higher values create a more stable scene with less flickering but more ghosting.  
Lower values create a scene with less ghosting but more aliasing and flickering.  
Valid values: 0.75 – 2.0                                                                                     |
| r_AntialiasingTAAJitterPattern       | Specifies the sampling pattern for temporal antialiasing.                                                                                                                                                     |
|                                      | Valid values: 0 = no subsamples | 1 = 2x | 2 = 3x | 3 = 4x | 4 = 8x | 5 = sparse grid, 8x8 | 6 = random | 7 = Halton 8x (default) | 8 = Halton random |
| r_AntialiasingTAA gestionMax         | Clamps the input luminance before temporal filtering to help with image stability. Extra bright pixels can ghost and cause bloom artifacts.                                                               |
|                                      | Default value: 100.0                                                                                                                               |
| r_AntialiasingTAA MotionDifferenceMax | Specifies the maximum difference of speed between the current pixel and its history pixel at which the current pixel is considered fully disoccluded. Lower values create a scene with less ghosting but more aliasing on disoccluded pixels. |
| r_AntialiasingTAA MotionDifferenceMaxWeight | Specifies the blend weight for the current frame at the maximum speed difference (defined by the r_AntialiasingTAA MotionDifferenceMax console variable).                     |
|                                      | Valid values: 0 = 100% of the history pixel | 1 = 100% of the current pixel                                                                                                                                |
|                                      | Default value: 0.5                                                                                                                               |
| r_AntialiasingTANewFrameFaloff       | Represents the amount of time, in seconds, for the history signal to reach 63% of the source signal. Lower values create faster convergence, which can reduce ghosting but introduce some aliasing. Higher values create slower convergence.  
Because higher values may not improve stability, you should adjust the color clamping factor before adjusting this value.  
Default value: 0.15                                                                                                                                 |
<table>
<thead>

<td>1 = enables this mode</td>
</tr>
<tr>
<td>Default value: 0</td>
<td></td>
</tr>
</tbody>
</table>

The following images illustrate the range of graphics quality that you can achieve depending on which antialiasing setting you use.
Temporal Antialiasing Limitations

Temporal antialiasing (TAA) is an inexpensive solution that reduces aliasing from all sources and works well with most content. Because it relies on screen-space information from previous frames, TAA has limitations in the following scenarios:

- Objects occlude other objects while in motion. In this scenario, the newly visible areas in the current frame don’t have a history value to blend with and can manifest as ghosting.
- Motion vectors are not present for objects in motion, which can result in subtle smearing artifacts. Motion vectors are not generated for merged vegetation, non-CGF-based particles, or transparent materials. In certain high-frequency signal scenarios, the most apparent artifact is flickering caused by subpixel jittering that alternates between bright and dark pixels.
- The content has a lot of subpixel triangles and normals. In this scenario, the subpixel detail can cause flickering artifacts with temporal subpixel jittering. When a bright edge that is surrounded by dark pixels becomes smaller, the neighborhood clamping heuristic causes the pixels to flicker between light and dark.
- Transparency does not write depth. In this scenario, certain transparent content can exhibit subtle smearing artifacts.

In these cases, you may prefer to use subpixel morphological antialiasing (SMAA) or fast approximate antialiasing (FXAA).

Temporal Antialiasing Best Practices

We recommend following these best practices when using temporal antialiasing (TAA).

- Build content to alias as little as possible.
- Use level of detail (LOD) to reduce subpixel detail for objects that are far away.
- Use the anti-flicker filter to help with flickering. The `r_AntialiasingTAAUseAntiFlickerFilter` console variable is enabled by default.

Controlling Supersampling

In addition to antialiasing, Lumberyard supports supersampling for very high quality rendering. Supersampling renders the scene at a higher resolution and downscales the image to obtain smooth and stable edges. Due to the high internal rendering resolution, supersampling is performance heavy and only suitable for games intended to be played on high-end computers.

Voxel-based Global Illumination (SVOGI)

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Sparse voxel octree global illumination (SVOGI), also known as voxel GI, is a global illumination solution based on voxel ray tracing. It does not require prebaking or manual setup of bounce lights or light volumes. This solution is experimental and may be memory intensive.
Voxel GI provides the following effects:

- Dynamic indirect light bounce from static objects and many dynamic objects.
- Large-scale ambient occlusion (AO) and indirect shadows from static objects such as brushes, terrain, and vegetation.

For every frame, thousands of rays are traced through voxels and shadow maps to gather occlusion and in-directional lighting.

To use this feature, you must enable (p. 1064) the SVOGI gem for your project.

You must also enable SVOGI per level.

**To enable SVOGI for your level**

1. In Lumberyard Editor, choose **Edit, Editor Settings, Global Preferences.**
2. In the Preferences window, under Experimental Features, select Lighting.
3. In the right pane, under Options, select the Total Illumination check box.
4. Click OK.

Integration Modes

You can apply voxel GI through several modes.

Mode 0

With mode 0, only opacity is voxelized. The bounced light is sampled directly from shadow maps—extended to reflective shadow maps—and compute shaders are not used.

Mode 0 has the following advantages:
• GPU memory usage is small (~16 MB).
• Indirect lighting is completely dynamic; moving sun does not cause any slowdown.
• Dynamic objects can bounce indirect lighting.

Mode 0 has the following disadvantages:
• Indirect lighting can have low quality (more noise), especially for small point lights.
• Only single bounce is possible.
• Only diffuse GI is possible.
• Environment probes are needed for specular highlights.

Modes 1, 2

With modes 1 and 2, albedo, normals, and several layers of radiance are voxelized together with opacity. Direct lighting is also injected into voxelization, where it is propagated within the voxelization and then sampled during the ray-tracing pass.

Modes 1 and 2 have the following advantages:
• Modes 1 and 2 support multiple bounces. The light source can be semi-static with multibounce support or be fully dynamic with single bounce support.
• Mode 2 supports traced speculars.
• They provide higher quality, smoother indirect lighting.

Modes 1 and 2 have the following disadvantages:
• Modes 1 and 2 use more GPU memory (64 MB+).
• Large semi-static multibounce lights cannot be moved freely, but moving sun may work fine.
• Dynamic objects cannot affect GI, but can receive it.

Note
If you receive a message that the display driver has stopped responding and has recovered, try this workaround from Microsoft.

Voxel GI Parameters

The following parameters are global for an entire level. You can use normal ambient lights to modulate or tint indirect light intensity locally.

Global illumination uses the sun and the seven largest static lights in the scene and the eight dynamic lights closest to the camera.
To enable voxel global illumination

1. In Lumberyard Editor, choose **Tools, Terrain Tool, Environment**.
2. In the **Environment** panel, under **Total_Illumination_v2**, adjust the following settings as needed.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Activate voxel GI for the level.</td>
</tr>
<tr>
<td>Integration mode</td>
<td>Set to 0, 1, or 2:</td>
</tr>
<tr>
<td></td>
<td>• 0 – AO + Sun bounce</td>
</tr>
<tr>
<td></td>
<td>• 1 – Diffuse GI mode (experimental)</td>
</tr>
<tr>
<td></td>
<td>• 2 – Full GI mode (experimental)</td>
</tr>
<tr>
<td></td>
<td>For more information, see <strong>Integration Modes (p. 1820)</strong>.</td>
</tr>
<tr>
<td>Number of bounces</td>
<td>Set the maximum number of indirect bounces. The first indirect bounce is completely dynamic. The remaining bounces are cached in SVO and are mostly static.</td>
</tr>
<tr>
<td>Diffuse cone width</td>
<td>Controls the width of the diffuse cone. Wider cones work faster but may cause overocclusion and increase light leaking.</td>
</tr>
<tr>
<td>Cone max length</td>
<td>Set the maximum length, in meters, of the tracing rays. Shorter rays work faster.</td>
</tr>
<tr>
<td>Use light probes</td>
<td>For integration mode 0, enable this parameter to multiply environment probes lighting with GI. Disable this parameter to replace diffuse contribution of environment probes with GI.</td>
</tr>
<tr>
<td></td>
<td>For integration modes 1 and 2, enable this parameter to use global environment probe for sky light instead of <strong>Time Of Day</strong> fog color.</td>
</tr>
<tr>
<td>Injection multiplier</td>
<td>Modulate light injection by controlling the intensity of bounce light.</td>
</tr>
<tr>
<td>Ambient offset red</td>
<td>Controls the amount of red in the environment. Higher values show more red in the level.</td>
</tr>
<tr>
<td>Ambient offset green</td>
<td>Controls the amount of green in the environment. Higher values show more green in the level.</td>
</tr>
<tr>
<td>Ambient offset blue</td>
<td>Controls the amount of blue in the environment. Higher values show more blue in the level.</td>
</tr>
<tr>
<td>Ambient offset bias</td>
<td>Controls the strength of the light in the environment. Higher values contribute to a brighter environment.</td>
</tr>
<tr>
<td>Saturation</td>
<td>Controls the color saturation of propagated light.</td>
</tr>
<tr>
<td>SSAO amount</td>
<td>Scales down screen space ambient occlusion (SSAO) or screen space directional occlusion (SSDO) amount and radius when GI is active.</td>
</tr>
</tbody>
</table>

3. (Optional) Use the **Voxel Coverage** advanced parameter on each material:
   a. Click **Tools, Material Editor**.
b. Select your material.
c. Under Advanced, modify the **Voxel Coverage** parameter to control the transparency of voxels for each material and manually fix overoccluded areas. The default value is 1.

**Note**
This parameter takes effect only when voxel global illumination is enabled.

### Debugging

You can use the following console variables to help debug voxel GI issues:

- `r_ShowRenderTarget svo_fin` – Displays the output of the voxel GI system.
- `r_profiler 1 | 2` – Retrieves GPU profiling information.
- `svoToggleShowVoxels` – Shows voxelization of the scene, which shows which voxels are on CPU memory and which are on GPU memory.
- `svoReset` – Performs hard reset of the system and recomputes all values.

**Important**
Do not use the `e_svoTI_*` console variables (for example, `e_svoTI_IntegrationMode`) to configure the voxel GI system. Any changes to these console variables in the configuration file will be overwritten by the individual level environment settings file. Instead, configure your settings in the **Total Illumination** (p. 1820) pane in Lumberyard Editor.

### Current Limits

The following limitations exist for the voxel GI system:

- The GI code doesn’t have a mechanism for detecting light modifications directly, but is constantly updating to capture changes to the lighting. This may introduce delay in the GI response to lights changing.
- Large-scale ambient occlusion and indirect shadows are properly cast only by static geometry.
- Voxel GI does not function on some forward-rendering components like particles or water.
- Some artifacts like ghosting, aliasing, light leaking, and noise may be noticeable.
- Procedural vegetation and merged vegetation do not cast occlusion or secondary shadows.
- If a camera is moved to a new location, it may take several seconds until occlusion works properly.
- Only objects and materials with shadow map casting enabled will generate correct bounced light.
- For dynamic objects, indirect light bounce will function only in areas near voxelized static geometry.
- Bounce light may have a noticeable delay of 1 to 2 frames.

Use of the `r_Supersampling=2` console variable may adversely affect the appearance of the voxel GI. You can set the **LowSpecMode** value two times lower to restore the appearance of the voxel GI. **Temporal AA** using `r_AntialiasingMode 2/3` works correctly as well.

### Fog Systems

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Lumberyard supports a standard fog system as well as a voxel-based volumetric fog system. Which one to use for your game comes down to balancing performance over visual quality. Volumetric fog looks superior but comes at a performance cost. The standard fog system is very cheap performance-wise to compute.

You can also add realistic-looking fog above water surfaces, as well as add volumetric fog shadows.

**Topics**
- Standard Fog (p. 1823)
- Volumetric Fog (p. 1825)

## Standard Fog

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard's standard fog system handles sunlight with dynamic shadows and exponential height fog density. However, in dense fog situations the fog's appearance may not be consistent between opaque and transparent materials.

You can add the **Fog Volume** component to an entity to create fog effects. For more information, see the **Fog Volume (p. 593)** component.

**Topics**
- Setting Global (Time of Day) Fog (p. 1823)
- Using Fog Volumes (p. 1823)
- Console Variables for Fog (p. 1824)

## Setting Global (Time of Day) Fog

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use global fog to simulate particles that are distributed uniformly along the ground and fall off exponentially with height above sea level. Global fog accurately accounts for time of day lighting and for scattered sunlight rays to produce haze at the horizon and halos around the sun. You can also use this effect to cast shadows for objects and clouds through the fog.

**To set global fog parameters**

1. In Lumberyard Editor, choose **Tools, Other, Time Of Day**.
2. In the **Parameters** pane, for **Fog**, adjust the **Fog Parameters (p. 1278)** as needed.
3. Close the **Time of Day** editor.

## Using Fog Volumes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Fog volumes are localized 3D areas that define an area where non-volumetric fog is present. Fog volumes do not change in dynamic, nonuniform ways like smoke does. When alpha-transparent objects are behind fog volumes, each pixel is fogged. However, this is not the case when objects are inside fog volumes.

Unlike global (Time of Day) fog that has an upward falloff direction, fog volumes can have an arbitrary falloff direction. Interesting fog shapes and effects can be achieved, including fog patches that vary in size, color, shape, density, and spacing over time, as well as being influenced by wind.

Observe these best practices when creating fog volumes

- Do not overlap fog volumes.
- Make sure indoor fog volumes don't cover more than one sector or they may be culled when the main sector becomes invisible.
- To avoid inaccurate rendering, don't apply nonuniform scaling to fog volumes.
- When using shadow maps inside fog volumes, make sure the environment `VolFogShadows` parameter is disabled.

You can add the **Fog Volume** component to an entity to create fog effects. For more information, see the [Fog Volume](p. 593) component.

**Console Variables for Fog**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/developer-preview) or visit the [AWS Game Tech blog](https://aws.amazon.com/blogs/gaming/) to learn more.

The following console variables can be used to control fog. For more information, see [Using the Console Window](p. 210).

<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>e_Fog</code></td>
<td>Toggles fog on and off.</td>
</tr>
<tr>
<td><code>e_FogVolumes</code></td>
<td>Enables local height/distance based fog volumes.</td>

</tr>
</tbody>
</table>

**Volumetric Fog**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Volumetric fog uses volume textures as a view-frustum-shaped voxel buffer to store incoming light and its properties. Volumetric fog supports regular light and sunlight with dynamic shadows, environment probes, ambient light, as well as variations in fog density. It also supports the application of volumetric fog with respect to opaque and transparent materials.

**Example**

In the following example, volumetric fog is disabled.

**Example**

In the following example, volumetric fog is enabled.
You can add the Fog Volume component to an entity to create fog effects. For more information, see the Fog Volume (p. 593) component.

You can specify how light components affect volumetric fog. For more information, see Light Component Fog Properties (p. 597).

You can also use the Particle Editor to place a particle emitter in your level to add fog density to an area. For more information, see the Volume Fog and Volume Thickness parameters for the Advanced Attribute in the Particles Attributes Reference (p. 1513).

To add localized nonvolumetric regions of fog, see Using Fog Volumes (p. 1823).

Topics
- Best Practices for Volumetric Fog (p. 1826)
- Setting Global (Time of Day) Volumetric Fog (p. 1827)
- Console Variables for Volumetric Fog (p. 1827)

Best Practices for Volumetric Fog

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

See the following best practices for working with volumetric fog.

- Attach a Fog Volume (p. 593) and a Box Shape (p. 818) component to the entity.
- Set the r_DeferredShadingTiled console variable to a value greater than 0. The recommended value is 1 to 2. This is required to use volumetric fog. For more information, see Using the Console Window (p. 210).
- To avoid performance problems, use the default values for the Ramp Start and Ramp End parameters located in the Time of Day editor. For more information, see Setting Global (Time of Day) Volumetric Fog (p. 1827).
In the **Time of Day Editor**, large values for the **Range** parameter can cause fog flicker and light leaking behind walls.

To correct this effect, you can adjust the value for the `r_VolumetricFogTexDepth` console variable accordingly.

**Example**

The default value for the `r_VolumetricFogTexDepth` console variable is 32 and the default value for **Range** is 64. If you want to use a larger range such as **Range**=256 and maintain the same visual quality, you need to set `r_VolumetricFogTexDepth` to 64.

When **Range** is 1024, set `r_VolumetricFogTexDepth` to 128.

### Setting Global (Time of Day) Volumetric Fog

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use global volumetric fog to simulate particles that are distributed uniformly along the ground and fall off exponentially with height above sea level. Global volumetric fog accurately accounts for time of day lighting and for scattered sunlight rays to produce halos around the sun.

Use the **Anisotropy** parameters to control the amount of sunlight that is scattered through fog and the direction. Set the **Anisotropy (atmosphere)** parameter close to 0 to achieve a uniform look across the entire sky. Set the **Anisotropy (sun radial)** parameter close to 1 to create a bloom effect around the sun.

The **Radial blend** parameters blend the **Anisotropy** parameters to create various effects. For example, you can create sun radial scattering by setting **Radial blend mode** to 1 and **Radial blend factor** to 1.

**To set global volumetric fog parameters**

1. In Lumberyard Editor, click **Tools, Other, Time Of Day**.
2. In the **Parameters** pane, for **Volumetric fog**, adjust the **Volumetric Fog Parameters** as needed.
3. Close the **Time of Day** editor.

### Console Variables for Volumetric Fog

You can specify the following console variables (CVARs) to enable volumetric fog effects. For more information, see Using the Console Window (p. 210).

<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>e_VolumetricFog</code></td>
<td>Toggles the <strong>Volumetric Fog</strong> component on or off</td>
<td>0 = Off,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = On</td>
</tr>
<tr>
<td>Console Variable</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------------</td>
<td>----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>r_VolumetricFogTexScale</td>
<td>Sets the width and height of the internal volume texture. Screen resolution divided by this factor is applied to the width and height of the fog volume.</td>
<td>The minimum value should be 2.</td>
</tr>
<tr>
<td>r_VolumetricFogTexDepth</td>
<td>Sets the depth for the internal volume texture.</td>
<td>This value should be multiples of 4, but less than 252.</td>
</tr>
<tr>
<td>r_VolumetricFogReprojectionBlendFactor</td>
<td>Sets the blending factor of the temporal reprojection filter. Higher values cause less flicker, but more ghosting.</td>
<td>0 = Turn off temporal reprojection.</td>
</tr>
<tr>
<td>r_VolumetricFogReprojectionMode</td>
<td>Sets the mode of ghost reduction for the temporal re-projection filter.</td>
<td>0 = Conservative mode. Ghost artifacts can appear when a light moves, but there is less flicker than in the advanced mode.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = Advanced mode. This mode has fewer ghost artifacts but slightly more flicker than the conservative mode.</td>
</tr>
<tr>
<td>r_VolumetricFogSample</td>
<td>Sets the number of sample points.</td>
<td>0 = 1 sample point in a voxel.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = 2 sample points in a voxel.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2 = 4 sample points in a voxel.</td>
</tr>
<tr>
<td>r_VolumetricFogShadow</td>
<td>Sets the shadow sample count for each sample point.</td>
<td>0 = 1 shadow sample per sample point.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = 2 shadow samples per sample point.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2 = 3 shadow samples per sample point.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3 = 4 shadow samples per sample point.</td>
</tr>
</tbody>
</table>
### Console Variable

<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>r_VolumetricFogDownscaledSunShadow</td>
<td>Replaces sun shadow maps with downscaled shadow maps or static shadow maps, if possible. This reduces the volumetric fog flicker for sun shadow.</td>
<td>0 = Disabled.</td>
</tr>
<tr>
<td></td>
<td>1 = Replace first and second cascades with downscaled shadow maps. Others are replaced with a static shadow map, if possible.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2 = Replace first, second, and third cascades with downscaled shadow maps. Others are replaced with a static shadow map, if possible.</td>
<td></td>
</tr>
<tr>
<td>r_VolumetricFogDownscaledSunShadowRatio</td>
<td>Sets the downscale ratio for sun shadow maps.</td>
<td>0 = 1/4 downscaled sun shadow maps.</td>
</tr>
<tr>
<td></td>
<td>1 = 1/8 downscaled sun shadow maps.</td>
<td>1 = 1/8 downscaled sun shadow maps.</td>
</tr>
<tr>
<td></td>
<td>2 = 1/16 downscaled sun shadow maps.</td>
<td>2 = 1/16 downscaled sun shadow maps.</td>
</tr>
<tr>
<td>r_VolumetricFogMinimumLightBulbSize</td>
<td>Sets the minimum size threshold for light attenuation bulb size for voxel-based volumetric fog.</td>
<td>Specify a value between 0 to 2.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> Small bulb sizes can cause light flicker.</td>
<td>Default value: 0.4</td>
</tr>
</tbody>
</table>

### Render Nodes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To visualize objects in a world, Lumberyard defines the concepts of the render node and render element. Render nodes represent general objects in the 3D engine. Among other things, they are used to build a hierarchy for visibility culling, allow physics interactions (optional), and rendering.
For actual rendering, render nodes add themselves to the renderer, passing an appropriate render
element that implements the actual drawing of the object. This process happens with the help of render
objects, as shown in the sample code below

Creating a New Render Node

The following example creates a render node called **PrismObject**. It is derived from **IRenderNode**,
defined in Code/CryEngine/CryCommon/IEntityRenderState.h.

1. Add the interface for **IPrismObjectRenderNode** to CryEngine/CryCommon/
   IEntityRenderState.h to make it publicly available.

   ```cpp
   struct IPrismRenderNode : public IRenderNode
   {
       ...
   };
   ```

2. Add a new enum to the list of already defined render nodes in CryEngine/CryCommon/
   IEntityRenderState.h.

   ```cpp
   enum EERType
   {
       ...
       eERType_PrismObject,
       ...
   };
   ```

3. Add **PrismObjectRenderNode.h** to Cry3DEngine.

   ```cpp
   #ifndef _PRISM_RENDERNODE_
   #define _PRISM_RENDERNODE_
   #pragma once

   class CPrismRenderNode : public IPrismRenderNode, public Cry3DEngineBase
   {
   public:
       // interface IPrismRenderNode
       ...

       // interface IRenderNode
   virtual void SetMatrix(const Matrix34& mat);
   virtual EERType GetRenderNodeType();
   virtual const char* GetEntityClassName() const { return "PrismObject"; }
   virtual const char* GetName() const;
   virtual Vec3 GetPos(bool bWorldOnly = true) const;
   virtual bool Render(const SRendParams &rParam);
   virtual IPhysicalEntity* GetPhysics() const { return 0; }
   virtual void SetPhysics(IPhysicalEntity*) {}
   virtual void SetMaterial(IMaterial* pMat) { m_pMaterial = pMat; }
   virtual IMaterial* GetMaterial(Vec3* pHitPos = 0) { return m_pMaterial; }
   virtual float GetMaxViewDist();
   virtual void GetMemoryUsage(ICrySizer* pSizer);
   virtual const AABB GetBBox() const { return m_WSBBox; }
   virtual void SetBBox( const AABB& WSBBox ) { m_WSBBox = WSBBox; }
   
   private:
   CPrismRenderNode();

   private:
   ~CPrismRenderNode();
   
   #endif  
   ```
4. Add PrismObjectRenderNode.cpp to Cry3DEngine.

```cpp
#include "StdAfx.h"
#include "PrismRenderNode.h"

CPrismRenderNode::CPrismRenderNode() : m_pMaterial(0)
{
  m_mat.SetIdentity();
  m_WSBBox = AABB(Vec3(-1, -1, -1), Vec3(1, 1, 1));
  m_pRE = (CREPrismObject*) GetRenderer()->EF_CreateRE(eDATA_PrismObject);
  m_dwRndFlags |= ERF_CASTSHADOWMAPS | ERF_HAS_CASTSHADOWMAPS;
}

CPrismRenderNode::~CPrismRenderNode()
{
  if (m_pRE)
    m_pRE->Release(false);
  Get3DEngine()->FreeRenderNodeState(this);
}

void CPrismRenderNode::SetMatrix(const Matrix34& mat)
{
  m_mat = mat;
  m_WSBBox.SetTransformedAABB(mat, AABB(Vec3(-1, -1, -1), Vec3(1, 1, 1)));
  Get3DEngine()->RegisterEntity(this);
}

const char* CPrismRenderNode::GetName() const
{
  return "PrismObject";
}

void CPrismRenderNode::Render(const SRendParams& rParam, const SRenderingPassInfo &passInfo)
{
  FUNCTION_PROFILER_3DENGINE;
  if(!m_pMaterial)
    return;

  // create temp render node to submit this prism object to the renderer
  CRenderObject *pRO = GetRenderer()->EF_GetObject_Temp(passInfo.ThreadID());                     // pointer could be cached
  if(pRO)
  {
    // set basic render object properties
    pRO->m_II.m_Matrix = m_mat;
    pRO->m_ObjFlags |= FOB_TRANS_MASK;
    pRO->m_fSort = 0;
    pRO->m_fDistance = rParam.fDistance;

    // transform camera into object space
    const CCamera& cam(passInfo.GetCamera());
    Vec3 viewerPosWS(cam.GetPosition());

```
// set render object properties
m_pRE->m_center = m_mat.GetTranslation();
SShaderItem& shaderItem(m_pMaterial->GetShaderItem(0));
GetRenderer()->EF_AddEf(m_pRE, shaderItem, pRO, passInfo,
EFSLIST_GENERAL, 0, SRendItemSorter(rParam.rendItemSorter));
}

void CPrismRenderNode::GetMemoryUsage(ICrySizer* pSizer) const
{
    SIZER_COMPONENT_NAME(pSizer, "PrismRenderNode");
pSizer->AddObject(this, sizeof(*this));
}

void CPrismRenderNode::OffsetPosition(const Vec3& delta)
{
    if (m_pRNTmpData) m_pRNTmpData->OffsetPosition(delta);
    m_WSBBox.Move(delta);
    m_mat.SetTranslation(m_mat.GetTranslation() + delta);
    if (m_pRE) m_pRE->m_center += delta;
}

void CPrismRenderNode::FillBBox(AABB & aabb)
{
    aabb = CPrismRenderNode::GetBBox();
}

EERType CPrismRenderNode::GetRenderNodeType()
{
    return eE>Type_PrismObject;
}

float CPrismRenderNode::GetMaxViewDist()
{
    return 1000.0f;
}

Vec3 CPrismRenderNode::GetPos(bool bWorldOnly) const
{
    return m_mat.GetTranslation();
}

IMaterial* CPrismRenderNode::GetMaterial(Vec3* pHitPos)
{
    return m_pMaterial;
}

5. To allow client code to create an instance of the new render node, extend the following function in /
   Code/CryEngine/Cry3DEngine/3DEngine.cpp

... #include "PrismRenderNode.h"
...
IRenderNode * C3DEngine::CreateRenderNode(EERType type)
{
    switch (type)
    {
    ...
    case eE>Type_PrismObject:
    {
        IPrismRenderNode* pRenderNode = new CPrismRenderNode();
        return pRenderNode;
    }
Generating Stars .dat File

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Stars .dat file contains star data that is used in sky rendering. This topic provides information you'll need if you want to modify the data in this file. It assumes you have some familiarity with generating binary files.

Star data is located in `Build\Engine\EngineAssets\Sky\stars.dat`. This data is loaded in the function `CStars::LoadData`, implemented in the file `CRESky.cpp`.

### File Format

The Stars .dat file uses a simple binary format; it can be easily modified using an editing tool. The file starts with a header, followed by entries for each star. The header specifies the number of entries in the file.

All types stored in little-endian format, float32 in IEEE-754 format.

Star data provided in the SDK is based on real-world information. Typically, you can also use existing star catalogs to populate this information for you.

The file elements are as follows:

#### Header (12 bytes)

<table>
<thead>
<tr>
<th>Name</th>
<th>Offset</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tag</td>
<td>0</td>
<td>uint32</td>
<td>0x52415453 (ASCII: STAR)</td>
</tr>
<tr>
<td>Version</td>
<td>4</td>
<td>uint32</td>
<td>0x00010001</td>
</tr>
<tr>
<td>NumStars</td>
<td>8</td>
<td>uint32</td>
<td>Number of star entries in the file</td>
</tr>
</tbody>
</table>

#### Entry (12 bytes)

<table>
<thead>

</tbody>
</table>
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard includes a preview of DirectX 12, which provides the framework for you to build DirectX 12 supported applications and develop features. DirectX 12 provides the following benefits for developing applications:

- Slightly faster overall GPU performance on NVIDIA cards.
- Slight increase in frame rate for scenes that are GPU-bound.
- Supported features from DirectX 12 and DirectX 11.3 that include the following:
  - Rasterizer-ordered view with order independent transparency.
  - Tiled resources that allow you to develop textures virtually that you can then use on terrain.
  - Optimized texture streaming.
  - Conservative rasterization helps you develop and optimize ray tracing or voxel rendering, which you can use to develop certain rendering techniques such as global illumination (GI).

Based on your scene, you may discover faster or slower performance across DirectX 11 and DirectX 12. For example, if you enable DirectX 12 you may see a slight performance degradation with CPU-bound scenes. Scenes with high draw calls may also see slower performance depending on the size of the scene and view distance.

**To enable DirectX 12 rendering in Lumberyard**

1. On Windows 10, install the latest Windows 10 SDK.
   
   **Note**
   Copy the Windows 10 SDK version. In Windows, you can find this value in Programs and Features.

2. In a text editor, open the `system_windows_pc.cfg` file and add the following parameter:

   ```
   r_Driver = DX12
   ```

3. Configure your Lumberyard project by doing one of the following:

   - With a text editor, open the `user_settings.options` file in the `lumberyard_version\dev\waf` directory and edit the following parameters, removing any leading semicolons to uncomment the line:
     - Under the [Build Options] section, set `win_build_renderer` to `DX12`.
     - Under the [Windows Options] section, set `win_vs2017_winkit` to your version of the Windows 10 SDK (for example, `10.1.17134.12`).

   Navigate to the `lumberyard_version\dev` directory and, in a command line window, enter the following:

   ```
   lmbr_waf configure
   ```

   - Or, with a command line window, navigate to the `lumberyard_version\dev` directory and enter the following:

   ```
   lmbr_waf configure --win-build-renderer=DX12 --win-vs2017-winkit=10.1.17134.12
   ```
4. In a command line window, build your project with the following command:

```
lmbr_waf build_win_x64_vs2017_profile -p game_and_engine
```

5. Start your game with the launcher. You can verify that your game has enabled DX12 in the top-right of the viewport.

**Note**

- If the DirectX version doesn't appear in the viewport, verify that the `r_DisplayInfo` console variable is set to 1 or 2. For more information, see Using the Console Window (p. 210).
- Currently, Lumberyard Editor does not support DirectX 12. If you open the game in the editor, the editor defaults to DirectX 11.

For more information about DirectX 12, see Taking Advantage of DirectX 11.2 Tiled Resources and Don't Be Conservative with Conservative Rasterization.
Programming in Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Programming with Lumberyard

Learn about the game development APIs and integrations available with Lumberyard (and for Lumberyard). This documentation covers the EBus messaging infrastructure for in-game communications between game systems, memory management and debugging, extending and customizing the Lumberyard editor and tools, networking, localization, and Twitch integration.

These topics are for game developers who have experience with C++ programming and common game design patterns.

In this section:

<table>
<thead>
<tr>
<th>Topic Area</th>
<th>Description</th>

**Working with Amazon Lumberyard systems APIs**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Amazon Lumberyard provides a number of APIs to access and invoke key parts of the Lumberyard engine from your game, including a new in-game console and a new event management system.

These C++ APIs are called from your code, and provide important infrastructure functionality for your game, including messaging and communications, and an in-game console with variable and functor support.

You can find these APIs defined in the following headers:

- Event.h (in %INSTALL_ROOT%\dev\Code\Framework\AzCore\AzCore\EBus\) for AZ::Event (p. 1842)
- IConsole.h (in %INSTALL_ROOT%\dev\Code\Framework\AzCore\AzCore\IConsole\) for AZ::Console (p. 1837)
- Interface.h (in %INSTALL_ROOT%\dev\Code\Framework\AzCore\AzCore\Interface\) for AZ::Interface (p. 1846)

Some of these systems APIs replace functionality from older versions, or provide alternative methods, such as AZ::Console for the CryConsole and AZ::Event for EBus.

For C++ API reference documentation, see the Amazon Lumberyard C++ API Reference.

**Topics**

- AZ::Console (p. 1837)
- AZ::Event<...> (p. 1842)
- AZ::Interface<T> (p. 1846)

**AZ::Console**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The AZ::Console class provides a set of macros for defining variables and mapping functions that you can use to interact with in-game variables and processes. Use the macros defined in this class to set the console variables (cvars) and functors (cfuncs) for your game, and then access them through the Lumberyard console.
AZ::Console is defined in the following header: %INSTALL-ROOT%\dev\Code\Framework\AzCore\AzCore\Console\IConsole.h

Note
The console found inside AzCore is a console and cvar system intended to replace the legacy CryEngine console and cvar system. This system is free of any CryEngine code, and depends only on AzCore.

AZ::Console features:

- **Stubbed** support for multiplayer (as of v1.24). Lumberyard will eventually enable cvar replication across multiplayer instances using GridMate.
- Basic access protections and anti-cheat mechanisms for locking down cvs and cfuncs in release builds.
- Default support for several C++ types, including bool (Boolean), stdint (all types), floats, doubles, vectors and quaternions, and enums (enumerations).
- Flexible and expandable type support. You can add support for new cvar types without altering the console code directly.
- Support for the legacy CryEngine console, specifically to reduce user confusion. For users of the in-game console, legacy cvs and AZ_CVAR cvs appear identical.

Important
As of Amazon Lumberyard version 1.24, AZ::Console does not support the following features present in the CryEngine console:
• Registration of cvars at runtime by name. Formerly, you could register a CryEngine cvar using `IConsole->Register<String/Int/Float>()` and then retrieve the value of that cvar with `IConsole->GetCVar()`. AZ::Console cvars must be declared at compile-time using one of the macros in `IConsole.h`.

• Custom cvar/cfunc autocomplete callbacks. Formerly, you could specify an autocomplete callback and attach it to a CryEngine cvar. AZ::Console currently does not support this functionality.

• Remote console support. The CryEngine console allows remote access by opening a socket on a provided port, and then listening for console commands issued to that socket. AZ::Console currently does not support this functionality.

Topics

- Console variables (cvars) (p. 1839)
- Console functors (cfuncs) (p. 1840)
- Optional flags (p. 1841)
- Adding support for new console variable types (p. 1842)

Console variables (cvars)

Declare a cvar using one of two macros from `IConsole.h`:

```
AZ_CVAR(_TYPE, _NAME, _INIT, _CALLBACK, _FLAGS, _DESC) //Standard cvar macro, provides no external linkage.
```

```
AZ_CVAR_EXTERNABLE(_TYPE, _NAME, _INIT, _CALLBACK, _FLAGS, _DESC) //Cvar macro that creates a console variable with external linkage.
```

Parameters:

- **_TYPE**: The base type of the cvar.
- **_NAME**: The name of the cvar.
- **_INIT**: The initial value to assign to the cvar.
- **_CALLBACK**: An optional callback function invoked when a cvar changes value. **Note**: These macros do not guarantee that this callback will be run on a specific thread. The implementor of the callback handler is responsible for ensuring thread safety.
- **_FLAGS**: One or more AZ::Console::FunctorFlags that are used to mutate behavior. Use the logical AND (`&&`) and OR (`||`) operators to combine flags. If you do not have any flags to set, use `FunctorFlags::None`.
- **_DESC**: String that provides a short description of the cvar for display.

To declare a new cvar in your code, include the `IConsole.h` header. Then use one of the cvar macros (such as `AZ_CVAR`) to declare your new console variable in your own code (.cpp) files.

**Note**

AZ_CVAR and AZ_CVAR_EXTERNABLE variables can be declared only in C++ code (.cpp) files. AZ_CVAR_EXTERNED variables, however, can be declared in either C++ code (.cpp) or header (.h) files.

Here are some examples.
AZ_CVAR(int32_t, cl_GameServiceRefreshTimeMs, 1000, nullptr, FunctorFlags::None, "Controls the auto-refresh delay for all gameService data, time in milliseconds");
AZ_CVAR(bool, cl_QuitOnHubDisconnect, false, nullptr, FunctorFlags::None, "If enabled, the client executable will terminate on disconnect");

void OnConsoleResUpdate(const int32_t& a_NewWidth)
{
    // Run update for new value
}
AZ_CVAR(int32_t, sv_ConsoleWidth, 160, OnConsoleResUpdate, FunctorFlags::ReadOnly, "The width of the server console window");

AZ_CVAR_EXTERNABLE(uint16_t, net_ServerRateMs, 33, nullptr, FunctorFlags::ReadOnly, "Server tick rate to use for network relevant simulations");

Optionally, use the following name prefixes to help organize groups of cvars:
- sv_: For server only cvars
- cl_: For client only cvars
- bg_: "Both games" for common cvars (client and server)

These prefixes are useful to quickly limit the scope of autocomplete, and to see groups of associated cvars in the console. You can use your own prefixes as well.

To make an existing console variable external (extern), use the AZ_CVAR_EXTERNED macro:

```
AZ_CVAR_EXTERNED(_TYPE, _NAME)
```

Make sure that the _TYPE and _NAME parameters match those of the previously defined cvar.

**Console functors (cfuncs)**

Console functions allow you to register a command with the console that's not associated with a specific type or value. In Lumberyard, they're purely a mechanism to allow a method to be invoked directly from the Lumberyard in-game console.

There are two types of cfuncs: one to invoke class member methods (AZ_CONSOLESFUNC), and one to invoke static methods (AZ_CONSOLEFREEFUNC).

To declare a class member method cfunc, use the AZ_FUNC macro from IConsole.h:

```
AZ_CONSOLESFUNC(_CLASS, _FUNCTION, _INSTANCE, _FLAGS, _DESC)
```

Parameters:
- _CLASS: The class that contains the method (function) for invocation.
- _FUNCTION: The method to invoke as a callback. **Note:** These macros do not guarantee that this callback will be run on a specific thread. The implementor of the callback handler is responsible for ensuring thread safety.
• _INSTANCE: The instance of the class on which this method gets invoked (usually set to this for the current instance).
• _FLAGS: One or more AZ::Console::FunctorFlags that are used to mutate behavior. Use the logical AND (&) and OR (|) operators to combine flags. If you do not have any flags to set, use FunctorFlags::None.
• _DESC: String that provides a short description of the cfunc for display.

Some examples of cfunc declarations:

```cpp
class Example
{
    public:
        Example() { AZ_CONSOLEFUNC(Example, Method, this, FunctorFlags::DontReplicate, 
            "Executes the Method method on this Example instance, invoke in the console using 
            Example.Method"); }
        void Method(const StringSet&) {}
};
```

To declare a cfunc for a static method (or other non-member function), use the AZ_CONSOLEFREEFUNC macro:

```cpp
AZ_CONSOLEFREEFUNC(_FUNCTION, _FLAGS, _DESC)
```

Parameters:
• _FUNCTION: The static method to invoke as a callback. Note: These macros do not guarantee that this callback will be run on a specific thread. The implementor of the callback handler is responsible for ensuring thread safety.
• _FLAGS: One or more AZ::Console::FunctorFlags that are used to mutate behavior. Use the logical AND (&) and OR (|) operators to combine flags. If you do not have any flags to set, use FunctorFlags::None.
• _DESC: String that provides a short description of the cfunc for display.

Example:

```cpp
void ForceEnableMetrics(const StringSet&) {}
AZ_CONSOLEFREEFREEFUNC(ForceEnableMetrics, FunctorFlags::Null, "If called, force enable metrics");
```

Optional flags

AZ::Console provides a set of flags that can be passed to cvar and cfunc declarations and indicate how they should be handled:

```cpp
enum class FunctorFlags
{
    Null = 0, // Empty flags
    DontReplicate = (1 << 0), // Should not be replicated (CURRENTLY UNUSED)
    ServerOnly = (1 << 1), // Should never replicate to clients (CURRENTLY UNUSED)
    ReadOnly = (1 << 2), // Should not be invoked at runtime
    IsCheat = (1 << 4), // Should not be shown in the console for autocomplete
    IsDeprecated = (1 << 5), // Command is deprecated, show a warning when invoked
    NeedsReload = (1 << 6), // Level should be reloaded after executing this command
};
```
Adding support for new console variable types

To add support for a new cvar type, override the two template methods that convert the custom type to a space-delimited string from a vector of space-delimited string inputs.

As an example, an override that converts AZ::Vector3 to a string and back to a value is declared like this:

```cpp
namespace AZ
{
    // CVar compatibility
    namespace ConsoleTypeHelpers
    {
        template <>
        AZStd::string ValueToString<AZ::Vector3>(const AZ::Vector3& a_Value);
        template <>
        bool StringSetToValue<AZ::Vector3>(AZ::Vector3& a_OutValue, const StringSet& a_Arguments);
    }
}
```

AZ::Event<...>

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The AZ::Event template class is used to subscribe to and publish single value messages across the different components of your game. It's designed to replace value-based event pub/sub patterns that are currently implemented using EBus, only with significantly simpler syntax. There are a number of benefits to this new system, including simpler code, fewer files, removal of aggregate interfaces where a handler only cares about a subset of events, and improved runtime performance when dispatching value changes to registered handlers.

AZ::Event is defined as a C++ template (template <typename... Params>) in the following header: %INSTALL-ROOT%\dev\Code\Framework\AzCore\AzCore\Ebus\Event.h

Important
As of Amazon Lumberyard version 1.24, AZ::Event limitations include the following:

- The event system is single-threaded only. Handlers should Connect() and Disconnect() on the same thread that is dispatching events.
- Handlers can be bound only to an existing event instance. You can't bind to an event prior to its creation (the way you can with an address by ID EBus).
- A handler can be bound only to a single event. You can't bind a single handler to more than one event.
- There are no return results for handlers. The handler function signature must have a void return result.
- There is no event queuing. A queue can be built as a modular handler wrapper, but in the single-threaded implementation, all events immediately dispatch to all handlers.
AZ::Event provides a Handler class and the following explicit constructors:

- Handler(std::nullptr_t)
- Handler(Callback callback)
- Handler(const Handler& rhs)
- Handler(Handler&& rhs)

AZ::Event::Handler has the following methods defined on it:

- To connect to a Handler instance: void Connect(Event<Params...>& event);
- To disconnect from a Handler instance: void Disconnect();

Example usage

- To create an event for handling, declare an instance of AZ::Event with the following C++ syntax:
  
  AZ::Event<{type}> {name_of_event};

  For example, to declare an event that can publish a Boolean value:

  AZ::Event<bool> isPlayerActive;

- To declare a handler that will process the event when it is signaled:

  AZ::Event<bool>::Handler playerActiveHandler([]({type} value) {});

  For example, to create a handler for the event from the previous example:

  AZ::Event<bool>::Handler playerActiveHandler([](bool value) {});

When you declare the event and the handler in your header, you can connect to the event and signal it. Here is a simple example using the declarations and calls from the prior examples:

```cpp
// Declaration in your header
AZ::Event<bool> isPlayerActive; // Declare the event
AZ::Event<bool>::Handler playerActiveHandler([](bool value) {}); // Declare our handler

// Usage in your code
handler.Connect(isPlayerActive); // Connect the handler to our event
// ...
isPlayerActive.Signal(true); // Signal the event to inform subscribers that the player is active
```

Here is a more complex example that signals multiple events with a class to handle them:

```cpp
class ExampleEventComponent
    : public AZ::Component
{
    public:
        using Event1Type = AZ::Event<const AZ::Vector3&>;
        using Event2Type = AZ::Event<float, float>

        void Tick()
        {
            // Update component state
            if (value1Changed)
            {
                m_event1.Signal(value1);
            }
```
if (value2Changed)
    {
        m_event2.Signal(value2.x, value2.y);
    }
}

void ConnectEvent1Handler(Event1Type::Handler& handler) { handler.Connect(m_event1); }
void ConnectEvent2Handler(Event2Type::Handler& handler) { handler.Connect(m_event2); }
private:
    Event1Type m_event1;
    Event2Type m_event2;
};
class ExampleHandlerComponent
 : public AZ::Component
{
public:
    ExampleHandlerComponent()
        : m_handler1([this](const AZ::Vector3& value) { this->OnEvent1Invoked(value); }),
          m_handler2([this](float value2x, float value2y) { this->m_value2x = value2x; this->m_value2y = value2y; })
    {
    }

    void Activate()
    {
        ExampleEventComponent* eventComponent = GetEntity()->FindComponent<ExampleEventComponent>();
        if (eventComponent)
        {
            eventComponent->ConnectEvent1Handler(m_handler1);
            eventComponent->ConnectEvent2Handler(m_handler2);
        }
    }

    void OnEvent1Invoked(int32_t value) { // do something with value }
private:
    ExampleEventComponent::Event1Type::Handler m_handler1;
    ExampleEventComponent::Event2Type::Handler m_handler2;
};

Performance

AZ::Event is roughly another 20% faster than even the lambda syntax for EBus, and over 40% faster than EBus's member function pointer model. These performance deltas scale linearly with the number of handlers, so AZ::Event is 40% faster than using standard EBus member function pointers whether there's 1,000 handlers attached, or 1,000,000.

To compare the EBus handler implementation code against AZ::Event, here is an example of code used to signal a change to a single value using EBus.

// Single-value message handler using EBus

// Bus interface
class EBusEventExample
 : public AZ::EBusTraits
{
public:
    using MutexType = NullMutex;
    static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Multiple;
    static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::Single;
    virtual void OnSignal(int32_t) = 0;
using EBusEventExampleBus = AZ::EBus<EBusEventExample>;

class EBusEventExampleImpl : public EBusPerfBaselineBus::Handler
{
public:

    EBusEventExampleImpl() { EBusEventExampleBus::Handler::BusConnect(); }
    ~EBusEventExampleImpl() { EBusEventExampleBus::Handler::BusDisconnect(); }

    void OnSignal(int32_t) override {};
};

// Usage
EBusEventExampleImpl handler;
EBusEventExampleBus::Broadcast(&EBusEventExample::OnSignal, 1);

And here is an example that performs the same work using AZ::Event.

// Single-value message handler implemented using AZ::Event
AZ::Event<int32_t> event; // Declare the event
AZ::Event<int32_t>::Handler handler([](int32_t value) {}); // Declare our handler

// Usage
handler.Connect(event); // Connect the handler to our event
event.Signal(1); // Signal an event, this will invoke our handler's lambda

Note the reduced lines of code, as well as the overall simpler code pattern. Try it out by porting some of your current EBus message handlers to use AZ::Event, and then test it using our built-in unit tests and benchmarks.

Unit testing and benchmarking

The AZ::Event system includes a number of unit tests and benchmarks to validate correct behavior and confirm the performance advantages over an equivalent EBus implementation.

To execute the unit tests, the following command-line arguments can be provided to the AzTestRunner:

%INSTALL-ROOT%\dev\Bin64\vc141.Test\AzCoreTests.dll AzRunBenchmarks --pause-on-completion --benchmark_filter=BM_EventPerf*

You should see unit testing output like this.

[==========] Running 7 tests from 1 test case.
[----------] Global test environment set-up.
[----------] 7 tests from EventTests
[ RUN      ] EventTests.TestHasCallback
[   OK ] EventTests.TestHasCallback (0 ms)
[ RUN      ] EventTests.TestScopedConnect
[   OK ] EventTests.TestScopedConnect (0 ms)
[ RUN      ] EventTests.TestEvent
[   OK ] EventTests.TestEvent (1 ms)
[ RUN      ] EventTests.TestEventMultiParam
[   OK ] EventTests.TestEventMultiParam (0 ms)
[ RUN      ] EventTests.TestConnectDuringEvent
[   OK ] EventTests.TestConnectDuringEvent (0 ms)
[ RUN      ] EventTests.TestDisconnectDuringEvent
[   OK ] EventTests.TestDisconnectDuringEvent (0 ms)
[ RUN      ] EventTests.TestDisconnectDuringEventReversed
[   OK ] EventTests.TestDisconnectDuringEventReversed (1 ms)
To execute the benchmarks, the following command-line arguments can be provided to the AzTestRunner:

```bash
%INSTALL-ROOT%\dev\Bin64vc141.Test\AzCoreTests.dll AzRunBenchmarks --pause-on-completion --benchmark_filter=BM_EventPerf*
```

You should see benchmark output like this.

<table>
<thead>
<tr>
<th>Benchmark name</th>
<th>benchmark time</th>
<th>cpu time</th>
<th>iterations</th>

**AZ::Interface<T>**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the `AZ::Interface<T>` template class to create global or application lifetime message request buses that support systems of type `T`. This template class is used to implement access for registered singletons across module boundaries. In this case, a singleton is an instance of a type that inherits `AZ::Interface::Registrar`. Once the singleton instance is registered, you can access the environment variables through code implemented on the instance. You can also make changes to the environment variables that can be viewed by other parts of your game's components.

Commonly, `AZ::Interface` should be used when you want to invoke methods on a core system like the renderer or the console from another component.

A system is an instance of a class that inherits the `Registrar` method from `AZ::Interface`. Systems that are registered with `AZ::Interface` are designed to replace global or application lifetime request buses that are currently implemented using `EBus`. There are a number of benefits to this new system, including vastly improved performance and compatibility with IDE standard code autocomplete functionality.

**Note**

Systems, in this usage, are key parts of the Lumberyard game engine. Some examples include the renderer, the console, the audio system, the input system, and the AI pathfinding system.

With `AZ::Interface`, you access these systems with this simplified syntax:

```cpp
AZ::Interface<{system-interface-here}>->Get()->PerformCommand
```

For example,

```cpp
AZ::Interface<IAudio>->Get()->PlaySound();
```

Likewise, you can use this syntax to invoke behaviors across systems for console functors (cfuncs) declared with `AZ::Console` (p. 1837).

`AZ::Interface<T>` provides a number of significant improvements over using a single handler `EBus`, such as:

- Improved performance. Calls to the singleton are a virtual function call that can often even be de-virtualized by the compiler, rather than a lock / list iterate / function dispatch to a virtual call.
- Improved debuggability. `AZ::Interface` is essentially just an `AZ::Environment` variable wrapper that enables extensible singletons within the Lumberyard engine.
AZ::Interface is defined as a C++ template (template <T>) in the following header: %INSTALL-ROOT%dev\Code\Framework\AzCore\AzCore\Interface\Interface.h

**Using AZ::Interface**

This is the process for registering a singleton thread for a system with AZ::Interface

- Obtain a raw interface pointer to a type T class instance for registration. You can assume that the registered system will outlive any cached references.
- Register the system with the interface at initialization time by calling Register() on the reference to it.
- Wait. If registration is successful, an AZ::Environment (which contains the environment variables for your game) is successfully attached and is ready to receive messages to update the environment variables.

To deregister a system, call Unregister() on AZ::Interface.

AZ::Interface defines the following static methods:

- static void Register(T* type) — Registers an instance of type T to AZ::Interface.
- static void Unregister(T* type) — Deregisters an instance of type T from AZ::Interface.
- static T* Get() — Gets a reference to an instance of type T that is registered with AZ::Interface.

It also defines a helper class, Registrar, that enables registration and deregistration from within the AZ::Interface class constructor and destructor, respectively.

```cpp
/**
 * A helper utility RAII mixin class that will register / unregister within the
 * constructor / destructor, respectively.
 *
 * Example Usage:
 * @code{.cpp}
 *      class System
 *          : public Interface<ISystem>::Registrar
 *      {
 *          
 *          @{endcode
 *      };
 * @endcode
 */

class Registrar : public T {
public:
    Registrar();
    virtual ~Registrar();
};
```

In most cases, you use Registrar instead of implementing registration directly.

Here’s an example of using AZ::Interface::Registrar to register a system with a single method, DoSomething(), defined for it.

```cpp
class ISystem {
public:
    virtual ~ISystem();
    virtual void DoSomething() = 0;
};
```
class System
    : public AZ::Interface<ISystem>::Registrar
{    
    public:
        void DoSomething() override;
};

// In client code.
// Check that the pointer is valid before use.
if (ISystem* system = AZ::Interface<ISystem>::Get())
{
    system->DoSomething();
}

Important

The restrictions for AZ::Interface are similar to that of a single-handler EBus:

- Use AZ::Interface on long-lived instances only, such as instances with global variables that live across the lifetime of a module or application.
- Because AZ::Interface uses AZ::Environment variables across DLL boundaries, you can only register/unregister after the AZ::Environment instance is attached after successful registration.
- AZ::Interface works with EBus, and you can soft-migrate EBus code by providing an AZ::Interface<T> handler for the same set of requests.
- **Thread safety is your responsibility.** Using AZ::Interface<T> does not make threads safe.

Vs. AZ::Event

AZ::Event (p. 1842) is a publish/subscribe (pub/sub) event handler that can be used when you want to subscribe to notifications from another component on the same thread. AZ::Interface, on the other hand, is a replacement for singletons, when you want to invoke methods on a core system like the renderer or the console.

Converting from an EBus implementation

Here is an example of converting a global request bus to AZ::Interface<T>.

**Example Original original EBus baseline**

```cpp
// Bus interface
class EBusRequests
    : public AZ::EBusTraits
{    
    public:
        using MutexType = NullMutex;
        static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Single;
        static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::Single;
        virtual void Request(int value) = 0;
};
using EBusEventExampleBus = AZ::EBus<EBusEventExample>;

// Bus implementation
class EBusEventExampleImpl
    : public EBusPerfBaselineBus::Handler
{    
    public:
```
Example EBus implementation converted to use AZ::Interface

To convert from all-in EBus usage to a global request bus that uses AZ::Interface but can still interoperate with Script Canvas, you must make a few changes:

- Create your pure virtual interface without any EBus code.
- Create an EBus wrapper that inherits from AZ::EBusTraits, and declare the EBus as AZ::EBus<{your-interface-class-name}, {your-ebus-wrapper-name}>.
- Create your implementation of your interface, inherit from your EBus wrapper handler, and do the following:
  - Call both Register() and BusConnect() in your class constructor.
  - Call both Unregister() and BusDisconnect() in your class destructor.

```cpp
// Our pure-virtual interface only
class IRequests
{
    public:
        virtual void Request(int value) = 0;
};

// EBus stuff
class EBusStuff
    : public AZ::EBusTraits
{
    public:
        using MutexType = NullMutex;
        static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Single;
        static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::Single;
    }
using EBusStuffBus = AZ::EBus<IRequests, EBusStuff>; // Note we specify the pure virtual interface first, and then the EBus stuff after

// Implementation, inherit from the pure-virtual interface
class RequestsImpl
    : public EBusStuffBus::Handler // Note we inherit from the bus handler
{
    public:
        AZ_RTTI(RequestsImpl, "{some guid}", IRequests); // AZ type info is required

        RequestsImpl()
        {
            AZ::Interface<IRequests>::Register(this);
            EBusStuffBus::Handler::BusConnect();
        }

        ~RequestsImpl()
        {
            EBusStuffBus::Handler::BusDisconnect();
            AZ::Interface<IRequests>::Unregister(this);
        }

        void Request(int value) override;
};
```

// Invoke a request
EBusRequestsBus::Broadcast(&EBusRequests::Request, 1);
Example

If you don't require interoperation with Script Canvas, you can avoid using EBus entirely, as seen in this example.

```cpp
// Our pure-virtual interface only
class IRequests
{
public:
    virtual void Request(int value) = 0;
};

// Implementation
class RequestsImpl : public IRequests
{
public:
    AZ_RTTI(RequestsImpl, "{some guid}", IRequests); // AZ type info is required

    RequestsImpl()
    {
        AZ::Interface<IRequests>::Register(this);
    }

    ~RequestsImpl()
    {
        AZ::Interface<IRequests>::Unregister(this);
    }

    void Request(int value) override;
};

// Invoke a request
AZ::Interface<IRequests>::Get()->Request(1);
```

Unit testing

The AZ::Interface system includes a number of unit tests to validate correct behavior.

To execute the unit tests, the following command-line arguments can be provided to the AzTestRunner:

```
%INSTALL-ROOT%\dev\Bin64vc141.Test\AzCoreTests.dll AzRunUnitTests --pause-on-completion --gtest_break_on_failure --gtest_filter=InterfaceTest*
```

You should see unit testing output like this:

```
[==========] Running 6 tests from 1 test case.
[----------] Global test environment set-up.
[----------] 6 tests from InterfaceTest
[ RUN      ] InterfaceTest.EmptyInterfaceTest
[       OK ] InterfaceTest.EmptyInterfaceTest (2 ms)
[ RUN      ] InterfaceTest.EmptyAfterDisconnectTest
[       OK ] InterfaceTest.EmptyAfterDisconnectTest (0 ms)
[ RUN      ] InterfaceTest.ValidInterfaceTest
[       OK ] InterfaceTest.ValidInterfaceTest (0 ms)
```
Working with the Event Bus (EBus) system

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Event buses (EBuses) are a general-purpose communication system that Lumberyard uses to dispatch notifications and receive requests. EBuses are configurable and support many different use cases.

To interact with the engine or other components in Lumberyard, include the component or system's EBus or API header in your code. Then make calls to the exposed EBuses. With this approach you can replace engine–level system APIs with implementations that you define in a gem. For example, you could replace Lumberyard's audio system with your own EBus handler. This would give you complete control over audio without having to recompile the engine.

For examples of EBus usage, see Usage and Examples (p. 1853).

For in-depth information about EBuses, including conceptual diagrams, see Event Buses in Depth (p. 1857).

For C++ API reference documentation on the core EBus code, see the EBus API Reference in the Amazon Lumberyard C++ API Reference.

How Components Use EBuses

Components commonly use EBuses in two ways: to dispatch events or to handle requests. A bus that dispatches events is a notification bus. A bus that receives requests is a request bus. Some components provide one type of bus, and some components provide both types. Some components do not provide an EBus at all. You use the EBus class for both EBus types, but you configure the EBuses differently. The following sections show how to set up and configure notification buses, event handlers, and request buses.

Notification Buses

Notification buses dispatch events. The events are received by handlers, which implement a function to handle the event. Handlers first connect to the bus. When the bus dispatches an event, the handler's function executes. This section shows how to set up a notification bus to dispatch an event and a handler to receive the event.

Setting up a Notification Bus

To set up a bus to dispatch events

1. Define a class that inherits from EBusTraits. This class will be the interface for the EBus.
2. Override individual EBusTraits properties to define the behavior of your bus. Three EBusTraits that notification buses commonly override are AddressPolicy, which defines how many addresses the EBus contains, HandlerPolicy, which describes how many handlers can connect to each address, and BusIdType, which is the type of ID that is used to address the EBus if addresses are used. For example, notification buses often need to have multiple addresses, with the addresses identified by entity ID. To do so, they override the default AddressPolicy with EBusAddressPolicy::ById and set the BusIdType to EntityId.

3. Declare a function for each event that the EBus will dispatch. Handler classes will implement these functions to handle the events.

4. Declare an EBus that takes your class as a template parameter.

5. Send events. The function that you use to send the event depends on which addresses you want to send the event to, whether to return a value, the order in which to call the handlers, and whether to queue the event.

   - To send an event to all handlers connected to the EBus, use Broadcast(). If an EBus has multiple addresses, you can use Event() to send the event only to handlers connected at the specified ID. For performance-critical code, you can avoid an address lookup by using Event() variants that take a pointer instead of an ID.
   - If an event returns a value, use BroadcastResult() or EventResult() to get the result.
   - If you want handlers to receive the events in reverse order, use BroadcastReverse() or EventReverse().
   - To send events asynchronously, queue the event. Queued events are not executed until the queue is flushed. To support queuing, set the EnableEventQueue trait. To queue events, use QueueBroadcast() or QueueEvent(). To flush the event queue, use ExecuteQueuedEvents().

Setting up a Handler

To enable a handler class to handle the events dispatched by a notification bus

1. Derive your handler class from <BusName>::Handler. For example, a class that needs to handle tick requests should derive from TickRequestBus::Handler.
2. Implement the EBus interface to define how the handler class should handle the events. In the tick bus example, a handler class would implement OnTick().
3. Connect and disconnect from the bus at the appropriate places within your handler class's code. Use <BusName>::Handler::BusConnect() to connect to the bus and <BusName>::Handler::BusDisconnect() to disconnect from the bus. If the handler class is a component, connect to the bus in Activate() and disconnect from the bus in Deactivate(). Non-components typically connect in the constructor and disconnect in the destructor.

Request Buses

A request bus receives and handles requests. Typically, only one class handles requests for a request bus.

Setting up a Request Bus

The first several steps for setting up a request bus are similar to setting up a notification bus. After that you also need to implement the handlers for handling the requests.

To set up a request bus

1. Define a class that inherits from EBusTraits. This class will be the interface for requests made to the EBus.
2. Override individual EBusTraits properties to define the behavior of your bus. Two EBusTraits that request buses commonly override are AddressPolicy, which defines how many addresses the EBus contains, and HandlerPolicy, which describes how many handlers can connect to each address. For example, because there is typically only one handler class for each request bus, request buses typically override the default handler policy with EBusHandlerPolicy::Single.

3. Declare a function for each event that the handler class will receive requests about. These are the functions that other classes will use to make requests of the handler class.

4. Declare an EBus that takes your class as a template parameter.

5. Implement a handler for the events as described in the previous section Setting up a Handler (p. 1852).

Usage and Examples

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This section provides examples in C++ of how to declare and configure an EBus, implement a handler, send messages, and receive return values. For information about using EBuses in Lua, see Using EBuses in Lua (p. 2693).

Topics
- Declaring an EBus (p. 1853)
- EBus Configuration Options (p. 1854)
- Implementing a Handler (p. 1855)
- Sending Messages to an EBus (p. 1856)
- Retrieving Return Values (p. 1856)
- Return Values from Multiple Handlers (p. 1856)
- Asynchronous/Queued Buses (p. 1857)

Declaring an EBus

Declaring an EBus is much like declaring any virtual interface class in C++. However, you can specify various configuration options that control how the EBuses is generated at compile time and how it behaves.

Here is a simple example of a basic interface and associated EBuses.

```cpp
class ExampleInterface : public AZ::EBusTraits
{
public:
    // ------------------ EBus Configuration -------------------
    // These override the defaults in EBusTraits.
    // One handler per address is supported.
    static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Single;

    // The EBus contains a single address.
    static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::Single;
    // ------------------------ Other -------------------------
}
```
virtual ~ExampleInterface() { };

// ------------------ Handler Interface -------------------
// Handlers inherit from ExampleInterfaceBus::Handler

// Handlers are required to implement this because it's pure virtual.
virtual void DoSomething() = 0;

// Handlers can override this, but are not required to.
virtual void SomeMessage() { }

// Returns a value and has a parameter.
virtual bool ReturnsValue(int x) = 0;
}

using ExampleInterfaceBus = AZ::EBus<ExampleInterface>;

Tip

Use descriptive names in EBuses, and avoid overloaded functions. Explicit and descriptive function names prevent future API name collisions when classes inherit your EBus interfaces. Avoiding overloaded functions improves the experience of using your EBuses. This is especially true from scripting environments such as Lua, in which descriptive names improve readability and clarity. For more information, see Components and EBuses: Best Practices (p. 1026).

EBus Configuration Options

EBus configuration options are key to controlling how the EBus behaves. The configuration options used in the previous example are explained in the following sections.

HandlerPolicy

The HandlerPolicy trait determines how many handlers connect to an address on the EBus and the order in which handlers at each address receive events. The following example specifies a single handler (p. 1858):

// One handler per address is supported.
static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Single;

The HandlerPolicy has two common uses:

- A singleton pattern in which various systems post messages or requests to a single system elsewhere in the codebase.
- A pattern where a specific component or an entity handles messages to the EBus. For example, you might have a mesh component that owns an entity. The mesh component handles all mesh-related queries addressed to the entity's ID.

Address Policy

The AddressPolicy trait defines how many addresses exist on the EBus. The following example specifies only a single address. An ID is not required.

// The EBus contains a single address.
static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::Single;

Practical use cases for a single address policy include any global EBus that is not tied to a specific entity, application-specific ID, or object.
**EBusAddressPolicy Options**

The `EBusAddressPolicy` has the following options:

- **Single** – The EBus uses a single address. No ID is used. The EBus can have a single handler (p. 1858) or many handlers (p. 1859).
- **ById** – The EBus has multiple addresses. The order in which addresses are notified when broadcasting events without an ID is not specified.
- **ByIdAndOrdered** – The EBus has multiple addresses. However, when broadcasting events without an ID, we want to control the order in which individual addresses are notified. The `BusIdOrderCompare` definition allows for arbitrary customization of ordering.

**EBusHandlerPolicy Options**

The `EBusHandlerPolicy` has the following options:

- **Single** – One handler per address is supported. Uses include an EBus with a single handler (p. 1858) or an EBus with addresses and a single handler (p. 1860).
- **Multiple** – Any number of handlers are supported. Ordering is ignored. Uses include many handlers (p. 1859) or an EBus with addresses and many handlers (p. 1861).
- **MultipleAndOrdered** – Any number of handlers are supported, and handlers are notified in a particular order. The `BusHandlerOrderCompare` definition allows for arbitrary customization of ordering.

**Implementing a Handler**

A handler of an EBus derives from `AZ::EBus<x>::Handler`. For convenience this was defined as `ExampleInterfaceBus` in the previous example (p. 1853). This means that the handler can be derived from `ExampleInterfaceBus::Handler`.

```cpp
#include "ExampleInterface.h"

// note: derives from bus handler, rather than directly from ExampleInterface
class MyHandler : protected ExampleInterfaceBus::Handler
{
public:
   void Activate();

protected:
   // Implement the handler interface:
   void DoSomething() override; // note: Override specified.
   void SomeMessage() override;
   bool ReturnsValue(int x) override;
};
```

Note that handlers are not automatically connected to an EBus, but are disconnected automatically because the destructor of `Handler` calls `BusDisconnect`.

In order to actually connect to the EBus and start receiving events, your handler must call `BusConnect()`:

```cpp
void MyHandler::Activate()
{
   // For a single EBus, this would be just BusConnect().
   // For multiple EBuses, you must specify the EBus to connect to:
   ExampleInterfaceBus::Handler::BusConnect();
}
You can call `BusConnect()` at any time and from any thread.

If your EBus is addressed, connect to the EBus by passing the EBus ID to `BusConnect()`.

```cpp
// connect to the EBus at address 5.
ExampleAddressBus::Handler::BusConnect(5);
```

### Sending Messages to an EBus

Anyone who can include the header can send messages to the EBus at any time. Using the previous example, a completely unrelated class can issue a `DoSomething` call on the EBus:

```cpp
// Note: You don't need to include MyHandler.h.
ExampleInterfaceBus::Broadcast(&ExampleInterfaceBus::Events::DoSomething);
```

EBuses also support a macro-based syntax. This syntax is being phased out, but uses of it can still be found in Lumberyard source code. The macro syntax for the previous example is as follows.

```cpp
#include "ExampleInterface.h" // Note: You don't need to include MyHandler.h.
...
EBUS_EVENT(ExampleInterfaceBus, DoSomething);
```

If your EBus is addressed, you can send events to a specific address ID. Events broadcast globally are received at all addresses.

```cpp
// Broadcasts to ALL HANDLERS on this EBus regardless of address (even if the EBus has addresses)
ExampleAddressBus::Broadcast(&ExampleAddressBus::Events::Test);

// Broadcasts only to handlers connected to address 5.
ExampleAddressBus::Event(5, &ExampleAddressBus::Events::Test);
```

### Retrieving Return Values

If you make a synchronous call, you can also supply a variable in which to place the result:

```cpp
// ALWAYS INITIALIZE YOUR RESULT!!!
// Since there may be nobody connected to the EBus, your result may not be populated.
bool result = false;
ExampleInterfaceBus::BroadcastResult(result, &ExampleInterfaceBus::Events::ReturnsValue, 2);
```

In this example, if there are no handlers connected to the EBus, the `result` variable is not modified. If one or more handlers are connected to the EBus, `operator=` is called on the `result` variable for each handler.

### Return Values from Multiple Handlers

In certain cases you might have to aggregate the return value of a function when there are multiple handlers. For example, suppose you want to send a message to all handlers that asks whether any one
handler objects to shutting down an application. If any one handler returns true, you should stop the shutdown. The following would not suffice:

```cpp
// Counterexample: returnValue contains only the result of the final handler.
bool returnValue = false;
SomeInterfaceBus::BroadcastResult(returnValue, &SomeInterfaceBus::Events::DoesAnyoneObject);
```

Because the EBus issues `operator=` for each handler, `returnValue` would contain only the result of the final handler.

Instead, you can create a class to collect your results that overrides `operator=`. There are several built-in types for this, and you can make your own:

```cpp
#include <AZCore/EBus/Results.h>
...
AZ::EBusAggregateResults<bool> results;
SomeInterfaceBus::BroadcastResult(results, &SomeInterfaceBus::Events::DoesAnyoneObject);
```

// results now contains a vector of all results from all handlers.

// alternative:
```cpp
AZ::EBusLogicalResult<bool, AZStd::logical_or<bool>> response(false);
SomeInterfaceBus::BroadcastResult(response, &SomeInterfaceBus::Events::DoesAnyoneObject);
```

// response now contains each result, using a logical OR operation. So all responses are OR'd with each other.

**Note**
Additional building blocks (for example, arithmetic results) are available inside the `results.h` file.

### Asynchronous/Queued Buses

To declare an EBus on which events can be queued and sent asynchronously, add the following to the EBus declaration:

```cpp
static const bool EnableEventQueue = true;
```

You can use `QueueBroadcast` and `QueueEvent` to enqueue events on an EBus so that you can flush them later from a controlled location or thread.

To flush the queue at the appropriate location or thread, invoke the following:

```cpp
ExampleInterfaceBus::ExecuteQueuedEvents();
```

### Event Buses in Depth

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Event buses (or EBus for short) are a general purpose system for dispatching messages. Ebuses have many advantages:
• **Abstraction** – Minimize hard dependencies between systems.

• **Event-driven programming** – Eliminate polling patterns for more scalable and high performing software.

• **Cleaner application code** – Safely dispatch messages without concern for what is handling them or whether they are being handled at all.

• **Concurrency** – Queue events from various threads for safe execution on another thread or for distributed system applications.

• **Predictability** – Provide support for ordering of handlers on a given bus.

• **Debugging** – Intercept messages for reporting, profiling, and introspection purposes.

You can use EBuses in many different ways. Following are some examples:

• As a direct global function call

• Dispatch processing to multiple handlers

• Queue all calls, acting like a command buffer

• As an addressable mailbox

• For imperative delivery

• For queued delivery

• Automatic marshalling of a function call into a network message or other command buffer

The EBus source code can be found in the Lumberyard directory location `<root>\dev\Code\Framework\AZCore\AZCore\EBus\EBus.h`.

**Bus Configurations**

You can configure EBuses for various usage patterns. This section presents common configurations and their applications.

**Topics**

• Single Handler (p. 1858)

• Many Handlers (p. 1859)

• EBus with Addresses and a Single Handler (p. 1860)

• EBus with Addresses and Many Handlers (p. 1861)

**Single Handler**

The simplest configuration is a many-to-one (or zero) communication bus, much like a singleton pattern.
There is at most one handler, to which any sender can dispatch events. Senders need not manually check and de-reference pointers. If no handler is connected to the bus, the event is simply ignored.

```cpp
// One handler is supported.
static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Single;

// The EBus uses a single address.
static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::Single;
```

### Many Handlers

Another common configuration is one in which many handlers can be present. You can use this configuration to implement observer patterns, subscriptions to system events, or general-purpose broadcasting.

![Diagram](image)

Events to the handlers can be received in defined or undefined order. You specify which one in the `HandlerPolicy` trait.

#### Example Without Handler Ordering

To handle events in no particular order, simply use the `Multiple` keyword in the `HandlerPolicy` trait, as in the following example:

```cpp
// Multiple handlers. Events received in undefined order.
static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Multiple;

// The EBus uses a single address.
static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::Single;
```

#### Example with Handler Ordering

To handle events in a particular order, use the `MultipleAndOrdered` keyword in the `HandlerPolicy` trait, and then implement a custom handler-ordering function, as in the following example:

```cpp
// Multiple handlers. Events received in defined order.
static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::MultipleAndOrdered;

// The EBus uses a single address.
static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::Single;

// Implement a custom handler-ordering function
```
EBus with Addresses and a Single Handler

EBuses also support addressing based on a custom ID. Events addressed to an ID are received by handlers connected to that ID. If an event is broadcast without an ID, it is received by handlers at all addresses.

A common use for this approach is for communication among the components of a single entity, or between components of a separate but related entity. In this case the entity ID is the address.

Example Without Address Ordering

In the following example, messages broadcast with an ID arrive at each address in no particular order.
// One handler per address is supported.
static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Single;

// The EBus has multiple addresses. Addresses are not ordered.
static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::ById;

// Messages are addressed by EntityId.
using BusIdType = AZ::EntityId;

Example With Address Ordering

In the following example, messages broadcast with an ID arrive at each address in a specified order.

// One handler per address is supported.
static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Single;

// The EBus has multiple addresses. Addresses are ordered.
static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::ByIdAndOrdered;

// Messages are addressed by EntityId.
using BusIdType = AZ::EntityId;

// Addresses are ordered by EntityId.
using BusIdOrderCompare = AZStd::greater<BusIdType>;

EBus with Addresses and Many Handlers

In the previous configuration, only one handler is allowed per address. This is often desirable to enforce ownership of an EBus for a specific ID, as in the singleton case above. However, if you want more than one handler per address, you can configure the EBus accordingly:
Example: Without Address Ordering

In the following example, messages broadcast with an ID arrive at each address in no particular order. At each address, the order in which handlers receive the message is defined by EBusHandlerPolicy, which in this example is simply ById:

```cpp
// Allow any number of handlers per address.
static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Multiple;

// The EBus has multiple addresses. Addresses are not ordered.
static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::ById;

// Messages are addressed by EntityId.
```
using BusIdType = AZ::EntityId;

Example: With Address Ordering

In the following example, messages broadcast with an ID arrive at each address in a specified order. At each address, the order in which handlers receive the message is defined by the EBusHandlerPolicy, which in this example is ByIdAndOrdered.

```cpp
// Allow any number of handlers per address.
static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Multiple;

// The EBus has multiple addresses. Addresses are ordered.
static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::ByIdAndOrdered;

// We address the bus EntityId.
using BusIdType = AZ::EntityId;

// Addresses are ordered by EntityId.
using BusIdOrderCompare = AZStd::greater<BusIdType>;
```

**Synchronous vs. Asynchronous**

EBus supports both synchronous and asynchronous (queued) messaging.

**Synchronous Messaging**

Synchronous messages are sent to any and all handlers when an EBus event is invoked. Synchronous messages limit opportunities for asynchronous programming, but they offer the following benefits:

- They don't require storing a closure. Arguments are forwarded directly to callers.
- They let you retrieve an immediate result from a handler (event return value).
- They have no latency.

**Asynchronous Messaging**

Asynchronous messages have the following advantages:

- They create many more opportunities for parallelism and are more future proof.
- They support queuing messages from any thread, dispatching them on a safe thread (like the main thread, or any thread that you choose).
- The code used to write them is inherently tolerant to latency and is easily migrated to actor models and other distributed systems.
- The performance of the code that initiates events doesn't rely on the efficiency of the code that handles the events.
- In performance-critical code, asynchronous messages can improve i-cache and d-cache performance because they require fewer virtual function calls.

For information on declaring an EBus for queing and sending messages asynchronously, see Asynchronous/Queued Buses (p. 1857).

**Additional Features**

EBuses contain other features that address various patterns and use cases:
Common Tasks, EBuses, and Handlers

- **Cache a pointer to which messages can be dispatched** – This is handy for EBuses that have IDs. Instead of looking up the EBus address by ID for each event, you can use the cached pointer for faster dispatching.

- **Queue any callable function on an EBus** – When you use queued messaging, you can queue a Lambda function or bound function against an EBus for execution on another thread. This is useful for general purpose thread-safe queuing.

---

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The following are some common game programming tasks and the EBuses and handlers that you can use to implement them.

**Detect Mouse, Keyboard, or Other Button Events**

<table>
<thead>
<tr>
<th>Bus</th>
<th>AZ::InputEventNotificationBus</th>
</tr>
</thead>
<tbody>
<tr>
<td>Events</td>
<td>OnPressed, OnHeld, OnReleased</td>
</tr>
<tr>
<td>File</td>
<td>InputEventBus.h</td>
</tr>
</tbody>
</table>

Use these events to detect when mouse, keyboard, or other buttons are pressed, held, or released.

**Detect Entity or Component Readiness**

<table>
<thead>
<tr>
<th>Bus</th>
<th>LmbrCentral::MeshComponentNotificationBus</th>
</tr>
</thead>
<tbody>
<tr>
<td>Events</td>
<td>OnMeshCreated, OnMeshDestroyed</td>
</tr>
<tr>
<td>File</td>
<td>MeshComponentBus.h</td>
</tr>
</tbody>
</table>

Even after an entity has been created and its components have been activated, visual data might not be fully loaded. The OnMeshCreated event occurs when the mesh creation is complete. This is useful if you want to access the underlying ICharacterInstance and ISkeletonAnim members in order to play animations. More generally, it is useful to declare a component or entity as "alive" or game ready, whatever that might mean for your application.

**Detect When a Member Joins or Leaves a Session**

<table>
<thead>
<tr>
<th>Bus</th>
<th>GridMate::SessionEventBus</th>
</tr>
</thead>
<tbody>
<tr>
<td>Events</td>
<td>OnMemberJoined, OnMemberLeaving</td>
</tr>
<tr>
<td>File</td>
<td>Session.h</td>
</tr>
</tbody>
</table>
You can use the SessionEventBus to detect when a member joins or leaves a network session. For documentation on this EBus, see Reacting to Session Events (p. 2032) in the Using Lumberyard Networking (p. 1990).

### Get and Set Physics Characteristics

<table>
<thead>
<tr>
<th>Bus</th>
<th>LmbrCentral::PhysicsComponentRequestBus</th>
</tr>
</thead>
<tbody>
<tr>
<td>Methods</td>
<td>AddImpulse, GetMass, SetMass, GetVelocity, SetVelocity, etc.</td>
</tr>
<tr>
<td>File</td>
<td>PhysicsComponentBus.h</td>
</tr>
</tbody>
</table>

The PhysicsComponentRequestBus contains useful methods for getting or setting the physical characteristics of objects like mass, density, velocity, and water damping. For an example of using a pointer directly to the underlying handler for better access to functions such as GetVelocity, see Direct Access to EBus Handlers (p. 1866).

### Get Notifications for Animation Events

<table>
<thead>
<tr>
<th>Bus</th>
<th>LmbrCentral::CharacterAnimationNotificationBus</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event</td>
<td>OnAnimationEvent</td>
</tr>
<tr>
<td>File</td>
<td>CharacterAnimationBus.h</td>
</tr>
</tbody>
</table>

If you have set up animations in the .animevents file in Geppetto, an OnAnimationEvent event is called for each animation event during animation playback. You can monitor this to get notifications for animation events. The string configured for the animation event in Geppetto is held in the LmbrCentral::AnimationEvent::m_animName variable.

### Get or Set the Location of an Entity in the World

<table>
<thead>
<tr>
<th>Bus</th>
<th>AZ::TransformBus</th>
</tr>
</thead>
<tbody>
<tr>
<td>Methods</td>
<td>GetWorldX, SetWorldX, GetWorldY, SetWorldY, etc.</td>
</tr>
<tr>
<td>File</td>
<td>TransformBus.h</td>
</tr>
</tbody>
</table>

The TransformBus contains many useful methods for getting or setting where in the world the entity is, such as xyz axis locations. For an example of using a pointer directly to the entity’s transform for more optimal access to functions such as GetBasisY (the entity’s forward vector), see Direct Access to EBus Handlers (p. 1866).

### Manually Play Animations

<table>
<thead>
<tr>
<th>Bus</th>
<th>LmbrCentral::SkinnedMeshComponentRequestBus</th>
</tr>
</thead>
<tbody>
<tr>
<td>Method</td>
<td>GetCharacterInstance</td>
</tr>
</tbody>
</table>
To play animations manually, use the ISkeletonAnim in the character instance. To get the ISkeletonAnim from the ICharacterInstance, use ICharacterInstance::GetISkeletonAnim().

**Use an EBus from Another Component**

<table>
<thead>
<tr>
<th>Bus</th>
<th>AZ::EntityBus</th>
</tr>
</thead>
<tbody>
<tr>
<td>Events</td>
<td>OnEntityActivated, OnEntityDeactivated</td>
</tr>
<tr>
<td>File</td>
<td>EntityBus.h</td>
</tr>
</tbody>
</table>

The OnEntityActivated and OnEntityDeactivated events are called after all of an entity's components have had their Activate() or Deactivate() function called. These events can be useful if you want your component to use an EBus that another component has already set up in its Activate() function.

**Use Tick Events**

<table>
<thead>
<tr>
<th>Bus</th>
<th>AZ::TickBus</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event</td>
<td>OnTick</td>
</tr>
<tr>
<td>File</td>
<td>TickBus.h</td>
</tr>
</tbody>
</table>

A tick is a unit of time generated by the component application. The OnTick event signals that the application has issued a tick and is called each frame. By default, handlers receive events based on the order in which the components are initialized, but you can override this. For more information, see Tick Bus and Components (p. 1019).

**Direct Access to EBus Handlers**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

At run time, EBuses form a communication backbone between a component and other noncomponent subsystems. In a nontrivial application, EBus activity can consume a substantial amount of CPU and memory usage. On data-cache (D-Cache)–sensitive devices such as consoles, the number of data lookups on each EBus call can potentially degrade performance. To reduce the number of data lookups, you can use a pointer to the EBus handler instead of calling the EBus.

The result of an EBus interaction is identical to a virtual function call on an EBus handler. As a result, you can implement this approach by getting a pointer directly to the handler at initialization time. Later, at run time, you make a direct call to the handler’s function. Because you know in advance whether or not a handler pointer is null, you do not have to initialize a request bus return value every time.

The code examples in this document compare the two approaches.
Using PhysicsComponentRequestBus to Get the Velocity Every Tick

The following example gets the velocity indirectly by using the physics component EBus.

class PlayerAnimationController : public AZ::Component, private AZ::TickBus::Handler
{
    public:
        // AZ::Component
        void Activate() override
        {
            AZ::TickBus::Handler::m_tickOrder = AZ::ComponentTickBus::TICK_PHYSICS + 1; // To be updated after the velocity is determined.
            AZ::TickBus::Handler::BusConnect(); // for OnTick
        }

        void Deactivate() override;
    }

    private:
        // AZ::TickBus::Handler
        void OnTick(float deltaTime, AZ::ScriptTimePoint time) override
        {
            // Get the velocity indirectly by using the physics component EBus.
            AZ::Vector3 velocity = AZ::Vector3::CreateZero();
            EBUS_EVENT_ID_RESULT(velocity, GetEntityId(), LmbrCentral::PhysicsComponentRequestBus, GetVelocity);

            // Do something with velocity here.
        }
};

The following example uses FindFirstHandler() to cache the handler and gets the velocity by calling the handler directly.

class PlayerAnimationController : public AZ::Component, private AZ::TickBus::Handler, private AZ::EntityBus::Handler
{
    public:
        // AZ::Component
        void Activate() override
        {
            AZ::EntityBus::Handler::BusConnect(GetEntityId()); // For OnEntityActivated/OnEntityDeactivated.
        }

        void Deactivate() override;
    }

    private:
        // AZ::EntityBus::Handler
        void OnEntityActivated(const AZ::EntityId &parentEntityId) override
        {
            // Do this after all the other entity's components have been activated so that the physics component has been already attached to the EBus.
            m_physicsComponentRequests = LmbrCentral::PhysicsComponentRequestBus::FindFirstHandler(GetEntityId());
            AZ::TickBus::Handler::m_tickOrder = AZ::ComponentTickBus::TICK_PHYSICS + 1; // To be updated after the velocity is determined.
            AZ::TickBus::Handler::BusConnect(); // for OnTick.
        }
};
void OnEntityDeactivated(const AZ::EntityId &parentEntityId) override
{
    AZ::TickBus::Handler::BusDisconnect();
    m_physicsComponentRequests = nullptr;
}

// AZ::TickBus::Handler
void OnTick(float deltaTime, AZ::ScriptTimePoint time) override
{
    // Get the velocity directly from the physics component handler.
    AZ::Vector3 velocity = m_physicsComponentRequests != nullptr ?
        m_physicsComponentRequests->GetVelocity() : AZ::Vector3::CreateZero();

    // Do something with velocity here.
}

LmbrCentral::PhysicsComponentRequests *m_physicsComponentRequests = nullptr;
};

Using TransformBus to Get the WorldTransform's Forward Vector Every Tick

The following example gets the world transform's forward vector by indirectly by using the transform EBus.

class PlayerAnimationController : public AZ::Component, private AZ::TickBus::Handler
{
    public:
        // AZ::Component
        void Activate() override
        {
            AZ::TickBus::Handler::m_tickOrder = AZ::ComponentTickBus::TICK_PHYSICS + 1; // //
            To be updated after the velocity is determined.
            AZ::TickBus::Handler::BusConnect(); // for OnTick
        }

    void Deactivate() override;
    {
        AZ::TickBus::Handler::BusDisconnect();
    }

    private:
        // AZ::TickBus::Handler
        void OnTick(float deltaTime, AZ::ScriptTimePoint time) override
        {
            // Get the forward vector indirectly by using the transform EBus.
            AZ::Transform worldTransform = AZ::Transform::Identity();
            EBUS_EVENT_ID_RESULT(worldTransform, GetEntityId(), AZ::TransformBus, GetWorldTM);
            AZ::Vector3 forward = worldTransform.GetBasisY();

            // Do something with "forward" here.
        }
    }
};

The following example caches the handler and calls it directly. Because every entity has a transform, the entity already has an API operation for accessing the transform. Using the EBus and the FindFirstHandler function is not necessary.

class PlayerAnimationController : public AZ::Component, private AZ::TickBus::Handler, private AZ::EntityBus::Handler
{
public:
    // AZ::Component
    void Activate() override
    {
        AZ::EntityBus::Handler::BusConnect(GetEntityId()); // for OnEntityActivated/OnEntityDeactivated
    }

    void Deactivate() override;
    {
        AZ::EntityBus::Handler::BusDisconnect(GetEntityId());
    }

private:
    // AZ::EntityBus::Handler
    void OnEntityActivated(const AZ::EntityId &parentEntityId) override
    {
        m_worldTransform = &GetEntity()->GetTransform()->GetWorldTM();
        AZ::TickBus::Handler::m_tickOrder = AZ::ComponentTickBus::TICK_PHYSICS + 1; // To be updated after the velocity is determined.
        AZ::TickBus::Handler::BusConnect(); // for OnTick
    }

    void OnEntityDeactivated(const AZ::EntityId &parentEntityId) override
    {
        AZ::TickBus::Handler::BusDisconnect();
        m_worldTransform = nullptr;
    }

    // AZ::TickBus::Handler
    void OnTick(float deltaTime, AZ::ScriptTimePoint time) override
    {
        // Get the forward vector directly from the AZ::Transform.
        AZ::Vector3 forward = m_worldTransform->GetBasisY();

        // Do something with "forward" here.
    }

    const AZ::Transform *m_worldTransform = nullptr;
};

Automating boilerplate with AZ Code Generator

AZ Code Generator is a command line utility that generates source code (or any data or text) from specially tagged source code. You can use it when the structure of the intended code is known in advance so that templates can be made for it. For example, you could generate boilerplate code for serialization or reflection.

AZ Code Generator parses a list of existing C++ source files and/or header files and generates intermediate data in JSON format. It passes the intermediate data to a series of templates.

The templates provide the format for the code that is generated. Templates make increased coding efficiency possible because they enable automatic updates of boilerplate code. When a template is
updated, all related generated code is regenerated in the next build. This removes the need to update the glue code manually or to use error-prone find-and-replace operations.

### Workflow Summary

The following steps describe how AZ Code Generator works with Waf to generate code.

1. The Waf build system invokes AZ Code Generator for the `.h` and `.cpp` source files that are specified in the `wscript` file.
2. AZ Code Generator runs one or more passes with the specified files.
3. Each pass includes the following:
   a. AZ Code Generator uses the Clang front-end compiler to produce an abstract syntax tree (AST) for each provided source file. The Clang parser attempts to compile the input. For increased speed, Clang can be instructed to not follow `#include` statements and to suppress all errors.
   b. The AST is translated into an intermediate JSON format.
   c. The intermediate JSON object is passed into a template driver as a Python script and then into a Jinja2 template. Each driver and template implements specific code generation tasks.
d. The template driver performs any preprocessing that you want on the intermediate JSON object.

e. The intermediate JSON is then passed to Jinja2 templates.

f. Each template driver can have an arbitrary number of templates, which can output to an arbitrary number of output files. Multiple templates can have the same output file or different output files as the template driver creator wants.

4. AZ Code Generator returns a list of generated files to the Waf build system.

5. The Waf build system completes the build process, including the generated code in the build.

The following sections provide more detail about this process.

**Waf**

The AZ Code Generator is fully integrated into the Using the Waf Build System (p. 63). You can use the Waf `az_code_gen` feature to invoke the AZ Code Generator. We recommend that you use Waf rather than the command line to start the `AzCodeGenerator.exe` utility.

For examples and more information about the Waf integration, see AZ Code Generator Integration with Waf (p. 1874).

**Clang**

The default front end of the AZ Code Generator is a Clang parser/compiler for C++ source code. AZ Code Generator uses Clang to parse source code (which might include custom tags) and generate the intermediate JSON data object. AZ Code Generator fully controls Clang's parser and compilation phase so that it can selectively suppress or enable features such as diagnostics. This gives AZ Code Generator the flexibility to ignore source code that might fail to compile and still attempt to generate a complete intermediate object.

**Intermediate JSON Data**

The Clang front end compiler outputs an intermediate JSON data structure that the generator passes to templates for further processing. An example intermediate JSON data object follows.

```json
[
  {
    'name': 'Component',
    'qualified_name': 'AZ::Component',
    'fields': [],
    'bases': [],
    'meta': {
      'path': 'D:\Repo\Ly\branches\AzComponents\Code\Tools\AzCodeGenerator\CodeGenTest.h'
    },
    'type': 'class',
    'annotations': {},
    'methods': []
  },
  {
    'name': 'TestingClass',
    'qualified_name': 'TheNamespace::TestingClass',
    'fields': [
      {
        'type': 'float',
        'name': 'm_field2',
        'qualified_name': 'TheNamespace::TestingClass::m_field2',
        'annotations': {}
      }
    ]
  }
]
```
AZ Code Generator and Python

AZ Code Generator depends on Python 3.7 or later to run template drivers and render Jinja templates. The Python C API is used to extend Python with methods in the azcg_extension module that permit template drivers to report dependencies, errors, and useful informational output. In Windows, Python 3.7 is included in the Lumberyard dev/Tools/Python directory. On macOS, AZ Code Generator uses the version of Python that is included with the operating system.

Note
To debug Python C API calls when using AZ Code Generator, you must download CPython. Then make a build for your intended debug OS.

Template Drivers and Template Rendering

You can use template drivers written in Python to alter the intermediate data structure before passing it to the template engine. After preprocessing, the template driver might direct the Jinja2 template engine to render one or many templates, depending on the generated code that you want.

AZ Code Generator uses the Jinja2 template engine, which is downloaded by the Python easy_install script in the \dev\Tools\Python\3.7.5\windows\Scripts directory. The engine is then copied into the Lumberyard 3rdParty\jinja2 directory. Lumberyard also provides a jinja_extensions module, which contains helper methods that you can use inside templates. These extensions are stored in the dev/Code/Tools/AzCodeGenerator/Scripts/jinja_extensions/ directory. For examples and more information about Jinja templates, see Code Generation Templates (p. 1880).

Generated Files

The following sample output was generated from a serialization template. The reference JSON object has been formatted for readability.
// THIS CODE IS AUTOGENERATED, DO NOT MODIFY

#include "stdafx.h"
#include <AZCore/serialization/serializecontext.h>
#include <AzCore/Math/Vector3.h>
#include "D:/Repo/Ly/branches/AzComponents/Code/Tools/AzCodeGenerator/CodeGenTest.h"

namespace Components
{
    void TestingClassReflect(AZ::ReflectContext* reflection)
    {
        AZ::SerializeContext* serializeContext = azrtti_cast<AZ::SerializeContext*>(reflection);
        if (serializeContext)
        {
            serializeContext->Class<TestingClass>()->SerializerForEmptyClass();
        }
    }
}

/*
// Reference JSON object

{ 'name': 'Component',
  'qualified_name': 'AZ::Component',
  'fields': [],
  'bases': [],
  'meta': { 'path': 'D:\Repo\Ly\branches\AzComponents\Code\Tools\AzCodeGenerator\CodeGenTest.h' },
  'type': 'class',
  'annotations': {},
  'methods': [] },

{ 'name': 'TestingClass',
  'qualified_name': 'TheNamespace::TestingClass',
  'fields': [
    { 'type': 'float',
      'name': 'm_field2',
      'qualified_name': 'TheNamespace::TestingClass::m_field2',
      'annotations': {} } ],
  'bases': [
    { 'name': 'Component',
      'qualified_name': 'AZ::Component' } ],
  'meta': {
AZ Code Generator Integration with Waf

AZ Code Generator is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

AZ Code Generator is fully accessible for any Waf target as the feature az_code_gen. The dev\Tools \Build\waf-<version_number>\lmbrwaflib\az_code_generator.py file contains the core of the Waf integration code. It includes the az_code_gen feature that can be used by any wscript file.

The minimum required information is a list of the files to pass into the code generator and at least one template driver. This list feeds the code generator one file at a time and invokes the templates specified by the driver. The files output from the driver are added as dependencies of the build task. Output files also have the option to be reinjected back into the C++ build for compilation. Output file paths are automatically added as include paths both for the current target build and as export_header entries.

Topics
- Basic Integration (p. 1874)
- Advanced Integration (p. 1875)
- Input Files (p. 1875)
- Template Drivers (p. 1876)
- Command Line Parameters (p. 1876)
- Waf Specific Options (p. 1876)

Basic Integration

In the wscript file for the target requiring generated code, add the az_code_gen feature as follows.
features = ['az_code_gen'],

Next, specify the files to pass as input to the code generator, as in the following example.

```python
az_code_gen = [
    {'files': ['MySourceFile.h'],
     'scripts': ['MyTemplateDriver.py']},
],
```

The paths given are relative to the target path in both cases.

Whenever the specified target is compiled, a code generation task passes in the `MySourceFile.h` file to the code generator. It also invokes the `MyTemplateDriver.py` file to control the output. For information on how to write a template driver, see Template Drivers (p. 1882).

**Advanced Integration**

The AZ Code Generator Waf integration uses passes to define the code generator tasks that must be run during build time. Each pass determines the set of files, drivers, and environment settings with which to run the code generator. Currently, all passes are run in parallel without any dependency checking between passes.

The following example shows the configuration of multiple passes.

```python
az_code_gen = [
    {'files': ['MyCode/MySourceFile.h'],
     'scripts': ['MyCode/MyTemplateDriver.py']},
    {'files': ['MyOtherCode/MyOtherSourceFile.h'],
     'scripts': ['MyOtherCode/MyOtherTemplateDriver.py']}
],
```

This example generates the following two code generation tasks.

1. Pass in the `MyCode/MySourceFile.h` file to the code generator and invoke the `MyCode/MyTemplateDriver.py` file to control the output.
2. Pass in `MyOtherCode/MyOtherSourceFile.h` to the code generator and invoke `MyOtherCode/MyOtherTemplateDriver.py` to control the output.

**Input Files**

Each pass provides a list of files that will be used as input to the code generator. This list can also contain string paths, nodes, and lists. Top-level string paths and nodes are passed individually to the code generator. Note the following:

- If you provide a list, all files or nodes in that list are used by the code generator at the same time. This allows for maximum flexibility, but typical usage is one input per task.
- The overhead of the Waf task and AZ Code Generator bootstrapping can be significant. To improve performance, you can pass in multiple input files in one list.
- The code generator invokes the same Clang and template driver pipeline for each input file.

The following example shows several input file specifications.
# Finds this file relative to the build context source node
files : [bld.srcnode.find_or_declare('Code/Framework/AzCore/Tests/CodeGen.h')],

'files' : [
# Pass both MyClass.h and MyClass.cpp at the same time to code generator to get more
# information about MyClass than just the header. Note the nested lists.
    ['MyClass.h', 'MyClass.cpp']
]

'files' : [
    # Any and all variations are allowed, but because lists provide only one layer of
    # lists are allowed only at the top level.
    'MySourceFile.h',
    'MyOtherSourceFile.cpp',
    bld.srcnode.find_or_declare('Code/Framework/AzCore/Tests/CodeGen.h'),
    ['MyClass.h', 'MyClass.cpp']
]

Template Drivers

To specify template drivers to use for each code generation pass, provide a list of string paths, relative to
the target path, as in the following example.

'scripts' : [
    '../../../Framework/AzFramework/CodeGen/AzClassCpp.py',
    '../../../Framework/AzFramework/CodeGen/AzEBusInline.py',
    '../../../Framework/AzFramework/CodeGen/AzReflectionCpp.py',
    '../../../Framework/AzFramework/CodeGen/AzClassInline.py'
],

Command Line Parameters

All command line parameters for the code generation utility can be specified in each code generation
pass. To do this, provide a list of arguments, as in the following example.

'arguments' : [
    '-OnlyRunDiagnosticsOnMainFile=true',
    '-SuppressDiagnostics=false',
    '-SuppressErrorsAsWarnings=false',
    '-output-redirection=file',
],

For a full list of parameters, see AZ Code Generator Parameters (p. 1877).

Waf Specific Options

The Waf integration provides additional options that can be specified in a list for each code generation
pass, as in the following example.

'options' : ['PrintOutputRedirectionFile'],

PrintOutputRedirectionFile – This option, when used in combination with the -output-
redirection=file parameter, directs Waf to provide AZ Code Generator a path to save extra output
during code generation. The path to this file is listed for each task during the build if errors occur.

Profile – This option enables profiler timings of clang parsing and script execution within the AZ Code
Generator tool.
AZ Code Generator Parameters

AZ Code Generator is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

For best results, pass the options for AZ Code Generator in to the Waf build system. However, you can also specify the parameters for AzCodeGenerator.exe on the command line.

Topics
- Waf Parameters (p. 1877)
- Clang Compilation Parameters (p. 1877)
- Intermediate Data (p. 1877)
- Front End (p. 1878)
- AZ Code Generator Parameter List (p. 1878)

Waf Parameters

Most parameters for AZ Code Generator are specified by the Waf integration. Parameters such as input, output, and include paths are automatically detected and forwarded. Other AZ Code Generator parameters control how AZ Code Generator deals with the source code input and the intermediate data that is generated.

Specify any of these in the arguments section of the az_code_gen pass in the wscript file.

Clang Compilation Parameters

The following AzCodeGenerator.exe parameters apply to Clang compilation.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>- SuppressIncludeNotFoundError</td>
<td>Suppresses unknown #include statements at compile time.</td>
</tr>
<tr>
<td>- OnlyRunDiagnosticsOnMainFile</td>
<td>Ignores build warnings and errors on all except the main file specified for compilation.</td>
</tr>
<tr>
<td>- SuppressDiagnostics</td>
<td>Ignores build warnings and errors on all files.</td>
</tr>
<tr>
<td>- SuppressErrorsAsWarnings</td>
<td>Downgrades any build errors to warnings. Allows Clang to succeed even if there are errors.</td>
</tr>
</tbody>
</table>

Intermediate Data

To include information about code outside of the input file in the intermediate JSON data, use the following option.

- inclusion-filter="wildcard filter for files to allow"
Front End
You can choose the front end to use by specifying either the `-Clang` (the default) or `-JSON` option.

AZ Code Generator Parameter List
The following list shows all AZ Code Generator parameters.
Usage: `AzCodeGenerator.exe [options]`

<table>
<thead>
<tr>
<th>Option</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-Clang</code></td>
<td>General</td>
<td>Uses the Clang compiler front end.</td>
</tr>
<tr>
<td><code>-clang-settings-file=&lt;string&gt;</code></td>
<td>Code parsing</td>
<td>The path to the file that contains Clang configuration settings.</td>
</tr>
<tr>
<td><code>-codegen-script=&lt;string&gt;</code></td>
<td>Python</td>
<td>The absolute path and file name of the code generation script to invoke.</td>
</tr>
<tr>
<td><code>-debug</code></td>
<td>General</td>
<td>Enables debug output.</td>
</tr>
<tr>
<td><code>-debug-buffer-size=&lt;uint&gt;</code></td>
<td>General</td>
<td>Buffers the last n characters of debug output until program termination. The default is 0, which specifies immediate print out.</td>
</tr>
<tr>
<td><code>-debug-only=&lt;debug string&gt;</code></td>
<td>General</td>
<td>Enables a specific type of debug output.</td>
</tr>
<tr>
<td><code>-define=&lt;string&gt;</code></td>
<td>Code parsing</td>
<td>Specifies a preprocessor definition.</td>
</tr>
<tr>
<td><code>-DelayedTemplateParsing</code></td>
<td>AST traversal</td>
<td>Consumes and stores template tokens for parsing at the end of the translation unit.</td>
</tr>
<tr>
<td><code>-EnableIncrementalProcessing</code></td>
<td>AST traversal</td>
<td>Enables incremental processing.</td>
</tr>
<tr>
<td><code>-force-include=&lt;string&gt;</code></td>
<td>Code parsing</td>
<td>List of headers to forcibly include in Clang parsing.</td>
</tr>
<tr>
<td><code>-help</code></td>
<td>General</td>
<td>Displays basic options in categorized format.</td>
</tr>
<tr>
<td><code>-help-hidden</code></td>
<td>General</td>
<td>Displays all available options in categorized format.</td>
</tr>
<tr>
<td><code>-help-list</code></td>
<td>General</td>
<td>Displays basic options in list format.</td>
</tr>
<tr>
<td><code>-help-list-hidden</code></td>
<td>General</td>
<td>Displays all available options in list format.</td>
</tr>
<tr>
<td><code>-include-path=&lt;string&gt;</code></td>
<td>Code parsing</td>
<td>The header includes the path.</td>
</tr>
<tr>
<td><code>-inclusion-filter=&lt;string&gt;</code></td>
<td>Code filtering</td>
<td>Specifies a wildcard filter so that files other than those specified by input-files are parsed by Clang into intermediate data.</td>
</tr>
<tr>
<td><code>-info-output-file=&lt;filename&gt;</code></td>
<td>General</td>
<td>File to which to append -stats output.</td>
</tr>
<tr>
<td><code>-input-file=&lt;string&gt;</code></td>
<td>Code parsing</td>
<td>(Required) Path to input file relative to the value of input-path.</td>
</tr>
</tbody>
</table>
### AZ Code Generator Parameters

<table>
<thead>
<tr>
<th>Option</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-input-path=&lt;string&gt;</td>
<td>Code parsing</td>
<td>(Required) The absolute path to input folder. All input-file paths must be relative to this folder.</td>
</tr>
<tr>
<td>-intermediate-file=&lt;string&gt;</td>
<td>Code parsing</td>
<td>Path to a file that stores the JSON AST from Clang parsing.</td>
</tr>
<tr>
<td>-JSON</td>
<td>General</td>
<td>Uses raw JSON input for the front end.</td>
</tr>
<tr>
<td>-noscripts</td>
<td>General</td>
<td>Disables the running of code generation scripts.</td>
</tr>
<tr>
<td>OnlyRunDiagnostics</td>
<td>Clang</td>
<td>Runs diagnostics (error and warning checking) only on the main file that is compiled. Ignores errors and warnings from all other files.</td>
</tr>
<tr>
<td>-output-path=&lt;string&gt;</td>
<td>Code parsing</td>
<td>(Required) The absolute path to the output folder.</td>
</tr>
<tr>
<td>-output-redirection</td>
<td>Output</td>
<td>Redirects output and error messages from Clang and Python internal utilities.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Options:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>=none – No output redirection. Clang and Python output to stdout and stderr.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>=null – Redirect Clang and Python to null, effectively suppressing output.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>=file – Redirect Clang and Python to disk. Use redirect-output-file to specify the path.</td>
</tr>
<tr>
<td>-output-using-json</td>
<td>Output</td>
<td>Outputs using JSON objects instead of plain text. Use this option to ease parsing for calling applications.</td>
</tr>
<tr>
<td>-print-all-options</td>
<td>General</td>
<td>Prints all option values after command line parsing.</td>
</tr>
<tr>
<td>-print-options</td>
<td>General</td>
<td>Prints nondefault options after command line parsing.</td>
</tr>
<tr>
<td>-profile</td>
<td>General</td>
<td>Enables AZ Code Generator's internal profiler and emits timings for Clang parsing and script execution.</td>
</tr>
<tr>
<td>-python-debug-path=&lt;string&gt;</td>
<td>Python</td>
<td>Path to Python debug libraries and scripts for AzCodeGenerator.exe to use in debugging.</td>
</tr>
<tr>
<td>-python-home=&lt;string&gt;</td>
<td>Python</td>
<td>(Required) The equivalent of the PYTHONHOME environment variable, which is ignored.</td>
</tr>
<tr>
<td>-python-home-debug=&lt;string&gt;</td>
<td>Python</td>
<td>The equivalent of the debug Python PYTHONHOME environment variable, which is ignored.</td>
</tr>
<tr>
<td>-python-path=&lt;string&gt;</td>
<td>Python</td>
<td>The path to Python libraries and scripts for AzCodeGenerator.exe.</td>
</tr>
<tr>
<td>-redirect-output-file=&lt;string&gt;</td>
<td>Output</td>
<td>The file path for redirected output. Use in combination with the -output-redirection=file option. The default file name is output.log.</td>
</tr>
<tr>
<td>-resource-dir=&lt;string&gt;</td>
<td>Code parsing</td>
<td>The path to the resource directory for Clang.</td>
</tr>
<tr>
<td>Option</td>
<td>Category</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-stats</td>
<td>General</td>
<td>Enables statistics output from program (available with asserts). Use the <code>-info-output-file=&lt;filename&gt;</code> option to specify the output file.</td>
</tr>
<tr>
<td>-SkipFunctionBodies</td>
<td>AST traversal</td>
<td>Does not traverse function bodies.</td>
</tr>
<tr>
<td>-SuppressDiagnostics</td>
<td>Clang compilation</td>
<td>Hides Clang compilation diagnostic information.</td>
</tr>
<tr>
<td>-SuppressErrorsAsWarnings</td>
<td>Clang compilation</td>
<td>Suppresses compilation errors during parsing by reporting them as warnings.</td>
</tr>
<tr>
<td>-SuppressIncludeNotFoundError</td>
<td>AST traversal</td>
<td>Suppresses #include not found errors.</td>
</tr>
<tr>
<td>-track-memory</td>
<td>General</td>
<td>Enables <code>-time-passes</code> memory tracking. Performance might be slow when this option is used.</td>
</tr>
<tr>
<td>-v</td>
<td>General</td>
<td>Outputs verbose debug information.</td>
</tr>
<tr>
<td>-version</td>
<td>General</td>
<td>Displays the version of AzCodeGenerator.exe.</td>
</tr>
<tr>
<td>-view-background</td>
<td>General</td>
<td>Executes the graph viewer in the background. This option creates a .tmp file that must be deleted manually.</td>
</tr>
</tbody>
</table>

**Code Generation Templates**

AZ Code Generator is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

AZ Code Generator uses the Jinja2 template engine for Python to render its output. The Jinja template engine outputs plain text with embedded variable and logic statements.

Jinja templates are designed to be highly readable and mimic the overall structure of the desired output. They are processed top to bottom. Any text outside of the control block in the template is sent directly to the output.

The following are some example templates. For more information about creating Jinja templates, refer to the Jinja Template Designer Documentation.

**Topics**

- Simple Example (p. 1881)
- Complex Example (p. 1881)
- Template Data (p. 1882)
Simple Example

A Jinja template can use text variables to replace text at predetermined locations in the output, as in the following example:

```plaintext
// Here's a {{ variable_name }} !
int {{ variable_name }} = {{ variable_value }};
```

In this example, the Jinja template is given the following input.

```json
{
  'variable_name' = 'foo',
  'variable_value' = 42
}
```

The following output results.

```plaintext
// Here's a foo !
int foo = 42;
```

Complex Example

Jinja allows for fairly complicated logic, branching and looping control structures. The following example template generates a class that has the public and private variables specified by the input:

```plaintext
// This class is auto-generated!
class {{ class.name }}
{
public:
    virtual ~{{ class.name }}() = default;

{% if class.members is defined %}
    {% for member_var in class.members if member_var.visibility is 'public' %}
        {{ member_var.type }} m_{{ member_var.name }}{{ if member_var.value is defined }} = {{ member_var.value }}{{ endif }};
    {% endfor %}
{% endif %}

private:
{% if class.members is defined %}
    {% for member_var in class.members if member_var.visibility is 'private' %}
        {{ member_var.type }} m_{{ member_var.name }}{{ if member_var.value is defined }} = {{ member_var.value }}{{ endif }};
    {% endfor %}
{% endif %}
};
```

In this example, the Jinja template is given the following input.

```json
{
    'class': {
        'name': 'MyClass',
        'members': [
            {
                'name': 'foo',
                'type': 'int',
                'visibility': 'public'
            },
            {
                'name': 'bar',
```
The template produces the following output.

```cpp
// This class is auto-generated!
class MyClass
{
public:
    virtual ~MyClass() = default;
    int m_foo;
    long m_bar;
private:
    float m_secretSauce = 98.6f;
};
```

### Template Data

The data that is available to the template is fully controlled by the Python template driver (p. 1882).

The following table lists the variables that are automatically added to the Jinja environment.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>extra_data</td>
<td>Python object that contains data returned by the apply_transformations (p. 1884) method of the template driver.</td>
</tr>
<tr>
<td>extra_str</td>
<td>String that contains the contents of extra_data in JSON format.</td>
</tr>
<tr>
<td>json_object</td>
<td>Python object that contains the decoded intermediate JSON after it has been processed by the template driver.</td>
</tr>
<tr>
<td>json_str</td>
<td>String that contains the encoded intermediate JSON after it has been processed by the template driver.</td>
</tr>
</tbody>
</table>

For information about the intermediate output, see Intermediate JSON Data Format (p. 1901).

**Note**

Because Jinja contains a limited feature set, attempting to do complex data transformations in Jinja templates produces overly complicated and generally unreadable templates. For this reason, we recommend that you perform any major data manipulation in the template driver before it is passed into the Jinja template engine. For more information, see Template Drivers (p. 1882).

### Template Drivers

AZ Code Generator is in preview release and is subject to change.
Template drivers are Python scripts that process the intermediate JSON data and route it into the Jinja2 output templates. The scripts preprocess the data from the Clang front end, execute the template rendering, and control where the generated output is written to disk.

These scripts are usually called by one or more code generation passes in WAF wscript files. Each Python script can reference multiple templates. This offers great flexibility in implementation, especially when multiple templates rely on the same preprocessed data.

Topics
- Specifying Drivers in Waf (p. 1883)
- Creating a Template Driver in Python (p. 1883)
- Minimal Template Driver (p. 1885)
- Rendering Templates (p. 1885)
- Configuring Automatic Build Injection (p. 1886)
- Preprocessing Intermediate Data (p. 1886)

Specifying Drivers in Waf
Drivers are specified by file name in each code generation pass. The file path is relative to the root of the wscript target. All drivers are invoked on each input file.

The following shows the structure of a sample Waf entry.

```python
'az_code_gen' = [
    {
        'files': [ '<files to gen>' ],
        'scripts': [ '<list of script file paths relative to current wscript folder>' ]
    }
]
```

For more details on how to specify passes, see AZ Code Generator Integration with Waf (p. 1874).

Creating a Template Driver in Python
To create a template driver in Python, you must import the TemplateDriver base class and override its methods. The code for the class can be found in the dev/Code/Tools/AzCodeGenerator/Scripts/az_code_gen/base.py file.

This class is automatically injected into Python by AZ Code Generator and only needs to be imported as az_code_gen.base, as in the following example.

```python
from az_code_gen.base import *
```

Methods to Override in the TemplateDriver Class
To implement your template driver, override the following methods in the TemplateDriver class.

- add_dependency

Call the add_dependency method to manually add a dependency to the az_code_gen task in Waf. The file path given should be absolute so that the render template can specify additional dependencies that
Waf does not automatically include. These dependencies might be external data files used to render the templates, or files that were used to generate the input data.

**Syntax**

```python
add_dependency(self, dependency_file)
```

**apply_transformations**

Override the `apply_transformations` method to manipulate the raw JSON object, which is passed in as the `obj` parameter. Manipulations are performed in place on the object. The object is then forwarded through the pipeline and is eventually passed to `jinja_args` of `render_templates`. Any object returned by this method is provided to the Jinja environment as `extra_data`.

**Syntax**

```python
apply_transformations(self, obj)
```

For an example of this method, see Preprocessing Intermediate Data (p. 1886).

**get_expected_tags**

Override the `get_expected_tags` method to return a list of tags that must be found in any input file. If the required tags are not present, this driver is skipped.

**Important**

This method is deprecated as of Lumberyard v1.6. After Lumberyard v1.6, all scripts will be processed regardless of expected tags, and `get_expected_tags` will not be invoked.

**Syntax**

```python
get_expected_tags(self)
```

**render_template_to_file**

Renders a template to disk. This method also adds the value of `output_file` as a dependency of the `az_code_gen` task in Waf.

**Syntax**

```python
render_template_to_file(self, template_file, template_kwargs, output_file, should_add_to_build=False)
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>template_file</code></td>
<td>Specifies the path to a template relative to the directory that contains the template driver .py file.</td>
</tr>
<tr>
<td><code>template_kwargs</code></td>
<td>Specifies a dictionary of key-value pairs to be passed to Jinja. Generally this should be treated as a passthrough variable for the <code>jinja_args</code> given to <code>render_templates</code>, but you can add additional key-value pairs.</td>
</tr>
<tr>
<td><code>output_file</code></td>
<td>Specifies the target file for the rendered Jinja output. The path is relative to the target output folder.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>should_add_to_build</td>
<td>A Boolean value that specifies whether Waf should add this file to the C++ build and linker. The default is false.</td>
</tr>
</tbody>
</table>

**render_templates**

Override `render_templates` to invoke template rendering by calling `render_template_to_file`.

**Syntax**

```python
render_templates(self, input_file, **jinja_args)
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input_file</td>
<td>The path relative to the input path that is used to invoke Clang.</td>
</tr>
<tr>
<td>jinja_args</td>
<td>The raw data from the intermediate JSON object after the template driver performs preprocessing on the object.</td>
</tr>
</tbody>
</table>

**Minimal Template Driver**

The minimum code required for a template driver is to derive from the `TemplateDriver` base class and implement a factory function to construct the template driver.

```python
from az_code_gen.base import *

class MyTemplateDriver(TemplateDriver):
    pass

# Factory function - called from launcher
def create_drivers(env):
    return [MyTemplateDriver(env)]
```

The `az_code_gen` module is automatically provided by AZ Code Generator. It contains the `TemplateDriver` and other useful methods from the `base.py` file.

The `create_drivers` function simply forwards the Jinja environment that is used to render templates. However, you can alter the function to perform other work when the driver is instantiated.

**Note**

The above bare-bones implementation works but does not generate any output.

**Rendering Templates**

To generate some output, you must implement the `render_templates` method, as in the following example.

```python
from az_code_gen.base import *

class MyTemplateDriver(TemplateDriver):
    def render_templates(self, input_file, **jinja_args):
```
```
self.render_template_to_file("MyTemplate.tpl", jinja_args, 'GeneratedCode.cpp')
```

# Factory function - called from launcher
def create_drivers(env):
    return [MyTemplateDriver(env)]

The `render_templates` method takes the relative `input_file` path and any arguments that were passed in from the `AZCodeGenerator.exe` utility. The `input_file` path usually contains inputs such as the intermediate `json_object` created by Clang.

Template drivers can extend this information by implementing the `apply_transformations` method. For more information, see Preprocessing Intermediate Data (p. 1886).

The `render_template_to_file` method takes a template file and argument key-value pairs to pass into the template engine directly and an output path to write the template engine render output to disk.

### Configuring Automatic Build Injection

At this point, the example generates a minimal `.cpp` file. The example above does not compile or link the `.cpp` file. This is appropriate if you intend to include the generated code manually using an `#include` in another file.

To inject the generated file automatically, add the `should_add_to_build` parameter to the `render_template_to_file` method and pass the parameter the value of `true`. The `should_add_to_build` parameter informs Waf that the generated file needs to be built and linked into the current target.

**Note**

Using the `should_add_to_build` parameter is not recommended for header files or other generated files that are not C++ code that must be compiled and linked.

The following example shows some build injected output.

```
from az_code_gen.base import *

class MyTemplateDriver(TemplateDriver):
    def render_templates(self, input_file, **jinja_args):
        self.render_template_to_file("MyTemplate.tpl", jinja_args, 'GeneratedCode.cpp',
                                      should_add_to_build=True)

# Factory function - called from launcher
def create_drivers(env):
    return [MyTemplateDriver(env)]
```

### Preprocessing Intermediate Data

Some cases require preprocessing of the intermediate data for easier consumption by the template engine. To do this, implement the `apply_transformations` method in your template driver. You can use this method to access the intermediate JSON data object directly before it gets passed to `render_templates`. An example follows.

```
from az_code_gen.base import *

class MyTemplateDriver(TemplateDriver):
    def render_templates(self, input_file, **jinja_args):
        self.render_template_to_file("MyTemplate.tpl", jinja_args, 'GeneratedCode.cpp')
```
def apply_transformations(self, obj):
    obj['my_custom_data'] = 42

# Factory function - called from launcher
def create_drivers(env):
    return [MyTemplateDriver(env)]

For information on the contents of the obj variable, see Intermediate JSON Data Format (p. 1901).

Custom Code Generator Annotations

AZ Code Generator is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can provide additional data to your template driver by attaching annotations and tags to your source code.

Topics
- Reference Annotations (p. 1887)
- Helper Macros (p. 1887)
- Example Annotations (p. 1888)

Reference Annotations

When you create custom code generator annotations, it is a good idea to refer for examples to the existing annotations in the dev/Code/Framework/AZCore/AZCore/Preprocessor/CodeGen.h file. The existing annotations use macros extensively as a workaround for the lack of proper annotations in C++.

Clang provides an annotate attribute that can be read at parse time. You can use the helper macros provided to create new annotations, as in the following example.

```python
__attribute__((annotate("<Some string here>")))
```

This attribute is wrapped with a macro that converts its contents into strings that can be parsed by the AZ Code Generator utility.

Helper Macros

AZ Code Generator has two helper macros for annotations: AZCG_CreateAnnotation and AZCG_CreateArgumentAnnotation.

AZCG_CreateAnnotation

AZCG_CreateAnnotation is the core macro that exposes the underlying Clang annotate attribute. The macro definition follows.

```python
// AZCG_CreateAnnotation
```
#define AZCG_CreateAnnotation(annotation) __attribute__((annotate(annotation)))

Any argument passed to AZCG_CreateAnnotation must be a string.

**AZCG_CreateArgumentAnnotation**

The AZCG_CreateArgumentAnnotation macro is commonly used for annotation macros. The macro definition follows.

```c
// AZCG_CreateArgumentAnnotation
#define AZCG_CreateArgumentAnnotation AZCG_CreateAnnotation(AZ_STRINGIZE(annotation_name) "(" AZ_STRINGIZE((__VA_ARGS__)) ")")
```

The AZCG_CreateArgumentAnnotation macro takes an annotation_name argument and a number of variable arguments. The values passed to the variable arguments are collapsed into a single string for parsing by the AZ Code Generator.

**Example Annotations**

This section provides example annotations. One example forwards arguments to the underlying macro, one places an annotation inside a class, and one injects code back into the originating file.

**Simple Annotation**

The following example creates a new annotation called AzExample that forwards its arguments to the underlying macro.

```c
//Sample Annotation
#define AzExample(...) AZCG_CreateArgumentAnnotation(AzExample, __VA_ARGS__)
```

In this example, the private and public names of the annotation are the same. However, the external and internal names do not have to match.

You can attach the AzExample annotation to most items in C++, as in the following example.

```c
// Sample Tag Usage
class ExampleClass
{
    AzExample(description("I am data!"))
    int m_myData;
}
```

The tags inside the annotation are placed in JSON format in the generated intermediate data object, as in the following example. Some data has been removed for readability.

```c
// Sample Tag JSON
{
    "type": "class",
    "name": " ExampleClass",
    "annotations": {},
    "fields": [
        {
            "name": "m_myData",
            "annotations": {
                "description": "I am data!"
            }
        }
    ]
}
```
Class Annotation Example

The following example directs the AZ Code Generator utility to attach a free-floating annotation to a class.

```
// Class Tag Macro
#define AzExampleClass(...) AZCG_CreateArgumentAnnotation(AzExampleClass, Class_Attribute, __VA_ARGS__) int AZ_JOIN(m_azCodeGenInternal, __COUNTER__);
```

AzExampleClass – Specifies the annotation name AzExampleClass (instead of AzExample, as in the previous example).

Class_Attribute – Causes the AZ Code Generator utility to attach the attribute to the class that contains the annotation. The annotation belongs to the annotations property of the class object.

__VA_ARGS__ – Specifies additional parameters that are converted into a single string and passed into the AZ Code Generator utility for parsing.

```
int AZ_JOIN(m_azCodeGenInternal, __COUNTER__) -- AZ_JOIN is a helper macro that takes two macro-level entries and joins them together without converting them to strings. Because Clang requires annotation attributes be attached to a function or variable, this example uses AZ_JOIN and a temporary integer member variable to do this. The temporary integer member variable is then ignored.
```

Adding the new tag to the previous example produces the following code:

```
//Class Tag Example
class ExampleClass
{
    AzExampleClass(MyExampleClassTags::description("I am an example class!"));
    AzExample(MyExamplePropertyTags::description("I am data!"))
    int m_myData;
}
```

This produces the following intermediate JSON object. Some data has been removed for ease of comprehension.

```
// Class Tag JSON
"type": "class",
"name": "SampleClass",
"annotations": {
    "MyExampleClassTags::description": "I am an example class!"
},
"fields": [
    {
        "name": "m_myData",
        "annotations": {
            "MyExamplePropertyTags::description": "I am data!"
        }
    }
]
```

Notice that the above JSON does not look exactly like the JSON in the intermediate files provided as part of AZ framework. This is because Lumberyard uses namespaces on its tags to also provide a hierarchy for the tags on its drivers and templates. We recommend that you import the `clang_cpp.py` file and run the `format_cpp_annotations(json_object)` function on the intermediate JSON. When you do, you can use all of the convenient patterns and functions in our drivers and scripts.
The following example shows the same intermediate JSON object after processing by format_cpp_annotations().

```json
// Output of format_cpp_annotations()
"type": "class",
"name": "SampleClass",
"annotations": {
  "MyExampleClassTags": {
    "description": "I am an example class!"
  },
  "fields": [
    {"name": "m_myData",
     "annotations": {
      "MyExamplePropertyTags": {
        "description": "I am data!"
      }
    }
  ]
}
```

Generated Code Injection Example

The following example shows how to automatically inject generated code back into the original file. The example extends the previously created AzExampleClass annotation by injecting code into the example class.

```cpp
// Code Injection Macro
#if defined(AZ_CODE_GENERATOR)
  #define AzExampleClass(ClassName, ...) AZCG_CreateArgumentAnnotation(AzExampleClass,
    Class_Attribute, identifier(ClassName), __VA_ARGS__) int AZ_JOIN(m_azCodeGenInternal,
    __COUNTER__);
#else
  #define AzExampleClass(ClassName, ...) AZ_JOIN(AZ_GENERATED_CODE_,ClassName)
#endif // AZ_CODE_GENERATOR
```

The updated annotation adds a new required parameter called ClassName, which is an identifier that is used to inject the code. The identifier is passed in to Clang as identifier(ClassName), and the data is provided to the intermediate JSON.

Up until this point, the annotation macro outside of AZ_CODE_GENERATOR has been blank. The next step is to have it expand to the identifier of the code-generated macro. This causes the generated code to replace the macro annotation when the generated file is put in an #include statement.

To implement this, the example sets the macro to become AZ_JOIN(AZ_GENERATED_,ClassName). As before, AZ_JOIN in this example renders this as AZ_GENERATED_CODE_EzExampleClass. The ClassName parameter provides a name at compile time for the generated macro.

**Note**
It is not required that ClassName be the actual name of the class where the tag is used. Other tags that use this mechanism can simply require any unique identifier.

When the previous example code is updated, the following code is produced:

```cpp
// Generated Injection Code
class ExampleClass
{
  AzExampleClass(ExampleClass, description("I am an example class!")));
  AzExample(description("I am data!")));
  int m_myData;
```
This code produces the following intermediate JSON. Note the new identifier annotation on the class. Some data has been removed for readability.

```json
// Generated Code Injection JSON
"type": "class",
"name": "SampleClass",
"annotations": {
  "AzExampleClass": {
    "identifier": "ExampleClass",
    "description": "I am an example class!"
  }
},
"fields": [
  {
    "name": "m_myData",
    "annotations": {
      "AzExample": {
        "description": "I am data!"
      }
    }
  }
]
```

This result doesn't compile until the following template code used with the annotation produces the intended macro.

```c++
// Template Code
{% if class.annotations.identifier is defined %}
#define AZ_GENERATED_CODE_{{ asStringIdentifier(class.annotations.identifier) }}
public:
{# This method is injected for all classes with the AzExampleClass tag #}
bool IsExampleClass(void) { return true; }
{% endif %}
```

This code generates the following code for injection:

```c++
// Generated Code for Injection
#define AZ_GENERATED_CODE_ExampleClass
bool IsExampleClass(void) { return true; }
```

If the generated header is placed in an `#include` statement in the original code, any code in this macro will be injected into `ExampleClass`.

## Waf Debugging with AZ Code Generator

AZ Code Generator is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can debug the integration output of Waf's Python scripts by using PyCharm and a few key debugging entry points. For more information about Waf integration itself, see AZ Code Generator Integration with Waf (p. 1874).
Topics

- Prerequisites (p. 1892)
- Identifying and Configuring Debug Output (p. 1892)
- Setting Up PyCharm for Debugging Waf (p. 1892)

Prerequisites

Before you start, follow the instructions for Setting Up PyCharm for Debugging Waf (p. 1892). The PyCharm debugger must be set up to debug \lmb\_waf before you can continue.

Identifying and Configuring Debug Output

All AZ Code Generator Waf integration output is prefixed with \texttt{az\_code\_gen}. To see additional output from both task creation and task execution, add \	exttt{--zones=az\_code\_gen} to the Waf command line. This exposes the commands that invoke AZ Code Generator and are useful for debugging the AZ Code Generator utility itself. For more information, see Debugging the AZ Code Generator Utility (p. 1899).

Debugging Wscript Configuration

To debug most configuration problems, it is best to set a breakpoint in the \texttt{create\_code\_generator\_tasks} method in \texttt{dev/Tools/Build/waf-<version>/\_\_waf/az\_code\_generator.py}. This method is called for each \texttt{wscript} file that uses the \texttt{az\_code\_gen} feature. It directly interprets the given passes and generates an \texttt{az\_code\_gen} task for each input file in each pass.

Debugging \texttt{az\_code\_gen} Task Creation

The \texttt{create\_az\_code\_generator\_task} feature creates \texttt{az\_code\_gen} tasks. It gathers most information and inserts it into the task. Each task gets added to the \texttt{az\_code\_gen\_group} Waf task to ensure it is executed prior to other tasks.

Debugging \texttt{az\_code\_gen} Task Execution

The \texttt{run} and \texttt{handle\_code\_generator\_output} commands are important points in task execution.

The \texttt{run} command takes the available information and generates a Clang-style arguments file prefixed with the @ symbol. The arguments file is passed on the command line to the AZ Code Generator utility.

\texttt{handle\_code\_generator\_output} - The AZ Code Generator utility returns a JSON object with one or more entries that are parsed by \texttt{handle\_code\_generator\_output}. If the AZ Code Generator utility returns an invalid, non-JSON response due to errors during execution, the Waf task returns the error message \texttt{No JSON-Object could be decoded}. To discover the return value that could not be handled, run the command outside of Waf.

Setting Up PyCharm for Debugging Waf

AZ Code Generator is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Version 1.28
1892
PyCharm is an integrated development environment for Python which includes a graphical debugger that is useful for debugging Waf.

**To set up PyCharm and Waf for debugging**

2. Start PyCharm.
3. At the welcome screen, choose **Open Directory**.
4. Navigate to the `lumberyard_version\dev` directory. There should be a file called `wscript` and `waf_branch_spec.py` under this folder.
5. Configure the Python interpreter.
   a. Choose **File**, **Settings**, **Project:dev**, **Project Interpreter** to open the project interpreter page.
   b. Click the gear icon on the right of the **Project Interpreter** and choose **Add**...
   c. Select the **Existing environment** radio button, and then click the ellipse (…) icon to the right of it.
   d. Navigate to the folder containing the python executable. The executable will be contained under the path `lumberyard_version\dev\Tools\Python\3.7.5\platform`, with the exact path depending on your platform. The Python executable file must be in the same folder as the project or you may have issues running Waf.
6. Set up a debugging profile for Waf.
   
a. To set up Waf for debugging, use the project explorer in the left pane. If you don't see the project explorer, press Alt+1. Navigate to the `\dev\Tools\Build\waf-<version>` node and expand it. You should see a file called `lmbr_waf` inside this node.
b. Right-click **lmbr_waf** and choose **Create lmbr_waf**

**Note**

The **Indexing...** operation must finish before the option appears. You can verify status in the bar at the bottom.
c. In the **Create Run/Debug Configuration** dialog, ensure that the following values are configured correctly:

- **Allow parallel run** should be unselected.
- **Parameters** is the command to use to run Waf for the run/debug session.
- **Python Interpreter** should be the interpreter that you specified earlier.
- The **Working directory** must be the *dev* directory.
7. Set up `wscript` files as debuggable Python files. Waf uses files called `wscript` to define the build rules per project. These are dynamically loaded Python modules that can be debugged like any other Python module.

   a. Choose **File**, **Settings**, **Editor**, **File Types**.
b. Choose Python in Recognized File Types. Select the + icon to the right of the Registered patterns section to add a new file type.

c. Under Registered Patterns, click the green plus sign (+).

d. In the Add Wildcard dialog box, enter wscript.

8. Turn off IncrediBuild.
   a. Open the _WAF_/usersettings.options file.
   b. Verify that use_incredibuild = False

9. (Optional) Enable file outlining. This feature makes it easier to navigate source files.

   To enable file outlining, right-click the Project tab and choose Show Members.

Template Driver Debugging

AZ Code Generator is in preview release and is subject to change.
Debugging the AZ Code Generator Utility

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Because template drivers are run from the AZ Code Generator executable using Python, you can't debug them directly. However, you can debug your driver and template code (and even Jinja2 itself) by using the `debug.py` file included with AZ Code Generator.

**To debug a template driver with a Python debugger like PyCharm or Visual Studio**

1. Set the debugger to execute the `Bin64\azcg\debug.py` file. This file launches the utility to generate input JSON and emulates a code-generation pass in Python so that you can debug as if you were attached to the utility.
2. Set the working directory to `Bin64\azcg`.
3. Enter the arguments for `AzCodeGenerator.exe` into a file with one argument per line. Or use a Waf-generated arguments file as described in Waf Debugging with AZ Code Generator (p. 1891).
4. Set the arguments file, prefixed with `@`, as the argument to the script.

The following arguments are required:

- `-codegen-script` – Absolute path to the driver script that you want to debug.
- `-input-path` – Absolute path on which source file paths are based. Usually this path is the same as the location of the wscript for a given target.
- `-input-file` – Relative path from input path to the source file that is used for input.
- `-output-file` – Absolute path where generated code will be written.

After you have completed the preceding steps, you should be able to launch your debugger and set breakpoints in your driver script.

For complete AZ Code Generator parameter information, see AZ Code Generator Parameters (p. 1877).

**Debugging the AZ Code Generator Utility**

AZ Code Generator is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When using Waf and the AZ Code Generator utility, you might need to debug Waf Python scripts (p. 1891) and your template drivers (p. 1898). You can also debug the AZ Code Generator utility itself, although it is less likely to be necessary. You can debug the AZ Code Generator utility by using Visual Studio in Windows or Xcode in macOS.

**Topics**

- Prerequisites (p. 1900)
- Debugging the AZ Code Generator Utility from the Waf build (p. 1900)
- Setting Visual Studio Debug Arguments (p. 1900)
- Setting Xcode Debug Arguments (p. 1901)
Prerequisites

The required preliminary steps depend on your operating system.

Windows Debugging

To debug AZ Code Generator using Visual Studio in Windows, you must generate a Visual Studio HostTools solution (.sln) file.

To generate a Visual Studio HostTools solution file

1. Enter the following command from the dev folder.

```
lmbr_waf.bat configure --enabled-game-projects= --specs-to-include-in-project-generation=host_tools --visual-studio-solution-name=HostTools
```

macOS Debugging

To enable Waf support for Xcode, perform the following steps to generate an Xcode project.

To generate an Xcode project

1. Open the dev/_WAF_/specs/all.json file.
2. Temporarily add AzCodeGenerator to modules.
3. Run ./lmbr_waf.sh configure to regenerate the Xcode project.
4. Open the dev/Solutions/LumberyardSDK.xcodeproj file.

Debugging the AZ Code Generator Utility from the Waf build

To debug the AZ Code Generator Utility from the Waf build, you must find the arguments file generated by Waf.

Waf generates an arguments file that is passed to AZ Code Generator as a command line parameter. All command line parameters from Waf for AZ Code Generator are contained inside the arguments file. This file is useful for debugging specific Waf AZ Code Generator invocations. To make the arguments file that you use available to Waf, add the --zones=az_code_gen option to the Waf command line.

Setting Visual Studio Debug Arguments

To set up debugging of AZ Code Generator from Visual Studio, perform the following steps.

To debug AZ Code Generator from Visual Studio

1. Perform the steps to set up Windows debugging as described in Prerequisites (p. 1900).
2. In the Visual Studio Solution Explorer, right-click AzCodeGenerator, and then select Properties.
3. Under Debugging, paste the path to the arguments file into Command Arguments.
4. Click OK to close the Property window.
5. Right-click AzCodeGenerator and then click Set as StartUp Project.
6. Press F5 to launch the debugger.
Setting Xcode Debug Arguments

To set up debugging of AZ Code Generator from Xcode, perform the following steps.

To debug AZ Code Generator from Xcode
1. Perform the steps to set up macOS debugging as described in Prerequisites (p. 1900).
2. In Xcode, under the Product, Scheme menu, choose AzCodeGenerator.
3. At the bottom of the Product, Scheme menu, choose Edit Scheme.
4. Under Arguments, add a new entry to Arguments Passed On Launch that contains your debug arguments.
5. Under Info, from the Executable drop down, select Other.
   a. Navigate to the directory dev/BinMac64.Debug/azcg/AzCodeGenerator.
   b. Click Choose.
6. Close the scheme editor.
7. Choose Product, Run to launch the debugger.

Intermediate JSON Data Format

AZ Code Generator is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. 
Download O3DE or visit the AWS Game Tech blog to learn more.

The following JSON shows the intermediate data format consumed by Jinja2 custom templates.

```json
{
    "meta": {
        "path": "<Path/To/Code/Generator/Input/File.ext>"
    },
    "objects": [
        {

...
Use the information in this section to learn about game input in Amazon Lumberyard.

Note
For information on the Input component that replaces legacy action maps, see Input (p. 642).

Input is what differentiates interactive experiences from all other entertainment media. Regardless of genre or operating system or device, every game is driven by some form of player interaction with a physical input device. There are many different types of input devices, each of which can produce a wide range of input data. Furthermore, the way this data is delivered to an application is rarely consistent across devices or operating systems. As a cross-operating system and device game engine, Lumberyard's goal is to provide independent access to input data from any supported device. The goal is to provide a common interface with these qualities:

- OS and device agnostic
- Extensible
- Efficient

In addition, input data should have these attributes:

- Must be obtainable by subscribing to input device events
- Must be obtainable on demand by polling the state or value of an input device
- Can be a custom payload, but adds no overhead when not used

Lumberyard's input system satisfies all of these requirements and replaces the deprecated input system.

AZ Framework Input

The Lumberyard input interface is called AZ framework input. AZ framework already provides abstracted interfaces for OS-specific features like file I/O and application lifecycle management, so the AZ framework code location is a natural fit.

The AZ framework input interface uses the AZCore EBus system and defines the following classes and EBuses:

- InputDevice – A base class that represents a physical input device.
- InputDeviceId – A device name and device index that together uniquely identify an InputDevice.
- InputDeviceNotificationBus – An EBus interface that subscribes to events from input devices when they connect or disconnect.
- InputDeviceRequestBus – An EBus interface that queries input devices about their associated input channels or current connected state.
- InputChannel – A base class that represents a specific source of input data (for example, the left mouse button). Input devices typically have multiple input channels.
- InputChannelId – A name that uniquely identifies an InputChannel.
- InputChannelNotificationBus – An EBus interface that subscribes to events from input channels when the channels are active or when their state or value changes.
- InputChannelRequestBus – An EBus interface that obtains an input channel from the input channel's ID. You can then query the input channel directly for its current state or value.
- InputChannelEventListener – An event monitor that inherits from InputChannelNotificationBus but provides additional features. Subscribers can use the additional features to receive events in priority order or filter events based on the source device or channel. Subscribers can also consume events so that the events aren't passed on to lower priority monitors.
**Processing the Input**

To process input, you can simply inherit from `AzFramework::InputChannelEventListener`. You can also create a filter to receive events only from specific input devices or channels, and then override `OnInputChannelEvent` to process the input data.

If you want to query the current input state directly, use `AzFramework::InputChannelRequestBus` to obtain an input channel's ID. Then query the input channel for its current state or value.

**Text Input Interfaces**

The following interfaces are designed to process text input. The input is delivered as a complete string of UTF-8 code points. This eliminates the requirement to keep track of and interpret individual code units or convert from other encodings.

- `InputTextEventNotificationBus` – An EBus interface that subscribes to text events from input devices or input channels.
- `InputTextEntryRequestBus` – An EBus interface that sends text entry requests. The requests inform input devices that the user is expecting to start or stop entering text.
- `InputTextEventListener` – An event monitor that inherits from `InputTextNotificationBus` but provides additional features. Subscribers can use the additional features to receive events in priority order or consume events so that the events aren’t passed on to lower priority monitors.

**Auxiliary Input Interfaces**

The following AZ framework input auxiliary interfaces are only implemented by certain input devices. You can use these interfaces to query or post data related to device activity like vibration effects, motion sensors, or the mouse cursor.

- `InputHapticFeedbackBus` – An EBus interface that sends haptic feedback requests to connected input devices.
- `InputMotionSensorRequestBus` – An EBus interface that sends motion sensor requests to connected input devices.
- `InputSystemCursorRequestBus` – An EBus interface that queries or changes the state, position, or appearance of the system cursor.

**Input Devices**

All input device classes inherit from `AzFramework::InputDevice`. While multiple instances of the same class can exist, every input device is identified by a unique `InputDeviceId`.

**Input Devices Included in Lumberyard**

The base class is designed so that you can inherit from it to implement new types of input devices. However, Lumberyard already includes implementations for the following devices:

<table>
<thead>
<tr>
<th>Device Type</th>
<th>Supported Operating Systems</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mouse</td>
<td>Windows, macOS</td>
</tr>
<tr>
<td>Keyboard</td>
<td>Windows and macOS</td>
</tr>
<tr>
<td>Gamepad</td>
<td>Windows, macOS, iOS, Android, consoles</td>
</tr>
</tbody>
</table>
This core set of input devices are managed by the `AzFramework::InputSystemComponent`. You can use this component to configure the type and number of input devices that your application creates at startup.

**Creating Input Devices**

You can create and implement new types of input devices by inheriting from `AzFramework::InputDevice` and creating or destroying instances of the new class as required. For examples, see the Configuring your Project for Virtual Reality (p. 3249), which define and create new types of input devices that inherit from `AzFramework::InputDevice`. Their code is located at the Lumberyard directory locations `\dev\Gems\Oculus` and `\dev\Gems\OpenVR`, respectively.

The implementation details of each input device differ depending on the device type and operating system. However, almost all devices follow a similar pattern. They use an OS-specific API to obtain raw input data for each frame and then update all the device's associated input channels accordingly.

When you implement an input device, use only your device's `TickInput` function to update the value of the input channels. This ensures that input events are delivered at the same time every frame.

Depending on how the input device gets the raw, operating system-specific input, you might have to use one of the following techniques:

- Polling the underlying input API on each call to your input device's `TickInput` function. For examples, see all `InputDeviceGamepad` implementations in the directory `\dev\Code\Framework\AzFramework\Input\Devices\Gamepad`.
- Queuing or coalescing input data from the application's main message loop until the next call to `TickInput`. For an example, see `InputDeviceMouse` in the directory `\dev\Code\Framework\AzFramework\Input\Devices\Mouse`.
- Ensuring input channels are updated in a thread-safe manner if no raw input is received on the main thread. For an example, see `InputDeviceTouchAndroid` in the directory `\dev\Code\Framework\AzFramework\Input\Devices\Touch`.

**Input Channels**

Input devices can have multiple input channels. Each channel represents a discrete source of input data that is uniquely identified by an `InputChannelId`.

Input channels use `AzFramework::InputChannelNotificationBus::OnInputChannelEvent` to broadcast events. A channel broadcasts events when the channel's state or value changes from one frame to the next or if the channel is still active or held. Input channels can also be accessed directly and polled at any time to query their current state and value.

**Creating Input Channels**

Like the `AzFramework::InputDevice` base class, you can inherit from `AzFramework::InputChannel` to implement new types of input data sources.
Input Channels Included in Lumberyard

Lumberyard provides the following input channel implementations that are used by the devices listed in the Input Devices (p. 1904) section. You can also use these implementations for new input devices.

<table>
<thead>
<tr>
<th>Input Channel</th>
<th>Example Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>InputChannelAnalog</td>
<td>Gamepad trigger</td>
</tr>
<tr>
<td>InputChannelAnalogWithPosition</td>
<td>Touch with pressure at a position</td>
</tr>
<tr>
<td>InputChannelAxis1D</td>
<td>Gamepad thumbstick x or y</td>
</tr>
<tr>
<td>InputChannelAxis2D</td>
<td>Gamepad thumbstick x and y together</td>
</tr>
<tr>
<td>InputChannelAxis3D</td>
<td>Motion sensor acceleration, rotation, or magnetic field</td>
</tr>

Using Memory Allocators in Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard’s memory management system determines how memory is allocated. In Lumberyard version 1.16, the memory management system has been refactored. All memory allocations go through one pipeline, and memory allocation can be tracked. This makes it easier and quicker to pinpoint memory leaks or optimize memory usage to improve game performance. This improvement is especially important for mobile and console applications, where memory resources are usually more constrained than in PC environments.

Lumberyard supports all the best known memory allocation schemes. You can use Lumberyard’s allocators to categorize allocations or keep similar allocations together to improve locality or reduce fragmentation.

**Note**
For best C++ practices for managing memory in Lumberyard, see Memory Management (p. 29).

**Topics**
- Manually Allocating Memory (p. 1907)
- AZ Memory Allocators (p. 1908)
- Applying Allocators to Your Classes (p. 1910)
- AZ Allocator Schemas (p. 1910)
- Creating an Allocator (p. 1911)
## Manually Allocating Memory

Lumberyard uses the following memory allocation functions. You can find the source code in the `lumberyard_version\dev\Code\Framework\AzCore\AzCore\Memory\` directory.

<table>
<thead>
<tr>
<th>Lumberyard Function</th>
<th>Replaces</th>
<th>Overloads and Descriptions</th>
</tr>
</thead>
</table>
| `aznew`             | `operator new` | Use instead of `new T()`. If `AZCORE_ENABLE_MEMORY_TRACKING` is defined, uses the bound allocator and record tracking information for `T`.  
**Note**  
There is no `azdelete` function. The built-in `operator delete` is sufficient. |
| `azmalloc`          | `malloc` | `azmalloc(size, [alignment])`  
Uses the `SystemAllocator` to allocate memory.  
`azmalloc(size, alignment, Allocator, [allocationName])`  
Uses the specified allocator to allocate memory. `allocationName` specifies a optional name for the allocation. |
| `azcalloc`          | `calloc` | `azcalloc(size, [alignment])`  
Uses `SystemAllocator` to allocate memory and fills the memory with zeroes.  
`azcalloc(size, alignment, Allocator, [allocationName])`  
Uses the specified allocator to allocate memory and fills the memory with zeroes. Optionally specifies a name for the allocation. |
| `azrealloc`         | `realloc` | `azrealloc(ptr, size)`  
Reallocates from `SystemAllocator`.  
`azrealloc(ptr, size, Allocator, [allocationName])`  
Reallocates from the specified allocator. Optionally specifies a name for the allocation. |
| `azfree`            | `free`   | `azfree(ptr)` |
### AZ Memory Allocators

The following diagram illustrates the hierarchy of AZ memory allocators.

<table>
<thead>
<tr>
<th>Lumberyard Function</th>
<th>Replaces</th>
<th>Overloads and Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>azcreate new with allocator</td>
<td>azcreate(T, [params])</td>
<td>Uses the SystemAllocator to allocate memory and passes optional parameters wrapped in () or {} to the constructor.</td>
</tr>
<tr>
<td>azcreate new with allocator</td>
<td>azcreate(T, params, Allocator, [allocationName])</td>
<td>Uses the specified allocator to allocate memory. Optionally specifies a name for the allocation.</td>
</tr>
<tr>
<td>azdestroy delete with allocator</td>
<td>azdestroy(T*)</td>
<td>Destroys memory. azdestroy should be used only with a corresponding azcreate function.</td>
</tr>
<tr>
<td>azdestroy delete with allocator</td>
<td>azdestroy(T*, Allocator)</td>
<td>Calls the destructor, frees memory, and returns the memory to the SystemAllocator.</td>
</tr>
<tr>
<td>azdestroy delete with allocator</td>
<td>azdestroy(T*, Allocator)</td>
<td>Calls the destructor, frees memory, returns the memory to the specified allocator.</td>
</tr>
</tbody>
</table>
- **OSAllocator** – Acts as the interface to operating system memory and should be used for direct operating system allocations on the C heap. OSAllocator is booted as early as possible in `main()`, and removed last, right before returning. If you don't create OSAllocator, the SystemAllocator creates it when needed.

OSAllocator uses system calls to allocate memory. The calls are not recorded or tracked. Other allocators use OSAllocator to obtain memory from the operating system. Drillers and memory tracking tools can use OSAllocator for data debugging.

- **BestFitExternalMapAllocator** – Uses external maps to store memory tracking information for uncached memory.

- **SystemAllocator** – The system allocator is the general purpose allocator for the AZ memory library. Like all other allocators, SystemAllocator is a singleton, but it must be initialized first and destroyed last. All other allocators use SystemAllocator for internal allocations.

- **LegacyAllocator** – Handles legacy memory allocations. For more information, see Legacy Memory Management (p. 1914).

- **PoolAllocator** – Performs extremely fast small object memory allocations. PoolAllocator can allocate sizes in a range specified by `m_minAllocationSize` to `m_maxPoolSize`.

  **Note**
  
  PoolAllocator is not thread safe. If you need a thread-safe version, use ThreadPoolAllocator, or inherit from ThreadPoolBase and then write custom code to handle the synchronization.

- **ThreadPoolAllocator** – Thread safe pool allocator. If you want to create your own thread pool heap, inherit from ThreadPoolBase, as Lumberyard requires a unique static variable for the allocator type.
Applying Allocators to Your Classes

To apply an allocator to your class, use the `AZ_CLASS_ALLOCATOR` macro in your class or directly call `AZ::AllocatorInstance<some_allocator>`. AZCore relies on `AZ_CLASS_ALLOCATOR` to specify the default allocator for the class or on explicit `azcreate` and `azdestroy` calls that specify the allocator in their signature.

- If your class does not implement `AZ_CLASS_ALLOCATOR` and you call `new` or `delete`, `new` or `delete` calls use the global operator `new` or `operator delete`.
- If your class does not implement `AZ_CLASS_ALLOCATOR` and you call `aznew`, you must implement a new operator that uses the `aznew` call signature.

AZ Allocator Schemas

Each allocator commonly implements the `IAllocator` interface and uses a schema to implement the allocation algorithms and bookkeeping. This strategy enables the same schema to be used in multiple allocators.

Allocators Schemas

<table>
<thead>
<tr>
<th>Schema</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>AZ::HphaSchema</code></td>
<td>This is the preferred schema. It combines a small block allocator for small allocations and a red-black tree for large allocations. This provides good general purpose performance. Use this schema if you're not sure which one to use.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td><code>HphaSchema</code> is based on Dimitar Lazarov's &quot;High Performance Heap Allocator&quot; (Game Programming Gems 7, Charles River Media, 2008, pp. 15–23).</td>
</tr>
<tr>
<td><code>AZ::HeapSchema</code></td>
<td>Uses <code>nedmalloc</code> internally. Because <code>nedmalloc</code> uses thread caches to accelerate the re-use of memory, <code>HeapSchema</code> can be useful for intensive allocation processing across multiple threads.</td>
</tr>
<tr>
<td><code>AZ::BestFitExternalSchema</code></td>
<td>A best-fit allocation scheme that uses an external map to store bookkeeping outside the memory being managed. Because the tracking node is stored outside the main chunk, Lumberyard can use this allocator with uncached memory. This is most useful for GPU resource management (for example, for textures, constant buffers, and compute buffers).</td>
</tr>
<tr>
<td><code>AZ::ChildAllocatorSchema</code></td>
<td>Acts as a pass-through schema to another allocator. Use this schema to create a new allocator based on an existing allocator like <code>SystemAllocator</code>. To properly tag the memory that each gem or logical subsystem allocates, each gem or subsystem can create its own child allocator. For more information, see Creating an Allocator (p. 1911).</td>
</tr>
<tr>
<td><code>AZ::PoolSchema</code></td>
<td>A specialized schema that implements a small block allocator for managing small, high-throughput allocations. Objects are typically pooled at the cost of using more memory.</td>
</tr>
</tbody>
</table>
Creating an Allocator

We recommend that each Lumberyard gem or logical subsystem create a ChildAllocator to properly tag the memory that it allocates. This practice makes it easier to budget resource usage and get a holistic view of it.

If you choose to write your own schema, be aware that caching significant chunks of memory can be problematic. Such caching can hamper the ability of other systems to evolve to fit the content in your game. Unless you have specific requirements, we recommend that you create a ChildAllocator that eventually uses the SystemAllocator. Using a ChildAllocator ensures that your memory is as recoverable and reusable as possible.

Prior to Lumberyard version 1.16, the most common mechanism for creating a new allocator was to inherit from SystemAllocator. This practice, which creates a completely separate free list of memory usage, results in the problem of memory being spread among disparate caches. In most cases, it is better to use the inheritance ChildAllocator<SystemAllocator>, which also makes it trivial to swap the base class of your custom allocator.

To create an allocator

1. Choose a schema to use, write a custom schema, or choose an existing allocator that you want to modify. For more information, see AZ Allocator Schemas (p. 1910).
2. Inherit from AllocatorBase<your_schema> to create your Allocator class.
3. Add AZ_TYPE_INFO so that AllocatorInstance<> can properly manage your type.

Using Your Own Allocators from Containers

To use your own allocator from a container, wrap your allocator in AZ::AZStdAlloc, like the following example.

```cpp
AZStd::vector<MyClass, AZ::AZStdAlloc<CustomAllocator>>
```

Child Allocator Example

The following code example adds a custom allocator for the Script Canvas gem (p. 1201).

Example

```cpp
// Declaration of a child allocator for the ScriptCanvas module.
```
namespace ScriptCanvas
{
    class ScriptCanvasAllocator
        : public AZ::AllocatorBase<AZ::ChildAllocatorSchema<AZ::SystemAllocator>>
    {
        public:

            AZ_TYPE_INFO(ScriptCanvasAllocator, "{2C6478E2-3B0D-4DFF-88E2-ABCB3F10B96E}");
            using Schema = AZ::ChildAllocatorSchema<AZ::SystemAllocator>;
            using Base = AZ::AllocatorBase<Schema>;
            using Descriptor = Base::Descriptor;

            ScriptCanvasAllocator()
                : Base("Script Canvas Allocator", "Child Allocator used to track Script Canvas allocations")
            {
                m_schema = new (&m_schemaStorage) Schema(Descriptor());
            }

            pointer_type Allocate(size_type byteSize, size_type alignment, int flags, const char* name, const char* fileName, int lineNum, unsigned int suppressStackRecord) override
            {
                return Base::Allocate(byteSize, alignment, flags, name, fileName, lineNum, suppressStackRecord);
            }

            pointer_type ReAllocate(pointer_type ptr, size_type newSize, size_type newAlignment) override
            {
                return Base::ReAllocate(ptr, newSize, newAlignment);
            }
        
        // Alias for using ScriptCanvasAllocator with std container types.
        using ScriptCanvasAZStdAlloc = AZ::AZStdAlloc<ScriptCanvasAllocator>;
    } // namespace ScriptCanvas

    // Specialize the AllocatorInstance for ScriptCanvas to provide the allocator stored within the ScriptCanvas gem.
    // The allocator is stored with the ScriptCanvas module and therefore its lifetime lasts as long as the
    // ScriptCanvas module is loaded.
    namespace AZ
    {
        template<>
        class AllocatorInstance<ScriptCanvas::ScriptCanvasAllocator>
        {
            public:

                using AllocatorType = ScriptCanvas::ScriptCanvasAllocator;
                using Descriptor = typename AllocatorType::Descriptor;
                friend class ScriptCanvas::ScriptCanvasModule;

                static AllocatorType& Get()
                {
                    if(!s_scriptCanvasAllocatorRef)
                    {
                        if (AZ::Environment::IsReady())
                        {
                            s_scriptCanvasAllocatorRef = AZ::Environment::FindVariable<AllocatorType>(AZ::AzTypeInfo<AllocatorType>::Name());
                            AZ_Error("ScriptCanvas", s_scriptCanvasAllocatorRef, "ScriptCanvasModule has not been loaded yet");
                        }
                    }
                    return *s_scriptCanvasAllocatorRef;
                }
        }
    } // namespace AZ
In the following code example, the ScriptCanvas module creates and owns the child allocator.

Example

```cpp
// ScriptCanvas module creates and owns the child allocator.
namespace ScriptCanvas
{
    // Stores an environment variable within the ScriptCanvas Module
    static AZ::EnvironmentVariable<ScriptCanvas::ScriptCanvasAllocator> s_scriptCanvasAllocator;

    // Create ComponentDescriptors and add them to the list.
    // The descriptors will be registered at the appropriate time.
    // The descriptors will be destroyed (and thus unregistered) at the appropriate time.
    ScriptCanvasModule::ScriptCanvasModule()
    {
        ScriptCanvasAllocator::Descriptor allocatorDescriptor;
        s_scriptCanvasAllocator = AZ::Environment::CreateVariable<ScriptCanvas::ScriptCanvasAllocator>(AZ::AzTypeInfo<ScriptCanvas::ScriptCanvasAllocator>::Name());
        s_scriptCanvasAllocator->Create(allocatorDescriptor);
    }

    ScriptCanvasModule::~ScriptCanvasModule()
    {
        s_scriptCanvasAllocator->Destroy();
    }

    AZ::ComponentTypeList ScriptCanvasModule::GetRequiredSystemComponents() const
    {
        return GetCommonSystemComponents();
    }
}
```
Static Initialization

In a monolithic build, at static initialization time (before the allocators are bootstrapped), allocations are routed directly to the underlying operating system. These static allocations are tracked in a fixed size set and sent back to the OS when they are freed. They are also reported separately to memory tracking in the Global category. To discover the memory that is being allocated globally, set a breakpoint in AZ::Internal::GlobalAlloc.

Legacy Memory Management

Starting in Lumberyard version 1.16, all Cry* allocation routines route to AZ::LegacyAllocator, which you can find in the lumberyard_version\dev\Code\CryEngine\CryCommon\LegacyAllocator.h file. LegacyAllocator has the same lifetime as OSAcclorator and obtains its memory from OSAcclorator.

Cry dynamic-link libraries override the new and delete functions instead of tagging their classes with allocators. This behavior is controlled with the USE_CRY_NEW_AND_DELETE macro (lumberyard_version\dev\Code\CryEngine\CryCommon\CryMemoryManager_impl.h). This practice should not be used outside Cry DLLs. When compiled monolithically, the LegacyAllocator catches any uses of global new or delete. This allows all allocations to be tracked and managed.

Note
As of Lumberyard version 1.16, operator new and operator delete overrides are restricted to Cry DLLs.

All Cry static functions that allocate memory have been removed or wrapped in StaticInstance<T>, which creates the functions only when the functions are first accessed. StaticInstance<T> can be used in any DLL which depends on CryCommon and includes the lumberyard_version\dev\Code\CryEngine\CryCommon\platform_impl.h file.

Note
Within AZ code, there is a NewAndDelete.inl file in the lumberyard_version\dev\Code\Framework\AzCore\AzCore\Memory\ directory. You can use this code within a gem DLL, but only in nonmonolithic mode. We do not recommend using this code except to track down untagged classes or allocations.

Code Example: Automatic Unreflection of Module Classes

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To automatically unreflect a module's reflected classes from the SerializeContext when the module unloads, you can create a class that contains an instance of a memory allocator separate from the SerializeContext.

To manage memory allocations of reflected GenericClassInfo classes within the module until the module is unloaded, use the class in a static variable context. Because static variable destructors are invoked when the module unloads, the destructor for the static variable can use the opportunity to unreflect all of the module's reflected GenericClassInfo classes.

This is a safety measure that can prevent shutdown errors. For example, if a gem that is no longer loaded has a reflected class, and you attempt to use SerializeContext to serialize that class, a shutdown error can occur.
Example DLL Cleanup Class

In the following code example, the `PerModuleGenericClassInfo` class tracks module-specific reflections of `GenericClassInfo` for each `SerializeContext` that is registered with the module (.dll file).

```cpp
// DLL Cleanup Class
class SerializeContext::PerModuleGenericClassInfo final
{
    public:
        PerModuleGenericClassInfo();
        ~PerModuleGenericClassInfo();

        /// Creates GenericClassInfo and registers it with the current module if it
        /// has not already been registered.
        /// Returns a pointer to the class that was created by deriving from GenericClassInfo.
        /// template <typename T>
        typename SerializeGenericTypeInfo<T>::ClassInfoType* CreateGenericClassInfo();

    private:
        /// Creates a local OSAllocator which will be used by the data members to
        /// allocate memory from the operating system heap.
        AZ::OSAllocator m_moduleOSAllocator;

        /// Creates a type alias to associative containers with a custom allocator interface.
        /// AZ::AZStdIAllocator wraps an IAllocator interface allocator and dynamically
        /// associates an allocator with a type.
        /// AZStd::unordered_map<AZ::Uuid, AZ::GenericClassInfo*,
        /// AZStd::hash<AZ::Uuid>, AZStd::equal_to<AZ::Uuid>, AZ::AZStdIAllocator>
        /// AZStd::unordered_set<SerializeContext*,
        /// AZStd::hash<SerializeContext*>, AZStd::equal_to<SerializeContext*>, AZ::AZStdIAllocator>
        GenericInfoModuleMap m_moduleLocalGenericClassInfos;
        SerializeContextSet m_serializeContextSet;
    
    // Initializes the OSAllocator and constructs the associative containers with OSAllocator.
    SerializeContext::PerModuleGenericClassInfo::PerModuleGenericClassInfo()
        : m_moduleLocalGenericClassInfos(AZ::AZStdIAllocator(&m_moduleOSAllocator))
        , mSerializeContextSet(AZ::AZStdIAllocator(&m_moduleOSAllocator))
    {
    }

    /// Cleans up all GenericClassInfo objects created within the current .dll and
    /// unregisters them from the SerializeContext.
    SerializeContext::PerModuleGenericClassInfo::~PerModuleGenericClassInfo()
    {
        // Cleans up the memory for the GenericClassInfo objects.
        for (const AZStd::pair<AZ::Uuid, AZ::GenericClassInfo*>& moduleGenericClassInfoPair :
             genericClassInfoContainer)
        {
            GenericClassInfo* genericClassInfo = moduleGenericClassInfoPair.second;
            // Explicitly invokes the destructor and clears the memory from the OSAllocator
            module.
            genericClassInfo->~GenericClassInfo();
            m_moduleOSAllocator.DeAllocate(genericClassInfo);
        }

        // Reconstructs the associative containers with the OSAllocator so that the previously
        // allocated memory is cleared. This ensures that the associative containers do not
        // attempt to deallocate memory within their destructors.
        m_moduleLocalGenericClassInfos =
            GenericInfoModuleMap(AZ::AZStdIAllocator(&m_moduleOSAllocator));
        m_serializeContextSet =
            SerializeContextSet(AZ::AZStdIAllocator(&m_moduleOS Allocator));
    }
```
HPHA Memory Debugging

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In Lumberyard 1.16 and later versions, the HPHA memory allocator provides memory debugging features to detect and trace common memory issues.

Enabling HPHA Memory Debugging

To avoid performance issues, debugging features are disabled by default.

To enable HPHA memory debugging

1. In the lumberyard_version\dev\Code\Framework\AzCore\AzCore\Memory\HphaSchema.cpp file, uncomment the following line:

```cpp
#define DEBUG_ALLOCATOR
```

2. Save the file.

3. Perform a build in debug mode. For more information, see Building Lumberyard projects (p. 61).
Characteristics and Limitations

Because of certain limitations, the HPHA debugger can help find memory issues but cannot guarantee their absence. When using HPHA memory debugging features, note the following:

- For the HPHA debugger to work, allocations must use the HPHA allocator. HPHA memory debugging does not cover allocations created by other allocators such as a PoolAllocator.
- Most of the HPHA memory debugging features assert when they detect a memory issue. When possible, the debugger prints a stack trace that indicates where the allocation happened. The stack trace is printed into the debugger output (not to the log) so that Visual Studio can recognize it. This makes it possible to double-click a trace and navigate directly to the corresponding file and line number.
- The HPHA memory debugger does not currently cover the following memory issues:
  - Buffer underflows.
  - "Far" buffer overflows. When detecting buffer overflows, Lumberyard detects changes up to 16 bytes after the memory block. If a buffer overflow writes on byte 17, Lumberyard does not detect it.
  - Lumberyard shuts down by terminating the application rather than by destroying objects. Because Lumberyard relies on the operating system to recover memory, it cannot detect issues related to shutdowns or the destruction of objects. To reproduce, isolate, and debug such memory issues, we recommend that you use unit tests.

How Memory Debugging Works

Some memory debugging features detect memory issues when an allocation is freed, and others detect issues when the HPHA allocator is destroyed. The memory debugging works by keeping a set of debug records for each allocation. When memory is requested or returned, the debugger compares the allocation or deallocation operation with the debug records. When anomalies are detected, the debugger enforces rules with asserts. The following sections describe the asserts that occur for the different memory operations.

Allocations

For memory allocation operations, the debugger performs the following tasks:

- If a previous allocation has the same pointer, the debugger asserts and prints the stack trace of the previous allocation. This usually occurs when a process overwrites the memory for the allocator's tracking structures. Because the allocator uses memory near the blocks that it allocates, a memory overflow or underflow in a neighboring block can overwrite the memory that the HPHA uses for memory tracking. When this occurs, the HPHA might consider a used block of memory to be "unused".
- Fills the memory with a quiet NaN (qNaN) pattern (0xFF, 0xC0, 0xC0, 0xFF). This is useful for detecting specific patterns of use in uninitialized memory and can detect most (but not all) cases. For more information about the qNaN pattern, see Deallocations (p. 1917).

Deallocations

For memory deallocation operations, the debugger performs the following tasks:

- Asserts if the debug record is not found. This can happen because of double deallocations or the deallocation of an invalid pointer.
- Asserts if a guard is invalid. When an allocation occurs, an additional 16 bytes ("the guard") are placed at the end of the allocation. For example, if the request is for 40 bytes, 56 bytes are assigned and 16 are used for the guard. Memory debugging assigns random values to the 16 bytes and places them in the debug record. When the deallocation happens, the 16 bytes are checked against the 16 bytes...
Overrun Detection

stored in the debug record. If they mismatch, the debugger asserts. This assert usually indicates a memory overflow (that is, an attempt to write beyond the requested size).

**Note**
This check cannot detect the cases in which the overflow writes the exact same random bytes or writes beyond the 16 byte guard.

- Asserts if the freed size does not match the allocation size. During allocation, the requested size is stored in the debug record. If the same size is not freed, a problem occurred during the deallocation.
- Refills the freed memory with the qNaN pattern. This makes it easier to detect memory accesses after the memory has been deallocated. Without this feature, the memory contents are usually available until some code reuses the memory. Filling the freed memory with the qNaN pattern helps detect this anomalous usage early.

Reallocations

Reallocations use a new block or an existing block depending on whether contiguous memory is available.

Reallocation to a New Block

When contiguous memory is not available, memory is reallocated to a new block. The debugger performs the following tasks:

- Asserts if the previous allocation is not found. Normally, the previous allocation still exists. The allocator creates a new allocation with a new memory address and then copies the contents of the previous allocation to the new allocation. If the pointer to the previous allocation is not in the debug records, the debugger asserts.
- Asserts if the guard of the previous allocation is invalid. For information on guards, see Deallocations (p. 1917).
- Asserts if a previous allocation has the same address as the new allocation. For more information, see Allocations (p. 1917).
- Fills the memory for the new allocation with the qNaN pattern. The previous block is copied over. The remaining unused part of the new allocation should have the qNaN pattern.

Reallocation to an Existing Block

When contiguous memory is available, the pointer to an existing block is used. The debugger performs the following tasks:

- Asserts if the allocation is not found.
- Asserts if the guard of the previous allocation is invalid. For information on guards, see Deallocations (p. 1917).
- Updates the debug record stack.
- Because the size has changed, writes a new guard.

Overrun Detection

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Overrun detection is an experimental feature available starting in Lumberyard version 1.21. It helps you detect corrupted memory at the time that the corruption occurs. If you think memory corruption might be caused by read or write operations outside of allocated memory, overrun detection can help you detect the problem.

**Note**
Overrun detection mode is similar to the Microsoft Debugging Tools for Windows GFlags with full page heap verification. However, it can be used with the Lumberyard memory allocators and does not require recompiling.

### Prerequisites and Limitations

The following are the prerequisites and limitations for using the Lumberyard overrun detection feature:

- You must build and run your project for Windows PC in a Debug or Profile build.
- Overrun detection is available only on platforms that use the Windows API.
- Only allocations that go through the Lumberyard allocators (p. 1906) benefit from overrun detection. Allocations that go through `new` or `malloc` do not use overrun detection unless you overload those functions to use the Lumberyard allocators.

### When to Enable Overrun Detection

The most common indicator of overwritten memory is a crash that occurs with no obvious explanation. The crash frequently occurs in a low-level system or structure, such as an AZStd:: container, or within the memory allocator. The memory overrun is not an out-of-memory error.

### Enabling Overrun Detection

Overrun detection is enabled by a setting in your project's `Game.xml` file.

**To enable overrun detection**

1. Open your project's `lumberyard_version\dev\project_name\Config\Game.xml` file.
2. Change `useOverrunDetection` from the default `false` to `true`, as shown in the following example.

```xml
<Class name="bool" field="useOverrunDetection" value="true" type="{A0CA880C-AFE4-43CB-926C-59AC48496112}"/>
```

### Using Overrun Detection

When overrun detection is enabled, debug your game as usual. Keep the following points in mind:

- Your game runs more slowly and uses significantly more memory with overrun detection enabled.
- If a system reads or writes outside allocated memory, the game crashes with a call stack at the point of the invalid read or write. An invalid read or write includes the usual `Exception thrown: invalid read/write` message near the end of the output. If this message does not appear, the exception is not a memory read or write bug.
- If the game doesn't crash, but locks up instead, you can pause the debugger to see where the game stopped.

**Note**
The detector doesn't always release memory after the memory is acquired from the operating system. Depending on the game, the detector can increase memory...
consumption as gameplay continues. If you run out of memory when you use the detector, a crash occurs in either WindowsPlatformAllocator::ReserveBytes or WindowsPlatformAllocator::CommitBytes.

Source Code Location

For the source code, see lumberyard_version\dev\Code\Framework\AzCore\AzCore\Memory\OverrunDetectionAllocator.*

Profiling, Testing, and Debugging Game Projects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard includes a number of tools that are used for testing builds, profiling performance, and debugging various issues that may be encountered.

Topics

• Profiler (p. 1920)
• Using AZ Test Scanner (p. 1958)
• Writing Tests for AzTest (p. 1961)
• Debugging Issues (p. 1966)
• Tracking File Access (p. 1972)

Profiler

Profiler is in preview release and is subject to change.

Profiler is a Lumberyard tool that can capture, save, and analyze network, CPU, and VRAM usage statistics. You can used the saved data to analyze network usage frame by frame, fix problems in the use of network bandwidth, and optimize the performance of your game.

To capture data, Profiler works with GridHub. When you launch Profiler, GridHub launches automatically as a supporting background process. For more information about GridHub, see Using GridHub (p. 1954).

Topics

• Profiler Tutorial (p. 1921)
• Creating and Using Annotations (p. 1934)
• Using Profiler for Networking (p. 1937)
• Using the Profiler for CPU Usage (p. 1947)
• Using Profiler for VRAM (p. 1951)
• Using GridHub (p. 1954)
Profiler Tutorial

Profiler is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can register an application in GridHub and use Profiler to capture, inspect, play back, and export the data that you collect.

Topics

- Registering Your Application (p. 1921)
- Launching Profiler (p. 1921)
- Capturing Data (p. 1921)
- Inspecting Data (p. 1923)
- Playing Back Data (p. 1927)
- Exporting Data (p. 1933)

Registering Your Application

To enable Profiler to capture information from your application, you must first register the application in GridHub. To do so, add `AzFramework::TargetManagementComponent` to the application's `SystemComponent`.

Note: Lumberyard's built-in applications already have this component added by default.

Launching Profiler

Unlike many Lumberyard utilities, you launch Profiler from its own executable file.

To launch profiler

- From the Lumberyard `dev\Bin64\` directory, run `Profiler.exe`.

Capturing Data

Profiler has two main modes of use: capture mode and inspection mode.
To use capture mode, perform the following steps.

**To capture data**

1. Click Target.

![Target: None](image1)

Profiler shows you the applications that are available for profiling:

![Target: None](image2)

2. Select a target application.

After you have selected a target, the target selector shows the state of the connection to the target. The next time you launch Profiler, it automatically selects your target for you, if it's available.

![Profiler interface](image3)

The window is divided horizontally into channels that have associated Profiler instances. A channel is a collection of Profiler instances that relate to a specific system.

3. Each Profiler instance in a channel has a unique color. A Profiler instance is active when its color is solid:

![Profiler instance](image4)

Click the color next to a Profiler instance. The color is no longer solid, showing that the Profiler instance is inactive:
Click the color again to turn on the display and activate the instance again.

4. After you have selected a target and chosen the Profiler instances that you want to see, click **Capture**.

After the capture begins, data begins to populate the channels.

5. To stop the data capture, click **Stop Capture**.

6. When prompted, save the captured data to disk. Profiler saves the data in a binary format file with a `.drl` extension, reloads the data from disk, and switches to inspection mode.

   **Note**

   If you do not save the data, it will be discarded.

**Inspecting Data**

You can use profiler to examine the data that you have captured.

**To inspect captured data**

1. In Profiler, click **File**, **Open Data**, or press **Ctrl+O**:
2. Navigate to the `.drl` file that contains your saved data and open it.

The main screen of the Profiler provides an overview of the channels of system information. This example uses a file that has 1162 frames of data:

You can use this main view to discover anomalies across channels, or to examine particular areas of interest at a high level.

When you open the main window, the scroll box at the bottom is on the right because the playback stopped at the end of the captured data.

Notice the red vertical line on the right.

3. Click in the channels area of the window.
The red vertical line moves to where you clicked. The frame indicator shows the new position of the red line. You can place the red line, which is called the scrubber, on any frame that you want to examine in detail. For finer control over the position of the scrubber, you can enter a number in the Frame indicator.

The scrubber moves accordingly.

4. To view detailed information about a frame on which the scrubber rests, click the Detailed Profiling Information icon next to the profiler instance whose data you would like to see:

Profiler instance information appears in a detail window.
Individual profilers present details in different ways, so their detail windows can look different. For information on system-specific detail windows in Profiler, see Using Profiler for Networking (p. 1937), Using the Profiler for CPU Usage (p. 1947), and Using Profiler for VRAM (p. 1951).

5. To return to capture mode from inspection mode, click the **LIVE** tab.
Playing Back Data

You can mark and play back a subset of your captured data.

Notice that after you moved the scrubber the first time, a yellow vertical line appeared on the right at the end of the data:

This yellow marker is movable and marks the end of your desired playback range. By default, it is at the end of the captured data but may be obscured by the red scrubber.
1. Scroll the window all the way to the left, to the beginning of the capture range.

![Profiler interface](image)

Now a yellow marker also appears at the beginning of the data. You can use these two yellow markers, which by default are at the beginning and end of the capture range, to restrict the range of playback to an area of data that you are interested in. You will use these shortly.

If you have many frames of data (as in this example), the initial view does not show you all frames by default.

2. To see all frames at once, click the **Frame Count Selector**, which determines the number of frames visible, and choose **All frames**:
Now you can see the entire range of captured data, with the yellow markers at the beginning and at the end:
3. Drag the two yellow markers to an area of data that you want to play back. You can ignore the position of the scrubber for now.
4. Click **Play** to start the playback:

As the data plays back, the scrubber moves from the first yellow marker to the second, and then loops back to the first.

Here are some tips to keep in mind:

- If the playback speed is too fast (the default is 60), use the **Playback Speed** option to adjust it from 1 through 60.
- If you click a location in the playback window during playback, the playback stops and moves the scrubber to the location that you clicked.
- You can place the scrubber on a frame that you are interested in and click the detail button for a profiler instance to see the detail window for the frame.
- For greater convenience and visibility, leave the profiler instance detail window open to see the data change in the detail window as the scrubber loops between markers.
5. Click **Stop** to stop the playback.

**Exporting Data**

Some Profiler instances have an export option that you can use to save data to a *.csv* file.

**To export data from a Profiler instance to a *.csv* file**

1. Click the **Save to CSV** icon for the Profiler instance whose data you want to save:

   ![Save to CSV icon](image)

   **Note**
   
   Not all profilers have the data export option.

2. To choose the fields that you want to export, click **Customize** in the export dialog box:

   ![Customize dialog box](image)
Creating and Using Annotations

Profiler is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In Profiler, annotations are a convenient way of highlighting per-frame log information from the data captured from your application. After you learn how annotations are used in Profiler, you can modify your application so that they appear in Profiler.

Topics

- Using Annotations (p. 1934)
- Creating Annotations (p. 1935)
- Viewing Annotations in Trace Messages Profiler (p. 1936)

Using Annotations

Annotations in the Lumberyard Profiler tool flag frames in your captured data that have associated log information. By default, annotations are turned off.

To use annotations

1. To turn on annotations in the Lumberyard Profiler tool, click Configure Annotations:

![Configure Annotations dialog box]

The Configure Annotations dialog box contains a list of available annotations and their display colors. For information on creating annotations for your application, see Creating Annotations (p. 1935).

2. When you select an annotation in the dialog box, a marker and line of the same color appears in the channel display. Note that you might have to scroll horizontally to find the marker.
3. To display details for the annotations that occurred on a frame, pause your pointer on an annotation marker. In the example image, IP addresses have been redacted out.

Creating Annotations

To create an annotation, you add one or more lines of C++ logging code to your application. The added code instructs Lumberyard's logging system to include the logging information that you specify as a part of your capture. Lumberyard transforms the logged messages into annotations for you. Then, in Profiler, when you click Configure Annotations, you actually choose which system's annotations are displayed (for example, GridMate or MultiplayerProject).

To create an annotation, place a line of C++ code like the following in your application:
The first parameter is the window (that is, system) of the trace (in this case, GridMate), and the second is the content of the trace that will be shown as the annotation.

The example results in the following annotation text:

GridMate - Connection <IP_Address>|64090 => <IP_Address>|57455 (Client) (Connections=1)!

The text displays in Profiler like this:

![Profiler annotation example](image)

**Alternatives to AZ_TracePrintf**

In your code, instead of using AZ_TracePrintf, you can use AZ_Error or AZ_Warning, depending on the degree of severity that you want. AZ_TracePrintf always logs a message, but is of the lowest concern from an inspection viewpoint.

The following example uses AZ_Error:

```cpp
if (networkTableContext.ReadValue(elementIndex,forcedDataSetIndex))
{
    AZ_Error("ScriptComponent",forcedDataSetIndex >= 1 && forcedDataSetIndex <= ScriptComponentReplicaChunk::k_maxScriptableDataSets,"Trying to force Property (%) to an invalid DataSetIndex(%d).",scriptProperty->m_name.c_str(),forcedDataSetIndex);
    if (forcedDataSetIndex >= 1 && forcedDataSetIndex <= ScriptComponentReplicaChunk::k_maxScriptableDataSets)
    {
        networkedTableValue.SetForcedDataSetIndex(forcedDataSetIndex);
    }
    else
    {
        AZ_Error("ScriptComponent",false,"Trying to force Property (%) to unknown DataSetIndex. Ignoring field." , scriptProperty->m_name.c_str());
    }
}
```

In the example, if either of the error conditions occur, an annotation is created.

**Viewing Annotations in Trace Messages Profiler**

Another way to confirm that your annotations are in place is by using the Trace Messages profiler.

In the Profiler Logging channel, click the Trace messages profiler details icon to see the logging systems currently in place:
The **Trace messages** profiler instance shows all the trace messages that were generated from the start of the capture to the currently analyzed frame. Messages are shown with the oldest message at the top and the newest message at the bottom:

You can use the **Window Filter** to show the system and/or **Message Filter** to show the message text that you are interested in.

The following example, filtered by "GridMate", shows the message specified by the line of code that was added to the application:

**Using Profiler for Networking**

Profiler is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Lumberyard Profiler tool to examine how your game uses network bandwidth, including its GridMate carrier connections and replica activity. You can use network-specific profilers to drill down further into the activity of specific replica chunks, RPCs, and data sets.

**Prerequisites**

This topic assumes familiarity with Lumberyard networking and the Lumberyard Profiler tool. For information on Lumberyard networking, see Using Lumberyard Networking (p. 1990). For an introduction to the Profiler tool, see Profiler (p. 1920).

**Topics**

- Carrier Profiler (p. 1938)
- Replica Activity Profiler (p. 1939)
Carrier Profiler

The Profiler tool has a GridMate channel with Carrier and Replica activity profiler instances. You can use the Carrier profiler detail view to examine the bandwidth usage of a selected GridMate carrier connection.

To open the detail view for the Carrier profiler

- Click the Detailed Profiling Information icon for Carrier in the GridMate channel:

The Carrier profiler detail view resembles the following image:

![Carrier Profiler Detail View](image)

This view uses all of the data supplied in the capture session to show an overview of the bandwidth usage through the GridMate carrier for the selected connection. It includes the following information:

- **Total Sent/Total Received** – The total number of bytes sent and the total number of bytes received on the selected connection.
• **User Data Sent/User Data Received** – The user data sent and the user data received on the selected connection. This data does not include the overhead associated with carrier or connection maintenance.

• **Packets Sent/Packets Received** – The number of packets sent and the number of packets received.

• **Return Trip Time (Latency)** – How many seconds the packets took to make a return trip.

**Replica Activity Profiler**

You can use the Replica Activity profiler to see how much replica bandwidth your application is using.

**To open the Replica Activity profiler**

• Click the **Detailed Profiling Information** icon for **Replica activity**.

The Replica Activity profiler detail view has a pair of **Bytes Sent** and **Bytes Received** graphs at the top, a toolbar to control the display in the middle, and a table of replicas at the bottom:
This view is useful for discovering how much bandwidth a single entity is using, and for finding what information is synchronized in response to particular events for particular entities.

Two main detail views are available for replica activity: **Replica** and **Chunk Type**. The view defaults to **Replica**, but Profiler remembers your most recent choice and uses it the next time you view replica activity details.
Using Replica View

In replica view, the table shows how much data each replica used in a given frame.

To change the view to Replica

- In the toolbar, choose Replica.

Each replica is represented by its associated color in the graphs above the toolbar. Replica view includes the following information:

- **Bytes Sent** – Shows bandwidth usage in bytes sent by the object for a particular frame.

- **Bytes Received** – Shows bandwidth usage in bytes received by the object for a particular frame.

To display or hide an individual line in the graph

- Double-click the associated row in the tree.

The toolbar also offers the following options:

- **Hide All** – Hides the line graphs of all replicas in the table.

- **Show All** – Shows the line graphs for all replicas in the table.

- **Hide Selected** and **Show Selected** – Use Ctrl+click to select individual replicas in the table, and then click **Hide Selected** or **Show Selected** to hide or show the graphs for the replicas that you selected.

- **Display Range** – Determines the number of frames that are shown in the graph, with the currently selected frame in the center. You can use this option to zoom in or out on the data.

To display replica chunk details for a particular replica

- Click its details icon.

The graph shows the bytes sent and received for a replica chunk, data set, and RCP:
You can use this details view to see what replica chunk types a given replica is using, how much data each replica chunk type is using, and how much bandwidth individual data sets and RPCs are using.

**Tip**
Click **Expand All** to list all replica chunks in all replicas, and every data set and remote procedure call (RPC) in each replica chunk:

</table>
To use the Replica Activity profiler tree view

- Do either of the following:
  - Select a row to highlight its corresponding line in the graph.
  - Double-click a row to display or hide the graph for the row.

The following information is available:

- **Display Name** – The debug name associated with the corresponding row of the table.

- **Sent Bytes** – The number of bytes sent for an item, including all information sent by children of the item.

- **Received Bytes** – The number of bytes received by an item, including all information received by children of the item.

**Chunk Type View**

Chunk type view shows you how much data each chunk type used in a given frame. The view is useful for seeing how much information a particular system might be using across all entities.

**To change the view to Chunk Type**

- In the toolbar on the main detail page for Replica activity, choose **Chunk Type**.

The chunk type view shows how much data a particular replica chunk type is using in a given frame:
To inspect chunk type details

- Click the details icon for the chunk type:

  The details window shows which replicas are using a chunk type's bandwidth, how much data they are using, and how much data the individual data sets and RPCs are using:
As before, you can expand the items in the tree to see detailed information about each:
Using the Profiler for CPU Usage

Profiler is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The CPU profiler gathers usage statistics about how long a function or method executed, how many times it was executed, who called it, and how much of a frame was spent on it. You can combine this information to get a systemwide view of usage, or isolate particular systems by filtering for specific threads.

To use the CPU profiler

1. To open the detail view for the CPU profiler, click the **Detailed Profiling Information** icon for the CPU profiler instance.
The CPU details view has a graph of CPU usage, a toolbar, and a tree view of calls made in a frame. Each call in the tree view has the same color as its corresponding line in the graph:

2. Pause your mouse on a line in the graph to see the call that the line represents and to display the specific value for the graph at the area near the cursor.

3. To show or hide the line graph of a row in the tree, double-click the row.

Understanding the Tree View

The CPU profiler tree view represents a call hierarchy of profiler log points (called hooks). A profiler hook that is active while another call is active shows as a child of the first hook. The hooks act as a stack: the last hook that was pushed onto the stack is the parent of the hook that was pushed onto the stack before it. The tree view has the following information:

Function

The function declaration where the profiler data point was generated.
Comment
A user-defined message that distinguishes specific events in the same function.

Excl. Time (Micro)
(Exclusive time) The time, in microseconds, spent executing this function and no other functions called by this function.

Incl. Time (Micro)
(Inclusive time) The time, in microseconds, spent executing this function and other functions called by this function.

Excl. Pct
(Exclusive percent) Exclusive time represented as a percent of total run time.

Incl. Pct
(Inclusive percent) Inclusive time represented as a percent of total run time.

Calls
The number of calls to this function.

Child Time (Micro)
The time, in microseconds, that functions that were called by this function took to execute.

Total Time (Micro)
A running total of the time, in microseconds, that was spent inside of this function.

Child Calls
How many functions this function called.

Total Calls
The running total of how many times this function was called.

Thread ID
The thread on which this function was executed

Controlling the Display
You can use the toolbar to control how the captured CPU data is displayed:

| Hide Selected | Show Selected | Hide All | Show All | Invert | Expand Tree |

Hide Selected
Hide the graph of the rows selected in tree view.

Show Selected
Show the graph of the rows selected in tree view.

Hide All
Hides the graph of all rows in the tree view.

Show All
Shows the graphs of all rows in the tree view.

Invert
Shows graphs for all rows in the tree view that are hidden; hides the graphs of all rows in the tree view that are showing.
**Expand Tree**

Expands all rows in the tree view hierarchy.

The right side of the toolbar offers more options:

- **All Threads**

  Use the thread selector to control which threads are shown in the tree view and in the graph:

  ![Thread Selector]

- **Incl. Time**

  Use this selector to choose the meaning of the time displayed.

  - **Incl. Time** – (Inclusive time) The time spent in this function inclusively.
  - **Excl. Time** – (Exclusive time) The time spent in this function exclusively.
• **Calls** – The number of times this function was called in the frame.
• **Acc. Time** – (Accumulated time) The total amount of time spent in this function up to the frame being analyzed.
• **Acc. Calls** – (Accumulated calls) – The total number of times this function was called up to the frame being analyzed.

<number> Frames

Use this selector to choose how frames of history are displayed in the graph:

![Frames selector](image)

Delta

Unused option.

Autozoom

When selected, maintains the approximate zoom level (number of frames displayed) whenever the graph changes.

Flat View

Flattens the tree of function calls (removes the hierarchical indentation), as in the following image:

![Function tree](image)

**Using Profiler for VRAM**

Profiler is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
You can use the video memory profiler (VRAM profiler) to determine which resources are contributing most to runtime VRAM usage in your game.

The VRAM profiler records the amount of video memory used by a game, including how many memory deallocations and allocations occurred during the capture. This latter information is useful in tracking down rendering performance bottlenecks.

You can also use the memory usage information from VRAM profiler to determine your game's minimum PC GPU (graphics processing unit) memory requirements, or to determine whether your game will run out of memory on a console or mobile device.

**Topics**
- Notes (p. 1952)
- Understanding the Captured Data (p. 1952)
- Inspecting the Data (p. 1953)

**Notes**

The VRAM profiler has the following attributes:

- The VRAM profiler has no graph view or tree view.
- The only supported export format is .csv. For steps on saving Profiler data to a .csv file, see Exporting Data (p. 1933).
- Lumberyard uses a variety of memory pooling schemes, so the actual allocated amount of VRAM is slightly more than what is reported.

**Understanding the Captured Data**

The following image shows how your saved .csv file appears in a spreadsheet application:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Category</td>
<td>Number of Allocations</td>
<td>Memory Usage</td>
</tr>
<tr>
<td>2</td>
<td>Texture</td>
<td>449</td>
<td>440542078</td>
</tr>
<tr>
<td>3</td>
<td>Buffer</td>
<td>1034</td>
<td>14778088</td>
</tr>
<tr>
<td>5</td>
<td>Resource Name</td>
<td></td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>$RT_ShadowPool</td>
<td>67108864</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>CachedShadowMap_0</td>
<td>35515592</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>$AutoDownload_4</td>
<td>16777216</td>
<td></td>
</tr>
<tr>
<td>9</td>
<td>$AutoDownload_3</td>
<td>16777216</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td>$AutoDownload_5</td>
<td>16777216</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>HeightMapAO_Depth_1</td>
<td>11184800</td>
<td></td>
</tr>
<tr>
<td>12</td>
<td>HeightMapAO_Depth_0</td>
<td>8388608</td>
<td></td>
</tr>
</tbody>
</table>

The captured data contains essentially two tables of information: an overview of memory allocation and usage (divided between texture and buffer assets), and a list of resources with the amount of VRAM that was allocated for each during the capture.

Detailed information about each heading follows.

**Category**

Indicates the type of allocation:
- **Texture** – Includes texture assets, dynamically generated textures, and frame buffers.
- **Buffer** – Includes vertex and index buffers, constant buffers, and other runtime buffers.
Number of Allocations

The number of allocation events recorded. When the capture starts, all active allocations are sent to the profiler as a starting number. Any new allocations or deallocations will increase or decrease this number.

Memory Usage

The total size, in bytes, of VRAM used.

Resource Name

The name and full path of the allocated resource. A resource name without a path usually denotes a runtime engine resource.

VRAM Allocation Size

The size, in bytes, of the allocation.

Inspecting the Data

When you first open the spreadsheet, the data is unordered. To sort the data, you can use a spreadsheet application:

To quickly and easily identify the largest offending assets or runtime resources, sort by VRAM Allocation Size in descending order, or by Resource Name from A to Z:
Negative VRAM Allocation Sizes

Some fields may have a negative number for **VRAM Allocation Size**, as in the following image:

<table>
<thead>
<tr>
<th>Resource Name</th>
<th>VRAM Allocation Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConstantBuffer</td>
<td>-256</td>
</tr>
</tbody>
</table>

These important occurrences show that a VRAM deallocation event occurred during the capture. If you observe a large number of deallocation entries over a short time period, your game might be experiencing a significance decrease in performance. To improve your game's performance across all operating systems, you should aim to have as few idle per-frame VRAM allocations and deallocations as possible.

**Why Some Textures Are Not Reported in the .csv File**

If you see a lot of allocations named `StreamingTexturePool` or entries like `$TexturePool_9_0000000002C59248`, this means the texture streaming system is active. The texture streaming system allocates all textures by default into a variety of cached texture pools. The VRAM profiler reports the size of the active streaming pools and not the names of the actual texture assets. To obtain the names and sizes of the allocated and loaded textures, set `r_TexturesStreaming=0` in your system configuration file, and then do another capture. This setting disables the texture streaming system and causes the true sizes of the texture allocations to be reported.

**Note**

In this situation, it is advisable to do two captures: one with `r_TexturesStreaming` enabled, and one with it disabled. When texture streaming is enabled, your VRAM usage is less because of texture eviction and the loading of lower resolution mipmap levels. The memory reporting is more accurate when texture streaming is enabled, but you get a much clearer view of your worst-case memory usage when texture streaming is disabled.

**Using GridHub**

GridHub is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
diagnostic and debugging tools Profiler.exe or LuaIDE.exe (located in the \dev\Bin64 directory), GridHub launches as a background process in Windows and enables their functionality. For more information about Profiler, see Profiler (p. 1920).

**Note**
Because GridHub listens for connections on the loopback address (127.0.0.1), you must run GridHub on the same computer as the target application.

**Topics**
- Registering an Application in GridHub (p. 1955)
- Viewing and Configuring GridHub (p. 1955)
- Troubleshooting GridHub (p. 1958)

**Registering an Application in GridHub**

To register an application in GridHub so that Profiler can capture information from the application, add AzFramework::TargetManagementComponent to the application's SystemComponent.

**Note**
Lumberyard's built-in applications already have this component added by default.

**Viewing and Configuring GridHub**

When you launch Profiler.exe or LuaIDE.exe, GridHub starts automatically and is represented by a globe icon in the Windows taskbar.

**To view and configure GridHub**

1. In the Windows taskbar, right-click the globe icon and choose **Show**:

![Show Icon](image)

The GridHub window has a configuration bar, a connections pane, and pane for viewing log messages:
2. You can use the configuration toolbar to view or change GridHub configuration:

The toolbar options are as follows:

**Session port** – Specifies the port on which GridHub listens for discovery requests.

**Connection slots** – Specifies the maximum number of applications that can be connected concurrently to GridHub.

**Hub name** – The name of your hub. By default, this is the name of the local computer.

**Note**

The name of the hub must be the neighborhood name to which the TargetManagementComponent connects.

**Enable Disconnection Detection** – Specifies whether the connection to GridHub is terminated when the source fails to respond.

**Add to Windows startup folder** – Specifies whether GridHub starts automatically when Windows starts.
Log activity – Starts or stops logging.

Start/Stop – Starts or stops GridHub. When GridHub is off, no connections are discovered or maintained.

3. When GridHub and your target application are active, your target application appears in the GridHub Connections list:

The columns in the Connections list provide the following information:

ID – The identifier of the connected application.

Name – The name of the connected application.

Connection ID – The identifier of the connection between GridHub and the application.

IsHost – Whether or not the connection is the connection host

IsLocal – Whether or not the connection is local.

IsReady – Whether or not the application is ready to handle further connections.

4. Use the Output window to see the log messages that GridHub generates as it manages connections:

When GridHub is terminated, the connections it established are also terminated.
Troubleshooting GridHub

If you experience difficulty using GridHub, check the following:

- Make sure that the neighborhood name in TargetManagerComponent is the same as the one in GridHub.
- Make sure that the port that GridHub is listening on is the same port as the one specified for TargetManagementComponent.
- Make sure that all applications are running on the same computer. The GridHub socket is bound to the loopback address 127.0.0.1.

Using AZ Test Scanner

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The AZ test scanner is a tool for running unit tests that are built into Lumberyard libraries and executables. This tool simplifies testing by automatically finding libraries and executables to test. It also provides flexibility for programmers to focus on testing the parts of Lumberyard that they care about.

The AZ test scanner has two components:

- An AZ test runner executable that loads libraries to test and capture the test results
- An AZ test Python module that performs the scanning and reporting functions

Creating Unit and Integration Test Builds

Unit and integration tests are not included in Lumberyard builds by default as they increase the overall size of a game project. Test code can also have unexpected effects on performance. To build components with tests included, you can use a special test variant that works with each configuration.

To create test builds, use the Waf build system (p. 63) in the same way that you create regular builds. The only difference is that you add test to the platform. You can create a test build on Windows using one of the following examples:

```bash
// Build with tests using debug configuration. Outputs to the Bin64vc141.Debug.Test folder.
lmbr_waf.bat build_win_x64_vs2017_debug_test -p all

// Build with tests using profile configuration. Outputs to the Bin64vc141.Test folder.
lmbr_waf.bat build_win_x64_vs2017_profile_test -p all

// Build with tests using debug configuration. Outputs to the Bin64vc142.Debug.Test folder.
lmbr_waf.bat build_win_x64_vs2019_debug_test -p all

// Build with tests using profile configuration. Outputs to the Bin64vc142.Test folder.
lmbr_waf.bat build_win_x64_vs2019_profile_test -p all
```

Note

Only Windows debug and profile builds are supported for testing. Other platforms are not supported. Release builds are not supported either.
Running Unit and Integration Test Builds

A completed test build includes the file `AzTestRunner.exe` in the `\Bin64\vc141\Test` folder. Although you can use this to run tests, we recommend that you use the test scanner that uses `AzTestRunner.exe` in an automated manner.

You have two ways to use the scanner:

- Include the AZ test module in your Python path: `python -m aztest`.
- Use the `lmbr_test.cmd` script located in the Lumberyard `\dev` folder. This automatically includes the AZ test module in your Python path and sends all script parameters to the module.

The following example uses the `lmbr_test.cmd` scripts. The scanner has several options but only requires one parameter to operate: the build directory to scan. You can use the following command to scan your entire test build:

```
// Scan entire test build and run all found tests
lmbr_test.cmd scan --dir Bin64\vc141\Debug\Test
```

**Note**
The default scan tests libraries only. It does not attempt to test any executables it finds. This is because executables that are not set up to run tests interrupt the scanner until you close the application.

The scanner produces three types of files. All files are created in the current working directory from which the scanner is called:

- The `aztest.log` file that contains a log of all test output
- Several `.xml` files that contain the test results of each library and executable that has tests, time stamped by default
- An `.html` file that contains a summary of the test results from the entire scan, time stamped by default

The full list of options is shown as follows:

The scanner runs only unit tests by default. This is because unit tests are designed to be fast and do not rely on engine resources. To run integration tests instead, use the `--integ` flag when calling the scanner:

```
// Scan test build and run integration tests on CrySystem.dll
lmbr_test.cmd scan --dir Bin64\vc141\Debug\Test --only CrySystem.dll --integ
```

**Note**
For best results, run integration tests on a single library or use an allow list. Scanning the full build might take hours to complete.

<table>
<thead>
<tr>
<th>Option</th>
<th>Required?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--dir, -d</td>
<td>Yes</td>
<td>The directory to scan for tests.</td>
</tr>
<tr>
<td>--runner-path</td>
<td>No</td>
<td>Path to the AZ test runner executable (the default is to look in the directory specified by --dir).</td>
</tr>
</tbody>
</table>
Using AZ Test Scanner

<table>
<thead>
<tr>
<th>Option</th>
<th>Required?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--add-path</td>
<td>No</td>
<td>Adds path to system path before running tests; used for resolving library or executable dependencies.</td>
</tr>
<tr>
<td>--output-path</td>
<td>No</td>
<td>Sets the path for output folder prefix (the default is <code>\dev\TestResults</code>).</td>
</tr>
<tr>
<td>--integ, -i</td>
<td>No</td>
<td>If set, runs integration tests instead of unit tests.</td>
</tr>
<tr>
<td>--no-timestamp</td>
<td>No</td>
<td>If set, removes the time stamp from output files.</td>
</tr>
<tr>
<td>--wait-for-debugger</td>
<td>No</td>
<td>If set, tells the AZ test runner executable to wait for a debugger to be attached before running tests.</td>
</tr>
<tr>
<td>--bootstrap-config</td>
<td>No</td>
<td>Path to a JSON configuration file for bootstrapping applications required by libraries.</td>
</tr>
<tr>
<td>--limit, -n</td>
<td>No</td>
<td>Sets a limit for the maximum number of modules to scan.</td>
</tr>
<tr>
<td>--only, -o</td>
<td>No</td>
<td>Sets a filter to run tests on only the specified library or executable name.</td>
</tr>
<tr>
<td>--whitelist-file</td>
<td>No</td>
<td>Path to a new line-delimited file used as an inclusion list. The new line-delimited file allows for regular expressions when matching.</td>
</tr>
<tr>
<td>--blacklist-file</td>
<td>No</td>
<td>Path to a new line-delimited file used as an exclusion list. The exclusion list takes precedence over the inclusion list. The new line-delimited file allows for regular expressions when matching.</td>
</tr>
<tr>
<td>--exe</td>
<td>No</td>
<td>If set, causes the scanner to call executables for testing. (The default is to test only libraries.)</td>
</tr>
</tbody>
</table>

The scanner also accepts additional parameters that are passed to the testing framework. For Lumberyard, GoogleTest, and GoogleMock for C++ are used for unit testing. You can enter parameters in the scanner command line as shown in the following example:

```
// Scan CrySystem.dll and shuffle the test order before running
lmbr_test.cmd scan --dir Bin64vc141.Test --only CrySystem.dll --gtest_shuffle
```

The scanner can also be called as a chained command using Waf. This means that you can build tests and run them using a single command line. The Waf command `run_tests` calls the scanner on the most recent build folder. For example:

```
// Build a debug test build and then run tests in it
lmbr_waf.bat build_win_x64_vs2017_debug_test -p all run_tests
```

The `run_tests` command automatically points to the `\Bin64vc141.Debug.Test` folder to scan. It also uses the `all` option for inclusion. The build step does not require the use of `run_tests`; it always matches the last build. You can also send all of the scanner parameters through using `--test-params:

```
// Run tests on the last build with additional parameters (use quotes to capture as string)
```

Version 1.28
1960
Writing Tests for AzTest

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Automated testing is important for any game project. To perform automated testing in Lumberyard, you can use AzTest and the AZ test scanner. This document shows you how to write the tests to build and run. For information on building and running unit and integration tests, see Using AZ Test Scanner (p. 1958).

Lumberyard and AzTest use the GoogleTest and GoogleMock frameworks for unit and integration tests. When you write your tests, we recommend that you consult the corresponding documentation.
Testing code with AzTest has three steps: Configure your module for testing, write the tests, and define global environments.

**Configuring Your Module for Testing**

If you want to add tests to a module or a gem that is included with Lumberyard, the configuration has already been done for you and you can skip this step. If you want to add tests to non-Lumberyard modules, projects, or tools, then you must configure them to use AzTest.

All modules and libraries in Lumberyard must be configured for use with Waf. If you are unfamiliar with configuring build modules in Waf, see Adding a Build Module (p. 125) before continuing.

**To configure your module for Waf**

1. Create a `.waf_files` content file that lists the files for the test. A separate `.waf_files` content file for test files keeps the test files from being compiled in normal builds. Your file name should make it clear that it contains only test files. Existing Lumberyard modules and gems use the naming convention `<module_name>_test.waf_files`.

   The following example shows a `.waf_files` file for a HelloWorld module.

   ```
   {
     "none":
     {
       "Tests":
       [  
        "HelloWorldTestMain.cpp"
       ]
     }
   }
   ```

   After you create the file, you must reference it in your module's `wscript`. To specify that the file is intended only for test builds, you must add `test_all_file_list` to the `wscript` configuration, as in the following example.

   ```
   # HelloWorld wscript
   def build(bld):
     bld.CryEngineModule(
       target    = 'HelloWorld',
       vs_filter = 'Engine',
       file_list = 'helloworld.waf_files',
       use       = ['AzCore'],

       # Testing
       test_all_file_list = 'helloworld_test.waf_files'
     )
   ```

2. Create a test hook for AZ Test Scanner. How you create a test hook depends on whether you want to build a dynamic library or an executable file. Static libraries are not currently supported for testing.

   - **To create a test hook for a dynamic library**

     Because the tests built into a dynamic library are not exposed, you must expose a separate test function for the AZ test scanner. To expose the test function, use a convenience macro that AzTest provides in a test-only * _test.waf_files file, as in the following example.

     ```
     // HelloWorldTestMain.cpp
     #include <AzTest/AzTest.h>
     ```
AZ_UNIT_TEST_HOOK(); // Runs unit tests
AZ_INTEG_TEST_HOOK(); // Runs integration tests

For differences between unit tests and integration tests, see Creating Unit Tests and Integration Tests (p. 1964).

- **To create a test hook for an executable file**

To build an executable file, you must expose a test function and modify the main function of the executable to run tests instead of normal program functions. The test function informs the AZ test scanner that tests have been included in the executable and that it is safe to continue.

The following example shows how to modify your main function:

```cpp
// Main.cpp
#if defined(AZ_TESTS_ENABLED)
#include <AzTest/AzTest.h>
DECLARE_AZ_UNIT_TEST_MAIN()
#endif

int main(int argc, char* argv[])
{
#if defined(AZ_TESTS_ENABLED)
INVOKE_AZ_UNIT_TEST_MAIN();
#endif
// Rest of your program
}
```

**Note**
Because the AZ_TESTS_ENABLED definition is defined only in test builds, it is a convenient definition to use in test-only code.

3. If necessary, use the `use` parameter in the `wscript` file to link AzTest to the module.

**Note**
In most cases, you do not have to perform this step. Waf automatically links AzTest in test builds for almost all build modules, including gems. The LumberyardApp build module is not linked automatically. If you build a Lumberyard app, you must link it manually.

As with the `*_test.waf_files` files, you must use AzTest only in a test build. To specify this when linking, add `test_all_use` to the `wscript` configuration, as in the following example.

```wscript
# HelloWorld wscript
def build(bld):
    bld.CryEngineModule(
        target    = 'HelloWorld',
        vs_filter = 'Engine',
        file_list = 'helloworld.waf_files',
        use       = ['AzCore'],

        # Testing
        test_all_file_list = 'helloworld_test.waf_files',
        test_all_use       = ['AzTest'],
    )
```

After you have performed these three steps, you can create a test build and test it with the AZ test scanner. Your HelloWorld library or executable should appear in the report, although at this point it does not have tests.
Creating Tests

After your module is configured for testing and visible to the AZ test scanner, you can start writing tests for it. Detailed information about writing tests is available in the GoogleTest and GoogleMock documentation. The following information describes characteristics specific to AzTest.

Creating a Simple Example Test

When using AzTest to write tests, include only the `AzTest.h` file in your test files instead of GoogleTest and GoogleMock, as in the following example.

```
// HelloWorldTests.cpp
#include <AzTest/AzTest.h>
#include "HelloWorld.h"

TEST(HelloWorldTests, HelloWorld_ReturnsHelloWorld)
{
    // Call HelloWorld() and compare it to the expected C-string
    ASSERT_STREQ("Hello World!", HelloWorld());
}
```

Creating Unit Tests and Integration Tests

Unit tests are designed to be run in isolation. Unit tests are expected to pass without requiring Lumberyard's engine systems or other assets. Integration tests are designed to be run with the game engine and have access to the engine's systems or assets.

To prevent unexpected failures, the different kinds of tests must be kept separate. Lumberyard does this by providing different hooks for each kind of test. Declare the tests as unit or integration, and call the AZ test scanner accordingly.

For tests that do not require fixtures, simply replace the `TEST` macro with `INTEG_TEST`, as in the following example.

```
// HelloWorldTests.cpp
#include <AzTest/AzTest.h>
#include "HelloWorld.h"

INTEG_TEST(HelloWorldTests, MessageOfTheDay_ReturnsCurrentMessageOfTheDay)
{
    // Call MessageOfTheDay() and compare it to the expected C-string
    // This is an integration test because MessageOfTheDay is stored in a database
    MessageDatabase messageDatabase = HelloWorld::GetTestMessageDatabase();
    ASSERT_STREQ("This is your message for the day!", messageDatabase.MessageOfTheDay());
}
```

For tests that do use fixtures, add the `Integ_` prefix to the fixture name to indicate that it is to be used only for integration tests, as in the following example.

```
// HelloWorldTests.cpp

class Integ_MessageDatabaseTests : public ::testing::Test
{
    protected:
        void SetUp() override
        {

```
m_messageDatabase = HelloWorld::GetTestMessageDatabase();
}
MessageDatabase m_messageDatabase;

TEST_F(Integ_MessageDatabaseTests, MessageOfTheDay_ReturnsCurrentMessageOfTheDay)
{
    ASSERT_STR("This is your message for the day!", messageDatabase.MessageOfTheDay());
}

**Note**

Fixtures cannot be shared between unit and integration tests. If you want to use the same fixture for both kinds of tests, create a base fixture and subclass for each type of test.

### Using Global Environments

It is often useful to create some global variables or mocks for testing the module. In Lumberyard, this might mean creating memory allocators or a test system environment. Because AzTest extends the support that GoogleTest provides, you must use the AzTest environments.

The following example shows how to define an AzTest global environment:

```cpp
// HelloWorldTestMain.cpp
#include <AzTest/AzTest.h>

class HelloWorldEnvironment : public AZ::Test::ITestEnvironment
{
protected:
    void SetupEnvironment() override
    {
        // Environment setup here
    }
    void TeardownEnvironment() override
    {
        // Environment teardown here
    }
}
```

To initialize the environments, use the test hooks that were mentioned previously. Because the macros are variadic, you can initialize as many environments as you require. The following example initializes the environment in the previous example:

```cpp
// HelloWorldTestMain.cpp
#include <AzTest/AzTest.h>

class HelloWorldEnvironment : public AZ::Test::ITestEnvironment
{
protected:
    void SetupEnvironment() override
    {
        // Environment setup here
    }
    void TeardownEnvironment() override
    {
        // Environment teardown here
    }
}
AZ_UNIT_TEST_HOOK(new HelloWorldEnvironment);

**Note**
You must dynamically allocate environments before you use the macro. This gives you full control over how environments are created at runtime. The order of environments is also significant. Environments earlier in the list are initialized earlier and removed later. This is important if a global environment depends on another environment that already exists.

## Debugging Issues

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard provides the following built-in debugging and profiling tools that you can use to locate and fix performance issues.

- **Character skeleton debugging** – Use the `p_draw_helpers` console variable to debug character skeleton issues.
- **Cinematics debugging** (p. 1632) – Debug cinematics issues.
- **Mannequin debugging** – Debug Mannequin system issues.
- **Particle debugging** (p. 1578) – Debug particles.
- **Vegetation debugging** (p. 1313) – Debug vegetation objects.

### Topics

- Crash logging (p. 1966)
- Using Console Debug Views (p. 1967)
- Using the `sys_asserts` Console Variable (CVAR) (p. 1968)

### Crash logging

Logging and reporting for crashes that occur in the Lumberyard Editor or your Lumberyard game can be turned on by modifying the `sys_dump_type` console variable. The type of crash log information generated depends on the value:

- **0** – Disable crash reporting.
- **1** – Generate a stack trace on crash
- **2** – Generate a stack trace and limited variable information.
- **3** – Full crash dump of the stack trace, variable information, and all memory.

Crash logs are written to the `Cache\project_name\platform\user\log\error.log` file.

By default, only the call stack for the main thread is in a crash dump. In order to get the stack trace of auxiliary threads, set the `sys_dump_aux_threads` console variable to 1.
Using Console Debug Views

The viewport window displays debugging information by default when you are in gameplay mode (Ctrl +G). You can toggle this information on or off by pressing the tilde (~) key. Use the following console variables and values to generate viewing modes in the viewport that are useful for debugging.

- **e_Camerafreeze 1** – Freezes the camera to see what is rendered from the camera's point of view and what is occluded. Also useful for debugging object culling and LOD.
- **e_DefaultMaterial 1** – Applies a uniform, flat, gray material to every surface in the level.
- **e_memoryProfiling 1** – Prints onscreen statistics for the amount of GPU memory that textures and buffers use.
- **e_TerrainBBoxes** – Displays terrain bounding boxes.
- **p_debug_joints 1** – Shows the mass of objects in kilograms and the joint that is linked to the object. To display joints, you must first enable **p_draw_helpers 1**.
- **p_draw_helpers 1** – Shows physics proxy meshes in addition to the render geometry.
- **r_DisplayInfo 0** – Disables the debugging text.
- **r_DisplayInfo 1 | 2 | 3 | 4** – Enables various levels of debugging text. Displays memory consumption, frame rate, triangle count, visible light sources, and drawcall count. Use a value of 2 to display more detailed information. Use a value of 3 to display only frames per second (FPS) and frame time in milliseconds.
- **r_wireframe 1 | 2** – Use a value of 1 to draw the level in wireframe mode. Use a value of 2 to draw the level in vertex mode. Both include the objects that are hidden from view.
- **r_ShowLines 2** – Overlays the wireframe only on the front-facing geometry. Anything behind this geometry isn't rendered.
- **r_TexBindMode 6** – Applies a uniform, flat, gray material with normal map information to every surface in the level.

### VRAM Usage: 1409.4MB

- Texture / Rendertargets - Size: 744.7MB - Allocations: 157
- Texture / Texture Assets - Size: 595.8MB - Allocations: 270
- Texture / Dynamic Textures - Size: 0.1MB - Allocations: 2
- Buffer / Vertex Buffers - Size: 12.0MB - Allocations: 189
- Buffer / Index Buffers - Size: 32.5MB - Allocations: 70
- Buffer / Constant Buffers - Size: 0.2MB - Allocations: 212
- Buffer / Other Buffers - Size: 24.1MB - Allocations: 8

Using DebugDraw Console Variables

Use the following console variables and values to display information about your level.

- **e_DebugDrawLodMinTriangles 1000** – Do not draw debug text for objects with less than 1000 triangles.
- **e_DebugDraw 1** – Displays the name of the .cfg used, polycount, and LOD.
- **e_DebugDraw 2** – Displays a color-coded polygon count.
- **e_DebugDraw 3** – Displays a color-coded LOD count. Flashing color indicates a single LOD.
- **e_DebugDraw 4** – Displays object texture memory usage.
- **e_DebugDraw 5** – Displays a color-coded number of render materials.
• e_DebugDraw 6 – Displays ambient color.
• e_DebugDraw 7 – Display triangle count, number of render materials, and texture memory.
• e_DebugDraw 8 – Displays RenderWorld statistics (with view cones).
• e_DebugDraw 9 – Displays RenderWorld statistics (with view cones without lights).
• e_DebugDraw 10 – Displays render geometry with simple lines and triangles.
• e_DebugDraw 11 – Displays render occlusion geometry.
• e_DebugDraw 12 – Displays render occlusion geometry without render geometry.
• e_DebugDraw 13 – Displays occlusion amount (used during AO computations).
• e_DebugDraw 15 – Displays helpers.
• e_DebugDraw 16 – Displays debug gun.
• e_DebugDraw 17 – Displays streaming information (buffer sizes).
• e_DebugDraw 18 – Displays streaming information (required streaming speed).
• e_DebugDraw 19 – Displays physics proxy triangle count.
• e_DebugDraw 20 – Displays object instant texture memory usage.
• e_DebugDraw 21 – Displays animated object distance to camera.
• e_DebugDraw 22 – Display object's current LOD vertex count.
• e_DebugDraw 23 – Display object in red if it is casting a shadow.
• e_DebugDraw 24 – Display objects with 0 LOD with red text.
• e_DebugDraw 25 – Display objects with 0 LOD with red text and objects with 1 LOD with blue text.

Using GBuffer Console Variables

Use the following console variables and values to display materials, colors, shadows, albedo, and other characteristics in your level.

• r_DebugGBuffer 1 – Shows normals of all assets in the level.
• r_DebugGBuffer 2 – Shows the roughness or glossiness of the surfaces.
• r_DebugGBuffer 3 – Shows the specular color of materials.
• r_DebugGBuffer 4 – Shows the albedo of all surfaces in the level.
• r_DebugGBuffer 5 – Shows the lighting model in the level. Gray = standard | Yellow = transmittance | Blue = POM self-shadowing.
• r_DebugGBuffer 6 – Shows the translucency values that are set on assets in the level. Black = none.
• r_DebugGBuffer 7 – Shows self-shadowing of materials that use Offset Bump mapping or Parallax Occlusion Mapping.
• r_DebugGBuffer 8 – Shows in red and yellow any asset that uses SSS. The brighter the color, the higher the SSS index.
• r_DebugGBuffer 9 – Shows whether specular colors are in a reasonable range as follows:
  • Blue – The specular color is too low.
  • Orange – The specular color is too high for dielectric materials.
  • Pink – The specular color is valid only for rusted or oxidized metals.

Using the sys_asserts Console Variable (CVAR)

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Manage assert notifications in Lumberyard with the `sys_asserts` console variable. The following table shows the possible values and their meanings.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Ignore assert condition checks. Assert expressions are not evaluated. This option offers the best performance of all of these values.</td>
</tr>
<tr>
<td>1</td>
<td>If asserts and assert call stacks are available, they are logged and printed to the console or terminal. This is the default value.</td>
</tr>
<tr>
<td>2</td>
<td>If asserts and assert call stacks are available, they are logged and printed to the console or terminal. This value displays a dialog box with options to ignore the current assert, ignore all asserts, or break on the assert.</td>
</tr>
</tbody>
</table>

**Note**
Prior to Lumberyard version 1.21, when a debugger was attached and an assert was triggered, the debugger triggered a breakpoint on the assert. In the new implementation, asserts print to the log at setting `sys_asserts=1` and display a dialog box at setting `sys_asserts=2`. This gives you the option to break on the assert rather breaking automatically.

**Example Outputs**

`sys_asserts=1` produces output similar to the following:

```
(System) - Trace::Assert
e:\dev\Code\CryEngine\Cry3DEngine\Particle.cpp(1289): (68792) 'void __cdecl CParticle::Update(const struct SParticleUpdateContext &,float,bool)'
(System) - e:\dev\code\cryengine\cry3dengine\particle.cpp (1290) : CParticle::Update
(System) - e:\dev\code\cryengine\cry3dengine\particlecontainer.cpp (777) : CParticleContainer::UpdateParticleStates
(System) - e:\dev\code\cryengine\cry3dengine\particlecontainer.cpp (731) : CParticleContainer::UpdateParticles
(System) - e:\dev\code\cryengine\cry3dengine\particleemitter.cpp (87) : <lambda_11fc931574fd38d67807576e751a0e04>::operator()
```

`sys_asserts=2` opens a dialog box like the following:
Debugging Issues

The following table describes the options for the **Assert** dialog box.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ignore</td>
<td>Ignores the current assert and continues running the application. The same assert no longer triggers the dialog box to display.</td>
</tr>
<tr>
<td>Ignore All</td>
<td>Prevents the current assert and all future asserts from displaying a dialog box. To prevent decreases in performance, prints debug information to the log only after completion.</td>
</tr>
<tr>
<td>Break</td>
<td>Breaks on the assert. If a debugger is attached, creates a breakpoint and breaks at the breakpoint in the debugger. If a debugger is not attached, stops the application.</td>
</tr>
</tbody>
</table>

**Setting the Assert Level at Initialization**

To set the assert level at engine initialization, add an entry to a project's `game.cfg` file. The following example shows a `game.cfg` file for the SamplesProject.

```plaintext
sys_game_name = "SamplesProject"
sysLocalization_folder = Localization
cs_useIMG_CAF = 0
collision_classes = "Ship=0,Shield=1,Asteroid=2"
r_DisplayInfo=3
sys_asserts=2
```

**Setting the Assert Level at Runtime**

You can set the `sys_asserts` console variable at runtime in the console window. The following image shows an example.
Setting the Assert Level for Mobile Devices

When debugging mobile platforms, you can use the Windows-based Universal Remote Console (p. 3209) to set the assert level in the command-line window of the application.
Setting an Assert in Source Code

To add an assert in source code, use the `AZ_Assert` macro.

```c
AZ_Assert(m_useCount >= 0, "AssetData has been deleted")
```

For more information, see Tracing (p. 31).

Tracking File Access

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

It's possible to track invalid file reads that occur during game run time. The error message Invalid File Access occurs when an attempt is made to read or open files from a thread that is not the streaming thread. These file access operations can cause stalls that can be quite severe.

**Note**

Only access attempts from the main thread and render thread are logged. This feature is disabled in RELEASE builds.

CVars

The following console variables enable different options for tracking file access.

```caps
sys_PakLogInvalidFileAccess
```

Version 1.28

1972
1 (default):

- Access is logged to game.log.
- Generates a perfHUD warning.
- The warning is displayed in red in the upper left corner of the screen.
- A 3 second-stall in non-release builds is induced.

**sys_PakMessageInvalidFileAccess**

- When a file is accessed, creates a popup dialog on the PC. At this point, you can choose to break into the debugger, or continue.

### Where invalid access is defined

The points which define when a file access attempt is considered invalid are set by implementing ICryPak::DisableRuntimeFileAccess to return true or false. The points may need to be tweaked for single player and multiplayer games.

### Exceptions

To add exceptions to file access tracking so that you can ignore files like game.log, create an instance of CDebugAllowFileAccess in the scope which accesses the file.

### Resolving file access callstacks

The files that you collect with pak_LogInvalidFileAccess must have their callstacks resolved. To do this requires the following tools from the XenonStackParse folder of the Tools directory:

- The .pdb files from the build
- The XenonStackParse tool
- The ProcessFileAccess.py helper script

The directory structure for running ProcessFileAccess.py should resemble the following:

```
<Root>
    --> XenonStackParse
    --> FileAccessLogs (this folder should contain the .pdb files)
    -------> Processed (this folder contains the output from XenonStackParse)
```

Run ProcessFileAccess.py from the FileAccessLogs directory (XenonStackParse uses the working directory to search for the .pdb files). The script creates a folder called Processed and a file within it that contains the resolved callstack for each of the log files.

---

**Lumberyard UI 2.0 Developer Documentation**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Introduced with Amazon Lumberyard version 1.25, UI 2.0 is the user interface framework used by Lumberyard's editors and tools. It uses the C++ Qt UI library and can be extended to support your own customizations and modifications.

---

Version 1.28
1973
What is Lumberyard UI 2.0?

UI 2.0 is designed to enable easy-to-use workflows and help your game designers and developers translate their ideas into quick simulations. When developing the new Lumberyard UI, we focused on these four tenets:

- Efficiency
- Accessibility
- Familiarity
- Modularity

To achieve this, we provided a complete set of Qt-based user interface building blocks so that you can create tools to fit your own needs, while still employing a coherent and standardized UI experience throughout the Lumberyard Editor.

When creating tools, developers have access to the controls that we're now using throughout Lumberyard, which includes the following elements:

- Breadcrumbs
- Browse edit (*input field with button*)
- Button
- Card
- Check box / toggle switch
- Color picker and color label
- Combo box
- Filtered search widget
- Gradient slider
- Hyperlinks
- Line edit
- Menu
- Progress indicators
- Radio buttons
- Reflected property editor
- Scrollbar
- Segment control
- Slider
- Sliders with combo box
- Spin-box (*Line edit with drag support*)
- Vector input spin-box
- Splitter
- Styled dock widget
- Tabs
- Table view
- Toolbar
- Tree view
- Typography
UI 2.0 overview

With Lumberyard 1.25 and later versions, developers can use Lumberyard's custom Qt widget library to create their own developer tools and modify existing tools to blend into the user experience of the rest of the Lumberyard Editor. We have provided a set of styles and user interaction patterns that are applied on top of the Qt framework, which is the C++ based library Lumberyard relies on for its UI. For more information about how UI 2.0 works and UI component development, see the Amazon Lumberyard UI Extensions Guide

Review the UI 2.0 components

Before you begin, make sure that you have Lumberyard 1.25 or later installed on your machine.

To review the UI components

1. Open File Explorer and go to your build directory. (For example, C:\{your-lumberyard-installation-path}\{version}\dev\Bin64vc141\ or Bin64vc142\.)
2. Double-click on **AmazonQtControlGallery.exe** to open the **UI 2.0 Qt Control Gallery** app.
3. Use the main dropdown menu to navigate through the pages. For each component, the right column shows a live example of how the widget will look and work inside the Lumberyard Editor or for your tool. The left column displays the code used to produce that result.

**Note**
The Gallery does not cover how to set up a window for your tool, or the basics of how the Qt library works. Its primary objective is to illustrate the attributes of the Lumberyard Component Gallery.
Object serialization

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Lumberyard engine offers object serialization to persist objects between sessions, transmit them between clients, or work with objects between the editor and the engine. The JSON-based serialization system is designed to be human-readable and -editable, while the XML system is used by many existing Lumberyard tools. Lumberyard also offers binary serialization, used internally by the Asset Processor.

In this section of the documentation, you'll learn how to register classes and enums for serialization, and how to work with JSON serializers. For more information on XML serialization for use with Lumberyard tools, see Serialization Context (p. 1033) and Reflecting a Component for Serialization and Editing (p. 977).

Register objects for serialization

Serialization in Lumberyard is done by registering classes with a serialization context, which takes information about the provided class and uses reflection mechanisms to determine which class members to emit and their types. Serialization is controlled through the AZ::SerializeContext class, declared in AZCore/Serialization/SerializeContext.h as part of the AzCore library.

Serialization requires access to an AZ::ReflectContext instance that can be safely cast to a AZ::SerializeContext object through the AzCore reflection system. There's a globally managed serialization context within the Lumberyard engine that you can retrieve through the AZComponentApplicationBus.

```
AZ::SerializeContext* serializeContext = nullptr;
AZ::ComponentApplicationBus::BroadcastResult(serializeContext,
&AZ::ComponentApplicationBus::Events::GetSerializeContext);
```

**Warning**
When using the global serialization context, only register an object for serialization in a Reflect function call. Registering outside of this function can cause race conditions. If you need to register for serialization at any other time, use a custom serialization context.

Register classes

Classes are registered on a serialization context with the AZ::SerializeContext::Class<T>() method, using the type T to determine which class to register. In order to be serialized, the class must be a specialization of AzTypeInfo registered with the AZ_TYPE_INFO_SPECIALIZE() macro, or have RTTI information set with the AZ_RTTI macro. The AZ::SerializeContext::Class<T>() method returns an AZ::SerializeContext::ClassBuilder object, which is used to store version and field information for the class.

```
AZ::SerializeContext::ClassBuilder

Version(unsigned int version, VersionConverter converter = nullptr)
```

Sets version information for the serialization.
Register objects

- **version** – The version of the class. Whenever the internal structure of the class changes, the version should be updated.
- **converter** – Converter function which translates older versions of the class to the provided version.

```cpp
template<class ClassType, class FieldType> Field(const char* name, FieldType ClassType::* address, AZStd::initializer_list<AttributePair> attributeIds = {})
```

Tags a field in a class for storage.
- **name** - The name to store the field as. Field names for the same class must be unique. Matching the member name isn't required.
- **address** - The address of the field to store, as a pointer to member or offset from the start of an instance of `ClassType`. If a pointer to member is used, all type information is inferred.
- **attributeIds** - Associate other attribute objects with this field.

```cpp
template<class ClassType, class BaseType, class FieldType> FieldFromBase(const char* name, FieldType BaseType::* address)
```

Create a field from a base class member. This can be used if you want to serialize a base class member without registering and serializing a whole base class, to decouple the serialized class from its base.
- **name** - The name to store the field as. Field names for the same class must be unique. Matching the member name isn't required.
- **address** - The address of the field to store, as a pointer to member or offset from the start of an instance of `BaseType`. If a pointer to member is used, all type information is inferred.

Example Registering a class for serialization

The following is an example from the Lumberyard Asset Processor code, demonstrating how a class can be registered for serialization.

```cpp
if (AZ::SerializeContext* serializeContext = azrtti_cast<AZ::SerializeContext*>(context))
{
    serializeContext->Class<AssetBuilderDesc>()
        ->Version(2)
        ->Field("Flags", &AssetBuilderDesc::m_flags)
        ->Field("Name", &AssetBuilderDesc::m_name)
        ->Field("Patterns", &AssetBuilderDesc::m_patterns)
        ->Field("BusId", &AssetBuilderDesc::m_busId)
        ->Field("Version", &AssetBuilderDesc::m_version)
        ->Field("AnalysisFingerprint", &AssetBuilderDesc::m_analysisFingerprint);
}
```

Register enums

Enums are registered on a serialization context with the `AZ::SerializeContext::Enum<T>()` method, using the type `T` to determine which enum to register. In order to be serialized, the enum **must** be a specialization of the `AzTypeInfo` using the `AZ_TYPE_INFO_SPECIALIZE()` macro. The `AZ::SerializeContext::Enum<T>()` method returns an `AZ::SerializeContext::EnumBuilder` object, which is used to store version and value information for the enum.

```cpp
AZ::SerializeContext::EnumBuilder
```

Version(unsigned int version, VersionConverter converter = nullptr)

Sets version information for the serialization.
- **version** – The version of the enum. Unlike classes, this doesn't need to change whenever an enum's definition is updated, and is mostly for conversion purposes.
• converter – Converter function which translates older versions of the enum to the provided version.

```cpp
template<class EnumType>
Value(const char* name, EnumType value)
```

Tags an enum value for serialization as part of the enum's information.

• name - The name to store the value as. Field names for the same enum must be unique. Matching the internal value name isn't required.

• value - The associated value to store for the enum. If this is a value associated with the enum, all type information is inferred.

**Important**
If you're serializing a member from a class with an enum type, that enum **must** be registered with the serializer.

### Example Registering an enum for serialization

The following is an example showing a sample declaration of an enum, and a short function that can be called to register it with the serialization system.

```cpp
eenum ExampleEnum : uint8_t
{
    BaseValue = 0,
    Flag1 = 0x1,
    Flag2 = 0x2,
    Flag3 = 0x4,
    Flag4 = 0x8
}

// AzTypeInfo must be set from within the AZ namespace
namespace AZ
{
    AZ_TYPE_INFO_SPECIALIZE(ExampleEnum, "{7ebef8a5-b40d-4a9a-8511-162da1dc02f0}");
}

void registerEnum(AZ::SerializeContext* context)
{
    if (AZ::SerializeContext* serializeContext = azrtti_cast<AZ::SerializeContext*>(context))
    {
        context->Enum<ExampleEnum>()
            ->Value("Base", ExampleEnum::BaseValue)
            ->Value("Flag1", ExampleEnum::Flag1)
            ->Value("Flag2", ExampleEnum::Flag2)
            ->Value("Flag3", ExampleEnum::Flag3)
            ->Value("Flag4", ExampleEnum::Flag4)
    }
}
```

## Object serialization to JSON format

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Starting with Lumberyard version 1.25, objects can be serialized out to the JSON format. JSON is a machine-readable format that's also designed to be easy for humans to read and edit, so that...
contributors can make small changes to data without requiring specialized tools or a detailed XML schema. Many programming languages also offer robust and easy to use support for JSON data, making the development of build and design tools for supporting your project outside of the Lumberyard editor easy.

In Lumberyard, using the JSON serialization format also offers the following benefits:

- **Minimal serialization** – Only data relevant to the object is serialized. Default values and information that can be retrieved at runtime aren’t stored. This reduces object size and makes manual editing easier.

- **Best-effort deserialization** – To complement the minimal serialization, the engine applies as much data as possible when deserializing. If a field is missing from the JSON input, default values are used. Fields in the JSON which aren’t supported by the object are ignored. This makes working with JSON less error-prone than XML, which requires a rigid structure.

- **Forgiving** – Because of the forgiving nature of JSON, serialization and deserialization can proceed even if it finds missing data while emitting a warning (and optionally reporting an error.) This extends to specialized data types used by Lumberyard such as vectors: If a 3D vector contains a 4th coordinate, it's simply ignored and a warning is reported. This makes manual editing and custom tooling much safer.

- **Easier to use with source control** – Source control systems can have difficulty with merging or generating useful diffs with XML files. Because of JSON's flexibility and limited format, it's easier to work with JSON files in your source control system as text files.

This section of the documentation covers serialization and deserialization of data in the JSON format, and how Lumberyard data types are mapped to JSON data types.

**Topics**

- Serialize and deserialize JSON objects (p. 1981)
- Data types in serialized JSON (p. 1987)

### Serialize and deserialize JSON objects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Once a class has been registered with a serialization context (p. 1978) objects of that class can be serialized and deserialized. Objects are serialized to JSON with the `AZ::JsonSerialization::Store()` function, and deserialized from JSON with `AZ::JsonSerialization::Load()`.

This article includes reference for these methods, examples of using serialization and deserialization, and how to interpret result codes from JSON the serializer. For information on how specific types are serialized, see Data types in serialized JSON (p. 1987).

### Serialization

Serialization into JSON is done with the static `AZ::JsonSerialization::Store()` method. This method has several overloads, depending on how you want the object to be serialized and what information is available at the time of serialization. By default, the global serialization context is used.
AZ::JsonSerialization::Store() overloads

template<typename T> static AZ::JsonSerializationResult::ResultCode
AZ::JsonSerialization::Store(rapidjson::Value& output,
rapidjson::Document::AllocatorType& allocator, const T& object,
AZ::JsonSerializerSettings settings = AZ::JsonSerializerSettings());

- output – The RapidJSON document or value to write to. Objects can be serialized at an arbitrary
  point in a JSON document by providing the appropriate value.
- allocator – The memory allocator used by RapidJSON.
- object – The object to serialize. This object's class must be registered with the provided
  serialization context.

When serializing, a second object of type T is created from the default constructor (if possible) to
provide default values.

- settings – Configuration for how to treat the serialization. If not provided, the default settings
  are used.

template<typename T> static AZ::JsonSerializationResult::ResultCode
AZ::JsonSerialization::Store(rapidjson::Value& output,
rapidjson::Document::AllocatorType& allocator, const T& object,
const T& defaultObject, AZ::JsonSerializerSettings settings =
AZ::JsonSerializerSettings());

- output – The RapidJSON document or value to write to. Objects can be serialized at an arbitrary
  point in a JSON document by providing the appropriate value.
- allocator – The memory allocator used by RapidJSON.
- object – The object to serialize. This object's class must be registered with the provided
  serialization context.
- defaultObject - An object providing the values to treat as the defaults during serialization.
  Any members of object with values that don't match defaultObject are guaranteed to be
  serialized.
- settings – Configuration for how to treat the serialization. If not provided, the default settings
  are used, except that default values will be stored in the output.

static AZ::JsonSerializationResult::ResultCode
AZ::JsonSerialization::Store(rapidjson::Value& output,
rapidjson::Document::AllocatorType& allocator, const void* object, const void*
defaultObject, const AZ::Uuid& objectType, AZ::JsonSerializerSettings settings
= AZ::JsonSerializerSettings());

- output – The RapidJSON document or value to write to. Objects can be serialized at an arbitrary
  point in a JSON document by providing the appropriate value.
- allocator – The memory allocator used by RapidJSON.
- object – The object to serialize, as anonymous data.
- defaultObject - An object providing the values to treat as the defaults during serialization.
  Any members of object with values that don't match defaultObject are guaranteed to be
  serialized. If a null pointer is passed as the default object, a temporary default may be created
during serialization.
- objectType - The UUID registered with the Lumberyard runtime representing the class for
  the provided object. The class represented by this UUID must be registered with the provided
  serialization context.
- settings – Configuration for how to treat the serialization. If not provided, the default settings
  are used, except that default values will be stored in the output provided defaultObject is not
  null.
**AZ::JsonSerializerSettings**

The behavior of the `AZ::JsonSerialization::Store()` methods can be controlled by setting an instance of `AZ::JsonSerializerSettings` as the settings argument.

```cpp
bool m_keepDefaults
```

If `true`, then defaults are written to the JSON value when serialized.

**Default:** `false`

```cpp
AZ::SerializeContext* m_serializeContext
```

The serialization context to query for information about how to serialize the provided object.

**Default:** The serialization context retrieved from the `ComponentApplicationBus` event bus.

```cpp
AZ::JsonSerializationResult::JsonIssueCallback m_reporting
```

Callback method invoked when an error is encountered during serialization. This function has no access to the object being serialized or the JSON value being written to, but can be used for altering result codes.

**Default:** The default issue reporter, which logs warnings and errors encountered in serialization.

```cpp
AZ::JsonRegistrationContext* m_registrationContext
```

JSON registration context. For examples of how to use a custom JSON context, see the source code.

**Default:** The registration context retrieved from the event bus.

### Example Serialization example

The following is a short example demonstrating how to serialize a simple class. Details regarding registering the class with the serialization context are omitted.

```cpp
class SerializableClass
{
    double m_var1;
    int m_var2;
}

// ... Register with serialization context

SerializableClass instance;
instance.m_var1 = 42.0;
instance.m_var2 = 88;

rapidjson::Document document;
AZ::JsonSerializationResult::ResultCode result = AZ::JsonSerialization::Store(document, document.GetAllocator(), instance);
if (result.GetProcessing() == AZ::JsonSerializationResult::Processing::Halted)
{
    AZ_Warning("Serialization", false,
                "Unable to fully serialize SerializableClass to json because %s.",
                result.ToString().c_str());
}

rapidjson::StringBuffer buffer;
rapidjson::Writer<decltype(buffer)> writer(buffer);
document.Accept(writer);
AZ_TracePrintf("Serialization", "SerializableClass as Json:\n%s", buffer.GetString());
```
Deserialization

Deserialization from JSON into an object is done with the static
AZ::JsonSerialization::Load() method. This method has two overloads - one for use when an
instance of the deserialized object type is available, and the other using void* and RTTI information.

AZ::JsonSerialization::Load() overloads

template<typename T> static AZ::JsonSerializationResult::ResultCode
AZ::JsonSerialization::Load(T& object, const rapidjson::Value& root,
AZ::JsonDeserializerSettings settings = AZ::JsonDeserializerSettings{});
• object - The object to load data into.
• root - The root of the JSON tree to deserialize from. This is normally a full JSON document, but
can be any JSON value that will deserialize correctly to type T.
• settings - Configuration for how to treat deserialization.

static AZ::JsonSerializationResult::ResultCode
AZ::JsonSerialization::Load(void* object, const AZ::Uuid& objectType,
const rapidjson::Value& root, AZ::JsonDeserializerSettings settings =
AZ::JsonDeserializerSettings{});
• object - A pointer to memory allocated as an object matching the type registered for
objectType.
• objectType - The UUID registered with the Lumberyard runtime representing the class for
the provided object. The class represented by this UUID must be registered with the provided
serialization context.
• root - The root of the JSON tree to deserialize from. This is normally a full JSON document, but
can be any JSON value that will deserialize correctly to the type identified by objectType.
• settings - Configuration for how to treat deserialization.

AZ::JsonDeserializerSettings

The behavior of the AZ::JsonSerialization::Load() methods can be controlled by setting an
instance of AZ::JsonDeserializerSettings as the settings argument.

bool m_clearContainers

If true, then container members of the target object to deserialize into are cleared before
beginning deserialization. This option has no effect for classes with a fixed layout.

Default: false
AZ::SerializeContext* m_serializeContext

The serialization context to query for information about how to deserialize to the object.

Default: The global serialization context retrieved from the ComponentApplicationBus event bus.
AZ::JsonSerializationResult::JsonIssueCallback m_reporting

Callback method invoked when an error is encountered during deserialization. This function has no
access to the object being serialized or the JSON value being written to, but can be used for altering
result codes.

Default: The default issue reporter, which logs warnings and errors encountered in deserialization.
AZ::JsonRegistrationContext* m_registrationContext

JSON registration context. For examples of how to use a custom JSON context, see the source code.

Default: The global registration context retrieved from the event bus.
Example Deserialization example

The following is a short example demonstrating how to deserialize. Details regarding how to load JSON data into memory and registering with the serialization context are omitted.

```cpp
rapidjson::Document document;  // ...read json document from file.
SerializableClass instance;
AZ::JsonSerializationResult::ResultCode result = AZ::JsonSerialization::Load(instance, document);
if (result.GetProcessing() == AZ::JsonSerializationResult::Processing::Halted)
{
    AZ_Warning("Deserialization", false,
        "Unable to fully deserialize SerializableClass from json because %s.",
        result.ToString().c_str());
}
```

Result codes

The JSON serializer uses the `AZ::JsonSerializationResult::ResultCode` type to report errors, warnings, and successful serialization and deserialization of objects. Result codes are broken down into three parts: task, processing result, and final outcome. These values can be obtained with the `GetTask()`, `GetProcessing()`, and `GetOutcome()` methods respectively. When checking results, you should first start with the processing to see if the task was successfully completed or if an error was encountered. For non-Success values, the task indicates where in processing the error was encountered, and the outcome reflects why the failure occurred.

To write serialization results to a string, use the `AZ::JsonSerializationResult::ResultCode::AppendToString()` and `AZ::JsonSerializationResult::ResultCode::ToString()`, or `AZ::JsonSerializationResult::ResultCode::ToOSString()` methods.

Processing results

Completed

- Processing completed successfully.

Altered

- Processing completed after encountering an error. Error recovery was performed, so the input and output will not necessarily match.

PartialAlter

- Processing completed after encountering multiple errors, and was able to perform error recovery by making multiple alterations.

Halted

- Processing failed and was unable to complete. This indicates an unrecoverable error or other serious failure.

Tasks

RetrieveInfo

- Retrieve information from the system, such as querying a serialization context.

CreateDefault

- Creation of a default instance to use to provide default values during processing.
Convert
Type conversion between values.
Clear
Clearing a field or value.
ReadField
Reading a field from JSON to write to an object value.
WriteValue
Writing from an object value to a JSON field.
Merge
Merging two JSON values or documents together.
CreatePatch
Creation of a patch to transform one JSON value to another.

Outcomes
Success
The task completed successfully.
Skipped
The task skipped a field or value.
PartialSkip
The task skipped one or more fields while processing a JSON object or array.
DefaultsUsed
Task completed using only default values.
PartialDefaults
Task completed using defaults for some values.
Unavailable
Task tried to use space which isn't available.
Unsupported
An unsupported action was requested while performing the task.
TypeMismatch
The source and target were unrelated, and no type conversion could be performed.
TestFailed
A test check against a value failed.
Missing
A required field or value was missing.
Invalid
A field or element contained an invalid value.
Unknown
Unknown information was encountered during the task.
**Catastrophic**

An unidentifiable or unknown catastrophic error occurred during the task.

**Data types in serialized JSON**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In addition to primitive C++ types that map directly to JSON types, Lumberyard supports serializing many AZStd library objects. JSON output and deserialized objects are entirely deterministic based on the appropriate C++ type. For some more information on how members are registered and how their types are determined through the reflection system, see JSON serialization (p. 1981).

This topic is a reference of the types supported by Lumberyard serialization and deserialization, how the serializer maps them by default, and information on how JSON types are coerced back to C++ types.

**Primitives**

The primitive types used in serialization are *booleans*, *integers*, *floating point numbers*, and *strings*. These C++ types map naturally to the native JSON boolean, number, and string types. The only string types supported for serialization are AZStd::string and OSString.

Deserialization can be conducted from any primitive JSON type to these C++ types as follows:

**Basic type mappings**

<table>
<thead>
<tr>
<th>C++ Type</th>
<th>JSON boolean</th>
<th>JSON number</th>
<th>JSON string</th>
</tr>
</thead>
<tbody>
<tr>
<td>bool</td>
<td>Direct mapping.</td>
<td>0 maps to false, all other values are true.</td>
<td>Case-insensitive comparison against &quot;true&quot; and &quot;false&quot; to map to the respective C++ values.</td>
</tr>
<tr>
<td>Integer types</td>
<td>True maps to 1, False to 0.</td>
<td>Direct mapping, where floating point values are truncated.</td>
<td>Tries to extract a 64-bit integer and convert to the target integer type.</td>
</tr>
<tr>
<td>Floating point types</td>
<td>True maps to 1, False to 0.</td>
<td>Direct mapping.</td>
<td>Tries to extract a 64-bit floating point and convert it to the target type.</td>
</tr>
<tr>
<td>Strings (AZStd::string and OSString only)</td>
<td>True is converted to &quot;True&quot;, and False to &quot;False&quot;.</td>
<td>String representation of the number.</td>
<td>Direct mapping.</td>
</tr>
</tbody>
</table>

**Pointers**

Pointers and smart pointer types are serialized out to the type that they point to as JSON values, following all of the rules for that type. For pointers to C++ objects, this means that the pointed-to object
must be registered with the serialization context being used. While most types can be safely serialized without any metadata, for derived classes, an additional $\texttt{type}$ key is serialized into the JSON object with the class' name. If there could possibly be a conflict in the class name, fully namespaced names or a class' UUID in the Lumberyard runtime can be used.

When deserializing, the $\texttt{type}$ value is used as a hint to determine which object to reconstruct if necessary. Otherwise, only the C++ type of the member is inspected. Deserialization proceeds memberwise, using the field mapping that was registered with the serialization context to map JSON object keys to C++ members.

**Enums**

In order to serialize enums, they need to be registered (p. 1979) with the same serialization context as the class being serialized. How values from an enum are serialized and deserialized depend on the details of the enum registration.

- **Enum value matches the value of a registered field** – The value is serialized as a string containing the field name.
- **Enum value can't be represented as ORed registered values** – The value is serialized as an integer.
- **Enum value can be represented as ORed registered values** – The value is serialized to an array containing strings of the field names that were ORed together.
- **Enum value can be represented as a mix of ORed registered values and unregistered values** – The value is serialized to an array containing the strings of the appropriate field names and a single integer that when ORed together, produce the serialized value.

**Example Serializing an enum**

These rules are best illustrated with a simple example to show an enum definition, its registration with the serialization context, and the serialization output for various values.

```c
enum ExampleEnum : uint8_t
{
    Flag1 = 1,
    Flag2 = 2,
    Flag3 = 4,
    Flag4 = 8,
    Flag5 = Flag2 | Flag3
}

//------
// Registration with SerializedContext
serializeContext->Enum<ExampleEnum>()
   ->Value("Flag1", ExampleEnum::Flag1)
   ->Value("Flag2", ExampleEnum::Flag2)
   ->Value("Flag4", ExampleEnum::Flag4)
   ->Value("Flag2Flag3Combo", ExampleEnum::Flag5)

//------

// ExampleEnum initialization with int
ExampleEnum(0) // Serializes as 0
ExampleEnum(1) // Serializes as "Flag1"
ExampleEnum(-1) // Serializes as 255
ExampleEnum(10) // Serializes as ["Flag2", "Flag4"]

// Declared ExampleEnum values
ExampleEnum::Flag1 // Serializes as "Flag1"
ExampleEnum::Flag3 // Serializes as 4
ExampleEnum::Flag5 // Serializes as "Flag2Flag3Combo"
```
// ORed together values
ExampleEnum::Flag1 | ExampleEnum::Flag4   // Serializes as ["Flag1", "Flag4"]
ExampleEnum::Flag2 | ExampleEnum::Flag3   // Serializes as "Flag2Flag3Combo"
ExampleEnum::Flag1 | ExampleEnum::Flag3 | ExampleEnum::Flag1 // Serializes as ["Flag1", "Flag2Flag3Combo"]
ExampleEnum::Flag4 | 16      // Serializes as ["Flag4", 16]

Deserialization behaves as expected based on these serialization outputs. Strings are first attempted to be mapped to a field name, and then the enum is assigned the field's value. If the string contains something other than a field name, a type conversion to an integer is attempted. Arrays have each element evaluated to convert to the enum field or an integer value, and then the results of those evaluations are ORed to produce the final deserialized value.

Vectors

Serialization supports 2D, 3D, and 4D vectors. An N-dimensional vector is serialized as a JSON array of N floating point numbers, in the order of the X, Y, Z, and W coordinate.

For deserialization, vectors can be read from an array of any length, but will only read up to the number of elements in the target type. If the array has fewer elements than the vector type, those vector components are assigned the default value of 0. Array elements follow the rules of deserialization for the C++ floating point type of the vector elements. Vectors can also be deserialized from JSON objects where the object keys map to the vector component name in a case-insensitive compare. Other keys are ignored, and components with missing keys use the default value.

Containers

Serialization supports a number of containers from AZStd. These include the array, vector, list, set, map, and tuple types.

Array types

The following types are serialized to JSON arrays:

- AZStd::array
- AZStd::fixed_vector
- AZStd::forward_list
- AZStd::list
- AZStd::vector
- AZStd::pair
- AZStd::tuple
- AZStd::set - Values in the serialized array are sorted
- AZStd::unordered_set - Values in the serialized array are sorted

Deserialization of a JSON array to a C++ array, list, vector, set, pair, or tuple type is a direct element-by-element conversion. The types of each array element are converted to the target container's value type according to the other JSON deserialization rules. Missing elements map to the default for the container's value type, and additional elements are ignored. Types other than JSON arrays will result in a conversion error when attempting to deserialize to one of these C++ types.

Map types

The serialization of map types (AZStd::map, AZStd::unordered_map, AZStd::unordered_multimap) depends on the map's key type. Maps with a serializable string type
(AZStd::string or OSString) as the key are serialized directly to JSON objects with equivalent key/value pairs. Maps with any other key type are serialized to JSON arrays, where every element is a key/value pair. For example, the map AZStd::map<uint8_t, uint8_t> = {0:1, 2:3} serializes to the JSON array ["Key": 0, "Value": 1], ["Key": 2, "Value": 3].

**Miscellaneous types**

Other internal types supported by JSON serialization are *UUID* and *color*.

AZ::Uuid are mapped to JSON strings by AZ::Uuid::ToString(), and strings are converted back to UUIDs from AZ::Uuid::CreateString().

Color types are serialized to JSON arrays containing 3 float values for RGB colors, and 4 values for RGBA. JSON arrays of 3 or 4 values can be deserialized directly back to RGB or RGBA, but JSON objects can also be deserialized to colors. For an object to be deserialized to a color, it must have exactly one key of the following names, with an equivalent value type.

**Color deserialization from JSON objects**

<table>
<thead>
<tr>
<th>Key</th>
<th>Value type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>Array of 3 floating point elements.</td>
<td>{ &quot;RGB&quot; : [1.0, 0.3, 0.2] }</td>
</tr>
<tr>
<td>RGBA</td>
<td>Array of 4 floating point elements.</td>
<td>{ &quot;RGBA&quot; : [1.0, 0.3, 0.2, 0.8] }</td>
</tr>
<tr>
<td>RGB8</td>
<td>Array of 3 integer elements with values in the range [0, 255].</td>
<td>{ &quot;RGB8&quot; : [255, 77, 51] }</td>
</tr>
<tr>
<td>RGBA8</td>
<td>Array of 4 integer elements with values in the range [0, 255].</td>
<td>{ &quot;RGBA8&quot; : [255, 77, 51, 204] }</td>
</tr>
<tr>
<td>HEX</td>
<td>A string containing 3 8-bit hex values representing the colors.</td>
<td>{ &quot;HEX&quot; : &quot;FF4D33&quot; }</td>
</tr>
<tr>
<td>HEXA</td>
<td>A string containing 4 8-bit hex values representing the colors and alpha channel.</td>
<td>{ &quot;HEXA&quot; : &quot;FF4D33CC&quot; }</td>
</tr>
</tbody>
</table>

**Using Lumberyard Networking**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard's GridMate networking system is designed for efficient bandwidth usage and low-latency communications. You can synchronize objects over the network with GridMate's replica framework. GridMate's session management integrates with major online console services and lets you handle peer-to-peer and client-server topologies with host migration. GridMate also supports in-game achievements, leaderboards, and cloud-based saved games through third-party social services such as Steam. For an example of how to set up a multiplayer project, see Multiplayer Sample (p. 155).
This section discusses the various components of, and setup requirements for, your Amazon Lumberyard game networking environment. For information about a diagnostic tool for networking, seeProfiler (p. 1920).

**Tutorial: Getting Started with Multiplayer**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This tutorial walks you through the steps to create a simple multiplayer test game level. These steps include binding an entity to the network and connecting a client to the host. At the end of the tutorial, you should have a level with a simple network bound entity that is ready for a multiplayer game.

This tutorial guides you through the following tasks:

- Create a level and add entities.
- Bind an entity's **Transform** component to the network.
- Connect a client to the server and verify network replication.

**Prerequisites**

This tutorial assumes the following:

- You installed Amazon Lumberyard.
- You created a game project. For more information, see Creating and Switching Game Projects (p. 44).
- Your game project has the **Multiplayer** gem. You can enable the gem in Lumberyard's Project Configurator (p. 43). After enabling the gem, build your project (p. 61).

**Note**

This tutorial uses Visual Studio 2017.

**Topics**
Step 1: Creating a Level and Adding a Sphere and a Box

Your first step is to create a level and prepare a simple sphere and box shape so that you can test Lumberyard's networking features.

To create a level, sphere, and box

1. In the Lumberyard Project Configurator, select a project that has the Multiplayer gem enabled, and then click Set as default.
2. Open Lumberyard Editor, create a level, and enter a name.
3. In the Lumberyard Editor viewport, right-click and choose Create entity.
4. With the entity selected, click Tools, Entity Inspector. Use the Entity Inspector to name the entity CameraEntity.
5. Click Add Component.
6. Select the Camera component to attach it to the entity.
7. In the Lumberyard Editor viewport, right-click and choose **Create entity**.
8. With the entity selected, use the **Entity Inspector** to name the entity **SphereEntity**.
9. In the **Entity Inspector**, click **Add Component**, **Rendering**, **Mesh** to attach a **Mesh** component to the **SphereEntity**.
10. In the **Mesh** component, click the (...) icon next to **Mesh asset**.
11. In the **Pick Static Mesh** window, expand **Engine, Objects, default**, and select **primitive_sphere.cgf**.
12. Click OK.
13. In the viewport, right-click and choose Create entity.
14. With the entity selected, use the Entity Inspector to name the entity BoxEntity.
15. In the Entity Inspector, click Add Component, Rendering, Mesh to attach a Mesh component to the BoxEntity.
16. In the Mesh component, click the (...) icon next to Mesh asset.
17. In the Pick Static Mesh window, under Engine, Objects, default, select primitive_cube.cgf.
18. Click OK.
19. In the viewport, select the SphereEntity. In the Entity Inspector, click Add Component, Physics, Rigid Body Physics.
20. Select the BoxEntity. In the Entity Inspector, click Add Component, Physics, Rigid Body Physics.

21. Select the SphereEntity. In the Entity Inspector, click Add Component, Physics, Mesh Collider.
22. Select the **BoxEntity**. In the **Entity Inspector**, click **Add Component**, **Physics**, **Mesh Collider**.

23. In the viewport, move the sphere and box entities above the plane so that they have room to fall.

   **To move the sphere and box entities above the plane**

   a. In the viewport, select the entity.

   b. On the **EditMode** toolbar, choose the **Move** icon.

   c. On the **EditMode** toolbar, choose the **Constrain to Z Axis** icon.

   d. In the viewport, drag the item up vertically.

24. In the **Entity Inspector**, **Rigid Body Physics** component, ensure that **At rest initially** is unchecked. This allows the sphere and box to begin simulating after the level is loaded.
You now have two simple component entities with rigid body physics in the level that you created.
Step 2: Binding Sphere Transform Components to the Network

After you create the initial level with the sphere and the box, you bind the sphere's Transform component to the network. This allows the sphere's changes to be replicated over the network to clients.

To bind the sphere's transform to the network

1. Select the sphere entity.
2. In the Entity Inspector, click Add Component, Networking, Network Binding. Adding the NetBinding component to the entity allows the host to replicate the Transform component of the sphere to all clients.
   
   ![Entity Inspector](image)

3. With the sphere entity selected, in the Transform component, ensure that the Network Sync, Sync to replicas property is enabled.
You have now created a server authoritative sphere entity that enables changes to the sphere to replicate over the network. However, you didn't bind the box to the network, so changes in the box will remain unreplicated.

**Step 3: Connecting a Client to the Server**

This step shows you how to connect a client to the server instance and then observe your networked sphere in action.

**To connect a client game to the host game**

1. In Lumberyard Editor, choose Game, Export to Engine, or press Ctrl+E to export your level.
2. Run the game launcher from the Bin directory that you are using. The name of your launcher is `your_game_project_name`Launcher.exe.
   
   For Visual Studio 2017, the directory is `lumberyard_version\dev\Bin64vc141\`.  
   
   For Visual Studio 2019, the directory is `lumberyard_version\dev\Bin64vc142\`.  
3. Press the `key (above the Tab key) to open the console.
4. Run the command `map MultiplayerTutorial` where `MultiplayerTutorial` is the name of the level to load.
5. Press the ` key to open the console. Run the command `mphost` to make your client host a network session.

6. Move the first launcher window to one side so that you will be able to see the second launcher window. Use the launcher again to open a second instance of the game. Press the ` key to open the second console.

7. Run the command `sv_port 0` to set the client port to 0 (the ephemeral port).

   **Note**
   On a single computer, only one process is allowed to bind to a particular port. Therefore, to run more than one game process on the same computer (as in this multiplayer sample), you
must use ephemeral ports. The sv_port console variable defines the UDP port on the local machine for the multiplayer sample, and the setting of 0 specifies the ephemeral port. This allows two clients on the same computer to talk to each other.

8. Run the command `mpjoin` to join to the host game. You should see the sphere synchronized by location on the client. However, the box will be desynchronized and have different locations on the client and host.

You have successfully created a simple networked level. You can now use the **Network Binding** component to connect clients to servers and synchronize transforms of entities.

### Related Tasks and Tutorials

You have created a simple networking sample to see the effects of networking in Lumberyard. See the following to learn more about what else you can add to your game:

- Configuring the Multiplayer Sample for Amazon GameLift (p. 2003)
- Using Amazon GameLift

### Configuring the Multiplayer Sample for Amazon GameLift

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To prepare the multiplayer sample for use with Amazon GameLift, follow the required procedures for server-side and client-side configuration.

### Server-Side Configuration

On the server side, overwrite the GridMate::OnSessionStarted() handler. In the handler, synchronize the session state and load the corresponding map if the CVAR sv_map is set in the Multiplayer::Utils::SynchronizeSessionState() function.
The following example shows code for server-side configuration.

```cpp
void GameManager::OnSessionCreated(GridMate::GridSession* session)
{
    m_gameSession = session;
    if (m_gameSession)
    {
        if (m_gameSession->IsHost())
        {
            if (gEnv->IsDedicated())
            {
                Multiplayer::Utils::SynchronizeSessionState(m_gameSession);
            }
        }
    }
}
```

Set the following server CVARs as needed:

gamelift_flexmatch_enable

gamelift_flexmatch_onplayerremoved_enable

gamelift_flexmatch_start_delay

For more details on these server CVARs provided by the Multiplayer Gem, see Server CVars (p. 1178).

**Client-Side Configuration**

On the client side, you must configure the following CVARs:

sv_port

sv_map

gamelift_aws_access_key

gamelift_aws_secret_key

gamelift_fleet_id or gamelift_alias_id

gamelift_queue_name

gamelift_end_point

gamelift_playerid

gamelift_matchmaking_config_name

You can set these CVARs with a console command or with the multiplayer sample user interface. For a list of all the supported CVARs in the Multiplayer Gem, see Multiplayer Gem CVars (p. 1176).

To use CVARs to set the client side configuration, enter the following console command.

```
+sv_port 33435 +gamelift_fleet_id <fleet> +gamelift_aws_access_key <aws access key>
+gamelift_aws_secret_key <aws secret key>
```

**To use the multiplayer sample user interface to configure Amazon GameLift**

1. By default, the multiplayer sample loads the Game Lobby map. To add or modify the CVARs, choose Amazon GameLift.
2. Fill in the details of the GameLift configuration and choose **Connect**.

3. To **create** a game session and join automatically, select the **Create Server** radio button and do the following:
   
i. Specify the **Server Name** and the **Map** (`sv_map`) to load.
   
ii. Enter the **Queue Name**, **Fleet ID**, or **Alias ID**.
   
iii. Choose the **Create Server** button.
4. To search for and join an active game session, select the Join Server radio button and do the following:
   
i. Specify the Queue Name, Fleet ID, or Alias ID.
ii. Choose Refresh. Active game sessions will be listed.
iii. Select a session and choose Join.

5. To use matchmaking to get placed in a game session, select the FlexMatch radio button and do the following:
i. Specify the matchmaking **Config Name**.
ii. Choose **Start Matchmaking**.

![GameLift Lobby](image)

**Create an Amazon GameLift Package**

To create a Amazon GameLift package, complete the following steps.

**To create a Amazon GameLift package**

1. Before you create an Amazon GameLift package, do the following:
   - Compile game assets
   - Build the Lumberyard executable
2. Run the following commands to create the Amazon GameLift package:

   ```bash
   mkdir GameLiftPackageWindows
   cp -r MultiplayerSample_pc_Paks_Dedicated/* GameLiftPackageWindows/
   cp -r Bin64vc141.Dedicated/* GameLiftPackageWindows/
   ```
3. Copy the corresponding Visual Studio redistributable into the `GameLiftPackageWindows` folder.
4. Verify the dedicated server runs from the `GameLiftPackageWindows` folder.
5. Upload your build and create a fleet from the Amazon GameLift console. For more information, see [Uploading Your Game to Amazon GameLift](#).
Secured Connection (Not Amazon GameLift Specific)

Amazon GameLift uses the OpenSSL-based secure socket driver to create a secured connection. However, instead of verifying the server, the secure socket driver can verify the client.

To enable a secured connection, make the following change to the `game.cfg` file:

\[
\text{gm_netsec_enable} = 1
\]

If client verification is needed, make the following change to the `game.cfg` file:

\[
\text{gm_netsec_verify_client} = 1
\]

**Note**

By default, the certificate and private key are loaded from the `multiplayersample.cert.pem` file (shared by the certificate and CA root) and from the `multiplayersample.key.pem` file. To specify different files, use the `gm_netsec_certificate` and `gm_netsec_private_key` CVARs.

Overview

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard enables multiplayer functionality through the following software layers:

- AZFramework
- Netbinding
- GridMate
  - Replica
  - Session
  - Carrier
  - Driver

These layers are illustrated in the following diagram.
NetBinding

The network binding API of the AzFramework library provides a way for components to synchronize their state over the network. The API is implemented on top of GridMate replicas. A special NetBindingComponent is responsible for the actual binding process, so entities that need to be synchronized need to have a NetBindingComponent added to them. When a game enters a multiplayer session, the NetBindingComponent collects replica chunks from the NetBindables on the entity, and adds them to a replica primary.
GridMate

GridMate is a library that enables you to easily add online features to your games on multiple operating systems and devices. The GridMate API library has two general categories: network synchronization and online systems. Each API is designed to be modular and extensible. Services can be enabled independently of each other, and different implementations can be provided for each API. Optional features are implemented as plugins for ease of customization. GridMate is built on top of Lumberyard's AzCore library. Service APIs are implemented using EBuses (AzCore's implementation of signal/slots) to improve modularity and extensibility. All GridMate allocations are piped through two specific allocators: GridMateAllocatorMP is used for allocations from the network synchronization APIs. GridMateAllocator is used for all other allocations, such as those from the online APIs and core system allocations. GridMate also supports debugging through AzCore's Driller framework. All network and replication events are reported and can be captured for logging and debugging purposes.

Replica

GridMate uses a single-primary replication model. For each replica, one node in the session owns the primary copy, and everyone else has a proxy copy. Replicas can be individually migrated from node to node at any time.

At the core of GridMate's replication model is the replica. Replicas, along with the chunks, datasets and RPCs that make up the replica, provide a mechanism for capturing and propagating the game state. Replicas also serve as the point of interaction for external game systems. Replicas can be owned by any node in the network and can be migrated to whichever node that can process them most efficiently.

Each node in the replication network runs a local instance of replica manager. As a node establishes connections to other nodes, it adds them to the replica manager as peers. This builds out its replication network.

One important design element of GridMate replicas is the broadcast nature of the system. Many replication systems allow users to specify replication targets directly, either per replica or per update. This attempt to enable bandwidth optimizations is error prone and puts the implementation burden on gameplay programmers who are often less familiar with network desynchronization issues. Instead, GridMate's approach follows the rule "when something happens, it happens for everyone".

Session

The session service is responsible for managing and maintaining the connectivity required to other members in a game session. GridMate's session service consists of a simple matchmaking API to facilitate integration with existing matchmaking services, and a session implementation that supports three topologies: P2P full mesh, client/server and a hybrid mode that consists of a full mesh network connected to a client/server network. Host migration is available when using full mesh topology. Host migration is a multi-step process that begins as nodes lose connectivity to the session host. The first step is host election: as nodes disconnect from the host, they broadcast a request for a new host election, and go through a series of voting rounds, until a majority is reached or the election process times out. The new host(s) then starts the migration process, dropping problematic connections and migrating replicas until the session is stable again before resuming normal operations. During this time the connection graph can be very unstable, and a variety of steps are taken to improve success rate.

Carrier

GridMate's carrier implementation provides reliable and unreliable messaging. Messages are sent over a channel. Each channel represents an independent stream of messages. Reliable and unreliable messages can be sent over the same channel. Within a channel, message delivery is always ordered, and out-of-order unreliable messages are always discarded. GridMate supports multiple channels to compartmentalize the effect of packet losses and reordering. GridMate provides separate dedicated channels for replication and voice chat traffic. To minimize impact to and from the game thread,
the current carrier implementation performs network sends and receives from a separate IO thread. Decoupling sends and receives into separate threads and incorporating epoll/IOCP is planned. The carrier API provides hooks for congestion control, connection handshakes and network simulators. Users can use the default implementations in GridMate or provide their own custom implementations.

Driver

The driver is the interface for the lowest level of the transport layer. Lumberyard ships with several driver implementations: SocketDriver is a generic socket driver that supports BSD/WinSock/Posix sockets on the corresponding operating systems. The SecureSocketDriver supports encrypted communication through the DTLS protocol by using OpenSSL.

Other GridMate Features

Other GridMate features include:

- **Online Service** - Provides essential user information used by the other APIs.
- **Achievements** - An API for in-game achievements support.
- **Leaderboards** - An API for leaderboard support.
- **Online Storage** - An API for online storage support.

CryNetwork Backward Compatibility (Deprecated)

Lumberyard has a backwards compatibility layer for the deprecated legacy networking system called "CryNetwork". This layer is mostly encapsulated inside the CryNetwork library and exposed through the INetwork interface. The layer is intended only for projects that were built using CryNetwork so that you can transition them to Lumberyard's network technology (NetBinding components and GridMate). Because the CryNetwork backward compatibility API layer uses CPU and bandwidth inefficiently, we strongly recommend that you do not build or release multiplayer games using it.

For information on the compatibility layer, see [CryNetwork Backward Compatibility](#).

Networking Architecture

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Fundamental Concepts

Lumberyard provides a network layer that supports a wide variety of game types on multiple operating systems and does not restrict game developers to using any particular network topology. You are able
to create games using three network topologies: P2P full mesh, client/server, and a hybrid mode that consists of a full mesh network connected to a client/server network. You can create gameplay objects that are server authoritative, and gameplay objects that are client authoritative.

In this discussion, peer and host have the following meanings:

**Peer** - A network node that is participating in a game session.

**Host** - A special kind of a peer that manages the game session. The host can run on one of the game clients or be a dedicated server.

Synchronization of the states of various networked game objects is achieved through the GridMate replication model. One important design element is the concept of a horizon. GridMate does not maintain a full graph of the replication network at each node. Instead, each node is only aware of the peers that it has a direct connection to; everything else is considered the "horizon". Nodes keep track of which replica updates are arriving from which peer (upstream) only for purposes of routing, so they know where to forward upstream requests and, in the case of hub nodes, where to send them downstream. Basically, if a node receives a request for a replica it doesn't own, it forwards it upstream.

**GridMate Architecture**

The following diagram shows the major components of the GridMate architecture and their relationships.
For more information, see the following pages.
Carrier

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Carrier is GridMate's messaging API. GridMate's reliable UDP implementation supports both reliable and unreliable messages. There is no out-of-order delivery. Out-of-order messages are queued if sent reliably, or discarded if sent unreliably.

The carrier sends messages through channels. The purpose of channels is to separate unrelated traffic, such as game state and voice chat. Message ordering is not enforced across channels.

The carrier API also provides hooks for congestion control and traffic simulation.

Channels and Message Priorities

Messages can be sent on different channels and have different priorities. Message ordering is always maintained between messages with the same priority sent on the same channel.

Channels provide a way to separate unrelated messages so that their ordering does not affect one other. When messages arrive out of order, they are either discarded or queued (and therefore delayed) depending on their reliability. Using different channels prevents unrelated messages from being unnecessarily dropped or delayed. For example, object replication traffic and voice chat traffic can be sent on different channels, so a missing reliable message for object replication would not cause voice chat data to be dropped, and vice versa.

Customizable Classes

You can customize the following classes to implement your own networking features:

- **Driver** - Carrier defers actual network operations to the driver, so different implementations can be provided for different operating systems and devices. This abstraction makes it possible to use OS or device-specific protocols from service providers such as Steam. The default implementation uses UDP and supports IPv4 and IPv6.

- **Simulator** - If a network simulator is present, the carrier passes all inbound and outbound traffic through it so different network conditions can be simulated. One simulator instance can be supplied per carrier instance. The default implementation can simulate different patterns for inbound and/or outbound latency, bandwidth caps, packet loss and packet reordering.

- **Traffic Control** - The traffic control module has two primary functions: provide network statistics and congestion control. Whenever messages are sent or received, they are passed along to the traffic control module so it can update its statistics, and also so it can provide feedback to limit the amount of data being sent. It also decides if messages should be considered lost and resent by the carrier.

CarrierDesc

CarrierDesc is the carrier descriptor. When you create a carrier, you use the CarrierDesc structure to specify the parameters for the current session.
### CarrierDesc Parameters

The following parameters can be supplied during carrier initialization:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>m_address</td>
<td>const char *</td>
<td>Specifies the local communication address to which the driver will bind. A value of 0 specifies any address. The default is nullptr.</td>
</tr>
<tr>
<td>m_connectionEvaluationThreshold</td>
<td>float</td>
<td>When a disconnection is detected, specifies the threshold at which all other connections are checked using ( m\text{-}connectionTimeoutMS \times m\text{-}connectionEvaluationThreshold ) to see if they are also failing because of a network failure. The default is 0.5f.</td>
</tr>
<tr>
<td>m_connectionTimeoutMS</td>
<td>unsigned int</td>
<td>Determines the time to allow for a connection attempt. The default is 5000 milliseconds.</td>
</tr>
<tr>
<td>m_disconnectDetectionPacketLossThreshold</td>
<td>float</td>
<td>Packet loss percentage threshold. Possible values are from 0.0 to 1.0, where 1.0 is 100 percent. The connection will be dropped after packet loss exceeds the value specified. The default is 0.3f.</td>
</tr>
<tr>
<td>m_disconnectDetectionRttThreshold</td>
<td>float</td>
<td>Specifies the RTT (round-trip time) threshold in milliseconds. The connection is dropped when the measured RTT is greater than the value specified. The default is 500.0f.</td>
</tr>
<tr>
<td>m_driver</td>
<td>class Driver *</td>
<td>Specifies a custom driver implementation. The default is nullptr.</td>
</tr>
<tr>
<td>m_driverIsCrossPlatform</td>
<td>bool</td>
<td>Specifies whether the driver maintains cross-OS and device compatibility. When true, the default driver drops to the most restrictive MTU (maximum transmission unit) across all supported operating systems and devices. The default is false.</td>
</tr>
<tr>
<td>m_driverIsFullPackets</td>
<td>bool</td>
<td>Specifies whether the driver ignores MTU limits. This parameter applies only to socket drivers and local area networks. An internet packet is usually around 1500 bytes. A value of true enables a maximum packet size of 64 KB. These big packets fail on the Internet but typically do not on local networks. The default is false.</td>
</tr>
<tr>
<td>m_driverReceiveBufferSize</td>
<td>unsigned int</td>
<td>Specifies the size of the internal receive buffer that the driver uses. A value of 0 specifies the default buffer size. This parameter can be used only if m_driver == null. The default is 0.</td>
</tr>
<tr>
<td>m_driverSendBufferSize</td>
<td>unsigned int</td>
<td>Specifies the size of the internal send buffer that the driver uses. A value of 0 specifies the default buffer size. This parameter can be used only if m_driver == null. The default is 0.</td>
</tr>
<tr>
<td>m_enableDisconnection</td>
<td>bool</td>
<td>Specifies whether the carrier drops connections when traffic conditions are bad. The default is true.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>This parameter should be set to <code>false</code> only when debugging.</td>
</tr>
<tr>
<td>m_familyType</td>
<td>int</td>
<td>Specifies the protocol family that the driver uses. A value of 0 specifies the default family.</td>
</tr>
<tr>
<td>m_port</td>
<td>unsigned int</td>
<td>Specifies the local communication port to which the driver binds. A value of 0 specifies the port assigned by the system.</td>
</tr>
<tr>
<td>m_securityData</td>
<td>const char *</td>
<td>Specifies a pointer to a string with security data. The default is <code>nullptr</code>.</td>
</tr>
<tr>
<td>m_sendBatchPacketCount</td>
<td>int</td>
<td>Specifies the number of full maximum transmission size (MTU) packets to queue before a send event is triggered. You can use this parameter to batch small messages into a single packet.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default value is 0, which means no batching. When <code>m_sendBatchPacketCount</code> is set to 0, all messages immediately trigger a send event on the carrier thread.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>To prevent data transmission from stalling, the carrier thread times out at the time specified by the <code>m_threadUpdateTimeMS</code> parameter. When the carrier thread receives a packet, it also checks the send queue for outgoing messages.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>This parameter is available in Lumberyard 1.16 and later versions.</td>
</tr>
<tr>
<td>m_simulator</td>
<td>class Simulator *</td>
<td>Optionally specifies a simulator through which all network messages are filtered. When specified, the carrier passes all inbound and outbound traffic through the specified simulator so that different network conditions can be simulated. You can specify one simulator instance per carrier instance.</td>
</tr>
<tr>
<td>m_threadCpuID</td>
<td>int</td>
<td>Restricts the carrier thread to a specific CPU core. The values that can be specified are operating system and device dependent. A value of -1 specifies no restriction. The default is -1.</td>
</tr>
<tr>
<td>m_threadInstantResponse</td>
<td>bool</td>
<td>Specifies whether I/O events wake up the carrier thread immediately. The default is <code>false</code>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Setting this value to <code>true</code> typically uses more bandwidth because messages (especially small messages) are grouped less efficiently.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>In Lumberyard 1.16 and later versions, <code>m_threadInstantResponse</code> affects only the reception of carrier thread packets. To send all messages immediately, the <code>m_sendBatchPacketCount</code> parameter must be set to 0 (the default).</td>
</tr>
<tr>
<td>Parameter</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>m_threadPriority</td>
<td>int</td>
<td>Specifies the thread priority for the carrier thread. The values that can be specified are operating system and device dependent. A value of −100000 inherits the priority from calling thread. The default is −100000.</td>
</tr>
<tr>
<td>m_threadUpdateTimeMS</td>
<td>int</td>
<td>Specifies, in milliseconds, how often the carrier thread is updated. This parameter is ignored if m_threadInstantResponse is true. Possible values are from 0 through 100. In general, the time interval should be higher than 10 milliseconds. Otherwise, it is more efficient to set m_threadInstantResponse to true. The default is 30 milliseconds.</td>
</tr>
<tr>
<td>m_trafficControl</td>
<td>class</td>
<td>Specifies a custom traffic control implementation that controls traffic flow to all connections and that handles issues like network congestion.</td>
</tr>
<tr>
<td>m_version</td>
<td>VersionType</td>
<td>Specifies the version of Carrier API that is being used. Carriers with mismatching version numbers are not allowed to connect to each other. The default is 1.</td>
</tr>
</tbody>
</table>

**Topics**

- Carrier Message Structure (p. 2017)
- The TCP Stream Driver (p. 2018)
- Using Windows Registered I/O with GridMate (p. 2020)

**Carrier Message Structure**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This topic describes the message structure used by the CarrierImpl networking class found in the Carrier.cpp file in the GridMate source code.

In the following sections, values in parentheses indicate the field's length in bits. For fields with variable length, the value indicates the minimum length.

**Datagram Format**

The overall datagram has the following structure.

```
DgramID (16) | Msg1 (64+) | Msg2 (24+) | ...
```

**Message Format**

The following diagram shows the possible message fields. Only the first two fields are present in every message header. All the other fields are sent only as necessary. In general, ChannelId and NumChunks are rarely sent. SeqNum and RelSeqNum are usually sent once per datagram.

```
Flags (8) | Length (16) | ChannelId (8) | NumChunks (16) | SeqNum (16) | RelSeqNum (16) | Payload (0+)
```
System Messages

Carrier system messages include ACK and ClockSync.

ACK

The ACK system message is used to ACK any received messages and to keep the connection alive. When there is no activity, an ACK containing only the first two fields is sent, otherwise, the actual fields sent vary depending on the pattern being ack'ed. At the very least, LastToAck is sent. If the sequence ack'ed contains gaps, a variable-length bit set is used; otherwise, the first sequence number being ack'ed is included. These possible message formats are shown in the following diagram.

<table>
<thead>
<tr>
<th>MsgId (8)</th>
<th>Flags (8)</th>
</tr>
</thead>
<tbody>
<tr>
<td>MsgId (8)</td>
<td>Flags (8)</td>
</tr>
<tr>
<td>MsgId (8)</td>
<td>Flags (8)</td>
</tr>
</tbody>
</table>

ClockSync

A ClockSync message is sent about once per second to keep all the clocks in the session in sync. The message format is as follows.

| MsgId (8) | Time (32) |

The TCP Stream Driver

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Starting with Lumberyard version 1.10, the GridMate library offers a TCP socket driver in addition to its existing UDP driver. Unlike UDP, the TCP protocol uses direct connections, which require a listening port and established server endpoint that clients can use. The GridMate library also adds an event bus that detects stream connect and disconnect events for TCP.

TCP Socket Driver Classes

The TCP socket driver has four public classes in the GridMate namespace that handle TCP packet traffic.

**GridMate::StreamSocketDriver**

This socket driver has methods that handle TCP connections.

**Stream Socket Methods**

<table>
<thead>
<tr>
<th>Action</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Establish a direct connection to a listening server</td>
<td>ResultCode ConnectTo(const SocketDriverAddressPtr&amp; addr)</td>
</tr>
<tr>
<td>Break an established TCP connection</td>
<td>ResultCode DisconnectFrom(const SocketDriverAddressPtr&amp; addr);</td>
</tr>
<tr>
<td>Start accepting connections to the server</td>
<td>ResultCode StartListen(AZ::s32 backlog);</td>
</tr>
<tr>
<td>Stop the server from accepting connections</td>
<td>ResultCode StopListen();</td>
</tr>
</tbody>
</table>
This call does not shut down the driver. You can start monitoring after the call.

<table>
<thead>
<tr>
<th>Action</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Poll the number of established connections</td>
<td>AZ::u32 GetNumberOfConnections() const;</td>
</tr>
<tr>
<td>Query whether a remote address endpoint is connected</td>
<td>bool IsConnectedTo(const SocketDriverAddressPtr&amp; to) const;</td>
</tr>
<tr>
<td>Query whether the driver is actively listening for new connections</td>
<td>bool IsListening() const;</td>
</tr>
</tbody>
</table>

**GridMate::StreamSocketDriverEventsBus**

The socket driver event bus has methods that detect connection and disconnection events.

**Stream Socket Events Bus Methods**

<table>
<thead>
<tr>
<th>Callback that occurs when</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>The socket driver establishes a connection</td>
<td>virtual void OnConnectionEstablished(const SocketDriverAddress&amp; address);</td>
</tr>
<tr>
<td>The socket driver detects a removed connection</td>
<td>virtual void OnConnectionDisconnected(const SocketDriverAddress&amp; address);</td>
</tr>
</tbody>
</table>

**GridMate::StreamSecureSocketDriver**

The secure stream socket driver has the following method that initializes cryptographic data for the driver. It calls the Initialize() method before setting up the key and/or certificate.

```
ResultCode InitializeSecurity(AZ::s32 familyType, const char* address, AZ::u32 port, AZ::u32 receiveBufferSize, AZ::u32 sendBufferSize, StreamSecureSocketDriverDesc& desc);
```

**GridMate::StreamSecureSocketDriver::StreamSecureSocketDriverDesc**

The secure stream socket driver requires a description structure to set up the cryptographic key, certificates, and options. The description structure has the following members.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>const char* m_privateKeyPEM;</td>
<td>A base64 encoded PEM format private key that is used on the server only.</td>
</tr>
<tr>
<td>const char* m_certificatePEM;</td>
<td>A base64 encoded PEM format certificate. This public certificate encrypts the Transport Layer Security (TLS) handshake.</td>
</tr>
<tr>
<td>const char* m_certificateAuthorityPEM;</td>
<td>A base64 encoded PEM format CA root certificate.</td>
</tr>
<tr>
<td>bool m_authenticateClient;</td>
<td>Ensures that both the client and server authenticate the PEM certificate. This setting is made on the server. The default is false; only the server is authenticated by default.</td>
</tr>
</tbody>
</table>
Security

You can optionally use the OpenSSL library with the TCP socket driver to support encryption of all streamed network traffic between server and clients. In Lumberyard, this security feature is currently available only for the Windows and Linux operating systems. The TCP socket driver implements these security features in the `GridMate::StreamSecureSocketDriver` class.

Set up server-side cryptographic keys and certificates as in the following example.

```cpp
GridMate::StreamSecureSocketDriver server;
GridMate::StreamSecureSocketDriver::StreamSecureSocketDriverDesc desc;
desc.m_certificatePEM = myCertPEM;
desc.m_privateKeyPEM = myPrivateKeyPEM;
const AZ::u16 port = 5555;
server.InitializeSecurity(GridMate::Driver::BSD_AF_INET, nullptr, port, 1024*64, 1024 * 64, desc);
```

The `InitializeSecurity()` method is used instead of the `Initialize()` method from the stream socket driver. You can also enable client-side certificate authentication in the secure driver description. The default is server side only.

Client-side setup is similar to the server side but does not require a private key, as in the following code example.

```cpp
GridMate::StreamSecureSocketDriver client;
GridMate::StreamSecureSocketDriver::StreamSecureSocketDriverDesc desc;
desc.m_certificateAuthorityPEM = myPublicCertPEM;
client.InitializeSecurity(GridMate::Driver::BSD_AF_INET, nullptr, 0, 1024 * 64, 1024 * 64, desc);
```

For more information about cryptographic key and security certificate options, see Enabling Encryption (p. 2069).

For more information about using the TCP stream driver, see Using the TCP Stream Driver (p. 2077).

Using Windows Registered I/O with GridMate

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Starting in Lumberyard version 1.16, GridMate carrier supports Microsoft's registered I/O (RIO) socket interface. RIO is a network traffic processing interface that provides lower latency and higher throughput to the Windows operating system kernel. Lumberyard implements RIO support in the `GridMate::RIOPlatformSocketDriver` class, which is fully contained in the carrier `SocketDriver` class.

For the Lumberyard source code, see the `SocketDriver.*` and `SecureSocketDriver.*` files in the `lumberyard_version\dev\Code\Framework\GridMate\GridMate\Carrier\` directory.

Prerequisites

The `SocketDriver` class uses the `RIOPlatformSocketDriver` class seamlessly if the following three requirements are met:

1. RIO is supported on the build computer.
2. RIO is supported at runtime on the computer that runs it.
3. RIO has been enabled by passing true to the isHighPerformance parameter in the SocketDriver class or SecureSocketDriver class.

Using the RIO Platform Socket Driver

To use the RIOPlatformSocketDriver class, initialize a custom SocketDriver or SecureSocketDriver class and assign it to the CarrierDesc::m_driver field, as shown in the following example.

Example

```cpp
class MyClass : public GridMate::SessionEventBus::Handler
{
public:
  void OnSessionDelete(GridMate::GridSession* session) override;

private:
  GridMate::SocketDriver* m_driver;
};

void MyClass::JoinSession() {
  // ...

  // Create an instance of SocketDriver that disables "full" (oversized) packets, enables cross-platform support, and
  // enables high performance socket interfaces.
  m_driver = new GridMate::SocketDriver(false, true, true);

  // Before hosting or joining a GridMate session, set the CarrierDesc::m_driver
  // property to the instance of SocketDriver.
  GridMate::SocketDesc carrierDesc;
  carrierDesc.m_driver = m_driver;

  // ...
}

// At the end of the GridMate session, delete the SocketDriver instance.
void MyClass::OnSessionDelete(GridMate::GridSession* session) {
  // ...

  delete m_driver;
  m_driver = nullptr;

  // ...
}
```

Caveats

When using the RIO platform socket driver, note the following:

- **RIO bypasses conventional socket buffers** – Because programs cannot depend on operating system buffering, your game should enable m_threadInstantResponse when it uses RIO.

- **RIO buffer sizes must be large enough to handle all buffering** – RIO requires code to preallocate fixed size buffers. This preallocation is handled in the RIOPlatformSocketDriver. The RIOPlatformSocketDriver converts the carrier descriptor (p. 2014) send and receive buffer sizes into a full packet buffer count.

- **The RIO platform driver is not compatible with the GridMate m_driverIsFullPackets setting** – GridMate “full” packets are oversized packets that are usable only for certain LAN networking...
applications. Such packets are not routable or compatible with the RIO platform driver. For this reason, set `m_driverIsFullPackets` to false when you use the RIO platform driver.

## Marshalling

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Data is written to the network using `WriteBuffer`, and data received is read using `ReadBuffer`. Each buffer specifies the endianness used.

All data marshalling, whether for a `DataSet` or RPC, is written using a specialization of the `Marshaler` type. There are a number of pre-defined marshalers for fundamental types (`int32`, `uint16`, `bool`, `float`, etc), as well as other common types like containers and bitfields.

Marshalers and read/write buffers have a close relationship. A marshaler reads or writes its data types from or to the buffer. If the type is a complex type like a class or container, then that marshaler marshals each of its fields with nested marshalers. The nested invocation of marshaler types continues until a fundamental type is written to the buffer with the endianness of the network. Additional custom marshalers can be implemented to support custom types or to perform domain-based compression. Default marshalers are implemented through template specialization.

The base `Marshaler` class in GridMate follows.

```cpp
namespace GridMate
{
    template<typename T>
    class Marshaler
    {
    public:
        void Marshal(WriteBuffer& wb, const T& value);
        void Unmarshal(T& value, ReadBuffer& rb);
    };
}
```

If a `Marshaler` instance is not specified with the data set or RPC declaration, the template specialization is used.

Implementation of the default marshaler for AZCore's `Vector3` math type can be found in `Code/Framework/GridMate/GridMate/Serialize/MathMarshal.h`:

```cpp
namespace GridMate
{
    template<>
    class Marshaler<AZ::Vector3>
    {
    public:
        typedef AZ::Vector3 DataType;
        static const AZStd::size_t MarshalSize = sizeof(float) * 3;
        void Marshal(WriteBuffer& wb, const AZ::Vector3& vec) const
        {
            Marshaler<float> marshaler;
            marshaler.Marshal(wb, vec.GetX());
            marshaler.Marshal(wb, vec.GetY());
            marshaler.Marshal(wb, vec.GetZ());
        }
    };
}
```
void Unmarshal(AZ::Vector3& vec, ReadBuffer& rb) const
{
    float x, y, z;
    Marshaler<float> marshaler;
    marshaler.Unmarshal(x, rb);
    marshaler.Unmarshal(y, rb);
    marshaler.Unmarshal(z, rb);
    vec.Set(x, y, z);
}

Markers

Notice the declaration of MarshalSize above. WriteBuffer supports the concept of markers. A marker is a placeholder that can be inserted into the buffer, so its value can be filled after additional data is written to the buffer. This is useful for prepending a length field in front of the actual data. Markers require that the data that is inserted be of fixed length, and MarshalSize is used to query this length. Therefore, marshalers that write data to the marker need to declare a valid MarshalSize.

Buffers

Write Buffers

Write buffers are backed by the following three types of allocation schemes:

Dynamic – Dynamically allocated and automatically grown

Static – Fixed size, allocated on the stack

Static In Place – Uses another buffer as its backing store

By default, the write function uses the default marshaler for the data type, but you can override the marshaler to create a custom marshaler.

There are two ways to write a type to a network buffer:

1) The following example uses the default marshaler for the type passed into Write(). In this example, the float marshaler is used.

WriteBuffer wb;
w.Write(1.0f);

2) The following example uses the HalfMarshaler, which compresses the float by half.

WriteBuffer wb;
w.Write(1.0f, HalfMarshaler());

Read Buffers

Read buffers have built-in overflow detection and do not read any data fields after the end of the buffer has been reached. You can check this by looking at the return value of the Read method. Note that if data isn’t read for a given value, then the value is left uninitialized.

Predefined Marshalers

GridMate includes the following predefined marshalers:
Fundamental C++ Types

<table>
<thead>
<tr>
<th>Floating point</th>
<th>Misc</th>
<th>Unsigned</th>
<th>Signed</th>
</tr>
</thead>
<tbody>
<tr>
<td>float</td>
<td>char</td>
<td>AZ::u8</td>
<td>AZ::s8</td>
</tr>
<tr>
<td></td>
<td>bool</td>
<td>AZ::u16</td>
<td>AZ::s16</td>
</tr>
<tr>
<td>enum (specify marshaled size by inheriting enum from a type)</td>
<td></td>
<td>AZ::u32</td>
<td>AZ::s32</td>
</tr>
<tr>
<td></td>
<td></td>
<td>AZ::u64</td>
<td>AZ::s64</td>
</tr>
</tbody>
</table>

Container Types

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Associative</th>
<th>Explicit Marshalers</th>
</tr>
</thead>
<tbody>
<tr>
<td>vector</td>
<td>map</td>
<td>ContainerMarshaler</td>
</tr>
<tr>
<td>list</td>
<td>set</td>
<td>MapContainerMarshaler</td>
</tr>
<tr>
<td>string</td>
<td>unordered_map</td>
<td></td>
</tr>
<tr>
<td></td>
<td>unordered_set</td>
<td>(Use these marshalers when the subtypes of the container require a non-default marshaler)</td>
</tr>
<tr>
<td></td>
<td>multimap</td>
<td></td>
</tr>
<tr>
<td></td>
<td>multiset</td>
<td></td>
</tr>
</tbody>
</table>

Utility Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConversionMarshaler&lt;SerializedType, OriginalType&gt;</td>
<td>Performs static casts between SerializedType (type on the wire) and OriginalType (type declared in user code).</td>
</tr>
<tr>
<td>AZ::Crc32</td>
<td>A CRC32 value.</td>
</tr>
<tr>
<td>AZStd::bitset</td>
<td>A class for arbitrary flags.</td>
</tr>
<tr>
<td>AZStd::pair</td>
<td>A std::pair class. Implicitly used by the map, unordered_map, and multimap marshalers.</td>
</tr>
<tr>
<td>AZ::Aabb</td>
<td>An axis aligned bounding box.</td>
</tr>
<tr>
<td>AZStd::chrono::duration</td>
<td>A time duration in 32 bit milliseconds.</td>
</tr>
<tr>
<td>GridMate::UnionDataSet</td>
<td>A type safe tagged union designed for network transmission.</td>
</tr>
</tbody>
</table>

Compression Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Float16Marshaler</td>
<td>Compresses a float32 to float16.</td>
</tr>
</tbody>
</table>
Overview

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HalfMarshaler</td>
<td>Compresses a float to half precision.</td>
</tr>
<tr>
<td>IntegerQuantizationMarshaler&lt;Min, Max, Bytes&gt;</td>
<td>Quantizes an integer in the range [Min, Max] to the number of bytes specified in Bytes.</td>
</tr>
</tbody>
</table>

Custom Marshalers

Creating a custom data marshaler is as simple as specializing the `GridMate::Marshaler` type, and implementing the expected `Marshal` and `Unmarshal` methods. If the data written is constant size, adding the member `MarshalSize` allows you to use the marshaler in scenarios where fixed sizes are required (such as markers).

Fixed Size Custom Marshaler

The following is an example of a fixed size custom marshaler.

```cpp
namespace GridMate
{
    template<class MyClass>
    class Marshaler
    {
    public:
        static const AZStd::size_t MarshalSize = sizeof(m_field1) + sizeof(m_field2);
        void Marshal(GridMate::WriteBuffer& wb, const MyClass& value) const
        {
            wb.Write(value.m_field1);
            wb.Write(value.m_field2);
        }
        void Unmarshal(MyClass& value, ReadBuffer& rb) const
        {
            rb.Read(value.m_field1);
            rb.Read(value.m_field2);
        }
    };
}
```

Sessions

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

GridMate session service provides session connectivity and management. Both hub-and-spoke (client/server) and P2P full-mesh topologies are supported.

You can also create multiple sessions for each GridMate instance. Each session creates its own carrier and replica manager instances, so there is no interaction between sessions. GridMate sessions support host migration when running in P2P mode.

Topics

- Starting and Stopping the Session Service (p. 2026)
- Hosting a Session (p. 2028)
- Searching for a Session (p. 2029)
Starting and Stopping the Session Service

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The session service is responsible for hosting or joining sessions and is represented by the `GridMate::SessionService` abstract class.

When a session service is created, a descriptor class derived from `GridMate::SessionServiceDesc` is passed in as a constructor argument.

The implementations of `GridMate::SessionService` that are included with the base Lumberyard engine are as follows.

<table>
<thead>
<tr>
<th>Implementation</th>
<th>Descriptor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>GridMate::LANSessionService</code></td>
<td><code>GridMate::SessionServiceDesc</code></td>
<td>Sessions hosted over a local area network.</td>
</tr>
</tbody>
</table>

Starting a Session Service

Only one session service can be present per `GridMate::IGridMate` instance.

**Note**
Attempting to register multiple session services causes an assert and overrides any previously registered session services.

You have two ways to start a session service:

- Create a session service object and register it with GridMate.
- Register an existing session service object with GridMate.

<table>
<thead>
<tr>
<th>Starting Method</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>GridMate::StartGridMateService()</code></td>
<td>Creates a session service object and registers it with <code>GridMate::IGridMate</code>.</td>
</tr>
<tr>
<td><code>GridMate::RegisterService()</code></td>
<td>Registers an existing session service object with <code>GridMate::IGridMate</code>.</td>
</tr>
</tbody>
</table>

Stopping a Session Service

The method for stopping the session service depends on how the session service was started.

<table>
<thead>
<tr>
<th>Starting Method</th>
<th>Stopping Method</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>GridMate::StartGridMateService()</code></td>
<td><code>GridMate::StopGridMateService()</code></td>
<td>The session service is stopped when <code>GridMate::IGridMate</code> is destroyed by</td>
</tr>
<tr>
<td>Starting Method</td>
<td>Stopping Method</td>
<td>Details</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------</td>
<td>---------</td>
</tr>
<tr>
<td>GridMate::RegisterService</td>
<td>GridMate::UnregisterService</td>
<td>The session is stopped and memory freed when GridMate::UnregisterService() is called.</td>
</tr>
<tr>
<td>GridMate::RegisterService</td>
<td>GridMate::UnregisterService</td>
<td>using the GridMate::GridMateDestroy() method.</td>
</tr>
</tbody>
</table>

**Examples**

The following examples assume that GridMate has been initialized.

**Starting and Stopping with GridMate::StartGridMateService**

The following example uses GridMate::StartGridMateService.

```cpp
void MyClass::StartSessionService()
{
    IGridMate* gridMate = gEnv->pNetwork->GetGridMate();
    if(gridMate)
    {
        // The session service is started and will be stopped when IGridMate is destroyed.
        GridMate::SessionServiceDesc desc;
        GridMate::StartGridMateService<GridMate::LANSessionService>(gridMate, desc);
    }
}
```

**Starting and Stopping with GridMate::RegisterService() and GridMate::UnregisterService()**

The following example uses GridMate::RegisterService() and GridMate::UnregisterService().

```cpp
void MyClass::StartSessionService()
{
    IGridMate* gridMate = gEnv->pNetwork->GetGridMate();
    GridMate::SessionService* sessionService = nullptr;
    if(gridMate)
    {
        GridMate::SessionServiceDesc desc;
        sessionService = aznew GridMate::LANSessionService(desc);
        gridMate->RegisterService(sessionService);
    }
    return sessionService;
}

void MyClass::StopSessionService(GridMate::SessionService* sessionService)
{
    IGridMate* gridMate = gEnv->pNetwork->GetGridMate();
    if(gridMate)
    {
        // Unregister the session service and free the session service pointer.
        gridMate->UnregisterService(sessionService);
    }
}
```
Hosting a Session

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A session can be hosted by calling `IGridMate::HostSession()` after the session service has been started. The session settings and configuration are set in the `GridMate::SessionParams` argument, which acts as a base class for certain implementations of `GridMate::SessionService`.

<table>
<thead>
<tr>
<th>Implementation of GridMate::SessionService</th>
<th>Implementation of GridMate::SessionParams</th>
</tr>
</thead>
<tbody>
<tr>
<td>GridMate::LANSessionService</td>
<td>GridMate::LANSessionParams</td>
</tr>
</tbody>
</table>

GridMate::SessionParams

The following table shows the supported parameters in `GridMate::SessionParams`.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>m_localMember</td>
<td>Yes</td>
<td></td>
<td>This is not required for a LAN session, only for consoles.</td>
</tr>
<tr>
<td>m_topology</td>
<td>No</td>
<td>ST_PEER_TO_PEER(CLIENT_SERVER): A client is only connected to the server.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>ST_PEER_TO_PEER: A client is connected to all other clients.</td>
<td></td>
</tr>
<tr>
<td>m_peerToPeerTimeout</td>
<td>Yes</td>
<td>10000</td>
<td>The time without a response, in seconds, after which a peer is disconnected.</td>
</tr>
<tr>
<td>m_numPublicSlots</td>
<td>Yes</td>
<td></td>
<td>The maximum number of players that can join the session.</td>
</tr>
</tbody>
</table>

GridMate::LANSessionParams

`GridMate::LANSessionParams` has the following additional parameter.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>m_port</td>
<td>No</td>
<td>0</td>
<td>The port to monitor for search requests from other clients. If 0, this</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>session is hidden to searches. Otherwise, the port number falls in the</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>range from 1 through 65536.</td>
</tr>
</tbody>
</table>

Events

The following table describes GridMate session service events.

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OnSessionCreated</td>
<td>A new session has just been created.</td>
</tr>
<tr>
<td>OnMemberJoined</td>
<td>A player has joined the session.</td>
</tr>
</tbody>
</table>
### Overview

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OnMemberLeaving</td>
<td>A player has left the session.</td>
</tr>
</tbody>
</table>

### Examples

The following example hosts a session. The example assumes that GridMate has been initialized and a session service registered.

```cpp
bool MyClass::HostSession()
{
    GridMate::IGridMate* gridMate = gEnv->pNetwork->GetGridMate();

    if(gridMate)
    {
        GridMate::LANSessionParams params;
        params.m_topology = GridMate::ST_CLIENT_SERVER;
        params.m_numPublicSlots = 10;
        params.m_port = 10000;
        params.m_flags = 0;
        params.m_localMember = gridMate->GetOnlineService()->GetUser();

        GridMate::Session session = gridMate->HostSession(&params,
            GridMate::CarrierDesc());
        if(session != nullptr)
        {
            // Failed to create the session..
            return true;
        }
    }
    return false;
}
```

### Searching for a Session

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You search for a session by calling `GridMate::StartGridSearch()` after the session service has been started. The session settings and configuration are set in the `GridMate::SearchParams`, which acts as a base class for certain implementations of `GridMate::SessionService`.

### Implementation of `GridMate::SessionService` vs. `GridMate::SearchParams`

<table>
<thead>
<tr>
<th>Implementation of <code>GridMate::SessionService</code></th>
<th>Implementation of <code>GridMate::SearchParams</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>GridMate::LANSessionService</td>
<td>GridMate::LANSearchParams</td>
</tr>
</tbody>
</table>

### GridMate::SearchParams

The following table shows the supported parameters in `GridMate::SearchParams`.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>m_localMember</td>
<td>Yes</td>
<td></td>
</tr>
</tbody>
</table>
GridMate::LANSearchParams

GridMate::LANSessionParams has the following additional parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>m_serverAddress</td>
<td>No</td>
<td>Empty</td>
<td>The address of a server to search for. If empty, a broadcast address is used.</td>
</tr>
<tr>
<td>m_serverPort</td>
<td>Yes</td>
<td></td>
<td>The port that game servers monitor for searches.</td>
</tr>
<tr>
<td>m_broadcastFrequencyMs</td>
<td>No</td>
<td>1000</td>
<td>The interval, in milliseconds, between search broadcast requests.</td>
</tr>
</tbody>
</table>

Search Results

When a search is complete, the OnGridSearchComplete() event is called. The results are found in the GridMate::GridSearch argument.

GridMate::GridSearch contains an array of search results.

To query the size of the array, use GridMate::GridSearch::NumResults().

To query individual results, use GridMate::GridSearch::GetResult().

The GridMate::SearchInfo object contains more details about the session (for example, the number of used and free player slots) and can be used when Joining a Session (p. 2031).

Events

The following table describes GridMate session search events.

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OnGridSearchStart</td>
<td>A grid search has started.</td>
</tr>
<tr>
<td>OnGridSearchComplete</td>
<td>A grid search has finished and contains the results.</td>
</tr>
</tbody>
</table>

Examples

The following example searches for all available sessions. The example assumes that GridMate has been initialized, a session service has been registered, and the class MyClass is listening for session events.

```cpp
void MyClass::StartSearch()
{
```
GridMate::IGridMate* gridMate = gEnv->pNetwork->GetGridMate();
if(gridMate)
{
    GridMate::LANSearchParams params;
    params.m_serverPort = 20000;
    params.m_localMember = gridMate->GetOnlineService()->GetUser();
    gridMate->StartGridSearch(&params);
}
void MyClass::OnGridSearchComplete(GridMate::GridSearch* search)
{
    if(search->GetNumResults() > 0)
    {
        // Found sessions that match the specified criteria
    }
}

## Joining a Session

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You have two ways to join a session:

- By **Searching for a Session (p. 2029)** and using a `GridMate::SearchInfo` object from the results.
- Directly to an existing game session by using a `GridMate::SessionIdInfo` object.

Regardless of the method, a session is joined using one of the overloaded `IGridMate::JoinSession()` functions after the session service has been started.

**Note**
The argument `GridMate::JoinParams` currently has no supported parameters.

### Events

The following table describes GridMate session join events.

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OnSessionJoined</td>
<td>The client has been successfully added to the session.</td>
</tr>
<tr>
<td>OnMemberJoined</td>
<td>A player has joined the session.</td>
</tr>
<tr>
<td>OnMemberLeaving</td>
<td>A player has left the session.</td>
</tr>
</tbody>
</table>

### Example

The following example joins a session that has been found as the result of a session search.

```cpp
void MyClass::OnGridSearchComplete(const GridMate::GridSearch* search)
{
    GridMate::IGridMate* gridMate = gEnv->pNetwork->GetGridMate();
    // Further code...
}
```
if(gridMate)
{
    if(search->GetNumResults() > 0)
    {
        GridMate::Session* session = gridMate->JoinSession(search->getResult(0),
        GridMate::JoinParams(), GridMate::CarrierDesc());
    }
}
void MyClass::OnSessionJoined(GridMate::GridSession* session)
{
    // Joined the session successfully
}

Reacting to Session Events

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Much of the session functionality is asynchronous because functions can be called, but the response is often not immediately available. For example, messages may be slowed by network transfer time, server processing, or the required response time.

The Working with the Event Bus (EBus) system (p. 1851) in Lumberyard is an event bus system that can send out events when asynchronous session functions are complete. This topic shows you how to set up your application to use the event bus and to connect and disconnect from it.

Setup

Your application must derive a class from GridMate::SessionEventBus::Handler. This class must contain certain overridden session events. However, not all events need to be implemented. An example follows.

class MyClass : public GridMate::SessionEventBus::Handler
{
    public:
        void OnSessionJoined(GridMate::GridSession* session) override;
        void OnMemberJoined(GridMate::GridSession* session, GridMate::GridMember* member)
        override;
        void OnMemberLeaving(GridMate::GridSession* session, GridMate::GridMember* member)
        override;
};

Connect

The following example shows how to connect to the session event bus and start receiving session events.

void MyClass::Init()
{
    GridMate::IGridMate* gridMate = gEnv->pNetwork->GetGridMate();
    if(gridMate)
    {
        GridMate::SessionEventBus::Handler::BusConnect(gridMate);
    }
}
**Disconnect**

The following example shows how to disconnect from the session event bus and stop receiving session events.

```cpp
void MyClass::Term()
{
    GridMate::IGridMate* gridMate = gEnv->pNetwork->GetGridMate();
    if(gridMate)
    {
        GridMate::SessionEventBus::Handler::BusDisconnect(gridMate);
    }
}
```

**Network Session Service Event Descriptions**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A description of each session event follows.

**virtual void OnSessionServiceReady()**

Callback that occurs when the session service is ready to process sessions.

**virtual void OnGridSearchStart(GridSearch* gridSearch)**

Callback when a grid search begins.

**virtual void OnGridSearchComplete(GridSearch* gridSearch)**

Callback that notifies the title when a game search query is complete.

**virtual void OnGridSearchRelease(GridSearch* gridSearch)**

Callback when a grid search is released (deleted). It is not safe to hold the grid pointer after this event.

**virtual void OnMemberJoined(GridSession* session, GridMember* member)**

Callback that notifies the title when a new member joins the game session.

**virtual void OnMemberLeaving(GridSession* session, GridMember* member)**

Callback that notifies the title that a member is leaving the game session.

**Warning**

The member pointer is not valid after the callback returns.

**virtual void OnMemberKicked(GridSession* session, GridMember* member)**

Callback that occurs when a host decides to kick a member. An OnMemberLeaving event is triggered when the actual member leaves the session.

**virtual void OnSessionCreated(GridSession* session)**

Callback that occurs when a session is created. After this callback it is safe to access session features. The host session is fully operational if client waits for the OnSessionJoined event.

**virtual void OnSessionJoined(GridSession* session)**

Called on client machines to indicate that the session has been joined successfully.
virtual void OnSessionDelete(GridSession* session)

Callback that notifies the title when a session is about to be terminated.

**Warning**
The session pointer is not valid after the callback returns.

virtual void OnSessionError(GridSession* session, const string& errorMsg)

Called when a session error occurs.

virtual void OnSessionStart(GridSession* session)

Called when the game (match) starts.

virtual void OnSessionEnd(GridSession* session)

Called when the game (match) ends.

virtual void OnMigrationStart(GridSession* session)

Called when a host migration begins.

virtual void OnMigrationElectHost(GridSession* session, GridMember*& newHost)

Called to enable the user to select a member to be the new Host.

**Note**
The value is ignored if it is null, if the value is the current host, or if the member has an invalid connection ID.

virtual void OnMigrationEnd(GridSession* session, GridMember* newHost)

Called when the host migration is complete.

virtual void OnWriteStatistics(GridSession* session, GridMember* member, StatisticsData& data)

Called at the last opportunity to write statistics data for a member in the session.

**Replicas**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Game sessions use replicas to synchronize the state of the session. To use a replica, you simply declare the states that must be synchronized and the remote procedure calls (RPCs) that are supported. After you bind the replica object to the network, the engine does the work. There is no need to worry about how to properly route messages or discover remote objects. When you add a local (primary) replica to the network, the replica is automatically discovered by remote nodes. In addition, corresponding remote proxy replica objects are created on the remote nodes. Only the owner of the replica is allowed to change states, and new states are automatically propagated to all other nodes. RPCs can be called from any node but are routed to the primary (owner) node for verification and processing.

**Topics**
- Replica (p. 2035)
- Replica Chunks (p. 2037)
- Datasets (p. 2040)
- Remote Procedure Calls (RPCs) (p. 2044)
Replica

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Replicas are core components of GridMate's replication system that are created by network-connected GridMate peers. When a peer creates a replica, GridMate propagates the replica over the network to synchronize the replica's state across the session. A locally created and owned replica is called a primary replica. The copy of the primary replica that connected peers receive is called a proxy replica. The synchronization and instantiation of replicas is handled by Replica Manager (p. 2047).

Replica Chunks

Every replica holds a collection of user-defined ReplicaChunk (p. 2037) objects that are synchronized with all the peers in the current session. A replica chunk is a container for user-defined DataSet (p. 2040) objects and Remote Procedure Calls (RPCs) (p. 2044). Any change to a DataSet object or a call to an RPC causes the replica to synchronize its state across the session.

Limitations

Replica chunks have the following limitations:

- Each replica can contain only 32 chunks.
- Chunks can be attached or detached only when a replica is not bound to a replica manager.

Creating a Replica and Attaching Chunks

To create a replica, invoke the following method:

```
GridMate::ReplicaPtr replica = GridMate::Replica::CreateReplica();
```

Most use cases require only one chunk per replica. To create a chunk and attach it to a replica by using a single call, use the CreateAndAttachReplicaChunk helper function, as in the following example:

```
GridMate::CreateAndAttachReplicaChunk<MyReplicaChunk>(replica, ...);
```

If you just want to attach a chunk to a replica, do the following:

```
replica->AttachReplicaChunk(myChunk);
```

For more information about the creation and propagation of replica chunks, see Replica Chunks (p. 2037).

Binding a Replica to the Session Replica Manager

In order for a replica to be synchronized, it must be bound to the session replica manager. After you create a replica and attach chunks to it, get the replica manager from the GridMate session (p. 2025). Then, bind the replica to it as follows:

```
GridMate::ReplicaManager* replicaManager = session->GetReplicaMgr();
replicaManager->AddMaster(replica);
```

Proxy replicas are automatically instantiated by remote peers' replica managers and, therefore, automatically bound.
Replica Ownership

When a peer creates a replica and binds it to the session replica manager, that peer becomes the owner of the replica. Each replica can be owned by only one peer. The replica owner is the only peer on the network that has the authority to change the state of the replica. For example, it can change the chunks’ datasets or directly execute its RPCs. Any state changes performed on a proxy replica are considered invalid and do not propagate throughout the session. RPCs can be called on a proxy replica, but the calls are forwarded to the owner for confirmation before they can be executed. Once this confirmation is given, the RPC is sent to all proxies and also executed locally by the peer. If the primary replica denies the execution, no peers receive the RPC call.

Changing Ownership

Replica ownership can be transferred from one peer to another, but the current owner of the replica must agree to the transfer. For information on how a replica owner can prevent transfer of ownership, see Replica Chunks (p. 2037).

Ownership transfer happens automatically when a session performs host migration on a peer-to-peer network. You can also request it explicitly by invoking the following method:

```cpp
replica->RequestChangeOwnership(); // Request ownership of a given replica for the local peer
```

Ownership transfer is an asynchronous process. When an ownership transfer is completed, each replica chunk is notified of the change by the `OnReplicaChangeOwnership` callback function.

Replica ID

Each replica has a unique ID associated with it. The replica ID is guaranteed to be unique within a particular GridMate session. You can use the replica ID to retrieve a replica from the session replica manager, as in the following example:

```cpp
GridMate::ReplicaManager* replicaManager = session->GetReplicaMgr();
GridMate::ReplicaPtr replica = replicaManager->FindReplica(myReplicaId);
if (replica == nullptr)
{
    // Replica with given ID does not exist
    return;
}
if (replica->IsProxy())
{
    // This is a proxy replica
}
if (replica->IsMaster())
{
    // This is a primary replica
}
```

Lifetime

The lifetime of a replica is controlled by a `GridMate::ReplicaPtr`, which is a reference-counted smart pointer. The replica manager retains a reference to every replica that is bound to it. It is therefore safe to omit a reference to the replica from user code; the replica is not destroyed as long as the reference is held in replica manager. However, you can force the replica manager to release its reference and free the replica by invoking the following method:
replica->Destroy();

Sample Code

This example creates a user-defined chunk, creates a replica, attaches the chunk to the replica, and binds the replica to the session replica manager.

```cpp
// User-defined ReplicaChunk class to be carried with the replica
class MyChunk : public GridMate::ReplicaChunk {
public:
    GM_CLASS_ALLOCATOR(MyChunk);
    typedef AZStd::intrusive_ptr<MyChunk> Ptr; // smartptr to hold the chunk
    static const char* GetChunkName() { return "MyChunk"; } // Unique chunk name
    bool IsReplicaMigratable() override { return false; } // Replica ownership
        // cannot be changed
    MyChunk() : m_data("Data", 0) {} // chunk constructor

    void OnReplicaActivate(const ReplicaContext& rc) override // Called when replica is bound
        // to the replica manager
    {
        // printing out whether it is a proxy or a primary replica
        if (IsMaster())
            printf("I am primary!\n");
        if (IsProxy())
            printf("I am proxy!\n");
    }

    GridMate::DataSet<int> m_data; // data this chunk holds
};
GridMate::ReplicaPtr replica = GridMate::Replica::CreateReplica(); // Creating a replica
GridMate::CreateAndAttachReplicaChunk<MyChunk>(replica); // Creating chunk of our custom type
        // and attaching it to the replica
GridMate::ReplicaManager* replicaManager = session->GetReplicaMgr(); // Getting replica manager instance
        // from current
session
replicaManager->AddMaster(replica); // Binding replica to the replica manager,
        // making local peer the owner of this replica

... // Starting from this point and up until replica destruction, the replica and MyChunk object
// that the replica is carrying are synchronized with other peers.
// Other peers receive the new replica and bind it to their replica managers. When this is done,
// OnReplicaActivate is triggered, and the "I am proxy" message is printed out on the remote peers.
// Every change of m_data DataSet results in the synchronization of the new value in
// the primary replica with all of the proxy replicas.
```

Replica Chunks

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
A replica chunk is a user extendable network object. One or more ReplicaChunk objects can be owned by a replica, which is both a container and manager for replica chunks. A replica is owned by a primary peer and is propagated to other network nodes as a proxy replica. The data that a replica chunk contains should generally be related to the other data stored within it. Since multiple chunks can be attached to a replica, unrelated data can be stored in other chunks within the same replica.

A replica chunk can contain Datasets (p. 2040) and/or Remote Procedure Calls (RPCs) (p. 2044). Datasets store arbitrary data, which only the primary replica is able to modify. Any changes are propagated to the chunks in proxy replicas on the other nodes. RPCs are methods that can be executed on remote nodes. They are first invoked on the primary, which decides whether the invocation will be propagated to the proxies.

**Replica Chunk Requirements and Limitations**

A replica chunk has several important attributes:

- It can have up to 32 DataSet definitions.
- It can have up to 256 RPC definitions.
- It is reference counted and therefore must be held by a smart pointer.
- It is not synchronized across the session until the replica manager is ready.

**Implementing a New Replica Chunk Type**

You have two ways to implement a new replica chunk type: handle data set changes and RPC calls ("game logic") inside the chunk, or outside the chunk. In both cases, the following apply:

- The name of the chunk type must be unique throughout the system. To achieve this, every replica chunk type must implement the static member function `const char* GetChunkName()`. The string returned by the `GetChunkName` function must uniquely identify the chunk type.
- To indicate whether the ownership of this type of chunk is transferrable, every chunk type needs to override the `bool IsReplicaMigratable()` virtual function. If any chunk in a replica is not migratable, the replica's ownership cannot be transferred from one peer to another.
- Every chunk type must define a smart pointer that holds the chunk type instances.

**Declaring a Replica Chunk Type with Internal Game Logic Handling**

To have your replica chunk class handle game logic directly, it should inherit from ReplicaChunk:

```cpp
class MyChunk : public GridMate::ReplicaChunk
{
public:
    GM_CLASS_ALLOCATOR(MyChunk); // Using GridMate's allocator

    MyChunk()
        : m_data("Data", 0) // Initializing integer DataSet to zero, and
        , MyRpcMethodRpc("MyRpcMethodRpc") // Initializing RPC by passing in its name; the
            // RPC name is for debugging purposes
    {
    }

typedef AZStd::intrusive_ptr<DataSetChunk> Ptr; // Defining smart pointer type
for this chunk

    static const char* GetChunkName() { return "MyChunk"; } // Unique chunk type name
    bool IsReplicaMigratable() override { return false; } // Specify whether the chunk
        // can participate in replica's ownership changes
    bool MyRpcMethod(int value, const GridMate::RpcContext& context)
}
```
Declaring a Replica Chunk Type with External Game Logic Handling

To have your replica chunk class act as a simple data carrier and forward data changes and events to a designated handler (an external class), inherit your handler class from ReplicaChunkInterface, and your replica chunk class from ReplicaChunkBase:

```cpp
class CustomHandler : public GridMate::ReplicaChunkInterface
{
public:
    GM_CLASS_ALLOCATOR(CustomHandler); // using GridMate's allocator

    void DataSetHandler(const int& value, const GridMate::TimeContext& context)
    {
        // Handle changes
    }

    bool RpcHandler(AZ::u32 value, const GridMate::RpcContext &context)
    {
        // Handle event here
        return true; // Propagate this call to all proxies
    }
};

class MyChunk : public GridMate::ReplicaChunkBase
{
public:
    GM_CLASS_ALLOCATOR(MyChunk); // Using GridMate's allocator

    MyChunk()
    : m_data("Data", 0) // Initializing integer DataSet to zero and assigning a name for it
    , MyRpcMethodRpc("MyRpcMethodRpc") // Initializing RPC by passing its name; the RPC's name is used for debugging purposes
    {
    }

    typedef AZStd::intrusive_ptr<DataSetChunk> Ptr; // Defining smart pointer type for this chunk
    static const char* GetChunkName() { return "MyChunk"; } // Unique chunk type name
    bool IsReplicaMigratable() override { return false; } // Whether chunk can participate in replica's ownership changes

    GridMate::DataSet<int>::BindInterface<CustomHandler, &CustomHandler::DataSetHandler> m_data;
    GridMate::Rpc<GridMate::RpcArg<AZ::u32>>::BindInterface<CustomHandler, &CustomHandler::RpcHandler> MyRpcMethodRpcPC;
};
```

Registering Chunk Type

Every user-defined replica chunk type should be registered with ReplicaChunkDescriptorTable to create the factory required by the Replica Manager (p. 2047).
To register replica chunks, use this call:

```cpp
GridMate::ReplicaChunkDescriptorTable::Get().RegisterChunkType<MyChunk>();
```

### Attaching a Replica Chunk to the Replica

You must add a replica chunk to a replica before you bind the replica to replica manager. After you bind the replica to replica manager, you cannot add or remove replica chunks to or from the replica.

To create a replica chunk, use this call:

```cpp
MyChunk::Ptr myChunk = GridMate::CreateReplicaChunk<MyChunk>({...});
```

Where `{...}` is forwarded to the `MyChunk` constructor.

To attach the chunk to a replica, use this call:

```cpp
replica->AttachReplicaChunk(myChunk);
```

Alternatively, you can create the chunk and attach it in one step:

```cpp
GridMate::CreateAndAttachReplicaChunk<MyChunk>(replica, {...});
```

After you add the chunk to the replica, the replica retains a smart pointer to the chunk. The chunk is released only when its replica is destroyed.

### Datasets

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use `DataSet` objects to synchronize the state of a session across the network. When a value in the dataset changes, the updates are propagated automatically. Datasets can be of any type, but they must support the assignment and comparison operators. Your `DataSet` declaration can specify a custom marshaler. If you do not specify a marshaler, the `DataSet` object uses `GridMate::Marshaler<T>`.

A `DataSet` must be declared inside a `ReplicaChunk` object. A `ReplicaChunk` object can contain up to 32 `DataSet` objects. You must supply a debug name to the dataset constructor.

The following example declares a `ReplicaChunk` object that has two `DataSet` objects of type `float`. One dataset uses the default marshaler. The other dataset uses a custom marshaler called `MyCustomMarshaler`.

```cpp
class MyChunkType : public GridMate::ReplicaChunk
{
    public:
        MyChunkType()
            : m_synchedFloat("SynchedFloat")
            , m_synchedHalf("SynchedHalf")
        {
        }

        GridMate::DataSet<float> m_synchedFloat;
        GridMate::DataSet<float, MyCustomMarshaler> m_synchedHalf;
};
```
Datasets can be optionally bound to a callback on the chunk interface so that the callback is called when new data arrives.

class MyChunkType : public GridMate::ReplicaChunk
{
public:
    MyChunkType()
        : m_synchedFloat("SynchedFloat")
    {
    }

    // Callback to call when new data arrives.
    void OnSynchedFloatData(const float& newValue, const GridMate::TimeContext& timeContext);

    GridMate::DataSet<float>::BindInterface<MyChunkType, amp;MyChunkType::OnSynchedFloatData> m_synchedFloat;
};

**Eventual consistency** is guaranteed for datasets. Normally, datasets propagate unreliably. To compensate for potential packet losses, and to minimize latency, GridMate handles events in the following order:

1. A user changes a value in the dataset.
2. The new value is broadcast to the remote peers.
3. The dataset stops changing.
4. A user-configurable grace period elapses.
5. A last update is sent reliably.
6. To conserve bandwidth, propagation is suspended until the next change.

You can change the length of the grace period in step 4 by calling `SetMaxIdleTime`:

```cpp
...
GridMate::DataSet<Vector3> m_pos;
...
...
... m_pos.SetMaxIdleTime(5.f);  // Suspend sending if m_pos has not changed for 5 ticks
...```

**Carrier ACK Feedback**

Lumberyard 1.12 introduced, as a preview feature, carrier ACK feedback.

In the default GridMate implementation, a change in a dataset causes four unreliable updates and then one reliable update to be sent. This technique can result in many reliable packets on the network. Because reliable packets require ordering, preceding packets cannot be processed until a lost packet is successfully retransmitted. The resulting delay can cause jitter.

To avoid this issue, you can enable carrier ACK feedback.

When carrier ACK feedback is enabled, a changed dataset propagates its update unreliably until the receiver sends an ACK to acknowledge that it received the update. This approach removes the requirement for updates to be sent reliably (step 5 in the previous section). Additionally, if a dataset update is acknowledged as received before the grace period specified by `MaxIdleTime`, GridMate saves bandwidth by not sending additional unneeded updates.
To enable carrier ACK feedback, set the `k_enableAck` property of `ReplicaTarget` to `true` in the `ReplicaTarget.cpp` file, as in the following example:

```cpp
...  
bool ReplicaTarget::k_enableAck = true;  
...
```

### Examples

The examples in this section show three ways to create datasets.

#### Example 1

The following example creates a `DataSet` object that uses the default marshaler to store a `u32` value.

```cpp
GridMate::DataSet<AZ::u32> m_data;
```

#### Example 2

The following example creates a `DataSet` object that stores a float. The data written to the network is half float size because of the specified marshaler.

```cpp
GridMate::DataSet<float, HalfMarshaler> m_data;
```

#### Example 3

The following example creates a `DataSet` object that stores an `s32` value using the default marshaler for `s32`. Whenever the `DataSet` value changes, the `DataSetHandler` function is called on the `MyReplicaChunk` instance. This is true for both primary and proxy nodes; the event is triggered on local data changes for the primary and upon received data changes for the proxies.

```cpp
class MyReplicaChunk : public GridMate::ReplicaChunk  
{  
  void DataSetHandler(const AZ::s32& value, const GridMate::TimeContext& context) { /* Data Changed Logic */  
    GridMate::DataSet<AZ::s32>::BindInterface<MyReplicaChunk, &MyReplicaChunk::DataSetHandler> Data;  
};
```

### Throttlers

Datasets can be throttled based on an optional throttler parameter to the template. The throttler can choose to send data or withhold downstream updates unless a certain condition has been met. The throttler must implement the `WithinThreshold` method using the following syntax.

```cpp
bool WithinThreshold(T previousValue, T currentValue);
```

The return value of the method determines whether to send the data to the proxy peers.

### Using Delta Compression in Lumberyard Networking

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
You can use Lumberyard networking's delta compression feature to reduce the amount of network traffic generated by dataset (p. 2040) updates.

By default, when a change is made to a non-compressed dataset, GridMate propagates the change by sending all of the data in the dataset across the network. Such a dataset is declared in the following way:

```cpp
GridMate::DataSet<float> m_myFloat;
```

An update to such a dataset uses four bytes on the network. To reduce this, you can use a compression marshaler like the `HalfMarshaler` located in `lumberyard_version\dev\Code\Framework\GridMate\GridMate\Serialize\CompressionMarshal.h`.

The following syntax specifies a dataset that uses the `HalfMarshaler` compression marshaler:

```cpp
GridMate::DataSet<float, HalfMarshaler> m_myFloat;
```

This compression marshaler reduces the network payload to two bytes, but at the cost of some precision.

**Delta Compression Overview**

Starting in Lumberyard version 1.18, you can use GridMate's delta compression feature to further reduce the payload to only one byte for each dataset update.

Delta compression reduces the network payload by sending only the data that changed (the "delta") instead of all data in the dataset. For example, if a float changes from 0.2 to 0.3, you can represent the change as +0.1 and encode the change in a single byte. Compared to a regular dataset, this reduces the average payload for float values by 66 percent compared to a regular dataset, or to 50 percent compared to a half marshaler compressed dataset.

GridMate supports delta compressed datasets for the two most frequently used types: `float` and `AZ::Vector3`.

The following syntax shows how to declare delta compressed datasets.

```cpp
#include <GridMate/Replica/DeltaCompressedDataSet.h>
DeltaCompressedDataSet<float, 5> m_myDeltaCompressedFloat;
DeltaCompressedDataSet<AZ::Vector3, 1> m_myDeltaCompressedVector3;
```

`DeltaCompressedDataSet` is a template that takes at least two parameters: a type and the delta range value as an unsigned integer. The delta range parameter is described in the next section.

**Delta Range**

The delta range parameter, which is unique to delta compression datasets, specifies the precision of delta compression. This value acts like a threshold. When the dataset has changed by an amount greater than the specified delta range, all data in the dataset is sent.

In the previous example, if the starting value is 0, data changes that remain within the range of -5 and +5 are compressed into one byte.

For calculation purposes, the precision of delta compression is double the delta range divided by 255, which is the size of one byte. For a delta range of 5, the precision is $5 \times 2 / 255 = 0.04$.

**Important**

Pay close attention to the required precision of your values. The highest precision for a `DeltaCompressedDataSet` is declared with a delta range of 1, as in the following example:
The precision in this case is \(1\times\frac{2}{255}=0.0078\).

**Note**
You can work around this precision limit by changing the measurement unit that you use. For example, instead of sending meters, you can send millimeters.

### Calculating Payload Reduction

Suppose a delta compressed dataset is declared in the following way:

```cpp
DeltaCompressedDataSet<float, 5> m_myDeltaCompressedFloat;
```

If a change is less than five (the configurable value specified in the second template parameter) then the update is delta-encoded in one byte. Otherwise, a full value is sent.

The following table illustrates the behavior of a sample delta compressed dataset in chronological order.

<table>
<thead>
<tr>
<th>Chronological Order</th>
<th>Value</th>
<th>Bytes Sent</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.0</td>
<td>4</td>
<td>Because this is the first value, it is sent as a full update.</td>
</tr>
<tr>
<td>2</td>
<td>0.1</td>
<td>1</td>
<td>The change is less than five, so a one-byte delta is sent.</td>
</tr>
<tr>
<td>3</td>
<td>4.9</td>
<td>1</td>
<td>The change is still less than five, so a one-byte delta is sent.</td>
</tr>
<tr>
<td>4</td>
<td>5.1</td>
<td>4</td>
<td>The change is greater than five, so a full update is sent.</td>
</tr>
<tr>
<td>5</td>
<td>5.3</td>
<td>1</td>
<td>The change since the last full update is less than five (5.3-5.1=0.2), so a one-byte delta is sent.</td>
</tr>
</tbody>
</table>

In practice, a slowly changing float value averages 1.4 bytes for each update.

**AZ::Vector3 Values**

The behavior for compressed float datasets is also applicable to the delta compression of `AZ::Vector3` values. However, each coordinate value in the vector is compressed into one byte, for a minimum total of three bytes. This compares favorably to the twelve bytes required for an uncompressed `AZ::Vector3` value.

### Remote Procedure Calls (RPCs)

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

RPCs allow games to send events or requests to remote nodes through replicas. They can be used to send messages to a specific node, or to route function calls to the authoritative node. For example, you can use RPCs to implement functions that change the position of an object. This ensures that changes happen only at the node that owns the object. For server-authoritative games, reliable RPCs can be used for sending frequent client input commands.

RPCs have the following characteristics:
Overview

- RPC arguments can be of any type, as long as a valid marshaler is provided.
- All RPC requests are routed to the primary replica.
- The RPC handler function in the primary replica chooses whether to propagate the RPC to proxy replicas.
- RPCs are not kept in the history, and late-joining clients might not receive RPCs requested before the client joined.

Like datasets, RPCs are declared as replica chunk members. An RPC handler function is bound to the RPC as part of the declaration. RPC requests are forwarded to the handler function along with the arguments and an RpcContext associated with the request.

The RPC handler function can perform additional checks before executing the request.

The handler for an RPC returns a Boolean value to GridMate. This value is used on the replica's primary node to determine whether the RPC is propagated to all proxies.

Remote procedure calls are always invoked first on the primary node for the replica. This is true whether the initial caller is a primary or proxy. The primary node's RPC handler decides whether the RPC should be propagated to the proxy nodes based on the return value of the RPC handler. The user returns true to mean “propagate to all replica proxies,” and false to mean “only invoke this RPC on the primary.”

RPCs have a constructor that requires a string. This is used for debugging and statistical purposes. Any debugging or network monitoring exposes the given RPC name. Using modern C++, the name can also be specified inline, as in the following example.

```cpp
Rpc<RpcArg<AZ::u32>>::BindInterface<MyClass, &MyClass::Func> Rpc = {"My RPC"};
```

Examples

The following examples show how RPCs can be used in GridMate.

Example 1

In the following example, Rpc1 is an RPC that takes a single parameter of type u32. It uses the default u32 marshaler.

```cpp
class MyReplicaChunk : public GridMate::ReplicaChunk
{
    bool Rpc1Handler(AZ::u32 val, const GridMate::RpcContext& context) { /* RPC Logic */ }
    GridMate::Rpc<GridMate::RpcArg<AZ::u32>>::BindInterface<MyReplicaChunk, &MyReplicaChunk::Rpc1Handler> Rpc1;
};
```

Example 2

In the following example, Rpc2 is an RPC that takes a single parameter of type s32. It uses IntegerQuantizationMarshaler, with a range from -100 to 100 and writes one byte to the wire.

```cpp
class MyReplicaChunk : public GridMate::ReplicaChunk
{
    bool Rpc2Handler(AZ::s32 val, const GridMate::RpcContext& context) { /* RPC Logic */ }
    GridMate::Rpc<GridMate::RpcArg<AZ::s32, GridMate::IntegerQuantizationMarshaler<-100, 100, 1>>::BindInterface<MyReplicaChunk, &MyReplicaChunk::Rpc2Handler> Rpc2;
};
```
Example 3

In the following example, Rpc3 is an RPC that takes two parameters; a u8 and a string. It uses the default marshalers for each argument.

```cpp
class MyReplicaChunk : public GridMate::ReplicaChunk
{
    bool Rpc3Handler(AZ::u8 val, const AZStd::string& str, const GridMate::RpcContext& context) { /* RPC Logic */ }
    GridMate::Rpc<GridMate::RpcArg<AZ::u8>, GridMate::RpcArg<const AZStd::string&>>::BindInterface<MyReplicaChunk, &MyReplicaChunk::Rpc3Handler> Rpc3;
};
```

Example 4

If you want to send a custom class as an RPC parameter, you must first write a marshaler for it, as in the following example.

```cpp
struct MyClass
{
    AZ::Crc32 m_name;
    AZ::u32 m_value;
};
namespace GridMate
{
    template<>
    class Marshaler<MyClass>
    {
        public:
        static const AZStd::size_t MarshalSize = Marshaler<AZ::Crc32>::MarshalSize + sizeof(AZ::u32);
        void Marshal(WriteBuffer& wb, const MyClass& value) const
        {
            wb.Write(value.m_name);
            wb.Write(value.m_value);
        }
        void Unmarshal(MyClass & value, ReadBuffer& rb) const
        {
            rb.Read(value.m_name);
            rb.Read(value.m_value);
        }
    };
}
```

An RPC that passes a parameter of the foregoing class might be declared like this:

```cpp
class MyReplicaChunk : public GridMate::ReplicaChunk
{
    bool Rpc4Handler(const MyClass& value, const GridMate::RpcContext& context) { /* RPC Logic */ }
    GridMate::Rpc<GridMate::RpcArg<const MyClass&>>::BindInterface<MyReplicaChunk, &MyReplicaChunk::Rpc4Handler> Rpc4;
};
```

For Rpc4, the first and only argument is a const reference to the MyClass object. The const MyClass& is specified to indicate that the Rpc4Handler function takes a const reference. This allows you to avoid making a copy of the object when it is passed to the handler function. Behind the scenes, GridMate stores a temporary value of MyClass, which is what the reference binds to. The temporary
referent is removed after the RPC has been called. You can also use this technique to marshal objects that are wrapped in smart pointers.

**Example 5**

In order to invoke an RPC on a given chunk instance, you can simply call the RPC, as in the following example.

```cpp
class MyReplicaChunk : public GridMate::ReplicaChunk
{
    bool Rpc5Handler(AZ::u32 val, const GridMate::RpcContext& context) { /* RPC Logic */ }
    GridMate::Rpc<GridMate::RpcArg<AZ::u32>>::BindInterface<MyReplicaChunk, &MyReplicaChunk::Rpc1Handler> Rpc5;
};

void Foo(MyChunkType* myChunkInstance)
{
    myChunkInstance->Rpc5(1);
}
```

Rpc5 is an RPC that takes a single parameter of type u32. It uses the default u32 marshaler. Calling Foo invokes the RPC on the replica chunk instance and passes in a value of 1.

**RPC Type Traits**

RPCs have an optional typetraits parameter. The following traits are expected in the traits class.

<table>
<thead>
<tr>
<th>Trait</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s_isReliable</td>
<td>true</td>
<td>Uses reliable transmission to send the RPC.</td>
</tr>
<tr>
<td>s_isPostAttached</td>
<td>true</td>
<td>Forces any dirty datasets to also be sent reliably in advance. This is useful if the RPC relies on the data in the datasets to be up to date on the destination peer.</td>
</tr>
</tbody>
</table>

**Replica Manager**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The replica manager is a subsystem that is responsible for managing the synchronization of replicas. The replica manager is responsible for the following:

- Marshaling and unmarshaling the replicas in each peer
- Forwarding replicas from one peer to another
- Handling ownership changes of replicas
- Managing replica lifetimes

**Managing Replica Lifecycle**

The replica manager must do the following:
• Keep track of all replicas by holding a reference-counted pointer to every primary and proxy replica object.
• Guarantee consistency across the session by capturing and propagating the last state of every replica before a replica is destroyed.
• Guarantee that all proxies reach eventual consistency before a replica is deactivated.
• Release all GridMate references to a replica object when the object has been destroyed.

Topics
• Binding a New Primary Replica to Replica Manager (p. 2048)
• Retrieving Replicas from Replica Manager (p. 2048)
• How Replica Manager Updates Replicas (p. 2048)
• Task Manager (p. 2049)

Binding a New Primary Replica to Replica Manager

After a new primary replica is created, it must be bound to the replica manager as follows:

```cpp
GridMate::ReplicaManager* replicaManager = session->GetReplicaMgr(); // Get replica manager from the current session
replicaManager->AddMaster(myReplica1); // Bind replica to replica manager
replicaManager->AddMaster(myReplica2); // Bind replica to replica manager
```

Proxy replicas are bound to their session's replica managers automatically. Each ReplicaManager instance holds a reference to every replica that is bound to it. That changes only when the user calls Destroy() on the replica or when the ReplicaManager itself is destroyed.

Retrieving Replicas from Replica Manager

Every replica has a numeric identifier that is unique in the session. To find a replica by its ID, invoke FindReplica(<ReplicaId>), as in the following example:

```cpp
GridMate::ReplicaPtr replica = replicaManager->FindReplica(<myReplicaId>);
AZ_Assert(replica != nullptr, "Replica with id=%d not found.", <myReplicaId>);
```

How Replica Manager Updates Replicas

The GridMate session triggers the replica manager to perform replica updates on a continuous basis. These updates include the following actions:

• Unmarshaling
• Update from replica
• Update replicas
• Marshaling

Marshaling: Sending Data to Other Peers

Changes in a replica must be replicated to every remote peer in the GridMate session. To communicate a change in one of its replicas, a peer's replica manager serializes the replica object into a send buffer. It then sends the object to the network. Replica marshaling occurs in two main phases:

• Data Preparation – A premarshaling phase that, based on changes in the replica, determines which RPCs and DataSet objects to send. This phase also validates the data integrity of the objects to be sent.
• **Actual Marshaling** – The transformation of a replica object into a byte stream. The actual data that must be marshaled depends on how much new information the primary replica has relative to its corresponding remote proxy replica. For example, new proxy replicas require all information about the primary replica. This includes its datasets (p. 2040), RPCs (p. 2044), and construction metadata. Previously synchronized proxy replicas require only the information from the primary replica that is different, including any pending RPC calls.

**Unmarshaling: Receiving Data from Other Peers**

In unmarshaling, the replica manager communicates with the remote peers, receives and parses new data from them, and updates its own replicas accordingly. These updates can include accepting new peers, instantiating new proxy replicas, handling ownership changes, or destroying proxy replicas.

**Note**

For more information about marshaling, see Marshalling (p. 2022).

**Update from Replica: Updating Proxy Replicas**

A change in a custom ReplicaChunk (p. 2037) results in an UpdateFromChunk callback that causes all proxy replicas to update their state. RPCs from proxy and primary replicas are processed and invoked during this step.

**Update Replicas: Updating Primary Replicas Locally**

A change in a custom replica chunk results in an UpdateChunk callback that causes all primary replicas on a local peer to update their states.

**Task Manager**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The replica manager holds two task manager instances: one for updating and one for marshaling replicas. Updating tasks are executed within the replica manager's UpdateFromReplica step, while marshaling tasks are executed in the Marshal step. Tasks can execute other tasks while running. TaskManager::Add queues the tasks in an ordered list. TaskManager::Wait executes a task and waits until it finishes. When an event fires in the replica system, replica manager adds the corresponding task into TaskSystem.

Here are few examples of this behavior:

• A user changes a dataset's value within a replica. The change needs to be marshaled to other peers. The OnReplicaChanged event is called on ReplicaManager, and ReplicaMarshalTask is queued for execution. Because replicas must be sent in the order of their creation, the task's priority is based on the replica's creation time. The queued task is executed at the appropriate time within the Marshal step.

• A new proxy replica is unmarshaled. When this happens, OnReplicaUnmarshaled() is called and ReplicaUpdateTask is queued. This task's priority is always zero because the order of execution is not important. UpdateFromReplica is called to notify the user of the new replica's data.
The network binding API in the AZ framework provides a way for components to synchronize their states over the network.

To enable network synchronization for a component, you must do the following:

1. Derive the component from `NetBindable` and implement the network binding interfaces.
2. Implement a new replica chunk type and add the datasets and RPCs necessary to provide synchronization.

Topics

- Synchronizing an Entity with a NetBindingComponent (p. 2050)
- Binding Process on Remote Nodes (p. 2050)
- Unbinding Process (p. 2050)
- NetBindable Component Flexibility (p. 2050)
- Entity IDs (p. 2050)
- Synchronizing Animations Across a Network (p. 2051)
- Creating a NetBindable Component (p. 2055)
- Transform Component Interpolation (p. 2059)

Synchronizing an Entity with a NetBindingComponent

Because a special `NetBindingComponent` is responsible for the actual binding process, entities that need to be synchronized must have a `NetBindingComponent` added to them. When a game enters a multiplayer session, the `NetBindingComponent` collects replica chunks from the `NetBindable` instances on the entity and adds them to a `Replica` (p. 2035) primary. A special `NetBindingChunk` captures and stores spawning and other binding information for the entity. `NetBindingComponent` instances activated during a multiplayer session automatically start the binding process.

Binding Process on Remote Nodes

As replicas arrive at remote nodes, `NetBindingChunk` starts the entity spawning and binding process on the remote node. The binding process is completely asynchronous. The replicas become active first. Then an entity spawn request is queued. After the entity becomes available, its `NetBindable` components are bound to their corresponding chunks. Finally, the entity is activated.

Unbinding Process

When replicas are removed, affected `NetBindingComponent` instances start the unbinding process. By default, entities that are unbound from proxy replicas are deleted, but this doesn’t have to be always the case. A game can choose to keep all entities in place and seamlessly switch to single-player mode.

NetBindable Component Flexibility

A `NetBindingComponent` must exist for an entity to be bound to the network. This allows `NetBindable` components to be used in single-player modes without any additional runtime cost. `NetBindable` instances can also be disabled for each instance. This gives you the additional flexibility: The transform component can provide entity transform synchronization by default, but for special entities, a physics or animation component can provide more advanced synchronization.

Entity IDs

In Lumberyard, every entity has a unique ID so that it can be referenced in the game. Entity IDs are 64-bit strings generated using an algorithm that ensures uniqueness across computing devices. To reduce
binding complexity, the net binding system spawns entities to be bound to proxy replicas using the same ID as the primary.

The following diagram shows how the net binding system binds an entity to the network and spawns an entity. It does this with the same ID that it binds to a proxy replica.

---

**Synchronizing Animations Across a Network**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the AnimGraph (p. 545) component to add an animation graph and motion set to a character. To synchronize the AnimGraph component's parameters (its EMotion FX animation state) across the network, use these two components:

- Network Binding (p. 700)
- Anim Graph Net Sync (p. 545)

The Anim Graph Net Sync component, which is included with the EMotion FX Animation (p. 1124) gem, requires the Network Binding component. You can add the Anim Graph Net Sync component to any entity that has the Anim Graph component.

**Topics**

- Adding Animation Synchronization to an Entity (p. 2052)
- Running the Samples Project in a Server and Client Configuration (p. 2055)
Adding Animation Synchronization to an Entity

The following procedure shows how to add the Network Binding and Anim Graph Net Sync components to the Rin character in the Advanced_RinLocomotion Sample (p. 151) level of the Samples Project (p. 146).

To add animation synchronization to an entity

1. In the Project Configurator, do the following:
   a. Follow the steps in Choosing a Game Project to Open (p. 47) to set the SamplesProject as your default project.
   b. Follow the steps in Enabling Gems (p. 1064) to enable the Multiplayer gem for the Samples Project.

2. Close the Project Configurator, and then launch Lumberyard Editor (p. 182).
3. In Lumberyard Editor, choose File, Open Level, or press Ctrl+O.
4. In the Open a Level dialog box, under Levels, Samples, choose Advanced_RinLocomotion, and then click Open.
6. In the viewport, zoom in and select the Rin character.

7. In the Entity Inspector, ensure that Rin appears in the Name field.
8. In the Entity Inspector search box, enter anim.
The AnimGraph component for Rin has four parameters:

- movement_speed
- movement_direction
- attacking
- jumping

Changes in these parameters are replicated to other network peers after you add the Network Binding and Anim Graph Net Sync components.

9. In the Entity Inspector, choose Add Component.
10. In the Entity Inspector search box, enter Network.
11. Choose Network Binding.

12. In the Entity Inspector, click Add Component.
13. In the Entity Inspector search box, enter anim.
14. Choose Anim Graph Net Sync.
The Anim Graph Net Sync component is added to the Rin entity.

By default, the Anim Graph Net Sync component synchronizes only the animation parameters. For greater precision, you can also choose to synchronize active nodes and motion nodes, which uses more network bandwidth.

15. Choose File, Save or press Ctrl+S to save the level.
Running the Samples Project in a Server and Client Configuration

Now that you have added the Net Binding and Anim Graph Net Sync components to the Rin entity, you can test the synchronization by running server and game launcher applications.

To test the animation graph network synchronization

1. In Lumberyard Editor, choose Game, Export to Engine, or press Ctrl+E to export your level to the Samples Project game launcher.
2. In the message box that reports The level was successfully exported, click OK.
3. Open a Windows command console on the lumberyard_version\dev\Bin directory that you are using.
   • For Visual Studio 2017, the directory is lumberyard_version\dev\Bin64vc141\.
   • For Visual Studio 2019, the directory is lumberyard_version\dev\Bin64vc142\.
4. Run the following command to start the server:
   
   SamplesProjectLauncher.exe +mphost +map advanced_rinlocomotion

5. Wait until the server game is running and the Rin character renders fully.
6. Press Alt+Tab to return to the command prompt.
7. Run the following command to start and connect the client:

   SamplesProjectLauncher.exe +mpjoin

8. Wait until the client game is running and the Rin character renders fully.
9. Press Alt+Tab to return to the server application.
10. Use the following keys to control the Rin character:
    • To move forward, left, backward, and right, press the W, A, S, and D keys, respectively.
    • To look around, move the pointer.
    • To attack, press the left mouse button.
    • To jump, press the Space key.
11. Observe how, as you move the Rin character in the server application, the Rin character in the client application performs the same movements as its counterpart in the server.
12. In the server application, press the backtick key (`) to open the console, and then enter quit.
13. In the client application, press the backtick key (`) to open the console, and then enter quit.

Creating a NetBindable Component

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

For a Lumberyard component to share data on the network, it must include the NetBindingComponent. The NetBindingComponent creates a replica (p. 2035) for the component and can bind any replica chunk (p. 2037) that a component creates to the replica.

To enable networking on a component

1. Inherit the component from AzFramework::NetBindable:
2. Modify the `AZ_COMPONENT` definition to include `AzFramework::NetBindable`:

```cpp
AZ_COMPONENT(ShipComponent,"{D466FD68-96C9-45AF-8A89-59402B0350F7}",
    AzFramework::NetBindable);
```

3. Modify SerializeContext to include `AzFramework::NetBindable`:

```cpp
if (serialize)
{
    serializeContext->Class<ShipComponent, AzFramework::NetBindable, AZ::Component>()
        ...
}
```

4. Implement the `AzFramework::NetBindable` interfaces:

```cpp
// Called during network binding on the primary. Implementations should create and
// return a new binding.
virtual GridMate::ReplicaChunkPtr GetNetworkBinding() = 0;

// Called during network binding on proxies.
virtual void SetNetworkBinding(GridMate::ReplicaChunkPtr chunk) = 0;

// Called when network is unbound. Implementations should release their references to
// the binding.
virtual void UnbindFromNetwork() = 0;
```

**Notes**

- If the `AZ_COMPONENT` definition change is missing, the NetBindingComponent does not recognize
  the component when it checks for components to add to the replica.
- If the SerializeContext definition is missing, the primary replica still functions correctly. However,
  the proxy cannot match the IDs because it is not serialized as an `AzFramework::NetBindable`
  interface.
- Changes to these definitions require a re-export of levels for the static IDs to match correctly.

**Network Binding Function Details**

The following functions are available for working with component entities on the network.

**GetNetworkBinding**

The component uses this function to create its ReplicaChunk and initialize any state it wants to
synchronize across the session. This function is called only on the primary ComponentEntity. The
ReplicaChunk that is returned is automatically attached to the appropriate Replica.

**SetNetworkBinding**

This function passes a ReplicaChunk to the component and initializes the internal data of
the component to match that of the ReplicaChunk. This function is called only on the proxy
ComponentEntity instances that are already bound to an appropriate Replica.
UnbindFromNetwork

The UnbindFromNetwork function is called to stop the component from reacting to data updates from the network. This can happen, for example, when the primary no longer exists, has been deactivated, or has relinquished control to the local source.

Creating a Chunk

After you have enabled the NetBindable interface on the component, you must create a ReplicaChunk object that will store any state that the component wants to share.

```cpp
class ShipComponentReplicaChunk : public GridMate::ReplicaChunkBase
{
public:
    AZ_CLASS_ALLOCATOR(ShipComponentReplicaChunk, AZ::SystemAllocator, 0);

    static const char* GetChunkName() { return "ShipComponentReplicaChunk"; }

    ShipComponentReplicaChunk()
        : SetFiring("SetFireLaser")
        , m_playerEntityId("PlayerEntityId")
    {
    }

    bool IsReplicaMigratable()
    {
        return true;
    }

    GridMate::Rpc< GridMate::RpcArg<bool> >::BindInterface<ShipComponent, 
        &ShipComponent::SetFiringRPC, NetworkUtils::ShipControllerRPCTraits> SetFiring;
    GridMate::DataSet<AZ::EntityId>::BindInterface<ShipComponent, 
        &ShipComponent::OnNewNetPlayerEntityId> m_playerEntityId;
};
```

Note

You must reflect this new replica chunk's datasets and RPCs in the component's Reflect function.

```cpp
AzFramework::NetworkContext* netContext = azrtti_cast<AzFramework::NetworkContext*>(context);
if (netContext)
{
    netContext->Class<ShipComponent>()
        .Chunk<ShipComponentReplicaChunk>()
        .RPC<ShipComponentReplicaChunk, ShipComponent>("SetFireLaser",
            &ShipComponentReplicaChunk::SetFiring)
        .Field("PlayerEntityId", &ShipComponentReplicaChunk::m_playerEntityId);
}
```

In order for the component to react to a change in the DataSet object, one of the following must occur:

- The replica chunk must signal to the component when the change occurs (in the example, this is done using the BindInterface extension to DataSet).
- The component must poll the replica chunk and check the DataSet object for changes.
Example: Filling Out the AzFramework::NetBindable Interface

The examples below illustrate the use of GetNetworkBinding, SetNetworkBinding and UnbindFromNetwork.

GetNetworkBinding

In the following example, the component creates the new replica chunk and initializes the data to be networked. This function is called by the primary replica to retrieve the binding from the component.

```cpp
GridMate::ReplicaChunkPtr ShipComponent::GetNetworkBinding()
{
    ShipComponentReplicaChunk* replicaChunk = GridMate::CreateReplicaChunk<ShipComponentReplicaChunk>();
    replicaChunk->SetHandler(this);
    m_replicaChunk = replicaChunk;
    return m_replicaChunk;
}
```

SetNetworkBinding

In the following example, the component is bound to the supplied replica chunk. It also relinquishes its local state to the state specified by the replica chunk. This function is called on proxies to hand their binding over to the component.

```cpp
void ShipComponent::SetNetworkBinding(GridMate::ReplicaChunkPtr chunk)
{
    chunk->SetHandler(this);
    m_replicaChunk = chunk;
    ShipComponentReplicaChunk* shipControllerChunk = static_cast<ShipComponentReplicaChunk*>(m_replicaChunk.get());
    SetPlayerEntityIdImpl(shipControllerChunk->m_playerEntityId.Get());
}
```

UnbindFromNetwork

```cpp
void ShipComponent::UnbindFromNetwork()
{
    m_replicaChunk->SetHandler(nullptr);
    m_replicaChunk = nullptr;
}
```

Maintaining State

The last step is to create checks to make sure that any local modifications to the preferred networkable state do not overwrite the networked state. In addition, you must update the replica chunk whenever the local state changes and the component is in control of the state.

```cpp
void ShipComponent::OnNewNetPlayerEntityId(const AZ::EntityId& playerEntityId, const GridMate::TimeContext& tc)
{
    (void)tc;
    SetPlayerEntityIdImpl(playerEntityId);
}

bool ShipComponent::SetFiringRPC(bool firing, const GridMate::RpcContext& rpcContext)
{

if (AllowRPCContext(rpcContext))
{
    SetFiring(firing);
}
return false;
}

// Component implementation of to set firing
void ShipComponent::SetFiring(bool firing)
{
    m_isFiring = firing;

    if (!AzFramework::NetQuery::IsEntityAuthoritative(GetEntityId()))
    {
        // If the ship component is not authoritative, send an RPC update to the replica chunk
        ShipComponentReplicaChunk* shipChunk = static_cast<ShipComponentReplicaChunk*>(m_replicaChunk.get());
        shipChunk->SetFiring(firing);
    }
    else
    {
        if (m_isFiring)
        {
            EBUS_EVENT_ID(GetGun(), ShipGunBus, StartFire);
        }
        else
        {
            EBUS_EVENT_ID(GetGun(), ShipGunBus, StopFire);
        }
    }
}

void ShipComponent::SetPlayerEntityIdImpl(AZ::EntityId playerEntityId)
{
    AZ_Error("ShipControllerComponent", !m_playerEntityId.IsValid() || !playerEntityId.IsValid(), "Trying to rebind an already bound ship");
    if (m_playerEntityId != playerEntityId)
    {
        m_playerEntityId = playerEntityId;
        HandleShipSetup();

        if (m_replicaChunk && AzFramework::NetQuery::IsEntityAuthoritative(GetEntityId()))
        {
            // If you are authoritative over the entity and the component is replicated, update the value of the DataSet and propagate to clients
            ShipComponentReplicaChunk* shipChunk = static_cast<ShipComponentReplicaChunk*>(m_replicaChunk.get());
            shipChunk->m_playerEntityId.Set(m_playerEntityId);
        }
    }
}

**Transform Component Interpolation**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/3dengine) or visit the [AWS Game Tech blog](https://aws.amazon.com/press-releases/3dengine) to learn more.

The **Transform (p. 878)** component supports local interpolation of its position and rotation values when it is synchronized over the network.
You can use the interpolation of transform values to smooth changes in the movement and orientation of your entities when they are controlled by your server application. In Lumberyard, networking is accomplished through replicas that can either be primary replicas or proxy replicas. Primary replicas are typically server application controllers that set the values directly. Proxy replicas, typically on client applications, receive regular updates from the primary replicas. Due to changing network conditions, updates can be delayed or come at varying time intervals. Under these conditions, interpolation enables your clients to smoothly the movement of entities being controlled over the network. It does this by gradually modifying transform values until they match the last received values from the network.

In Lumberyard Editor, you can use the Entity Inspector to alter these settings in the Transform component's Network Sync section.

To have your entity synchronized across the network, your entity must have the Network Binding component, and you must enable Sync to replicas. The interpolation mode settings have no effect if your entity does not have the network binding component.

You can handle position and rotation interpolation separately.

Position interpolation refers to the smoothing of position between network updates and interruptions. This is useful if your objects change location and you notice visual jitter or sudden changes in orientation due to network conditions.

Rotation interpolation refers to the smoothing of rotation between network updates and interruptions. This is useful if your objects rotate and you notice visual jitter or sudden changes in orientation due to network conditions.

For each of these settings, you can either choose no interpolation at all, which is the default choice, or linear interpolation. For example, if your object never moves and thus has no need to smooth position over time, then you can leave Position interpolation mode set to None. If your object rotates and you notice visual jitter or sudden changes in its position under poor network conditions, you can set Rotation Interpolation to Linear. This setting can lead to smoother change in rotation over time.

Note
Scale interpolation is not supported in the Transform component.
Network Optimization of the Transform Component

The Transform component is optimized for network bandwidth. If your entity is synchronized over the network but only changes position, then only new position values are sent across the network. This avoids the network cost of sending the entire transform. The same is true for rotation or scale of the transform. This is done automatically. You do not have to change any settings to use this feature.

For information on providing your own interpolation logic for the Transform component, see Providing Your Own Interpolation Logic for the Transform Component (p. 2061).

Providing Your Own Interpolation Logic for the Transform Component

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add your own interpolation logic for the Transform component by using a common framework available in C++. This topic shows you how to use C++, serialization, and the Lumberyard Editor UI to write your own interpolation mode.

Topics
- Adding Your Interpolation Mode to the Lumberyard Editor UI (p. 2061)
- Implementing Interpolation Logic in C++ (p. 2063)
- Rotation Interpolation (p. 2067)

Adding Your Interpolation Mode to the Lumberyard Editor UI

You can start from the user interface in the editor for the Transform component — specifically, with the interpolation options. The following image shows the Transform component's None or Linear interpolation options in the Entity Inspector.

Seeing how these options are implemented in the code can help you understand the changes that are required to add your own options.
The **None** and **Linear** interpolation options in the Entity Inspector come from the serialization of 
`AzToolsFramework::TransformComponent::Reflect`, which is the editor variation of 
`TransformComponent`.

The following related source code can be found in the file `dev\Code\Framework\AzToolsFramework\AzToolsFramework\ToolsComponents\TransformComponent.cpp`.

```cpp
namespace AzToolsFramework
{
    void TransformComponent::Reflect(AZ::ReflectContext* context)
    {
        // Reflect data for script, serialization, editing.
        if (AZ::SerializeContext* serializeContext = azrtti_cast<AZ::SerializeContext*>(context))
        {
            ... 
            if (AZ::EditContext* ptrEdit = serializeContext->GetEditContext())
                
            ptrEdit->Class<TransformComponent>("Transform", "Controls the placement
            of the entity in the world in 3d")
                ... 
            
            ClassElement(AZ::Edit::ClassElements::Group, "Network Sync")
                ->
            
            EnumAttribute(AzFramework::InterpolationMode::NoInterpolation, 
                "None")
                ->
            
            EnumAttribute(AzFramework::InterpolationMode::LinearInterpolation, 
                "Linear");
                ...
        }
        ...
    }
}
```

A line of code like the following adds these options to Lumberyard Editor. It contains an enum value and 
a string name for the value that appears in the editor. The reflection code for the position and rotation 
options is similar.

```cpp
EnumAttribute(AzFramework::InterpolationMode::NoInterpolation,"None")
```

`AzFramework:: InterpolationMode:: NoInterpolation` is an enum value from the 
`AzFramework` namespace. You can find the related source code in the file `dev\Code\Framework \AzFramework\AzFramework\Math\InterpolationSample.h`.

```cpp
namespace AzFramework
```
/**
 * Behavior types for smoothing of transform between network updates.
 */
enum class InterpolationMode : AZ::u32
{
    NoInterpolation,
    LinearInterpolation,
    MyInterpolation,       // <--- NEW CONTENT
};

Following this example, you can add your own enum value. The following example calls it MyInterpolation.

namespace AzFramework
{
    /**
     * Behavior types for smoothing of transform between network updates.
     */
    enum class InterpolationMode : AZ::u32
    {
        NoInterpolation,
        LinearInterpolation,
        MyInterpolation,       // <--- NEW CONTENT
    };
}

Next, update AzToolsFramework:: TransformComponent ::Reflect as in the following example.

namespace AzToolsFramework
{
    void TransformComponent::Reflect(AZ::ReflectContext* context)
    {
        // Reflect data for script, serialization, editing.
        if (AZ::SerializeContext* serializeContext = azrtti_cast<AZ::SerializeContext*>(context))
        {
            ...
            DataElement(AZ::Edit::UIHandlers::ComboBox,
                        &TransformComponent::m_interpolatePosition,
                        "Position Interpolation", "Enable local interpolation of position.")->
                EnumAttribute(AzFramework::InterpolationMode::NoInterpolation,
                    "None")->
                EnumAttribute(AzFramework::InterpolationMode::LinearInterpolation,
                    "Linear")->
                EnumAttribute(AzFramework::InterpolationMode::MyInterpolation, "My Mode")->       // <--- NEW CONTENT
            ...
        }
    }
}

Implementing Interpolation Logic in C++

Now that Lumberyard Editor has your new option, you can implement it in your code.

The AzToolsFramework:: TransformComponent is simply a component that the editor uses to create the game component counterpart AzFramework:: TransformComponent. Examine the
following source code for the TransformComponent class. The code shows where the interpolation samples are kept and the interpolated value is calculated. The code is in the file dev\Code\Framework\AzFramework\AzFramework\Components\TransformComponent.h.

```cpp
namespace AzFramework
{
    class TransformComponent
        : public AZ::Component,
        public AZ::TransformBus::Handler,
        public AZ::TransformNotificationBus::Handler,
        public AZ::EntityBus::Handler,
        public AZ::TickBus::Handler,
        private AZ::TransformHierarchyInformationBus::Handler,
        public NetBindable
    {
        ...

        private:
        ...

        void CreateTranslationSample();
        void CreateRotationSample();

        AZStd::unique_ptr<Sample<AZ::Vector3>> m_netTargetTranslation; // <--- Sample>

        AZStd::unique_ptr<Sample<AZ::Quaternion>> m_netTargetRotation;
        AZ::Vector3 m_netTargetScale;
        ...
    } // namespace AZ
}
```

Sample<> is the base abstract class for all interpolation logic. Notice that it's abstracted away to support either vectors for position or quaternions for rotation. The following code shows the source for the Sample class in the file dev\Code\Framework\AzFramework\AzFramework\AzFramework\Math\InterpolationSample.h.

```cpp
namespace AzFramework
{
    template<typename Value>
    class Sample
    {
    public:
        virtual ~Sample() = default;
        using TimeType = unsigned int;

        Sample()
            : m_targetValue()
            , m_targetTimestamp(0)
            , m_previousValue()
            , m_previousTimestamp(0)
        {
        }

        void SetNewTarget(Value newValue, TimeType timestamp) // <---- Network stack provides you these values every time it gets them.
        {
            m_targetValue = newValue;
            m_targetTimestamp = timestamp;
        }

        virtual Value GetInterpolatedValue(TimeType time) = 0; // <---- Provide your own interpolation logic here.
    }
}
```
The simplest implementation is no interpolation at all, for which the code is already written. You can find it in the same file: `dev\Code\Framework\AzFramework\AzFramework\Math\InterpolationSample.h`.

```cpp
template<typename T>
class UninterpolatedSample;

template<>
class UninterpolatedSample<AZ::Vector3> final : public Sample<AZ::Vector3>
{
public:
    AZ::Vector3 GetInterpolatedValue(TimeType /*time*/) override final
    {
        return GetTargetValue();
    }
};
```

The following code shows an implementation of linear interpolation that is included with Lumberyard (`dev\Code\Framework\AzFramework\AzFramework\Math\InterpolationSample.h`).

```cpp
namespace AzFramework
{
    template<typename T>
    class LinearlyInterpolatedSample;

    template<>
    class LinearlyInterpolatedSample<AZ::Vector3> final : public Sample<AZ::Vector3>
    {
    public:
        AZ::Vector3 GetInterpolatedValue(TimeType time) override final
        {
            AZ::Vector3 interpolatedValue = m_previousValue;
            if (m_targetTimestamp != 0)
            {
                if (m_targetTimestamp <= m_previousTimestamp || m_targetTimestamp <= time)
                {
                    if (m_targetTimestamp <= m_previousTimestamp || m_targetTimestamp <= time)
                    {
```

Version 1.28
2065
interpolatedValue = m_targetValue;
}
else if (time > m_previousTimestamp)
{
    float t = float(time - m_previousTimestamp) / float(m_targetTimestamp -
        m_previousTimestamp);
    
    // lerp translation
    AZ::Vector3 deltaPos = t * (m_targetValue - m_previousValue);
    interpolatedValue = m_previousValue + deltaPos;

    AZ_Assert(interpolatedValue.IsFinite(), "interpolatedValue is not
finite!");
}

SetPreviousValue(interpolatedValue, time);
return interpolatedValue;
};

The following example shows a completed implementation called `MyInterpolatedSample` that provides only vector interpolation for position.

```cpp
namespace AzFramework
{
    template<typename T>
    class MyInterpolatedSample;

    template<>
    class MyInterpolatedSample<AZ::Vector3> final : public Sample<AZ::Vector3>
    {
        ...
    }
}
```

Finally, you must enable `TransformComponent` to choose your class implementation. You can do that in the switch case statement in `AzFramework::TransformComponent::CreateTranslationSample()`. The source code is in the file `dev\Code\Framework\AzFramework \AzFramework\Components\TransformComponent.cpp`.

```cpp
void AzFramework::TransformComponent::CreateTranslationSample()
{
    switch(m_interpolatePosition)
    {
        case InterpolationMode::LinearInterpolation:
            m_netTargetTranslation = AZStd::make_unique<LinearlyInterpolatedSample<AZ::Vector3>>();
            break;
        case InterpolationMode::NoInterpolation:
            default:
                m_netTargetTranslation = AZStd::make_unique<UninterpolatedSample<AZ::Vector3>>();
                break;
    }
}
```

Provide a new case statement for your enum option. The option creates an instance of your `MyInterpolationSample` class.

```cpp
void AzFramework::TransformComponent::CreateTranslationSample()
```
Synchronizing Game State Using Scripts

That's it! Now you can select your new option in the Entity Inspector, and your custom interpolation logic does the work.

Rotation Interpolation

The preceding example shows how to provide your own position interpolation. Rotation interpolation is similar, but with the following minor differences:

- You have to provide template implementation of `MyInterpolationSample<Quaternion>`.
- You have to write similar code in `AzFramework::TransformComponent::CreateRotationSample()` instead of in `::CreateTranslationSample()`.
- In the location for the interpolation options, the `AzToolsFramework::TransformComponent` has a separate definition for rotation interpolation.

Synchronizing Game State Using Scripts

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can synchronize game state by using the Lua `ScriptComponent`. The initial steps of synchronizing game state using the Lua `ScriptComponent` are similar to any other component. There are two main steps:

1. You must add a `NetBindingComponent` to the definition of the entity that contains the script and the `ScriptComponent` and whose state you want to synchronize.
2. Inside the script, any properties that need to be synchronized must be tagged accordingly. For more information, see Network Binding Properties (p. 2691) in the Writing Lua Scripts (p. 2683) topic.

When these steps are completed, your game state data should synchronize correctly.

Using Encryption

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
GridMate uses the OpenSSL implementation of Datagram Transport Layer Security (DTLS) to support encryption of all UDP traffic sent between clients and servers.

**Limitations**

GridMate's implementation of encryption has the following limitations:

- Only 64-bit Windows is supported.
- Only client-server topologies are supported.

**Implementation Support**

GridMate supports encryption for the following implementations:

- Server and client authentication
- Self-signed certificates
- A single strong OpenSSL cipher

**Cipher**

GridMate uses the following single OpenSSL cipher for all encrypted connections: **ECDHE-RSA-AES256-GCM-SHA384**.

This cipher uses the technologies listed in the following table:

**Cipher Technologies in GridMate**

<table>
<thead>
<tr>
<th>Technology</th>
<th>Role</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECDHE</td>
<td>Key exchange</td>
<td><strong>Ephemeral Elliptic Curve Diffie-Hellman</strong> anonymous key agreement protocol</td>
</tr>
<tr>
<td>RSA</td>
<td>Peer authentication</td>
<td><strong>RSA</strong> algorithm used to authenticate client and server</td>
</tr>
<tr>
<td>AES256</td>
<td>Symmetric encryption cipher</td>
<td><strong>Advanced Encryption Standard</strong> that uses a 256-bit key</td>
</tr>
<tr>
<td>GCM</td>
<td>Block cipher mode of operation</td>
<td><strong>Galois/Counter Mode</strong> authenticated encryption algorithm</td>
</tr>
<tr>
<td>SHA384</td>
<td>Hashing algorithm</td>
<td><strong>SHA-2</strong> with a 384-bit digest size</td>
</tr>
</tbody>
</table>

**Topics**

- Building with Encryption (p. 2068)
- Enabling Encryption (p. 2069)

**Building with Encryption**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
When you include the GridMate library in your project, encryption support is automatically provided. However, because the GridMate library is statically linked, you must first make some modifications to the WAF build script (p. 125) (wscript) that uses GridMate.

Building Your Project with Encryption

To use encryption with GridMate, you must modify your .wscript file to add a dependency on GridMate, link the OpenSSL library, and specify OpenSSL library paths.

To modify your .wscript file to use OpenSSL with GridMate

1. Add the following line to create a dependency on GridMate:

   ```
   use = ['GridMate']
   ```

2. Add the following line to link the OpenSSL library:

   ```
   win_lib = ['ssleay32', 'libeay32']
   ```

3. Add the OpenSSL library paths, as in the following example. Within the Lumberyard install directory, these paths are in the folder `dev\Code\SDKs\OpenSSL\lib`:

   ```
   win_x64_debug_libpath = [ bld.Path('Code/SDKs/OpenSSL/lib/vc120_x64_debug') ],
   win_x64_profile_libpath = [ bld.Path('Code/SDKs/OpenSSL/lib/vc120_x64_release') ],
   win_x64_release_libpath = [ bld.Path('Code/SDKs/OpenSSL/lib/vc120_x64_release') ],
   win_x64_debug_dedicated_libpath = [ bld.Path('Code/SDKs/OpenSSL/lib/vc120_x64_debug') ],
   win_x64_profile_dedicated_libpath = [ bld.Path('Code/SDKs/OpenSSL/lib/vc120_x64_release') ],
   win_x64_release_dedicated_libpath = [ bld.Path('Code/SDKs/OpenSSL/lib/vc120_x64_release') ]
   ```

Building Without Encryption

If your project uses GridMate, but does not require support for encryption, ensure that the GridMateForTools line is in your .wscript file:

```
use = ['GridMateForTools']
```

Enabling Encryption

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To enable encryption with OpenSSL in a GridMate session, perform the following steps.

To enable encryption in a GridMate session

1. To set the encryption parameters, create an instance of SecureSocketDesc. The parameters are described in SecureSocketDesc (p. 2070).

2. Create an instance of SecureSocketDriver that passes in the instance of SecureSocketDesc. The instance of SecureSocketDesc must be available for the duration of the GridMate session.

3. Before hosting or joining a GridMate session, define CarrierDesc by setting the CarrierDesc::m_driver property to the instance of SecureSocketDriver. If no instance
of SecureSocketDriver is provided, an unencrypted driver is used that provides plaintext communication.

4. You can delete the SecureSocketDriver instance at the end of the GridMate session, ideally in the OnSessionDelete event on the SessionEventBus.

The GridMate Session Encryption Example (p. 2071) at the end of this topic has sample code for these steps.

**SecureSocketDesc**

The constructor for SecureSocketDriver requires a SecureSocketDesc object that provides all encryption configuration required for the secure connection. The configuration parameters are described in the following table.

**SecureSocketDesc Configuration Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>m_privateKeyPEM</td>
<td>Base-64 encoded string PEM private key.</td>
</tr>
<tr>
<td>m_certificatePEM</td>
<td>Base-64 encoded string PEM public certificate.</td>
</tr>
<tr>
<td>m_certificateAuthorityPEM</td>
<td>Base-64 encoded string PEM certificate authority.</td>
</tr>
<tr>
<td>m_authenticateClient</td>
<td>If set to 1, the client is expected to provide a signed certificate for authentication. To implement this, m_certificatePEM must be set on the client, and the server needs to set up m_certificateAuthorityPEM. The default setting is 0.</td>
</tr>
</tbody>
</table>

**Server Authentication Only**

You can use the server authentication only configuration when the client needs to verify the authenticity of the server to which it connects. The server has a secret private key and a public certificate signed by a certificate authority. This is the most common configuration.

**Server Authentication Only Configuration**

<table>
<thead>
<tr>
<th>Role</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client</td>
<td>m_certificateAuthorityPEM</td>
</tr>
<tr>
<td>Server</td>
<td>m_privateKeyPEM, m_certificatePEM, m_certificateAuthorityPEM</td>
</tr>
</tbody>
</table>

**Client and Server Authentication**

Use this configuration when the client must verify authenticity of the server and the server must verify authenticity of the client. The client has its own unique private key and corresponding signed public certificate. The server has its own unique private key and corresponding signed public certificate.

It's possible to share or use the same certificate authority for both, but keys and certificates must be unique to each peer.

**Client and Server Authentication Configuration**

<table>
<thead>
<tr>
<th>Role</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client</td>
<td>m_privateKeyPEM, m_certificatePEM, m_certificateAuthorityPEM</td>
</tr>
</tbody>
</table>
Self-signed Certificates

You can use self-signed certificates for development purposes.

**Warning**
Do not use self-signed certificates for production environments.

When you use self-signed certificates, there is no certificate authority to sign the public certificates. To permit the absence of a certificate authority, set `m_certificateAuthorityPEM` to the same value as `m_certificatePEM`.

GridMate Session Encryption Example

The following code snippet enables encryption in a GridMate session.

```cpp
class MyClass : public GridMate::SessionEventBus::Handler
{
public:
    void OnSessionDelete(GridMate::GridSession* session) override;

private:
    GridMate::SecureSocketDriver* m_secureDriver;
};
void MyClass::JoinSession() {
    // ...
    // Create an instance of SecureSocketDesc and set its encryption parameters.
    GridMate::SecureSocketDesc secureDesc;
    secureDesc.m_privateKeyPEM = "...
    secureDesc.m_certificatePEM = "...
    secureDesc.m_certificateAuthorityPEM = "...

    // Create an instance of SecureSocketDriver that passes in the instance of SecureSocketDesc.
    m_secureDriver = new GridMate::SecureSocketDriver(secureDesc);

    // Before hosting or joining a GridMate session, set the CarrierDesc::m_driver property to the instance of SecureSocketDriver.
    carrierDesc.m_driver = m_secureDriver;

    // ...
}

// At the end of the GridMate session, delete the SecureSocketDriver instance in the OnSessionDelete event.
void MyClass::OnSessionDelete(GridMate::GridSession* session) {
    // ...
    delete m_secureDriver;
    m_secureDriver = nullptr;
    // ...
}
```
How To Generate a Private Key and Public Certificate

You can use the `openssl req` command to generate a self-signed certificate from OpenSSL, as in the following example.

```
dev/Code/SDKs/OpenSSL/bin/openssl req -x509 -newkey rsa:2048 -keyout key.pem -out cert.pem -days 365 -nodes
```

The arguments are as follows.

- `-x509` – The certificate format.
- `-newkey` – The type of key. This example generates an RSA key with 2048 bits.
- `-keyout` – The name of the key PEM file that will be generated
- `-out` – The name of the cert PEM file that will be generated

Upon execution, the command prompts for additional user input required to generate the certificate.

Controlling Bandwidth Usage

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

GridMate (p. 1990) provides several ways to control the bandwidth that your game uses, including bandwidth throttling and the prioritization of replica (p. 2035) updates.

Controlling the Send Rate

You can use GridMate to control the server send rate, which is a common technique for reducing bandwidth usage in multiplayer games. In this scenario, a multiplayer game is hosted by a dedicated server to which clients send their replica changes at their default rate (for example, 60 frames per second). To reduce bandwidth usage, you lower the server send rate (for example, to 20 transmissions per second). To avoid jitter when this technique is used, the client must be able to interpolate the game state that it receives from the server.

To control the server send rate in GridMate, set the time interval for replica data transmissions:

```
ReplicaMgr* replicaManager = session->GetReplicaMgr(); // Get the replica manager instance.
This assumes the session has been established.
replicaManager->SetSendTimeInterval(100); // Set the send interval to 100 milliseconds. 10 updates per second will be sent.
```

Setting the `SetSendTimeInterval` to 0 sends the data at the engine's frame rate. The default is 0.

Bandwidth Limiter

Another technique is to limit outgoing bandwidth in exchange for increased latency in the replication of objects. In GridMate, you can do this by setting a bandwidth limit on replica manager. To do so, specify a byte limit for `SetSendLimit`, as in the following example:

```
ReplicaMgr* replicaManager = session->GetReplicaMgr(); // Get the replica manager instance.
This assumes the session has been established.
```
Controlling Bandwidth Usage

```cpp
replicaManager->SetSendLimit(10000);  // Set the transmission limit to 10 kilobytes per second.
```

Setting `SetSendLimit` to 0 disables the bandwidth limiter. The default is 0.

**Controlling Burst Length**

You can use the GridMate limiter to accommodate short bursts in bandwidth if your bandwidth usage is not already at its maximum. This can be useful in many game applications. For example, when a user is in a multiplayer lobby, the corresponding bandwidth usage is quite low. However, when the user joins the game, the bandwidth usage spikes as the initial game state replicates from the server to the client. To control the length of the burst permitted, specify the desired number of seconds for `SetSendLimitBurstRange`, as in the following example:

```cpp
ReplicaMgr* replicaManager = session->GetReplicaMgr();  // Get the replica manager instance.
replicaManager->SetSendLimitBurstRange(5.f);  // Set the maximum permitted length of the burst to 5 seconds.
```

Bursts in bandwidth usage are allowed for the number of seconds specified, after which the bandwidth is capped to the value set by `SetSendLimit`. The default value for `SetSendLimitBurstRange` is 10 seconds. If bandwidth usage has already reached its limit when the burst occurs, bandwidth usage continues to be capped, and the `SetSendLimitBurstRange` setting has no effect.

**Prioritization of Replica Updates**

Every replica chunk (p. 2037) has a priority that you can assign. The priority is represented by an integer from 0 through 65534. Larger integers represent higher priorities. Replicas with higher priorities are sent first. The default is 32768.

This prioritization is especially important when you use the bandwidth limiter because you can use it to define which objects are more important and which are less important. If your game has a bandwidth cap and you have prioritized your replicas appropriately, the objects with higher priority are sent more often. The objects with lower priority are sent only when there is enough bandwidth to accommodate them.

For convenience, GridMate provides five predefined priorities that you can use for custom replica chunks:

```cpp
static const ReplicaPriority k_replicaPriorityHighest = 0xFFFE;  // Decimal 65534, highest priority.
static const ReplicaPriority k_replicaPriorityHigh = 0xC000;  // Decimal 49152, high priority.
static const ReplicaPriority k_replicaPriorityNormal = 0x8000;  // Decimal 32768, normal priority. This is the Default.
static const ReplicaPriority k_replicaPriorityLow = 0x4000;  // Decimal 16384, low priority.
static const ReplicaPriority k_replicaPriorityLowest = 0x0000;  // Decimal 0, lowest possible priority.
```

By default, all chunks have normal priority (`k_replicaPriorityNormal`). You can use these predefined priorities as is, or use them to create your own, as in the following example:

```cpp
// A replica chunk with this priority will be sent before all the chunks with Normal priority, but after all the chunks with High priority:
```
const ReplicaPriority k_myCustomPriority = (k_replicaPriorityNormal + k_replicaPriorityHigh) / 2; // (=Decimal 40960)

The priority for the whole replica is the maximum priority found in its chunks. Priority for a chunk can be set after the chunk is created, or at any point during its lifetime, as in the following example:

MyChunk::Ptr myChunk = GridMate::CreateReplicaChunk<MyChunk>(...);
myChunk->SetPriority(k_replicaPriorityLow); // Sets low priority for myChunk.

Chunks with the same priority are sent and received in the order of their creation. Replicas created earlier are sent and received first.

**Tuning Bandwidth at Runtime**

You can tune bandwidth usage while the game is running by using the following configuration variables (CVars):

<table>
<thead>
<tr>
<th>CVar</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gm_replicasSendTime</td>
<td>The time, in milliseconds, between replica transmissions. A value of 0 binds the interval to the GridMate tick rate.</td>
</tr>
<tr>
<td>gm_replicasSendLimit</td>
<td>The limit, in bytes, of the amount of replica data that can be sent per second. A value of 0 disables the limit.</td>
</tr>
<tr>
<td>gm_burstTimeLimit</td>
<td>The time, in seconds, that bursts in bandwidth are allowed. Bursts are allowed only if the bandwidth is not capped when the burst occurs.</td>
</tr>
</tbody>
</table>

**Using Bit Packing in Lumberyard Networking**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Most built-in C++ types use more than one byte in memory. Even a Boolean value uses one byte. On some operating systems, it can use more. However, the Lumberyard networking system, GridMate, optimizes networking traffic by tightly packing your data into the network payload.

**Boolean Values**

GridMate is intelligent enough to pack a Boolean value into a single bit. For example, if a replica chunk contains several Boolean fields, each field uses a single bit during network transmission. In the following example, GridMate serializes the payload for MyChunk into just three bits.

```cpp
class MyChunk : public ReplicaChunk
{
    ...
    public:
        ....DataSet<bool> m_field1; // This field occupies only one bit.
        ....DataSet<bool> m_field2; // This field occupies only one bit.
        ....DataSet<bool> m_field3; // This field occupies only one bit.
};
```
Tip

Using AZStd::bitset is unnecessary and is often less efficient. Because AZStd::bitset writes its payload in full bytes, packing one Boolean or eight Booleans into AZStd::bitset takes a whole byte. It is better to use DataSet<bool> instead of DataSet<AZStd::bitset>.

Implementing Bit Packing for a Custom Class

The following steps show you how to implement bit packing for a custom class.

1. Declare an Integer Variable That Uses Only the Required Number of Bits

If you have some custom types that you want to pack efficiently, declare an integer variable that uses only the required number of bits. The following simple example declares a flags variable for storing flags in a bit field.

```cpp
struct CustomClass
{
    int flags : 4; // C declaration of an integer value that uses only 4 bits.
};
```

2. Provide a Custom Marshaler

For best results, provide a custom marshaler as in the following example:

```cpp
class MarshalerCustomClass
{
    public:
    void Marshal(WriteBuffer& wb, const CustomClass& value) const
    {
        AZ::u8 tmp = value.flags;
        wb.WriteRaw(&tmp, { 0, 4 }); // Writes 4 bits and 0 bytes from 'tmp'.
    }

    void Unmarshal(CustomClass& value, ReadBuffer& rb) const
    {
        AZ::u8 tmp;
        rb.ReadRaw(&tmp, { 0, 4 }); // Reads just 4 bits and no full bytes.
        value.flags = tmp;
    }
};
```

3. Pass the Marshaler Type as a DataSet Argument

Now, when you declare a DataSet for a CustomClass variable, you can simply pass the marshaler type into the template arguments for DataSet. The following example shows the syntax.

```cpp
DataSet<CustomClass, MarshalerCustomClass> m_value;
```

In this implementation, the example uses a total of only 4 bits to serialize CustomClass.

4. Read and Write Data at the Bit Level

The following example shows how ReadBuffer supports direct control over reading data at the bit level.

```cpp
bool ReadBuffer::ReadRaw(void* source, PackedSize size);
// PackedSize is a special type that you can use to define granularity at the bit level.
// For example PackedSize(0, 1) means 1 bit.
// PackedSize(4, 5) means 4 bytes and 5 bits.
```
The `WriteBuffer` method has the same capability. The following example uses both the `ReadBuffer` and `WriteBuffer` methods.

```cpp
/*
 * This example takes advantage of the bit packing feature in GridMate.
 */
struct CustomClass3
{
    int flags : 7;  // Uses only seven bits.
    bool b;         // Uses only one bit.
};
/*
 * Marshaler for PackedSize objects.
 */
class MarshalerCustomClass3
{
public:
    void Marshal(WriteBuffer& wb, const CustomClass3& value) const
    {
        AZ::u8 tmp = value.flags;
        wb.WriteRaw(&tmp, { 0, 7 });
        wb.WriteRawBit(value.b);
    }
    void Unmarshal(CustomClass3& value, ReadBuffer& rb) const
    {
        AZ::u8 tmp;
        rb.ReadRaw(&tmp, { 0, 7 });
        value.flags = tmp;
        rb.ReadRawBit(value.b);
    }
};
 DataSet<CustomClass3, MarshalerCustomClass3> m_field;
```

**Setting up a Lobby**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

By default, the Lumberyard engine does not provide any specific lobby implementation, but instead provides the code interface required to construct one. The Multiplayer Gem (p. 1171) does, however, provide some useful constructs that aid in lobby creation using a basic lobby implementation using components (p. 532), that can be used as is, or as a reference.

For more information, see the Multiplayer Gem (p. 1171).

**Creating Dedicated Servers**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
In Lumberyard, you can create a build of your game that runs on a headless dedicated server. A
dedicated server build omits the packages and modules that a headless server does not require and has a
smaller compiled size.

Resources to Include

The package that you build for the dedicated server must include the resources that are required to run
the game on the client. You can use Lumberyard’s asset pipeline to exclude certain resources that are not
needed on the server. For more information, see Configuring the Asset Pipeline (p. 269).

Client and Server

Amazon GameLift splits sessions between client and server, but Lumberyard does not. Lumberyard
recommends that you not compile critical server logic on clients or include client data in the server
package.

Waf Build Configuration

To generate a dedicated server build that you can use locally or upload to Amazon GameLift, attach
the _dedicated label to your build configuration in Waf. For more information on using Waf to set
up the dedicated server, see Creating a Dedicated Server (p. 158). The topic is part of the Multiplayer
Sample (p. 155), which includes an example of a dedicated server.

Linux Support

Lumberyard has a Linux version of the dedicated server. For information on how to compile and build
dedicated server packages in Linux, see Creating Lumberyard Executables for Linux (p. 3269).

Using the TCP Stream Driver

To use the TCP stream socket driver, you specify connection parameters for internal buffers, a listening
port, and the maximum number of connections.

After you construct the new stream driver, you can use the socket driver for server or client work. For
server work, the driver can monitor for connections. For client work, the driver can connect to a server’s
endpoint address and port.

To start accepting new connections on the server, call the StartListen() method. When new clients
connect or disconnect, the socket driver sends events through the event bus.

During the setup for the carrier instance, call the StartListen() method for servers and the
ConnectTo() method for clients. You can do this before you assign the m_driver member of the
CarrierDesc structure.

Stream Connection Setup

To construct a stream socket driver, specify the maximum number of connections (1 for clients), the
maximum packet size, and the byte sizes for the internal buffers for inbound and outbound traffic.

To prepare the socket driver, use the Initialize() method with a socket family. IPv4 and IPv6 are
supported. Specify binding parameters and socket buffer sizes. The driver uses internal buffers to spool
streamed traffic during the `Update()` call. GridMate processes the `Update()` call when it is using the carrier instance.

**Constructing the TCP Socket Driver**

The following code example shows how to construct the TCP socket driver.

```cpp
// Specify the maximum number of connections that the server accepts.
const AZ::u32 maxConnections = 32;

// Specify the largest packet to be sent.
const AZ::u32 maxPacketSize = 1024 * 64;

// Specify the size of the internal byte buffer that stores incoming bytes from the socket.
const AZ::u32 inboundBufferSize = 1024 * 64;

// Specify the size of the internal byte buffer that stores outbound bytes to the socket.
const AZ::u32 outboundBufferSize = 1024 * 64;

GridMate::StreamSocketDriver server(maxConnections, maxPacketSize, inboundBufferSize, outboundBufferSize);
```

Note the following:

- The sizes are specified in bytes.
- The maximum packet size should be less than or equal to the outbound buffer size.
- Both buffer sizes are stored in application memory.

**Initializing the Socket Driver**

The following code example shows how to initialize the TCP socket driver.

```cpp
// For IPv4, specify driver BSD_AF_INET. For IPv6, specify BSD_AF_INET6.
const AZ::s32 familyType = GridMate::Driver::BSD_AF_INET;

// Specify the address of the Ethernet card to bind to.
const char* address = "127.0.0.1";

// Specify the port for the server to monitor.
const AZ::u32 serverPort = 2017;

// Specify that TCP sockets cannot send broadcast packets.
const bool isBroadcast = false;

// Set the receive buffer size for each new socket.
const AZ::u32 receiveBufferSize = 1024 * 256;

// Set the send buffer size for each new socket.
const AZ::u32 sendBufferSize = 1024 * 64;
server.Initialize(familyType, address, serverPort, isBroadcast, receiveBufferSize, sendBufferSize);
```

Note the following:

- Both server and client have to use the same socket family `AF_*` type.
- The address can be `nullptr`, which means bind to all the available network interfaces.
- The `isBroadcast` flag is always set to `false`, since a TCP socket is not able to send broadcast packets.
- The receive and send buffer size are specified in bytes and refer to the TCP stack's buffer size for the socket.
Setting Up a Stream Socket Event Bus Handler

An event bus handler instance monitors connection events from GridMate’s stream socket driver. The following code shows a simple stream socket event handler.

```cpp
struct ConnectionHandler : public GridMate::StreamSocketDriverEventsBus::Handler
{
    ConnectionHandler(GridMate::IGridMate* gridMate)
    {
        m_ConnectionCount = 0;
        GridMate::StreamSocketDriverEventsBus::Handler::BusConnect(gridMate);
    }
    ~ConnectionHandler()
    {
        m_ConnectionCount = -1;
        GridMate::StreamSocketDriverEventsBus::Handler::BusDisconnect();
    }
    void OnConnectionEstablished(const SocketDriverAddress& address) override
    {
        m_ConnectionCount++;
    }
    void OnConnectionDisconnected(const SocketDriverAddress& address) override
    {
        m_ConnectionCount--;
    }
    bool DidConnect()
    {
        return m_ConnectionCount > 0;
    }
    AZ::s32 m_ConnectionCount;
};
```

Processing a Server

After you construct and initialize the stream socket driver, use the `StartListen()` method to instruct the server to accept clients. The `StartListen()` method takes a `backlog` parameter that specifies the incoming connection request limit. The driver emits successful connections to its event bus.

When you are finished with the server process, but before you shut down GridMate, call the `StopListen()` method. To disconnect a client, you can use the `DisconnectFrom()` method on the server’s driver instance.

Processing a Client

To connect a client to a server, create a socket driver address. To start the connection process, use the `ConnectTo()` method. When the stream socket driver establishes a connection to the server, it sends a connect event.

To disconnect from the server, the client code uses the `DisconnectFrom()` method. The driver sends a disconnect event when the server gracefully disconnects from the client.

Sending and Receiving Data from the Stream Driver

To send and receive data from the stream driver, you use the `Send()` and `Receive()` methods just as you do with the UDP driver.

For both sending and receiving, the `data` and `data size` values should be equal to or greater than the maximum packet size. If the `Send()` method does not return `GridMate::Driver::EC_OK`, then the connection to the remote endpoint has been closed.
The `Receive()` method returns the number of bytes written to the data buffer. If it returns zero (0) bytes and returns a result code of `GridMate::Driver::EC_OK`, then no more packets are ready to be read.

### Using GridMate for Large-Scale Worlds

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

GridMate is Lumberyard's networking system. Interest manager is Lumberyard's solution to large-scale networked worlds.

**Topics**

- The Relationship Between Replica Manager and Interest Manager (p. 2080)
- Interest Manager (p. 2081)
- Slice Caching and Entity Lifecycle Management (p. 2082)
- Multiplayer Sample Implementation (p. 2082)
- Proximity Net Interest Component (p. 2084)
- Writing Your Own Interest Manager Attributes, Rules and Rule Handlers in C++ (p. 2086)

### The Relationship Between Replica Manager and Interest Manager

Interest manager is an optional feature that controls the sending of replicas in large-scale network game applications. Replica Manager (p. 2047) works without interest manager. However, replica manager sends replicas to all peers. Thus, all associated entities with the Network Binding component on them appear on all peers. When the Interest Manager component is created and initialized, it tells the replica manager to no longer broadcast all replicas to all peers. Interest manager acts as an overseer of replica manager and coordinates replicas and peers.
Broadcasting all replicas to all peers is not feasible for large-scale networked worlds. For these applications, you can use interest manager to control which replicas are broadcast to which peers and under what conditions. The following diagram shows the relationship between interest manager, clients, and replicas.

### Interest Manager Update Logic

1. **Init**
   - SetAutoBroadcast to false

2. **Loop** (for each rule handler)
   - **Update**

3. **Loop** (for each rule handler)
   - **GetLastResult**
   - **InterestMatchResult**
     - process matches
   - **OnReplicaChanged**
     - if a replica list of peers have changed
     - Marshal
     - removes or adds replicas from peers as necessary

---

**Interest Manager**

Broadcasting all replicas to all peers is not feasible for large-scale networked worlds. For these applications, you can use interest manager to control which replicas are broadcast to which peers and under what conditions. The following diagram shows the relationship between interest manager, clients, and replicas.
In this arrangement, replicas have attributes. Each peer can have rules that define the conditions under which attributes are matched and sent to or removed from that peer. Your server or authoritative peer can have several rule handlers that match rules to attributes. Interest manager does the work of matching and merging results and sending or removing replicas from the appropriate peers.

Suppose that you want to build a spatial system that replicates objects based on where your client peer is located within your world. An attribute would be a geometrical volume that represents the location and bounds of the replica. A rule would define a geometrical volume that your client considers in its vicinity of interest. A rule handler would perform smart spatial matching among these spatial objects.

At a low level, GridMate uses the following constructs to implement attributes, rules, and handlers:

```cpp
GridMate::ProximityInterestAttribute
GridMate::ProximityInterestRule
GridMate::ProximityInterestHandler
```

The Multiplayer Sample (p. 155) that is included with Lumberyard contains a practical implementation of these. For detailed information on writing your own attributes, rules, and rule handlers, see Writing Your Own Interest Manager Attributes, Rules and Rule Handlers in C++ (p. 2086).

### Slice Caching and Entity Lifecycle Management

NetBindingSystem caches slices for interest manager. Slice instances are cached and reused for the entities from the same slice instance. Whenever a replica is activated, the cache is searched to see if a slice that contains the entity is already in the cache. If the lookup is successful, the entity is reused.

When a game entity is no longer needed (that is, UnBindGameEntity is called), NetBindingSystem decides whether to deactivate the entity or destroy it. If the entity is in the cache, NetBindingSystem deactivates the entity. If the entity is not found in the cache, NetBindingSystem destroys the entity.

### Multiplayer Sample Implementation

The Multiplayer sample shows how to achieve interest-based filtering of networked entities in your own application.

Because the goal is to control entities, interest manager must work with entities and components. The Multiplayer sample uses the following components to accomplish this:

- Interest Manager
- Game Player Net Interest
- Proximity Net Interest

While the sample is not comprehensive, it provides a starting point for you to understand the technology and implement a system that matches your needs.

### Interest Manager Component

Lumberyard’s AzFramework::InterestManagerComponent is intended for use as a system component in your application.

The InterestManagerComponent initializes both the interest manager and the following built-in rule handlers:

- Proximity rule handler (GridMate::ProximityInterestHandler) – Use the proximity rule handler to specify, based on their spatial proximity, which entities appear in each of your peers. The rule handler uses axis-aligned bounding boxes.
• Bitmask rule handler (GridMate::BitmaskInterestHandler) – Use the bitmask rule handler to filter out replicas based on their bit mask value. This is useful for entities whose presence is determined by custom grouping.

To register InterestManagerComponent as a system component, override AZ::Module::GetRequiredSystemComponents(). As a system component, the InterestManagerComponent is initialized before any other nonsystem entities and nonsystem components. For more information, see System Components (p. 1098).

For reference, see the following code. The source file is \dev\MultiplayerSample\Gem\Code\Source\MultiplayerSampleModule.cpp.

class MultiplayerSample
    : public CryHooksModule
{
    public:
        MultiplayerSample()
            : CryHooksModule()
        {
            // System Components
            RegisterSystemComponent<AzFramework::InterestManagerComponent>(); // enabling interest management
            ...
        }
    template<class T>
        void RegisterSystemComponent()
        {
            m_descriptors.push_back(T::CreateDescriptor());
            m_systemComponents.push_back(azrtti_typeid<T>())
        }
    /**
     * Add required SystemComponents to the SystemEntity.
     */
    AZ::ComponentTypeList GetRequiredSystemComponents() const
    {
        return m_systemComponents; // this is how Lumberyard will get your system components and attach them on your behalf
    }
    ...
    AZ::ComponentTypeList m_systemComponents;
};

Game Player Net Interest

The game player net interest rule (MultiplayerSample::GamePlayerNetInterest) defines the entities in which the game player is interested and contains the GridMate::ProximityInterestRule. The console variable mps_interestRadius determines the radius of the game player's interest. The Multiplayer sample uses the following procedure to create the player entity. You can find the source code in the file dev\MultiplayerSample\Gem\Code\Source\Components\Spawn\PlayerSpawnComponent.cpp.

void PlayerSpawnComponent::SpawnPlayerEntity()
{
    if (m_playerEntity == nullptr)
    {
        m_playerEntity = aznew AZ::Entity("Game Player");
        if (m_playerEntity)
        {
            m_playerEntity->CreateComponent<GamePlayerComponent>();
        }
    }
}
m_playerEntity->CreateComponent<GamePlayerNetInterest>();
m_playerEntity->CreateComponent<AzFramework::NetBindingComponent>();
m_playerEntity->Init();
m_playerEntity->Activate();
AZ::EntityBus::MultiHandler::BusConnect(m_playerEntity->GetId());
}
...
}

The rule is created in GamePlayerNetInterest::BindTargetEntity(), which is called when the replica of this entity is bound. The source code location is \dev\MultiplayerSample\Gem\Code \Source\Components\Networking\GamePlayerNetInterest.cpp.

void GamePlayerNetInterest::BindTargetEntity(const AZ::EntityId& entityId)
{
    ... PeerId peerId = InvalidReplicaPeerId;
    EBUS_EVENT_ID_RESULT(peerId, GetEntityId(), GamePlayerInterfaceBus, GetPeerId); // Find our own peer ID.
    ProximityInterestHandler* proximityInterest = nullptr;
    EBUS_EVENT_RESULT(proximityInterest, AzFramework::InterestManagerRequestsBus, GetProximityInterest);
    if (proximityInterest)
    {
        m_proximityRule = proximityInterest->CreateRule(peerId); // Finally, create the interest manager rule.
    }
    ...}

After the rule is created, the spatial information can be set at any time. The Multiplayer sample uses OnTick to update the player's location. GamePlayerNetInterest retrieves the latest transform of the player location and sets the local proximity rule accordingly. The source code is in GamePlayerNetInterest.cpp.

void GamePlayerNetInterest::OnTick(float deltaTime, AZ::ScriptTimePoint time)
{
    ... AZ::Transform worldTM;
    EBUS_EVENT_ID_RESULT(worldTM, m_targetEntityId, AZ::TransformBus, GetWorldTM); // This updates your local proximity rules that define which entities you are interested in.
    m_proximityRule->Set(AZ::Aabb::CreateCenterRadius(worldTM.GetPosition(), m_interestRadius));
}

**Proximity Net Interest Component**

The Proximity Net Interest component describes the attribute for the entity to which it is attached. The component listens to the transform changes of the entity and updates its internal attribute accordingly. This allows interest manager to control the entity's presence on peers based on the peers' game player net interest. In the **Entity Inspector**, the name of this component is **Proximity Interest attribute**.
Entities that are filtered by interest manager have the Proximity Net Interest component attached. This component listens to transform changes of TransformComponent and updates its GridMate attribute accordingly. The following is the related code snippet from `dev\MultiplayerSample\Gem\Code\Source\Components\Networking\ProximityNetInterest.cpp`.

```c++
void ProximityNetInterestComponent::OnTransformChanged(const AZ::Transform& localTM, const AZ::Transform& worldTM)
{
    ...
    AZ::Aabb bbox = AZ::Aabb::CreateNull();
    CollisionInfo info;
    EBUS_EVENT_ID_RESULT(info, GetEntityId(), CollidableBus, GetCollisionInfo); // Get our bounding box.
    if (info.m_shape)
    {
        bbox = info.m_shape->GetEncompassingAabb();
    }
    m_attribute->Set(bbox); // Update GridMate::ProximityInterestAttribute value for the interest manager.
    ...
}
```
Writing Your Own Interest Manager Attributes, Rules and Rule Handlers in C++

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can freely extend the GridMate interest manager system with your own logic. To create a custom rule handler, inherit and implement the `GridMate::BaseRulesHandler` C++ interface. The following snippet shows the code for the `BaseRulesHandler` class.

```cpp
// dev\Code\Framework\GridMate\GridMate\Replica\Interest\RulesHandler.h
namespace GridMate
{
    class InterestManager;

    /**
     * BaseRulesHandler: base handler class.
     * RulesHandler's job is to provide InterestManager with matching pairs of attributes and rules.
     */
    class BaseRulesHandler
    {
        public:
            BaseRulesHandler() : m_slot(0) {}

            virtual ~BaseRulesHandler() { };

            /**
             * Ticked by InterestManager to retrieve new matches or mismatches of interests.
             */
            virtual void Update() = 0;

            /**
             * Returns result of a previous update.
             * This only returns changes that happened on the previous tick, not the whole world state.
             */
            virtual const InterestMatchResult& GetLastResult() = 0;

            /**
             * Called by InterestManager when the given handler instance is registered.
             */
            virtual void OnRulesHandlerRegistered(InterestManager* manager) = 0;

            /**
             * Called by InterestManager when the given handler is unregistered.
             */
            virtual void OnRulesHandlerUnregistered(InterestManager* manager) = 0;

            /**
             * Returns the InterestManager that this handler is bound to, or nullptr if it's unbound.
             */
            virtual InterestManager* GetManager() = 0;

        private:
            friend class InterestManager;
    }
```
Of interest is the method `GetLastResult`, which returns `InterestMatchResult`. `InterestMatchResult` is essentially an unordered map between replicas and a list of the peers on which the replicas should be present. If a peer is not on the list for a replica and has the replica's proxy, the interest manager removes the replica's proxy. The following code shows the declaration of the `InterestMatchResult` class.

```cpp
using InterestPeerSet = unordered_set<PeerId>;

/**
 * InterestMatchResult: a structure to gather new matches from handlers.
 * Passed to handler within matching context when handler's Match method is invoked.
 * User must fill the structure with changes that handler recalculated.
 * Specifically, the changes should have all the replicas that had their list of
 * associated peers modified.
 * Each entry replica - new full list of associated peers.
 */
class InterestMatchResult : public unordered_map<ReplicaId, InterestPeerSet>
```

It's up to you to decide how you want your rule handler to match up rules and attributes. To help you get started, GridMate provides some simple base classes for rules and attributes, as the following code shows.

```cpp
/**
 * Base class for interest rules.
 */
class InterestRule
{
public:
    explicit InterestRule(PeerId peerId, RuleNetworkId netId)
        : m_peerId(peerId), m_netId(netId)
    {}
    PeerId GetPeerId() const { return m_peerId; }
    RuleNetworkId GetNetworkId() const { return m_netId; }

protected:
    PeerId m_peerId; ///< the peer this rule is bound to
    RuleNetworkId m_netId; ///< network id
};

/**
 * Base class for interest attributes.
 */
class InterestAttribute
{
public:
    explicit InterestAttribute(ReplicaId replicaId)
        : m_replicaId(replicaId)
    {}
```
Using Amazon GameLift

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard supports hosting dedicated servers on the cloud by using Amazon GameLift. GameLift is a managed AWS service for deploying, operating, and scaling session-based multiplayer games. GameLift is built on AWS's highly available cloud infrastructure and allows you to quickly scale high-performance game servers up and down to meet player demand – without any additional engineering effort or upfront costs. It reduces the time required to build a multiplayer backend from thousands of hours to just minutes.

To use GameLift in your project, there are two options:

- Enable the GameLift Gem (p. 1130) in your project. Lumberyard has integrated Amazon GameLift, which makes it easier for you to use GameLift.
- Enable the Lumberyard Multiplayer Gem (p. 1171) in your project (which requires the GameLift Gem).

For information about configuring GameLift for the multiplayer sample, see Configuring the Multiplayer Sample for Amazon GameLift (p. 2003). For information, see Add modular features and assets with Gems (p. 1064). For more information about GameLift, see Amazon GameLift.

- Amazon GameLift API Reference

Testing your Amazon GameLift Integration

Before you make your first Amazon GameLift fleet, verify your integration using GameLift Local. GameLift Local is included as part of the GameLift Server SDK download. It is run as a Java process.

With GameLift Local, you can test most aspects of your GameLift integration, with the exception of matchmaking. For details and other limitations, see the complete documentation for Testing Your Integration in the Amazon GameLift Developer Guide.
The following example demonstrates how to test MultiPlayerSample on Windows.

1. **Start GameLift Local.**

   Open a command prompt window, navigate to the directory containing the file GameLiftLocal.jar, and run it. By default, GameLift Local listens for requests from game clients on port 8080. To specify a different port number, use the `-p` parameter, as shown in the following example:

   ```java
   java -jar GameLiftLocal.jar -p 9080
   ```

   **Important**
   Use the same port in the `gamelift_endpoint` cvar for the game client launcher.

   When GameLift Local starts, you see logs indicating that two local websockets were started, one listening for your game server and one listening for your game client or the AWS CLI. Logs continue to report activity on the two local servers, including communication to and from your game components.

2. **Start the MultiPlayerSample dedicated server.**

   Open a new command window, navigate to the directory containing the game server, and run it using the following command-line options:

   ```
   MultiplayerSampleLauncher_Server.exe +sv_port 33435 +gamelift_start_server +map MultiplayerSample
   ```

   In the GameLift Local console, log messages indicate that your game server has connected to the GameLift Local service, initialized the GameLift Server SDK with `InitSDK()`, and called `ProcessReady()`. If successful, you are now ready to host a game session.

   **Tip**
   For details on these and other calls, see GameLift interactions.

3. **Start the MultiPlayerSample client.**

   Start the launcher using the following command-line options:

   ```
   MultiplayerSampleLauncher.exe +sv_port 33435 +gamelift_fleet_id fleet-123 +gamelift_uselocalserver 1 +gamelift_endpoint 127.0.0.1:9080 +gamelift_aws_access_key any_string +gamelift_aws_secret_key any_string +gamelift_region us-west-2
   ```

   **Note**
   Note that the `gamelift_uselocalserver` cvar is set to 1 to indicate the use of a local server, and the `gamelift_endpoint` cvar is set to the local endpoint with the same port used to start GameLift Local. You do not need real AWS credentials when testing local; you can set the access key and secret key to any string.

**Troubleshooting Amazon GameLift integration**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the following information to help you diagnose and fix common problems that you might encounter while working with Amazon GameLift.

**Topics**
Fleets failing to go active

As a first step, sign in to the Amazon GameLift console and check the fleet's events to get more details on the problem. Here you can examine the output of the install script and get more information regarding where GameLift is seeing problems.

Missing dependencies

If your process is failing on launch, then the most likely cause is that you failed to package or install all of the server's dependencies. On Windows, this typically means missing dynamic link libraries (DLLs). Check the following:

- Check your `install.bat` or `install.sh` output. Ensure that the script installed what was required to run on GameLift.

  **Note**
  For Windows fleets, debug builds of the dedicated server will fail on launch, since they require debug Visual Studio Redistributables which Lumberyard cannot provide. Consider using profile builds instead on GameLift.

  **Note**
  For Linux fleets, look at the `MultiplayerSample_CreateGameLiftPackage.sh` script to see how to generate an `install.sh` for use on Amazon Linux 2.

- Remote into the fleet and ensure that the `bootstrap.cfg` is correct. Many failures can be caused by a misconfigured bootstrap. Try manually running the process to discover what might be missing on launch.

- If you are using Windows to prepare packages for Linux development, ensure that the box marked **Setup for Linux Dedicated Server** is selected in the Setup Assistant, otherwise GameLift integration files can be missing. This is a requirement for using `MultiplayerSample_LinuxPacker.bat`, for example.

Crashing process

If your process is crashing, then remote into the fleet and check the server logs to discover the source of the crash. Lumberyard logs to either `C:\Game\user\log` (Windows) or `/local/game/user/log` (Linux).

Not responding to GameLift callbacks

Ensure that your process is responding to callbacks from GameLift, especially the health check callback. If your process is not responding, then ensure your Amazon EC2 instance is not CPU-bound or memory-bound, which might cause the server to be unstable or slow to respond. Try reducing the number of concurrent servers per instance, or try a larger EC2 instance.

Clients unable to connect

If your clients fail to connect to the server, then check the following configurations:

- Ensure that the expected server fleet port(s) are open in Amazon GameLift. This can be checked from the fleet console and the CLI.

- Ensure that your server is listening on the port reported to GameLift via the `ProcessParameters` object passed to `ProcessReady()`.
• Ensure that your clients do not have the sv_port cvar set to something unexpected. We recommend that you leave this at the ephemeral port.

• If you are using MultiplayerSample as a basis for your fleets, verify that the server and client have the same self-signed certificate. You must use a consistent certificate across clients and server fleets. For more information about self-signed certificates, see About Self-Signed Certificates in the Multiplayer Sample (p. 158).

• Verify that gm_netsec_enable is consistent between your clients and fleets. It is on by default for the dedicated server, but you can turn it off by passing +gm_netsec_enable 0 in the startup params.

**Additional information**

For additional troubleshooting tips and information, see the following topics:

• Debug GameLift fleet issues
• Accessing GameLift fleet instances remotely
• Testing your GameLift integration
• Multiplayer Sample troubleshooting (p. 159)

**Useful Console Commands**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the following commands in Lumberyard when working with a network server.

`gm_debugdraw debug_draw_level`

Sets the debug draw level. Accepts as a parameter a number who's bits represent the flags for the debug data to draw. For example, when set to 1, displays an overlay with GridMate network statistics and information.

The available bit flags come from the enum DebugDrawBits and are as follows:

```c
enum DebugDrawBits
{
    Basic           = BIT(0),
    Trace           = BIT(1),
    Stats           = BIT(2),
    Replicas        = BIT(3),
    Actors          = BIT(4),
    EntityDetail    = BIT(5),

    Full            = Basic | Trace | Stats | Replicas | Actors,
    All             = 0xffffffff,
};
```

`gm_disconnectDetection`

When set to 0, disables disconnect detection. This is useful when you are debugging a server or client and don’t want to be disconnected when stepping through code. The default value is 1.

`gm_dumpstats`

Write GridMate network profiling stats to file.
Using Multiplayer Analytics

Lumberyard User Guide Lumberyard User Guide

Using Multiplayer Analytics

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard includes the Multiplayer Analytics Gem for analyzing your network traffic live using an in-game overlay. When this GridMate Gem is enabled, you can bring up an in-game UI by pressing the HOME key.

gm_dumpstats_file

The file to which GridMate profiling stats are written. The default is net_profile.log.

gm_net_simulator

Activate GridMate network simulator to simulate latency, packet loss, bandwidth restrictions, and other conditions. For available options, enter gm_net_simulator help.

gm_setdebugdraw

Display an overlay with detailed GridMate networking statistics and information. A user-friendly helper command for gm_debugdraw debug_draw_level. Possible parameters are Basic, Trace, Stats, Replicas, and Actors.

gm_stats_interval_msec

Set the interval, in milliseconds, for gathering network profiling statistics. The default is 1000.

gm_tracelevel trace_level

Set the GridMate debugging trace verbosity level. The default is 0. The higher the value, the greater the verbosity. Typical values range from 1 to 3.

mpstart [<local_port>]

Starts a LAN session by initializing the network system and optionally setting the local UDP port that initializes the socket. The default port is 64090. To use the ephemeral port, set the port to 0. This is useful if you want to connect to a server on the same computer as the client.

mphost

Create a session as host. The server listens for incoming connections on the port specified in mpstart.

mpjoin [<server_addr>] [<server_port>]

Connect to a server at the optionally specified <server_addr> and <server_port>. The defaults are localhost and 64090, respectively.

map <map_name>

Loads the level with the specified map name. Replace <map_name> with the name of the map you want to use. To view a list of available levels, enter map, and then press the tab key.

mpdisconnect

Terminate the current game instance session.

sv_port local_port

Sets the local UDP port that initializes the socket. The default port is 30090. To use the ephemeral port, set the port to 0. This is useful if you want to connect to a server on the same computer as the client.
If you don't have any clients connected to your server, or you are running a single player game, you will see the following minimal UI:

Once you have a client connected to your server, you will see total bandwidth data:

In order to get detailed information of network traffic, you need to select Analyze network traffic.
Now you can expand either incoming or outgoing replica updates.

The **MultiplayerSample** level shows the network payload for each unique replica name. If you have multiple replicas that share the name, their data gets combined.

You can see the total average kilobits per second, average bytes per replica update, maximum byte per replica type update, and the overall bytes sent for a given replica name. You can also drill in deeper into each replica.
At the next level of detail you can see the network costs per replica chunks. You can drill in one more time to see the cost per DataSet and Remote Procedure Call.

### Tip
You can filter by replica name using the Filter field. For example, you can choose to only show replicas that have "small" in their name. (Case is ignored.)

Using this analytics tool, you can figure out which replicas are your most expensive network data, and then drill down to find which particular chunks and fields are the most expensive items for you. Since this tool is live and in-game, you might find it useful to record a video of your project with the overlay on while performing a particular game test, and then observe what changes occur in your network usage pattern.

### Note
All values update once every second.

---

## Engaging Broadcasters and Viewers on Twitch

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/game-tech/) or visit the AWS Game Tech blog to learn more.

Lumberyard is integrated with Twitch so that you can build games that engage with broadcasters and viewers on Twitch.

### Twitch ChatPlay

The Twitch ChatPlay feature within Lumberyard helps you build gameplay that interacts in real time with Twitch viewers. For example, you can build a game where viewers can vote on game outcomes, gift power-ups to their favorite players, or change the level based on the number of viewers watching the player.

### Twitch JoinIn

The Twitch JoinIn feature within Lumberyard helps you build multiplayer games that allow Twitch broadcasters to invite fans to join them side by side in the game. Once invited, a fan can jump into the broadcaster's game with a single click in the Twitch chat channel, while others continue to watch.

### Twitch API
Twitch API functionality in Lumberyard is based on the publicly available RESTful functions described in the Twitch API reference. Each of these functions has a corresponding call in the Lumberyard TwitchApiRequestBus that will queue an HTTP request. You can listen for the response to this request on the TwitchApiNotifyBus.

Prerequisites

To use the Twitch gem and add Twitch support to your Lumberyard project, you must:

- Be authorized as a Twitch development partner. To register, visit the Twitch Developer Portal at https://dev.twitch.tv/.

Topics

- Twitch ChatPlay System (p. 2096)
- Twitch C++ API Reference (p. 2099)

Twitch ChatPlay System

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Twitch ChatPlay provides a flexible framework to create customized game interactions between broadcasters and spectators on Twitch, the world’s leading social video platform and community for gamers.

Twitch ChatPlay includes support for chat commands, polls, and surveys that can be triggered by Twitch viewers through the Twitch chat channel. For example, you can create a chat command #cheer that triggers celebration animations in your game.

Twitch ChatPlay is implemented by a set of Script Canvas nodes that establish a connection to a Twitch channel and use incoming traffic as a game input, like any other input device.

Twitch ChatPlay includes the following components and services:

- Twitch IRC servers
- Twitch ID authentication
- Twitch account

The following diagram illustrates Twitch ChatPlay’s server-side components.
The following diagram illustrates Twitch ChatPlay's client-side components.

Using the Twitch Chat API Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Adding the Twitch Chat API Gem to your project enables you to connect to the Twitch IRC and interact with players using Twitch ChatPlay.
Twitch ChatPlay includes support for chat commands, polls, and surveys that can be triggered by Twitch viewers through the Twitch chat channel.

For gem setup steps, read the Twitch Chat API Gem (p. 1208) documentation.

Gem Usage

Once the gem has been added to your project and you have setup a Twitch account and OAuth token, you are ready to connect to Twitch IRC using C++, Lua, or Script Canvas and join a channel.

Connect to Twitch ChatPlay

Use the `ConnectToChatplay` function to connect to ChatPlay by providing your OAuth token (1st argument), and your username (2nd argument). Once connected, you should see a message confirming that Twitch is connected through the `TwitchChatPlayNotificationBus`. You will need to listen to this bus in C++ or Lua, or by simply using the Script Canvas node to receive the message.

Join a channel

Use the `JoinChannel` function to join a channel on Twitch. If your account has moderator control of that channel, you can use moderator features with your ChatPlay connection.

Game usage

Examples of how to use a ChatPlay connection in your game include the following:

- React to new subscribers of the channel.
- Listen to messages in the channel and filter them using a keyword system (p. 2098).
- Respond to specific keywords.
- Implement voting using keywords.

All of these can be implemented using a bus call in C++, Lua, or Script Canvas nodes. Look in the directory Gems\TwitchChatPlay\Assets for Lua and Script Canvas usage examples.

Keyword System

ChatPlay enables you to search incoming messages from Twitch for keywords. Your game can respond to these messages. Here are some rules and recommendations to follow when creating keywords for your game:

To create keywords

Three functions are used to set keywords in the system. The first two are also accessible through Script Canvas. Be sure to set a keyword only once, using one of the following handlers:

1. `SetKeywordWithDefaultHandler` – Adds a keyword for use throughout a session. The keyword will automatically have its handler assigned to the `TwitchChatPlayNotificationBus`, and messages will be sent through that system when the keyword is triggered.
2. `SetKeywordWithFormattedHandler` – Adds a keyword that will be parsed into username and message, in separate fields.
3. `SetKeywordWithSpecificHandler` – Adds a unique function to the keyword that will be called when that keyword is hit. This handler can be set to multiple keywords, but different handlers may be used for different keywords. For example, you could have "!vote" go to a `CountVote` function, while "!subscribe" goes to the `PlayFanfare` function.

To enable or disable keywords
Keywords can be enabled and disabled using the `ActivateKeywordMatching` command. You could easily turn voting on and off with this command, for example. You can also call `RemoveKeyword` if you no longer need a particular keyword.

**Choosing and using keywords**

A common Twitch pattern is to provide keywords in the format: `!<keyword> <value>`. For example, `!vote yes`.

We recommend that you use this format for your keywords for simplicity, though it is not required. Simply enter your keywords in this format, and enable the system to use them by setting `UseTwitchPattern` to true.

**Troubleshooting**

If keywords don't seem to be working, verify that your incoming keywords match the chosen keyboard format. You can pass the messages through or set a custom handler to help determine if users are acting in an unexpected way, or if the default keyword matching is too limited for your needs.

**Twitch C++ API Reference**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Twitch API and its RESTful functions are represented by two EBus's in Lumberyard:

- `TwitchApiRequestBus`
- `TwitchApiNotifyBus`

**Note**

If you are using the legacy Twitch v5 Gem, the EBus's are the `TwitchRequestBus` and the `TwitchNotifyBus`.

EBus is the interface that's used to make RESTful requests to the Twitch API. For each function in the Twitch API Reference, there is a corresponding call in the `TwitchApiRequestBus` that will queue an HTTP request. The Twitch API Gem also includes additional EBus functions, which are detailed in the following sections.

For general information about using event buses in Lumberyard, see Working with the Event Bus (EBus) system (p. 1851).

Each call made on the `TwitchApiRequestBus` leads to a response you can subscribe to and listen to on the `TwitchApiNotifyBus`. Because calls are made asynchronously, responses are not guaranteed to arrive in the same order as requested. Each response typically includes the following data:

- a unique `TwitchApi::ReceiptId`
- a `TwitchApi::ResultCode`
- data from the JSON response

To determine which response corresponds to a request, you can compare the `ReceiptId` in your requests to the `ReceiptId` in the responses.

To determine if the call was successful, check if `result.m_result` is equal to `ResultCode::Success`. 
The requested data can be found in `result.m_value.m_data`. The TwitchApi Gem handles parsing the JSON responses served by the Twitch API into these data structs. These structs are also reflected in Lumberyard’s BehaviorContext so that they are fully usable from Lua and ScriptCanvas. Note that the structs are not necessarily identical to the JSON response format returned by Twitch. They may have been packed down to reduce layers.

Example handler for `GetExtensionAnalytics`.

```cpp
void OnGetExtensionAnalytics(const ExtensionAnalyticsResult& result) override
{
    if( result.GetId() == sentRequest.GetID() )
    {
        // Display Extension Analytics info. Note this call can return multiple results.
        cout << "Request Twitch Extension Analytics Info" << endl;
        if(result.m_result == TwitchApi::ResultCode::Success)
        {
            // Iterate through all results
            for (const TwitchApi::ExtensionAnalyticsDatum& datum : result.m_value.m_data)
            {
                cout << " Extension Id   : " << datum.extension_id << endl;
                cout << " Type           : " << datum.type << endl;
                cout << " URL            : " << datum.url << endl;
                cout << " Started-At Time: " << datum.started_at << endl;
                cout << " Ended-At Time  : " << datum.ended_at << endl;
            }
        }
        else
        {
            cout << "Failed Result: " << result.m_result << endl;
        }
    }
}
```

`ExtensionAnalyticsResult` is populated from the JSON response received from the Twitch API. The JSON response would have been formatted like this:

```json
{
    "data": [
    {
        "extension_id": "abcdefg",
        "URL": "https://my.twitch.test/123",
        "type": "overview_v1",
        "date_range": {
            "started_at": "2018-04-30T00:00:00Z",
            "ended_at": "2018-05-01T00:00:00Z"
        }
    }
    ]
}
```

Note that the JSON has `started_at` and `ended_at` contained within the `date_range` object. The TwitchApi Gem simplifies the response struct for this call by eliminating `date_range` and placing `started_at` and `ended_at` adjacent to the rest of the data. As a design decision, the TwitchApi Gem tries to keep structs as lean as possible so each response struct may be a leaner version of the JSON response.

**Topics**
- `TwitchApiRequestBus` (p. 2101)
- `TwitchApiNotifyBus` (p. 2105)
TwitchApiRequestBus

The TwitchApiRequestBus includes functions that correspond to their counterparts defined in the Twitch API Reference, plus the following additional functions.

SetApplicationID

Sets the Twitch application ID. This must be called before any other API operation, and should only be called once. You will not receive a notification from this call.

Usage Example

```cpp
/*
** Set a string to hold our Twitch Application ID.
*/
AZStd::string applicationId = "0123456789abcdef0123456789";
TwitchApi::TwitchApiRequestBus::Broadcast(&TwitchApiRequests::SetApplicationId, applicationId);
```

Parameters

applicationID (AZStd::string)

The Twitch application ID that you obtain from Twitch when you create an application.

Return

No return value.

SetAppAccessToken

Sets the Twitch app access OAuth token. When you set the app access token, a new AppAccessTokenNotify event is generated on the TwitchApiNotifyBus EBus and TwitchApi::TwitchApiNotifications::AppAccessTokenNotify() is called.

Usage Example

```cpp
/*
** Set a string to hold our Twitch app access OAuth bearer token.
*/
AZStd::string appToken = "0123456789abcdef0123456789";
TwitchApi::TwitchApiRequestBus::Broadcast(&TwitchApiRequests::SetAppAccessToken, appToken);
```

Parameters

token (AZStd::string)

The Twitch app access OAuth bearer token.

Return

No return value.
**AppAccessTokenNotify Callback**

*token (AZStd::string)*

The Twitch app access OAuth token that was set.

**SetUserAccessToken**

Sets the Twitch user access OAuth token. When you set the user access token, a new `UserAccessTokenNotify` event is generated on the `TwitchApiNotifyBus` EBus and `TwitchApi::TwitchApiNotifications::UserAccessTokenNotify()` is called.

**Usage Example**

```cpp
/*
 ** Set a string to hold our Twitch user access OAuth bearer token.
 */
AZStd::string userToken = "0123456789abcdef0123456789";
TwitchApi::TwitchApiRequestBus::Broadcast(&TwitchApiRequests::SetUserAccessToken, userToken);
```

**Parameters**

*token (AZStd::string)*

The Twitch user access OAuth bearer token.

**Return**

- No return value.

**UserAccessTokenNotify Callback**

*token (AZStd::string)*

The Twitch user access OAuth token that was set.

**SetUserId**

Sets the Twitch user ID. When you set the user ID, a new `UserIdNotify` event is generated on the `TwitchApiNotifyBus` EBus and `TwitchApi::TwitchApiNotifications::UserIdNotify()` is called.

**Usage Example**

```cpp
/*
 ** Set a string to hold our Twitch user ID.
 */
AZStd::string userId = "0123456789abcdef0123456789";
TwitchApi::TwitchApiRequestBus::Broadcast(&TwitchApiRequests::SetUserId, userId);
```
Parameters

**userId (AZStd::string)**

The Twitch User ID. This can be obtained from Twitch by querying a user name.

Return

No return value.

**UserIdNotify Callback**

**userID (AZStd::string)**

The user ID that was set.

**GetApplicationId**

Gets the cached Twitch application Id. There is no notification from this call.

Usage Example

```cpp
/*
 ** Get our Twitch Application ID.
 */
AZStd::string applicationId;
TwitchApi::TwitchApiRequestBus::BroadcastResult(applicationId, &TwitchApiRequests::GetApplicationId);
```

Parameters

No parameters.

Return

**applicationId (AZStd::string)**

The Twitch application ID. This is obtained from Twitch when you create the application.

**GetAppAccessToken**

Gets the cached Twitch app access OAuth token. There is no notification from this call.

Usage Example

```cpp
/*
 ** Get the Twitch app access OAuth bearer token.
 */
AZStd::string oAuthToken;
TwitchApi::TwitchApiRequestBus::BroadcastResult(oAuthToken, &TwitchApiRequests::GetAppAccessToken);
```
Parameters

No parameters.

Return

oAuthToken (AZStd::string)

The Twitch app access OAuth bearer token.

GetUserAccessToken

Gets the cached Twitch user access OAuth token. There is no notification from this call.

Usage Example

```cpp
/*
** Get the Twitch user access OAuth bearer token.
*/
AZStd::string oAuthToken;
TwitchApi::TwitchApiRequestBus::BroadcastResult(oAuthToken, &TwitchApiRequests::GetUserAccessToken);
```

Parameters

No parameters.

Return

oAuthToken (AZStd::string)

The Twitch user access OAuth bearer token.

GetUserId

Gets the cached Twitch user ID. There is no notification from this call.

Usage Example

```cpp
/*
** Get the Twitch user ID.
*/
AZStd::string userId;
TwitchApi::TwitchApiRequestBus::BroadcastResult(userId, &TwitchApiRequests::GetUserId);
```

Parameters

No parameters.
Return

userid (AZStd::string)

The Twitch user ID.

TwitchApiNotifyBus

The TwitchApiNotifyBus includes handler functions that correspond to the request functions found in the TwitchApiRequestBus, including the following callbacks to the request functions defined by the TwitchApi Gem.

AppAccessTokenNotify

Notification event for when the Twitch app access OAuth token is set.

Usage Example

```cpp
// Event gets broadcast.
TwitchApiNotifyBus::QueueBroadcast(&TwitchApiNotifyBus::Events::AppAccessTokenNotify, rAppAccessToken);

// Event handled in override of TwitchApi::TwitchApiNotifications::AppAccessTokenNotify.
void AppAccessTokenNotify(const AZStd::string& appAccessToken)
{
    // Do something with the app access OAuth token.
}
```

Parameters

token (AZStd::string)

The Twitch app access OAuth bearer token.

Return

No return value.

UserAccessTokenNotify

Notification event for when the Twitch user access OAuth token is set.

Usage Example

```cpp
// Event gets broadcast.
TwitchApiNotifyBus::QueueBroadcast(&TwitchApiNotifyBus::Events::UserAccessTokenNotify, rUserAccessToken);

// Event handled in override of TwitchApi::TwitchApiNotifications::UserAccessTokenNotify.
void UserAccessTokenNotify(const AZStd::string& userAccessToken)
{
    // Do something with the user access OAuth token.
}
```

Parameters

token (AZStd::string)

The Twitch user access OAuth bearer token.
Return

No return value.

**UserIdNotify**

Notification event for when the Twitch user ID is set.

**Usage Example**

```cpp
// Event gets broadcast.
TwitchApiNotifyBus::QueueBroadcast(&TwitchApiNotifyBus::Events::UserIdNotify, rUserId);

// Event handled in override of TwitchApi::TwitchApiNotifications::UserIdNotify.
void UserIdNotify(const AZStd::string& userId)
{
    // Do something with the user ID.
}
```

**Parameters**

- `userId` (*AZStd::string*)
  - The Twitch User ID.

**Return**

No return value.

---

**Implementing Connected Features with Cloud Canvas**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

**Topics**

- Features (p. 2107)
- Example Uses (p. 2107)
- Tools (p. 2107)
- Knowledge Prerequisites (p. 2108)
- Cloud Canvas Overview (p. 2108)
- Cloud Gems (p. 2127)
- Cloud Canvas Gameplay Design and Engineering Guide (p. 2221)
- Cloud Canvas Software Engineering Guide (p. 2224)
- Administering Cloud Canvas (p. 2348)
- Using the Cloud Canvas Command Line (p. 2390)

Deeply integrated with AWS, Cloud Canvas is a suite of tools and solutions (cloud gems, resource groups, script canvas nodes) designed to achieve two main goals:
1. Make it easy for you to build cloud-connected features, so you can focus on innovation rather than on undifferentiated backend infrastructure.

2. Make it possible for you to create fantastic new experiences made possible by the availability of the on-demand, global storage and compute provided by AWS.

With Cloud Canvas, you can add a cloud-connected feature to your game in as little as 30 minutes. A single engineer can do this, freeing up the rest of your team to think about innovation and player experience.

Features

Cloud Canvas offers a wide range of helpful features:

- **Cloud gems (p. 2127)** that provide cloud-connected features such as Message of the Day, Leaderboards, and Dynamic Content. These cloud gems can be used in a few clicks as is, or as samples to fuel your custom developments and ideas.
- The **Cloud Gem Framework (p. 2257)**, on top of which cloud gems are built, allows you to add pre-packaged, cloud-connected features in a few clicks. You can use the Cloud Gem Framework to build your own cloud gems (p. 2259).
- Tools to enable a team to build a game with cloud-connected features.
- A **CloudGemAWSScriptBehaviors (p. 2289)** gem that exposes AWS services such as Amazon S3, Amazon Cognito, AWS Lambda, and HTTP utilities to script.
- Tools to manage AWS resources and permissions that determine how game developers and players access them.
- Management of AWS deployments so that development, test, and live resources are maintained separately.
- Methods for players to be authenticated (anonymous and authenticated). Players can be authenticated from a variety of devices and access their game data by logging in with an Amazon, Facebook, or Google account.

Example Uses

Consider the many ways you can use Amazon Web Services for connected games:

- Store and query game data such as player state, high scores, or world dynamic content: Amazon S3 and DynamoDB
- Trigger events in real time and queue data for background processing: Amazon SQS and Amazon SNS
- Execute custom game logic in the cloud without having to set up or manage servers: AWS Lambda
- Employ a daily gift system that tracks player visits and rewards frequent visits: Amazon Cognito, Amazon S3, DynamoDB, AWS Lambda
- Present a message of the day or news ticker that provides updates on in-game events: Amazon Cognito, Amazon S3, AWS Lambda

For tutorials on Cloud Canvas, see Tutorial: Getting Started with Cloud Canvas (p. 2116) and Lumberyard Tutorials.

Tools

You can access Cloud Canvas functionality by using any of the following:

- **Cloud Canvas C++ APIs** – For software development.
Knowledge Prerequisites

You need the following to take advantage of Cloud Canvas:

- **An understanding of AWS CloudFormation Templates** – Cloud Canvas uses the AWS CloudFormation service to create and manage AWS resources. Our goal is for Cloud Canvas to minimize what you need to know about AWS CloudFormation and AWS in general.
- **Familiarity with JSON** – Cloud Canvas leverages JSON for storing configuration data, including AWS CloudFormation Templates. Currently, you'll need to be familiar with this text format to work with the Cloud Canvas resource management system. A JSON tutorial can be found [here](#).

Cloud Canvas Overview

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Cloud Canvas helps you manage cloud resources and connect your game with the AWS cloud. Understanding its concepts will benefit anyone on your team who interacts with the cloud-connected components of your game, including designers, programmers, and testers.

This section covers the following:

- What Cloud Canvas is and how it relates to your AWS account
- The Amazon Web Services that Cloud Canvas supports
- How Cloud Canvas helps you manage your resources
- How your game can communicate with the cloud through cloud gems

Prerequisites

Before reading this topic, you should have a basic understanding of the Lumberyard engine (p. 1).

AWS, Cloud Canvas, and Lumberyard

Amazon Web Services (AWS) is an extensive and powerful collection of cloud-based services. You can use these services to upload or download files, access databases, execute code in the cloud, and perform many other operations. A cloud service saves you the trouble of maintaining the infrastructure that it relies on.

Cloud-Based Resources

When you want to use an AWS cloud service, you do so through a resource, a cloud-based entity that is available for your use, help, or support. Resources include a database, a location for storing files, the code that a service runs, and more.

When you create a resource, it exists in the cloud, but you can use it and manage its content. You also specify the permissions that individuals or groups have to access or use the resource. For example, you might allow anyone in the public to read from your database but not write to it or modify it.
Resource Groups

In order to create a connected game feature such as a high score table, you create a resource group in Cloud Canvas. The resource group defines the AWS resources that your feature requires. Each connected game feature therefore is implemented as a resource group in Cloud Canvas.

AWS Accounts

Your resources are owned by an AWS account. The AWS account allows you and your team to share access to the same resources. For example, your team's AWS account might own a database resource so that you and your teammate can both work with the same database.

You, or someone on your team, is an administrator. The administrator creates the AWS account for your team and gives individuals on the team access to the account's resources.

Lumberyard, Cloud Canvas, and Cloud Gems

Cloud Canvas is a Lumberyard Gem (extension) that enables your Lumberyard games to communicate with AWS resources. To integrate the communication with Amazon Web Services directly into your game logic, you can use cloud gems (p. 2127).

For example, you can use cloud gems to create leaderboards, messages of the day, in-game surveys, and speech recognition and text-to-speech capabilities for your game.

Amazon Web Services Supported by Cloud Canvas

Several AWS offerings are available through Cloud Canvas that can enhance your game.

File Storage in the Cloud

For storing files in the cloud, Cloud Canvas supports Amazon Simple Storage Service (Amazon S3). Amazon S3 offers a storage resource called a bucket, which you can think of as a large folder. You can build a directory structure in an Amazon S3 bucket just like a directory on a local computer. Amazon S3 buckets have a number of uses in games, including the following:

- Storing files that your game can download. These files can be levels, characters, or other extensions for your game. You can add new files after your game has shipped. Because your game uses Cloud Canvas to download and integrate this content, your customers do not need to download a new client.
- Your game can upload player-generated content. For example, your game might take a screenshot whenever a player beats the last boss. Cloud Canvas uploads the screenshot to your bucket, and your game makes the screenshot available on a website or to other players of the game.

Databases

For storing data like a person's name, phone number, and address in the cloud, Cloud Canvas supports the Amazon DynamoDB database service. Amazon DynamoDB operates on resources called tables. These tables grow and adapt as you build and iterate your game.

Here are some ways in which you can use Amazon DynamoDB table resources in your game:

- Track account details and statistics for a player. Give each player a unique ID so that you can look up a player's hit points, inventory, gold, and friends.
- Add or remove fields to accommodate new resource groups in your game.
- Perform data analyses. For example, you can run complex queries to find out how many players have unlocked a particular achievement.
- Manage game-wide resource groups or events such as a querying a high score table or retrieving a message of the day.
Executing Cloud-Based Logic

For executing code in the cloud, Cloud Canvas supports the AWS Lambda service. AWS Lambda executes resources called functions. You provide the code for a Lambda function, and your game calls the Lambda service through Cloud Canvas to run the function. The Lambda service returns the data from the function to the game.

Your Lambda functions can even call other Amazon Web Services like Amazon DynamoDB and perform operations on their resources. Following are some examples:

- **Submit a high score** – A Lambda function can accept a player's ID and new score, look up the player ID in the database, compare the score with existing scores, and update the highest score if necessary.
- **Sanitize your data** – A Lambda function can check for malicious or unusual input. For example, if a player tries to upload a new high score of 999,999,999 when the best players can't reach 1,000, your Lambda function can intercept the submission and either reject it or flag it for review.
- **Perform server-side authoritative actions** – Cloud Canvas can call your Lambda functions to control in-game economies. For example, when a player tries to purchase an item, your Lambda function can check a database to verify that the player has enough money to pay for the item. The function can then deduct the amount from the player's account, and add the item to the player's inventory.

Identity and Permissions

For managing the identity of the player and controlling access to AWS resources in the cloud, Cloud Canvas supports the Amazon Cognito service.

Amazon Cognito can create unique anonymous identities for your players that are tied to a particular device. It can also authenticate identities from identity providers like Login with Amazon, Facebook, or Google. This provides your game with a consistent player IDs that can seamlessly transition from anonymous use on a single device to authenticated use across multiple devices. Consider these examples:

- Players start playing your game anonymously and store their progress locally on their device. Later, to "upgrade" their experience, you ask them to be authenticated through one of the login providers mentioned. After players provide an authenticated ID, you can store their progress in the cloud, and they can access their progress across multiple devices.
- You can specify which AWS resources players are allowed to access. For example, you can enable the "Get the Latest High Scores" Lambda function to be called not only by your game, but by anyone, including external websites. But you could specify that the "Submit High Scores" function only be called by players of your game so that your high score table remains secure. You can use Cloud Canvas to manage these permissions.

Understanding Cloud Canvas Resource Manager

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Game development is an inherently local activity. You have a local copy of your game code, assets, and other resources. You build, test, and tweak over and over on your local computer.

The cloud is different. It is an alien environment. You put resources "out there" that the game depends on. But those resources don’t live on your computer system. The process of using and modifying the resources in the cloud isn’t the same as for resources that are local.

Cloud Canvas Resource Manager bridges this gap. It lets you have local descriptions of the AWS resources in the cloud that your game needs and provides ways to create and interact with the actual
instances of those resources in AWS. Your resource could be a database table, a file storage bucket, or code that runs in response to an event.

For team projects, the source code and assets that you are using likely come from a source control system. The changes you make are shared with other people who work on the project through that source control system. Different people can be working at the same time with different versions (“branches”) of the code and with different versions of assets without interfering with each other.

When you develop a game that uses cloud resources in AWS, those resources may be shared by different people who work on the game at the same time. Sometimes you need different versions of those resources to exist in the cloud. You also want to ensure that the people developing the game use the version of the resources in the cloud that matches the version of the code and assets they are working with.

After the game is released, the players will use a production copy while your team uses another, private copy to work on bug fixes and new content.

You’ll also want to do the following:

- Be sure that players cannot access the development versions of game resources
- Prevent the development team from making changes that could break the released game
- Protect player information like e-mail addresses from unauthorized access by team members

The Cloud Canvas Resource Manager provides the tools you need to do the following:

- Maintain descriptions of the AWS resources that your game depends on
- Create as many copies of the AWS resources as needed for your releases and development teams
- Help you secure access to those resources

The Role of AWS CloudFormation

The Cloud Canvas Resource Manager integrates the use of AWS CloudFormation into the Lumberyard game development environment. With AWS CloudFormation you can maintain descriptions of the AWS resources you need in text file templates that you can check into your source control system.
descriptions can be branched and merged along with the rest of your game code and assets. When you need actual instances of the resources to be created in AWS, **Cloud Canvas Resource Manager** passes the descriptions to AWS CloudFormation, which uses the template files to create, update, or delete resources in AWS to match the descriptions.

You can use resource manager to organize your descriptions into any number of **resource groups**. Each group can describe all the resources needed by a game feature, such as a high score tracking system. For details, see [Resource Definitions](#p.2236).

With resource manager you can create as many **deployments** of the resources as you need. You could have a deployment for the dev team, another for the QA team, and another for the released game, or any other arrangement that suits your needs. Each deployment contains a complete and independent instance of all of the project's resources. Deployments are implemented using AWS CloudFormation **stack** resources. For details, see [Resource Deployments](#p.2247).

You can choose the deployment that you want to work with in Lumberyard Editor. For example, if you create a "QA" deployment and use it to test your game, Lumberyard Editor automatically maps the references to resources in your game code to the "QA" instance of those resources.

Similarly, you can also specify the deployment to be used for release builds of the game. For details, see [Resource Mappings](#p.2250).

Each deployment comes with an AWS managed policy and an AWS role that you can use to grant specific AWS users and groups access to that deployment. For example, players are granted access to specific resources within a deployment. For details, see [Controlling Access to Resources](#p.2370).

**A Closer Look at AWS CloudFormation Stacks**

A Cloud Canvas Resource manager project consists of one or more AWS CloudFormation stacks. All stack templates are stored as files in the project's source control system.

- A single **project stack** that contains the resources that support Cloud Canvas Resource Manager itself. The project stack template is stored as a file in the project's source control system.

- **Any number of deployment stacks**. A deployment represents a complete and independent set of all the resources needed by the game. Each deployment stack contains a child stack for each resource group. All deployment stacks are defined using a single AWS CloudFormation stack template.
• One deployment access stack per deployment stack. A deployment's access stack defines the resources used to grant access to a deployment, including IAM Roles and Amazon Cognito Identity Pools. They are distinct from deployment stacks because game developers need to be able to update deployment stacks but not change the permissions associated with the deployment.

• Any number of resource group stacks. Each resource group represents a set of resources related to an arbitrary game feature. Resource group stacks exist only as children of deployment stacks. Each resource group has its own stack template, which defines the resource group's stack for each deployment.

So, if there are 3 deployments and 4 resource groups, you have a total of 12 resource group stacks, 3 deployment stacks, 3 deployment access stacks, and 1 project stack (19 stacks total). You'll also have a total of 7 stack templates, one for the project stack, one for all the deployment stacks, one for all the deployment access stacks, and one each for each resource group. The following image illustrates this scenario.

Cloud Canvas Resource Management

In addition to communicating with Amazon Web Services, Cloud Canvas can also help you manage your resources. Amazon Web Services can help create and manage any cloud resources that a game resource group needs. Once you implement the resource group you can use Cloud Canvas deployments to manage the resources for development, test, and live versions of your game.

Defining the Resources

You can create cloud resources by using AWS CloudFormation templates. AWS CloudFormation is an Amazon Web Service with which you can define, create, and manage AWS resources predictably and repeatedly by using templates. The templates are JSON-formatted text files that you use to specify the collection of resources that you want to create together as a single unit (a stack).
In a template, each resource gets its own AWS CloudFormation definition in which you specify the parameters that govern the resource. AWS CloudFormation templates are beyond the scope of this topic, but for now it’s enough to understand that you can define (for example) a template with an Amazon DynamoDB table and two AWS Lambda functions. For an example AWS CloudFormation template that creates an Amazon DynamoDB table, see the AWS CloudFormation User Guide.

Deployments

While you are working on a new resource group, your quality assurance team might have to test it. You want to provide a version of your resource group that the test team can use while you continue to work on your own version. To keep the corresponding resources of the different versions distinct, Cloud Canvas gives you the ability to create separate deployments. Deployments are distinct instances of your product’s features.

In a scenario like the one described, you might create three deployments: one for the development team, one for the test team, and one for live players. Each deployment’s resources are independent of each other and can contain different data because (for example) you don’t want the data entered by the test team to be visible to players.

With Cloud Canvas you can manage each of these deployments independently of one another, and you can switch between deployments at will. After making changes, you can use Cloud Canvas to update your feature or deployment and update the corresponding AWS resources.

Team Workflow Using Deployments

The following workflow example illustrates how Cloud Canvas deployments work:

1. The test team finds a bug. You fix the bug in your Lambda code.
2. You switch to the dev deployment and upload the new version of the Lambda function. The Lambda code in the test and live deployments remain untouched for now, and they continue working as is.
3. After you are satisfied that the bug has been fixed, you update the Lambda code in the test deployment. The test team can now test your fix. The live deployment continues unchanged.
4. After the test team approves the fix, you update the live deployment, propagating the fix to your live players without requiring them to download a new version of the game.

Managing Permissions Using Cloud Canvas

Managing permissions is an important part of building a secure cloud-connected game. Maintaining separate and distinct permissions is important in the phases of development, testing, and production. You can apply permissions to your development and test teams, to the AWS resources that your game uses, and to the players of your game. A key objective is to secure your game’s AWS resources against hackers and other forms of abuse.

You can use permissions to specify exactly who is allowed to do what to the AWS resources that are part of your game. For example, if you have a game feature that uploads screenshots, you can create an Amazon S3 bucket to store the screenshots. You can set permissions for the game to be able to write (send files) to the bucket, but not read from the bucket. This prevents inquisitive users from examining the files that have been uploaded. On the other hand, you can give your team members permissions to read files from the bucket so that they can review and approve them. With Cloud Canvas you can also set the permissions for individual deployments. For example, live and test deployments can have different permission sets.

Like features, you can define permissions through AWS CloudFormation templates. The permissions are applied any time that you update your cloud resources using the Cloud Canvas resource management tools.

For more information, see Controlling Access to Resources (p. 2370).
Cloud Gems Overview

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A Lumberyard gem (p. 1064) is an individual package of specific functionality and assets. The gem includes everything required for you to include that functionality in your project.

Lumberyard cloud gems are Lumberyard gems (p. 1064) that provide AWS functionality for a game. A more complete definition of a cloud gem might be the following:

A cloud gem is an individual package of specific cloud-connected functionality, assets and AWS resource definitions. A cloud gem includes everything required for you to include that cloud-connected functionality in your project.

Cloud Gems Included with Lumberyard

Lumberyard includes many cloud gems that you can enable for your game project. For a list of the cloud gems that are included with Lumberyard, see Cloud Gems (p. 2127). For information on enabling cloud gems in your project, see Enabling Gems (p. 1064).

Cloud Gem Framework

The Cloud Gem Framework is a software development kit (SDK) that is included with Lumberyard. You can use the framework to implement the cloud gems that come with Lumberyard, as well as your own cloud gems. For more information, see Cloud Gem Framework (p. 2257).

Pricing

Cloud Canvas uses AWS CloudFormation templates to deploy AWS resources to your account. Although there is no additional charge for Cloud Canvas or AWS CloudFormation, charges may accrue for using the associated AWS services. You pay for the AWS resources created by Cloud Canvas and AWS CloudFormation as if you created them manually. You only pay for what you use as you use it. There are no minimum fees and no required upfront commitments, and most services include a free tier.

For pricing information on the AWS services that Cloud Canvas supports, visit the following links.

Amazon Cognito Pricing
Amazon DynamoDB Pricing
AWS Lambda Pricing
Amazon S3 Pricing
Amazon SNS Pricing
Amazon SQS Pricing

To see pricing for all AWS services, visit the Cloud Services Pricing page.
Tutorial: Getting Started with Cloud Canvas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Cloud Canvas connects Lumberyard with Amazon Web Services (AWS) and uses cloud gems to enable connected features in your game. This tutorial shows you how to deploy the resources for a cloud gem enabled project to AWS and guides you through the following tasks:

- Signing up for an AWS account.
- Creating an AWS Identity and Access Management (IAM) user to administer your Cloud Canvas project.
- Enabling cloud gems in your project.
- Adding your IAM administrative credentials to Lumberyard.
- Uploading resources to AWS and creating a deployment.

Optionally, you can also learn how to inspect your resources in AWS, create IAM users and groups for administrative purposes, and remove Cloud Canvas deployments and resources from AWS.

Prerequisites

Before starting this tutorial, complete the following:

- Install and set up (p. 7) Lumberyard.
- Read Implementing Connected Features with Cloud Canvas (p. 2106).

Step 1: Sign up for AWS

When you sign up for AWS, you can access all its cloud capabilities. Cloud Canvas creates resources in your AWS account to make these services accessible through Lumberyard. You are charged only for the services that you use. If you are a new AWS customer, you can get started with Cloud Canvas for free. For more information, see AWS Free Tier.

If you or your team already have an AWS account, skip to Step 2.

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account

2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

Note

- You must provide a payment method in order to create your account. Although the tutorials here fall within the AWS Free Tier, be aware that you can incur costs.
- Make a note of your AWS account number, which you will use in the next step.
Step 2: Create an IAM User to Administer the Cloud Canvas Project

After you sign up for an AWS account, you need an IAM user with appropriate permissions to administer a Cloud Canvas project. IAM allows you to manage access to your AWS account.

AWS requires that you provide credentials to verify that you have the appropriate permissions for the AWS services that you access. You enter these credentials into Lumberyard Editor as part of setting up your project.

The IAM user that you create will belong to a group that has administrator permissions. This allows users in this group to create the Cloud Canvas resources and make them accessible through Lumberyard. Administrative users in this group will have special permissions beyond the scope of a normal Cloud Canvas user.

In a team environment, you—as a member of the administrator's group—can create IAM users for each member of your team. With IAM, you can set permissions specifically for each person's role in a project. For example, you might specify that only designers can edit a database, or prevent team members from accidentally writing to resources with which your players interact.

For more information on IAM and permissions, see the IAM User Guide.

Create an IAM User and an Administrator Group

This section guides you through IAM best practices by creating an IAM user and an administrator group in your account to which the IAM user belongs.

To create an IAM user and group in your account

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, click Users.
3. Click Add user.
4. For User name, enter a user name like CloudCanvasAdmin. The name can contain letters, digits, and the following characters: plus (+), equal (=), comma (,), period (.), at (@), underscore (-), and hyphen (-). The name is not case sensitive and can be a maximum of 64 characters.
5. Select the check box next to Programmatic access.
6. Select the check box next to AWS Management Console access, select Custom password, and then enter a new password in the text box.
   
   Note
   When you create a user for someone else, you can select Require password reset so that the user must create a new password when the user first signs in.

7. Click Next: Permissions.
8. Click Create group.
9. In the Create group dialog box, enter a name like CloudCanvasAdministrators for the group. The name can contain letters, digits, and the following characters: plus (+), equal (=), comma (,), period (.), at (@), underscore (-), and hyphen (-). The name is not case sensitive and can be a maximum of 128 characters.
10. In the Policy name list, select the check box next to AdministratorAccess. This policy provides the necessary permissions to create and administer a Cloud Canvas project.
   
   Warning
   The AdministratorAccess policy allows almost all permissions within the AWS account and should be attached only to the administrator of the account. Otherwise, other team members can perform actions that incur unwanted charges in your AWS account.

11. Click Create group.
12. In the list of groups, select the check box for your new group if it is not already selected. If necessary, click Refresh to see the group in the list.
13. Click **Next: Review** to review your choices.
14. When you are ready to proceed, click **Create user**.

Your IAM user is created along with two important credentials: an access key and a secret access key. Later, you enter these credentials into Lumberyard Editor to access the AWS resources in your project.

15. Click **Show** to view your secret access key and password, or click **Download .csv** to download the credentials in a .csv file. Your credentials will look something like this:

- Access key ID: AKIAIOSFODNN7EXAMPLE
- Secret access key: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY

You can also click **Send email** to receive login instructions by email. After this point, you cannot view the secret access key from the AWS Management Console.

**Important**
Keep the keys confidential in order to protect your AWS account, and never email them. Do not share them outside your organization, even if an inquiry appears to come from AWS or Amazon.com. No one who legitimately represents Amazon will ever ask you for your secret key.

16. You have now created an IAM user called **CloudCanvasAdmin** and a **CloudCanvasAdministrators** administrator group to which the user belongs. To confirm this, click **Groups** in the navigation pane. Under **Group Name**, click **CloudCanvasAdministrators**. The **CloudCanvasAdmin** user appears in the list of users for the group.

**Note**
In this tutorial, you add only one IAM user to the administrator group, but you can add more if required.

If you lose your secret access key, you must create a new set of keys.

**To create a new set of keys**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, click **Users**.
3. In the **User name** list, click the user name for which you want to generate new access keys.
4. On the **Summary** page, click the **Security credentials** tab.
5. In the **Access keys** section, click **Create access key**.

**Step 3: Enable One or More Cloud Gems in Your Project**

Cloud Canvas functionality is enabled in Lumberyard through gems (p. 1064) and cloud gems (p. 2127). Gems are extensions that share code and assets among Lumberyard projects. Cloud gems are gems that use the power of AWS to provide connected features. To enable gems and cloud gems in your project, you use the **Project Configurator** (p. 43).

This tutorial uses the Lumberyard CloudGemSamples project, which includes many of the cloud gems that come with Lumberyard.

**To enable the CloudGemSamples project**

1. Open the Lumberyard Project Configurator, located at `lumberyard-version\dev\Bin64\BuildPlatform\ProjectConfigurator.exe`. For example, when using Visual Studio 2017 as your build platform, the Project Configurator is located at `lumberyard-version\dev\Bin64\vc141\ProjectConfigurator.exe`. 
2. Click **CloudGemSamples**.
3. In the upper-right corner of the Project Configurator, click **Set as default**.

**Step 4: Add Administrator Credentials to Lumberyard**

In order to begin managing a Cloud Canvas project, you add the IAM user credentials that you generated earlier to a profile that Cloud Canvas can easily reference. To do this, you can use either Lumberyard Editor or a command line prompt.

**To enter your credentials in Lumberyard Editor**

1. Use one of the following methods to launch Lumberyard Editor:
   - From the desktop, double-click the Lumberyard Editor icon.
   - From Lumberyard Setup Assistant, on the **Summary** page, click **Launch Editor**.
   - For Visual Studio 2017, navigate to the `lumberyard-version\dev\Bin64vc141` directory and double-click `Editor.exe`.
2. In Lumberyard Editor, choose **AWS, Credentials manager**.
3. In the **Credentials Manager** dialog, click **Add profile**.
4. In the **Add profile** dialog box, enter the following information:
   - For **Profile name**, enter a name of your choice (for example, **CloudCanvasAdmin**).
   - For **AWS access key** and **AWS secret key**, enter the access key and secret key.
Important
Do not share these credentials with anyone, and do not check them into source control. These credentials grant control over your AWS account, and a malicious user could incur charges.

5. Click Save.
6. In Credentials Manager, click OK.

You have now created a profile to administer a Cloud Canvas project. The profile name is associated with your credentials, and saved locally on your machine in your AWS credentials file. This file is normally located in your C:\Users\user_name\.aws\ directory. As a convenience, other tools such as the AWS Command Line Interface or the AWS Toolkit for Visual Studio can access these credentials.

Step 5: Upload Resources to AWS and Create a Deployment

You are now ready for the resources defined by your project to be created in AWS.

This is a two-part process:
1. Creating a project stack in AWS that contains the resources that your cloud gems require.
2. Creating a deployment. A deployment is a separate, independent copy of your project's AWS resources for a dedicated purpose (for example, development, testing, or production).

To upload resources to AWS

1. In Lumberyard Editor, choose **AWS, Cloud Canvas, Resource Manager**.
2. In **Resource Manager**, click **Upload all resources**.

3. In the **Initialize Resource Manager** dialog box, click **Yes**.

4. In the **Initialize Cloud Canvas Resource Manager** dialog box, review the fields provided.
Overview

• **Project stack name** – This name defaults to the name of your project. You can provide a different name if you want.

• **AWS profile** – This is the profile that you prepared in the previous procedure. You can click **Edit** to edit this profile or **Add profile** to add another profile.

• **AWS region** – This defaults to **us-east-1**, which supports all Lumberyard cloud gems. Not all cloud gems are supported in all AWS regions.

5. Click **Create**. The **Progress log** indicates **Operation in progress**. Creating the project stack in AWS takes about 5 to 10 minutes.

6. In the **Create deployment** dialog box, enter a name for your deployment (for example, **dev**, **test**, or **prod**).
7. Click **Create**. The deployment operation takes about 10 minutes.

**Step 6: Learn More**

See the following resources.

<table>
<thead>
<tr>
<th>Task</th>
<th>Topic</th>
</tr>
</thead>
<tbody>
<tr>
<td>Learn more about each of the cloud gems (including cloud gems not in the CloudGemSamples project)</td>
<td>Cloud Gems (p. 2127)</td>
</tr>
<tr>
<td>Add additional gems and cloud gems to a project</td>
<td>Enabling Gems (p. 1064)</td>
</tr>
<tr>
<td>Use the AWS Management Console to see your resources in AWS</td>
<td>Inspect Your Resources in AWS (p. 2124)</td>
</tr>
</tbody>
</table>
Inspect Your Resources in AWS

This topic shows you how to sign in to the AWS Management Console and use the console to inspect the AWS CloudFormation stacks that you created.

To sign in to the AWS Management Console as your IAM user

1. Retrieve the AWS account ID that you received when you created your AWS account. To sign in as your CloudCanvasAdmin IAM user, use this AWS account ID.
2. In a web browser, enter the following URL with your account ID:

   https://My_AWS_Account_ID.signin.aws.amazon.com/console/

   For example, if your AWS account ID is 1234-5678-9012, you sign in at https://123456789012.signin.aws.amazon.com/console/.

   For convenience, you can create a bookmark of your URL for future use.

   **Tip**
   To create a bookmark for your account sign-in page in your web browser, you should manually type the sign-in URL for your account in the bookmark entry. Do not use your web browser bookmark feature because redirects can obscure the sign-in URL.
3. Enter the CloudCanvasAdmin IAM user name that you created.
4. Enter the password for the user and choose **Sign In**.

   You are now successfully signed into the AWS Management Console.

To inspect your resources in AWS

1. Ensure that the AWS region, which appears on the upper-right of the console screen, is set to the region that you specified when you had Cloud Canvas deploy its resources in Step 5 (p. 2120) of the tutorial. This tutorial uses the US East (N. Virginia) Region.
2. Do one of the following:
   - In the AWS services search box, enter CloudFormation, and then click CloudFormation.
   - Expand All services and under Management Tools, click CloudFormation.
3. On the Stacks page, you can see the individual stacks that have been created for your cloud gems and for your deployment.
Overview

Note
If a stack update operation is still in progress, the stack shows the status UPDATE-IN-PROGRESS. Otherwise, the status shows CREATE-COMPLETE. You can click the Refresh icon to update the status.

Create IAM Users and Groups to Administer Cloud Canvas Teams

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To manage your team members' access to AWS resources, you create IAM users, a group for the users, and then attach the appropriate Cloud Canvas customer managed policies to the group. The policies that Cloud Canvas creates for your IAM users are more restrictive than those for an administrator. You can use these policies so that your team members do not inadvertently incur charges without administrator approval.

To create IAM users and a user group with managed policies

1. Sign in to the AWS Management Console with your CloudCanvasAdmin credentials. See Inspect Your Resources in AWS (p. 2124).
2. Do one of the following:
   - In the AWS services search box, enter IAM, and then click IAM.
   - Expand All services and under Security, Identity & Compliance, click IAM.
3. In the navigation pane, click Users.
4. Click Add user.
5. On the Add user page, in the User name box, enter an IAM user name for a team member.
   The user name can contain of letters, digits, and the following characters: plus (+), equal (=), comma (,), period (.), at (@), underscore (-), and hyphen (-). The name is not case sensitive and can be a maximum of 64 characters.
6. For each additional user, click Add another user, and then enter a user name.
7. Under Select AWS access type, select Programmatic access and/or AWS Management Console access, depending on the access that you want each user to have.
If you choose AWS Management Console access, the Console password and Require password reset options appear.

- **Console password** – Enter a password or choose to have a password generated automatically (default).
- **Require password reset** – Requires your users to create a password at their next sign in. This is selected by default.

8. Click **Next: Permissions**.

9. Click **Create group** to create an IAM group for your new users.

10. On the **Create group** page, for **Group name**, enter a name for the group (for example, *CloudCanvasDevelopers*).

    The group name can contain letters, digits, and the following characters: plus (+), equal (=), comma (,), period (.), at (@), underscore (-), and hyphen (-). The name is not case sensitive and can be a maximum of 128 characters.

11. To find the IAM customer managed policy that Cloud Canvas created for you, click **Filter policies** and then select **Customer managed**.

12. Select the appropriate policies that you want to apply to the group. To decide which policies to include, use the information in the following table.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DeploymentAccess</td>
<td>Grants the user read-only access to information from a specific deployment stack. Mainly used to describe information for resources used in the stack.</td>
</tr>
<tr>
<td>DeploymentOwnerAccess</td>
<td>Grants full access to the deployment stack.</td>
</tr>
<tr>
<td>ProjectAccess</td>
<td>Grants a user read-only access to the configuration of the project stack.</td>
</tr>
<tr>
<td>ProjectOwnerAccess</td>
<td>Grants full access to the project stack and deployments in that stack.</td>
</tr>
<tr>
<td>ServiceLambdaExecution</td>
<td>Do not use.</td>
</tr>
</tbody>
</table>

13. Click **Create group**.

14. Click **Next: Review**. The **Review** page lists the user names that you created and summarizes the permissions that are to be granted.

15. Click **Create users**.

    After you successfully created your users, you can view the access key ID, secret access key, and automatically generated password for each new user. You can also email users instructions to sign in to the AWS Management Console.

16. Click **Download .csv** to download a .csv file that has the keys for all the users that you created. Make sure you preserve the credentials in a safe place.

    **Important**
    - After this point, you cannot view the secret access key from the AWS Management Console. You must deliver each user his or her keys securely.
As an administrator, it is your responsibility to keep your team and your AWS account secure. Amazon provides some best practices and options for how to manage your team’s access keys on the Managing Access Keys for IAM Users page in the IAM User Guide. You are encouraged to read this thoroughly.

17. Click Close.

Next, have your team members use Lumberyard Editor to create their AWS profiles with the credentials that you provided.

**To have users create AWS profiles**

1. In Lumberyard Editor, have each user choose AWS, Credentials manager.
2. Have the user enter a new profile name and his or her access and secret access keys.

   **Important**
   Stress the importance to your users of keeping their keys secure and not sharing them.

For information regarding limits on the number of groups and users in an AWS account, see Limitations on IAM Entities and Objects in the IAM User Guide.

**Cloud Gems**

Some cloud Gems have been deprecated and are no longer supported.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A cloud gem is an individual package of specific cloud-connected functionality, assets, and AWS resource definitions. A cloud gem includes everything required for you to add cloud-connected functionality to your project.

Lumberyard includes the following cloud gems. You can enable them in a project from the Lumberyard Project Configurator (p. 43) tool.

- **Compute Farm** (p. 2154) (deprecated) – Divide and conquer large-scale tasks for processing on a fleet of Amazon EC2 instances.
- **Defect Reporter** (p. 2155) (deprecated) – Streamlines and customizes the collection and management of defect report data from users.
- **Dynamic Content** (p. 2155) – Allows Lumberyard .pak files that contain new and updated game assets to be uploaded to the cloud for later automatic downloading to the game client.
- **Game Metrics** (p. 2186) (deprecated) – Collects event data on player behaviors for analysis or triggering event actions.
- **In-Game Survey** (p. 2187) (deprecated) – Create surveys for your game, test them, and publish them.
- **Leaderboard** (p. 2188) (deprecated) – Stores a player's high scores and provides leaderboards that show player rankings.
- **Message Of The Day** (p. 2188) (deprecated) – Schedules the delivery of messages (for example, new product announcements or holiday greetings) to game clients.
- **Player Account** (p. 2188) – Provides a standalone player authentication and management solution that uses Amazon Cognito.
Cloud Gems

- **Speech Recognition** (p. 2203) (deprecated) – Add speech recognition and natural language processing to your Lumberyard game. The Speech Recognition Cloud Gem uses the Amazon Lex service, which recognizes and understands spoken input.
- **Text-to-Speech** (p. 2203) (deprecated) – Enhance your gameplay and workflows with synthesized speech. The Cloud Canvas Text-to-Speech (TTS) Cloud Gem uses Amazon Polly, which is a text-to-speech service that turns text into lifelike speech.
- **Web Communicator** (p. 2204) – Send AWS cloud service events to your game’s connected editors or clients. Your editors or game clients can use this information to update themselves without having to poll AWS for updates.

**Topics**

**Using the AWS Script Behaviors Cloud Gem**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the AWS Script Behaviors cloud gem in Amazon Lumberyard to implement some common AWS behaviors for your game. To implement these behaviors, you can use Script Canvas or Lua script. These behaviors include decoding URLs, performing HTTP GET operations, transferring files to and from Amazon S3, and invoking AWS Lambda functions. For programmatic information regarding the AWS Script Behaviors cloud gem, see AWS Behavior Context Reflections (p. 2289).

**Prerequisites**

To use the features of this cloud gem, perform the following steps.

1. Enable **Cloud Gem AWS Script Behaviors** in Project Configurator. The examples in this section use the **CloudGemSamples** project, which you can also enable in Project Configurator. The AWS Script Behaviors cloud gem is enabled in the **CloudGemSamples** project by default.
2. Open the Cloud Canvas Resource Manager and update your deployment or upload all the resources in the **CloudGemAWSScriptBehaviors** resource group.

**Topics**
- Decoding a URL with Script Canvas (p. 2129)
- Performing HTTP GET with Script Canvas (p. 2132)
- Uploading a File to Amazon S3 with Script Canvas (p. 2136)
Decoding a URL with Script Canvas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the AWSBehaviorURL Decode node in Script Canvas to decode an encoded URL, as in the following example:

```
```

When the URL is decoded, the escape characters are converted to normal characters, as in the following example:

```
https://docs.aws.amazon.com/lumberyard/latest/userguide/cloud-canvas-intro.html
```

Topics

- Step 1: Add Nodes to Decode a URL (p. 2129)
- Step 2: Add Nodes to Display the Result (p. 2130)
- Step 3: Test the URL Decoder (p. 2131)

Step 1: Add Nodes to Decode a URL

The following procedure shows you how to create a Script Canvas graph that decodes a URL.

To create a graph that decodes a URL node

1. In Lumberyard Editor, choose Tools, Script Canvas.
2. In the Node Palette, expand Utilities and drag the On Graph Start node to the canvas.
3. On the right, in Variable Manager, click Create Variable.
4. In the Variable Type search box, enter AWSBehaviorURL, or scroll down to AWSBehaviorURL.
5. Click AWSBehaviorURL. In Node Inspector, AWSBehaviorURL Variable appears. The default name of the variable is Variable 1.
6. In the Node Inspector, expand AWSBehaviorURL to show the URL box. For URL, which is the input field for the variable, enter an encoded URL (for example, http%3A%2F%2Fdocs.aws.amazon.com%2Flumberyard%2Flatest%2Fuserguide%2Fcloud-canvas-intro.html).
7. From the Variable Manager, press Shift and drag Variable 1 AWSBehaviorURL to the canvas to create the Get Variable 1 node. (You can also drag AWSBehaviorURL to the canvas and then select Get Variable from the drop-down menu.)
8. Connect the Out pin of the On Graph Start node to the In pin of the Get Variable 1 node.
9. In the Node Palette, expand AWS, AWSBehaviorURL.
10. Drag the Decode node to the right of the Get Variable 1 node on the canvas.
11. Connect the Out pin of the Get Variable 1 node to the In pin of the Decode node.
12. Connect the AWSBehavioralURL pin of the Get Variable 1 node to the AWSBehavioralURL:0 pin of the Decode node.
Step 2: Add Nodes to Display the Result

At this point, if you saved the graph and started the level, the Get Variable node would pass its value to the Decode node, which would decode it. However, you wouldn't see the result. To see the result, you must add AWSBehaviorURLNotificationBus nodes and a Print node to the graph. These nodes monitor for AWSBehaviorURL events and show you the decoding results in the Lumberyard console window.

**To display the decoded URL in the console window**

1. In the Node Palette, expand AWS, AWSBehaviorURLNotificationBus.
2. Drag OnError to the canvas. Place the node under the three nodes that are already connected.
3. Drag OnSuccess to the canvas and place it under the OnError node.
4. In the Node Palette, expand Utilities, Debug and then drag Print to the right of the two AWSBehaviorURLNotificationBus nodes on the canvas. The Print node displays messages in the Lumberyard Editor console.
5. Connect the Out pins of the AWSBehaviorURLNotificationBus OnError and OnSuccess nodes to the In pin of the Print node.
6. Connect the String pins of the AWSBehaviorURLNotificationBus OnError and OnSuccess nodes to the Value pin on the Print node. Your canvas should look similar to the following image:
7. Save the canvas with a name like `MyUrlDecoder.scriptcanvas`. The default file location is the `lumberyard_version\dev\project_name\scriptcanvas` directory.

8. Exit the Script Canvas editor.

Step 3: Test the URL Decoder

Now you are ready to attach the script canvas to an entity and test it.

To test the URL decoder

1. In Lumberyard Editor, right-click the viewport and choose Create entity.
2. In Entity Inspector, click Add Component.
3. Under Scripting, click Script Canvas to add a Script Canvas (p. 818) component to the entity.
4. Under Script Canvas, click the browse button (…).
5. In the Pick Script Canvas dialog box, choose the canvas that you created – for example, `myurldecoder (Script Canvas)`, and then click OK.
6. If the Lumberyard console window is not already open, press ` or choose Tools, Console to open the console window. If the console window is already open and you want to clear it, press Ctrl+Shift+C.

7. Press Ctrl+G to start the level. The decoded URL appears in the console, as in the following example. The relevant output is bold text.

```
general.enter_game_mode
Returned:
(Found resource management based identity pool %s.) - us-east-1:guid
(Found resource management based identity pool %s for authenticated access.) - us-east-1:guid
(CloudCanvas) - Anonymous Credentials pulled successfully for identity pool us-east-1:guid.
Disable Accelerators
(Script Canvas) - http://docs.aws.amazon.com/lumberyard/latest/userguide/cloud-canvas-intro.html
SetGlobalState 11->2 'LEVEL_LOAD_TEXTURES'->'RUNNING' 69.1 seconds
general.exit_game_mode
```

Performing HTTP GET with Script Canvas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the AWSBehaviorHTTP Get node in Script Canvas to perform an HTTP GET operation on a URL that you specify.

**Topics**

- Step 1: Add Nodes to Perform an HTTP GET Operation (p. 2132)
- Step 2: Add Nodes to Display the Response (p. 2133)
- Step 3: Add Nodes to Display the Success or Failure of the Operation (p. 2133)
- Step 4: Perform a Test GET (p. 2135)

**Step 1: Add Nodes to Perform an HTTP GET Operation**

The following procedure shows you how to create a Script Canvas graph that performs an HTTP GET operation.

**To create a graph that performs an HTTP GET operation**

1. In Lumberyard Editor, choose Tools, Script Canvas.
2. In the Node Palette, expand Utilities and drag the On Graph Start node to the canvas.
3. On the right, in Variable Manager, click Create Variable.
4. In the Variable Type search box, enter AWSBehaviorHTTP, or scroll down to AWSBehaviorHTTP.
5. Click AWSBehaviorHTTP. In Node Inspector, AWSBehaviorHTTP Variable appears. The default name of the variable is Variable 1.
6. In Node Inspector, expand AWSBehaviorHTTP to show the URL box.
7. For URL, which is the input field for the variable, enter a URL for the GET operation (for example, http://example.com/).
8. From the Variable Manager, press Shift and drag Variable 1 AWSBehaviorHTTP to the canvas to create the Get Variable 1 node. (You can also drag AWSBehaviorHTTP to the canvas and then select Get Variable from the drop-down menu.)
9. Connect the **Out** pin of the **On Graph Start** node to the **In** pin of the **Get Variable 1** node.

10. In the **Node Palette**, expand **AWS, AWSBehaviorHTTP**.

11. Drag the **Get** node to the right of the **Get Variable 1** node on the canvas.

12. Connect the **Out** pin of the **Get Variable 1** node to the **In** pin of the **Get** node.

13. Connect the **AWSBehaviorHTTP** pin of the **Get Variable 1** node to the **AWSBehaviorHTTP:0** pin of the **Get** node.

**Step 2: Add Nodes to Display the Response**

To show the response to the HTTP request, you add an **AWSBehaviorHTTPNotificationsBus GetResponse** node, a **ToJSON** node, and **Print** nodes to the graph. The nodes show you the result in the Lumberyard console window.

**To show the response to the HTTP request in the console window**

1. In the **Node Palette**, expand **AWS, AWSBehaviorHTTPNotificationsBus**.
2. Drag **GetResponse** to the canvas. Place the node under the three nodes that are already connected.
3. In the **Node Palette**, expand **Utilities, String Map** and then drag **ToJSON** to the right of the **GetResponse** node.
4. Connect the **Out** pin of the **GetResponse** node to the **In** pin of the **ToJSON** node.
5. Connect the **StringMap** pin of the **GetResponse** node to the **StringMap: 0** pin of the **ToJSON** node.
6. In the **Node Palette**, expand **Utilities, Debug** and then drag four **Print** nodes to the right of the **ToJSON** node on the canvas and align them vertically. **Print** nodes display messages in the Lumberyard Editor console. After you connect them, each **Print** node will display a different part of the GET response in the console.
7. Connect the **Out** pin of the **ToJSON** node to the **In** pin on the first **Print** node.
8. Connect the **Result: String** pin of the **ToJSON** node to the **Value** pin on the first **Print** node.
9. Connect the **Out** pin of the **GetResponse** node to the **In** pin of the three remaining **Print** nodes.
10. Connect the **Number** pin of the **GetResponse** node to the **Value** pin of the second **Print** node.
11. Connect the first **String** pin of the **GetResponse** node to the **Value** pin of the third **Print** node.
12. Connect the second **String** pin of the **GetResponse** node to the **Value** pin of the fourth **Print** node.

**Step 3: Add Nodes to Display the Success or Failure of the Operation**

Next, you add nodes to display the success or failure of the GET operation.

**To display the success or failure of the GET operation in the console window**

1. In the **Node Palette**, expand **AWS, AWSBehaviorHTTPNotificationsBus**.
2. Drag **OnError** to the canvas. Place the node under the other nodes that are already connected.
3. Drag **OnSuccess** to the canvas and place it under the **OnError** node.
4. From **Node Palette, Utilities, Debug**, drag a **Print** node to the right of the **OnError** and **OnSuccess** nodes.
5. Connect the **Out** pins of the **OnError** and **OnSuccess** nodes to the **In** pin of the new **Print** node.
6. Connect the **String** pins of the **OnError** and **OnSuccess** nodes to the **Value** pin of the new **Print** node. Your canvas should look similar to the following image:
7. Save the canvas with a name like `MyHttpGetTest.scriptcanvas`. The default file location is the `lumberyard_version\dev\project_name\scriptcanvas` directory.

8. Exit the Script Canvas editor.
Step 4: Perform a Test GET

Now you are ready to attach the script canvas to an entity and then test it.

To test HTTP GET

1. In Lumberyard Editor, right-click the viewport and choose Create entity.
2. In Entity Inspector, click Add Component.
3. Under Scripting, click Script Canvas to add a Script Canvas (p. 818) component to the entity.
4. Under Script Canvas, click the browse button (...).
5. In the Pick Script Canvas dialog box, choose the canvas that you created – for example, myhttpgettest (Script Canvas), and then click OK.
6. If the Lumberyard console window is not already open, press ` or choose Tools, Console to open the console window. If the console window is already open and you want to clear it, press Ctrl+Shift+C.
7. Press Ctrl+G to start the level. The console reports the success of the operation and displays the response, as in the following example. The JSON output in the example has been formatted for readability.

```plaintext
general.enter_game_mode
Returned:
(Found resource management based identity pool %s.) - us-east-1:
(Found resource management based identity pool %s for authenticated access.) - us-east-1:
(cloudCanvas) - Anonymous Credentials pulled successfully for identity pool us-east-1:
guid.
Disable Accelerators

Uploading a File to Amazon S3 with Script Canvas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the AWSBehaviorS3Upload node in Script Canvas to upload a file from your computer to the Amazon S3 bucket that you specify. If the object that you specify already exists, it is overwritten.

Topics
- Step 1: Add Nodes that Upload a File to Amazon S3 (p. 2136)
- Step 2: Add Nodes to Display the Result (p. 2137)
- Step 3: Test Upload a File to Amazon S3 (p. 2138)
- Step 4: Verify the Upload (p. 2139)

Step 1: Add Nodes that Upload a File to Amazon S3

The following procedure shows you how to create a Script Canvas graph that uploads a file to Amazon S3. The example uses the file lumberyard_version\dev\Cache\CloudGemSamples\pc\cloudgemsamples\levels\awsbehaviorexamples\testdata\s3example.txt that is included with Lumberyard.

To upload a file to Amazon S3

1. In Lumberyard Editor, choose Tools, Script Canvas.
2. In the Node Palette, expand Utilities and drag On Graph Start to the canvas.
3. On the right, in Variable Manager, click Create Variable.
4. In the Variable Type search box, enter AWSBehaviorS3Upload, or scroll down to AWSBehaviorS3Upload.
5. Click AWSBehaviorS3Upload. In Node Inspector, AWSBehaviorS3Upload Variable appears. The default name of the variable is Variable 1.
6. In Node Inspector, expand AWSBehaviorS3Upload to show the input fields. Type the values in the following table into the corresponding boxes. KeyName is the name that the file will have on Amazon S3.

<table>
<thead>
<tr>
<th>Input Field</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BucketName</td>
<td>CloudGemAWSScriptBehaviors.s3nodeexamples</td>
<td>Name of the Amazon S3 bucket for the uploaded file.</td>
</tr>
<tr>
<td>KeyName</td>
<td>uploadtest.txt</td>
<td>Name of the file as it will appear in the Amazon S3 bucket.</td>
</tr>
<tr>
<td>LocalFileName</td>
<td>levels\awsbehaviorexamples\testdata\s3example.txt</td>
<td>Path (relative to the project folder) and name of the file to be uploaded. File path aliases like @user@ are supported. The path resolves to @assets@ by default.</td>
</tr>
<tr>
<td>Input Field</td>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td><strong>ContentType</strong>: text/html</td>
<td>Content type of the object to be uploaded. Because you are uploading a text file, the content type is text/html.</td>
</tr>
</tbody>
</table>

7. From the Variable Manager, press Shift and drag Variable 1 AWSBehaviorS3Upload to the canvas to create the Get Variable 1 node. (You can also drag AWSBehaviorS3Upload to the canvas and then select Get Variable from the drop-down menu.)

8. Connect the Out pin of the On Graph Start node to the In pin of the Get Variable 1 node.

9. In the Node Palette, expand AWS, AWSBehaviorS3Upload.

10. Drag the Upload node to the right of the Get Variable 1 node on the canvas.

11. Connect the Out pin of the Get Variable 1 node to the In pin of the Upload node.

12. Connect the AWSBehaviorS3Upload pin of the Get Variable 1 node to the AWSBehaviorS3Upload:0 pin of the Upload node.

**Step 2: Add Nodes to Display the Result**

Next, to see the success or failure of the operation, add AWSBehaviorS3UploadNotificationBus nodes and a Print node to the graph. The nodes monitor for AWSBehaviorS3UploadNotificationBus events and show you the result in the Lumberyard console window.

**To display the success or failure of the upload operation in the console window**

1. In the Node Palette, expand AWS, AWSBehaviorS3UploadNotificationBus.

2. Drag OnError to the canvas. Place the node under the three nodes that are already connected.

3. Drag OnSuccess to the canvas and place it under the OnError node.

4. In the Node Palette, expand Utilities, Debug and drag Print to the right of the two AWSBehaviorS3UploadNotificationBus nodes on the canvas. The Print node displays messages in the Lumberyard Editor console.

5. Connect the Out pins of the AWSBehaviorS3UploadNotificationBus OnError and OnSuccess nodes to the In pin of the Print node.

6. Connect the String pins of the AWSBehaviorS3UploadNotificationBus OnError and OnSuccess nodes to the Value pin on the Print node. Your canvas should look similar to the following image:
7. Save the canvas with a name like `MyS3UploadTest.scriptcanvas`. The default file location is the `lumberyard_version\dev\project_name\scriptcanvas` directory.

8. Exit the Script Canvas editor.

**Step 3: Test Upload a File to Amazon S3**

Now you are ready to attach the script canvas to an entity and test the script.

**To test uploading to Amazon S3**

1. In Lumberyard Editor, right-click the viewport and choose Create entity.
2. In Entity Inspector, click Add Component.
3. Under Scripting, click Script Canvas to add a Script Canvas (p. 818) component to the entity.
4. Under Script Canvas, click the browse button (...).
5. In the Pick Script Canvas dialog box, choose the canvas that you created – for example, `mys3uploadtest (Script Canvas)`, and then click OK.
6. If the Lumberyard console window is not already open, press ` or choose **Tools, Console** to open the console window. If the console window is already open and you want to clear it, press **Ctrl+Shift+C**.

7. Press **Ctrl+G** to start the level. The console reports the success of the operation, as in the following example.

   ```
   general.enter_game_mode
   Returned:
   (Found resource management based identity pool %s.) - us-east-1:guid
   (Found resource management based identity pool %s for authenticated access.) - us-east-1:guid
   (CloudCanvas) - Anonymous Credentials pulled successfully for identity pool us-east-1:guid.
   Disable Accelerators
   (Script Canvas) - File Uploaded
   general.exit_game_mode
   ```

**Step 4: Verify the Upload**

To verify that the file has been uploaded to Amazon S3, you can use the AWS Management Console.

**To verify that the test file has been uploaded to Amazon S3**

1. In a text editor, open the `lumberyard_version\dev\Cache\CloudGemSamples\pc\user\AWS\user-settings.json` file.

2. In the `user-settings.json` file, locate the Amazon S3 name for the `CloudGemAWSScriptBehaviors.s3nodeexamples` bucket. The Amazon S3 bucket name is in the string for the `PhysicalResourceId` attribute, as in the following example:

   ```json
   "CloudGemAWSScriptBehaviors.s3nodeexamples": {
      "PhysicalResourceId": "cgsamples14-221-cgsamples14-221dep-s3nodeexamples-16ud5gt53zjx7",
      "ResourceType": "AWS::S3::Bucket"
   }
   ```

3. In Lumberyard Editor, choose **AWS, Open AWS Console, S3**.

4. In the Amazon S3 management console, open the bucket that you identified in step 2.

5. The `s3uploadtest.txt` file appears in the bucket.

**Downloading a File from Amazon S3 with Script Canvas**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the **AWSBehaviorS3Download** node in Script Canvas to download a file from an Amazon S3 bucket.

**Topics**

- Step 1: Prepare a Test File for Download (p. 2140)
- Step 2: Add Nodes to Download a File from Amazon S3 (p. 2140)
- Step 3: Add Nodes to Display the Result (p. 2141)
- Step 4: Test Download the File from Amazon S3 (p. 2142)
Step 1: Prepare a Test File for Download

The following procedure shows you how to upload a file to Amazon S3 that you can later download with a Script Canvas script.

To prepare a test file for download from Amazon S3

1. In a text editor, create a plain text file and save it as downloadtest.txt.
2. In a text editor, open the `lumberyard_version\dev\Cache\CloudGemSamples\pc\user\AWS\user-settings.json` file.
3. In the `user-settings.json` file, locate the Amazon S3 name for the `CloudGemAWSScriptBehaviors.s3nodeexamples` bucket. The Amazon S3 bucket name is in the string for the `PhysicalResourceId` attribute, as in the following example:

   ```json
   "CloudGemAWSScriptBehaviors.s3nodeexamples": {
     "PhysicalResourceId": "cgsamples14-221-cgsamples14-221dep-s3nodeexamples-16ud5gt53zjx7",
     "ResourceType": "AWS::S3::Bucket"
   }
   ```

4. In Lumberyard Editor, choose AWS, Open AWS Console, S3.
5. In the Amazon S3 management console, open the bucket that you identified in step 3.
6. Click Upload to upload the downloadtest.txt to the bucket that is mapped to `CloudGemAWSScriptBehaviors.s3nodeexamples`.

Step 2: Add Nodes to Download a File from Amazon S3

Now you can create a Script Canvas script that downloads the file.

To create a Script Canvas script to download a file from Amazon S3

1. In Lumberyard Editor, click Tools, Script Canvas.
2. In the Node Palette, expand Utilities and drag On Graph Start to the canvas.
3. On the right, in Variable Manager, click Create Variable.
4. In the Variable Type search box, enter AWSBehaviorS3Download, or scroll down to AWSBehaviorS3Download.
5. Click AWSBehaviorS3Download. In Node Inspector, AWSBehaviorS3Download Variable appears. The default name of the variable is Variable 1.
6. In Node Inspector, expand AWSBehaviorS3Download to show the input fields. Type the values in the following table into the corresponding boxes.

<table>
<thead>
<tr>
<th>Input Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>BucketName</td>
<td>CloudGemAWSBehavior.s3nodeexamples</td>
</tr>
<tr>
<td>KeyName</td>
<td>downloadtest.txt</td>
</tr>
<tr>
<td>LocalFileName</td>
<td>s3downloadtest.txt</td>
</tr>
<tr>
<td>ContentType</td>
<td>text/html</td>
</tr>
</tbody>
</table>

7. From the Variable Manager, press Shift and drag Variable 1 AWSBehaviorS3Download to the canvas to create the Get Variable 1 node. (You can also drag AWSBehaviorS3Download to the canvas and then select Get Variable from the drop-down menu.)
8. Connect the Out pin of the On Graph Start node to the In pin of the Get Variable 1 node.
9. In the Node Palette, expand AWS, AWSBehaviorS3Download.
10. Drag the Download node to the right of the Get Variable 1 node on the canvas.
11. Connect the Out pin of the Get Variable 1 node to the In pin of the Download node.
12. Connect the AWSBehaviorS3Download pin of the Get Variable 1 node to the AWSBehaviorS3Download:0 pin of the Download node.

Step 3: Add Nodes to Display the Result

Next, to see the success or failure of the operation, you add AWSBehaviorS3DownloadNotificationBus nodes and a Print node to the graph. The nodes monitor for AWSBehaviorS3DownloadNotificationBus events and show you the result in the Lumberyard console window.

To display the success or failure of the download operation in the console window

1. In the Node Palette, expand AWS, AWSBehaviorS3DownloadNotificationBus.
2. Drag OnError to the canvas and place the node under the three nodes that are already connected.
3. Drag OnSuccess to the canvas and place it under the OnError node.
4. In the Node Palette, expand Utilities, Debug and drag Print to the right of the two AWSBehaviorS3DownloadNotificationBus nodes on the canvas. The Print node displays messages in the Lumberyard Editor console.
5. Connect the Out pins of the AWSBehaviorS3DownloadNotificationBus OnError and OnSuccess nodes to the In pin of the Print node.
6. Connect the String pins of the AWSBehaviorS3DownloadNotificationBus OnError and OnSuccess nodes to the Value pin on the Print node. Your canvas should look similar to the following image:
7. Save the canvas with a name like `MyS3DownloadTest.scriptcanvas`. The default file location is the `lumberyard_version\dev\project_name\scriptcanvas` directory.

8. Exit the Script Canvas editor.

Step 4: Test Download the File from Amazon S3

Now you are ready to attach the script canvas to an entity and test it.

To test downloading a file from Amazon S3

1. In Lumberyard Editor, right-click the viewport and choose Create entity.
2. In Entity Inspector, click Add Component.
3. Under Scripting, click Script Canvas to add a Script Canvas (p. 818) component to the entity.
4. Under Script Canvas, click the browse button (…).
5. In the Pick Script Canvas dialog box, choose the canvas that you created - for example, `mys3downloadtest (Script Canvas)`, and then click OK.
6. If the Lumberyard console window is not already open, press ~ or choose Tools, Console to open the console window. If the console window is already open and you want to clear it, press Ctrl+Shift+C.
7. Press **Ctrl+G** to start the level. The console reports the success of the operation as follows.

```
(Script Canvas) – File Downloaded
```

The file `s3downloadtest` file is downloaded to the `lumberyard_version\dev` directory.

### Generating an Amazon S3 Presigned URL With Script Canvas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

You can use [presigned URLs](#) to share Amazon S3 objects with others. The **Presign** node in Script Canvas generates a presigned URL that links to an Amazon S3 object that you specify.

**Add Nodes that Generate a Presigned URL**

**To use the Presign node to presign a URL**

1. Upload a plain text file named `presigntest.txt` to the `s3nodeexamples` bucket.
2. In Lumberyard Editor, choose **Tools, Script Canvas**.
3. In the **Node Palette**, expand **Utilities** and drag **On Graph Start** to the canvas.
4. In **Variable Manager**, click **Create Variable**.
5. In the **Variable Type** search box, enter `AWSBehaviorS3Presign`, or scroll down to `AWSBehaviorS3Presign`.
6. Click `AWSBehaviorS3Presign`. In **Node Inspector**, `AWSBehaviorS3Presign Variable` appears. The default name of the variable is **Variable 1**.
7. In **Node Inspector**, expand **AWSBehaviorS3Presign** to show the input fields. Type or choose the values in the following table.

<table>
<thead>
<tr>
<th>Input Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>BucketName</td>
<td>CloudGemAWSBehavior.s3nodeexamples</td>
</tr>
<tr>
<td>KeyName</td>
<td>presigntest.txt</td>
</tr>
<tr>
<td>RequestMethod</td>
<td>GET</td>
</tr>
<tr>
<td>ContentType</td>
<td>text/html</td>
</tr>
</tbody>
</table>

8. From the **Variable Manager**, press **Shift** and drag **Variable 1 AWSBehaviorS3Presign** to the canvas to create the **Get Variable 1** node. (You can also drag `AWSBehaviorS3Presign` to the canvas and then select **Get Variable** from the drop-down menu.)
9. Connect the **Out** pin of the **On Graph Start** node to the **In** pin of the **Get Variable 1** node.
10. In the **Node Palette**, expand **AWS, AWSBehaviorS3Presign**.
11. Drag the **Presign** node to the right of the **Get Variable 1** node on the canvas.
12. Connect the **Out** pin of the **Get Variable 1** node to the **In** pin of the **Presign** node.
13. Connect the `AWSBehaviorS3Presign` pin of the **Get Variable 1** node to the `AWSBehaviorS3Presign:0` pin of the **Presign** node.
Add Nodes to Display the Result

Next, to see the success or failure of the operation, you add `AWSBehaviorS3PresignNotificationBus` nodes and a `Print` node to the graph. The nodes monitor for `AWSBehaviorS3PresignNotificationBus` events and show you the result in the Lumberyard console window.

**To display the success or failure of the presign operation in the console window**

1. In the **Node Palette**, expand `AWS, AWSBehaviorS3PresignNotificationBus`.
2. Drag **OnError** to the canvas. Place the node under the three nodes that are already connected.
3. Drag **OnSuccess** to the canvas and place it under the **OnError** node.
4. In the **Node Palette**, expand **Utilities, Debug** and drag **Print** to the right of the two `AWSBehaviorS3PresignNotificationBus` nodes on the canvas. The **Print** node displays messages in the Lumberyard Editor console.
5. Connect the **Out** pins of the `AWSBehaviorS3PresignNotificationBus OnError` and **OnSuccess** nodes to the **In** pin of the **Print** node.
6. Connect the **String** pins of the `AWSBehaviorS3PresignNotificationBus OnError` and **OnSuccess** nodes to the **Value** pin on the **Print** node. Your canvas should look similar to the following image:
7. Save the canvas with a name like `MyS3PresignTest.scriptcanvas`. The default file location is the `lumberyard_version\dev\project_name\scriptcanvas` directory.

8. Exit the Script Canvas editor.

**Test Generate a Presigned URL**

Now you are ready to attach the script canvas to an entity and test it.

**To test the presigned Amazon S3 URL**

1. In Lumberyard Editor, right-click the viewport and choose `Create entity`.
2. In Entity Inspector, click `Add Component`.
3. Under Scripting, click `Script Canvas` to add a `Script Canvas (p. 818)` component to the entity.
4. Under Script Canvas, click the browse button (…).
5. In the Pick Script Canvas dialog box, choose the canvas that you created – for example, `mys3presigntest (Script Canvas)`, and then click OK.
6. If the Lumberyard console window is not already open, press ` or choose Tools, Console to open the console window. If the console window is already open and you want to clear it, press Ctrl+Shift+C.

7. Press Ctrl+G to start the level. The console reports the success of the operation, as in the following example.

```
 invaders.txt - https://s3.amazonaws.com//presigntest.txt?X-Amz-Algorithm=AWS4-HMAC-SHA256%26X-Amz-Credential={string}
```

### Invoking an AWS Lambda Function from Script Canvas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the **InvokeAWSLambda** node to invoke an AWS Lambda function.

**Note**

This tutorial uses an example Lambda function that is included with Lumberyard. For information on using your own Lambda function, see Making a Custom Lambda Function Available to Script Canvas (p. 2149).

**Topics**

- Prerequisites (p. 2146)
- Step 1: Add Nodes to Invoke an AWS Lambda Function (p. 2146)
- Step 2: Add Nodes to Display the Result (p. 2147)
- Making a Custom Lambda Function Available to Script Canvas (p. 2149)

**Prerequisites**

To complete the procedures in this tutorial, perform the following steps.

1. In the Project Configurator, choose the **CloudGemSamples** project.
2. Use Cloud Canvas Resource Manager or the `lmbr_aws` command to upload the resources for the project. This creates a project stack and a deployment in AWS.

After you perform these steps, your `lumberyard_version\dev\CloudGemSamples\Config\deployment_name.player.awsLogicalMappings.json` file should have an entry for CloudGemAWSScriptBehaviors.AWSBehaviorLambdaExample like the following example:

```
"CloudGemAWSScriptBehaviors.AWSBehaviorLambdaExample": {  
  "PhysicalResourceId": "CloudGemSamples-cgsamples-AWSBehaviorLambdaExample-T4F05C8V5QQR",  
  "ResourceType": "AWS::Lambda::Function"
},
```

### Step 1: Add Nodes to Invoke an AWS Lambda Function

The following procedure shows you how to create a Script Canvas graph that invokes an AWS Lambda function.

**To create a graph that invokes an AWS Lambda function**

1. In Lumberyard Editor, choose Tools, Script Canvas.
2. In the **Node Palette**, expand **Utilities** and drag the **On Graph Start** node to the graph.

3. On the right, in **Variable Manager**, click **Create Variable**.

4. In the **Variable Type** search box, enter **AWSLambda**, or scroll down to **AWSLambda**.

5. Click **AWSLambda**. In **Node Inspector**, **AWSLambda Variable** appears. The default name of the variable is **Variable 1**.

6. In **Node Inspector**, expand **AWSLambda** to show the **functionName** and **requestBody** boxes.

7. For **functionName**, select a Lambda function which is currently mapped by the Cloud Canvas Resource Manager. This tutorial uses the function **CloudGemAWSScriptBehaviors.AWSBehaviorLambdaExample**. You can find the example Lambda function in the `lumberyard_version\dev\Gems\CloudGemAWSScriptBehaviors\AWS\lambda-code\AWSBehaviorLambdaExample\main.py` file. The function simply returns a "Hello World" string.

8. For **AWSBehaviorLambdaExample**, leave **requestBody** blank. The **requestBody** field specifies a JSON string that can contain data to pass to the Lambda function.

9. From the **Variable Manager**, press **Shift** and drag **Variable 1 AWSLambda** to the graph to create the **Get Variable 1** node. (You can also drag **AWSLambda** to the graph and then select **Get Variable** from the drop-down menu.)

10. Connect the **Out** pin of the **On Graph Start** node to the **In** pin of the **Get Variable 1** node.

11. In the **Node Palette**, expand **AWS, AWSLambda**.

12. Drag the **InvokeAWSLambda** node to the right of the **Get Variable 1** node on the graph.

13. Connect the **Out** pin of the **Get Variable 1** node to the **In** pin of the **InvokeAWSLambda** node.

14. Connect the **AWSLambda** pin of the **Get Variable 1** node to the **AWSLambda:0** pin of the **InvokeAWSLambda** node.

**Step 2: Add Nodes to Display the Result**

Next, to see the success or failure of the operation, you add **AWSLambdaHandler** nodes and a **Print** node to the graph. The nodes monitor for **AWSLambdaHandler** events and show you the result in the Lumberyard console window.

**To display the output of the Lambda function in the console window**

1. In the **Node Palette**, expand **AWS, AWSLambdaHandler**.

2. Drag **OnError** to the graph. Place the node under the three nodes that are already connected.

3. Drag **OnSuccess** to the graph and place it under the **OnError** node.

4. In the **Node Palette**, expand **Utilities, Debug** and drag **Print** to the right of the two **AWSLambdaHandler** nodes on the graph. The **Print** node displays messages in the Lumberyard Editor console.

5. Connect the **Out** pins of the **AWSLambdaHandler OnError** and **OnSuccess** nodes to the **In** pin of the **Print** node.

6. Connect the **String** pins of the **AWSLambdaHandler OnError** and **OnSuccess** nodes to the **Value** pin on the **Print** node.

**Example**

Your graph should look similar to the following image.
7. Save the file with a name like `MyLambdaFunctionTest.scriptcanvas`. The default file location is the `lumberyard_version\dev\project_name\scriptcanvas` directory.

8. Close the Script Canvas editor.

**Step 3: Test the Lambda Function**

Now you are ready to attach the Script Canvas graph to an entity and test the script.

**To test the Lambda function**

1. In Lumberyard Editor, right-click the viewport and choose Create entity.
2. In the **Entity Inspector**, click **Add Component**.

3. Under **Scripting**, click **Script Canvas** to add a **Script Canvas** (p. 818) component to the entity.

4. Under **Script Canvas**, click the browse button (...).

5. In the **Pick Script Canvas** dialog box, choose the file that you created – for example, **mylambdafunctiontest (Script Canvas)**, and then click **OK**.

6. To open the Lumberyard console window, press `` or choose **Tools**, **Console**. If the console window is already open and you want to clear it, press **Ctrl+Shift+C**.

7. Press **Ctrl+G** to start the level. The console shows the "Hello World" result, as in the following example.

```python
general.enter_game_mode
Returned:
(Found resource management based identity pool %s.) - us-east-1:guid
(Found resource management based identity pool %s for authenticated access.) - us-east-1:guid
(CloudCanvas) - Anonymous Credentials pulled successfully for identity pool us-east-1:guid.
(Disable Accelerators)
(Script Canvas) - "Hello World"
```

### Making a Custom Lambda Function Available to Script Canvas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com) or visit the [AWS Game Tech blog](https://aws.amazon.com) to learn more.

You can make custom Lambda function available to Script Canvas with the following steps:

1. Use the Project Configurator to add **Cloud Gem AWS Script Behaviors** to your project. For information on adding gems to your game project, see **Enabling Gems** (p. 1064).

2. In Lumberyard Editor, use the Cloud Canvas Resource Manager to add a Lambda resource to the **CloudGemAWSScriptBehaviors** resource group. When you perform this step, Lumberyard creates a directory named after your function and a placeholder **main.py** code file for you. The code directory and file look like the following:

   ```
lumberyard_version\dev\Gems\CloudGemAWSScriptBehaviors\AWS\lambda-code
your_function_name\main.py
```

3. Add your function code to the **main.py** file.

4. Use the Cloud Canvas Resource Manager to upload the resources to AWS. After you complete this step, your Lambda function becomes available to Script Canvas.

This topic shows you how to perform the second and fourth steps: use the Cloud Canvas Resource Manager to add a custom Lambda function to the **CloudGemAWSScriptBehaviors** resource group, and upload your Lambda function to AWS.

**Topics**

- Adding a Lambda Function Resource (p. 2150)
- Uploading Your Custom Lambda Function to AWS (p. 2152)
Adding a Lambda Function Resource

With Lumberyard Editor, you can add a Lambda function resource to the `CloudGemAWSScriptBehaviors` resource group.

To add a custom Lambda function to the CloudGemAWSScriptBehaviors resource group

1. In Lumberyard Editor, choose **AWS**, **Cloud Canvas**, **Resource Manager**.
2. Under **Resource Groups**, select **CloudGemAWSScriptBehaviors**.

3. Click **Add resource**, and then choose **Lambda function**.

![Resource Manager screenshot](image)
4. In the Add a Lambda function dialog box, specify the following values.

- **Name** – The name of the Lambda function.
- **Handler** – Specifies the code source for the function in the format `python_filename.function_name`. To use the `main.py` file that Lumberyard creates for you, specify `main.function_name`. For example, for a function named `MyCustomAWSLambdaFunction`, enter `main.MyCustomAWSLambdaFunction`.

For more information about Lambda function handlers, see Lambda Function Handler (Python) in the [AWS Lambda Developer Guide](#).

- **Player invokable** – Choose Yes. This option gives the player the permission to invoke the Lambda function.
These properties are added to the resource-template.json file in the
lumberyard_version\dev\Gems\CloudGemAWSScriptBehaviors\AWS directory.

5. Click OK. Now you are ready to add code to the main.py file that Lumberyard created for you at the following location:

lumberyard_version\dev\Gems\CloudGemAWSScriptBehaviors\AWS\lambda-code \your_function_name\main.py

Uploading Your Custom Lambda Function to AWS

After you add your Lambda function code to the main.py file, you are ready to upload it to AWS to make it available to Script Canvas.

To upload your Lambda function code to AWS

1. In Lumberyard Editor, choose AWS, Cloud Canvas, Resource Manager.
3. In Cloud Canvas Resource Manager, click Upload resources to upload your Lambda function to AWS.
4. In the Upload group resources dialog box, click Yes to approve any changes to security, if you agree.
Cloud Canvas Resource Manager notifies you when the Lambda resources have been created in AWS.

Now when you use Node Inspector to add an AWSLambda Variable node to a Script Canvas graph, your Lambda function becomes available in the functionName box.

For more information, see Invoking an AWS Lambda Function from Script Canvas (p. 2146).
Compute Farm Cloud Gem

This cloud Gem is deprecated and no longer supported. Some functionality is broken because of its dependency on the Cloud Gem Portal, which was removed in Lumberyard 1.28. Complete documentation for this Gem from previous versions of Lumberyard can be found in the Documentation Archive.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Compute Farm cloud gem is a tool for large-scale divide and conquer tasks that can be processed on a fleet of Amazon EC2 instances. This cloud gem is particularly suited for heavy-duty, computationally intensive Windows tasks like nav mesh generation, static lightmap baking, and terrain generation. In general, the Compute Farm cloud gem is designed for tasks that can be highly parallelized with recursive subdivision.

The Compute Farm cloud gem has the following three major aspects:

1. **Harness** – The brain of the cloud gem that orchestrates the task. The harness is a Python script that runs on every Amazon EC2 instance. The script continuously polls the Amazon Simple Workflow Service (SWF) for decisions that need to be made and activities that must be run. You can customize the harness for your own purposes.

2. **Amazon Machine Image (AMI)** – An image of the machine to do the task. The AMI must be prepared with all the necessary software to perform the task as well as a copy of the harness. The Compute Farm cloud gem includes a script to build the AMI.

3. **Launch Configuration and Auto Scaling Group** – After the AMI is created, you must create an Amazon EC2 Launch Configuration and an Amazon EC2 Auto Scaling Group to control the fleet of Amazon EC2 instances that will run the AMI. You set the Auto Scaling Group to the desired number of Amazon EC2 instances.

**Workflow Summary**

The harness receives and processes events from Amazon SWF, and runs three categories of task: divide, build and merge.

The harness must be extended with Python scripts that perform these three tasks for the target. In the dictionary sorting example that is included with the cloud gem, these tasks are the following:

- **Divide** a dictionary of words into multiple parts.
- **Build** a subset of the dictionary by sorting it.
- **Merge** the two sorted subsets back into one sorted subset.

For a high-level explanation and demonstration of the Compute Farm cloud gem for large scale terrain generation, see the 2018 GDC classroom session on YouTube. Developers who are interested in this particular implementation can reach out to us at lumberyard-feedback@amazon.com.

**Account Limits**

Your use of the Compute Farm cloud gem is subject to the limits on your AWS account. The following are the most relevant limits that you are likely to encounter:
• Limits on the number of on-demand Amazon EC2 instances that you can run for a particular type. For more information, see Q: How many instances can I run in Amazon EC2?

• Limits on your EBS volume storage. For more information, see Amazon Elastic Block Store (Amazon EBS) Limits in the Amazon Web Services General Reference.

• For large number of active instances, throttling limits on Amazon SWF. For more information, see Amazon SWF Limits in the Amazon Simple Workflow Service Developer Guide.

To request limit increases, see the AWS Support Center.

Defect Reporter Cloud Gem

This cloud Gem is deprecated and no longer supported. Some functionality is broken because of its dependency on the Cloud Gem Portal, which was removed in Lumberyard 1.28. Complete documentation for this Gem from previous versions of Lumberyard can be found in the Documentation Archive.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Defect Reporter cloud gem makes it easy for you and your developers and testers to gather, view, and manage defect reports from your game. The Defect Reporter cloud gem offers the following advantages:

• **Automated, error-free collection of data** – Instead of relying on the player to manually send the data, the most important data from the client is automatically captured. The contextual information that is included in the reports increases the likelihood of having actionable data and reduces the need to investigate with the customer.

• **Ease of reporting** – Players can submit reports from within the game without having to use email, forums, or open a browser. Players can easily report errors, which can increase the number of reports and reduce the number of unreported defects.

• **Ease of annotation** – Players can view the data that a report captures, annotate the report, and respond to any custom data collection queries that you provide.

Using Dynamic Content Manager

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Dynamic Content Cloud Gem and its Dynamic Content Manager to manage dynamic content updates for your game through AWS. You can use Dynamic Content Manager to create manifests and packages, add files to the packages, and upload the manifest and packages to the AWS Cloud. This ensures that your clients have the latest content for your game.

**Topics**

• Managing Dynamic Content Packages (p. 2165)

• Updating Dynamic Content (p. 2167)
- Using the Dynamic Content CLI (p. 2169)
- Testing the Dynamic Content System (p. 2177)
- Dynamic Content Engineering Details (p. 2181)

Prerequisites

This tutorial assumes the following:

- You are using a Lumberyard project that has the Dynamic Cloud Gem enabled (in the Project Configurator (p. 43), choose Cloud Gem Dynamic Content).
- You have created a project stack and deployment stack in Cloud Canvas Resource Manager (p. 2110) with the CloudGemDynamicContent resource group.

Note

If you do not have a deployment with the CloudGemDynamicContent resource group, the Dynamic Content Manager interface is disabled.

To use the Dynamic Content Manager to upload dynamic content

1. In Lumberyard Editor, choose AWS, Cloud Canvas, Dynamic Content Manager.

![Dynamic Content Manager](image)

2. In Dynamic Content Manager, click Create a new manifest.
A manifest is a file that keeps track of the dynamic content files that you deliver to customers. A manifest records the following information:

- The content files that have changed locally
- The files that are included in any file packages
- Differences between the local packages and the packages in the cloud that are staged for delivery to customers
- The target operating systems and devices for this manifest

You can create as many manifests as you require. For example, you can create specialized manifests for different types of assets.

3. Choose a name for the manifest. The name should reflect the purpose of the manifest.
4. Select the target operating systems and devices that you prefer to work on for this manifest.
5. When you create a manifest, the manifest is empty and has no files or packages.
Click **Add Files** or **Add Folder** and choose one of the target operating systems.

6. In the file browser, choose the files that you want to add to the manifest.
Because the original assets might not be in a form that your game can consume, the file browser opens to the location of your game projects asset cache. For example, your game OS might require textures to be in .dds format, but the original asset for a texture might be a .png file. The Asset Processor converts the files to the appropriate format and stores them in the asset cache, so the asset cache is your safest choice. However, if you have processed assets elsewhere in your file system, you are free to include them.

**File Warnings**

If the files that you selected are not supported by the current manifest or not supported by the OS that you selected, you are warned accordingly.

If the files that you selected are not in your game projects asset cache (and have therefore not been processed by the Asset Processor), you are notified of the error.

7. The left pane of Dynamic Content Manager shows the files that you added to the manifest. You can add files for different target operating systems and sort the files by their name, OS, or status. After you have some files in the file manager, you can select one or more files and remove them. You can remove the files by right-clicking them or by clicking Remove Files.
Now you are ready to add a package to the manifest.

Click **New Package**.

8. Enter a name for the package and choose the operating system or device type for it.

9. The new package appears in the right pane of **Dynamic Content Manager**. You can sort the packages by column.
Each package is stored in a .pak file, which is the archived file format that Lumberyard uses for its released game assets. You can have one or more packages per manifest, and you can assign the same file to multiple packages. This is useful when you have common files and operating system or device-specific files that you need to deliver in one package. It is also useful if you want to create bundles of items that might share assets.

10. To add files to the package that you created, drag the files from the manifest on the left to the package on the right. You can drag multiple files into the same .pak file.

You can drag operating system or device-specific files to a package with that OS type only. If you drag multiple files to a package and the OS type of these files does not match that of the package, Lumberyard warns you about the incompatible files.
The icons that appear in the **Packages** pane are described as follows.

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>!</td>
<td>A file in a package has been updated in the asset cache. The contents of the package have been updated, so you might want to upload the package again.</td>
</tr>
<tr>
<td>✗</td>
<td>The package is not in the cloud. This can occur when the package has not yet been uploaded.</td>
</tr>
<tr>
<td>🔉</td>
<td>A package has changed with respect to its copy in the cloud. The contents of the package have been updated, so you might want to upload the package again.</td>
</tr>
<tr>
<td>✔️</td>
<td>The local package matches the package in the cloud. No action is necessary.</td>
</tr>
</tbody>
</table>

**Notes**

- You can remove individual files from a package, but to help prevent inadvertent removal, this action is limited to one file at a time.
- You can also use **Dynamic Content Manager** to delete packages, but deleting a package does not delete the staged packages in the cloud. To delete staged packages in the cloud, you must use the `lmbr_aws delete-uploaded-content` command to manage the service side of a cloud gem.

11. You can change the target operating systems or devices for the current manifest at any time.

   a. Click the settings button and choose **Change Target Platforms**.

   ![Dynamic Content Manager](image)

   b. Choose the operating systems or devices that you want. If none are selected, all supported operating systems and devices are added.
After you update the target operating systems and devices, **Dynamic Content Manager** lists only the files and packages for the ones that you selected. You can add files and folders only for the selected target OS or device.

12. When you are ready, click **Upload Packages**.

13. (Optional) To sign your packages, select **Sign packages with security key**.

14. If you haven't yet generated key pairs, click **Next** to generate a new key pair, and then click **Continue**.
You can also use the file menu to generate a new key pair at any time.

15. After the new key pair is generated, click **Upload**. This action both creates the package files locally and uploads them to your private staging bucket in the AWS Cloud.

The status bar of the main window shows upload process messages.
An animation in the **S3 Status** column indicates the package that is being uploaded.

By default, Lumberyard marks them as **Private**. When you are ready, you can transition the package to the **Public** stage to make it available for download by game clients. For more information on this step, see Package Stages (p. 2166).

### Managing Dynamic Content Packages

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Dynamic Content Cloud Gem provides an easy way for you to update your game content for your customers. After a release, you can update content without an app submission or traditional patch process. The Dynamic Content Cloud Gem provides a framework for you to group outdated assets into manifests. You can assign groups of assets together into .pak files (.zip files), and distribute these files to customers according to your own rules or schedules.

**Prerequisites**

To use the Dynamic Content Cloud Gem, you must meet these requirements:

- You must be using a Lumberyard Editor project that has the Dynamic Content Cloud Gem enabled (in the Project Configurator, select **Cloud Gem Dynamic Content**).
- You have a project stack created in Cloud Canvas Resource Manager (p. 2110).
- You have created a deployment stack in Cloud Canvas Resource Manager.
- You have created dynamic content packages that contain the updates. For more information, see Using Dynamic Content Manager (p. 2155).

To get a list of uploaded dynamic content packages, enter the following command

```bash
$ lmbr_aws dynamic-content list-uploaded-content
```

[WAF] Engine Root: C:\Amazon\Lumberyard\1.28.0.0\dev\WheelCustomization.manifest.pak PUBLIC {'Hash': 'af6282f222669294e2ac12ac59871e297', 'Size': '2048'}
Package Stages

You can use separate deployment stacks to handle different release workflows. For this purpose, the Dynamic Content Cloud Gem supports the following publishing stages.

- **Private** – The packages are never downloaded by the game client. When you upload new or altered content to the cloud from Dynamic Content Manager, your packages and manifest are always put in the Private stage. This empowers you to choose when and how your changes are released to customers.

- **Scheduled** – The packages are conditionally downloaded by the game client based on a specific date and time.

- **Public** – The packages are available to everyone that uses the deployment.

You can use these stages to add an additional layer of protection against inadvertent deployments of dynamic content to your players.

To transition a package from one stage to another, use the set-staging-status command to edit the package's staging status. See Editing Packages (p. 2166) later in this topic for an example.

Package Nesting

Each stage includes entries for your manifests and packages. Packages are nested according to the hierarchy that you determine when you create them. In the following example, the root-level manifest package is WheelCustomization.manifest.pak. It has two child asset packages, WheelCustomization_assets.shared.pak and WheelCustomization_data.shared.pak.

You can edit or delete root-level packages. However, you cannot edit child packages. You can only delete child packages.

Editing Packages

Use the set-staging-status command to edit the state of an uploaded root-level package. You can transition the content from one stage to another, schedule a window when it is available for download, select which child packages you would like to include in the transition, and much more. See the lmbr_aws dynamic-content set-staging-status (p. 2174) CLI documentation for full details.

Example: Transition a package to PUBLIC

This example shows how to transition a package and all its child packages to the public stage, using the filename of the root-level package.
Important

If you do not use `--include-children`, the child packages become orphans in the current stage and no longer visible to the game client.

Deleting Manifests and Packages

Use the `delete-uploaded-content` command to delete an uploaded manifest or package.

Example: Delete a manifest

This example shows how to delete a manifest, using the filename of the uploaded manifest. By including the `--confirm-deletion` flag, you confirm that you want to perform this deletion. Without this flag, the command will show you what would be deleted.

```
$ lmbr_aws dynamic-content delete-uploaded-content --file-path WheelCustomization.json --confirm-deletion
```

Tip

You can delete a specific version of a manifest using the optional `--version-id` argument.

Example: Delete a package and any children

This example shows how to delete a root package and all its child packages, using the filename of the uploaded root-level package. Without the `--confirm-deletion` flag, this command only shows what would be deleted.

```
$ lmbr_aws dynamic-content delete-uploaded-content --file-path WheelCustomization.manifest.pak
```

Tip

You can delete a specific version of a package using the optional `--version-id` argument.

Updating Dynamic Content

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To update dynamic content use the `lmbr_aws` CLI to upload new manifest content. We recommend that you enable dynamic content versioning to pre-stage and schedule the release of new versions so that players can still download previous versions while new content is uploaded. Dynamic content versioning also enables rollback to previous versions without having to re-upload the previous content.
Updating Dynamic Content with lmbr_aws

To perform dynamic content updates, enter the following command.

```
lmbr_aws dynamic-content upload-manifest-content --manifest-path <manifest name> --staging-status <PUBLIC|PRIVATE|WINDOW>
```

- `<manifest name>` – Specifies the filename of the manifest in the manifests directory (for example, `DynamicContentTest.json`).
- `<PUBLIC|PRIVATE|WINDOW>` – (Optional) Use PUBLIC to release the content immediately. Use WINDOW with `--start-date` and `--end-date` to specify a range during which the content will be publicly available. Defaults to PRIVATE.

Dynamic Content Versioning

Using dynamic content versioning, you can pre-stage and schedule the release of new dynamic content versions. Versioning your content is not required, but when enabled, provides the following advantages:

- Players can still download previous versions of your dynamic content while new content is uploaded, with no impact to availability. Without versioning enabled, clients will receive errors when packages in the S3 bucket are in the process of being updated, until the update completes.
- Developers have the ability to quickly rollback dynamic content to a previous version. Without versioning enabled, developers are required to re-upload previous content, which impacts availability and mitigation speed.

**Important**

When planning your versioning strategy, remember to take into consideration that normal S3 pricing applies to each version of an object.

Periodically, you might want to clear deprecated versions using the provided CLI commands, or define custom lifecycle management rules on the content bucket. However, please note that you will not be able to roll back to a version that has been cleared.

For more information on lifecycle management rules, see Object lifecycle management in the Amazon S3 Developer Guide.

Enabling dynamic content versioning

Dynamic content versioning is an optional feature. To use it, you must enable it by adding a tag to the deployment.

**To enable versioning on a new deployment**

Create the deployment with versioning enabled, as shown in the following CLI command:

```
lmbr_aws deployment create --deployment <deployment_name> --tags content-versioning
```

**To enable versioning on an existing deployment**

1. Add the `content-versioning` tag to the deployment.

   ```
   lmbr_aws deployment tags --add content-versioning --deployment <deployment_name>
   ```

2. Update the deployment stack.

   ```
   lmbr_aws deployment update --deployment <deployment_name>
   ```
Existing dynamic content table entries will also be migrated to the new `VersionedStagingSettingsTable` DynamoDB table after object versions are enabled.

Note that the dynamic content gem enables you to upload content with or without using manifests. When manifests are adopted, these files will also be versioned, and you have the option to update the staging status of all manifest content versions. However, if you skip manifests and upload a folder directly to the content bucket, you will have to manage the staging status of each `.pak` version separately.

**Suspending versioning**

To suspend dynamic content versioning, use the `suspend-versioning` CLI command. For details on the arguments available to this command, see dynamic-content suspend-versioning (p. 2175).

Note that suspending versioning will not revert the versioned S3 bucket to an unversioned state. Existing objects do not change after the suspension, but the S3 bucket will stop accruing new versions of the same object.

To resume versioning, follow the Enabling dynamic content versioning (p. 2168) instructions for an existing deployment.

**Using the Dynamic Content CLI**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When you enable the Dynamic Content Cloud Gem, associated commands become available in the `lmbr_aws` CLI. You can then use these commands to update dynamic content and perform operations on manifest files and buckets.

The following `lmbr_aws` CLI extension commands are enabled by the Dynamic Content Cloud Gem.

**dynamic-content add-file-to-pak**

Add a given file to the specified `.pak` file.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- `--file-name <file_name>`
  
  File entry to add.

- `--manifest-path <manifest_path>`
  
  (Optional) Path and filename of the manifest file to use. You can specify either a full path or a filename that exists in the folder `game\DynamicContent\Manifests\`. Defaults to `game\DynamicContent\Manifests\default.json`.

- `--pak-file <pak_file>`
  
  Pak file to add the file to.

- `--platform-type <OS_type>`
  
  (Optional) Operating system of the file entry to add.

**dynamic-content add-manifest-file**

Adds a file to the content manifest for the project.
In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- **--file-name <filename>**
  
  The name of the file, including the local directory (for example, staticdata/csv/gameproperties.csv, where local directory is staticdata/csv/.

- **--cache-root <cache directory>**

  (Optional) The reference for the local cache directory (for example, @assets@). The default is @assets@.

- **--bucket-prefix <prefix>**

  The bucket prefix under which to store the file in the content bucket.

- **--manifest-path <manifest_path>**

  (Optional) Path and filename of the manifest file to use. You can specify either a full path or a filename that exists in the folder game\DynamicContent\Manifests\.

  Defaults to game\DynamicContent\Manifests\default.json.

- **--output-root <default directory path>**

  (Optional) The path of the default directory to which to write. The default is @user@.

- **--platform-type <OS_type>**

  (Optional) The operating system type for the .pak file.

### dynamic-content add-pak

Add a new pak entry to the manifest.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- **--manifest-path <manifest_path>**

  (Optional) Path and filename of the manifest file to use. You can specify either a full path or a filename that exists in the folder game\DynamicContent\Manifests\.

  Defaults to game\DynamicContent\Manifests\default.json.

- **--pak-name <pak_name>**

  Name of the pak (the final filename will be <pak-name>..<OS>.pak).

- **--platform-type <OS_type>**

  (Optional) The operating system type for the .pak file.

### dynamic-content build-new-paks

Create .pak files based on manifest files which have changed.
In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- `--all`
  (Optional) Upload all .pak files regardless of the results of the file check.
- `--manifest-path <manifest_path>`
  (Optional) Path and filename of the manifest file to use. You can specify either a full path or a filename that exists in the folder `game\DynamicContent\Manifests\`. Defaults to `game\DynamicContent\Manifests\default.json`.

**dynamic-content clear-dynamic-content**

Empty the bucket and table content.

In addition to the Common Arguments (p. 2391), this command accepts the following argument:

- `--all-versions`
  (Optional) Remove all versions of the manifest and pak files.
- `--noncurrent-versions`
  (Optional) Remove all the noncurrent versions of dynamic content. Requires confirmation on the command line following the use of this command, unless `--confirm-deleting-noncurrent-versions` is also used.
- `--confirm-deleting-noncurrent-versions`
  (Optional) Confirm that you know this command will delete all the noncurrent versions of files in the content bucket, and that you will not be able to roll back any previous version after this operation. Useful for automation.

**dynamic-content compare-bucket-content**

Compares manifest content to the bucket by checking HEAD metadata.

In addition to the Common Arguments (p. 2391), this command accepts the following argument:

- `--manifest-path <manifest_path>`
  (Optional) Path and filename of the manifest file to use. You can specify either a full path or a filename that exists in the folder `game\DynamicContent\Manifests\`. Defaults to `game\DynamicContent\Manifests\default.json`.
- `--manifest-version-id <manifest version ID>`
  (Optional) Version of the standalone manifest pak. You can retrieve the available version ID's by using the `list-file-versions` command.

  Defaults to the latest version.

**dynamic-content create-new-manifest**

Create a new manifest.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- `--manifest-name <manifest_name>`
Name of the new manifest.

- **--manifest-path** `<manifest_path>`

(Optional) Path and filename of the manifest file to use. You can specify either a full path or a filename that exists in the folder `game\DynamicContent\Manifests\`. Defaults to `game\DynamicContent\Manifests\default.json`.

- **--target-platforms** `<target_OS> [<target_OS> ...]`

(Optional) Target operating systems for this new manifest (the default is all supported operating systems and devices).

### `dynamic-content delete-uploaded-content`

Delete a manifest or package.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- **--file-path** `<file_path>`

  The manifest or package file in the bucket.

- **--version-id** `<version_id>`

  (Optional) Version ID of the file. Defaults to the latest version.

- **--confirm-deletion**

  (Optional) Confirms that you want this command to delete the specified content. Omit this argument to preview what would be deleted.

### `dynamic-content generate-keys`

Generate a new public/private key pair for use by the dynamic content system.

In addition to the Common Arguments (p. 2391), this command accepts the following argument:

- **--key-name** `<key_name>`

  The name of the key file to use.

### `dynamic-content list-bucket-content`

Lists the manifest files in the content bucket.

In addition to the Common Arguments (p. 2391), this command accepts the following argument:

- **--manifest-path** `<manifest_path>`

  (Optional) Path and filename of the manifest file to use. You can specify either a full path or a filename that exists in the folder `game\DynamicContent\Manifests\`. Defaults to `game\DynamicContent\Manifests\default.json`.

- **--manifest-version-id** `<manifest version ID>`

  (Optional) Version of the standalone manifest pak. You can retrieve the available version ID's by using the `list-file-versions` command.
Defaults to the latest version.

**dynamic-content list-file-versions**

List all versions of a manifest or pak file found in the content bucket. Returns newest to oldest version based on uploaded date.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- `--file-name <filename>`
  (Optional) Name of the manifest or pak file.

**dynamic-content list-uploaded-content**

List all uploaded content.

The Common Arguments (p. 2391) can also be used with this command.

**dynamic-content migrate-staging-settings**

Migrate existing staging settings when content versioning is enabled or suspended. Existing data should be migrated automatically during the deployment update, so you will only need this command if the deployment fails to update.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- `--deployment-name <deployment name>`
  (Optional) Name of the deployment for which staging settings should be migrated.

  Defaults to the current active deployment.

**dynamic-content remove-manifest-file**

Removes a file from the content manifest for the project.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- `--file-name <filename>`

  Removes a file from the content manifest for the project. The file removed matches the value for `--file-name` that is specified in the `add-manifest-file` command.

- `--manifest-path <manifest_path>`

  (Optional) Path and filename of the manifest file to use. You can specify either a full path or a filename that exists in the folder `game\DynamicContent\Manifests\`.

  Defaults to `game\DynamicContent\Manifests\default.json`.

**dynamic-content request-url**

Requests a URL for the specified file.

In addition to the Common Arguments (p. 2391), this command accepts the following argument:

- `--file-path <file_path>`
The file in the bucket.

dynamic-content set-staging-status

Sets the staging status of the specified file.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- **--file-path <file_path>**
  The file in the bucket.
- **--version-id <version_id>**
  (Optional) Version ID of the file.
  Defaults to the latest version.
- **--staging-status <PUBLIC|PRIVATE|WINDOW>**
  Use PUBLIC to make the file immediately public. Use WINDOW with start-date and end-date to specify a range during which the file will be publicly available.
- **--start-date <start_date>**
  (Optional) Start date value for windowed staging. Use NOW or UTC date/time in the format "Jan 15 2021 14:30".
- **--end-date <end_date>**
  (Optional) End date value for windowed staging. Use NEVER or UTC date/time in the format "Jan 31 2021 14:30".
- **--include-children**
  (Optional) Set the staging status for all the children paks.
  Defaults to false.

**Warning**
There is a risk of a race condition if the staging status of a file is updated while a new version of the same file with a different staging status is uploaded at the same time from a different machine. The file could end up with an unexpected staging status in this case. To avoid this issue, specify the version ID when using the set-staging-status command.

dynamic-content show-logs

Show recent log events.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- **--minutes <minutes>**
  (Optional) The number of minutes of log events to show prior to now.
  Defaults to 10 minutes.

dynamic-content show-manifest

List all entries in the content manifest.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:
• --file-name <filename>
  (Optional) The file entry (local directory + key) to show.
• --manifest-path <manifest_path>
  (Optional) Path and filename of the manifest file to use. You can specify either a full path or a
  filename that exists in the folder game\DynamicContent\Manifests\. Defaults to game\DynamicContent\Manifests\default.json.
• --manifest-version-id <manifest version ID>
  (Optional) Version of the standalone manifest pak. You can retrieve the available version ID's by using
  the list-file-versions command. Defaults to the latest version.
• --platform-type <OS_type>
  (Optional) The operating system type of the file to list.
• --section <section>
  (Optional) Section to show (Paks or Files).

**dynamic-content show-signature**

Show the signature which would be created for a specified file.

In addition to the Common Arguments (p. 2391), this command accepts the following argument:

• --file-name <file_name>
  (Optional) The filename for which to show the signature.

**dynamic-content suspend-versioning**

Suspend dynamic content versioning.

Note that suspending versioning will not revert the versioned S3 bucket to an unversioned state. Existing
objects do not change after the suspension, but the S3 bucket will stop accruing new versions of the
same object.

To resume versioning, follow the instructions to Enabling dynamic content versioning (p. 2168) on an
existing deployment.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

• --deployment-name <deployment name>
  (Optional) Name of the deployment for which versioning should be suspended. Defaults to the current active deployment.
• --confirm-versioning-suspension
  (Optional) Confirms that you know this command will suspend content versioning, and that you need
to re-enable and update the deployment to resume versioning. Useful for automation.

**dynamic-content test-signature**

Tests whether a base64 signature is valid for the specified string.
In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- **--signature** `<signature>`  
  Base64 encoded signature.
- **--to-sign** `<string_to_sign>`  
  The string to sign.

**dynamic-content update-manifest**

Updates the manifest with current file hashes.

In addition to the Common Arguments (p. 2391), this command accepts the following argument:

- **--manifest-path** `<manifest_path>`  
  (Optional) Path and filename of the manifest file to use. You can specify either a full path or a filename that exists in the folder `game\DynamicContent\Manifests\`.  
  Defaults to `game\DynamicContent\Manifests\default.json`.

**dynamic-content update-target-platforms**

Update the target operating system of a manifest file.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- **--manifest-path** `<manifest_path>`  
  (Optional) Path and filename of the manifest file to use. You can specify either a full path or a filename that exists in the folder `game\DynamicContent\Manifests\`.  
  Defaults to `game\DynamicContent\Manifests\default.json`.
- **--target-platforms** `<target_OS> [<target_OS> ...]`  
  (Optional) Updated target operating systems for this new manifest (the default is all supported operating systems and devices).

**dynamic-content upload-manifest-content**

Updates the manifest and uploads changed manifest content to the content bucket.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- **--manifest-path** `<manifest_path>`  
  (Optional) Path and filename of the manifest file to use. You can specify either a full path or a filename that exists in the folder `game\DynamicContent\Manifests\`.  
  Defaults to `game\DynamicContent\Manifests\default.json`.
- **--deployment-name** `<deployment_name>`  
  (Optional) Which deployment to upload content to.  
  Defaults to the current active deployment.
- **--staging-status** `<PUBLIC|PRIVATE|WINDOW>`
(Optional) Use PUBLIC to make the new content immediately public. Use WINDOW with start-date and end-date to specify a range during which the content will be publicly available.

Defaults to PRIVATE.

- **--start-date** `<start_date>`
  (Optional) Start date value for windowed staging. Use NOW or UTC date/time in the format "Jan 15 2021 14:30".

- **--end-date** `<end_date>`
  (Optional) End date value for windowed staging. Use NEVER or UTC date/time in the format "Jan 31 2021 14:30".

- **--signing**
  (Optional) Add file signatures to the content table for client side verification.

  Defaults to no signature.

- **--invalidate-existing-files**
  (Optional) Invalidate existing files with the same name in the CloudFront edge cache. Only effective if dynamic content is delivered via CloudFront. For details on using this service with dynamic content, see the topic on Using Amazon CloudFront (p. 2185).

  Defaults to no invalidation.

- **--replace**
  (Optional) Removes older versions when a new version has been uploaded.

- **--all**
  (Optional) Updates all content in the manifest regardless of whether it appears to have been updated already.

### Testing the Dynamic Content System

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard contains a basic level called **DynamicContentTest** that you can use to verify that the dynamic content system is functioning properly. The level is located in the `dev\CloudGemSamples\Levels\CloudGemTests\DynamicContentTest` directory.

**Prerequisites**

To test any cloud gem, you must have a deployment with the necessary resources. These resources are created through the Cloud Canvas Resource Manager. For detailed instructions on creating these resources, see Initializing Cloud Canvas Resource Manager (p. 2349).

For the test, you are likely to play the role of both content creator and game client. Because the editor prefers loose files to .pak files, you might want to run the engine in game client mode instead of editor mode. When you run the engine in editor mode, updated data does not take precedence during run time. If you do want to run the test in editor mode, you can change this setting by entering the console command `sys_PakPriority=1` before you start the test. After testing, if you want the editor to return to preferring loose files (the default), enter the console command `sys_PakPriority=0`.

Version 1.28
2177
To run the level as a game client, you must export the mappings from your deployment stack to your `\dev\project_name\Config` directory. As of Lumberyard 1.11, separate mappings are exported for the player game client and game server to differentiate the resources that are visible to each. To export the mappings, select your deployment in Cloud Canvas Resource Manager and click Export Mapping. The exported files have the format `<deployment_name>.player.awsLogicalMappings.json` and `<deployment_name>.server.awsLogicalMappings.json`.

After you have exported a mapping to the Config directory, you can use the mapping when you run a game launcher such as `\dev\Bin64vcNNN\CloudGemSamplesLauncher.exe`. If you have more than one mapping, use the `-cc_override_resource_map <mappings_file>` option to specify one when you run the launcher. For more information, see Selecting a Deployment with a PC Launcher (p. 2358).

The test level contains a button that requests an update of a predefined dynamic content manifest that describes a single `.pak` file. The `.pak` file references a `gameproperties.csv` file. The static data system uses the properties file to reflect a property value to Lua and to a text control that displays the property value.

When the level starts, the text box displays the current value of the property. Pressing the button starts the update process. During the update, the client checks the dynamic content system for new data. When it detects new data, it downloads the data and reflects the new value.

### Data Preparation

To create data that is considered "new" for the purposes of the test, perform the following steps.

#### To prepare data for the test

1. Open the `gameproperties.csv` file in the `\dev\CloudGemSamples\StaticData\CSV` directory. The file contents are similar to the following:

   ```
   GameProperty,Value
   DynamicMessage,"LOCAL DATA"
   ```

2. Set the "LOCAL DATA" message to a string that you want to receive when the data is updated (for example, "UPDATED").

3. Save the file.

4. Do one of the following:
   - At a command line prompt, enter the following command:
     ```
     lmbr_aws dynamic-content upload-manifest-content --manifest-path DynamicContentTest.json --staging-status PUBLIC
     ```
   - Use the packer tool to upload the manifest content. The manifest file that packs up `gameproperties.csv` is `DynamicContentTest.json`. Normally you should not have to alter `DynamicContentTest.json` for testing purposes. However, if you want to use it to ensure that your test contains no old test data, configure it like this:

   ```json
   {
     "Files": [
       {
         "bucketPrefix": "",
         "cacheRoot": "@assets@",
         "hash": "",
         "keyName": "gameproperties.csv",
         "localFolder": "StaticData/CSV",
     }
   }
   ```
At this point, you have created and uploaded a .pak file that contains the current version of your gameproperties.csv file and your manifest.

5. Stage the uploads as PUBLIC, which means that they are ready for download. If you used the command line option in the previous step to upload your data, this was done for you with the --staging-status PUBLIC option.

   If you used the packer tool to perform the upload, transition the package to PUBLIC using the following command:

   ```
   lmbr_aws dynamic-content set-staging-status --file-path DynamicContentTest.json --staging-status PUBLIC
   ```

6. Change your gameproperties.csv file message back to "LOCAL DATA" or its original message. Do this so that you can be sure that your updated message comes from the downloaded content.

Running the Test

After you have saved the gameproperties.csv file to reflect local data, you can run the test.

To test the dynamic content system

1. Start the DynamicContentTest level. When you start the level, you should see the most recent message that you entered in the game properties file ("LOCAL DATA" in step 6 of Data Preparation (p. 2178)).

2. Click Update. You should see the update in 3 to 10 seconds, depending on Lambda function latency.

Diagnosing Failures

When diagnosing a failure, you must determine how far your updated data went in the processing chain.

Check the .pak File for Upload

First, open the .pak file that was to be uploaded with 7-Zip or a similar utility. The file is in the location CloudGemSamples\DynamicContent\Paks\DynamicContentTest.shared.pak. The .pak file contains the .csv file that the end client should have received. If something is wrong with the .pak file, the packing process was faulty and should be repeated. If so, delete the .pak file. In your gameproperties.csv file, edit the message you want. Configure the DynamicContentManifest.json as indicated in the Data Preparation (p. 2178) section earlier in this document. Run the upload command again. Finally, recheck that your .pak file has the correct .csv file and data.

Check the Downloaded .pak File

If your local .pak file for upload is free of errors, check the file that was downloaded. The downloaded file is located in the directory for your game project (for example, CloudGemSamples\pc\user\dynamiccontent\paks\DynamicContentTest.shared.pak). Perform the same inspection on this file as you did for the file in the upload location. If the data is what you expect, the client did not receive the new data. This can occur because of a download failure, or because the data in the Amazon
S3 bucket is incorrect. You can use the AWS console to inspect the corresponding files in your Amazon S3 bucket.

If the downloaded .pak file was updated correctly, then the problem might be one of the following:

- The dynamic content system itself did not reload the file.
- The dynamic content system did not accept the new data. Check whether $sys_PakPriority$ is set to 0. In editor mode, you must set this to 1. For more information, see the Prerequisites (p. 2177) section earlier in this document.
- The test is not reflecting the file correctly and requires further diagnosis.

**Test Implementation Details**

Because DynamicContent and StaticData are system components, they do not have to be added to the entity in the test level. Since in most cases the dynamic content that Lumberyard loads would persist longer than any entity, the example here shows you how to use the SystemComponent. The entity in this level contains only Lua script and test logic.

1. In the script, the example connects to the EBus, loads the canvas, and waits for the button event.

   ```lua
   function DynamicContentTest:OnAction(entityId, actionName)
       Debug.Log("Received Action: ", actionName)

       if actionName == "ButtonPressed" then
           if DynamicContentRequestBus.Event == nil then
               Debug.Log("No Content Request Events found")
           return
           end
           DynamicContentRequestBus.Event.RequestManifest(SystemEntityId, "DynamicContentTest.json")
           self:UpdateText()
       end
   end
   ```

   When the button is pressed, the code requests the new manifest. The content specified by the manifest is automatically retrieved.
2. After the content is retrieved, a `NewPakContentReady` event fires.

```javascript
function DynamicContentTest:NewPakContentReady(outputFile)
    Debug.Log("Received pak update: " .. outputFile)
    self:UpdateGameProperties()
end
```

In the test example, you already know that the `.pak` file contains game properties data. In more complex implementations, you might need to query the contents of the file.

3. The `UpdateGameProperties()` function requests that the static data system load the `.csv` file.

```javascript
function DynamicContentTest:UpdateGameProperties()
    if StaticDataRequestBus:HasEventAdded(StaticDataRequestBus::Event_Nil)
        Debug.Log("No StaticData Request Events Found")
        return
    end
    StaticDataRequestBus:RequestAddEventForStaticData(StaticDataRequestBus::Event_LoadRelativeFile(SystemEntityId, "StaticData/CSV/gameproperties.csv")
end
```

4. The file load triggers the `TypeReloaded` event, which calls the `UpdateText()` function.

```javascript
function DynamicContentTest:TypeReloaded(outputFile)
    if outputFile == "gameproperties" then
        self:UpdateText()
    end
end
```

At this point, the user interface text has been updated with the new game property value.

5. Because the example attached to the `SystemComponent`, and the sample might be running in the editor, the cleanup routine manually removes the dynamic content.

```javascript
function DynamicContentTest:OnDeactivate()
    DynamicContentRequestBus:ClearAllContent(SystemEntityId)
    self.uiCanvasNotificationLuaBusHandler:Disconnect()
    self.dynamicContentUpdateBus:Disconnect()
    self.staticDataUpdateBus:Disconnect()
end
```

### Dynamic Content Engineering Details

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This topic provides programmatic details about the dynamic content update process. This includes manifest file information, Dynamic Content Cloud Gem EBus events, and Dynamic Content Cloud Gem service API. For information about the `lmbr_aws` CLI extensions enabled by the Dynamic Content Cloud Gem, see Using the Dynamic Content CLI (p. 2169).

#### Manifest File

In your Lumberyard installation, the default location of the manifest file is `<GameFolder>/AWS/DynamicContent/DynamicContentManifest.json`.

The following is a simple example manifest for the `SamplesProject` `DontDie` sample.
"Files": [ 
{ 
"hash": "3bebdb5bd88c79c42e5f7f3dc4e900", 
"outputRoot": "@user@", 
"bucketPrefix": "static-data", 
"keyName": "gameproperties.csv", 
"cacheRoot": "@assets@", 
"platformType": ", 
"localFolder": "staticdata/csv" 
} 
] 

The following table describes the properties in the manifest file.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hash</td>
<td>MD5 hash of the file.</td>
</tr>
<tr>
<td>outputRoot</td>
<td>Base output directory.</td>
</tr>
<tr>
<td>bucketPrefix</td>
<td>Prefix inside the bucket for the file</td>
</tr>
<tr>
<td>keyName</td>
<td>Name of the file key in the bucket, which will be appended to the beginning of the hash. The final key name has the format bucketPrefix/keyName.</td>
</tr>
<tr>
<td>cacheRoot</td>
<td>Root directory to search for copies of the outdated file asset.</td>
</tr>
<tr>
<td>platformType</td>
<td>Windows (pc), macOS (osx_gl), or Linux (linux). An empty value specifies all operating systems.</td>
</tr>
<tr>
<td>localFolder</td>
<td>Directory to write locally within the outputRoot. The full output has the format outputRoot/localFolder/keyName.</td>
</tr>
</tbody>
</table>

**EBus Events**

The Dynamic Content Cloud Gem provides an EBus API and includes calls exposed to Lua. The basic top-level update request looks like this:

```lua
CloudCanvas::DynamicContent::DynamicContentRequestBus::BroadcastResult(
    requestSuccess, 
    &CloudCanvas::DynamicContent::DynamicContentRequestBus::Events::RequestManifest, 
    manifestName)
```

requestSuccess (bool) – Specifies whether the request was successfully sent.

manifestName (char*) – Name of the manifest file (for example, DynamicContentTest.json). The system handles .pak file and operating system naming conventions (for example, DynamicContentTest.shared.pak).

**Requesting pak files without using manifest**

Use the following API calls to request pak files without using a manifest:

```lua
CloudCanvas::DynamicContent::DynamicContentRequestBus::BroadcastResult(
    requestSuccess, 
    &CloudCanvas::DynamicContent::DynamicContentRequestBus::Events::UpdateFileStatusList, 
    uploadRequests,
```
autoDownload);

requestSuccess (bool) – Specifies whether the request was successfully sent.

uploadRequests (AZStd::vector<AZStd::string>) – List of bucket keys.

autoDownload (bool) – Specify true to download files automatically.

CloudCanvas::DynamicContent::DynamicContentRequestBus::BroadcastResult(
    requestSuccess,
    &CloudCanvas::DynamicContent::DynamicContentRequestBus::Events::UpdateFileStatus,
    fileName,
    autoDownload);

requestSuccess (bool) – Specifies whether the request was successfully sent.

fileName (char*) – Name of the pak file to request.

autoDownload (bool) – Specify true to download files automatically.

Versioning Support

Requesting pak files using versioned manifest

Use the following API calls to request pak files using a manifest when versioning is enabled:

CloudCanvas::DynamicContent::DynamicContentRequestBus::BroadcastResult(
    requestSuccess,
    &CloudCanvas::DynamicContent::DynamicContentRequestBus::Events::RequestVersionedManifest,
    manifestName,
    versionId);

requestSuccess (bool) – Specifies whether the request was successfully sent.

manifestName (char*) – Name of the manifest file (for example, DynamicContentTest.json).

The system handles .pak file and operating system naming conventions (for example, DynamicContentTest.shared.pak).

versionId (char*) – Version ID of the manifest. Uses the current active (public) version if not specified.

CloudCanvas::DynamicContent::DynamicContentRequestBus::BroadcastResult(
    requestSuccess,
    &CloudCanvas::DynamicContent::DynamicContentRequestBus::Events::RequestVersionedFileStatus,
    fileName,
    outputFile,
    versionId);

requestSuccess (bool) – Specifies whether the request was successfully sent.

fileName (char*) – Name of the pak file to request.

outputFile (char*) – Name of the output pak file.

versionId (char*) – Version ID of the file. Uses the current active (public) version if not specified.

Requesting pak files without using manifest

Use the following API calls to request files without using a manifest when versioning is enabled:
requestSuccess (bool) – Specifies whether the request was successfully sent.

requestMap (AZStd::unordered_map<AZStd::string, AZStd::string>) – Map of file names to file version IDs.

autoDownload (bool) – Specify true to download files automatically.

requestSuccess (bool) – Specifies whether the request was successfully sent.

fileName (char*) – Name of the pak file to request.

autoDownload (bool) – Specify true to download files automatically.

versionId (char*) – Version ID of the file. Uses the current active (public) version if not specified.

Manifest Received
The following EBus events are triggered when a manifest has been received successfully or unsuccessfully.

Success

EBUS_EVENT(CloudCanvas::DynamicContent::DynamicContentRequestBus, ManifestUpdated, bucketName, bucketPrefix)

When all .pak files are complete, a RequestCompleted event is broadcast.

Failure

EBUS_EVENT(CloudCanvas::DynamicContent::DynamicContentRequestBus, ManifestFailed, bucketName, bucketPrefix, errorStr)

Service API
The Dynamic Content Cloud Gem exposes API calls through Amazon API Gateway for the game client.

The following table lists the calls.

<table>
<thead>
<tr>
<th>Client API Call</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/client/content POST</td>
<td>Request presigned URLs for a list of files, based on the provided version IDs. The active version will be returned if no version ID is specified. Returns the URLs or a failure message.</td>
</tr>
</tbody>
</table>
Using Amazon CloudFront

Amazon CloudFront is a fast content delivery network (CDN) service that can extend S3 to securely deliver data to customers with low latency and high transfer speeds at an additional cost. You can take advantage of it when using the DynamicContent gem. To learn more about Amazon CloudFront, read the Amazon CloudFront documentation.

Enable the CloudFront extension

To enable the Amazon CloudFront feature, add deployment tag `content-distribution` when you create a deployment with CloudGemDynamicContent enabled:

```bash
imbr_aws deployment create --deployment {deployment_name} --tags content-distribution
```

To learn how to create a project stack and deployment stack using CloudCanvas command line, read Using the Cloud Canvas Command Line.

Using this deployment tag will add a few more AWS resources to your deployment stack including a Amazon CloudFront distribution and an S3 bucket. All of the signed URLs from the DynamicContent gem will be created using Amazon CloudFront automatically after the feature is enabled.

Create and upload CloudFront key pairs

Each AWS account that you use to create Amazon CloudFront signed URLs or signed cookies—your trusted signers—must have its own Amazon CloudFront key pair, and the key pair must be active. This is required for using Amazon CloudFront with the DynamicContent gem. Read the AWS document Creating Amazon CloudFront Key Pairs for Your Trusted Signers to learn how to create your own key pairs.

Note that IAM users can't create Amazon CloudFront key pairs. You must log in using root credentials to create key pairs. To learn more about the root credentials, read The AWS Account Root User.

After you have created and downloaded the key pairs, upload your private key using the following CLI command:

```bash
imbr_aws dynamic-content upload-cf-key --key-path {path_to_private_key} --deployment-name {deployment_to_use}
```

The expected name format for your private key is `pk-<accountkey>.pem`. Your key will be securely stored in an S3 bucket called `AccessBucket`.

Invalidate files from CloudFront edge caches

By default, Amazon CloudFront caches a response from Amazon S3 for 24 hours. If your request lands at an edge location that served the Amazon S3 response within 24 hours, Amazon CloudFront uses the cached response even if you updated the content in Amazon S3. In this case, you may get outdated content after uploading the same named files.

When updating your content you can invalidate the cache for files being update by adding the `--invalidate-existing-files` argument to your CLI command:

```bash
imbr_aws dynamic-content upload-manifest-content --manifest-path {path_to_manifest} --deployment-name {deployment_to_use} --staging-status {staging_status} --invalidate-existing-files
```

You can also invalidate the cached response for a specific file using the following CLI command:

```bash
imbr_aws dynamic-content invalidate-file --file-path {file_name_in_s3_bucket} --caller-reference {unique_identity}
```

`--caller-reference` requires a value that you specify to uniquely identify an invalidation request. Amazon CloudFront uses the value to prevent you from accidentally resubmitting an identical request. If you make a second invalidation request with the same value for caller reference, and if the rest of the request is the same, Amazon CloudFront doesn't create a new invalidation request.
Game Metrics Cloud Gem

This cloud Gem is deprecated and no longer supported. Some functionality is broken because of its dependency on the Cloud Gem Portal, which was removed in Lumberyard 1.28. Complete documentation for this Gem from previous versions of Lumberyard can be found in the Documentation Archive.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Game Metrics cloud gem to collect event data on player behaviors, which you can then analyze or trigger event actions. This gem uses a service API with the Cloud Gem Framework for event submission, Amazon S3 for data storage, Amazon Athena as the query engine, and Amazon QuickSight as the data visualizer.

You can enable this gem to do the following:

- View realtime data about users playing the game.
- Run queries and generate reports on player behavior over time.
- Visualize player activity in the game world.
- Record player events, even if players are offline.

**Note**
The Game Metrics cloud gem is only supported in regions where FIFO is supported. For more information, see Amazon SQS FIFO (First-In-First-Out) Queues in the Amazon Simple Queue Service Developer Guide.

Example Overview

The following illustrates how AWS services process game events.

When events are generated from your game, the following occurs:

1. Events submitted by REST requests are first processed by the Amazon API Gateway Lambda handler called the `FIFO_producer` (producer). This producer breaks the request into smaller chunks in order to upload a maximum of 256KB per chunk, which is the maximum payload size an SQS message can support. Because the size of a single event, including attributes, can't exceed 256KB, the producer returns an error if an event exceeds this limit.
2. A Lambda process called the **FIFO_consumer** (consumer) processes the SQS messages.

3. The consumer is triggered every five minutes and self-replicates when one of the following conditions are met:
   - SQS queue growth exceeds 5%, which is checked every 15 seconds.
   - SQS queue count exceeds 3000 messages.

The consumer processes as many SQS messages as possible within its five minute lifespan, aggregates the events of the same type into a single parquet file, and then saves the file to a specific S3 key.

4. Another Lambda function called the **amoeba_generator** is triggered every 20 minutes and aggregates all files in a single key path into a single file. This process maximizes IO (input/output) performance when loading the files by the database. AWS Glue crawlers crawl the data bucket and identify a common schema; this schema defines the tables for Athena to use.

5. The S3 files are made available to Athena for querying through AWS Glue. AWS Glue updates Athena's database schema every hour. The S3 event data is partitioned (or indexed) by the hour. This means the lowest level of granularity when using Athena partitions is by the hour.

   **Note**
   Sending queries based on partitions can greatly reduce costs and improve query performance. For more information, see Partitioning Data in the Amazon Athena User Guide.

The Game Metrics cloud gem includes the following default Athena partitions:

<table>
<thead>
<tr>
<th>Partitions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_event_name</td>
<td>Name of the event.</td>
</tr>
<tr>
<td>p_server_timestamp_strftime</td>
<td>Server time stamp (UTC) of the event in the format %Y%m%d%H0000.</td>
</tr>
<tr>
<td>p_server_timestamp_year</td>
<td>Year of the server time stamp (UTC).</td>
</tr>
<tr>
<td>p_server_timestamp_month</td>
<td>Month of the server time stamp (UTC).</td>
</tr>
<tr>
<td>p_server_timestamp_day</td>
<td>Day of the server time stamp (UTC).</td>
</tr>
<tr>
<td>p_server_timestamp_hour</td>
<td>Hour of the server time stamp (UTC).</td>
</tr>
<tr>
<td>p_event_source</td>
<td>Data source of the event. The default value is &quot;cloudgemmetric&quot; or &quot;cloudgemdefectreporter&quot;.</td>
</tr>
<tr>
<td>p_client_build_identifier</td>
<td>Build identifier associated with the event.</td>
</tr>
<tr>
<td>p_data_sensitivity</td>
<td>Encryption level of the data.</td>
</tr>
<tr>
<td>p_event_schema_hash</td>
<td>Hash of the event schema.</td>
</tr>
</tbody>
</table>

**In-Game Survey Cloud Gem**

This cloud Gem is deprecated and no longer supported. Some functionality is broken because of its dependency on the Cloud Gem Portal, which was removed in Lumberyard 1.28. Complete documentation for this Gem from previous versions of Lumberyard can be found in the Documentation Archive.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the In-Game Survey Cloud Gem to create surveys for your game and test them in the InGameSurveySample. Your players can see active surveys and submit answers to them.

**Leaderboard Cloud Gem**

This cloud Gem is deprecated and no longer supported. Some functionality is broken because of its dependency on the Cloud Gem Portal, which was removed in Lumberyard 1.28. Complete documentation for this Gem from previous versions of Lumberyard can be found in the Documentation Archive.

You can use the Leaderboard cloud gem to create, view, and customize leaderboards by deleting scores, banning players, and removing bans.

**Message Of The Day Cloud Gem**

This cloud Gem is deprecated and no longer supported. Some functionality is broken because of its dependency on the Cloud Gem Portal, which was removed in Lumberyard 1.28. Complete documentation for this Gem from previous versions of Lumberyard can be found in the Documentation Archive.

You can use the Message of the Day Cloud Gem to schedule messages that your game consumes.

**Player Account Cloud Gem**

The Player Account Cloud Gem provides a standalone player authentication and management solution that uses Amazon Cognito. The cloud gem includes a player registration API, built-in two-step verification, and support for both anonymous and authenticated players. You can use the `lmbr_aws` CLI to administer players and manually register, delete, ban, and update their accounts.

**Legal Restrictions**

You are responsible for (a) providing legally adequate privacy notices to your end users; (b) obtaining any necessary consent from the end user for the collection, use, transfer, and storage of any name, password,
other login information, or personally identifiable information or personal data of any end user that you (or any third-party plug-in or service provider you use) may access; (c) using and authorizing others to access and use the information only for the purposes permitted by the end user; and (d) ensuring the information is collected, used, transferred, and stored in accordance with all laws, rules, and regulations applicable in jurisdictions in which your applications are used.

Using the Player Account Cloud Gem

Player accounts have the following automatic or required fields:

- **Amazon Cognito Identity ID** – The unique ID of the player in the Amazon Cognito database. This ID field is initially empty and is filled after the player signs in for the first time.
- **Account ID** – An automatically assigned ID.
- **User Name** – The Amazon Cognito user name, required during account creation.
- **Email** – The email of the player, required during account creation.
- **Account Status** – The current status of the account. The following statuses are possible:
  - **Archived** – The account has been archived due to inactivity. You can change this from the Amazon Cognito console.
  - **Compromised** – This account requires further investigation from Amazon Cognito console.
  - **Disabled** – The player account is currently disabled. You can reenable it on the Amazon Cognito console.
  - **Force Change Password** – An AWS administrator has used Amazon Cognito to create the player account, and the player now must change their temporary password before they can successfully sign in.
  - **Reset Required** – The player's account was imported, but the player has not logged in.
  - **Unconfirmed** – The player account hasn't confirmed the account's email address or phone number. The account is unusable until it has been confirmed.
  - **Unknown** – The account is in an unknown state. Use the Amazon Cognito console to investigate further.

In addition, this gem supports setting the following optional fields:

- **Player Name**
- **Family Name**
- **Given Name**
- **Nickname**
- **Gender**
- **Locale**

Only the **Username** and **Email** fields are required when creating a new player account. Validation is performed server-side using the OpenID Connect specification rules.

Use the `lmbr_aws player-account` (p. 2189) CLI commands to add, edit, confirm, ban, and show players in your game.

Using the Player Account CLI

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
When you enable the Player Account Cloud Gem, associated commands become available in the `lmbr_aws` CLI. You can then use these commands to perform player account operations.

The following `lmbr_aws` CLI extension commands are enabled by the Player Account Cloud Gem.

**player-account add-player**

Create a new player account in Amazon Cognito. Validation is performed server-side using the OpenID Connect specification rules.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- `--username <username>`
  Amazon Cognito username of the account to create.
- `--email <email_address>`
  Email address of the player.
- `--playername <player_name>`
  (Optional) Player name of the player.
- `--familyname <family_name>`
  (Optional) Family name of the player.
- `--givenname <given_name>`
  (Optional) Given name of the player.
- `--nickname <nickname>`
  (Optional) Nickname of the player.
- `--gender <gender>`
  (Optional) Gender of the player. The values "male" and "female" are defined by the OpenID Connect specification, but any value may be used.
- `--locale <locale>`
  (Optional) Locale of the player.

**player-account ban-player**

Ban a player account by account ID.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- `--account-id <account_id>`
  Account ID to ban.

**player-account confirm-player**

Confirm a player account whose status is "Unconfirmed" to make it usable.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- `--username <username>`
Amazon Cognito username of the account to confirm.

**player-account edit-player**

Edit the attribute values of a player account by account ID. Validation is performed server-side using the OpenID Connect specification rules.

In addition to the [Common Arguments](p. 2391), this command accepts the following arguments:

- **--account-id** `<account_id>`
  
  Account ID to edit.

- **--email** `<email_address>`
  
  (Optional) New email address for the player.

- **--playername** `<player_name>`
  
  (Optional) New player name for the player.

- **--familyname** `<family_name>`
  
  (Optional) New family name for the player.

- **--givenname** `<given_name>`
  
  (Optional) New given name for the player.

- **--nickname** `<nickname>`
  
  (Optional) New nickname for the player.

- **--gender** `<gender>`
  
  (Optional) New gender for the player. The values "male" and "female" are defined by the OpenID Connect specification, but any value may be used.

- **--locale** `<locale>`
  
  (Optional) New locale for the player.

**player-account remove-player-ban**

Remove the ban on a player account by account ID.

In addition to the [Common Arguments](p. 2391), this command accepts the following arguments:

- **--account-id** `<account_id>`
  
  Account ID for which the ban should be removed.

**player-account reset-player-password**

Reset the password for a player account by username.

In addition to the [Common Arguments](p. 2391), this command accepts the following arguments:

- **--username** `<username>`
  
  Amazon Cognito username of the account for which the password should be reset.
player-account show-banned-players

List all banned players.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

• --page-token <page_token>
  (Optional) The pagination token to get to the next page.

player-account show-logs

Show recent log events.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

• --minutes <minutes>
  (Optional) Display log events for the specified number of minutes before now. The default is 10 minutes.

player-account show-players

List all registered players, using optional filters.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

• --filter-type <AccountId | PlayerName | CognitoIdentity | CognitoUsername | CognitoEmail>
  (Optional) Type of filter to apply.
• --filter-value <filter_value>
  (Optional) String value to use for the filter.
• --page-token <page_token>
  (Optional) The pagination token to get to the next page.

player-account show-player-details

List account details for a player by account ID.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

• --account-id <account_id>
  Account ID for which to show details.

Testing the Player Account Cloud Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To test the Player Account Cloud Gem, you can use the CloudGemSamples project that is included with Lumberyard. This sample contains a level named PlayerAccountSample. The player account sample
level provides a menu from which players can create an account, verify their email addresses, sign in and out of their accounts, and recover their passwords by email.

The Player Account Sample Level

The following table describes the files for the player account sample level.

<table>
<thead>
<tr>
<th>Location</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\dev\CloudGemSamples \Levels \PlayerAccountSample</td>
<td>A level that contains an entity with the Lua script component.</td>
</tr>
<tr>
<td>\dev\CloudGemSamples \Scripts\PlayerAccount</td>
<td>The Lua scripts that manage the UI canvases and interact with the Player Account Cloud Gem's EBus API.</td>
</tr>
<tr>
<td>\dev\CloudGemSamples\UI \Canvases\PlayerAccount</td>
<td>The UI canvases displayed for the player.</td>
</tr>
</tbody>
</table>

Note that in the sample, UI canvases do not include functionality for displaying error messages graphically; instead, error messages are output to the console. If you integrate this gem into an existing project, you should use the UI canvas to show error messages. For example, you could do this when the confirmation code is incorrect or the password does not meet the minimum password length. For more information on using the Player Account Cloud Gem in an existing project, see Integrating the Player Account Cloud Gem into an Existing Project (p. 2196).

The following diagram shows how the UI canvases are connected. For more information on the Amazon Cognito user pool signup process, see the Signing Up and Confirming User Accounts page in the Amazon Cognito Developer Guide.

Prerequisites

This tutorial assumes the following:

- You are using a Lumberyard project that has **Cloud Gem Player Account** enabled.
- You have created a project stack in Cloud Canvas Resource Manager (p. 2110).
- You have a deployment stack with Player Account Cloud Gem resources in Cloud Canvas Resource Manager.
If you don’t meet the prerequisites, follow the steps in Enabling Gems (p. 1064) to add Cloud Gem Player Account in the Project Configurator. For information on creating a project stack and a deployment stack, see Tutorial: Getting Started with Cloud Canvas (p. 2116).

**PlayerAccountSample Tutorial**

To test the Player Account Cloud Gem

1. In the Project Configurator, select the CloudGemSamples project.
2. Start Lumberyard Editor.
3. On the Welcome to Lumberyard Editor screen, click Open level, Levels, PlayerAccountSample, Open.
4. Click AWS, Cloud Canvas, Select a Deployment.
5. Click the deployment that you want to use, and then click OK.
6. Press Ctrl+G to start the game.
7. In the main menu of the sample, click Create Account.

![Player Account Menu](image)

**Note**

If the Create Account option does not appear, click Sign Out and try again.

8. Enter a user name, password, and an email account to which you have access.

```
Username: TestUser
Password: ********
Email: 
```

9. Click Create.
10. From the email account, copy the confirmation code that you receive.
11. In Lumberyard, paste the confirmation code into the Verification Code box, and then click Verify.

```
Username: TestUser
Verification Code: 123456
```

Version 1.28

2194
12. Sign in using the password that you specified earlier. This tests the custom authentication flow.

13. Click **Manage Account**.

The main menu displays the player name that you specified.

14. Click **Edit Account**.

15. Type in a name for **Player Name**, and then click **Save**. This step tests the player service API.
16. Press ESC to stop the game.

17. Open a command prompt to your Lumberyard dev directory.

18. Use the `show-players` command to verify the player has been created.

```bash
$ lmbr_aws player-account show-players
```

```json
{
    "AccountId": "b8103676-1234-5678-9abc-def012345678",
    "CognitoUsername": "TestUser",
    "IdentityProviders": {
        "Cognito": {
            "IdentityProviderId": "Cognito",
            "create_date": 1613433006.709,
            "email": "mary@example.com",
            "enabled": True,
            "gender": "None",
            "last_modified_date": 1613433006.709,
            "status": "FORCE_CHANGE_PASSWORD",
            "username": "Mary Major"
        }
    }
}
```

19. Use the `edit-player` command to change the player name, to test the administrative service API. Replace the account ID shown in the example below with the actual account ID from the output of the previous step.

```bash
$ lmbr_aws player-account edit-player --account-id b8103676-1234-5678-9abc-def012345678 --playername "Major Mary"
```

20. Use the `show-player-details` command to verify the change in the profile for the player. Replace the account ID shown in the example below with the actual account ID of the player used in the previous step.

```bash
$ lmbr_aws player-account show-player-details --account-id b8103676-1234-5678-9abc-def012345678
```

Integrating the Player Account Cloud Gem into an Existing Project

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To integrate the Player Account Cloud Gem into an existing project, you must enable the Player Account Cloud Gem, update your deployment stack, and integrate the gem into your game menu.
To integrate the Player Account Cloud Gem into an existing project

1. Enable the gem. In the Project Configurator, click **Cloud Gem Player Account**.

2. **Create or update the project stack (p. 2350).**

   The Player Account Cloud Gem uses an Amazon Cognito user pool.

3. **Create or update the deployment stack (p. 2352).** Be sure the CloudGemPlayerAccount resource group is added to your deployment. If your deployment doesn't have the CloudGemPlayerAccount resource group, make sure that the Cloud Gem Player Account gem is enabled in the Project Configurator.

4. At a command prompt, enter the following command to update the deployment access stack.

   ```
   lmbr_aws deployment update-access
   ```

   This ensures that the CloudGemPlayerAccount resource group is correctly linked to the PlayerAccess identity pool in the deployment access stack.

5. Integrate the gem into your game menu. We recommend that you include the following features:

   - **A global signout** – This security feature allows players to invalidate an account's tokens across all devices if a device has been lost or stolen. The sample level shows how to offer this as a standalone feature. If the previous password was compromised and already used to obtain authentication tokens, you can also have the menu automatically globally sign out after a password change. To implement this functionality, do the following:
     1. Monitor the CloudGemPlayerAccountNotifications::OnChangePasswordComplete EBus event.
     2. When you receive confirmation that the password change has succeeded, send the following event.

       ```
       EBUS_EVENT(CloudGemPlayerAccountRequestBus, GlobalSignOut, username)
       ```

   - **Email verification** – An email verification step ensures that email can be used to recover account access if a password has been forgotten. You can customize the content of the verification emails by using Lambda triggers. To add a new Lambda trigger to the AWS CloudFormation template, use the LambdaConfig property of PlayerUserPool in the dev\Gems\CloudGemPlayerAccount\AWS\resource-template.json file. For more information, see Customizing User Pool Workflows by Using AWS Lambda Triggers.

Building the Menus for the Player Account Cloud Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To build the menus, use the code for CloudGemPlayerAccountRequestBus and CloudGemPlayerAccountNotificationBusHandler in the dev\Gems\CloudGemPlayerAccount\Code\Include\CloudGemPlayerAccount\CloudGemPlayerAccountBus.h file. Keep in mind the following points:

- Most of the EBus events are wrappers for Amazon Cognito user pool API operations. For the Amazon Cognito API reference, see Amazon Cognito Identity Provider.
• To return the user name for the currently logged-in player, call the `GetCurrentUser` function, which has a corresponding `OnGetCurrentUserComplete` event. This function and EBus event are not part of the Amazon Cognito user pool API but are needed for most calls to the API.

• The `GetCurrentUser` function also loads the credentials that were returned and caches them inside the gem's system component. As a result, subsequent calls to `GetCurrentUser` are faster.

• The act of signing in also caches the player's credentials inside the gem's system component.

For information about Player Account Cloud Gem functions for creating accounts, password recovery, signing in and out, and account management, see Player Account Cloud Gem Implementation Details (p. 2199).

Storing Data Associated with a Player Account

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Each player account has a randomly generated account ID. When you store data associated with a player, use this ID instead of the identifiers provided by the Amazon Cognito user and identity pools. You should do this for the following reasons:

• Lumberyard uses the `PlayerAccounts` table defined in the `dev\Gems\CloudGemPlayerAccount\AWS\resource-template.json` file to map account IDs to Amazon Cognito IDs. By associating a player's data with the account ID, you can move all of the player's data from one identity to another by simply updating the mapping.

• The Amazon Cognito ID on the Amazon Cognito identity pool is not guaranteed to stay the same for a particular player. For example, it can change if identities are merged. Amazon Cognito identity pools are public facing and do not prevent the merging of identities.

• If you configure the `PlayerAccess` identity pool to support identity providers other than the Amazon Cognito user pool, the user pool's user name cannot be used for players that use another provider.

• If a user name is deleted from the Amazon Cognito user pool, the name can be reused. Amazon Cognito user pools are publicly visible and do not prevent a player from deleting his or her own user name.

A `PlayerName` field is provided in the `PlayerAccounts` table as an example of how to store player data for an account. The Amazon Cognito user pool supports storing a variety of attributes and could also be used for storing player data. However, this is not recommended if you configure the `PlayerAccess` identity pool to use more than one identity provider. In such a scenario, some players might not have a user in the Amazon Cognito user pool.

**Warning**
Do not store the data for unauthenticated (guest or anonymous) players who are using an Amazon Cognito ID directly or indirectly on the server. The reasons not to store this data are the following:
• A person who knows the Amazon Cognito ID for an unauthenticated account can claim the identity by linking it to a user that the person controls. The identity's original owner cannot recover the account if an original device is lost or the identity is stolen. For more information on identity pools, see Identity Pools.

• The local copy of the unauthenticated Amazon Cognito ID is overwritten with a new one when the player logs in and out.

• The player has no way to recover an unauthenticated Amazon Cognito ID after it has been overwritten locally. The identity still exists in the identity pool, but the identity and data associated with its Amazon Cognito ID effectively become orphaned.

• The buildup of orphaned identities can be misleading when trying to determine the actual number of players.

• If a player uses an unauthenticated identity and then creates a new account, the account ID from the unauthenticated identity does not carry over to the new account.

**Obtaining Player Account IDs**

You can use the following techniques to obtain player account IDs and account information programmatically.

**To get a player's account ID in game** – Call GetPlayerAccount on the CloudGemPlayerAccountRequestBus. This EBus is defined in the dev\Gems\CloudGemPlayerAccount\Code\Include\CloudGemPlayerAccount\CloudGemPlayerAccountBus.h file. The player's account ID is in the AccountResultInfo parameter of CloudGemPlayerAccountNotificationBusHandler::OnGetPlayerAccountComplete.

**To get the account ID from a Lambda function located behind an API Gateway** – Because Amazon API Gateway provides the Amazon Cognito ID to the Lambda function, the Lambda function can look up the account ID. To quickly look up the account ID, you can use the global secondary index CognitoIdentityIdIndex of the PlayerAccounts table. The PlayerAccounts table is defined in the dev\Gems\CloudGemPlayerAccount\AWS\resource-template.json file.

**To get the caller's account information without relying on the caller to provide its account ID** – Use the request's authentication parameters. For an example, see the code in the dev\Gems \CloudGemPlayerAccount\AWS\lambda-function-code\api\account.py file.

**Player Account Cloud Gem Implementation Details**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the API operations described on this page to manage player accounts with the Player Account Cloud Gem (p. 2188).
Functions and Callbacks

Most functions for the Player Account Cloud Gem have a corresponding callback that supplies the results of the call. The results contain the information gathered or error information. To make calls to and receive responses from player registration and login component API operations, you use the EBus (p. 1851).

The callbacks use this naming convention: For every function X, the corresponding callback function is named OnXComplete. For example, when a response to an EBus call of SignUp() is ready, the response is sent through the EBus to OnSignUpComplete(). For more examples, see dev\Gems\CloudGemPlayerAccount\Code\Include\CloudGemPlayerAccount \CloudGemPlayerAccountBus.h.

HasCachedCredentials() is an exception to this convention because it is a synchronous call and has no corresponding handler.

Functions for Key Player Account Cloud Gem Tasks

You can use the functions described in this section for new account creation, password recovery, player sign-in, and account management. Most of the source code for the classes and functions can be found in the Lumberyard directory dev\Gems\CloudGemPlayerAccount\Code\Source.

Creating an Account (CloudGemPlayerAccountBus)

Use the following functions for creating new accounts.

SignUp(username, password, attributes)

Creates an account. The attributes parameter contains relevant data (for example, email, address, name, and profile). A confirmation email or text message is sent to the player as part of the signup. Password recovery requires a valid email address.

OnSignUpComplete(resultInfo, deliveryDetails, wasConfirmed)

A callback function that returns the results (p. 2201) of the signup. The deliveryDetails (p. 2202) attribute contains details about where the confirmation code was sent.

ResendConfirmationCode(username)

Resends the confirmation code to the player. The confirmation code received from the player is passed as an argument to ConfirmSignUp(username, confirmationCode).

Password Recovery (CloudGemPlayerAccountSystemComponent)

Use the following functions if a player has forgotten a password and has an account with a valid email or phone number.

ForgotPassword(username)

Causes a confirmation code to be sent to the player.

OnForgotPasswordComplete(resultInfo, deliveryDetails)

Contains information regarding the password reset.

ConfirmForgotPassword(username, password, confirmationCode)

Receives the confirmation code, user name, and new password from the player and sets the new password.

Sign In and Sign Out

Use the following functions to sign players in and out of your game.
InitiateAuth(username, password)

Call this function to sign in players. Sign-in is a two-step process. When InitiateAuth finishes, the server issues a challenge to which the client must respond correctly. Currently, authorization by username and password is supported; MFA and other forms of additional authentication are not.

You have two ways to sign out: SignOut(username) and GlobalSignOut(username).

SignOut

Clears all cached authentication information from memory, so that the player's credentials are essentially forgotten. No server-side changes occur, so the authentication information, if it were known, could still be used. The SignOut function always succeeds, even if the player is not actually signed in.

GlobalSignOut

Invalidates all access and refresh tokens for the player on all devices that the player might be signed into. Unlike SignOut, GlobalSignOut can succeed only when the player is signed in.

Account Management (CloudGemPlayerAccountSystemComponent)

All of the following functions require that the player be signed in.

ChangePassword(username, previousPassword, proposedPassword)

Allows a player to update a password without the use of a confirmation code.

DeleteOwnAccount(username)

Deletes the player's account. Use this function with caution.

GetUser(username)

Retrieves attributes (for example, email, address, name, and profile) that have been associated with the player's account.

UpdateUserAttributes(username, attributes)

Updates the specified set of attributes. If any updates require verification, confirmation codes are sent. Details are found in the deliveryDetailsArray parameter that is passed to OnUpdateUserAttributesComplete. Note that it is possible to update attributes that previously did not have any associated information.

VerifyUserAttribute(username, attributeName, confirmationCode)

Following a call to UpdateUserAttributes, verifies a single attribute that requires confirmation. Most attribute updates do not require verification.

DeleteUserAttributes(username, attributesToDelete)

Removes the specified set of attributes from the player's account. The attributes can be added again with a call to UpdateUserAttributes.

Key Player Account Cloud Gem Classes and Functions

This section describes key classes and functions in the Player Account Cloud Gem.

BasicResultInfo Class

The BasicResultInfo class bundles together information returned in almost all responses from the component. The class has no functions to be used at run time and contains the following values, which are public:
wasSuccessful

A Boolean that indicates whether the request succeeded.

username

The name of the player for which a request was made.

errorTypeName

The name of the error type.

errorTypeValue

The numeric value of the error type. If errorTypeValue is greater than or equal to 0, it corresponds to a standard CognitoIdentityProviderErrors value. Otherwise, an unexpected error occurred. Most commonly, the player has not yet signed in for the operation. In this case, see the error information in errorTypeName for details.

errorMessage

A human readable string that describes the error.

DeliveryDetails Class

The DeliveryDetails class provides details related to the sending of confirmation codes to the player. It contains the following string functions:

GetAttributeName()

The name of the attribute for which a confirmation code was sent (for example, email).

GetDeliveryMedium()

The medium used to send the confirmation code (for example, EMAIL).

GetDestination()

The destination to which the confirmation code was sent. The destination is partially obscured for security (for example, d***@a***.com).

DeliveryDetailsArray Class

The DeliveryDetailsArray class is a collection of DeliveryDetails objects and contains the following functions:

GetSize()

The number of DeliveryDetails objects in the array.

At(index)

Returns a copy of the object at the specified index.

UserAttributeValues Class

UserAttributeValues maps attribute names like address, email, and family_name to attribute values. An attribute value can be a string up to 256 characters. In general, the attributes are those used by the OpenID Connect specification. See the UserAttributeValues.h file for details.

Phone numbers must follow these formatting rules:
• The phone number must start with a plus (+) sign, followed immediately by the country code.
• The phone number can contain only the + sign and digits.
• You must remove characters such as parentheses, spaces, or dashes from the phone number before submitting the value. For example, a United States–based phone number must follow the format +14325551212.

Resource Group

The Player Account Cloud Gem uses an Amazon Cognito user pool that contains all registered players. It is set as an authentication provider with PlayerAccessIdentityPool. For more information, see Controlling Access to Resources (p. 2370).

Speech Recognition Cloud Gem

This cloud Gem is deprecated and no longer supported. Some functionality is broken because of its dependency on the Cloud Gem Portal, which was removed in Lumberyard 1.28. Complete documentation for this Gem from previous versions of Lumberyard can be found in the Documentation Archive.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Speech Recognition Cloud Gem to add speech recognition and natural language processing to your Lumberyard game. The Speech Recognition Cloud Gem uses the Amazon Lex service, which recognizes the intent of spoken player input so that your game can react accordingly. Your players can use natural language and do not have to memorize or use specific phrases to initiate commands.

Text to Speech Cloud Gem (Using Amazon Polly)

This cloud Gem is deprecated and no longer supported. Some functionality is broken because of its dependency on the Cloud Gem Portal, which was removed in Lumberyard 1.28. Complete documentation for this Gem from previous versions of Lumberyard can be found in the Documentation Archive.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Text-to-Speech (TTS) Cloud Gem to enhance your gameplay and workflows with synthesized speech. The Cloud Canvas Text-to-Speech (TTS) Cloud Gem uses Amazon Polly, which is a text-to-speech service that turns text into lifelike speech. Amazon Polly offers dozens of lifelike voices in a variety of languages. The service also creates lip synchronization from the text that you provide. You can import the generated audio and speech mark files into your dialogue system. Currently, the Text-to-Speech Gem supports playback of PCM (pulse-code modulation) files.

You can use the text-to-speech service in two ways:

• You can prepackage speech content and include it with your game so that your clients can access it immediately.
- Your clients can invoke the Amazon Polly service to provide text to speech while your game is running.

In the first approach, you prepare voices and dialogues that players require and store them on the client. This removes the need for the client to connect to the backend to generate and download lines that are known to be necessary. The trade-off is that the client must store the files locally.

**Web Communicator Cloud Gem**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Web Communicator cloud gem to inform your game's connected clients, editors, or servers of events from other cloud gems. Your game clients, editors, or servers can use this information to take action (such as updating themselves) without restarting or polling AWS services for updates.

The following diagram shows how the Web Communicator cloud gem connects cloud gems like Dynamic Content to the receivers of the events.

Cloud gems like Dynamic Content send events through Lumberyard's cross-gem communication system (p. 2319) to the Web Communicator cloud gem. The Web Communicator cloud gem sends the event to the client through AWS IoT, which maintains a persistent socket connection with the client. Your game can use this channel of communication to notify the client that new content is available. The client can then download the new content or update itself as needed.
Note
You can publish and receive from your game client, editor, or server. However, to reduce potential expenses, the default implementation on all channels is receive only.

Publishing Messages

You can publish messages directly through AWS IoT or send them through the Web Communicator API first for validation. Each method is useful for the following applications:

- **Directly through AWS IoT** – For communication between trusted parties (for example, from editor to editor).
- **Web Communicator API** – For game client messages that require validation before publishing.

You can use the AWS IoT console or the game client to subscribe and listen to messages. For more information on using this console to view messages, read View MQTT messages with the AWS IoT MQTT client. You can use the `lmbr_aws web-communicator list-channels` and `list-users` commands to find the subscription topic to listen to.

User ID and Status Table

The Web Communicator cloud gem supports a simple DynamoDB table that records the Amazon Cognito Identity and status of registered users. The `lmbr_aws` CLI provides commands to list users and modify their status. Setting a user’s status to “banned” revokes the user’s AWS IoT policy and prevents the user from connecting or receiving further messages.

Connection Types

The Web Communicator cloud gem can use WebSocket or OpenSSL connections.

WebSocket Connections

Web Communicator uses WebSocket connections and Amazon Cognito identities by default. WebSocket connections, which use Message Queuing Telemetry Transport (MQTT) clients and AWS Signature Version 4, attach the AWS IoT policy to the Amazon Cognito Identity of the user. AWS Signature Version 4 is a protocol for authenticating inbound API requests to AWS services over WebSocket connections. For more information, see Authenticating Requests (AWS Signature Version 4) in the AWS General Reference.

For samples of Amazon Cognito and AWS IoT policies that Web Communicator creates, see Web Communicator Cloud Gem Authentication and AWS Policies.

OpenSSL Connections

OpenSSL connections, which are commonly used for embedded devices, use the MQTT protocol and certificate authentication. In OpenSSL connections, each device has a certificate and a private key that are used for encrypted communications.

You can use the `lmbr_aws web-communicator register-client` command to generate the certificates and keys that OpenSSL requires. The client can connect through OpenSSL after the certificates and keys are installed in the `@user@certs/aws` directory. The Web Communicator service attaches the appropriate policy to the certificate. The certificate and private key are returned to the client and cached on the client.

Note
By default, only WebSocket connections can be registered directly from the client. This behavior can be changed in the `client_request.py` request_registration call.
AWS IoT Pricing

AWS IoT prices connectivity per million minutes of connection or per device per year. Message pricing is per million messages and decreases with volume pricing. For more information, see AWS IoT Core Pricing.

Topics

- Using the Web Communicator CLI (p. 2206)
- Testing the Web Communicator Cloud Gem (p. 2207)
- Communicating to Clients from a Cloud Gem (p. 2213)
- Web Communicator Cloud Gem Authentication and AWS Policies (p. 2218)
- Web Communicator Cloud Gem Service API (p. 2219)

Using the Web Communicator CLI

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When you enable the Web Communicator Cloud Gem, associated commands become available in the `lmbr_aws` CLI. You can then use these commands to register and manage client connections, and send messages to those clients.

The following `lmbr_aws` CLI extension commands are enabled by the Web Communicator Cloud Gem.

**web-communicator list-channels**

List all existing channels.

The Common Arguments (p. 2391) can also be used with this command.

**web-communicator list-users**

List all existing users.

The Common Arguments (p. 2391) can also be used with this command.

**web-communicator register-client**

Register an OpenSSL or WebSocket client connection. Saves the device cert, port, endpoint, and private keys to the following files in the current or specified folder:

- `webcommunicatorkey.pem`
- `webcommunicatordevice.pem`
- `deviceInfo.json`

These files should be placed in the user storage directory for your application or platform. For example, on a PC, the directory is `lumberyard_version\dev\Cache\project_name\pc\user\certs\aws`.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

- `--type <OPENSSL | WEBSOCKET>`
  
  Type of connection to register.
• --path <folder_path>
  (Optional) Output folder in which to save the registration files. Defaults to the current directory.

**web-communicator send-message**

Send a message to all clients on a channel, or to a specific user.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

• --channel-name <channel>
  Channel name on which to send the message.
• --message <message>
  Message to broadcast. Maximum 1024 characters.
• --client-id <client_ID>
  (Optional) Amazon Cognito account ID of the client to whom the message should be sent. If this is omitted, the message will be broadcast to all clients on the channel.

**web-communicator set-user-status**

Set the user status of a client to either "banned" or "registered".

• --client-id <client_ID>
  Amazon Cognito account ID of the client for which the status should be set.
• --status <REGISTERED | BANNED>
  Status to set.

**web-communicator show-logs**

Show recent log events.

In addition to the Common Arguments (p. 2391), this command accepts the following arguments:

• --minutes <minutes>
  (Optional) Display log events for the specified number of minutes before now. The default is 10 minutes.

**Testing the Web Communicator Cloud Gem**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To perform a simple test of the Web Communicator cloud gem, you can use the CommunicatorSample level that is included with Lumberyard.

**Prerequisites**

This tutorial assumes the following:
Lumberyard User Guide Lumberyard User Guide
Cloud Gems

- Your Lumberyard project has the Web Communicator and Player Account cloud gems enabled (in the Project Configurator, choose Cloud Gem Web Communicator and Cloud Gem Player Account).
- You used the Cloud Canvas Resource Manager or the lmbr_aws command line tool (p. 2390) to create the following:
  - A project stack (p. 2350) for your project.
  - A deployment (p. 2352) for your project that includes the CloudGemWebCommunicator and CloudGemPlayerAccount resource groups.
- You have an email account for testing.

Test Workflow Summary

The test workflow uses the PlayerAccountSample level, the CommunicatorSample level, and the AWS IoT management console in the following ways:

A. PlayerAccountSample – To create an player account (authenticated identity) for testing. Web Communicator uses authenticated identities by default.
B. CommunicatorSample – To register a WebSocket, connect the WebSocket, and request a channel list.
C. AWS IoT management console – To publish a test message that appears in the CommunicatorSample level.

Test Workflow Steps

The following sections describe each of the workflow steps in detail.

A. Using PlayerAccountSample to Create a Player Account

In this step, you use the PlayerAccountSample level to create a player account and sign in with it.

To create a player account for the test

1. Follow Testing the Player Account Cloud Gem (steps 1-11) to create a player account. To verify the account, submit the verification code that is emailed to you.
2. With the PlayerAccountSample level still running, sign in to the PlayerAccountSample level with the credentials that you created (Testing the Player Account Cloud Gem step 12).
3. Press ESC to exit the level.

B. Using CommunicatorSample to Register and Connect a Websocket

In this step, register and connect a Websocket that can receive messages from AWS IoT.

To register and connect a Websocket

1. In Lumberyard Editor, choose File, Open.
2. In the Open a Level dialog box, choose CommunicatorSample, and then click Open. If you are using a launcher and need to restart, your authenticated identity should be found on startup.
3. Press Ctrl+G to start the level. The sample level looks similar to the following image.
4. Click **Register WebSocket**.

The status changes to **Registered**.

5. Click **Connect WebSocket**.
6. Click **Request List**.

The status changes to **Connected**.
Your test channels are listed in the sample level user interface.

7. Leave the CommunicatorSample level running.

Now that you have registered and connected a WebSocket, you are ready to test it.

C. Using the AWS IoT Management Console to Publish a Test Message

In this step, you send a test from the message AWS IoT console to the CommunicatorSample level.

To send a test message to the CommunicatorSample level

1. Do one of the following:
   * Press Alt+Tab to change to your browser.
   * Open a browser on another computer that has internet access.

2. In your browser, sign in to the AWS Management Console with the AWS credentials that you used to create your project stack and deployment.

3. Choose Services, Internet of Things, IoT Core to open the AWS IoT console.

4. In the left navigation pane of AWS IoT console, choose Test.
5. Navigate to the **Publish** section at the bottom of the page.

Publish

Specify a topic and a message to publish with a QoS of 0.

cgs624803/dep/CloudGemWebCommunicator

```
{
  "Channel": "CloudGemWebCommunicator",
  "Message": "This is a test"
}
```
6. In the **Publish** section, enter the following information:

   a. For **Specify a topic**, specify your channel as `project_name/deployment_name/CloudGemWebCommunicator` (for example, `cgs624803/dep/CloudGemWebCommunicator`).

   b. For **Message**, add a message that uses the following syntax:

   ```json
   {      
   "Channel":"CloudGemWebCommunicator",      
   "Message":"This is a test"      
   }
   ```

7. Choose **Publish to topic**.

8. Return to the CommunicatorSample level to see the results. If you are on the same computer, press **Alt+Tab** to return to Lumberyard Editor.

   The sample level shows the message that you sent from AWS IoT.

   ![Communicating to Clients from a Cloud Gem](image)

**Communicating to Clients from a Cloud Gem**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To send messages to the Web Communicator service, your cloud gem can use the default channel that the Web Communicator cloud gem provides or a channel that you define. Web Communicator can validate the message type and pass the message to AWS IoT for distribution to one or more clients.

**Note**

Because the caller of a cross-gem request cannot be identified, any cloud gem can make a request to broadcast on any valid channel. For this reason, you should consider the behavior of any gems in your project that implement cross-gem communication.

To have your cloud gem send events through Web Communicator to connected clients, perform the following steps:

1. (Optional) Define Broadcast and/or Private Channels (p. 2214)
2. Add the Web Communicator Service Interface ID to Your Gem’s resource-template.json File (p. 2214)

3. Send the Lambda Request from Your Service (p. 2215)

4. Handle the Response on the Client (p. 2216)

1. (Optional) Define Broadcast and/or Private Channels

You can optionally define your own channels in your cloud gem’s resource-group-settings.json file. A channel consists of a unique name, a type (BROADCAST or PRIVATE) and an optional CommunicationChannel. To reduce the number of subscriptions required on the server, the communication channel system allows your channel to make use of a base channel by embedding your actual channel name in the message. When messages are broadcast from other cloud gems as EBus (p. 1851) events, the channel name is embedded in the message and parsed on the client.

To declare broadcast and/or private channels, add them to your cloud gem's resource-group-settings.json file in the GemSettings, CloudGemWebCommunicator, Channels section. The following example is from the Dynamic Content (p. 2155) cloud gem.

```json
{
   "GemSettings":
   {
      "CloudGemWebCommunicator":
      {
         "Channels":
         [
            {
               "Name": "CloudGemDynamicContent",
               "Types": ["BROADCAST","PRIVATE"],
               "CommunicationChannel": "CloudGemWebCommunicator"
            }
         ]
      }
   }
}
```

The relevant fields are as follows.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Specifies the name of the channel.</td>
</tr>
<tr>
<td>Types</td>
<td>The type of channel that you want to enable. This can be BROADCAST, PRIVATE, or both.</td>
</tr>
<tr>
<td>CommunicationChannel</td>
<td>The name of the base WebCommunicator channel (for example, CloudGemWebCommunicator). For purposes of efficiency, the channel that actually carries the message is packed into the base channel. The name of the carried channel (in this example, CloudGemDynamicContent) is embedded in the message itself. Lumberyard unpacks this name transparently on the client side for the EBus handler.</td>
</tr>
</tbody>
</table>

2. Add the Web Communicator Service Interface ID to Your Gem’s resource-template.json File

The request API between your cloud gem and the Web Communicator gem is built on the cross-gem communication system (p. 2319). The interface for the Web Communicator's broadcast and send API operations are defined in the lumberyard_version\dev\Gems\CloudGemWebCommunicator\AWS\api-definition\sendmessage_1_0_0.json file.
To make this interface callable from your cloud gem's service Lambda function, you add an InterfaceID property to the lumberyard_version\dev\Gems\gem_name\AWS\resource-template.json file.

In the ServiceLambdaConfiguration section, under Properties, add a Services section entry like the following.

```
"Services": [
  {
    "InterfaceId": "CloudGemWebCommunicator_sendmessage_1_0_0",
    "Optional": "True"
  }
]
```

**Note**

If you expect the Web Communicator to be continuously available, set the Optional property to False.

For more information, see the Using an Interface (p. 2322) section of the cross-gem communication topic.

### 3. Send the Lambda Request from Your Service

To send a message from your cloud gem to one or more clients, your cloud gem's Lambda code makes a call to the Web Communicator. The call includes the message that you want to either broadcast to multiple clients or send to an individual user.

First, in the Python module from which you want to make the messaging request, specify the following import statements.

```
import cgf_lambda_settings
import cgf_service_client
```

#### Broadcasting a Message

To broadcast a message, use the `__send_communicator_broadcast` function and pass the message text in the message parameter, as in the following example.

```python
def __send_communicator_broadcast(message):
    interface_url =
    cgf_lambda_settings.get_service_url("CloudGemWebCommunicator_sendmessage_1_0_0")
    if not interface_url:
        print('Messaging interface not found')
        return

    client = cgf_service_client.for_url(interface_url, verbose=True, session=boto3._get_default_session())
    result = client.navigate('broadcast').POST({"channel": "CloudGemDynamicContent", "message": message})
```

#### Sending a Message Directly to a Client

To send a message directly to a client, use the `__send_communicator_direct` function. As before, pass the message text in the message parameter, but this time specify the ID of a specific client in the client_id parameter.

```python
def __send_communicator_direct(message, client_id):
    interface_url =
    cgf_lambda_settings.get_service_url("CloudGemWebCommunicator_sendmessage_1_0_0")
    if not interface_url:
print('Messaging interface not found')
return

client = cgf_service_client.for_url(interface_url, verbose=True,
session=boto3._get_default_session())
result = client.navigate('send', client_id).POST({"channel": "CloudGemDynamicContent",
"message": message})

4. Handle the Response on the Client

To handle the response on the client, subscribe manually or automatically to messages from Web Communicator, and then create a handler that processes the incoming messages.

Requesting a Connection

To request a connection, use the RequestConnection function.

CloudGemWebCommunicatorRequestBus.Broadcast.RequestConnection("connection_type")

For connection_type, specify either WEBSOCKET or OPENSSL.

Requesting a Registration

To request a registration, use the RequestRegistration function.

CloudGemWebCommunicatorRequestBus.Broadcast.RequestRegistration("connection_type")

For connection_type, specify either WEBSOCKET or OPENSSL.

Subscribing to Channels

You can use the RequestChannelList function to request and subscribe to the channels to which the client listens.

Subscribing to All Channels

To request and subscribe to all the channels that the client requires, use the RequestChannelList function.

CloudGemWebCommunicatorRequestBus.Broadcast.RequestChannelList()

You can also subscribe individually to channels, but using the RequestChannelList function is more straightforward and should be considered the standard approach.

Subscribing to Individual Channels

To subscribe to channels manually, use the RequestSubscribeChannel function and specify the name of the channel in the channelName parameter, as in the following example.

CloudGemWebCommunicatorRequestBus.Broadcast.RequestSubscribeChannel(channelName)

Note

If you specified the CommunicationChannel property in the channel definitions step (p. 2214) (that is, you are using a base channel), specify that value for the channelName parameter.

Unsubscribing from a Channel

To unsubscribe from a channel, use the RequestUnsubscribeChannel function and specify the name of the channel in the channelName parameter, as in the following example.
CloudGemWebCommunicatorRequestBus.Broadcast.RequestUnsubscribeChannel(channelName)

**Disconnecting**

To disconnect, use the `RequestDisconnect` function.

CloudGemWebCommunicatorRequestBus.Broadcast.RequestDisconnect()

**Create a Message Handler**

After you subscribe the client to one or more channels, create a message handler that processes the messages from Web Communicator.

**In Lua**

In Lua, in an `OnActivate` call, set up an EBus connection to listen for Web Communicator updates:

```lua
if CloudGemWebCommunicatorUpdateBus ~= nil then
    Debug.Log("Listening for communicator updates")
    self.communicatorUpdateBus = CloudGemWebCommunicatorUpdateBus.Connect(self,
        WebCommunicator.ModuleEntity)
else
    Debug.Log("Web Communicator not found")
end
```

Next, declare your message handler, as in the following example.

```lua
function DynamicContentTest:MessageReceived(channelName, messageData)
    if self:IsDynamicContentUpdate(channelName) then
        Debug.Log("DynamicContent update received: " .. messageData)
        DynamicContentRequestBus.Event.HandleWebCommunicatorUpdate(DynamicContent.ModuleEntity,
            messageData)
    end
end
```

For a sample Lua script, see `lumberyard_version\dev\CloudGemSamples\Scripts \CommunicatorSample.lua`.

**In C++**

In C++, declare a component handler class like the following:

```cpp
class SomeHandler :
public CloudGemWebCommunicator::CloudGemWebCommunicatorUpdateBus::Handler
virtual void ConnectionStatusChanged(const AZStd::string& connection) = 0;

Resources

For more information, see the following:

- For a sample level, see the CommunicatorSample (p. 2207) sample level in the CloudGemSamples project.
- For more information about cross-gem communication in Cloud Canvas, see Cross-Gem Communication (p. 2319).
- For the Web Communicator cloud gem API, see Web Communicator Cloud Gem Service API (p. 2219).
- For the Web Communicator cloud gem source code, see the files in the lumberyard_version\dev\Gems\CloudGemWebCommunicator\Code\ directory and its subdirectories.

Web Communicator Cloud Gem Authentication and AWS Policies

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The default Web Communicator authentication system uses authenticated Amazon Cognito users with AWS Signature Version 4. For more information, see Authenticating Requests (AWS Signature Version 4) in the AWS General Reference.

Note
Lumberyard advises against implementing unauthenticated access. If you surrender control over which users can connect to your AWS IoT network, you can incur unexpected costs.

Connection to AWS IoT requires two policies, which Web Communicator generates for you:

- A PlayerAccess role that can connect to, subscribe to, and receive messages from any AWS resource that is added to Web Communicator.
- An AWS IoT policy that allows authenticated users to use their Amazon Cognito Identity as their client ID for connection purposes. The policy grants the aggregate channel the permissions that have been requested from the other cloud gems.

You do not have to make changes to these generated policies to use them. The following sections provide reference samples of the generated policies if you want to modify them.

Amazon Cognito Policy Sample

The following sample Amazon Cognito policy grants the IotPlayerPermissions1 user permissions to connect, subscribe, and receive.

```json
{
    "Action": [
        "iot:Connect",
        "iot:Subscribe",
        "iot:Receive"
    ],
    "Resource": [
        "*
    ],
    "Effect": "Allow",
```

Version 1.28
2218
AWS IoT Policy Sample

The following sample AWS IoT policy is attached to a client. The final AWS IoT policy is an aggregation of channels from the cloud gems that the client uses.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["iot:Connect"],
      "Resource": [
      ]
    },
    {
      "Effect": "Allow",
      "Action": ["iot:Receive"],
      "Resource": ["*" ]
    },
    {
      "Effect": "Allow",
      "Action": ["iot:Subscribe"],
      ]
    }
  ]
}
```

Web Communicator Cloud Gem Service API

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Web Communicator cloud gem service API contains the following general requests and client requests. These calls are exposed on the client by the code in `lumberyard_version\dev\Gems\CloudGemWebCommunicator\Code\AWS\ServiceApi\CloudGemWebCommunicatorClientComponent.*`. You do not have to manage these calls directly on the client.

- GET `/service/status` (p. 2220)
- GET `/client/channels` (p. 2220)
General Requests

The Web Communicator cloud gem service API contains a request to get service status.

GET /service/status

Returns the service's status. This request is useful for testing connectivity.

Client Requests

GET /client/channels

Requests a list of channels available to the client. Returns a ChannelRequestResult object.

The ChannelRequestResult object contains a ChannelRequestResultArray object

The ChannelRequestResultArray object contains a ChannelInfo object.

### ChannelInfo Object

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ChannelName</td>
<td>String</td>
<td>The name of the channel to which to connect.</td>
</tr>
<tr>
<td>CommunicationChannel</td>
<td>String</td>
<td>The name of the communication channel.</td>
</tr>
<tr>
<td>CommunicationType</td>
<td>String</td>
<td>Can be one of RECEIVE, SEND, or BOTH.</td>
</tr>
<tr>
<td>Subscription</td>
<td>String</td>
<td>The name of the subscription.</td>
</tr>
</tbody>
</table>

POST /client/channel

Posts a message to a client channel.

The request parameter is a BroadcastRequest object.

### BroadcastRequest Object

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ChannelName</td>
<td>String</td>
<td>The channel to which to publish.</td>
</tr>
<tr>
<td>Message</td>
<td>String</td>
<td>The message to send.</td>
</tr>
</tbody>
</table>

GET /client/registration/\{registration_type\}

Requests the registration of a new client. Returns a RegistrationResult object and a ChannelRequestResult object.

Request Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>registration_type</td>
<td>String</td>
<td>Type of connection that the client uses. Specify OPENSSL or WEBSOCKET.</td>
</tr>
</tbody>
</table>
### RegistrationResult Object

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectionType</td>
<td>String</td>
<td>Can be OPENSSL or WEBSOCKET.</td>
</tr>
<tr>
<td>DeviceCert</td>
<td>String</td>
<td>For OpenSSL connections, a one time only device certificate.</td>
</tr>
<tr>
<td>Endpoint</td>
<td>String</td>
<td>The AWS IoT connection address.</td>
</tr>
<tr>
<td>EndpointPort</td>
<td>Double</td>
<td>The AWS IoT connection port.</td>
</tr>
<tr>
<td>PrivateKey</td>
<td>String</td>
<td>For OpenSSL connections, a one time only private key.</td>
</tr>
<tr>
<td>Result</td>
<td>String</td>
<td>Can be DENIED or SUCCESS.</td>
</tr>
</tbody>
</table>

The `ChannelRequestResult` object contains a `ChannelRequestResultArray` object.

The `ChannelRequestResultArray` object contains a `ChannelInfo` object.

For the contents of the `ChannelInfo` object, see GET /client/channels (p. 2220).

### Cloud Canvas Gameplay Design and Engineering Guide

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use Cloud Canvas's deployments, resource groups, and cloud gems (provided by yourself or others) to design and engineer the cloud connected features of your game.

**Topics**

- Cloud Canvas Tools in Lumberyard Editor (p. 2221)
- Managing Cloud Canvas Profiles (p. 2223)
- Using Resource Manager in Game Design (p. 2224)

### Cloud Canvas Tools in Lumberyard Editor

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The tools in Lumberyard Editor make it easy for you to connect your game to AWS. To get started, click AWS in the Lumberyard Editor menu bar:
The **AWS** menu has the following options:

- **Credentials manager** – Select or manage one or more AWS profiles that provide credentials to access your AWS account. For more information, see Managing Cloud Canvas Profiles (p. 2223).

- **Cloud Canvas** – Choose from among the following options:
  
  - **Select a Deployment** – Specify the set of AWS resources for the project that you want Lumberyard Editor to work with. For more information, see Making a Cloud Canvas Deployment Active (p. 2355).
  
  - **Cloud Canvas Resource Manager** – Define and manage the AWS resources for your Lumberyard project. For a conceptual introduction to resource manager, see Understanding Cloud Canvas Resource Manager (p. 2110).
  
  - **Dynamic Content Manager** – Manage dynamic content updates for your game through AWS. For more information, see Using Dynamic Content Manager (p. 2155).

- **Commerce** – Choose from among the following options for monetizing your game:
  
  - **Merch by Amazon** – Create themed T-shirts for your game.
  
  - **Publishing on Amazon** – Distribute your Windows and macOS applications to customers.

- **GameLift** – Use the Amazon GameLift service to rapidly deploy and scale session-based multiplayer games with no upfront costs. For more information, see Amazon GameLift. The **GameLift** menu itself also has links to more information.

- **Open AWS Console** – Get quick access to the main AWS Management Console and to the consoles for Amazon Cognito, DynamoDB, Amazon S3, and Lambda:

These links use your currently active AWS profile to connect to AWS. You can use **Credentials Manager** to select which profile is active.
Managing Cloud Canvas Profiles

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Credentials Manager in Lumberyard Editor or the command line to manage one or more AWS profiles that provide the credentials required to access your AWS account.

The profile is saved locally on your machine in your AWS credentials file. This file is normally located in your `C:\Users<user name>\.aws` directory. The AWS Command Line Interface and the AWS Toolkit for Visual Studio can access these credentials.

Important
Do not share these credentials with anyone, and do not check them into source control. These grant control over your AWS account, and a malicious user could incur charges.

For more information, see AWS Security Credentials.

To open Credentials Manager

To open Credentials Manager, do one of the following:

- In Lumberyard Editor, click AWS, Credentials manager.
- In Cloud Canvas Resource Manager, click the name of the current profile in the Resource Manager toolbar:

You can use the Credentials Manager to select an existing AWS profile, edit an AWS profile, or add a new AWS profile.

To edit an existing AWS profile, click Edited selected profile. To add an AWS profile, click Add profile.

When adding or editing a profile, Lumberyard prompts you for the following:

Profile name – The name used for the profile.

AWS Secret Key – The AWS secret key needed to access the account.

AWS Access Key – The AWS access key needed to access the account.

To add your credentials by using the command line

1. Open a command line window and change to the root Lumberyard directory, which is the `dev` subdirectory of your Lumberyard installation directory (for example, `C:\lumberyard_version\dev`).
2. Enter the following at the command prompt, and then press Enter. Replace `<profile-name>` with a name of your choice (for example, `CloudCanvasAdminProfile`). Replace `<secret-key>` and `<access-key>` with the secret key and access key of your AWS account.

```
lmbr_aws profile add --profile <profile-name> --make-default --aws-secret-key <secret-key> --aws-access-key <access-key>
```

The `--make-default` option establishes the profile as your default profile for Cloud Canvas. The default profile eliminates the need to specify the profile each time you use Lumberyard Editor or run an `lmbr_aws` command.

**Using Resource Manager in Game Design**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use Cloud Canvas Resource Manager to make deployments active, test mappings, use protected deployments, and to delete deployments and resources.

For information, see the following links in the Working with Deployments (p. 2352) section of the Cloud Canvas documentation.

- Making a Cloud Canvas Deployment Active (p. 2355)
- Testing Different Mappings (p. 2357)
- Using Protected Deployments (p. 2359)
- Deleting Cloud Canvas Deployments and Their Resources (p. 2360)

**Cloud Canvas Software Engineering Guide**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This section provides in-depth information for Cloud Canvas Resource Manager and the cloud gem framework.

**Topics**

- Resource Manager in Depth (p. 2224)
- Cloud Gem Framework (p. 2257)

**Resource Manager in Depth**

The effective use of Cloud Canvas Resource Manager is key to the success of any cloud-connected game project. This section provides in-depth information for software engineers.
For information on permissions in Resource Manager, see Understanding the Resource Manager Security System (p. 2370).

- Custom Resources (p. 2252)

Understanding Resource Status Descriptions

The status of AWS resources is displayed in the Cloud Canvas Resource Manager in places such as the progress log. The following list provides descriptions of common resource status codes. To see the reason for the current status, you can pause your mouse on the status text in the resource manager.

Create in progress – The resource is in the process of being created in AWS.
Create complete – The resource has been successfully created in AWS.
Create failed – The resource could not be created in AWS.
Update in progress – The resource is in the process of being updated in AWS.
Update complete – The resource was successfully updated in AWS.
Update failed – The resource could not be updated in AWS.
Delete in progress – The resource is in the process of being deleted in AWS.
Delete complete – The resource has been deleted in AWS.
Rollback in progress – An operation has failed and AWS CloudFormation is attempting to restore the resource to its previous state.
Rollback failed – A rollback has failed. The AWS resources in a CloudFormation stack that have this status are in an inconsistent state. You may have to delete and recreate the stack.

Editing Resource Manager Files

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The navigation pane in the **Cloud Canvas Resource Manager** dialog contains a number of nodes that represent text files that are stored on disk. The resource-template.json (p. 2227) node is one example.

The child nodes of template files each represent one section of the parent node template file. These child nodes can help you locate and edit the resource definition sections of the parent node template file.

**Using the Internal Editor**

When you select a text file node in the navigation pane, the file content and text editing options are shown in the detail pane of **Cloud Canvas Resource Manager**. You can use the detail pane to view and edit the contents of the file. Use the **Edit, Search** menu item to search for text, and the **Previous** and **Next** buttons to navigate from one match to the next. After you have modified a file, you can save it by clicking **Save** in the toolbar or by choosing **File, Save**.

**Note**

The changes that you make in the template file child nodes are always saved to the parent node template file.

**Using an External Editor**

You can use an external script editor instead of the **Cloud Canvas Resource Manager** to edit files. You can specify which editor to use in Lumberyard Editor.

**To specify an external script editor**

- In Lumberyard Editor, click **File, Global Preferences, Editor Settings, General Settings, Files, External Editors, Scripts Editor**.

**To open a file in an external script editor**

- Right-click the file in the navigation pane and choose **Open in script editor**:

To copy the path of the template file to the clipboard, right-click the file in the navigation pane and choose **Copy path to clipboard**.

**Notes**

Note the following:

- Opening a child node of a template file in a script editor opens the full (parent) file for editing.
• If your project files are under source control, Lumberyard prompts you to check out files before they can be edited. The source control icon on the toolbar dynamically displays the status of a selected file in source control.
• If the contents of the file change on disk while there are unsaved changes in the editor, Lumberyard prompts you to load the updated contents from disk and replace the modified contents in the editor.

Working with JSON Files

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Some of the nodes in the Cloud Canvas Resource Manager navigation pane represent JSON template or settings files for your project. The content of these files is described in detail in Resource Definitions (p. 2236). When you select one of these nodes in the navigation pane, the detail pane shows the contents of that file. You can edit the file directly in the resource manager or use an external editor. For more information, see Editing Resource Manager Files (p. 2225).

In the navigation pane, some template file nodes have child nodes. Each of the child nodes represents one section of its parent node template file. These child nodes make it easier to find and edit the corresponding sections of the parent node template file. Any changes that you make in a child node are always saved in the corresponding section of the parent template file.

The following template is found in each resource group under the Resource Groups node:

resource-template.json

Each resource group has a resource-template.json node and a lambda-function-code child node. The resource-template.json file defines the group's resources. For more information, see resource-template.json (p. 2237). In the navigation pane, each of the nodes under resource-template.json represents one of the resources defined in a section of the resource-template.json file.

The following templates are found under the Administration (advanced) node:

project-settings.json

The project-settings.json file contains project configuration data. For more information, see project-settings.json (p. 2248).

project-template.json

The project-template.json file defines the resources used by Cloud Canvas Resource Manager. For more information, see project-template.json (p. 2238).

deployment-template.json

The deployment-template.json file defines the AWS CloudFormation stack resources for each of the projects resource groups. For more information, see deployment-template.json (p. 2238).

deployment-access-template.json

The deployment-access-template.json file defines the AWS CloudFormation stack resources that control access to each deployment's resources. For more information, see deployment-access-template.json (p. 2238) and Controlling Access to Resources (p. 2370).

user-settings.json

The user-settings.json file contains user specific settings. For more information, see user-settings.json (p. 2237).
Viewing the Cloud Canvas Progress Log

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Cloud Canvas Resource Manager Progress log shows the progress of AWS CloudFormation stack updates. During the update, the progress log expands from the bottom of the detail pane to display the progress of the update. You can adjust the amount of space the log uses by dragging the divider line between the panes.

To hide the progress log, drag the divider downward.

Working with Resource Groups

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Resource groups define the AWS resources that cloud-connected game features such as high score tables require. You define the resource groups locally and then upload them to AWS, where the features you specify are created in the cloud.

You can use the Cloud Canvas Resource Manager to manage resource groups collectively or individually. You can create a resource group locally, specify the AWS resources that you want the resource group to have, and then upload the resource group definition to have it created in AWS. This document shows you how to use Cloud Canvas Resource Manager to perform these and other resource group-related tasks.
Managing Resource Groups

To see the status of the resource groups that belong to your project's current deployment, click Resource Groups in the Cloud Canvas configuration navigation pane. Note the following:

- If you select Resource Groups and no AWS profile is configured, Lumberyard prompts you to provide one. A profile is required for Lumberyard to display the status of your project’s resources. For more information, see Managing Cloud Canvas Profiles (p. 2223).
- If you select Resource Groups and deployments exist but no deployment is active, Lumberyard prompts you to select one. For more information, see Making a Cloud Canvas Deployment Active (p. 2355).

The Resource Groups detail pane lists the resource groups in your current deployment:

![Resource Groups detail pane](image)

The Resource Groups detail pane has the following options:

**Upload all resources**

Starts the process of modifying your resources in AWS as needed to match all the definitions in all of your local resource groups. As the update proceeds, resource groups with the Pending status of Create change to the Status of Create complete. The update might take a few minutes.
Note the following:

- If you have not yet initialized your Lumberyard project with an AWS account for the resources that you want to upload, Lumberyard prompts you to do so. To prepare your Lumberyard project for use with AWS, you must be an administrator of the AWS account that you use. For more information, see Initializing Cloud Canvas Resource Manager (p. 2349).

- After you have initialized the project, Lumberyard prompts you to create a deployment for it. A deployment creates all the AWS resources that are specified in your resource group definition.

For more information, see Create Deployment (p. 2353).
Add resource group

Adds a new resource group definition to your Lumberyard project. A resource group definition represents a single game feature like a high score system. The definition specifies the AWS resources that the feature will use.

Clicking Add resource group opens the New resource group dialog:

Provide the following information:

- **Resource group name** – The name of the resource group. The name must be alphanumeric. Lumberyard uses this name to create an AWS CloudFormation stack resource definition in the deployment-template.json (p. 2238) file.

- **Example resources** – (Optional) Choose to include example resources in the resource group. You can study the examples to see how resources are defined in a resource group, or modify the examples to turn them into a feature for your project.

Resource group status

Shows the status of the AWS CloudFormation stack of each resource group in the active deployment. Resource group shows the resource group name. For descriptions of the remaining fields in this table, see Stack Resources Table (p. 2351) in the Working with Project Stacks (p. 2350) section.

Progress log

Shows the progress of AWS CloudFormation stack updates. For more information, see Viewing the Cloud Canvas Progress Log (p. 2228).

Managing Individual Resource Groups

Each child node of Resource Groups represents a resource group in your Lumberyard project. When you select one of these resource groups, the detail pane shows the status of the resource group.
Adding Resources to a New Resource Group

When you create a resource group, the group does not yet have any AWS resource definitions. Use the **Add resource** option to add one:

Importing Resources

You can also click **Import resource** to import an AWS resource that already exists in your AWS account. For more information, see Importing Resource Definitions into Cloud Canvas (p. 2242).

Creating Resources in AWS

The resource definitions that you add are created locally and only describe the AWS resources that you want to use. The resources themselves are not created in AWS until you click **Create resources**.
Individual Resource Group Status

You can use a resource group's status pane to manage the resource group.

In addition to Add resource and Import resource, the status pane for a resource group has the following options:

Upload Lambda code

Use this option to upload Lambda function code without updating the entire project stack.

Upload resources

After you have created one or more resource definitions, you click Upload resources to start the process of creating the resources in AWS. Resource creation follows the local resource definitions that you created with the Add resource option.
As the update proceeds, the resources with the Pending status of Create change to the Status of Create complete.

Remove resource group

Click Remove resource group to remove the selected resource group from your local configuration.

To delete the actual resources from AWS, use the Delete resources option as described in the section that follows.

Note
The remove resource operation does not remove the resource group's configuration data from the local disk. As long as that data exists on disk, you can restore the resource group by adding a new resource group with the same name.

Delete resources

The Delete resources option appears after you have removed a resource group from your local configuration (for example, by clicking Remove resource group) when the resources defined by the resource group still exist in AWS.
When you click **Delete resources**, Lumberyard prompts you to confirm the deletion of resources in AWS for the deployment that is currently active in Lumberyard Editor. You must select the **It is OK that this will permanently DELETE resources** check box before you can click **Yes**.

After you click **Yes**, the deletion operation might take several minutes to complete.

**Stack resources**

The **Stack resources** table shows the status of each of the AWS resources that you defined for the resource group. For descriptions of the fields in this table, see **Stack Resources Table** (p. 2351) in the **Working with Project Stacks** (p. 2350) section.

**resource-template.json**

For information about this node, see **Working with JSON Files** (p. 2227).

**lambda-function-code**

The **lambda-function-code** node and its child nodes correspond to the lambda-function-code directory in your project. The lambda-function-code directory contains the code that implements the AWS Lambda function resources that are defined by your resource group. For more information, see **The lambda-function-code Directory** (p. 2236). Also see related information for the **project-code** (p. 2235) node.

**project-code**

This node is located at the bottom of the **Administration (advanced)** section in the resource manager navigation tree. The project-code directory contains the code that implements the AWS Lambda
function resources that Cloud Canvas Resource Manager uses. For more information, see The project-code Directory (p. 2240). The project-code node contains file and directory child nodes. Click a file node to see or edit its contents in the detail pane. For more information, see Editing Resource Manager Files (p. 2225).

**Resource Definitions**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Resource definitions for your game project are AWS CloudFormation template files that determine the resources (for example, DynamoDB databases, Lambda functions, and access control information) that will be created in AWS for the game. Game code uses AWS resources and expect those resources to exist and to be configured in a specific way. The resource definitions determine this architecture and configuration.

**Game Resource Definitions**

A description of the resources required by the game is stored in files under the dev\{game\}\AWS directory, where dev is the Lumberyard installation \dev subdirectory and \{game\} is the directory identified by the sys_game_folder property in the \dev\bootstrap.cfg file. For example, if your game is the Samples Project, your resource definition path might be C:\lumberyard_version\dev \SamplesProject\AWS. These files should be checked into the project's source control system along with your other game code and data.

The default \{game\}\AWS directory contents are created by the lmbr_aws project create (p. 2405) command.

In addition, some user-specific configuration data is kept in the dev\Cache\{game\}\{OS\}\user\AWS directory. The contents of this directory should not be checked into the project's source control system.

The following shows the contents of these AWS directories.

```
dev\{game\}\AWS\resource-group\{resource-group-name\}lambda-function-code\(Lambda function Code)resource-template.jsonlocal-project-settings.json
dev\Cache\{game\}\{OS\}\user\AWS\user-settings.json
```

The .json files are described in the following sections.

**resource-group\{resource-group\} Directory**

The AWS resources used by the game are organized into separate resource groups. The resource-group directory contains these in individual \{resource-group\} subdirectories. Each \{resource-group\} subdirectory is typically named after your game project and can contain a lambda-function-code directory and a resource-template.json file.

**The lambda-function-code Directory**

The lambda-function-code subdirectory is present when a resource template defines Lambda function resources. This directory can contain source files that implement those functions. Lumberyard uploads the code from this directory when using the template to update the AWS CloudFormation stack.
Use of the lambda-function-code directory is deprecated. For more information, see Lambda Code Directories (p. 2240).

**resource-template.json**

A resource-template.json file is an AWS CloudFormation template that defines the AWS resources associated with each resource group. You can specify any AWS resource type supported by AWS CloudFormation in your resource-template.json file. For a list of the available resource types, see the AWS CloudFormation AWS Resource Types Reference.

To determine the resource group stacks to include in a deployment, Lumberyard reads the resource-template.json files in AWS\resource-group subdirectories and in the AWS subdirectories of enabled cloud gems. Following are two examples.

```
\dev\CloudGemSamples\AWS\resource-group\CloudGemAWSBehavior\resource-template.json
\dev\Gems\CloudGemMessageOfTheDay\AWS\resource-template.json
```

**local-project-settings.json**

The dev\*\AWS\local-project-settings.json file contains a ProjectStackId identifier that points to AWS, the Cloud Gem Framework version number, and a list of any resource groups that have been disabled for the project. The following example shows the format of the local-project-settings.json file for the Cloud Gem Samples project:

```
{
    "ProjectStackId": "arn:aws:cloudformation:{aws-region}:{aws-access-id}:stack/CloudGemSamples/{uuid}",
    "DisabledResourceGroups": [],
    "FrameworkVersion": "1.1.1"
}
```

Note
Prior to Lumberyard 1.11, the local-project-settings.json file kept a list of enabled resource groups. By default, all of a cloud gem's resource groups are enabled when the cloud gem is enabled. Listing only the disabled resource groups makes it easier to identify them for debugging. See resource-group disable (p. 2409).

Note
As of Lumberyard 1.8, the project-settings.json file is stored in the project's Configuration Bucket (p. 2248). The bucket is defined by the project's AWS CloudFormation stack template.

**ProjectStackId Property**

The ProjectStackId property identifies the AWS CloudFormation stack for the project. This stack contains the resources used by Cloud Canvas to manage your Lumberyard project. Initially, the ProjectStackId property is not present in the local-project-settings.json file. After the project stack is created, the ProjectStackId property is written to the file and is the project's AWS CloudFormation stack ID.

The ProjectStackId property is set by the project create (p. 2405) command. If for some reason you want to associate the project with an existing project stack, you can use the AWS Management Console to look up the stack's ARN and paste it into the local-project-settings.json file (navigate to AWS CloudFormation, select the stack, select Overview, and then copy the value of the Stack Id property).

**user-settings.json**

The user-settings.json file contains user-specific configuration data. The file is created on the first run of the Cloud Canvas Resource Manager or the first time that lmb CLAWS is run on a project.
File Location

The `user-settings.json` file is found at `dev\Cache\{game}\{OS}\user\AWS\user-settings.json`. It is not in the `dev\{game}\AWS` directory along with the other files described in this section because it should not be checked into the project's source control system.

Default AWS Profile

The `DefaultProfile` section of the `user-settings.json` file contains the AWS profile that the `lmbr_aws` command uses for the project. To set the profile for a Cloud Canvas project, use the following command:

```
lmbr_aws profile default --set profile_name
```

For more information, see profile default (p. 2404).

Project Template Files

Cloud Canvas project template files are [AWS CloudFormation templates](https://aws.amazon.com/cloudformation/) that define resources, stacks, and deployment permissions for a project. Following are the project template files:

- `project-template.json`
- `deployment-template.json`
- `deployment-access-template.json`

The content of each of these template files can be supplemented with a corresponding `*-extensions.json` file. Starting in Lumberyard 1.10, these files are located in the `\Gems\CloudGemFramework\vN\ResourceManager\resource_manager\templates` directory, where `N` represents a Cloud Gem framework version number.

`project-template.json`

The `project-template.json` file is an AWS CloudFormation template that defines project-wide resources that support the Cloud Canvas resource management system. For information about Cloud Canvas Resource Manager, see Understanding Cloud Canvas Resource Manager (p. 2110). For security-related information, see Understanding the Resource Manager Security System (p. 2370).

`deployment-template.json`

In versions of Lumberyard prior to 1.10, the project's copy of the `deployment-template.json` file contained stack definitions for each of the project's resource groups. These resources are now inserted into the base template before it is passed to AWS CloudFormation. To determine the resource group stacks to include, Lumberyard reads the `resource-template.json` files in `AWS\resource-group` subdirectories and in the `AWS` subdirectories of enabled gems.

`deployment-access-template.json`

The `deployment-access-template.json` file is an AWS CloudFormation Template that defines the resources used to secure a deployment. For information about Cloud Canvas Resource Manager, see Understanding Cloud Canvas Resource Manager (p. 2110). For security-related information, see Understanding the Resource Manager Security System (p. 2370).

Parameters

The deployment access stack defines parameters that identify the deployment and other resources that are needed to set up security for the deployment. A value for each of these parameters is provided by Cloud Canvas when a deployment is created.
**Resources**

This section describes some of the key resources that are defined in the example deployment-access-template.json file.

**Player**

The Player resource describes the IAM role that determines the access granted to the player. For example, for the game to invoke a Lambda function, the player must be allowed the lambda:InvokeFunction action on the Lambda function resource.

The role's policies are determined by the PlayerAccess metadata elements found on resources in the project's resource templates (see resource-template.json (p. 2237)). The role's policies are updated by the PlayerAccess custom resources that appear in the deployment-access-template.json (p. 2238) and in the resource-template.json (p. 2237) files. The PlayerAccessIdentityPool Amazon Cognito identity pool resource allows players to assume this role.

For more information, see PlayerAccessIdentityPool (p. 2239) and Controlling Access to Resources (p. 2370).

**PlayerLoginRole**

The PlayerLoginRole resource describes the IAM role that is temporarily assumed by the player as part of the login process.

For more information, see Controlling Access to Resources (p. 2370).

**PlayerLoginIdentityPool**

The PlayerLoginIdentityPool resource describes the Amazon Cognito identity pool that provides the player with a temporary identity during the login process.

For more information, see Controlling Access to Resources (p. 2370).

**PlayerAccessIdentityPool**

The PlayerAccessIdentityPool resource describes the Amazon Cognito identity pool that provides the player with a temporary identity during the login process.

For more information, see Controlling Access to Resources (p. 2370).

**Template Extension Files**

Starting in Lumberyard 1.10, you can use the following extension files to add resources to the project templates:

- deployment-access-template-extensions.json
- deployment-template-extensions.json
- project-template-extensions.json

You can use the extension files to define new outputs, metadata, and resources. The addition of template parameters is not supported.

To create extension files, you can use the lmbr_aws project create-extension-template (p. 2406) command. To create a template file of a particular type, use the corresponding argument, as the following examples show.

- To create a project-template-extensions.json file, type:

  ```bash
  lmbr-aws project create-extension-template --project
  ```
• To create a deployment-template-extensions.json file, type:

```
lmbr-aws project create-extension-template --deployment
```

• To create a deployment-access-template-extensions.json file, type:

```
lmbr-aws project create-extension-template --deployment-access
```

In the base (nonextension) template files, the Custom::AccessControl resource DependsOn property includes all the resources defined in the extension files if the DependsOn property does not specify AccessControl.

**Code Directories**

The location and naming of code directories has changed in Lumberyard 1.10. For more information, see [Cloud Gem Framework and Resource Manager Versioning (p. 2342)](#).

**Lambda Code Directories**

Starting in Lumberyard 1.10, we recommend that you put your Lambda code in `AWS\lambda-code\<lambda-name>` directories (for example, `dev\Gems\CloudGemPlayerAccount\AWS\lambda-code`) and your shared code in a `common-code` directory (for example, `dev\Gems\CloudGemPlayerAccount\AWS\common-code`).

In versions of Lumberyard prior to 1.10, the code for a resource group's Lambda functions was kept in an `AWS\lambda-function-code` directory. As of Lumberyard 1.10, the use of `AWS\lambda-function-code` and `AWS\<lambda-name>-lambda-code` directories is no longer recommended. Support for them will be removed in a future release. Instead, we recommend that you put your Lambda code in `AWS\lambda-code\<lambda-name>` directories.

In addition, the use of the `shared-lambda-code` directory is no longer recommended. Support for it will also be removed in a future release. Instead, use the more flexible `common-code` directory. For more information, see [Using Shared Code (p. 2342)](#). For information about upgrading your projects and cloud gems to version 1.0.0 of the Cloud Gem framework, see [Updating Projects and Cloud Gems to Version 1.0.0 of the Cloud Gem Framework (p. 2345)](#).

**The project-code Directory**

The `dev\Gems\CloudGemFramework\v\AWS\project-code` subdirectory contains the source code for the AWS CloudFormation Custom Resource handler that is used in the project's AWS CloudFormation templates. For information about custom resources, see [Custom Resources (p. 2252)](#).

It also contains the code that implements the token exchange step of the player login process. For more information, see [Controlling Access to Resources (p. 2370)](#).

**Permissions Metadata for Resource Definitions**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

To determine what permissions should go into a policy, the Custom::AccessControl resource looks for Cloud Canvas permissions metadata on resource definitions in resource group stacks. In the following example, the metadata on the Messages resource gives the SayHello AWS Lambda function permission to put items into a Amazon DynamoDB table. The metadata on the SayHello resource gives players permission to invoke the SayHello Lambda function.

```
...
```
"Messages": {
  "Type": "AWS::DynamoDB::Table",
  "Properties": {
    "AttributeDefinitions": [
      {
        "AttributeName": "PlayerId",
        "AttributeType": "S"
      }
    ],
    "KeySchema": [
      {
        "AttributeName": "PlayerId",
        "KeyType": "HASH"
      }
    ],
    "ProvisionedThroughput": {
      "ReadCapacityUnits": { "Ref": "ReadCapacityUnits" },
      "WriteCapacityUnits": { "Ref": "WriteCapacityUnits" }
    }
  },
  "Metadata": {
    "CloudCanvas": {
      "Permissions": [
        {
          "AbstractRole": "SayHello",
          "Action": "dynamodb:PutItem"
        }
      ]
    }
  }
},

"SayHello": {
  "Type": "AWS::Lambda::Function",
  "Properties": {
    "Description": "Example of a function called by the game to write data into a DynamoDB table.",
    "Handler": "main.say_hello",
    "Role": { "Fn::GetAtt": [ "SayHelloConfiguration", "Role" ] },
    "Runtime": { "Fn::GetAtt": [ "SayHelloConfiguration", "Runtime" ] },
    "Code": {
      "S3Bucket": { "Fn::GetAtt": [ "SayHelloConfiguration", "ConfigurationBucket" ] },
      "S3Key": { "Fn::GetAtt": [ "SayHelloConfiguration", "ConfigurationKey" ] }
    }
  },
  "Metadata": {
    "CloudCanvas": {
      "Permissions": [
        {
          "AbstractRole": "Player",
          "Action": "lambda:InvokeFunction"
        }
      ]
    }
  }
},
...

You can use the `lmbr_aws` command line tool to manage permissions metadata on the resource definitions in a resource group's `resource-template.json` file. For more information, see Permission Metadata Management (p. 2383).
Properties

Each Cloud Canvas Permission metadata object can have the following properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AbstractRole</td>
<td>Required string or list of strings. Identifies the role whose policy will reflect the permission. For more information, see Role Mapping Metadata (p. 2377).</td>
</tr>
<tr>
<td>Action</td>
<td>Required string or list of strings. Identifies the actions to be placed in the policy. This is used as the Action property of a Statement in the policy. See AWS Service Actions and Condition Context Keys for Use in IAM Policies for a list of actions supported by IAM.</td>
</tr>
<tr>
<td>ResourceSuffix</td>
<td>Optional string or list of strings. Provides values that are appended to the ARN in the Resource property of a statement in the policy. There is one Resource property value for each suffix listed. If no suffixes are listed, the Resource property value is the resource ARN with no suffix.</td>
</tr>
</tbody>
</table>

Importing Resource Definitions into Cloud Canvas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Cloud Canvas resource importer to add definitions of existing AWS resources to a Cloud Canvas resource group. You can add resources by using the Cloud Canvas Resource Manager in Lumberyard Editor or at a command line prompt.

Importing Resources using Lumberyard Editor

In Lumberyard Editor, you can import a resource by specifying an Amazon Resource Name (ARN) or by choosing from a list.

To import a resource by using an ARN

1. From the Lumberyard Editor top menu, choose AWS, Cloud Canvas, Resource Manager.
2. In the navigation pane, select a resource group.
3. In the detail window, click Import resource, Import using ARN. You can also open the context (right-click) menu for the resource in the navigation pane and choose Import resource, Import using ARN.
4. In the Import using ARN dialog box, provide the ARN and name of the resource that you are going to import. Both are required.
After you have provided both items of information, the **Import** button is enabled.

5. **Import**.

**To import a resource by choosing from a list**

1. From the Lumberyard Editor top menu, choose **AWS, Cloud Canvas, Resource Manager**.
2. In the navigation pane, select a resource group.
3. In the detail window, choose **Import resource, Import using ARN**. You can also open the context (right-click) menu for the resource in the navigation pane and choose **Import resource, Import using ARN**.
4. In the **Import from list** dialog box, choose the AWS Region of the resource for **Region**. The default value is the region of the project stack if it exists. Resources start loading in the list as soon as you choose a region that has importable resources.
5. You can use the AWS service selector to filter the resources by service, and then use the **Search** box to filter resources by name.

6. Select the check box to the left of each resource that you want to import.

7. **Configure.**

8. In the **Configuration** dialog box, provide a reference name for each resource, or accept the default. The default name is the original name of the resource on AWS.

9. To delete a selected resource from the list, open the context (right-click) menu for the resource and choose **Delete.**

10. When you are ready, click **Import.** A progress bar displays. An **Import Error** message informs you of any errors that occur.
11. Click X to close the Import from list dialog box. The resources that you imported are listed in the details pane of Cloud Canvas Resource Manager.

**Importing Resource Definitions Using the Command Line**

To list and import resources using the Cloud Canvas command line, see resource-importer list-importable-resources (p. 2412) and resource-importer import-resource (p. 2411).

**Understanding Resource Definitions**

When you use the Cloud Canvas resource importer to import the definition of a resource, it is important to understand that you are importing the resource's definition, not the resource itself. For example, suppose you use the AWS console to create a high score table in DynamoDB called Table A. You create a game client that uploads scores, and send out the client to your players. Table A begins to populate with data from the players of your game.

You then decide to use Cloud Canvas to manage your resources and deployments. Using the Cloud Canvas Resource Manager, you import Table A because it has the exact configuration values that you want, and it has worked well for your use cases.

When you create a deployment with the imported resource, the deployment contains Table B, which is a new table with Table A's structure but not its data. Table B is managed by Cloud Canvas and has the same behavior as Table A. However, Table B is not a reference to Table A, and it does not have Table A's data or history. Keep this distinction in mind when you import resource definitions.

**Automatically Imported Resource Definitions**

Some of the existing resources that you select might be related to other resources. For example, Lambda functions can respond to events from the selected triggers. You can use event notifications from an Amazon S3 bucket to send alerts or trigger workflows. Cloud Canvas imports the related resources for you automatically.

Cloud Canvas uses the following naming conventions for automatically imported resource definitions.

<table>
<thead>
<tr>
<th>Source</th>
<th>Naming Convention</th>
<th>Example Name of Imported Resource</th>
</tr>
</thead>
<tbody>
<tr>
<td>DynamoDB table, Lambda function, Amazon SNS topic, Amazon SQS queue</td>
<td><code>&lt;resource_name&gt;</code> + &quot;AutoAdded&quot; + <code>&lt;resource_type&gt;</code> + <code>&lt;counter&gt;</code></td>
<td>LambdaFunctionAutoAddedtable0</td>
</tr>
<tr>
<td>Lambda function configuration resource??</td>
<td><code>&lt;lambda_function_name&gt;</code> + &quot;Configuration&quot;</td>
<td>LambdaFunctionConfiguration</td>
</tr>
<tr>
<td>Lambda function policy resource</td>
<td><code>&lt;lambda_function_name&gt;</code> + &quot;Permission&quot;</td>
<td>LambdaFunctionPermission</td>
</tr>
<tr>
<td>DynamoDB table Lambda function event source</td>
<td><code>&lt;DynamoDB_table_name&gt;</code> + &quot;EventSource&quot;</td>
<td>DynamoTableEventSource</td>
</tr>
</tbody>
</table>
Resources Supported for Import

The following sections list the resource attributes and related resources that Cloud Canvas imports for each supported AWS service.

Dynamo DB Tables

For DynamoDB tables, Cloud Canvas imports the following resource attributes:

- AttributeDefinitions
- GlobalSecondaryIndexes
- KeySchema
- LocalSecondaryIndexes
- ProvisionedThroughput
- StreamSpecification

Amazon S3 Buckets

For Amazon S3 buckets, Cloud Canvas imports the following resource attributes:

- CorsConfiguration
- LifecycleConfiguration
- NotificationConfiguration
- Tags
- VersioningConfiguration
- WebsiteConfiguration

For Amazon S3 buckets, Cloud Canvas also imports the following related resources:

- Lambda functions
- Amazon SQS queues
- Amazon SNS topics

Lambda Functions

For Lambda functions, Cloud Canvas imports the following resource attributes:

- Code
- Description
- Handler
- MemorySize
- Role
- Runtime
- Timeout
- VpcConfig

For Lambda functions, Cloud Canvas also imports the following related resources:

- Lambda function configurations
• Lambda function permissions
• DynamoDB tables
• Event source mappings

**Amazon SNS Topics**

For Amazon SNS topics, Cloud Canvas imports the following resource attributes:

• DisplayName
• Subscription

For Amazon SNS topics, Cloud Canvas also imports any Lambda functions that are related resources.

**SQS Queues**

For SQS queues, Cloud Canvas imports the following resource attributes:

• DelaySeconds
• MaximumMessageSize
• MessageRetentionPeriod
• ReceiveMessageWaitTimeSeconds
• RedrivePolicy
• VisibilityTimeout

**Resource Deployments**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You implement deployments using AWS CloudFormation stacks. You create and manage the stacks using tools provided by Lumberyard.

A project may define any number of deployments, up to the limits imposed by AWS CloudFormation (for more information, see AWS CloudFormation Limits). Each deployment contains a completely independent set of the resources that the game requires. For example, you can have separate development, test, and release deployments so that your development and test teams can work independently of the deployment used for the released version of the game.

An AWS account that hosts a Lumberyard project contains the following resources:

• `{project}` – An AWS CloudFormation stack that acts as a container for all the project's deployments.
• `{project}`-Configuration – An S3 bucket used to store configuration data.
• `{project}`-ProjectResourceHandler – A Lambda function that implements the handler for the custom resources used in the templates. See Custom Resources (p. 2252).
• `{project}`-ProjectResourceHandlerExecution – An IAM role that grants the permissions used by the ProjectResourceHandler Lambda function when it is executing.
• `{project}`-PlayerAccessTokenExchange – A Lambda function that implements the token exchange step in the player login process. For more information, see Controlling Access to Resources (p. 2370).
• `{project}`-PlayerAccessTokenExchangeExecution– An IAM role that grants the permissions used by the PlayerAccessTokenExchange Lambda function when it runs.

• `{project}`-{deployment} – AWS CloudFormation stacks for each of the project's deployments.

• `{project}`-{deployment}Access – AWS CloudFormation stacks that control access to each of the project's deployments.

• `{project}`-{deployment}-PlayerAccessTokenExchangeIdentityPool – An Amazon Cognito identity pool used for player identity. For more information, see Controlling Access to Resources (p. 2370).

• `{project}`-{deployment}-PlayerLoginIdentityPool – An Amazon Cognito identity pool that provides the temporary player identity used during the player login process. For more information, see Controlling Access to Resources (p. 2370).

• `{project}`-{deployment}-{resource-group} – An AWS CloudFormation stack for each resource group of the project.

• `{project}`-{deployment}-{resource-group}-{resource} – The resources defined by a resource group. Because of how AWS CloudFormation works, parts of these names have unique identifiers appended to them. For example, for a project named MyGame with a deployment named Development and a feature named HighScore, the actual name of a Scores resource would be something like: MyGame-Development-1FLFSUKM3MC4B-HighScore-1T7DK9P46SQF8-Scores-1A1NIH66ZKPKRI. The tools provided by Lumberyard hide these actual resource names under most circumstances.

• `{project}`-{iam-policy-or-role} – An IAM policy or role that manages resource and deployment permissions. For more information, see Cloud Canvas Built-In Roles and Policies (p. 2373).

Configuration Bucket

The configuration Amazon S3 bucket is used to store configuration data for the project. The bucket is located at `/s3/buckets/<projectname>-configuration-<ID>/`. The tools provided with Cloud Canvas manage uploads to this bucket.

The upload directory contains objects that are uploaded from the `{game}/AWS` directory by the Cloud Canvas tools when stack management operations are performed. The uploads for each operation get assigned a unique `{upload-id}` value to prevent concurrent operations from impacting each other.

**project-settings.json**

The `project-settings.json` file contains project configuration data.

The structure of the `project-settings.json` file is as follows:

```json
{
    "key": "value",
    "deployment": {
        "deployment": {
            "key": "value",
            "resource-group": {
                "resource-group": {
                    "key": "value"
                }
            }
        }
    }
}
```

The `{key}` and `{value}` pairs represent individual settings. The pairs at the root apply to the project. The pairs under `{deployment}` apply to that deployment. The pairs under `{resource-group}` apply to that resource group. Either or both of `{deployment}` and `{resource-group}` can be *, to indicate
the settings they contain apply to all deployments or resource groups, respectively. Settings under a
named entry take precedence over settings under a * entry.

**Note**
As of Lumberyard 1.8, the `ProjectStackId` property is stored in the `dev\<project name>\AWS\local-project-settings.json` file. For more information, see ProjectStackId Property (p. 2237).

**DefaultDeployment Property**
The `DefaultDeployment` property identifies the deployment that is to be used by default when
working in Lumberyard Editor. The `DefaultDeployment` property in the `user-settings.json` file overrides this setting. The project and user defaults can be set using the `lmbr_aws deployment default` command. The DefaultDeployment setting is also used by the `lmbr_aws mappings update` command.

**ReleaseDeployment Property**
The `ReleaseDeployment` property identifies the deployment that is to be used in release builds of
the game. The `ReleaseDeployment` setting is used by the `lmbr_aws mappings update` command.

**DeploymentStackId Property, PendingDeploymentStackId**
The `DeploymentStackId` property identifies the AWS CloudFormation stack for a deployment. The `PendingDeploymentStackId` property identifies a stack whose deployment is pending. The project's resource groups are children of these stacks. For more information, see Resource Deployments (p. 2247).

The `DeploymentStackId` property is set by the `deployment create` command. If for some reason you want to associate the deployment with an existing deployment, you can use the AWS Management Console to look up the stack's ARN and paste it into the `project-settings.json` file (navigate to AWS CloudFormation, select the stack, select Overview, and then copy the value of the Stack Id property).

**DeploymentAccessStackId Property**
The `DeploymentAccessStackId` property identifies the AWS CloudFormation stack for the resources
that control access to a deployment.

The `DeploymentAccessStackId` is set by the `deployment create` command. If for some reason you want to associate the deployment with an existing deployment stack, you can use the AWS Management Console to look up the stack's ARN and paste it into the `project-settings.json` file (navigate to AWS CloudFormation, select the stack, select Overview, and then copy the value of the Stack Id property).

**parameter Property**
The `parameter` property provides the values for resource template parameters. The property must be in
the following format.

```
{
  ...
  "parameter": {
    "{template-parameter-name-1}": {template-parameter-value-1},
    ...
    "{template-parameter-name-n}": {template-parameter-value-n}
  }
  ...
}
```
Resource Mappings

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Resource mappings map the friendly names used in a game’s Resource Definitions (p. 2236) to the actual names of the resources created for one or more specific Resource Deployments (p. 2247). For example, a DynamoDB table name like LeaderboardTable would get mapped to a name like the following:

CloudGemSamples-CGSamplesDeployment-CloudGemLeaderboard-78AIXR0N0O4N-LeaderboardTable-1I1ZC6YO7KU7F

In the preceding example, CloudGemSamples is the name of the project stack, CGSamplesDeployment is the name of the deployment, and CloudGemLeaderboard is the name of the resource group. The 78AIXR0N0O4N and 1I1ZC6YO7KU7F parts of the resource name are inserted by AWS CloudFormation to guarantee that the resource name is unique over time. Thus, even if a resource is deleted and a new one with the same logical name is created, the physical resource ID will be different.

Usually different deployments, and consequently different mappings, are used for game development and for the released version of a game. Furthermore, different development, test, and other teams often work with their own deployments so that each team has distinct mappings.

The deployment used by default during development is specified in the project-settings.json (p. 2248) file. The file is located in the Amazon S3 configuration bucket at /s3/buckets/<projectname>-configuration-<ID>/project-settings.json. The file can be overridden for each user by the dev\Cache\{project\}pc\user\AWS\user-settings.json (p. 2237) file. You can change the default deployment by using the lmbr_aws deployment default (p. 2394) command or by using the Cloud Canvas Resource Manager (p. 2356).

The mappings that are used during development when the game is launched from the Lumberyard IDE by pressing Ctrl+G are stored in the user-settings.json (p. 2237) file. This file is updated automatically when the default deployment changes, when the default deployment is updated, and when Lumberyard Editor is started. To refresh it manually, you can use the lmbr_aws mappings update (p. 2402) command.

When a game launcher application created in Lumberyard launches a release build of a game, the mappings for the player and server roles are stored in the dev\{project\}Config\ directory. These mappings can be updated manually using the lmbr_aws mappings update --release (p. 2402) command. The command creates a <deployment_name>.player.awsLogicalMappings.json file for the player role and a <deployment_name>.server.awsLogicalMappings.json file for the server role. You can specify the deployment for the release mappings by using the --deployment {deployment_name} argument of the lmbr_aws mappings update command.

The Mappings Component

As of Lumberyard 1.11, the mapping functionality is implemented by a Mappings component within the Cloud Gem Framework Gem. The Mappings component (dev\Gems\CloudGemFramework \vN\Code\Source\MappingsComponent.h) is a required system component that replaces the former implementation in \dev\Code\CryEngine\LmbrAWS\Configuration\ClientManagerImpl. The Mappings component loads the <deployment_name>.player.awsLogicalMappings.json and <deployment_name>.server.awsLogicalMappings.json files from disk.

The Mappings Component EBus

The mappings component implements an EBus (p. 1851) found at dev\Code\CryEngine\CryCommon \CloudCanvas\CloudCanvasMappingsBus.h. When the Cloud Gem Framework makes calls to a
service API, it uses this EBus to translate the service name to the ARN. This EBus provides access to the mapping calls described in the following code.

```cpp
// Given the friendly name of the resource, return the ARN (physical name).
virtual AZStd::string GetLogicalToPhysicalResourceMapping(const AZStd::string& logicalResourceName) = 0;

// Set a friendly (logical) to ARN (physical) mapping for the specified resource type.
virtual void SetLogicalMapping(AZStd::string resourceType, AZStd::string logicalName, AZStd::string physicalName) = 0;

// Return all mappings that have the specified type (for example, AWS::Lambda::Function or Custom::ServiceApi).
virtual AZStd::vector<AZStd::string> GetMappingsOfType(const AZStd::string& resourceType) = 0;

// Return all mapping data.
virtual MappingData GetAllMappings() = 0;

// Load mappings from disk.
virtual bool LoadLogicalMappingsFromFile(const AZStd::string& mappingsFileName) = 0;

// If the protected flag is set in the mapping, the following function returns true.
// Because protected resources are likely to be live and customer facing, users should be
// warned accordingly and given the option not to connect.
virtual bool IsProtectedMapping() = 0;

// Set the mapping to protected.
virtual void SetProtectedMapping(bool isProtected) = 0;
```

In general, you should not have to access the low level mappings. Both ScriptCanvas and FlowNodes accept friendly names and translate them to ARNs before they make requests to AWS.

**Using Mappings in AWS Flow Nodes**

AWS flow nodes that define TableName (DynamoDB), FunctionName (Lambda), QueueName (Amazon SQS), TopicARN (Amazon SNS), or BucketName (Amazon S3) ports work with mappings. Set the port to a value like `{resource-group}.{resource}` where `{resource-group}` is the name of the resource group that defines the resource, and where `{resource}` is the name of the resource that appears in the Resources section of the resource group's resource-template.json file.

**Using Mappings in Lambda Functions**

Lambda function resources defined as part of a resource group often need to access other resources defined by that resource group. To do this, the function code needs a way to map a friendly resource name to the actual resource name used in AWS API calls. The LambdaConfiguration resource provides a way to such mappings, as well as other settings, to the lambda code. For more information, see LambdaConfiguration (p. 2256).

**Resource Manager Resource Group Parameters**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Cloud Canvas Resource Manager uses AWS CloudFormation templates to describe the AWS resources needed for a project. AWS CloudFormation templates can have parameters. You provide the values for these parameters when a template creates or updates a stack.
AWS CloudFormation template parameters are useful when you want separate deployments of a resource group to be configured differently. For example, you could configure an internal test instance of Amazon DynamoDB to use lower throughput than a public instance.

Follow the steps below to use AWS CloudFormation template parameters for your resource groups.

To use template parameters

1. Define a parameter in the AWS CloudFormation template. You must provide a default value for the parameter. Be sure not to remove or modify the parameter definitions used by Cloud Canvas (for example, `ConfigurationBucket` or `ConfigurationKey`).

2. Reference the parameter when you define a resource. You can use parameters to provide values for resource properties, including passing settings to Lambda functions through the `CloudCanvas::LambdaConfiguration (p. 2256)` resource.

3. Use the `lmbr_aws parameter list`, `parameter set`, and `parameter clear` commands to view and set parameter values. These commands are described later in this document.

4. Update (or create) the resource group stack using the `lmbr_aws resource-group upload` command, or click **Upload Resources** in the Cloud Canvas Resource Manager window in Lumberyard Editor.

Parameter Configuration

A project's parameter configuration is stored in a `project-settings.json (p. 2248)` file object in the project's configuration bucket. The bucket is defined by the project's AWS CloudFormation stack template.

You can specify parameter values for a specific deployment or for all deployments by using the `*` character as a wildcard in place of a deployment name. You can also specify parameter values for a specific resource group or for all resource groups by using the `*` in place of a resource group name. If you provide a parameter value for both a wildcard (`*`) entry and a named entry, the value from the named entry overrides the value from the wildcard entry.

The following table shows the `lmbr_aws` commands for listing, setting, and clearing parameter values. Your project must be initialized (that is, a project stack must have been created) before you can list, set, or clear parameter values. For usage details, visit the corresponding links in the table.

<table>
<thead>
<tr>
<th><code>lmbr_aws</code> command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>parameter list</code> (p. 2403)</td>
<td>Lists the parameters currently configured for your project.</td>
</tr>
<tr>
<td><code>parameter set</code> (p. 2403)</td>
<td>Sets parameter configuration for your project.</td>
</tr>
<tr>
<td><code>parameter clear</code> (p. 2402)</td>
<td>Clears the specified parameter configuration for your project.</td>
</tr>
</tbody>
</table>

Custom Resources

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Cloud Canvas provides a number of **AWS CloudFormation custom resources** that can be used in the AWS CloudFormation template files for the project, deployment, and resource group. These custom resources are implemented by the Lambda function code found in the `dev\{game\}\AWS\project-code` directory and the `ProjectResourceHandler` resource defined in the `dev\{game\}\AWS\project-`
template.json file. Rather than static entities, these resources act more like library functions. Each custom resource has input and output properties.

A summary list of custom resources follows.

- **CognitoIdentityPool** *(p. 2253)* – Manages Amazon Cognito identity pool resources.
- **CognitoUserPool** *(p. 2254)* – Manages Amazon Cognito user pool resources.
- **EmptyDeployment** *(p. 2255)* – Used in the deployment-template.json when there are no resource groups defined.
- **LambdaConfiguration** *(p. 2256)* – Provides configuration data for Lambda function resources and maintains the Lambda function's execution role.
- **Helper** *(p. 2256)* – Provides convenience functions for use in templates.
- **Cloud Gem Framework Service API** *(p. 2305)* – Provides programmatic access to cloud gem functionality that you can use to implement cloud-connected features in your game.

For information on controlling access to resources, see Controlling Access to Resources *(p. 2370)*.

**CognitoIdentityPool**

The Custom::CognitoIdentityPool resource is used in the deployment-access-template.json file to create and configure Amazon Cognito identity pool resources.

**Input Properties**

- **ConfigurationBucket**
  
  Required. The name of the Amazon S3 bucket that contains the configuration data.

- **ConfigurationKey**
  
  Required. The Amazon S3 object key prefix where project configuration data is located in the configuration bucket. This property causes the custom resource handler to be executed by AWS CloudFormation for every operation.

- **IdentityPoolName**
  
  Required. The name of the identity pool.

- **UseAuthSettingsObject**
  
  Required. Must be either true or false. Determines whether the Amazon Cognito identity pool is configured to use the authentication providers that were created from the add-login-provider command.

- **AllowUnauthenticatedIdentities**
  
  Required. Must be either true or false. Determines whether the Amazon Cognito identity pool is configured to allow unauthenticated identities. See Identity Pools for more information on Amazon Cognito's support for authenticated and unauthenticated identities.

- **Roles**
  
  Optional. Determines the IAM role assumed by authenticated and unauthenticated users. See SetIdentityPoolRoles for a description of this property.

**Output Properties**

- **IdentityPoolName**
The name of the identity pool (same as the `IdentityPoolName` input property).

- `IdentityPoolId`

  The physical resource name of the identity pool.

**CognitoUserPool**

The `Custom::CognitoUserPool` resource is used in the [Player Account Cloud Gem (p. 2188)](resource-template.json) file to create and configure Amazon Cognito user pool resources. You can use this resource to add Amazon Cognito user pools and link them to an Amazon Cognito identity pool.

**Input Properties**

- `PoolName`
  
  Required. The name of the user pool.

- `ConfigurationKey`
  
  Required. The Amazon S3 object key prefix where project configuration data is located in the configuration bucket. This property causes the custom resource handler to be executed by AWS CloudFormation for every operation.

- `ServiceToken`
  
  Required. The handler for this custom resource type.

- `ClientApps`
  
  Required. A list of client apps to be created for the user pool. At least one must be provided.

- `LambdaConfig`
  
  Optional. A map of a Lambda trigger name to a Lambda function ARN. This map is passed to the Amazon Cognito `CreateUserPool` API when a user pool is created and to the Amazon Cognito `UpdateUserPool` API when a user pool is updated.

**Metadata: Linking a User Pool to an Identity Pool**

To link a `Custom::CognitoUserPool` to a `Custom::CognitoIdentityPool`, you add an Identities section to the Metadata CloudCanvas section, as in the following example.

```json
"Metadata": {
  "CloudCanvas": {
    "Identities": [
      {
        "IdentityPoolName": "PlayerAccess",
        "ClientApp": "DefaultClientApp"
      }
    ]
  }
}
```

The handler for `Custom::CognitoIdentityPool` looks for this metadata on `Custom::CognitoUserPool` resources when it configures the identity pool. The `IdentityPoolName` in the user pool's metadata must match the `IdentityPoolName` in the identity pool's properties. `ClientApp` must be one of the apps listed in the user pool's `ClientApps` property.

**Output Properties**

- `UserPoolName`
The name of the user pool.

- **UserPoolId**

  The ID of the user pool.

- **ClientApps**

  A list that contains the ClientId and ClientName of each of the user pool's client apps.

- **PhysicalResourceId**

  The physical resource ID of the user pool.

**EmptyDeployment**

The Custom::EmptyDeployment resource is used in the deployment-template.json file when there are no resource groups defined. This is necessary to satisfy the AWS CloudFormation requirement that a template define at least one resource.

This resource supports no input or output properties.

**ResourceGroupConfiguration**

The Custom::ResourceGroupConfiguration resource is used in the deployment-template.json to identify the location of the copy of the resource-template.json file in the configuration bucket that should be used for a specific resource group.

**Input Properties**

- **ConfigurationBucket**

  Required. The name of the Amazon S3 bucket that contains the configuration data.

- **ConfigurationKey**

  Required. The Amazon S3 object key prefix where the deployment configuration data is located in the configuration bucket.

- **ResourceGroup**

  Required. The name of the resource group that is to be configured.

**Output Properties**

- **ConfigurationBucket**

  The name of the Amazon S3 bucket that contains the configuration data. This is always the same as the ConfigurationBucket input property.

- **ConfigurationKey**

  The Amazon S3 object key prefix where the specified resource group's configuration data is located in the configuration bucket. This is the input ConfigurationKey with the string ResourceGroup and the value of ResourceGroup appended.

- **TemplateURL**

  The Amazon S3 URL of the resource group's copy of the resource-template.json in the configuration bucket. This value should be used as the resource group's TemplateURL property value.
**LambdaConfiguration**

The `Custom::LambdaConfiguration` resource is used in `resource-template.json` files to provide configuration data for Lambda function resources.

**Input Properties**

- **ConfigurationBucket**
  Required. The name of the Amazon S3 bucket that contains the configuration data.

- **ConfigurationKey**
  Required. The Amazon S3 object key prefix where configuration data for the resource group is located in the configuration bucket.

- **FunctionName**
  Required. The friendly name of the Lambda function resource being configured.

- **Settings**
  Optional. Values that are made available to the Lambda function code.

- **Runtime**
  Required. Identifies the runtime used for the Lambda function.

**Output Properties**

- **ConfigurationBucket**
  The name of the Amazon S3 bucket that contains the configuration data. This is always the same as the `ConfigurationBucket` input property.

- **ConfigurationKey**
  The Amazon S3 object key prefix where the specified function's zipped code is located in the configuration bucket.

- **Runtime**
  The Lambda runtime used by the function. This is always the same as the input `Runtime` property value.

- **Role**
  The ID of the Lambda function execution created for this function.

For information on how the `LambdaConfiguration` custom resource is used to allow Lambda functions to perform specified actions on specific project resources, see *Controlling Access to Resources* (p. 2370).

**Helper**

The `Custom::Helper` resource is used in templates to perform simple tasks similar to those performed by AWS CloudFormation's *Intrinsic Functions*.

**Input Properties**

- **Input**
  Provides a JSON object that is processed by the custom resource handler.
Output

The output is the processed version of the JSON object that is provided by the `Input` property.

Helper Function

The `Helper` resource supports the following function. The function is applied to the `Input` property value by resource handler to produce its output.

`HelperFn::LowerCase`

Converts a string to lowercase.

Syntax

```json
{ "HelperFn::LowerCase" : "converted-string-value" }
```

Example

The following example from the `project-template.json` file uses `HelperFn::LowerCase` to lower the case of a stack name.

```json
{
  ...
  "Resources": {
    ...
    "Helper": {
      "Type": "Custom::Helper",
      "Properties": {
        "Input": {
          "LowerCaseStackName": { "HelperFn::LowerCase": { "Ref": "AWS::StackName" } }
        },
        "ServiceToken": ...
      }
    },
    ...
    { "Fn::Join": [ "", [ "arn:aws:s3:::", { "Fn::GetAtt": [ "Helper", "LowerCaseStackName" ] }, "-*" ] ] }
    ...
  }
}
```

Cloud Gem Framework

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Lumberyard Cloud Gem Framework makes it easy to build popular cloud-connected features, such as dynamic content, leaderboards, and daily messages. The Cloud Gem Framework contains Cloud gems – Modular packages of discrete functionality and assets that include everything necessary for a game developer to include that functionality into their project, including backend and client functionality.

Cloud gems can be used out of the box in production, and they come with full source code in case you want to customize their behavior.

Topics

Lumberyard User Guide

Getting Started with the Cloud Gem Framework

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard cloud gems make it easy to create cloud-connected functionality for your games. You can use the cloud gems included with Lumberyard, or use Lumberyard's Cloud Gem Framework to create your own cloud gems.

Cloud Gems

Cloud gems are Lumberyard gems that use Cloud Canvas Resource Manager (p. 2110) (CCRM) to define AWS resources that support their operation. CCRM provides the infrastructure needed to create, configure, and access AWS resources. A cloud gem defines resources and implements the required operations to create a complete game subsystem.

Cloud gems use general purpose AWS features that operate in your AWS account. They are not game-specific services operated by Amazon. Cloud gems follow a serverless microservice architecture that makes use of AWS Lambda functions for computation, and Amazon DynamoDB, Amazon RDS, and Amazon S3 for data storage. However, a cloud gem can use any AWS service.

For example, a cloud gem could provide a leaderboard system that uses a DynamoDB table to store high scores. The gem could use an AWS Lambda function to validate submitted scores and allow fraudulent high scores to be deleted.

In this scenario, CCRM performs the following tasks:

• Creates the DynamoDB table and Lambda function defined by the gem.
• Enables the game client to invoke the API to submit a score.
• Protects the integrity of the leaderboard by removing fraudulent scores automatically.
• Permits the creation of a user interface that enables an authorized employee to remove fraudulent scores manually.

Cloud Gem Framework

The Cloud Gem Framework is a collection of tools and API operations that support the creation and operation of cloud gems.
The following diagram shows a high-level view of the Cloud Gem Framework architecture.

The Cloud Gem Framework contains the following major components:

- **Cloud Gem Framework Service API (p. 2305)** – An API that provides a secure interface to a cloud gem's functionality.
- **AWS API Jobs (p. 2286)** – Integrates the AWS API with the Lumberyard job execution systems (not illustrated).
- **HTTP Request Job (p. 2265)** – A Lumberyard job for executing HTTP requests (not illustrated).

### Creating a Cloud Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard includes some cloud gems, such as leaderboards and dynamic content distribution, that provide full-featured services. You can use these gems in your games with a minimum of effort. Because the full source code for these cloud gems is included with Lumberyard, you can customize them or use them as examples for developing your own cloud gems.

You can develop your own cloud gems to create discrete packages of custom, cloud-connected functionality to enhance your game. Cloud gems leverage the power of AWS, benefit from the security model of AWS and Lumberyard, and can communicate with one another to create a seamless gaming experience.

You can easily create your own cloud gem by using the `lmbr_aws cloud-gem create` command.

### Prerequisites

1. Ensure that the Cloud Gem Framework gem is enabled for your project. Do one of the following:
   - Use the *Enabling Gems (p. 1064)* to enable the **Cloud Gem Framework** gem.
   
   OR
   
   - From the `\dev\Tools\LmbrSetup\Win` directory, enter the following command. Replace `<projectname>` with the name of your project.

```
lmbr gems enable <projectname> CloudGemFramework
```
2. Ensure that your project's Cloud Gem Framework resources correspond to the latest version of the Cloud Gem Framework gem. From a command prompt window on the \dev directory, enter the following command:

```bash
lmbr_aws project update-framework-version
```

3. If your cloud gem will use the Cloud Gem Framework Service API (p. 2305), do one of the following:
   - In Running Lumberyard Setup Assistant (p. 16), choose Compile the game code
   - OR
   - From a command prompt window on the \dev\Tools\LmbrSetup\Win directory, enter the following command:

```bash
lmbr capabilities enable compilegame
```

### To create a cloud gem

- From the \dev directory, enter the `lmbr_aws cloud-gem create` command. Use the following syntax:

```bash
lmbr_aws cloud-gem create --gem {gem-name} --initial-content {content-option} --enable
```

The syntax options are as follows.

- `--gem {gem-name}` – Specifies the name of the cloud gem.
- `--initial-content {content-option}` – Specifies the starter content for the cloud gem. For a list of content options, see `cloud-gem create` (p. 2392).
- `--enable` – Enables the cloud gem in your project.

### Example

The following command example creates a cloud gem called `MyCloudGem` that is enabled in the current project and has Amazon API Gateway and AWS Lambda function resources.

```bash
lmbr_aws cloud-gem create --gem MyCloudGem --initial-content api-lambda --enable
```

### Results of the Command

Depending on the parameter that you choose for the `--initial-content` option, the `cloud-gem create` command can do much of the initial cloud gem code work for you. For example, choosing the `api-lambda` parameter creates the following resources locally:

- A `\dev\Gems\{gem-name}\vN\ gem.json` file that declares a dependency on the Cloud Gem Framework.
- A `\dev\Gems\{gem-name}\vN\AWS` directory that includes the following items:
  - A `lambda-code` directory that contains skeleton `ServiceLambda` API code. `ServiceLambda` is an AWS Lambda function that implements your cloud gem's functionality.
  - A `swagger.json` file that describes the API for the cloud gem. For more information about the `swagger.json` file, see `Cloud Gem Framework Service API` (p. 2305).
  - A `resource-template.json` (p. 2237) file that defines the initial resources for the cloud gem. In the `api-lambda` example, the `resource-template.json` file specifies the following:
    - `ServiceApi`, `ServiceLambda`, and `ServiceLambdaConfiguration` resources.
• An output for the service API URL.
• An AccessControl resource configured as described in Controlling Access to Resources (p. 2370).

**Note**
Some gems have an obsolete cgp-resource-code directory.
• A `\dev\Gems\{gem-name\}\vN\Code\` directory with skeleton code that was automatically generated from the swagger.json file. The Code directory contains generated Using the Waf Build System (p. 63) files and the following subdirectories:
  • `\AWS\ServiceAPI\` – Contains `{gem-name}`ClientComponent.h and `{gem-name}`ClientComponent.cpp files. Use the skeleton code in these files to implement a Lumberyard component that you can use to invoke the cloud gem's service API operations from C++ or Lua.
  • `\Include\{gem-name\}\`– Contains a `{gem-name}`Bus.h EBus (p. 1851) file.
  • `\Source\`– Contains skeleton component, gem module and system component files.
  • `\Tests\`– Contains a skeleton `{gem-name}`Test.cpp file

**Developing your Cloud Gem**

After you use the `lmbr_aws cloud-gem create` command, you can further develop your cloud gem by doing the following:

• Add resource definitions that the cloud gem requires to the resource-template.json file. In Cloud Canvas Resource Manager, click Upload all resources to create and deploy the AWS resources that are defined in your resource-template.json file.
• Implement the cloud gem's functionality by adding code to the lambda-code directory.
• Add paths and operations to the swagger.json file that expose the functionality of your cloud gem. For more information, see Cloud Gem Framework Service API (p. 2305).
• Use Lumberyard components, EBus (p. 1851), and other features to implement game client functionality for the gem. Place the code in the cloud gem's `\dev\Gems\<gem-name>\vN\Code directory. You can use the generated service API client to access the functionality in the cloud gem's ServiceLambda Lambda function.

**Lambda Language Support in the Cloud Gem Framework**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

Lumberyard has support for Lambda deployment packages that include Lambda functions written in Node.js, Python 3.7 or later, Java, Go, or the .NET framework.

**To add a non-Python Lambda function to a cloud gem**

1. Add a new Lambda function and Lambda configuration to the Resources block of your resource_template.json file.

The following example shows the entries for the .NET Lambda function in the resource_template.json file of the AWS Lambda Language Demo cloud gem.

```json
[ ... ]
"Resources": {  
  "AccessControl": {  
```

Version 1.28

},
  "FunctionName": "DotnetLambda",
  "Runtime": "dotnetcore1.0",
  "ServiceToken": {
    "Ref": "ProjectResourceHandler"
  }
},
  "Type": "Custom::LambdaConfiguration"
],
[ ... ]

2. Follow the instructions in Creating a Deployment Package to create a Lambda function deployment package for the runtime that you are using.

3. Use the FunctionName property of the function's LambdaConfiguration section to name the packaged .zip or .jar file.

4. Put the package file (for example, DotnetLambda.zip) in the lumberyard_version\dev\Gems \gem_directory\vN\AWS\lambda-code\ directory.

Notes

When you create non-Python Lambda functions for use with Cloud Canvas, note the following:

- The Visual Studio tools for .NET Lambda functions do not generate a Lambda function deployment package automatically. For steps, see .NET Core CLI in the AWS Lambda Developer Guide.
- When you use the Eclipse IDE and Apache Maven to build a Java .jar package, Maven generates a .jar file named project-SNAPSHOT.jar. The Cloud Canvas uploader supports this naming convention and the project.jar file.
- Each runtime has its own format for the Handler property. See the following table.

<table>
<thead>
<tr>
<th>Language</th>
<th>Handler Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>.NET</td>
<td>Project::namespace.class::function</td>
</tr>
<tr>
<td>Java</td>
<td>package.class</td>
</tr>
<tr>
<td>Go</td>
<td>class must implement the RequestHandle class.</td>
</tr>
<tr>
<td></td>
<td>The name of the executable generated by the go build command.</td>
</tr>
</tbody>
</table>

Examples and Sample Level

The AWS Lambda Language Demo cloud gem included with Lumberyard contains skeleton "Hello World" Lambda function examples in Python, Java, .NET, Go, and node.js. You can find the relevant files in the lumberyard_version\dev\Gems\AWSLambdaLanguageDemo\v1\AWS\lambda-code directory.

Running the Sample Level

The CloudGemSamples project cloud gem includes a sample level named LambdaLanguage that shows Cloud Canvas support for Lambda languages.

Prerequisites

Running the sample requires the following prerequisites:
• You are using Lumberyard version 1.16 or later.
• Your Lumberyard project has the CloudGemSamples project enabled (in the Project Configurator (p. 43), choose CloudGemSamples).
• You used the Cloud Canvas Resource Manager (p. 2110) or the lmbr_aws command line tool (p. 2390) to create the following:
  • A project stack (p. 2350) for your project.
  • A deployment (p. 2352) for your project that includes the AWSLambdaLanguageDemo resource group.

To run the LambdaLanguage sample level

1. In Lumberyard Editor, choose File, Open or press Ctrl+O.
2. In the Open a Level dialog box, expand Levels.
3. Choose LambdaLanguage, and then click Open.
4. Click Play Game or press Ctrl+G to switch to gameplay mode. After a short pause, a message reports success, as seen in the following image.

<table>
<thead>
<tr>
<th>Sample Application</th>
<th>Resource Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>DotNetLambda</td>
<td>AWS Toolkit for Visual Studio and .NET Core CLI</td>
</tr>
<tr>

</tr>
<tr>
<td>JavaJarLambda</td>
<td>Creating a .jar Deployment Package Using Maven and Eclipse IDE (Java)</td>
</tr>
<tr>
<td>NodeLambda</td>
<td>Creating a Deployment Package (Node.js)</td>
</tr>
</tbody>
</table>

Additional Resources

For information on how the sample applications were built, see the following topics in the AWS Lambda Developer Guide.
Making HTTP Requests Using the Cloud Gem Framework

The Cloud Gem Framework and this documentation are in preview release and are subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Cloud Gem Framework Gem provides C++ classes and EBus interfaces to execute HTTP requests using the AZ::Job system. Your game client can use this feature to make HTTP requests for data from a public API such as Twitter or from a custom API. For example, your game could make HTTP requests to Twitter to see who is tweeting about your game.

To enable your game code to make HTTP requests

1. In the Project Configurator (p. 43), enable the Cloud Canvas Common and Cloud Gem Framework gems for your project.
2. In Lumberyard Editor, in Entity Inspector, click Add Component.
3. From the Cloud Gem Framework section, add the HttpClientComponent to an entity in your scene.
4. To make HTTP requests from your game code, perform one of the following steps:
   - From a Lua script component attached to your entity, add code based on the following example.
     ```lua
     local url = "https://my.url.com"
     local http_method = "GET"
     local json_body = "{}"
     ```
   - From C++, use Lumberyard’s EBus (p. 1851), as in the following example.
     ```cpp
     AZStd::string url = "https://my.url.com"
     AZStd::string httpMethod = "GET"
     AZStd::string jsonBody = "{}"
     EBUS_EVENT(HttpClientComponentRequestBus, MakeHttpRequest, url, httpMethod, jsonBody);
     ```
   - From C++, use HttpRequestJob, as in the following example.
     ```cpp
     AZStd::string url = "https://my.url.com"
     AZStd::string httpMethod = "GET"
     AZStd::string jsonBody = "{}"
     auto job = aznew HttpRequestJob(true, ServiceJob::GetDefaultConfig(),
     [this](int responseCode, AZStd::string content)
     {
       // handle success
     },
     [this](int responseCode)
     {
       // handle failure
     });
     job->SetUrl(url.c_str());
     job->SetHttpMethod(httpMethod);
     job->SetJsonBody(jsonBody.c_str());
     ```
Getting HTTP Responses Using Script

To get responses from a HTTP request, your script class needs an `HttpClientComponentNotificationBus` as in the following example.

```lua
function httpClientUsageExample:OnActivate()
    self.notificationHandler = HttpClientComponentNotificationBus.Connect(self, self.entityId);
end
```

Next, your script class must implement the `HttpClientComponentNotificationBus` functions `OnHttpRequestSuccess` and `OnHttpRequestFailure` as in the following example.

```lua
function myscript:OnHttpRequestSuccess(responseCode, responseBody)
    Debug.Log("HTTP RESPONSE -- " .. responseCode);
    Debug.Log("HTTP BODY -- " .. responseBody);
end

function myscript:OnHttpRequestFailure(errorCode)
    Debug.Log("HTTP Error-- " .. errorCode);
end
```

Getting HTTP Responses Using C++

To get the notifications in C++, you must create a component that inherits from `HttpClientComponentNotificationBus::Handler`. This class must implement `OnHttpRequestSuccess` and `OnHttpRequestFailure` and should be placed on the same entity as the `HttpClientComponent` in your level.

Cloud Gem Framework Resource Manager Hooks

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Cloud Canvas Resource Manager ensures that the AWS resources that the game uses match the definitions of those resources in the game's source code. However, you might need to add functionality to these processes. For example, for the Dynamic Content Cloud Gem, you must upload any default packages for the project immediately after you create a new deployment.

The resource manager provides some Python hook modules for cloud gems. The code for these modules is located in the `resource-manager-code` directory found in the cloud gem's AWS directory (for example, `\dev\Gems\CloudGemDynamicContent\AWS\resource-manager-code`).

The following modules are supported:

- `update.py` – Contains functions that are called before and after stack update operations. For more information, see Update Hook Functions (p. 2283).
- `command.py` – Contains functions that add new CLI and GUI support to the resource manager. For more information, see Command Hook Functions (p. 2284).

Hook Function Parameters

All hook functions are called with the following:
• A parameter that represents the hook function
• Some keyword arguments that are specific to each hook function

The parameter that represents the hook function is a `HookModule` object (p. 2275). The most important property provided by the `HookModule` object is `context`, which is a `Context Object` (p. 2267). The `Context` object gives your hook function access to the Cloud Canvas Resource Manager configuration data for the project.

**Futureproofing Your Functions**

When you write a hook function, always add Python's `**kwargs` construct as the last argument. That way your function can gracefully accept (and ignore) arguments that future versions of resource manager might add after your function is written.

For example, suppose resource manager passes `arg_a` and `arg_b` arguments to your hook function. You declare the hook function as follows:

```python
def a_hook(hook, arg_a, arg_b, **kwargs)
```

Later, when resource manager adds an `arg_c` argument, your hook function does not break. Your function still accepts `arg_a` and `arg_b` but can ignore `arg_c` because `arg_c` was passed through the `kwargs` parameter.

**Cloud Canvas Resource Manager Objects**

Cloud Canvas Resource Manager includes Python objects that you can use to access project configuration data and perform various project operations.

**Note**
The source code for these objects is located in the Lumberyard dev\Tools\lmbr_aws \AWSResourceManager directory.

**Context Object**

The `Context` object has properties that provide access to project configuration and that perform operations such as adding resource definitions to a resource group template.

You can get a `Context` object instance from the `context` property of the `HookModule` object instance passed to hook functions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws</td>
<td>An AWSContext object.</td>
</tr>
<tr>
<td>config</td>
<td>A ConfigContext object.</td>
</tr>
<tr>
<td>gem</td>
<td>A GemContext object.</td>
</tr>
<tr>
<td>hooks</td>
<td>A HookContext object.</td>
</tr>
<tr>
<td>resource_groups</td>
<td>A ResourceGroupContext object.</td>
</tr>
<tr>
<td>stack</td>
<td>A StackContext object.</td>
</tr>
<tr>
<td>view</td>
<td>A ViewContext object.</td>
</tr>
</tbody>
</table>

Other properties or functions of this object are internal to resource manager and should not be used.
AWSContext Object

The AWSContext object has helper functions and properties related to AWS clients and credentials.

You can get an AWSContext object instance from the aws property of a Context object.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>assume_role(logical_role_id, deployment_name)</td>
<td>Assumes a role that uses the current AWS credentials. New clients that were created from the client function use the temporary credentials that were created by assuming the role. These credentials have a 3600 second (5 minute) lifetime.</td>
</tr>
<tr>
<td></td>
<td>The logical_role_id parameter can be the logical name of a AWS::IAM::Role resource defined in the project-template.json or deployment-access-template.json files. In the case of a role that is defined in the deployment-access-template.json file, the deployment_name identifies the actual role that will be assumed.</td>
</tr>
<tr>
<td>client(service_name, region=None, use_role=True)</td>
<td>Creates a Python AWS API (boto3) client for the specified AWS service. If use_role is True, the client uses the credentials that are created when assume_role was called.</td>
</tr>
<tr>
<td></td>
<td>The returned object is a wrapper around the actual boto3 client object. The wrapper logs all API call attempts and responses when the --verbose option is passed to lmbr_aws. This aids in debugging.</td>
</tr>
<tr>
<td></td>
<td>The client wrapper also performs retries with exponential back off.</td>
</tr>
<tr>
<td>get_credentials_file_path()</td>
<td>Returns the full path to the .aws/credentials file.</td>
</tr>
<tr>
<td>get_default_profile()</td>
<td>Gets the AWS credentials profile name that is used by default when clients are created.</td>
</tr>
<tr>
<td>get_temporary_credentials(logical_role_id, deployment_name, duration_seconds)</td>
<td>Creates temporary credentials by using the current credentials to assume a role.</td>
</tr>
<tr>
<td></td>
<td>The logical_role_id parameter can be the logical name of a AWS::IAM::Role resource defined in the project-template.json or deployment-access-template.json files. In the case of a role defined in the deployment-access-template.json file, the deployment_name identifies the actual role that will be assumed.</td>
</tr>
<tr>
<td></td>
<td>The return value is a Python dict with the following properties:</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>AccessKeyId</td>
<td>Returns an AWSCredentials object that contains the data read from the .aws/credentials file.</td>
</tr>
<tr>
<td>SecretAccessKey</td>
<td></td>
</tr>
<tr>
<td>SessionToken</td>
<td></td>
</tr>
<tr>
<td>load_credentials()</td>
<td></td>
</tr>
<tr>
<td>profile_exists(profile_name)</td>
<td>Determines whether the specified profile exists in the .aws/credentials file.</td>
</tr>
<tr>
<td>save_credentials(credentials)</td>
<td>Saves a modified AWSCredentials object into the .aws/credentials file.</td>
</tr>
<tr>
<td>session</td>
<td>The boto3 session object that is used by client().</td>
</tr>
<tr>
<td>set_default_profile</td>
<td>Sets the AWS credentials profile that is used when clients are created. This resets the session property.</td>
</tr>
</tbody>
</table>

Other properties or functions of this object are internal to resource manager and should not be used.

**AWSCredentials Object**

The AWSCredentials object contains AWS credential information that is read from the .aws/credentials file. This is essentially a wrapper around a Python ConfigParser object. The AWSCredentials object handles the AWS credential file's use of the default section, which conflicts with how ConfigParser handles defaults.

To get an AWSCredentials object instance, use the load_credentials function on an AWSContext object.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add_section(section_name)</td>
<td>Adds a section.</td>
</tr>
<tr>
<td>get(section_name, option_name)</td>
<td>Gets the value of an option in a section.</td>
</tr>
<tr>
<td>has_option(section_name, option_name)</td>
<td>Determines whether an option exists in a section.</td>
</tr>
<tr>
<td>has_section(section_name)</td>
<td>Determines whether a section exists.</td>
</tr>
<tr>
<td>items(section_name)</td>
<td>Returns a list of name value pairs of the options in a section.</td>
</tr>
<tr>
<td>options(section_name)</td>
<td>Returns a list of options in a section.</td>
</tr>
<tr>
<td>read(path)</td>
<td>Reads credentials from a file with the specified path.</td>
</tr>
<tr>
<td>remove_option(section_name, option_name)</td>
<td>Removes an option from a section.</td>
</tr>
<tr>
<td>remove_section(section_name)</td>
<td>Removes a section.</td>
</tr>
</tbody>
</table>
### Name | Description
---|---
sections() | Returns a list of section names. Each profile is represented by a section.
set(section_name, option_name, value) | Sets an option value.
write(path) | Writes credentials to a file with the specified path.

Other properties or functions of this object are internal to resource manager and should not be used.

**ConfigContext Object**

The ConfigContext object has properties and functions that provide access to project and deployment configuration data.

You can get a ConfigContext object instance from the `config` property of a Context object.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws_directory_path</td>
<td>The full path to the currently enabled game project (as determined by the <code>bootstrap.cfg</code> file or options passed to <code>lmbr_aws</code>).</td>
</tr>
<tr>
<td>base_resource_group_directory_path</td>
<td>The directory where resource groups that are defined by the project (as opposed to those defined by gems) are located. This is typically the <code>resource-group</code> subdirectory that is found in the directory identified by <code>aws_directory_path</code>.</td>
</tr>
<tr>
<td>clear_user_default_deployment()</td>
<td>Clears the default deployment setting.</td>
</tr>
<tr>
<td>clear_user_default_profile()</td>
<td>Clears the default AWS credentials profile name. This does not update the <code>.aws/credentials</code> file. The name of the default profile is saved in the Cloud Canvas Resource Manager's user settings file.</td>
</tr>
<tr>
<td>configuration_bucket_name</td>
<td>The name of the project's Configuration Amazon S3 bucket.</td>
</tr>
<tr>
<td>copy_default_lambda_function_content(destination_path)</td>
<td>Copies the default Lambda function content to the specified location.</td>

<td>Copies the content from the default project AWS directory to the specified location.</td>
</tr>
<tr>
<td>copy_default_resource_group_content(destination_path)</td>
<td>Copies the content from the default resource group to the specified location.</td>
</tr>
<tr>
<td>copy_example_resource_group_content(destination_path)</td>
<td>Copies the content from the example resource group to the specified location.</td>
</tr>
</tbody>
</table>
| default_deployment | The name of the deployment that is the default for the current user if a default name has been specified. If a default has been specified, the value is that of Version 1.28

2270
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_default_deployment</td>
<td>user_default_deployment; otherwise, it is that of project_default_deployment.</td>
</tr>
<tr>
<td>deployment_access_template</td>
<td>A Python object that contains the content of the deployment access template file.</td>
</tr>
<tr>
<td>deployment_access_template_path</td>
<td>The full path to the project's deployment-access-template.json file.</td>
</tr>
<tr>
<td>deployment_names</td>
<td>A list that contains the names of the project's deployments.</td>
</tr>
<tr>
<td>deployment_stack_exists</td>
<td>Determines whether a deployment stack exists.</td>
</tr>
<tr>
<td>finalize_deployment_stack_ids</td>
<td>Commits the pending deployment and deployment access stack IDs as the deployment's actual stack IDs. See set_pending_deployment_stack_id and set_pending_deployment_access_stack_id.</td>
</tr>
<tr>
<td>game_directory_path</td>
<td>The full path to the currently enabled game project (as determined by the bootstrap.cfg file or the options that are passed to lmbr_aws).</td>
</tr>
<tr>
<td>gem_directory_path</td>
<td>The full path to the directory where gems are defined. This is the Gems subdirectory of the directory identified by root_directory_path.</td>
</tr>
<tr>
<td>get_default_deployment_stack_name</td>
<td>Gets the default stack name for a deployment with the specified name.</td>
</tr>
<tr>
<td>get_deployment_access_stack_id</td>
<td>Gets the ARN of a deployment access stack. If the specified deployment stack doesn't exist, raises a HandledError or returns None if optional is True.</td>
</tr>
<tr>
<td>get_deployment_stack_id</td>
<td>Gets the ARN of a deployment stack. If the specified deployment stack doesn't exist, raises a HandledError or returns None if optional is True.</td>
</tr>
<tr>
<td>get_game_directory_name</td>
<td>Gets the name of the game directory from the bootstrap.cfg file.</td>
</tr>
<tr>

<td>A Python object that contains the content of the project template file.</td>
</tr>
<tr>
<td>project_template_path</td>
<td>The full path to the project's project-template.json file.</td>
</tr>
<tr>
<td>protect_deployment(deployment_name)</td>
<td>Marks a deployment as protected. It requires special confirmation before you can connect debug builds of the game to protected deployments. See also unprotected_deployment and get_protected_deployment_names.</td>
</tr>
<tr>
<td>refresh_user_settings()</td>
<td>A function that reloads the user_settings object from the user settings file.</td>
</tr>
<tr>
<td>release_deployment</td>
<td>The name of the deployment that has been designed as the release deployment of the project.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>remove_deployment(deployment_name)</td>
<td>Removes a deployment from the project's configuration.</td>
</tr>
<tr>
<td>root_directory_path</td>
<td>The full path to the Lumberyard root directory (the \dev directory), which contains project-specific directories.</td>
</tr>
<tr>
<td>save_deployment_access_template()</td>
<td>Saves the current deployment_access_template object to the project's deployment-access-template.json file.</td>
</tr>
<tr>
<td>save_deployment_template()</td>
<td>Saves the current deployment_template object to the project's deployment-template.json file.</td>
</tr>
<tr>
<td>save_project_template()</td>
<td>A function that saves the current project_template object to the project's project-template.json file.</td>
</tr>
<tr>
<td>set_pending_deployment_access_stack_id(deployment_access_stack_id)</td>
<td>Sets the ID for a deployment access stack that is being created. For more information, see finalize_deployment_stack_ids and set_pending_deployment_stack_id.</td>
</tr>
<tr>
<td>set_pending_deployment_stack_id(deployment_stack_id)</td>
<td>Sets the ID for a deployment stack that is being created. For more information, see finalize_deployment_stack_ids and set_pending_deployment_access_stack_id.</td>
</tr>
<tr>
<td>set_project_default_deployment(deployment_name)</td>
<td>Sets the project's default deployment for the project. Overridden by the value for user's default deployment if one is specified.</td>
</tr>
<tr>
<td>set_release_deployment(deployment_name)</td>
<td>Sets the release deployment for the project.</td>
</tr>
<tr>
<td>set_user_default_deployment(deployment_name)</td>
<td>Sets the default deployment for the user. After it is set, overrides the project default deployment.</td>
</tr>
<tr>
<td>set_user_default_profile(profile_name)</td>
<td>Sets the user's default AWS credentials profile. This does not update the user's .aws/credentials file; the name of the default profile is saved in the Cloud Canvas Resource Manager's user settings file.</td>
</tr>
<tr>
<td>unprotectedeployment(deployment_name)</td>
<td>Reverses the action of protect_deployment.</td>
</tr>
<tr>
<td>user_default_deployment</td>
<td>The name of the deployment that has been designated as the default by the current user. For more information, see project_default_deployment and default_deployment.</td>
</tr>
<tr>
<td>user_default_profile</td>
<td>The user's default AWS profile name as read from user settings.</td>
</tr>
</tbody>
</table>
### Name | Description
--- | ---
user_directory_path | The full path to the user directory in the Lumberyard cache directory. This is where user-specific configuration is stored.
user_settings | A Python object that contains the contents of the user settings file.
user_settings_path | The full path to the JSON format text file that resource manager uses to store user-specific configuration. This configuration includes default deployment and AWS credentials profile names. This path is typically the `user-settings.json` file in the directory specified by `user_directory_path`.

Other properties or functions of this object are internal to resource manager and should not be used.

**Gem Object**

The Gem object provides access to gem-specific configuration data. To get Gem object instances, use the `enabled_gems` property of a GemContext object.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws_directory</td>
<td>The full path to the gem's AWS directory.</td>
</tr>
<tr>
<td>aws_directory_exists</td>
<td>True if the gem's AWS directory exists.</td>
</tr>
<tr>
<td>display_name</td>
<td>The gem display name.</td>
</tr>
<tr>
<td>file_object</td>
<td>A Python object that contains the contents of the gem's <code>gem.json</code> file.</td>
</tr>
<tr>
<td>name</td>
<td>The name of the gem.</td>
</tr>
<tr>
<td>project_resources</td>
<td>Project resource definitions that are inserted into the project's stack template before the template is uploaded. These definitions are read from a <code>project-template.json</code> file in the gem's AWS directory.</td>
</tr>
<tr>
<td>resource_group_name</td>
<td>The gem's resource group name, if any. A gem has a resource group name only if it has a <code>resource-template.json</code> file.</td>
</tr>
<tr>
<td>root_directory</td>
<td>The full path to the gem's directory.</td>
</tr>
<tr>
<td>uuid</td>
<td>The unique ID of the gem.</td>
</tr>
</tbody>
</table>

Other properties or functions of this object are internal to the resource manager and should not be used.

**GemContext Object**

The properties and methods of the GemContext object provide access to the project's gem configuration.
You can get a GemContext object instance using the gems property of a Context object.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled_gems</td>
<td>A list containing a gem object for each gem that is enabled for the project.</td>
</tr>
<tr>
<td>get_by_resource_group_name(resource_group_name)</td>
<td>Returns the gem object associated with the specified resource group, or None if the resource group doesn't exist or isn't associated with a gem. By default the resource group name is the same as the gem name, but a ResourceGroupAlias property can be put in the gem's gem.json file to override this default.</td>
</tr>
</tbody>
</table>

Other properties or functions of this object are internal to resource manager and should not be used.

**HandledError Object**

A HandledError object is Python Exception object. You can use it in a hook function to cause an expected error to be displayed without producing a stack trace. In general, the resource manager considers other kinds of exceptions to be unexpected errors and might show additional debug information that users should not see for expected errors.

The HandledError class is defined in the AWSResourceManager.errors module (\dev\Tools \lmbr_aws\AWSResourceManager\errors.py). To create an instance, see the following example.

```python
from AWSResourceManager.errors import HandledError

def my_function():
    if something_is_wrong:
        raise HandledError('Something is wrong.')
```

**HookModule Object**

The first argument (and the only positional argument) passed to a hook function is a HookModule object that represents the hook module itself. This object's properties give you access to project configuration data.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>context</td>
<td>Provides access to a Context object.</td>
</tr>
<tr>
<td>hook_name</td>
<td>The name of the cloud gem that defines the hook module.</td>
</tr>
<tr>
<td>hook_path</td>
<td>The full path to the cloud gem's AWS directory where the hook module is defined.</td>
</tr>
</tbody>
</table>

Other properties or functions of this object are internal to resource manager and should not be used.

**HookContext Object**

The HookContext object provides functionality for working with Cloud Canvas Resource Manager hooks.
You can get a HookContext object instance from the hooks property of the Context object.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>call_module_handlers(module_name, handler_name, args=(), kwargs={}, deprecated=False)</td>
<td>Calls the hook function identified by handler_name in the module identified by module_name. Use the kwargs parameter to pass keyword arguments to the handler function. The args parameter can only be used if deprecated is True. If deprecated is True, a warning regarding the deprecated function is displayed.</td>
</tr>
<tr>
<td>call_single_module_handler(module_name, handler_name, defining_module_name, args=(), kwargs={}, deprecated=False)</td>
<td>Calls a hook function defined by the gem or resource group that is specified by the defining_module_name parameter. For a description of the other parameters, see call_module_handlers.</td>
</tr>
</tbody>
</table>

Other properties or functions of this object are internal to resource manager and should not be used.

**ProjectSettings Object**

The ProjectSettings object manages the project configuration data that is stored in the project-settings.json file in the project's Amazon S3 Configuration bucket.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get_deployment(deployment_name)</td>
<td>Returns the configuration dictionary for the specified deployment. The dictionary contains the following keys:</td>
</tr>
<tr>
<td></td>
<td>DeploymentStackId – The ARN of the deployment stack.</td>
</tr>
<tr>
<td></td>
<td>DeploymentAccessStackId – The ARN of the deployment access stack.</td>
</tr>
<tr>
<td></td>
<td>resource-group – The resource group configuration dictionary for the deployment. For a description of this value, see get_resource_group_settings.</td>
</tr>
<tr>
<td>get_deployments()</td>
<td>Returns the entire configuration dictionary for deployments. The deployment name is the key. The special deployment name *, which contains settings for all deployments, can be present. For a description of the value dictionary, see get_deployment.</td>
</tr>
<tr>
<td>get_project_default_deployment()</td>
<td>Returns the default deployment for the project.</td>
</tr>
<tr>
<td>get_release_deployment()</td>
<td>Returns the release deployment for the project.</td>
</tr>
<tr>
<td>get_resource_group_settings(deployment_name)</td>
<td>Returns a dictionary containing the resource group configuration for the specified deployment. The resource group name is the key. The special resource group name *, which contains settings for all resource groups, can be present.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>remove_deployment(deployment_name)</td>
<td>Removes the configuration for the specified deployment name. To commit this change, call save.</td>
</tr>
<tr>
<td>remove_project_default_deployment()</td>
<td>Clears the default deployment for the project. To commit this change, call save.</td>
</tr>
<tr>
<td>remove_release_deployment()</td>
<td>Clears the release deployment for the project. To commit this change, call save.</td>
</tr>
<tr>
<td>save()</td>
<td>Saves the current configuration to the Amazon S3 bucket.</td>
</tr>
<tr>
<td>set_project_default_deployment(deployment_name)</td>
<td>Sets the default deployment for the project. To commit this change, call save.</td>
</tr>
<tr>
<td>set_release_deployment(deployment_name)</td>
<td>Sets the release deployment for the project. To commit this change, call save.</td>
</tr>
</tbody>
</table>

Other properties or functions of this object are internal to resource manager and should not be used.

**ResourceGroup Object**

The ResourceGroup object encapsulates a resource group's configuration. If multiple resource group stacks for a given resource group exist, each resource group stack is associated with a single deployment.

To get ResourceGroup object instances, use a ResourceGroupContext object.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add_output(logical_id, description, value, force=False)</td>
<td>Adds an output value to the resource group's resource template. If force is False, an existing output that has the same name is not replaced but is replaced if force is True. To save the changes, call save_template. Returns True if outputs are added.</td>
</tr>
<tr>
<td>add_parameters(parameter_definitions, force=False)</td>
<td>Adds parameter definitions to the resource group's resource template. The parameter_definitions parameter is a dictionary that is merged into the parameter definitions in the template. If force is False, existing definitions are not replaced but are replaced if force is True. To save the changes, call save_template. Returns True if parameter definitions are added.</td>
</tr>
<tr>
<td>add_resources(resource_definitions, force=False, dependencies=None)</td>
<td>Adds resource definitions to the resource group's resource template. The resource_definitions parameter is a dictionary that is merged into the template's current Resources object value. If</td>
</tr>
</tbody>
</table>
### Name | Description
--- | ---
force | If `force` is `False`, existing definitions are not be replaced but are replaced if `force` is `True`. The `dependencies` parameter can be a dictionary that specifies a list of values that are added to the existing resources `DependsOn` list. New resources are always added to the `AccessControl` resource's `DependsOn` list even if the `dependencies` parameter is not specified. To save the changes, call `save_template`. Returns `True` if resource definitions are added.

copy_directory(source_path, relative_destination_path='.', force=False) | Copies the contents of a specified directory into the resource group's directory. If a value for `relative_destination_path` is specified, the content is written into the specified subdirectory in the resource group directory. If `force` is `False`, existing files are not replaced, but are replaced if `force` is `True`. Returns `True` if any files are copied.

copy_file(source_path, relative_destination_path, force=False) | Copies a file to the resource group directory. The `relative_destination_path` parameter can contain the destination file name or a destination path and file name. If `force` is `False`, existing files are not replaced but are replaced if `force` is `True`. Returns `True` if the file is copied.

create_file(relative_destination_path, initial_content, force=False) | Creates a file in the resource group directory. The `relative_destination_path` parameter can contain the destination file name or a destination path and file name. The `initial_content` parameter should contain the initial text content for the file. If `force` is `False`, existing files are not replaced but are replaced if `force` is `True`. Returns `True` if the file is created.

directory_path | The full path to the resource group directory.

game_cpp_code_path | The full path to the directory where the C++ code associated with the resource group should be written. This parameter is used when service API client code is generated.

get_pending_resource_status(deployment_name) | Gets a dictionary that describes the resource group's pending resource status. The status is determined by comparing the configured resource definitions, Lambda code, and parameter values to the current definitions, code, and values.

get_stack_id(deployment_name, optional=False) | Gets the resource group's stack ID for the specified deployment. If no stack exists for the resource group, raises a `HandledError` or returns `None` if optional is `True`. 

Version 1.28
2278
### get_stack_parameters(deployment_name, uploader)
Get stack parameter for the specified deployment. The uploader parameter must be an Uploader object, which is used to determine the values for the ConfigurationBucket and ConfigurationKey parameters.

### get_template_with_parameters(deployment)
Returns a Python object that contains the contents of the resource group's resource-template.json file. The template's default parameter values are set according to the parameter configuration for the specified deployment.

### is_gem
True if the resource group is defined by a gem; False if the resource group is defined in the project's resource-group directory.

### name
The name of the resource group.

### remove_output(logical_id)
Removes an output value from the resource group's resource template. Returns True if the output value existed and was removed. To save the changes, call save_template.

### remove_parameters(parameter_names)
Removes parameter definitions from the resource group's resource template. The parameter_names parameter must be a list of the names of the parameters to remove. Returns True if the parameter definitions are removed.

### remove_resources(resource_names)
Removes resource definitions from the resource group's resource template. The resource_names parameter must be a list of the logical names of the resources to remove. Returns True if the resource definitions are removed. To save the changes, call save_template.

### save_template()
Saves the current value of the template property to the resource group's resource-template.json file.

### template
A Python object that contains the content of the resource group's resource-template.json file.

### template_path
The full path to the resource group's resource-template.json file.

Other properties or functions of this object are internal to resource manager and should not be used.

**ResourceGroupContext Object**

The ResourceGroupContext object provides access to resource group configuration data. To get a ResourceGroupContext object, use the resource_groups property of the Context object.
Name | Description
--- | ---
get(name, optional=False) | Returns a ResourceGroup object for the specified resource group. If the resource group doesn't exist, raises a HandledError or none if optional is True.
keys() | Returns the names of the resource groups in a list.
values() | Returns a list of ResourceGroup objects.

Other properties or functions of this object are internal to resource manager and should not be used.

**StackContext Object**

The StackContext object provides a number of helper functions that are useful when working with AWS CloudFormation stacks. To get a StackContext object instance, use the stack property of the Context object.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| confirm_stack_operation(stack_id, stack_description, args, pending_resource_status, ignore_resource_types = []) | Displays pending changes and a confirmation prompt for the pending stack operation. 

The args parameter should be the parsed command line arguments for the command. It is used to avoid displaying prompts if the necessary --confirm-... options are provided.

The ignore_resource_types parameter is a list of resource types that are not included in the list of changes shown to the user. This parameter filters changes to the Custom::EmptyDeployment resource.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| create_using_template(stack_name, template_body, region, created_callback=None, capabilities=[]) | Uses the provided template to start a stack creation operation. Displays stack events until the create operation is complete. If the value for created_callback is not None, the value must be a called function that has the created stack ID as its only parameter.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| create_using_url(stack_name, template_url, region, parameters=None, created_callback=None, capabilities=[]) | Uses a template identified by a URL to start a stack creation operation. Displays stack events until the create operation is complete. If the value for created_callback is not None, the value must be a called function that has the created stack ID as its only parameter.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| delete(stack_id, pending_resource_status=None) | Starts a stack delete operation and displays stack events until the delete operation is complete.

If provided, the pending_resource_status parameter specifies the resources to be deleted from an Amazon S3 bucket in preparation for deletion of the bucket itself. To retrieve a value for this parameter, use the
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get_pending_resource_status function on a ResourceGroup object, or</td>
<td>get_pending_resource_status function on the StackContext object. Preparing an S3 bucket for deletion deletes all the objects from the bucket unless the bucket specifies a DeletionPolicy property value of Retain.</td>
</tr>
<tr>
<td>use the get_pending_resource_status function on the StackContext</td>
<td></td>
</tr>
<tr>
<td>object. Preparing an S3 bucket for deletion deletes all the objects</td>
<td></td>
</tr>
<tr>
<td>from the bucket unless the bucket specifies a DeletionPolicy</td>
<td></td>
</tr>
<tr>
<td>property value of Retain.</td>
<td></td>
</tr>
<tr>
<td>describe_resources(stack_id, recursive=True, optional=False)</td>
<td>Uses the AWS CloudFormation describe_stack_resources API to return a description of a stack's resources. The content of the StackResources structure is converted to a dictionary keyed on the resource's logical ID.</td>
</tr>
<tr>
<td></td>
<td>If recursive is True, the descriptions of the resources in the nested stacks are also returned. In this case the resource's logical ID has the form <code>&lt;nested-stack-logical-id&gt;.&lt;nested-resource-logical-id&gt;</code>.</td>
</tr>
<tr>
<td></td>
<td>If the stack does not exist, a ValueError is raised if optional is False. Otherwise, an empty dictionary is returned.</td>
</tr>
<tr>
<td>describe_stack(stack_id, optional=False)</td>
<td>Returns a dictionary that contains the data returned by a call to the AWS CloudFormation describe_stacks API. If the stack does not exist, raises a ValueError or returns None if optional is True.</td>
</tr>
<tr>
<td>get_current_parameters(stack_id)</td>
<td>Gets a stack's current AWS CloudFormation template parameter values.</td>
</tr>
<tr>
<td>get_current_template(stack_id)</td>
<td>Gets a Python object that contains the stack's current AWS CloudFormation template.</td>
</tr>
<tr>
<td>get_pending_resource_status(stack_id, new_template={}, new_parameter_values={}, new_content_paths={})</td>
<td>Gets a dictionary that describes a stack's pending resource status. The status is determined by comparing the configured resource definitions, Lambda code, and parameter values to the current definitions, code, and values.</td>
</tr>
<tr>
<td></td>
<td>The new_template parameter is the resource definition template to which the stack's current template will be compared.</td>
</tr>
<tr>
<td></td>
<td>The new_parameter_values parameter is a dictionary of parameter values that will be compared to the stack's current parameter values.</td>
</tr>
<tr>
<td></td>
<td>The new_content_paths parameter is a dictionary that maps logical resource names to a list of full directory or file paths. The paths specify where content related to each resource is stored. A resource has pending update status if any of these files have changed since the last resource status update.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>get_physical_resource_id(stack_id,</td>
<td>Gets the physical ID of a resource in the specified stack. If expected_type is specified, the resource type is verified to be that type. If the type returned is not the type specified, raises a HandledError. If the specified resource does not exist, raises a HandledError or returns None if optional is True.</td>
</tr>
<tr>
<td>logical_resource_id, expected_type=None,</td>
<td></td>
</tr>
<tr>
<td>optional=False)</td>
<td></td>
</tr>
<tr>
<td>get_resource_arn(stack_id, logical_resource_id)</td>
<td>Gets the ARN for a resource in the specified stack.</td>
</tr>
<tr>
<td>get_stack_status(stack_id)</td>
<td>Gets status information for the stack. This function calls the AWS CloudFormation describe_stacks API and returns the StackStatus property of the first entry in the Stacks array of the response.</td>
</tr>
<tr>
<td>id_exists(stack_id)</td>
<td>Determines whether a stack with the specified ID (ARN) exists.</td>
</tr>
<tr>
<td>name_exists(stack_name, region)</td>
<td>Determines whether a stack with the specified name exists in the specified region.</td>
</tr>
<tr>
<td>update(stack_id, template_url, parameters={}, pending_resource_status={}, capabilities={})</td>
<td>Starts a stack update operation and displays stack events until the update operation is complete. If provided, the pending_resource_status parameter specifies the resources to be deleted from an S3 bucket in preparation for deletion of the bucket itself. To retrieve a value for this parameter, use the get_pending_resource_status function on a ResourceGroup object. Or use the get_pending_resource_status function on the StackContext object. Preparing an S3 bucket for deletion deletes all the objects from the bucket unless the bucket specifies a DeletionPolicy property value of Retain.</td>
</tr>
</tbody>
</table>

Other properties or functions of this object are internal to resource manager and should not be used.

**ViewContext Object**

The ViewContext object contains methods that produce Cloud Canvas Resource Manager output messages. Hook functions typically do not require these functions. For more information, see the source code for this object.

**Uploader Object**

You can use an Uploader object function to upload content to the project global area of the project's Configuration bucket. You pass Uploader object instances to the hook functions before_project_update, after_project_update, before_resource_group_update, and after_resource_group_update.
### Context

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>context</td>
<td>The current Context object.</td>
</tr>
<tr>
<td>bucket</td>
<td>The name of the project's Configuration bucket.</td>
</tr>
<tr>
<td>key</td>
<td>The object name prefix that is used when naming uploaded objects.</td>
</tr>
</tbody>
</table>

#### upload_content(name, content, description)

Uploads the specified content using `key` + '/ + name as the object name. A description of the upload is shown to the user.

#### upload_file(name, path)

Uploads a file using `key` + '/ + name as the object name.

#### upload_dir(name, path, alternate_root = None)

Uses `key` + '/' + name as the base object name to recursively upload the contents of a directory. If `alternate_root` is not None, the value specified is used as the object name prefix instead of `key`.

#### zip_and_upload_directory(directory_path, file_name=None, aggregated_directories=None, aggregated_content=None)

Recursively compresses the contents of a directory into a .zip file. It uses `key` + '/' + directory-name.zip as the object name to upload the file. The directory-name is the name of the directory at the end of directory_path.

You can use the file_name argument to override the directory-name.zip part of the object name.

The aggregated_directories argument can be an optional dictionary that specifies the paths of additional directories whose contents are included in the .zip file. The keys are the path location in the .zip file where the content is put.

The aggregated_content argument can be a dictionary that contains additional content to include in the .zip file. The keys are the path location in the .zip file where the content is put.

### Update Hook Functions

Update hooks are implemented in a cloud gem's Gem\<gem-name>\AWS\resource-manager-code\update.py file. If update hooks are defined in the module, the resource manager uses the parameters that are described in the Hook Function Parameters (p. 2266) section to call the following functions.

#### after_project_updated

The after_project_updated hook function is called after a project stack update operation finishes successfully.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>project_uploader</td>
<td>An Uploader object that you can use to upload additional data.</td>
</tr>
</tbody>
</table>
after_resource_group_updated

The after_resource_group_updated hook function is called after a resource group stack update operation finishes successfully.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deployment_name</td>
<td>The name of the deployment that was updated.</td>
</tr>
<tr>
<td>resource_group_name</td>
<td>The name of the resource group that was updated.</td>
</tr>
<tr>
<td>resource_group_uploader</td>
<td>An Uploader object that you can use to upload additional data.</td>
</tr>
</tbody>
</table>

before_project_updated

The before_project_updated hook function is called before a project stack update operation begins.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>project_uploader</td>
<td>An Uploader object that you can use to upload data for the operation.</td>
</tr>
</tbody>
</table>

before_resource_group_updated

The before_resource_group_updated hook function is called before a resource group stack update operation begins.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deployment_name</td>
<td>The name of the deployment being updated.</td>
</tr>
<tr>
<td>resource_group_name</td>
<td>The name of the resource group being updated.</td>
</tr>
<tr>
<td>resource_group_uploader</td>
<td>An Uploader object that can be used to upload additional data.</td>
</tr>
</tbody>
</table>

gather_writable_check_list

The gather_writable_check_list hook function is called before an update operation to gather a list of writable files. If any of the local files to be updated are read-only, the resource manager gives the user an opportunity to make the files writable (for example, with a source control system).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>check_list</td>
<td>A list of the full paths of writeable files.</td>
</tr>
</tbody>
</table>

Command Hook Functions

If the following command line hook functions exist in a module, they are defined in a cloud gem's Gem \
<gem-name>\AWS\resource-manager-code\command.py file. The resource manager uses the parameters in the Hook Function Parameters (p. 2266) section to call the following functions.
add_cli_commands

Adds additional commands to the command line parser. Called before command line argument parsing. Cloud Canvas Resource Manager uses the Python `argparse` module for command line parsing. All commands are grouped into a number of different subparsers. For example, the commands `lmbr_aws project list-resources` and `lmbr_aws deployment list` contain the subparsers `project` and `deployment`, which define a `list-resources` and `list` command, respectively.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subparsers</td>
<td>The subparser collection object returned by the <code>argparse add_subparsers</code> function. Use the hook function to add a subparser to the collection. Then, add the commands to the subparser.</td>
</tr>
<tr>
<td>add_common_args</td>
<td>Adds a set of common arguments to a command. This function adds the following arguments. For a description of these arguments, see Using the Cloud Canvas Command Line (p. 2390).</td>
</tr>
</tbody>
</table>

  --aws-access-key  
  --aws-secret-key  
  --profile  
  --assume-role  
  --root-directory  
  --game-directory  
  --aws-directory  
  --user-directory  
  --verbose  
  --no-prompt

The common arguments are processed by `lmbr_aws`. The hook does not typically process these options.

This function can take the following parameters:

- `parser` – The `argparse` defined parser object to which the arguments are added.
- `no_assume_role` – True specifies that the `--assume-role` common argument is not added; False specifies that it is.

add_cli_view_commands

Adds additional methods to the `ViewContext` object. Called before other command line commands.
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>view_context</td>
<td>A ViewContext object.</td>
</tr>
</tbody>
</table>

**add_gui_commands**

Adds commands to the Cloud Canvas Resource Manager in Lumberyard Editor. When the resource manager window is first opened, Lumberyard Editor initializes the resource manager Python subsystem, which calls `add_gui_commands`.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handlers</td>
<td>A dictionary that maps user interface command names to the handler functions that process them. The command names are passed to Python from the user interface.</td>
</tr>
</tbody>
</table>

**add_gui_view_commands**

Adds additional methods to the `ViewContext` object. Called before a GUI command is executed.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>view_context</td>
<td>A ViewContext object.</td>
</tr>
</tbody>
</table>

### Running AWS API Jobs Using the Cloud Gem Framework

The Cloud Gem Framework and this documentation are in preview release and are subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

The Cloud Gem Framework Gem provides C++ classes that can execute any C++ AWS API call by using the Lumberyard job execution system. This allows the operation to be performed on background threads that are managed by the job system.

**To use AWS API Jobs in your project**

1. In the [Creating Lumberyard projects](#) (p. 43), enable the Cloud Canvas Common and Cloud Gem Framework gems for your project.
2. We recommend that you put the code that uses AWS in a gem, but this is not required. If you do use a gem, make the Cloud Gem Framework and Cloud Canvas Common gems dependencies of your gem by adding the following to your gem's `gem.json` file.

```json
"Dependencies": [
  {
    "Uuid" : "6fc787a982184217a5a553ca24676cfa",
```
3. Activate your gem for your project.

4. In your gem or game project's `.wscript` file, make the following changes:

   a. To the list of includes, add:

   ```
   bld.Path('Code/SDKs/AWSNativeSDK/include')
   ```

   b. To the list of used static libraries, add `CloudGemFrameworkStaticLibrary`.

   c. Add `AWS_CPP_SDK_CORE` and other AWS API dynamic libraries as required. For a list of available aliases like `AWS_CPP_SDK_LAMBDA` and other library names, see the `dev\_WAF\_3rd_party\aws_native_sdk_shared.json` file.

   d. Add the security libraries for operating systems other than Windows, as in the following `.wscript` file for a gem.

   ```python
   SUBFOLDERS = []
   def build(bld):
       import lumberyard_sdks
       bld.DefineGem(  
           includes = [bld.Path('Code/SDKs/AWSNativeSDK/include')],  
           file_list = ['cloudcanvassample.waf_files'],  
           use = ['CloudGemFrameworkStaticLibrary'],  
           uselib = ['AWS_CPP_SDK_CORE', 'AWS_CPP_SDK_LAMBDA'],  
           darwin_lib = ['curl'],  
           linux_lib = ['curl'],  
           ios_lib = ['curl'],  
           appletv_lib = ['curl'],  
           ios_framework = ['security'],  
           appletv_framework = ['security']  
       )
       bld.recurse(SUBFOLDERS)
   ```

5. Include the `CloudGemFramework\AwsApiJob.h` header and the AWS SDK header files that are required for calling an API, as in the following example:

   ```
   #include <CloudGemFramework/AwsApiRequestJob.h>

   #pragma warning(disable: 4355) // <future> includes ppltasks.h which throws a C4355 warning: 'this' used in base member initializer list
   #include <aws/lambda/LambdaClient.h>
   #include <aws/lambda/model/InvokeRequest.h>
   #include <aws/lambda/model/InvokeResult.h>
   #include <aws/core/utils/Outcome.h>
   #include <aws/core/utils/memory/stl/AWSStringStream.h>
   #pragma warning(default: 4355)
   ```
6. Using code similar to the following, run an AWS API job. An alternative approach is to extend the job class (like `LambdaInvokeRequestJob` in the example) and provide overrides for the `OnSuccess` and `OnFailure` methods.

```cpp
using LambdaInvokeRequestJob = AWS_API_REQUEST_JOB(Lambda, Invoke);

auto job = LambdaInvokeRequestJob::Create(
    [](LambdaInvokeRequestJob* job) // OnSuccess handler - runs on job thread
    {
        Aws::IOStream& stream = job->result.GetPayload();
        std::istreambuf_iterator<AZStd::string::value_type> eos;
        AZStd::string content =
            AZStd::string{std::istreambuf_iterator<AZStd::string::value_type>(stream), eos};
        AZ_Printf("Example", "Got response %s", content.c_str());
    },
    [](LambdaInvokeRequestJob* job) // OnError handler (optional) - runs on job thread
    {
        AZ_Printf("Example", "Was error %s", job->error.GetMessageA().c_str());
    });

AZStd::string content = "...";

std::shared_ptr<Aws::StringStream> stream = std::make_shared<Aws::StringStream>();
*stream << content.c_str();

job->request.SetFunctionName("...");
job->request.SetBody(stream);
job->Start();
```

7. If your project uses the **Cloud Canvas Resource Manager**, get the physical resource ID and the logical resource ID of the AWS resource for each resource group. These IDs cause your AWS API call to use the correct resource for the active deployment. This ensures that your development, test, and released versions of a game don’t interfere with each other.

```cpp
#include <CloudCanvasCommon/CloudCanvasCommonBus.h>

AZStd::string functionName;
EBUS_EVENT_RESULT(functionName, CloudCanvasCommon::CloudCanvasCommonRequestBus,
    GetLogicalToPhysicalResourceMapping, "RESOURCE-GROUP.RESOURCE");

job->request.SetFunctionName(functionName.c_str());
```

8. If your project uses the **Cloud Canvas Resource Manager**, the AWS API is called using the player’s AWS credentials. These credentials are provided by the anonymous Amazon Cognito Identitypool that Cloud Canvas creates for your project. If you do not use **Cloud Canvas Resource Manager** or want to use other credentials, you can use code like the following to override the default configuration.

```cpp
#include <aws/core/auth/AWSCredentialsProvider.h>

LambdaInvokeRequestJob::Config config = LambdaInvokeRequestJob::GetDefaultConfig();
const char* accessKey = "...";
const char* secretKey = "...";

config.credentialsProvider = std::make_shared<Aws::Auth::SimpleAWSCredentialsProvider>(accessKey, secretKey);
config.requestTimeoutMs = 20000;

auto job = LambdaInvokeRequestJob::Create(
    ..., // OnSuccess handler
    ..., // OnError handler
    &config
);
AWS Behavior Context Reflections

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The CloudGemAWSScriptBehaviors gem uses the behavior context to expose AWS services such as Amazon Cognito, AWS Lambda, Amazon S3, and HTTP utilities to script. The `dev\CloudGemSamples\Scripts` directory has sample Lua code for each reflection. To try the samples, run the AWSBehaviorExamples level in the CloudGemSamples project.

**API Service**

API service behavior context reflections include a class and EBus that interact with Amazon API Gateway.

**AWSBehaviorAPI Class**

Calls methods that are exposed through the Amazon API Gateway service. The class properly signs requests with appropriate credentials in an HTTP request. The class translates the logical resource names in Cloud Canvas to physical names. This makes the class easy to use with other cloud gems.

**Properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string HTTPMethod</td>
<td>Specifies the HTTP method that calls the API. This string is API specific. Valid strings are: GET, POST, DELETE, PUT, and PATCH.</td>
</tr>
<tr>
<td>string Query</td>
<td>A standard URL query string that passes parameters to the API. This string is only the query and function portion of the URL and has the format <code>player/messages?time=now&amp;lang=eng</code>.</td>
</tr>
<tr>
<td>string ResourceName</td>
<td>Specifies the logical resource name of the API to call. Accepts only API Gateway resource names. Returns an error if other resource types are specified.</td>
</tr>
</tbody>
</table>

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void Execute()</td>
<td>Performs the HTTP request with the specified properties.</td>
</tr>
</tbody>
</table>

**AWSBehaviorAPINotificationsBus**

The `AWSBehaviorAPINotificationsBus` has the following methods.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void GetResponse(int responseCode, string responseData)</td>
<td>Called when the HTTP request returns a response. The <code>responseCode</code> parameter contains the HTTP response status code.</td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>response code; the <code>responseData</code> parameter contains the response data, which is often a JSON string.</td>
</tr>
<tr>
<td>void OnError(string <code>requestBody</code>)</td>
<td>Called when the API call fails. The <code>requestBody</code> parameter contains the request body.</td>
</tr>
<tr>
<td>void OnSuccess(string <code>resultBody</code>)</td>
<td>Called when the API call succeeds. The <code>resultBody</code> parameter contains the request response body.</td>
</tr>
</tbody>
</table>

**Lambda Service**

Lambda service behavior context reflections include a class and EBus that interact with AWS Lambda.

**AWSLambda Class**

Invokes an AWS Lambda function.

**Properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string <code>functionName</code></td>
<td>The logical function name in Cloud Canvas that you want to invoke.</td>
</tr>
<tr>
<td>string <code>requestBody</code></td>
<td>Optional. Specifies request parameters to pass to the Lambda invocation.</td>
</tr>
</tbody>
</table>

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void InvokeAWSLambda()</td>
<td>Invokes the specified Lambda function.</td>
</tr>
</tbody>
</table>

**AWSLambdaHandler**

The `AWSLambdaHandler` EBus has the following methods.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void OnError(string <code>errorBody</code>)</td>
<td>Called when the Lambda invocation fails. The <code>errorBody</code> parameter contains the information that was returned in the Lambda error response.</td>
</tr>
<tr>
<td>void OnSuccess(string <code>resultBody</code>)</td>
<td>Called when the Lambda invocation succeeds. The <code>resultBody</code> parameter contains the information that was returned by the Lambda function, if any.</td>
</tr>
</tbody>
</table>

**S3 Service**

S3 behavior context reflections include classes and EBuses that interact with Amazon S3.
AWSBehaviorS3Upload Class

 Uploads a local file to an Amazon S3 bucket.

**Properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string bucketName</td>
<td>Specifies the logical name in Cloud Canvas for the destination Amazon S3 bucket.</td>
</tr>
<tr>
<td>string contentType</td>
<td>Specifies the MIME file type of the file to be uploaded.</td>
</tr>
<tr>
<td>string keyName</td>
<td>Specifies the destination key for the file. The destination key is the file name that appears in Amazon S3 and must be unique to the bucket.</td>
</tr>
<tr>
<td>string localFileName</td>
<td>Specifies the fully qualified path name of the local file to be uploaded.</td>
</tr>
</tbody>
</table>

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void Upload()</td>
<td>Uploads the file with the specified properties.</td>
</tr>
</tbody>
</table>

AWSBehaviorS3UploadNotificationsBus

The AWSBehaviorS3UploadNotificationsBus has the following methods.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void OnError(string errorBody)</td>
<td>Called when the file upload fails. The errorBody parameter contains the error information returned by Amazon S3, if any.</td>
</tr>
<tr>
<td>void OnSuccess(string resultBody)</td>
<td>Called when the file upload succeeds. The resultBody parameter contains the information that is returned by Amazon S3, if any.</td>
</tr>
</tbody>
</table>

AWSBehaviorS3Download Class

Downloads a file from an Amazon S3 bucket to the local file system.

**Properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string bucketName</td>
<td>Specifies the logical name in Cloud Canvas for the Amazon S3 source bucket.</td>
</tr>
<tr>
<td>string keyName</td>
<td>Specifies the key name (the file name) of the Amazon S3 source file.</td>
</tr>
<tr>
<td>string localFileName</td>
<td>Specifies the fully qualified path of the location to which the downloaded file is written.</td>
</tr>
</tbody>
</table>
### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void Download()</td>
<td>Downloads the file with the specified properties.</td>
</tr>
</tbody>
</table>

#### AWSBehaviorS3DownloadNotificationsBus

The **AWSBehaviorS3DownloadNotificationsBus** has the following methods.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void OnError(string errorBody)</td>
<td>Called when the file download fails. The <code>errorBody</code> parameter contains error information returned by Amazon S3.</td>
</tr>
<tr>
<td>void OnSuccess(string resultBody)</td>
<td>Called when the file download succeeds. The <code>resultBody</code> parameter contains information returned by Amazon S3.</td>
</tr>
</tbody>
</table>

#### AWSBehaviorS3Presign Class

Provides a presigned URL for a specified Amazon S3 file. This is a URL that can be shared that allows authenticated access to the specified file.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string bucketName</td>
<td>Specifies the logical name in Cloud Canvas for the target S3 bucket.</td>
</tr>
<tr>
<td>string keyName</td>
<td>Specifies the key name (the file name) of the target Amazon S3 file.</td>
</tr>
<tr>
<td>string requestMethod</td>
<td>The HTTP method to generate for the URL. Valid strings are PUT, POST, DELETE, and GET.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void Presign()</td>
<td>Gets a presigned URL for the specified Amazon S3 file.</td>
</tr>
</tbody>
</table>

#### AWSBehaviorS3PresignNotificationsBus

The **AWSBehaviorS3PresignNotificationsBus** has the following methods.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void OnError(string errorBody)</td>
<td>Called when the operation fails. The <code>errorBody</code> parameter contains error information returned by Amazon S3.</td>
</tr>
</tbody>
</table>
Utilities

Utility classes and EBuses provide functionality for HTTP, JSON, URL, and string operations.

AWSBehaviorHTTP Class

The AWSBehaviorHTTP class implements a simple general-purpose HTTP GET request. You can use the class to get any webpage or presigned URL.

Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string URL</td>
<td>The URL to get.</td>
</tr>
</tbody>
</table>

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void Get()</td>
<td>Gets the URL specified by the URL property.</td>
</tr>
</tbody>
</table>

AWSBehaviorHTTPNotificationsBus

The AWSBehaviorHTTPNotificationsBus has the following methods.

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void OnSuccess(string resultBody)</td>
<td>Called when the GET operation succeeds. The resultBody parameter contains the request response body.</td>
</tr>
<tr>
<td>void OnError(string errorBody)</td>
<td>Called when the GET operation fails. The errorBody parameter contains the error body.</td>
</tr>
</tbody>
</table>
| void GetResponse(int responseCode, StringMap headerMap, string contentType, string responseBody) | Called when the request returns a response. The parameters contain the following information:  
  * headerMap – Contains all the header information. It can be passed to a StringMap (p. 2295) map property.  
  * contentType – Contains the MIME content type for the response data.  
  * responseBody – Contains the response data in string format. |
**JSON Class**

Traverses and parses JSON data. This class reads but does not write JSON data. To write JSON data, use the string utilities provided in the language that you are using.

Some languages do not provide iterator support for JSON. To accommodate these languages, the JSON class maintains a current value state that gets updated as it traverses the tree of JSON data. Because JSON data consists of objects and arrays, the current value is either the value of the current object key or the value at the current position in the array. For examples, see the sample code in the \dev\CloudGemSamples\Scripts\AWSBehaviorJSONTest.lua file.

The JSON class has no properties. The following table lists its methods.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int EnterArray()</td>
<td>If the current value is an array, sets the current value to the first element of the array and returns the number of array elements.</td>
</tr>
<tr>
<td>void EnterObject(string key)</td>
<td>If the current value is an object, sets the current value to the value of the specified key.</td>
</tr>
<tr>
<td>void ExitArray()</td>
<td>If the current value was set by using EnterArray, sets the current value to the array that was entered before the call to EnterArray.</td>
</tr>
<tr>
<td>void ExitCurrentObject()</td>
<td>If the current value was set by using EnterObject, sets the current value to the object that was entered before the call to EnterObject.</td>
</tr>
<tr>
<td>void FromString(string JSONString)</td>
<td>Loads the JSON object from a JSON string. Parsing errors are logged to the console.</td>
</tr>
<tr>
<td>boolean GetBoolean()</td>
<td>If the current value is a Boolean, returns the value of the Boolean. If the current value is not a Boolean, returns false.</td>
</tr>
<tr>
<td>double GetDouble()</td>
<td>If the current value is a double, returns the value of the double. If the current value is not a double, returns 0.</td>
</tr>
<tr>
<td>integer GetInteger()</td>
<td>If the current value is an integer, returns the value of the integer. If the current value is not an integer, returns 0.</td>
</tr>
<tr>
<td>string GetString()</td>
<td>If the current value is a string, returns the value of the string. If the current value is not a string, returns an empty string.</td>
</tr>
<tr>
<td>boolean IsArray()</td>
<td>Returns true only if the current value is an array.</td>
</tr>
<tr>
<td>boolean IsBoolean()</td>
<td>Returns true only if the current value is a Boolean.</td>
</tr>
<tr>
<td>boolean IsDouble()</td>
<td>Returns true only if the current value is a double.</td>
</tr>
<tr>
<td>boolean IsInteger()</td>
<td>Returns true only if the current value is an integer.</td>
</tr>
<tr>
<td>boolean IsObject()</td>
<td>Returns true only if the current value is an object.</td>
</tr>
<tr>
<td>boolean IsString()</td>
<td>Returns true only if the current value is a string.</td>
</tr>
<tr>
<td>void LogToDebugger()</td>
<td>Displays the entire JSON object in the console in human readable format.</td>
</tr>
<tr>
<td>boolean NextArrayItem()</td>
<td>Sets the current value to the next element of the array. If the current element is the last element in the array, returns false.</td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>string ToString()</td>
<td>Returns the entire JSON object as a string.</td>
</tr>
</tbody>
</table>

The JSON class has no corresponding EBus.

**AWSBehaviorURL Class**

The `AWSBehaviorURL` class provides "URL decode" functionality. It removes any escape characters from the specified URL and returns the resulting string.

**Properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string URL</td>
<td>The URL to decode.</td>
</tr>
</tbody>
</table>

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void Decode()</td>
<td>Decodes the specified URL.</td>
</tr>
</tbody>
</table>

**AWSBehaviorURLNotificationsBus**

The `AWSBehaviorURLNotificationsBus` has the following methods.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void OnError(string error)</td>
<td>Called if the URL was not successfully decoded. The <code>error</code> parameter contains the reasons for the failure.</td>
</tr>
<tr>
<td>void OnSuccess(string result)</td>
<td>Called if the URL was successfully decoded. The <code>result</code> parameter contains the decoded string.</td>
</tr>
</tbody>
</table>

**StringMap Class**

A simple mapping of string key–value pairs. The `StringMap` class is most often used with the HTTP Get class but is useful for general string map operations.

**Properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>map</td>
<td>Contains a string map that was received from another method for parsing.</td>
</tr>
</tbody>
</table>

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void Clear()</td>
<td>Removes all key–value pairs from the map.</td>
</tr>
</tbody>
</table>
### StringMap Class Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>int GetSize()</code></td>
<td>Returns the number of key–value pairs currently stored in the map.</td>
</tr>
<tr>
<td><code>string GetValue(string key)</code></td>
<td>Returns the value at the specified key. If the key that was specified doesn't exist, returns an empty string without adding the key to the map.</td>
</tr>
<tr>
<td><code>boolean HasKey(string key)</code></td>
<td>Returns true if the map contains the specified key.</td>
</tr>
<tr>
<td><code>void LogToDebugger()</code></td>
<td>Displays all key–value pairs in the console.</td>
</tr>
<tr>
<td><code>void RemoveKey(string key)</code></td>
<td>Removes the key–value pair from the map that corresponds to the specified key. If the specified key does not exist, fails without returning an error.</td>
</tr>
<tr>
<td><code>void SetValue(string key, string value)</code></td>
<td>Sets the value of the specified key to the specified value. If the key doesn't exist, the key–value pair is added to the map. If the key does exist, its existing value is overwritten with the specified value.</td>
</tr>
</tbody>
</table>

The `StringMap` class has no corresponding EBus handlers.

### Adding AWS Resources to a Cloud Gem

**Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.**

Cloud Canvas cloud gems can be used out of the box, without interacting with the code and the Cloud Gem Framework (p. 2257) that powers them. However, you might be interested in modifying existing cloud gems and creating your own cloud gems, possibly for distribution to others. If so, you might need to add support for additional AWS CloudFormation types beyond the ones natively supported by Cloud Canvas. This topic provides information on how to do that.

Cloud Canvas gems provide AWS CloudFormation templates that specify the AWS resources that the gem requires. AWS CloudFormation templates support AWS resource types, which are prefixed with `AWS::`. They also support `AWS::CloudFormation::CustomResource` custom resource types or any resource type prefixed with `Custom::`. The template file for a cloud gem is located at `lumberyard_version\dev\Gems \gem_name\AWS \resource_template.json`. The `resource_template.json` file is a specialized version of a AWS CloudFormation template that provides metadata specific to Cloud Canvas.

While AWS CloudFormation templates support a large catalog of AWS resource types, the templates for Cloud Canvas gems are more limited in scope. When creating a Cloud Canvas gem, you have the following options:

- Use one of the subset of types in the `AWS::` namespace that are directly supported by Cloud Canvas (no additional work required).
- Add support for `AWS::` types not already supported by Cloud Canvas.
- Add your own `Custom::` resource types that execute custom Lambda function code when instances of that type are created, modified or deleted.

Custom resources are a good way to integrate your in-house services and access AWS services that are not directly supported.
Topics

- Resource Type Specification (p. 2297)
- Adding Support for New AWS:: and Custom:: Types (p. 2301)
- Versioning of Custom Resources (p. 2303)

Resource Type Specification

Resource types are specified in a Cloud Canvas project-template.json file. For types that Cloud Canvas natively supports, the file is located at Gems\CloudGemFramework\version\AWS\project-template.json. The existing resource is named CoreResourceTypes.

**Note**

You should not interact with this file. You are not prevented from modifying this file to support new types or even change the support for existing types. However, your changes are not received or usable by others with whom you share your gem.

The template file for new types that you want to add support for in your gem is located at lumberyard_version\dev\Gems\gem_name\AWS\project_template.json.

Resources are specified in the template as follows:

```json
{
  "Resources": {
    "<resource-name>": {
      "Type": "Custom::ResourceTypes",
      "Properties": {
        "ServiceToken": {
          "Fn::GetAtt": [
            "ProjectResourceHandler",
            "Arn"
          ]
        },
        "LambdaConfiguration": <lambda-configuration>,
        "LambdaTimeout": <seconds>,
        "Definitions": {
          <definition>,
          <definition>,
          ...
        }
      }
    }
  }

<lambda-configuration> := {
  "Fn::GetAtt": {
    [ "<lambda-resource-name>", "ComposedLambdaConfiguration" ]
  }
}

<definition> := {
  "<type-name>": {
    "PermissionMetadata": {
      "RestrictActions": [ "<action>", "<action>", ... ],
      "DefaultRoleMappings": [ {
        "role-mapping",
        "role-mapping",
        "...
      }]}
    }
  }
}
"ArnFormat": "<arn-format>",
"ArnFunction": <lambda-function-spec>,
"HandlerFunction": <lambda-function-spec>,
"DisplayInfo": {
    "AWSConsoleUrls": [
        <console-url>
    ]
}

<console-url> := {
    "Label": "<label>",
    "Url": "<url>"
}

<lamba-function-spec> := {
    "Function": "<function-handler>",
    "HandlerPolicyStatement": [
        <policy>,
        <policy>,
        ...
    ],
}

<lamba-resource-definition> := {
    "Properties": {
        "ConfigurationBucket": {
            "Ref": "Configuration"
        },
        "ConfigurationKey": {
            "Ref": "ConfigurationKey"
        },
        "FunctionName": "<lambda-folder-name>",
        "Runtime": "python3.7",
        "ServiceToken": {
            "Fn::GetAtt": [
                "ProjectResourceHandler",
                "Arn"
            ]
        },
    }
    "Type": "Custom::LambdaConfiguration"
}

Values to Specify

Replace the following items in the template with your own values as required.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;resource-name&gt;</td>
<td>Specifies a custom name for the resource. The name must be unique in the template.</td>
</tr>
<tr>
<td>&lt;lambda-resource-name&gt;</td>
<td>Specifies the name of a Custom::LambdaConfiguration element that you include to provide Lambda code for your types. This entry is required if you specify either the ArnFunction or HandlerFunction entries.</td>
</tr>
<tr>
<td>&lt;lambda-timeout&gt;</td>
<td>Specifies the timeout, in seconds, to apply to the specified ArnFunction or HandlerFunction entries.</td>
</tr>
<tr>
<td>&lt;lambda-directory-name&gt;</td>
<td>Specifies the name of a subdirectory to add to your gem's \AWS \project-code\lambda-code directory. This subdirectory</td>
</tr>
<tr>
<td>Item</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>contains Lambda code that is required for the ArnFunction or HandlerFunction entries.</td>
<td></td>
</tr>
<tr>
<td>&lt;type-name&gt;</td>
<td>Specifies a AWS CloudFormation type in the AWS:: namespace or a custom type that is prefixed with Custom:: .</td>
</tr>
</tbody>
</table>

**Elements in the Type Definition**

This section describes the other elements in a type definition.

**PermissionMetadata**

Optional. Contains the metadata configuration information for an instance of the type that controls permissions.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;action&gt;</td>
<td>Specifies an IAM action that instances of the resource type are permitted to have in the role that is created for them. Wildcards are permitted.</td>
</tr>
<tr>
<td>&lt;role-mapping&gt;</td>
<td>Specifies a default Cloud Canvas role mapping (p. 2377) to apply to instances of this type.</td>
</tr>
</tbody>
</table>

**ArnFormat**

Required if ArnFunction is not specified. Specifies the ARN for instances of the resource in the <arn-format> format string. The following substitutions are allowed:

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;region&gt;</td>
<td>Specifies the region of the AWS CloudFormation stack.</td>
</tr>
<tr>
<td>&lt;account-id&gt;</td>
<td>Specifies the AWS account ID.</td>
</tr>
<tr>
<td>&lt;resource-name&gt;</td>
<td>Specifies the physical resource ID of the resource instance.</td>
</tr>
</tbody>
</table>

The following example specifies the ARN for a Lambda function:

```
arn:aws:lambda:<region>;<account-id>;function:<resource-name>
```

**ArnFunction**

Required if ArnFormat is not specified. Specifies a module and function to retrieve the ARN for the resource.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;function-handler&gt;</td>
<td>Specifies a reference to a function in the string format: Module.Function. The module must be located in the resource_types subdirectory of your gem's ServiceLambda directory.</td>
</tr>
<tr>
<td>Item</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>&lt;policy&gt;</td>
<td>Specifies an IAM policy statement that specifies the permissions that the</td>
</tr>
<tr>
<td></td>
<td>Lambda function requires to execute. The HandlerPolicyStatement can be</td>
</tr>
<tr>
<td></td>
<td>omitted if the Lambda function requires no permissions.</td>
</tr>
</tbody>
</table>

ArnFunction is required by some resources that do not have an ARN that can be computed from the substitutions in ArnFormat, such as an Amazon SQS queue. An Amazon SQS queue requires a call to the GetQueueAttributes API to obtain its ARN. ArnFunction supports the same substitutions as ArnFormat.

**Note**

Be sure that you specify any required permissions for your function in the HandlerPolicyStatement element of the PermissionMetadata field. These permissions are shared with the HandlerFunction if one exists.

**HandlerFunction**

Required if the type begins with Custom:::. Specifies a module and function that runs custom code in response to the Create, Update, and Delete events of the custom resource.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;function-handler&gt;</td>
<td>Specifies a reference to a function in the string format: Module.Function. This module must be located in the resource_types subdirectory of your gem's ServiceLambda directory.</td>
</tr>
<tr>
<td>&lt;policy&gt;</td>
<td>Specifies an IAM policy statement that specifies the permissions that the</td>
</tr>
<tr>
<td></td>
<td>Lambda function requires to execute. The HandlerPolicyStatement can be</td>
</tr>
<tr>
<td></td>
<td>omitted if the Lambda function requires no permissions.</td>
</tr>
</tbody>
</table>

Custom resources (that is, entries in the Resources section of the form "Type": "Custom:::<name>") should define their ServiceToken to point to the Cloud Canvas ProjectResourceHandler. The ProjectResourceHandler dispatches the events to your module so that your custom code can run with the correct permissions.

Be sure to specify any required permissions for your function in the HandlerPolicyStatement element of the PermissionMetadata field. These permissions are shared with the ArnFunction if it exists. Custom resource handlers process the events as defined by AWS CloudFormation.

**DisplayInfo**

Optional. Contains user interface information to display. Currently, this consists exclusively of <console-url>, which has a <label> and a <url>. The <url> is relative to https://console.aws.amazon.com/ and can use the same substitutions as ArnFormat.

The following example specifies links to view resources in the AWS Management Console and in CloudWatch Logs.

```json
"AwsConsoleUrls": [ 
  { 
    "Label": "View resource in AWS console",
    "Url": 
      "/lambda/#/functions/<resource-name>"
  },
  
```
Adding Support for New AWS:: and Custom:: Types

The steps to create a Custom:: type and an AWS:: type are almost identical. The main difference is that a custom type must execute a Lambda function when an instance of the type is created, updated or deleted. A custom type must therefore supply values for LambdaConfiguration (optionally for LambdaTimeout) and for HandlerFunction. An AWS type needs to call a Lambda function only if it cannot supply its ARN from simple string substitution of the values in the ArnFormat field. Therefore, for most AWS types, you can omit the LambdaConfiguration, LambdaTimeout, and HandlerFunction fields from the template entirely.

To add an AWS:: resource type

1. If your gem does not have a project-template.json file in its AWS directory, create the file and give it the following structure:

   ```json
   {
     "Resources": {
     }
   }
   
   ```

2. Create a new resource in your project-template.json file of the type Custom::ResourceTypes. The type should have properties that correspond to the Resource Type Specification (p. 2297). You can use a single Custom::ResourceTypes entry for multiple resource definitions.

3. To add a resource definition with the AWS::-prefixed typename to the resource, do one of the following:

   a. If the ARN is easily computable from the region, account ID, and resource name fields, specify the corresponding formatting pattern in the ArnFormat field.

   b. If the ARN is not easily computable from the region, account ID, and resource name fields, perform the following steps:

      a. Create a uniquely named `lambda-directory-name` directory for your gem as follows:

         ```bash
         AWS\project-code\lambda-code\lambda-directory-name\resource_types
         ```

      b. In your Resources block, add a resource with a custom `<lambda-resource-name>` name as the key. Create the `<lambda-resource-definition>` contents following the Resource Type Specification (p. 2297).

      c. Replace the `lambda-directory-name` in the definition with the `lambda-directory-name` that you created.

      d. Add the LambdaConfiguration field (and optionally the LambdaTimeout field) to the main Properties section of your resource definition. Replace `<lambda-resource-name>` with your `<lambda-resource-name>` in the `<lambda-configuration>` block.

      e. Write a Lambda function that returns the ARN for a resource of your type. Place the Lambda function in your gem's AWS\project-code\lambda-code\lambda-directory-name\resource_types directory.

      f. Add an ArnFunction field to your resource definition as a dictionary. In the dictionary, add the following items:

         a. In the Function field, provide the name of the handler in the format Module.Function.
• If your function requires access to any AWS services, create a PolicyStatement field and add the necessary policy statements to it.

4. Provide any relevant display information or links in the DisplayInfo field.

5. Add a resource of your AWS::-prefixed type to your resource-template.json file.

To add a Custom:: resource type

1. If your gem does not already have a project-template.json file in its AWS directory, create the file and give it the following structure:

```json
{
   "Resources": {
   }
}
```

2. Create a new resource in your project-template.json file of the type Custom::ResourceTypes. The type should have properties that correspond to the Resource Type Specification (p. 2297). You can use a single Custom::ResourceTypes entry for multiple resource definitions.

3. Create a uniquely named lambda-directory-name directory for your gem as follows:

AWS\project-code\lambda-code\lambda-directory-name\resource_types

4. In your Resources block, add a resource with a custom <lambda-resource-name> name as the key. Create the <lambda-resource-definition> contents following the Resource Type Specification (p. 2297).

5. Replace the lambda-directory-name in the definition with the lambda-directory-name that you created.

6. Add the LambdaConfiguration field (and optionally the LambdaTimeout field) to the main Properties section of your resource definition. Replace <lambda-resource-name> with your <lambda-resource-name> in the <lambda-configuration> block.

7. To add a resource definition with your own the Custom:: prefixed type name to the resource, perform the following steps:

   a. Specify any role metadata or restrictions for the type in the PermissionMetadata field.
   
   b. Provide a reference to your service API in the ServiceApi field.

   c. Write a Lambda function that processes Create, Update and Delete events for the custom resource. Place the code in your AWS\project-code\lambda-code\lambda-directory-name\resource_types directory.

   d. Add a HandlerFunction field to your resource definition as a dictionary. In the dictionary, add the following items:

      • In the Function field, provide the name of the handler in the format Module.Function.
      • If your function requires access to any AWS services, create a PolicyStatement field and add the necessary policy statements to it.

   e. If the ARN is easily computable from the region, account ID and resource name fields, specify the formatting pattern as the ArnFormat field.

   f. If the ARN is not easily computable from the region, account ID, and resource name fields, perform the following steps:

      i. Write a Lambda function that returns the ARN for a resource of your type. Place the Lambda function in your gem's AWS\project-code\lambda-code\lambda-directory-name\resource_types directory. You can use the same file as you did for your main handler and just give the function a different name (for example, arn_handler.)
ii. Add an ArnFunction field to your resource definition as a dictionary. In the dictionary, add the following items:

- In the Function field, provide the name of the handler in the format Module.Function.
- If your function requires access to any AWS services, create a PolicyStatement field and add the necessary policy statements to it.

8. Provide any relevant display information or links in the DisplayInfo field.
9. Add a resource of your Custom:: prefixed type to your resource-template.json file.

Versioning of Custom Resources

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In Lumberyard 1.15 and earlier versions, the most recent version of Lambda code was used to process custom resource instance events. This caused rollback issues when existing resources were processed by newer versions of the same code.

Starting in Lumberyard version 1.16, custom resources are locked by default to the version of the code that you used to create the resources. If the code changes and an existing resource instance is updated or deleted, the same version of the code that created the resource processes the event.

When new custom resource code is deployed, it does not replace the older code. Resources that are created with the new code will be tied to the new code version.

Version Coercion

If necessary, you can override the locking of a custom resource to the version of the code with which it was created. To specify a different Lambda function version for a custom resource instance's update and delete events, specify a value for CustomResourceVersion in the Cloud Canvas metadata that you have obtained from the AWS Lambda console.

Example

The following code specifies a value of 3 for CustomResourceVersion.

```
"MyCustomResource": {
  "Metadata": {
    "CloudCanvas": {
      "CustomResourceVersion": "3"
    }
  },
  "Type": "Custom::MyCustomType",
  "Properties": {
    "ServiceToken": {
      "Ref": "ProjectResourceHandler"
    }
  }
}
```

After you make this change, the specified version of the Lambda function will process the resource the next time that the resource is updated or deleted.

Removing the CustomResourceVersion metadata entry restores the default behavior of using the version that created the resource. Therefore, if you want a custom resource to always use a newer version of a handler, you must always specify a value for CustomResourceVersion.
Warning
Coercing a custom resource to process events with code different from the code that instantiated the resource exposes the resource group to risk of rollback failure. You are responsible for determining the version of the Lambda function that you want your instance to use. You can find the version from the AWS Lambda console.

Note
You can specify $LATEST as the value for CustomResourceVersion. However, this replicates the unsafe behavior in previous versions of Lumberyard of using the most recent Lambda code version to process custom resource instance events. This practice is not recommended for environments where failed stack updates cannot be tolerated.

Retention of Lambda Functions

Prior to Lumberyard version 1.16, if you deleted a type definition and then updated your project stack, the Lambda functions associated with the type definition were also deleted. These functions might include custom resource handler Lambda or ARN handler Lambda functions.

This behavior could result in rollback errors and a potentially unrecoverable stack when you tried to update instances of the resource type. For this reason, Lambda functions associated with resource types now remain in your account indefinitely and are deleted only when the project is deleted.

Note
Lambda functions are deleted in AWS only when you run lmbr_aws project delete. If you delete your project stack locally but not in AWS, the Lambda functions associated with your resource types will remain. To delete them, you can use the AWS console or the Cloud Canvas cleanup tool (p. 2362). Because the cleanup tool can be very destructive, use it with caution, and do not use it on production deployments.

Removing Unused Custom Resource Code

As you develop new custom resources or upgrade existing ones, Lambda function versions that are no longer referenced by any instances can remain in your AWS account. In most cases, the existence of these orphaned Lambda functions should not affect your AWS account's Lambda Limits.

However, if you need to remove such instances, you can run the following command:

```
lmbr_aws project clean-custom-resources
```

This command deletes all custom resource Lambda functions in a project that satisfy the following criteria:

- The function is not the most recent version.
- No existing custom resource instances were created using that version.
- No custom resource instances are currently using that version through the version coercion (p. 2303) technique.

Physical IDs

Previously, the PhysicalResourceId that a custom resource handler returned was the same as the physical ID of the resource in its AWS CloudFormation stack.

With the advent of versioning in Lumberyard 1.16, custom resources embed their own version information in AWS CloudFormation's PhysicalResourceId. If you are writing a Lambda function and need to extract the embedded ID from the AWS CloudFormation physical ID, use the `get_embedded_physical_id` function, as in the following example.
from cgf_utils import custom_resource_utils
actual_physical_id = custom_resource_utils.get_embedded_physical_id(stack_physical_id)

To access this module, make sure the .import file in your Lambda function directory includes CloudGemFramework_Utils.

For source code, see the lumberyard_version\dev\Gems\CloudGemFramework\vN\AWS\common-code\Utils\cgf_utils\cgf_utils.custom_resource_utils.py module.

ARN Handlers

Unlike custom resource handlers, ARN handlers are not version-locked. Determining an ARN is typically a simple operation that does not require versioning.

Backwards Compatibility

Custom resources that were instantiated in Lumberyard projects prior to 1.16 will continue to use the most recent version of the custom resource Lambda code to process their update and delete events. If you want the safety benefits of versioning, you must delete existing custom resource instances and recreate them.

Cloud Gem Framework Service API

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard cloud gems provide services that configure and manage a game's operation. The services are implemented by AWS Lambda function resources. The game and tools access these services through the Amazon API Gateway. The code that you provide runs in a Lambda function. API Gateway manages access to the service, provides caching for frequently used results, and supports request throttling.

The following diagram shows how the Cloud Gem Framework service API interacts with the game client, AWS Lambda, and API Gateway.
The Lumberyard game engine and tools use API operations to communicate with your cloud gem service. These APIs are described in the cloud gem’s /dev/Gems/<gem-name>/AWS/swagger.json file. This file describes the input and output data for each of the operations that can be performed by the service. The swagger.json file uses the swagger API definition format, which is an open source framework for RESTful API operations.

The following is an example swagger.json file.

```json
{
    "swagger": "2.0",
    "info": {
        "version": "1.0.0",
        "title": "$RestApiResourceName$",
        "description": "API for the $ResourceGroupName$ service ($DeploymentName$ deployment)."
    },
    "schemes": [
        "https"
    ],
    "consumes": [
        "application/json"
    ],
    "produces": [
        "application/json"
    ],
    "x-amazon-cloud-canvas-lambda-dispatch": {
        "lambda": "$ServiceLambdaArn$"
    }
}
```
paths: {
  "/service/status": {
    "x-amazon-cloud-canvas-lambda-dispatch": {
      "module": "service_status"
    },
    "get": {
      "operationId": "get_service_status",
      "description": "Returns the service's status. Useful for testing connectivity.",
      "responses": {
        "200": {
          "description": "A successful service status response.",
          "schema": {
            "$ref": "#/definitions/ServiceStatus"
          }
        }
      }
    }
  },
  "/admin/messages": {
    "post": {
      "description": "Add a message to the message table",
      "parameters": [
        {
          "name": "msg",
          "in": "body",
          "required": true,
          "schema": {
            "$ref": "#/definitions/MessageData"
          }
        }
      ],
      "responses": {
        "200": {
          "description": "Unique ID for this new message",
          "schema": {
            "$ref": "#/definitions/DetailedMessageData"
          }
        }
      }
    },
    "get": {
      "description": "Get the list of N messages starting at a given index and filter with all, active, expired or planned",
      "parameters": [

      },
      "endTime": {
        "description": "The date time in which to stop displaying the message. Example: Jul 19 2017 16:00",
        "type": "string"
      }
    }
  }
}
Cloud Canvas uses these API descriptions to generate Lumberyard engine components that execute service APIs for the game. In addition, the API descriptions are used to configure API Gateway to work with your service.
Resources

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A cloud gem's service API is implemented based on the resources that are defined in the cloud gem's resource-template.json (p. 2237) file. The following are the key resources for a cloud gem:

- **ServiceAPI** – An AWS CloudFormation custom resource provided by the Cloud Gem Framework. The handler for this resource configures API Gateway to use the cloud gem's swagger.json file.
- **ServiceLambda** – An AWS Lambda function that implements the cloud gem's functionality.
- **ServiceLambdaConfiguration** – An AWS CloudFormation custom resource provided by Cloud Canvas Resource Manager that configures (p. 2256) the ServiceLambda resource.

To add definitions for these resources to a resource-template.json file, enter the following command.

```
lmbr_aws cloud-gem-framework add-service-api-resources --resource-group <gem-name>
```

In addition to adding the resources mentioned, the add-service-api-resources command does the following:

- Adds a swagger.json file to the cloud gem's AWS directory, if one doesn't already exist.
- Adds the ServiceAPI and ServiceLambda resources to the AccessControl resource definition's DependsOn property. This insures that the AccessControl resource is processed by AWS CloudFormation after the ServiceAPI and ServiceLambda resources have been processed.

To use the service API resources that you add to a resource-template.json file, you must upload those resources to AWS. To upload them, you can use the lmbr_aws resource#group upload command, the lmbr_aws deployment upload command, or click Upload Resources in the Resource Manager feature in Lumberyard Editor.

**Custom::ServiceApi Resource**

The handler for the Custom::ServiceApi AWS CloudFormation resource is provided by the Cloud Gem Framework. This handler creates, updates, and deletes API Gateway REST API, operation, deployment, and stage resources as needed.

ServiceApi resource definitions accept the following parameters:

```json
{
  "Resources": {
    ...
    "ServiceApi": {
      "Type": "Custom::ServiceApi",
      "Properties": {
        "ServiceToken": { "Ref": "ProjectResourceHandler" },
        "ConfigurationBucket": { "Ref": "ConfigurationBucket" },
        "ConfigurationKey": { "Ref": "ConfigurationKey" },
        "CacheClusterSize": { "Ref": "ServiceApiCacheClusterSize" },
        "CacheClusterEnabled": { "Ref": "ServiceApiCacheClusterEnabled" },
        "MethodSettings": { ... },
        "SwaggerSettings": {
          "ServiceLambdaArn": { "Fn::GetAtt": [ "ServiceLambda", "Arn" ] }
        }
      }
    }
  }
```

Version 1.28
2311
ServiceToken

Identifies the Lambda function that implements the custom resource handler.

ConfigurationBucket

Identifies the bucket that contains the uploaded swagger.json file.

ConfigurationKey

Identifies the location in the bucket where the swagger.json file is uploaded.

CacheClusterSize

Provides the API Gateway cacheClusterSize value when you create or update the API Gateway stage.

CacheClusterEnabled

Provides the API Gateway cacheClusterEnabled value when you create or update the API Gateway stage.

MethodSettings

Not implemented.

SwaggerSettings

Provides values that you insert into the uploaded swagger.json file before it is passed to API Gateway. For example, you can use $ServiceLambdaArn$ in the swagger.json file to insert the value of the SwaggerSettings ServiceLambdaArn property.

The following settings are automatically defined for you:

ResourceGroupName

The name of the resource group that is defined the ServiceApi resource.

DeploymentName

The name of the deployment that the ServiceApi resource is in.

RoleArn

The ARN of the role that grants API Gateway the permission to invoke the ServiceLambda (or other permissions configured by the Cloud Canvas Resource Manager Security System (p. 2370)).

Region

The AWS region where the RESTful API resides.

RestApiResourceName

The name to use for the API Gateway REST API resource. API Gateway takes this value from the swagger infoObject title property (set to $RestApiResourceName$ in the default swagger.json file). This is the stack name of the resource group with the ServiceApi logical resource ID appended (usually -ServiceApi).

Operations

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
A cloud gem’s service API can implement multiple distinct operations. You define operations in the `swagger.json` file by adding `operationObject` instances to a `pathItemObject`. For each operation, you can define the input data that the operation requires and the output data that it produces. The input data can include path, query, and body parameters. For more information on using swagger to define APIs, see http://swagger.io/.

API Gateway routes API requests to the cloud gem’s Lambda function. When you upload the cloud gem’s resources to AWS, the cloud gem’s `swagger.json` file is processed. This processing creates the request and response mappings that API Gateway uses to call the cloud gem’s Lambda function. This configuration is controlled by the `x-amazon-cloud-canvas-lambda-dispatch` (p. 2318) extension objects in the `swagger.json` file.

Service API operations are implemented in the `ServiceLambda` AWS Lambda function resource. The code for the Lambda function comes from the cloud gem’s `lambda-function-code` directory. The Cloud Gem Framework provides a service request dispatch module. For more information, see Request Execution (p. 2314).

The following diagram illustrates both request and upload processing.

### Topics
- Default Request Mapping (p. 2313)
- Default Response Mapping (p. 2314)
- Request Execution (p. 2314)

#### Default Request Mapping

A JSON object that implements the request operation is sent to the Lambda function. The JSON object contains the module and function name and the operation's parameters, as the following skeletal syntax shows.

```json
{
    "module": "<module-name>",
    "function": "<function-name>",
    "parameters": {
```
The default module name is derived from the operation path. A path like /player/{id}/highscores results in a module name like player_highscores. Parameters in the path are skipped. The paths /player and /player/{id} both map to the module name player. In this case the handler function in that module can use the existence of an id parameter value to determine the corresponding behavior. The path / (and /{param}) are mapped to the module name root.

The default function name is the operation name like GET, POST, or PUT.

These defaults can be overridden by specifying the module and/or function properties of an x-amazon-cloud-canvas-lambda-dispatch extension object. For more information, see Cloud Gem Framework Extension Object (p. 2318).

Parameter names are taken from the parameter definitions in the swagger.json file. Path, query, and body parameter types are supported.

Default Response Mapping

The Lambda function returns the value to the client as a JSON object such as the following:

```
{
"result":<lambda-return-value>
}
```

If the Lambda function exits with an error (for example, by raising an unhandled exception), it returns the JSON object in the following format.

```
{
"errorMessage":"<error-message>",
"errorType":"<error-type>"
}
```

If the error message received from the Lambda function starts with the text Client Error:, then an HTTP 400 response is sent to the client. The errorMessage and errorType properties received from the Lambda function are forwarded to the client.

If the error message received from the Lambda function does not start with Client Error:, or no error message is received at all, an HTTP 500 response is sent to the client. As a security measure, the errorMessage returned to the client is always An internal server error has occurred, and errorType is ServiceError. This is to avoid sending the exception message to the client. Doing so could provide information that could allow an attacker to discover exploits in your service implementation.

In both the HTTP 400 and HTTP 500 cases, no other information (such as a stack trace) is sent to the client; this also is a security measure.

Request Execution

The Cloud Gem Framework has built-in support for service API Lambda functions that are implemented in Python. No built-in support is provided for Node.js or Java Lambda functions. To support these languages, implement the Lambda function handler to look for the module and function properties on the event object that the Lambda function provides. You also might need to override the default values generated for the x-amazon-cloud-canvas-lambda-dispatch (p. 2318) module and function properties during the swagger.json file processing.
A service.py module file is provided for you in the service's AWS Lambda function. This module's dispatch function uses the module and function properties of the event object to dispatch the request to the service code that you provide. These properties are set by the request mapping that configures API Gateway.

Place your service code in your resource group's lambda-function-code/api directory. The dispatcher uses importlib.import_module to load the modules from that directory. If the specified function has the @service.api decorator, the dispatcher invokes the function on that module, as in the following example.

```python
import service
@service.api
def post(request, submission, user_id):
    ...
```

The first argument passed to the function is a dispatch.Request object. The request object has the following properties.

- **event** – The event object that AWS Lambda passes to the dispatch handler. The contents of the object are determined by the request template. Additional properties added to the template through the x-amazon-cloud-canvas-lambda-dispatch object's additional-request-template-content property are also located here.

- **context** – The Python context object that AWS Lambda passes to the dispatch handler.

The request object's parameters are passed to the handler function as keyword arguments (that is, by using Python **parameters).

**Error Handling**

A ClientError class is provided in the errors.py file. This class extends RuntimeException and ensures that the error message is prefixed with Client Error:. This triggers an HTTP 400 response from API Gateway as described in Default Response Mapping (p. 2314).

If other exceptions are raised during processing, a generic Internal Service Error message is sent to the client.

**Security**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When you make APIs available on the Internet, you must be concerned with security. A best practice is to limit API access to only the people who require it. However, some APIs must be called by the game client. These APIs can be called by any game player or potentially anyone on the Internet.

For all APIs, consider the following:

- Use the access control mechanism described in the next section to limit API access to only those who require it.

- Don't trust parameter values provided by the client. Verify that the parameter values match expectations before you use them. Be careful when inserting parameter values into query strings that are sent to DynamoDB or other services. For more information, see code injection.
• API Gateway automatically protects your backend systems from distributed denial-of-service (DDoS) attacks, whether attacked with counterfeit requests (Layer 7) or SYN floods (Layer 3). However, this does not protect from less frequent requests that do not trigger API Gateway's protections. These other requests might still have a significant impact on your operating costs due to excessive I/O or on game performance.

Access Control

Configuring access control for a service API involves setting three distinct sets of permissions:

1. The `execute-api` operation, enforced by API Gateway.
2. The Lambda `Invoke` function, enforced by AWS Lambda.
3. Access to the cloud gem resource, enforced by the resource's AWS service (for example, Amazon DynamoDB or Amazon S3.)

In all three cases, you use the Cloud Canvas Resource Manager Security (p. 2370) system to configure access. This involves putting Permissions metadata on the `ServiceApi` and `ServiceLambda` resource definitions, as well as on the definitions of resources accessed by the `ServiceLambda` code. This is illustrated in the following diagram:

The permissions granted by `ServiceApi` are described in detail in the next section. `ServiceLambda` gives `ServiceApi` permission to invoke the Lambda function. Other resources give `ServiceLambda` the permissions that the Lambda function requires.

Service API Permissions

You can secure service API operations on an individual basis. For example, you could give permission to submit high scores to the game, and permission to delete fraudulent high scores to someone who manages operations.

By default, only valid AWS IAM credentials can execute operations. This is done using swagger security requirement and security definitions objects that are added to each operation during upload processing (p. 2318), unless the swagger operation object already defines a security object. You can
configure API Gateway to use other forms of security, or none at all, by putting security objects in
swagger object definitions in your swagger.json file.

To grant permission to execute an operation, modify your resource-template.json file to include
metadata on the ServiceApi resource definition, as in the following example.

```json
{
  "Resources": {
    ...,
    "ServiceApi": {
      "Type": "Custom::ServiceApi",
      "Properties": { ... },
      "Metadata": {
        "CloudCanvas": {
          "Permissions": [
            {
              "AbstractRole": ["ProjectOwner", "DeploymentOwner"],
              "Action": "execute-api:*",
              "ResourceSuffix": "/**"
            },
            {
              "AbstractRole": "Player",
              "Action": "execute-api:Invoke",
              "ResourceSuffix": "//*/POST/score/*"
            },
            {
              "AbstractRole": "DevOps",
              "Action": "execute-api:Invoke",
              "ResourceSuffix": "//*/DELETE/score/*"
            }
          ]
        }
      }
    }
  }
  ...
}
```

The AbstractRole property determines who has permission to call the API. Cloud Canvas has
built in Player, ProjectOwner, and DeploymentOwner roles. You can create others as required.
The abstract role specified here is mapped to an actual AWS IAM role using metadata on the role
definitions. For details, see Understanding the Resource Manager Security System (p. 2370).

The Action and ResourceSuffix are used by the Cloud Canvas Resource Manager access control to
generate an AWS IAM policy document statement. This process is described in Statement Reference of
IAM Policies for Executing API in API Gateway.

The Action property determines what the permission allows someone to do. When you grant
permissions to the Player abstract role, specify the permission execute-api:Invoke. This gives
the player permission to invoke the API. When you grant permissions to the ProjectOwner and
DeploymentOwner abstract roles, specify the permission execute-api:*. This grants permission to
invoke the API and manage the API's cache. For other roles, use your own requirements to determine
whether to grant a role permission to manage the cache, invoke the API, or both.

The access control system calculates the ARN of the API Gateway REST API resource to which the
action can be applied. The ResourceSuffix property from the Permission metadata provides
only the /stage-name/HTTP-VERB/resources-path-specifier part of the ARN described in the
Statement Reference of IAM Policies for Executing API in API Gateway.

For ServiceAPI, the stage-name is always api. You can specify either /api/... or /*/... in the
ResourceSuffix property value. A ResourceSuffix value of /api/* or /* grants permissions for all
operations on all paths of the service API.
Cloud Gem Framework Extension Object

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The swagger specification allows tools like the Cloud Gem Framework and API Gateway to define extension objects. These objects allow the `swagger.json` file to provide custom configuration data for the tool. The extension object that the Cloud Gem Framework uses is `x-amazon-cloud-canvas-lambda-dispatch`. This extension object simplifies the configuration of API Gateway for use with an AWS Lambda function.

You can place the `x-amazon-cloud-canvas-lambda-dispatch` object in any of the following swagger objects:

- **swagger object** – Sets the defaults for all paths and operations.
- **path item object** – Sets the defaults for all the path's operations and overrides the defaults set on the parent swagger object.
- **operation object** – Sets values for the operation and overrides the defaults set on the parent path and swagger objects.

The `x-amazon-cloud-canvas-lambda-dispatch` object supports the following properties:

- **lambda** – The ARN of the Lambda function that the operation invokes.
- **module** – The name of the module that defines the service function that processes the request.
- **function** – The name of the function that processes the request. The dispatch module in the Lambda function uses the `function` property and the `module` property to call your code when it receives a request. The dispatch module is described in the Upload Processing (p. 2318) section that follows.
- **additional-properties** – An object that provides properties that are added to the generated `x-amazon-apigateway-integration` object described in the next section.
- **additional-request-template-content** – A string that is inserted into the generated application/json request template, which is described in the next section.
- **additional-response-template-content** – An object that specifies additional content that is inserted into the generated application/json response template. This template is described in the next section. Properties named 200, 400, and 500 are supported. These correspond to the successful (200) and error (400 and 500) responses.

See the API Gateway documentation for more information about mapping templates.

Upload Processing

Before the `swagger.json` file is uploaded to API Gateway, the `x-amazon-cloud-canvas-lambda-dispatch` extension objects in the file are processed. This produces the `x-amazon-apigateway-integration` extension objects that configure API Gateway to call your cloud gem's AWS Lambda function.

The `x-amazon-cloud-canvas-lambda-dispatch` object and processing hide a lot of the complexity, and flexibility, of the `x-amazon-apigateway-integration` extension object. The Cloud Gems Framework provides a straightforward and recommended mapping to the API operations that are implemented in Lambda functions. API Gateway offers many other features that can be extremely useful when you must match an API that was implemented elsewhere or use API Gateway as a proxy for existing backend implementations.
You can still use all the power of the \texttt{x-amazon-apigateway-integration} object in your cloud gem API operations. If you include the object in the operation objects of your \texttt{swagger.json} file, the processing described here is skipped for the operation.

\textbf{Note}
You can also use the \texttt{lmbr\_aws\ cloud-gem-framework\ service-api-process-swagger} command to process the \texttt{swagger.json} file.

At minimum, the swagger object can include an \texttt{x-amazon-cloud-canvas-lambda-dispatch} object with a Lambda property. You can allow the module and function for each operation be determined automatically, or you can use \texttt{x-amazon-cloud-canvas-lambda-dispatch} objects to specify them.

The default \texttt{swagger.json} file provided by the Cloud Gem Framework contains the following \texttt{x-amazon-cloud-canvas-lambda-dispatch} object. The string \texttt{$ServiceLambdaArn$} is replaced with the \texttt{ServiceLambdaArn\ SwaggerSettings} property value provided in the \texttt{ServiceApi} resource definition.

\begin{verbatim}
"x-amazon-cloud-canvas-lambda-dispatch": {
  "lambda": "$ServiceLambdaArn$"
}
\end{verbatim}

When the \texttt{swagger.json} file is processed, an \texttt{x-amazon-apigateway-integration} object is added to every swagger operation object that does not have one. These objects have the following properties:

- \texttt{type} – Specify \texttt{AWS} to enable AWS Lambda function integration.
- \texttt{uri} – Construct the URI of the Lambda function with the value of the \texttt{x-amazon-cloud-canvas-lambda-dispatch} object's \texttt{lambda} property.
- \texttt{credentials} – The \texttt{Custom::ServiceApi} resource creates the ARN of a role. The role has a policy that is described in \textit{Access Control} (p. 2316).
- \texttt{requestTemplates} – A \texttt{application/json} template that causes a request as described in \textit{Default Request Mapping} (p. 2313). You can include additional content by using the \texttt{x-amazon-cloud-canvas-lambda-dispatch} object's \texttt{additional-request-template-content} property. This property can be used to pass other values, such as those defined by the \$context object, to the Lambda function. The additional request template content should start with a ', ' (and for consistent formatting, should start with ', \n ' and use ', \n ' between properties).
- \texttt{responses} Specifies – \texttt{application/json} templates for 200 (success), 400 (client error) and 500 (service error) responses as described in \textit{Default Response Mapping} (p. 2314). The 400 and 500 responses are inserted into the swagger responses object. However, you should define a 200 response that specifies a scheme that describes the data that the operation returns.
- Additional properties as specified by the \texttt{x-amazon-apigateway-integration-properties} property.

\textbf{Cross-Gem Communication}

\begin{verbatim}
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Cloud gems can use the cross-communication feature to expose their API operations to one another and use each other's backend services. For example, Lumberyard's \textit{Player Account Cloud Gem (p. 2188)} provides a banned player service that the \textit{Leaderboard Cloud Gem (p. 2188)} uses to limit fraudulent scores. You can also use cloud gem cross-communication to notify multiple gems when an event occurs.

To implement cross-gem communication, you define, implement, and use a Cloud Gem Framework \textit{Service API (p. 2305)} web service interface.
\end{verbatim}
Defining an Interface

To define a Cloud Gem Framework service interface, you use the swagger API definition (also known as the OpenAPI Specification) format to create a \interface-name\_interface-version\_json file. You then place the file in the \lumberyard\_version\dev\Gems\gem-name\AWS\api-definition directory. For an example in Lumberyard, see the \lumberyard\_version\dev\Gems \CloudGemPlayerAccount\AWS\api-definition\banplayer_1_0_0.json file.

The interface's full name has the format \gem-name\_interface-name\_interface-version. The \interface-version is a three part version number. The number follows the Semantic Versioning 2.0.0 standard but uses an underscore (_) separator instead of a period (.). When your interface definition changes, increment its version number according to this standard.

When the directory service maps available interface endpoints to client requests for endpoints, it takes the interface version into account. This enables clients that were built with an older minor version of an interface to use newer minor versions of the interface.

To define paths, operations, and data formats for the interface, you follow the swagger specification just as you would with any other swagger definition.

Implementing an Interface

To implement an interface, a gem's swagger.json file uses an x-cloud-gem-framework-interface-implementation extension object in a path object. The interface implementation object has the following properties:

- \interface – The full interface name (\gem-name\.interface-name\_interface-version) of the implemented interface.
- \module – The name of the Python module directory that contains the API implementation. If not provided, the full interface name is used. This directory contains the child modules with functions named as specified by the interface definition.

The referenced interface definition and the gem's swagger definition are merged before they are uploaded to configure Amazon API Gateway. The path objects in the interface definition are effectively inserted as child paths of the path object that defines the interface implementation extension object. The data definitions in each interface are given a unique prefix to prevent collisions with definitions from the gem's swagger definition or other interfaces.

For example, if the gem's swagger.json file contains the following:

```json
{
  ...
  "paths": {
    "/foo": {
      "x-cloud-gem-framework-interface-implementation": {
        "interface": "ExampleGem_ExampleInterface_1_0_0"
      }
    },
    "/bar": {
      "get": ...
    }
  }
}
```
"definitions": {
    "Bar": ...
  }
}

And the interface definition contains this:

{
  ...
  "paths": {
    "/aaa": { "get": { ... "$ref": "/definitions/ExampleData" ... } }  
    "/bbb": ... 
  },
  "definitions": {
    "ExampleData": ...
  }
}

The resulting swagger is something like the following:

{
  ...
  "paths": {
    "/foo/aaa": { "get": { ... "$ref": "ExampleGem_ExampleInterface_1_0_0.ExampleData" ... } }  
    "/foo/bbb": ... 
    "/bar": {
      "get": ...
    }
  },
  "definitions": {
    "Bar": ...
    "ExampleGem_ExampleInterface_1_0_0.ExampleData": ...
  }
}

Currently, you must manually implement the interface in the service code, although tooling that simplifies the implementation is planned for a future release.

To implement the interface, use the @service.api annotated methods that you use for other service API operations (p. 2314). To implement the API, the functions in your modules must use the names specified by the x-amazon-cloud-canvas-lambda-dispatch (p. 2318) extension object. To override the defaults, put x-amazon-cloud-canvas-lambda-dispatch extension objects that include module and function properties in your interface definition.

In the preceding example, extension objects were not used to override the defaults, so the code that implements the interface would have the following structure:

```python
api\  
  __init__.py  
bar.py  
  def get ...
foo_aaa.py  
  def get ...
foo_bbb.py  
```

**Note**
Currently, specifying the interface's path parameter inside the gem swagger file is not supported. Specify the path parameter in the interface swagger definition file instead.
Using an Interface

Calling the API operations that your interface defines from AWS Lambda functions is straightforward.

To use an Interface in a Lambda function

1. Specify the interface in the `Custom::LambdaConfiguration (p. 2256)` resource definition's `Services` property, as in the following example:

   ```json
   "ServiceLambdaConfiguration": {
     "Type": "Custom::LambdaConfiguration",
     "Properties": {
       "Services": [
         {
           "InterfaceId": "ExampleGem_ExampleInterface_1_0_0",
           "Optional": "False"
         },
         ...
       ],
       ...
     }
   },
   ...
   }
   ``

   The `Optional` property specifies whether the specified interface must exist. If `Optional` is `False` and no gem provides the specified interface, the deployment fails.

2. From your Lambda function code, get a client for the service. To do this:
   a. Use the `cfg_lambda_settings.get_service_url` function to get the service URL for the interface.
   b. Pass the URL to the `cfg_service_client.for_url` function, as in the following example:

   ```python
   import cfg_service_client
   import cfg_lambda_settings
   import boto3
   interface_url =
   cfg_lambda_settings.get_service_url("ExampleGem_ExampleInterface_1_0_0")
   service_client =
   cfg_service_client.for_url(interface_url, verbose=True,
   session=boto3._get_default_session())
   result =
   service_client.navigate('aaa').GET();
   ```

   Cloud Canvas ensures that the Lambda function has permission to call the service endpoints.

Game Clients

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Cloud Gem Framework can generate game clients for your service API.

The game client can call some API operations on behalf of the player. Other operations are callable only by other tools. By default, the client uses the AWS credentials by assuming the `Player` role through an Amazon Cognito identity pool. This process, described in detail in `Player Identity (p. 2379)`, is illustrated in the following diagram.
Generating a Game Client

Generating a game client is straightforward.

**To generate a game client**

Enter the following command:

```
lmbr_aws cloud-gem-framework generate-service-api-code --resource-group <group>
```

The `generate-service-api-code` command reads the `swagger.json` file that contains definitions for the resource group's service API. The command creates a C++ header file that implements a Lumberyard component. The header file is named `<group>ClientComponent.h`.

The directory location of the header file depends on whether `<group>` refers to a cloud gem or a project-defined resource group.

**Generated Component Header File Locations**

<table>
<thead>
<tr>
<th>Parameter Type</th>
<th>Header File Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>cloud gem</td>
<td>Gems&lt;gem&gt;\Code\AWS\ServiceApi</td>
</tr>
<tr>
<td>resource group</td>
<td>Code&lt;game&gt;\AWS&lt;group&gt;\ServiceAPI</td>
</tr>
</tbody>
</table>

**Component Header File Accessibility**

For a gem, the default location of the generated header file does not make it accessible outside of that gem. Typically, a cloud gem's service API is private to the gem, and the gem exposes its functionality through its own custom component. If you want to provide direct access to the cloud gem's API from other gems or game code, you can move the generated header file into the gem's `Code\Include` directory.
Notes

- To use the generated client, add the generated file to your gem or project's WAF file list, and then build the gem or project (p. 61).
- You can use the generated client component to invoke the API from C++ or Lua. For more information, see Calling a Game API (p. 2336).
- For sample code, see Generated Game Client Code Example (p. 2324).

Generated Game Client Code Example

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The following client code was generated by the swagger.json file for the Message of the Day Gem that is included with Lumberyard. The swagger file for the gem defines many operations. For brevity, the example shows client code for only the following GET and PUT operations:

- GET /admin/messages?index={index}&count={count}&filter={filter}
- PUT /admin/messages/{msg_id}

For comments, see the Examining the Generated Game Client Code (p. 2335) section that follows the example.

```cpp
// Example Generated Game Client
#pragma once
#include <AzCore/Component/Component.h>
#include <AzCore/Component/Entity.h>

Examining the Generated Game Client Code

The following table provides additional information for the generated game client code example in the previous section. The line numbers indicate the location in the code that the comments refer to.

<table>
<thead>
<tr>
<th>Line Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>24, 25</td>
<td>The C++ namespace for the API. This is always <code>&lt;resource-group-name&gt;::ServiceApi</code>.</td>
</tr>
<tr>
<td>56, 75, 110, 124</td>
<td>The <code>PutAdminMessageReturnType</code> struct contains the PUT operation's return data as defined by the swagger file. In this case, it is an empty object and has no properties.</td>
</tr>
<tr>
<td>67, 92, 112, 137</td>
<td>The <code>WriteJson</code> method is generated to handle the serialization of <code>PutAdminMessageReturnType</code> objects to JSON text format. JSON format is required for the data to be sent to the service. A similar function is generated for each of the type definitions in the <code>swagger.json</code> file.</td>
</tr>
<tr>
<td>150</td>
<td>The <code>CLOUD_GEM_SERVICE</code> macro defines a class that provides information that is common to all of the service's requests.</td>
</tr>
<tr>
<td>152</td>
<td>The <code>Configure</code> function is called when the generated component is initialized. You can add code to this function to change the default configuration for the service. For example, the following code increases the timeout for <code>GetServiceStatus</code> requests.</td>
</tr>
<tr>
<td></td>
<td>```cpp</td>
</tr>
<tr>
<td></td>
<td>void Configure()</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>GetServiceStatusRequestJob::GetDefaultConfig()-&gt;requestTimeoutMs = 20000;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>If you regenerate the client, your changes to the <code>Configure</code> method are lost.</td>
</tr>
<tr>
<td>157, 202</td>
<td>A <code>Request</code> class such as <code>PutAdminMessagesRequest</code> is generated for each of the operations defined in the <code>swagger.json</code> file. This class encapsulates the HTTP method and path that are used to make the request. The <code>Parameters</code> struct in the class defines the fields for each of the request's parameters that are specified by the swagger file.</td>
</tr>
<tr>
<td>200, 240</td>
<td>The Lumberyard job system executes API requests asynchronously. This work is performed by the <code>CloudGemFramework::ServiceRequestJob</code> class and specialized by the <code>PutAdminMessagesRequest</code> class declared previously. The C++ <code>using</code> statement creates an alias for that type.</td>
</tr>
</tbody>
</table>
Calling a Game API

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To call your API operations, you can use C++, the client component, a request job, or Lua.

Topics

- Calling an API from C++ (p. 2336)
- Using Lua to Call an API (p. 2339)

Calling an API from C++

To invoke a service API from C++, you can use an EBus event handler from the generated client component. You can also use the generated service request job class directly. If you want to make requests from a component, consider using the client component. If you want to perform a sequence of operations, consider using the job class.

Using the Client Component to Call an API

The following example from the CloudGemLeaderboard service API shows a component that invokes GetServiceStatusRequestJob. There are two ways to receive the request's response:

1. Use an object that inherits from the service's response handler.
2. Connect to the generated component's notification bus.

The example shows both methods.
// Sample API Caller
#include <AzCore/Component/Component.h>
#include <AzCore/Component/Entity.h>
#include <AzCore/Serialization/EditContext.h>
#include <AzCore/Serialization/SerializeContext.h>
#include <AzCore/EBus/EBus.h>

#include <AWS/ServiceAPI/CloudGemLeaderboardClientComponent.h>
#include <CloudGemLeaderboard/CloudGemLeaderboardBus.h>
class SampleResponseHandler :
    public CloudGemLeaderboard::ServiceAPI::CloudGemLeaderboardResponseHandler
{
public:
    void HandleGetServiceStatusSuccess(CloudGemLeaderboard::ServiceAPI::GetServiceStatusRequestJob* job, AZ::Entity* entity) override
    {
        // Look at job->result for response data
        AZ_Printf("Got response: %s", job->result.status.c_str());
    }

    void HandleGetServiceStatusError(CloudGemLeaderboard::ServiceAPI::GetServiceStatusRequestJob* job, AZ::Entity* entity) override
    {
        // Look at job->error for error data
    }
};

class SampleAPICallerComponent :
    public AZ::Component,
    public CloudGemLeaderboard::ServiceAPI::CloudGemLeaderboardNotificationBus::Handler
{
public:
    SampleResponseHandler* m_responseHandler;
    AZ_COMPONENT(SampleAPICallerComponent, "{aedd6408-e2f0-4250-a181-b0ef41085a94}");
    virtual ~SampleAPICallerComponent() = default;
    static void Reflect(AZ::ReflectContext* reflection)
    {
        AZ::SerializeContext* serializeContext = azrtti_cast<AZ::SerializeContext*>(reflection);
        if (serializeContext)
        {
            // We must include any fields we want to expose to the editor or Lua in the serialize context
            serializeContext->Class<SampleAPICallerComponent>()
                ->Version(1);

            AZ::EditContext* editContext = serializeContext->GetEditContext();
            if (editContext)
            {
                editContext->Class<SampleAPICallerComponent>("SampleAPICallerComponent",
                    "Component to call CloudGemLeaderboard GetServiceStatus")
                    ->ClassElement(AZ::Edit::ClassElements::EditorData,"
                        ->Attribute(AZ::Edit::Attributes::AppearsInAddComponentMenu,
                          AZ_CRC("Game"));
                }
            }
        }
    }

    void Activate() override
    {
        CloudGemLeaderboard::ServiceAPI::CloudGemLeaderboardNotificationBus::Handler::BusConnect(m_entity->GetId());
    }
Using the Request Job to Call an API

In some situations you might want more control over how your background jobs are executed. For example, you might want to change the thread pool that certain requests use or perform multiple requests on a background thread. You can use the generated request job classes directly to make these changes.

In its simplest form, you can use the request job class in the following example. This is the same code that is in line 452 of the generated request component.

```cpp
PutAdminMessagesRequestJob* job = PutAdminMessagesRequestJob::Create(
    [responseHandler, this](PutAdminMessagesRequestJob* job)
    {
        // Handle success
        responseHandler->HandlePutAdminMessagesSuccess(job, m_entity);
    },
    [responseHandler, this](PutAdminMessagesRequestJob* job)
    {
        // Handle error
        responseHandler->HandlePutAdminMessagesError(job, m_entity);
    });

job->parameters.msg = msg;
job->parameters.msg_id = msg_id;
job->Start();
```
To learn about other ways to use the request job class, explore the `ServiceApiRequestJob` class definition and see *Running AWS API Jobs Using the Cloud Gem Framework* (p. 2286).

**Using Lua to Call an API**

The following code example shows how to call a service API from a Lua script.

```lua
-- Service status getter
local leaderboardstatusgetter = {
    Properties = {
    }
}

function leaderboardstatusgetter:OnActivate()
    self.notificationHandler = CloudGemLeaderboardNotificationBus.Connect(self, self.entityId)
    CloudGemLeaderboardRequestBus.Event.GetServiceStatus(self.entityId, nil)
end

function leaderboardstatusgetter:OnDeactivate()
    self.notificationHandler:Disconnect()
end

function leaderboardstatusgetter:OnGetServiceStatusRequestSuccess(response)
    Debug.Log(response.status)
end

function leaderboardstatusgetter:OnGetServiceStatusRequestError(error)
    Debug.Log(error.message)
end

return leaderboardstatusgetter
```

**Publishing Your API**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Service API operations are implemented by API Gateway, which has an open source serverless web application that you can use to create your own developer portal. A developer portal on API Gateway empowers you to do the following:

- List your API operations in catalog form.
- Allow programmers to sign up.
- Display documentation that helps programmers understand your API.
- Let programmers test your API and provide feedback.
- Grow a programmer ecosystem.
- Monetize your API and grow API product revenue.

For more information, see Generate Your Own API Gateway Developer Portal.

**Using the Cloud Gem Framework Command Line**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
You can use the `lmbr_aws cloud-gem-framework` command line for working with Cloud Canvas Cloud Gems (p. 2127) and the Cloud Gem Framework Service API (p. 2305).

**Note**
For general information on the `lmbr_aws` command line tool, including common syntax, configuration, and arguments, see Using the Cloud Canvas Command Line (p. 2390).

**Commands**

Following are details of the `lmbr_aws cloud-gem-framework` commands.

**add-service-api-resources**

Adds the resources to implement a `swagger.json` file-based service API to a resource group.

The `add-service-api-resources` command accepts the following arguments:

- `--resource-group {resource-group-name}` or `-r {resource-group-name}`
  - Required. The name of the resource group or cloud gem.
- `--force`
  - Optional. Forces the replacement of existing resource definitions. By default, existing resource definitions with the same names are not changed.

For more information about the `add-service-api-resources` command, see Resources (p. 2311) in the Cloud Gem Framework Service API (p. 2305) documentation and Getting Started with the Cloud Gem Framework (p. 2258).

**generate-service-api-code**

Generates component and Lambda function code to support a service API that is described in a gem or resource group `swagger.json` file. The generated code is created in subdirectories under the `\dev\Gems\<gem-name>\Code` directory.

The `generate-service-api-code` command accepts the following arguments:

- `--gem {gem-path}` or `-g {gem-path}`, `--resource-group {resource-group-path}` or `-r {resource-group-path}`
  - Required. The path of a cloud gem or resource group subdirectory that provides the `swagger.json` file that is used to generate the code (for example, `C:\lumberyard_version\dev\Gems\MyCloudGem\v1`).
- `--component-client-path {component-client-path}`
  - Optional. The output path for the component client code files `<gem-name>ClientComponent.h` and `<gem-name>ClientComponent.cpp`. The default location is the `\dev\Gems\{cloud-gem-name\}\VN\Code\AWS\ServiceApi` directory.
- `--update-waf-files`
  - Optional. Adds the generated `.h` and `.cpp` code files to the `.waf_files` file that is in the gem's `\dev\Gems\<gem name>\Code` subdirectory. The `.waf_files` file is a manifest file for the Waf build of the gem.

The following sample `.waf_files` file is for a gem called MyCloudGem. Its full path is `\dev\Gems\MyCloudGem\Code\mycloudgem.waf_files`. 

```
For more information about the `generate-service-api-code` command, see Generating a Game Client (p. 2323) and Getting Started with the Cloud Gem Framework (p. 2258) For more information about Waf, see Using the Waf Build System (p. 63).

**remove-service-api-resources**

Remove the resources that implement a `swagger.json` file-based service API operation from a resource group.

The `remove-service-api-resources` command accepts the following arguments:

- `--resource-group {resource-group-name}` or `-r {resource-group-name}`
  
  Required. The name of the resource group.

**service-api-process-swagger**

Processes the Cloud Canvas extension objects that are defined in a `swagger.json` file and produces swagger definitions that can be imported into Amazon API Gateway.

The `service-api-process-swagger` command accepts the following arguments:

- `--resource-group {resource-group-name}` or `-r {resource-group-name}`
  
  Required. The name of the resource group.

- `--input {file-path}`
  
  Optional. The file from which the `swagger` JSON is read. For the cloud gems that are included with Lumberyard, the default is `dev/Gems/{gem-name}/swagger.json`.

- `--output {file-path}`
  
  Optional. The file to which the processed `swagger` JSON is written. By default, the output is written to `stdout` (the command line console window).

For more information about the `service-api-process-swagger` command, see Cloud Gem Framework Extension Object (p. 2318).
Using Shared Code

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The `lmbr_aws cloud-gem-framework add-service-api-resources (p. 2340)` command adds a service API to a resource group. Prior to Lumberyard version 1.10, it copied the service Lambda code for dispatching service API calls from the

```
CloudGemFramework\AWS\resource-manager-code
\default-resource-group-content\lambda-function-code directory to the resource group's
lambda-function-code directory.
```

In version 1.10, Lumberyard adds a general purpose code sharing mechanism. You can use this mechanism to include a single copy of the service API dispatch code in all the Lambda functions that require it. Place the code to be shared in a subdirectory of a gem's `AWS\common-code` directory. The subdirectory name is the name of the code package.

An `.import` file can be found in a gem's `AWS` directory or a project's resource group directory. The file can be placed any of the following directories to indicate that the code depends on a set of specified packages:

- `lambda-code\<lambda-name>\`
- `lambda-function-code`
- `<lambda-name>-lambda-code`
- `resource-manager-code`
- `common-code\<package-name>\`

You can use the `common-code\<package-name>\` directory to add dependencies recursively. The `lambda-code\<lambda-name>` directory is new in Lumberyard 1.10. For more information about this directory, see Lambda Code Directories (p. 2240).

The `.import` file has the following format:

```
<gem-name>\<package-name>
<gem-name>\<package-name>
...
```

The entries in the `.import` file instruct the Cloud Gem framework to include the contents of the specified gem's `AWS\common-code\<package-name>` directory. For Lambda code, the contents of the directory are included in the `.zip` file that contains other Lambda code. When resource manager loads the code specified by `sys.path` (the Python default module search path, or `PYTHONPATH`), the `resource-manager-code` directory is included in that path.

The service API dispatch code can be found at `Gems\CloudGemFramework\v<N>\AWS\common-code\LambdaService`. The `Gems\CloudGemFramework\v<N>\AWS\common-code\LambdaSettings` directory contains code for accessing injected settings.

Cloud Gem Framework and Resource Manager Versioning

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Lumberyard offers a versioning system that makes it easier to update a project from one version of the Cloud Gem Framework and the **Cloud Canvas Resource Manager** to another. The versioning system has the following advantages:

- Cloud gems can have separate versions.
- Cloud gems can specify the version of Lumberyard that they work with.
- The resource manager and Cloud Gem Framework are implemented in directory structures that support versioning.
- Lumberyard can provide multiple versions of the Cloud Gem Framework and the resource manager at the same time.
- Lumberyard can innovate while still supporting gems that depend on early versions of the framework.

This document describes these changes at an architectural level. For concrete steps on updating existing projects and gems to use versioning, see Updating Projects and Cloud Gems to Version 1.0.0 of the Cloud Gem Framework (p. 2345).

**Versioning Convention**

Lumberyard gems use a simplified semantic versioning, which defines version numbers in the form `major.minor.revision`. Lumberyard increments the major version for changes that cause previous code not to work, including any change that breaks the code or configuration that is not directly controlled by the Cloud Gem Framework.

Every major version change is released by creating a new code base in a new `\dev\Gems\CloudGemFramework\vN` directory, where `N` is the major version number.

Minor updates replace the code in the `\dev\Gems\CloudGemFramework\vN` directory. Earlier major versions of the framework continue to be released with Lumberyard for an unspecified amount of time before they are removed from the release.

**Multiple Versions of the Cloud Gem Framework Gem**

The new directory structure in Cloud Gem Framework 1.0.0 enables coexistence of multiple versions of the Cloud Gem Framework Gem. Gem implementation has moved from the `\dev\Gems\CloudGemFramework\` directory to the `\dev\Gems\CloudGemFramework\v<N>` directory. The intent is that all nonbreaking changes be made in the `v<Current>` directory. When breaking changes occur, a `v<Next>` directory is created to contain the updated implementation. The `v<Current>` directory contents remain either unchanged or updated without breaking changes. A gem can now have different versions of its `gem.json` file in the `v1` and the `v2` directory, for example. This enables the gem to specify different versions. Lumberyard's build and project configuration tools support gems in subdirectories.

**Note**

The **Cloud Canvas Resource Manager** now allows gems to be in directories other than `\Gems\<gem-name>`. The `resource-group add` (p. 2408) `lmbr_aws resource-group add` command's `--gem` option now takes an optional value that specifies the gem directory path. The specified directory path can be either relative to the current working directory or a full path.

**Applying Framework Updates to a Project**

When Lumberyard releases a new major version of the framework, you can choose when to disable the old framework version and when to enable the new one.

If a minor version of the framework is released and you replace the framework configuration in the `CloudGemFramework\vN` directory, errors will occur. The errors are displayed in the console when you load your project into Lumberyard Editor.

After the new version is discovered and enabled, the next step is to update the project's infrastructure in AWS as dictated by the new framework version. The `lmbr_aws` tool and the Cloud Canvas Resource
Manager detect when an upgrade is needed by checking the project's current framework version in two places: the `local-project-settings.json` file and in the project's Amazon S3 configuration bucket. If either value is not exactly the same as the framework version, the command exits with an error and takes no action.

To update your project infrastructure, use the `lmbr_aws project update-framework-version` command. If the `update-framework-version` command detects a framework version change, it performs the following actions:

1. Executes the `before_project_framework_version_change(hook, from_version, to_version)` hook method in plugin update.py modules.
2. Updates the project stack.
3. Executes the `after_project_framework_version_change(hook, from_version, to_version)` hook method in plugin update.py modules.
4. Saves the new framework version to the `local-project-settings.json` file and to the project configuration bucket in Amazon S3.

The project's framework version is updated after all hooks are successfully called and all updates completed.

**Update Deployments Manually**

The `lmbr_aws project update-framework-version` command never updates deployment, deployment access, or resource group stacks. The update hooks can make changes to resource templates, Lambda code, and other items. However, you must perform all deployment, deployment access and resource group stack updates separately after the `project update-framework-version` command completes.

To help custom tools deal with old stacks, the framework version that is in effect for the stack is provided by the `FrameworkVersion` template parameter. If this parameter is not present, the tool should assume that the stack predates version 1.1.0 of the framework.

In the case of a major version change, Lumberyard tools (including `lmbr_aws`) can refuse to work with any stack that has not yet been updated. However, for minor version changes, the tools should continue to work with deployment and resource group stacks that have not yet been updated.

To update the deployment stack (and all of its resource group stacks), you can use the `lmbr_aws deployment update (p. 2397)` command. To update the deployment access stack, you can use the `deployment update-access (p. 2397)` command.

**Resource Manager Merged into the Cloud Gem Framework Gem**

In Lumberyard 1.10, resource manager functionality has been taken over by the Cloud Gem Framework Gem. Accordingly, and to allow resource manager to be versioned, the contents of the \dev\tools \lmbr_aws\ directory have moved to the dev\Gems\CloudGemFramework\v<N>\ResourceManager directory, with the following exceptions:

- The \dev\tools\lmbr_aws\ directory still contains the cli.py and gui.py modules. These modules are loaded by the `lmbr_aws.cmd` file and the resource manager user interface in Lumberyard Editor. These modules discover which project is current by looking in the \dev \bootstrap.cfg file. They then look in the project's \dev\project_name\gems.json file to get the `Version` value for CloudGemFramework. The modules then forward the request to the corresponding cli.py or gui.py module for the specified version of the framework. If no version of the framework is enabled, a warning message that the gem must be enabled is displayed.
- The dev\Tools\lmbr_aws\test\ directory still contains the RunAllTests.cmd, cleanup.cmd, and Python module files that support them. The RunAllTests.cmd file has been updated to run tests from the CloudGemFramework\v<N>\ directory. As new releases occur, the file will be updated to include all versions of the framework.
Global Project Code Directories and Project Templates

In Cloud Gem Framework 1.0.0 (Lumberyard version 1.10), the project code directories and project templates have also changed to support versioning.

Project Code Directories

The `<project>`\AWS\project-code directory formerly contained code for the following Lambda functions:

- ProjectPlayerAccessTokenExchangeHandler
- ProjectResourceHandler
- ProjectServiceLambda

Previously, this Lambda code was copied from the \dev\tools\lmbr_aws\AWSResourceManager\default-project-content\project-code directory when the project was created.

This code is now located in the Gems\CloudGemFramework\vN\AWS\lambda-code directory in subdirectories divided by Lambda function.

**Note**

Using a `<gem>`\AWS\project-code or a `resource-group`\<resource-group>\project-code directory to inject code into the project Lambda function is no longer supported.

Project Templates

The following template files have moved to the Gems\CloudGemFramework\vN\ResourceManager\resource_manager\templates directory.

- deployment-access-template.json
- deployment-template.json
- project-template.json

When the framework updates a stack, it uses these templates as a base to create the project's actual templates. Then it uploads the templates to AWS CloudFormation.

**Note**

Starting in Lumberyard 1.10, you can use extension files to add resources to each of these templates. For more information, see Template Extension Files (p. 2239).

Sharing Code

The lmbr_aws cloud-gem-framework add-service-api-resources (p. 2340) command adds a service API to a resource group. Before Lumberyard version 1.10, it copied the service Lambda code for dispatching service API calls from the CloudGemFramework\AWS\resource-manager-code \default-resource-group-content\lambda-function-code directory to the resource group's lambda-function-code directory.

In version 1.10, Lumberyard adds a general purpose code sharing mechanism. You can use this mechanism to include a single copy of the service API dispatch code in all the Lambda functions that require it. For more information, see Using Shared Code (p. 2342).

Updating Projects and Cloud Gems to Version 1.0.0 of the Cloud Gem Framework

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
A cloud gem is a gem that depends on the Cloud Gem Framework (p. 2257). Starting in Lumberyard 1.10 (and Cloud Gem Framework 1.0.0), gem versioning support (p. 2342) makes the work of updating Lumberyard cloud gem projects much easier. However, manual steps are required to update projects and gems that were created before Cloud Gem Framework version 1.0.0.

**Updating Existing Cloud Gem Projects**

To update an existing cloud gem project, you must update the project's gems.json file and runtime configuration.

**To update an existing Lumberyard project**

1. In the project's dev\<project-name>\gems.json file, find the entry for CloudGemFramework. Change the Version value to 1.0.0 and the Path value to Gems/CloudGemFramework/v1, as in the following example.

   ```json
   {
     "Path": "Gems/CloudGemFramework/v1",
     "Uuid": "6fc787a982184217a5a553ca24676cfa",
     "Version": "1.0.0",
     "_comment": "CloudGemFramework"
   },
   ```

2. In a command prompt window, run the following command to update the project's runtime configuration.

   ```cmd
   dev\Tools\LmbrSetup\Win\lmbr.exe projects populate-appdescriptors -projects <project-name>
   ```

   For more information about populate-appdescriptors, see Projects Commands (p. 58) in the documentation for Managing Game Projects with Lmbr.exe (p. 56).

**Update the Project's AWS Directory**

To update the project's AWS directory, you must delete the project, deployment access, and deployment template files. But before you delete the template files, you must save any roles or resources that you added.

**To update the AWS directory**

1. Delete the <project>\AWS\project-code directory. If you have made changes to this code, you must update the CloudGemFramework\\Wm\lambda-code directory content to preserve the changes that you made.

2. If you added roles or other resources to the <project>\AWS\project-template.json file, create a <project>\AWS\project-template-extensions.json file and copy those resource definitions into the project-template-extensions.json file.

3. Delete the <project>\AWS\project-template.json file.

4. If you added roles or other resources to the <project>\AWS\deployment-access-template.json file, create a <project>\AWS\deployment-access-template-extensions.json file and copy those resource definitions into the deployment-access-template-extensions.json file.

5. Delete the <project>\AWS\deployment-access-template.json file.

6. If you added resources to the <project>\AWS\deployment-template.json file, create a <project>\AWS\deployment-template-extensions.json file and copy those resource definitions into the deployment-template-extensions.json file.
7. Delete the `<project>`\AWS\deployment-template.json file.

**Update the Project's Resource Group Directories**

When no Lambda resources exist for a resource group, you can simply remove the resource group's Lambda code directories.

**To remove Lambda code directories from a project resource group**

1. For each `<project>`\AWS\resource-group\<resource-group-name> directory, check whether its resource-template.json file defines AWS Lambda function resources.
2. If the resource-template.json file does not define any Lambda resources, delete the following directories:
   - `<project>`\AWS\resource-group\<resource-group-name>\lambda-function-code
   - `<project>`\AWS\resource-group\<resource-group-name>\<lambda-name>-lambda-code
3. If the resource-template.json file defines AWS Lambda function resources, perform the steps described in Updating Lambda Code (p. 2347).

**Updating Existing Cloud Gems**

To update an existing cloud gem, you must update the gem's gem.json file and either remove its Lambda code directories or update its Lambda code.

**To update an existing cloud gem**

1. In the `<gem>`\gem.json file, find the entry for CloudGemFramework. Change VersionConstraints to the following value.

   ```json
   "VersionConstraints": [ "~>1.0" ],
   ```

2. If the `<gem>`\AWS\resource-template.json file does not exist or does not define any AWS Lambda function resources, delete the `<gem>`\AWS\lambda-function-code directory and any `<gem>`\AWS\<lambda-name>-lambda-code directories. Otherwise, perform the steps in Updating Lambda Code (p. 2347).

**Updating Lambda Code**

Updating Lambda code involves reorganizing your existing Lambda code directories and creating .import files as needed. For information on the reasons for this directory restructuring, see Cloud Gem Framework and Resource Manager Versioning (p. 2342).

**To update your Lambda code**

1. For each of the following Lambda code directories, perform the steps that follow.
   - `<project>`\AWS\resource-group\<resource-group-name>\lambda-function-code
   - `<project>`\AWS\resource-group\<resource-group-name>\<lambda-name>-lambda-code
   - `<gem>`\AWS\lambda-function-code
   - `<gem>`\AWS\<lambda-name>-lambda-code
2. If the code directory contains the service.py and errors.py files that support service API dispatching, delete them and add an .import file with the following content to the directory:
3. If the code directory contains a CloudCanvas subdirectory, delete the subdirectory. If you did not have to create an .import file in step 2, add an .import file that has the following content:

```java
CloudGemFramework.LambdaService
```

If you already created an .import file in step 2, add CloudGemFramework.LambdaSettings to the .import file, as in the following example:

```java
CloudGemFramework.LambdaService
CloudGemFramework.LambdaSettings
```

4. Move the contents of the code directory (along with the new .import file, if any) into a `<parent-dir>\lambda-code\<lambda-name>` directory. Note the following:

- If you had code for multiple Lambda functions in the single `lambda-function-code` directory, decide which modules to put into the subdirectory of the `lambda-code` directory, and place them there.
- If you have code that is used by multiple Lambda functions, put that code in a `<parent-dir>\common-code\<import-name>` directory. To include the code with the rest of the Lambda code when it is uploaded, use an .import file.

For more information about these changes, see Cloud Gem Framework and Resource Manager Versioning (p. 2342).

## Administering Cloud Canvas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/lumberyard/) or visit the AWS Game Tech blog to learn more.

This section provides information for administering your Lumberyard project's AWS account and its use of the AWS cloud.

### Topics

- Setting Up a Project to Use Resource Manager (p. 2348)
- Working with Deployments (p. 2352)
- Freeing Up AWS Resources (p. 2361)
- Understanding the Resource Manager Security System (p. 2370)

## Setting Up a Project to Use Resource Manager

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/lumberyard/) or visit the AWS Game Tech blog to learn more.

After initializing Cloud Canvas Resource Manager so that your Amazon Lumberyard project can use AWS, you can use Resource Manager to configure the stacks for your project.

### Topics
• Initializing Cloud Canvas Resource Manager (p. 2349)
• Working with Project Stacks (p. 2350)

Initializing Cloud Canvas Resource Manager

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When you perform an operation that requires an AWS account, and no account has been associated with your Lumberyard project, the Initialize Cloud Canvas Resource Manager dialog prompts you for the required information.

To initialize Cloud Canvas Resource Manager

1. When prompted to initialize the Cloud Canvas Resource Manager, provide the following information:

   • For Project stack name, enter the name of an AWS CloudFormation stack that you will create. The stack will contain the AWS resources that Cloud Canvas Resource Manager will use for your project. By default, Lumberyard uses the name of your project for the stack name. A stack with the name that you specify must not already exist in your AWS account for the region you select.

   • For AWS Credentials, select from the list of available profiles or create a new one. If you have no AWS profiles on your computer, you are prompted for an AWS secret key and an AWS access key. You can also edit an existing one.

   In order to use Lumberyard with AWS, you must provide administrative credentials for your AWS account either directly, or through an AWS profile. For information on how to get these credentials from AWS, see the Tutorial: Getting Started with Cloud Canvas (p. 2116).

   • For AWS region, specify the AWS data center where your resources will reside. You must choose a region that supports all the AWS services that your game uses. The region you choose must also
support the Amazon Cognito service, which Lumberyard uses to establish player identity, and AWS CloudFormation, which Lumberyard uses to create and manage resources. For more information about the capabilities of different regions, see AWS Regions and Endpoints.

2. Click Create to start the initialization process. In the navigation tree, the Project stack (p. 2350) node is selected, and in the detail pane, the Progress log (p. 2228) shows the progress of the initialization.

## Working with Project Stacks

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When you select the Project stack node in the Cloud Canvas Resource Manager navigation pane, the detail pane shows information about the AWS CloudFormation stack that Cloud Canvas is using.

![Cloud Canvas Resource Manager](image)

Note the following:

- If you select a project stack node and no AWS profile is configured, Lumberyard prompts you to provide one. A profile is required for Lumberyard to display the status of your project's resources. For more information, see Managing Cloud Canvas Profiles (p. 2223).
- If you select the Project stack node when the project has not been initialized for use with Cloud Canvas, Lumberyard prompts you to initialize the project and create a project stack. For more information, see Initializing Cloud Canvas Resource Manager (p. 2349).

### Project Stack Status Table

The Project stack status table shows the status of the AWS CloudFormation stack that contains the resources used by your project's resource groups.

This table has the following columns:

- **Pending** – Indicates when changes have been made to the local stack templates or code but not yet uploaded to AWS. Pausing your mouse pointer on a value in this column displays the reason why the change is pending. Following are the possible values:
- **Create** – The stack is defined locally but has not been created in AWS.
- **Update** – The stack's template and/or Lambda function code has been changed locally but not yet uploaded to AWS.
- **Delete** – The stack has been removed from the local definitions but has not been deleted in AWS. If you are using a source control system, this status can indicate that a new stack has been added to the project. However, your local copy of the source control is out of date and doesn't contain the definition for the new stack.
- **--** – No change is pending.

**Status** – The status of the AWS CloudFormation stack. See Understanding Resource Status Descriptions (p. 2225) for a description of the values this column can have. To see additional status information, pause your pointer on the status indicator.

**Created** – The time the stack was created.

**Updated** – The time the stack status was updated.

**ID** – A truncated version of the AWS ID for the stack. To see the full ID, pause your pointer on the truncated ID.

**Upload Resources**

Click **Upload resources** to start the process of modifying, creating, or deleting resources in AWS so that they match your local definitions of them. A dialog box shows the changes that will be applied.

The table of changes has the same columns as the stack resource status table but also includes a column for **Impacts**. If a change has the potential to affect the security of your project, the **Impacts** column contains the text **Security**. Before you can start an operation that has a security impact, you must select the option **It is OK that this will impact resource SECURITY**. Review any security changes carefully before you apply them.

Similarly, before you can start an operation that deletes one or more resources, you must select the option **It is OK that this will permanently DELETE resources**.

**Stack Resources Table**

The **Stack resources** table shows the status of the resources that your project is using.
This table has the following columns:

**Pending** – Indicates that changes have been made locally but not yet uploaded to AWS. Pausing your mouse on a value in this column displays the reason why the change is pending. Following are the possible values:

- **Create** – The resource is defined locally but has not been created in AWS.
- **Update** – The resource has been changed locally but not yet uploaded to AWS.
- **Delete** – The resource has been removed from the local definitions but has not been deleted on AWS.
  If you are using a source control system, this status can indicate that a new resource has been added to the project. However, your local copy of the source control is out of date and doesn't contain the definition for the new resource.
- **--** – No change is pending.

**Resource Name** – The logical name of the resource.

**Type** – The type of the resource (for example, a Lambda function, Amazon S3 bucket, or a custom resource).

**Status** – The current condition of the resource. For a description of the possible status values, see **Understanding Resource Status Descriptions (p. 2225)**. To see additional status information, pause your pointer on the status.

**Timestamp** – The time of the most recent change.

**ID** - A truncated version of the AWS ID for the stack. To see the full ID, pause your pointer on the truncated ID.

**Working with Deployments**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

**Topics**

- **Create Deployment** (p. 2353)
- **Deployment Status Table** (p. 2354)
- **Individual Deployment Nodes** (p. 2354)
- **Making a Cloud Canvas Deployment Active** (p. 2355)
- **Testing Different Mappings** (p. 2357)
- **Using Protected Deployments** (p. 2359)
- **Deleting Cloud Canvas Deployments and Their Resources** (p. 2360)

A deployment is an independent copy of the AWS resources that your game uses. Deployments are useful for maintaining a safe separation among game lifecycle phases such as development, test, and production. In the resource manager navigation pane, the **Deployments** node shows you the status of your project’s deployments. You can also use it to create a new deployment.
Note: If the **Deployments** node is selected when no AWS profile is configured, Lumberyard prompts you to provide a profile. The status of the project's deployments cannot be displayed unless a profile is provided. For more information, see [Managing Cloud Canvas Profiles](#) (p. 2223).

**Create Deployment**

Click **Create deployment** to start the creation of a deployment:

When uploading resources for the first time, you may see this version of the dialog:

Provide a name for **Deployment name**. Lumberyard appends this name to the project stack name to create an AWS CloudFormation stack for the deployment.
To start the deployment creation process, click OK. In the resource manager navigation pane, a node for the deployment appears under Deployments. In the detail pane, the Viewing the Cloud Canvas Progress Log (p. 2228) provides details about the creation process.

**Deployment Status Table**

The Deployment status table shows the status of the AWS CloudFormation stack for each deployment. Deployment shows the deployment name. For descriptions of the remaining fields in this table, see Stack Resources Table (p. 2351) in the Working with Project Stacks (p. 2350) section.

**Individual Deployment Nodes**

The child nodes of the Deployment node each represent one of the Lumberyard project's deployments. When a Deployment node is selected, the detail pane shows the current status of the selected deployment.

![Deployment Status Table](image)

**Note**

If a Deployment node is selected when no AWS profile is configured, Lumberyard prompts you to provide a profile. The status of the project’s deployments cannot be displayed unless a profile is provided. For more information, see Managing Cloud Canvas Profiles (p. 2223).

**Individual Deployment Status Table**

The <Deployment Name> deployment status table shows the status of the AWS CloudFormation stack for the selected deployment. For descriptions of the contents of this table, see Project Stack Status Table (p. 2350) in the Working with Project Stacks (p. 2350) section.

**Upload All Resources**

Click Upload all resources to start the process of modifying, creating, or deleting resources in the current AWS deployment so that they match your local definitions for all resource groups.
Delete Deployment

Click **Delete deployment** to start the process of deleting the deployment's resources from AWS. The resources defined by all resource groups will be deleted.

For more information about deleting deployments, see Deleting Cloud Canvas Deployments and Their Resources (p. 2360).

Stack Resources Table

The **Stack resources** table shows the status of each of the resources defined by all the resource groups for the selected deployment. For descriptions of the fields in this table, see Stack Resources Table (p. 2351) in the Working with Project Stacks (p. 2350) section.

Making a Cloud Canvas Deployment Active

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can select the deployment that you want Lumberyard Editor to consider active. The active deployment is the deployment that you work with in Lumberyard Editor. Lumberyard Editor uses the active deployment's resources when you launch your game. When you select the Working with Resource Groups (p. 2228) node or an Managing Individual Resource Groups (p. 2231) node in the Cloud Canvas Resource Manager navigation pane, the status information that appears corresponds to the active deployment.

You can also select the deployment that you want to be active by default for all team members.

**Note**

To select a deployment, you must have initialized Cloud Canvas Resource Manager to work with your AWS account and created a deployment. For more information, see Initializing Cloud Canvas Resource Manager (p. 2349) and Create Deployment (p. 2353).

Making a Deployment Active

You have several ways to make a deployment active in Cloud Canvas Resource Manager.

**To make a deployment active**

- To make a deployment active, do one of the following:
  - In Lumberyard Editor, click AWS, **Cloud Canvas, Select a deployment**.
• In the **Cloud Canvas Resource Manager** toolbar, click the name of the current deployment, or click **(none)** if none is configured:

![Current deployment: (none)](image)

When prompted, choose the deployment that you want to make active:

![Select deployment](image)

One or more of the deployments may be marked **protected**. For more information, see **Using Protected Deployments** (p. 2359).

• In the **Cloud Canvas Resource Manager** navigation pane, right-click the deployment that you want to make active, and then click **Make active deployment**:

![Deployments](image)

### Making a Deployment the Default

You can use the **Cloud Canvas Resource Manager** to make a deployment the default.

**To make a deployment active by default for all team members**

1. In Lumberyard Editor, click **AWS, Cloud Canvas, Cloud Canvas Resource Manager**.
2. In the **Cloud Canvas configuration** navigation tree, expand **Administration (advanced)**, and then expand **Deployments**.

3. Right-click the deployment that you want to make the default, and then click **Make default deployment**:

![Image of Cloud Canvas configuration tree with deployments expanded]

To use the command line to make a deployment the default

- To use the command line to make a deployment the default, enter the following command:

```
lmbr_aws deployment default --set <deployment name>
```

### Testing Different Mappings

**Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.**

**Download O3DE** or visit the **AWS Game Tech blog** to learn more.

To test your client with different Cloud Canvas resource deployments, you can export mappings by using Cloud Canvas Resource Manager or the **lmbr_aws** command line.

**Note**

As of Lumberyard 1.11, separate mappings are exported for the player game client and game server to differentiate the resources that are visible to each.

**To export mappings from Cloud Canvas Resource Manager**

- In Resource Manager, do one of the following:
  - Left click a deployment and click **Export Mapping** in the main window.
  - Right click the name of a deployment name the list, and then select **Export Mapping** from the context menu.

The following image shows both options.
To export a mapping from the command line

- Enter the following command, where `<name>` is the name of your deployment.

```
lmbr_aws mappings update --deployment <name>
```

The mapping files for the specified deployment are created in the `\dev\<project_name\>Config` directory and have the format `<deployment_name>.player.awsLogicalMappings.json` and `<deployment_name>.server.awsLogicalMappings.json`.

**Tip**

Using the command line to export mappings makes it easy for you to create scripts for testing or development.

**Selecting a Deployment with a PC Launcher**

After you have exported one or more mappings, you can choose the mapping to use when you run a game launcher such as the one at `dev\Bin64\vcNN\CloudGemSamples\CloudCanvas\CloudGemSamplesLauncher.exe`.

To direct the launcher to use a specific deployment, use the command line option `cc_override_resource_map`, as in the following example.
CloudGemSamplesLauncher.exe -cc_override_resource_map Config\dev.player.awsLogicalMappings.json

The argument for the `cc_override_resource_map` parameter specifies the mapping file that you want to use.

If you have exported a single mapping file to the launcher, the launcher uses that mapping file by default. If you have exported multiple mapping files to the launcher, you must select a mapping by using the `cc_override_resource_map` parameter. If you don't specify a mapping after multiple mappings have been exported, the launcher gives an error message, and no mapping is loaded.

Using Protected Deployments

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use Cloud Canvas to mark specific deployments as protected. Protected status makes it more difficult for users like programmers, testers, or game developers to inadvertently connect a development game client to live resources.

When a user starts a protected game, a message box notifies the user that he or she is attempting to use a protected deployment. The user is given the option to not connect before any potentially harmful data is transmitted.

The protection feature purposely uses a message box that "breaks" automation. If the scripts that run tests are configured to use a protected deployment, the Lumberyard client will not continue without human intervention.

When Protected Deployments Are Detected

When a game is run from Lumberyard Editor, protection is always detected. When a game is run from a Windows launcher, protection is detected only when the launcher is running in debug mode.

Marking a Deployment as Protected

Currently, you must set the protection from the `lmbr_aws` command line tool by using the `protect-deployment` command.

The `protect-deployment` command uses the following parameters.

- `--set <deployment_name>` – Specifies that the deployment is protected.
- `--clear <deployment_name>` – Specifies the deployment is not protected.
- `--show` - Displays a list of currently protected deployments.

To display the protected status of deployments, you can also use either the `list-deployments` or `list-mappings` command.

Viewing Protected Status in Cloud Canvas Resource Manager

In Cloud Canvas Resource Manager, you can view, but not change, the status of protected deployments. The ability to change the protected status of deployments from Lumberyard Editor is planned for a future release.

Note

Setting a deployment to protected does not prevent you from deploying or deleting resources by using Cloud Canvas Resource Manager or the `lmbr_aws` command line tool; it only enables
the warning functionality. For this reason, be careful not to make unnecessary changes to critical deployments. A more comprehensive model for protecting deployments is planned for a future version of Lumberyard.

**Deleting Cloud Canvas Deployments and Their Resources**

Delete Cloud Canvas Deployments and Their Resources.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To remove Cloud Canvas functionality from your Lumberyard project and the AWS resources related to it, you can use Cloud Canvas Resource Manager or the Cloud Canvas command line.

**Warning**

Only administrators should perform these actions. If you remove all AWS resources managed by Cloud Canvas for your Lumberyard project, the players of your game will not be able to access any of the Cloud Canvas resource groups that implement your game's cloud connected features.

**To use Cloud Canvas Resource Manager to delete Cloud Canvas deployments and their resources**

1. If you have checked Lumberyard into source control, ensure that the `<root>\<game>\AWS\project-settings.json` file has been checked out and is writeable.
2. In Lumberyard Editor, choose AWS, Cloud Canvas, Cloud Canvas Resource Manager.
3. In the Cloud Canvas configuration navigation pane, expand Administration (advanced), and then expand Deployments. The list of the deployments in the project appears.
4. Select the deployment to delete and click Delete deployment.
5. When prompted to confirm, click Yes to start the process of deleting the deployment's resources from AWS. The process might take a few minutes.
6. To remove all of the project's resources from AWS, follow the same steps to delete each of the project's deployments.

**To use the command line to delete Cloud Canvas deployments and their resources**

1. If you have checked Lumberyard into source control, ensure that the `<root>\<game>\AWS\project-settings.json` file has been checked out and is writeable.
2. Open a command line prompt and change to your the Lumberyard `dev` directory.
3. Determine the project's deployment names by entering the following command:
4. Enter the following command for each of the deployments that you want to delete:

```
lmbr_aws deployment delete --deployment <deployment name>
```

**Note**
To remove all Cloud Canvas functionality from your project, use the `delete-deployment` command to delete all of deployments that were listed by `list-deployments`. Then remove the project stack as described in the step that follows.

5. After you have deleted all deployments, you can delete the resources that Cloud Canvas uses to manage your project by entering the following command:

```
lmbr_aws project delete
```

This removes all AWS resources that are related to your Cloud Canvas project.

**Freeing Up AWS Resources**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

After a time of intensively testing or developing Lumberyard game projects that use Cloud Canvas, your attempts to create resources in AWS might fail or result in rollback loops. For example, you might receive error messages like the following:

```
CREATE FAILED for Configuration (AWS::S3::Bucket with ID "bucket_id"). You have attempted to create more buckets than allowed.
```

```
CREATE FAILED for ServiceApi (Custom::ServiceApi with ID "api_id"). Failed to create resource. Unexpected RuntimeError occurred: [...] An error occurred (BadRequestException) when calling the ImportRestApi operation: Maximum number of API operations has been reached. Please contact AWS if you need additional API operations.
```

These errors occur when you exceed limits that some AWS services have on the number of resources that you can create per account. The number of resources allowed per account varies by service and by resource. The following table shows some limits for some AWS resources that are commonly used with Cloud Canvas:

<table>
<thead>
<tr>
<th>AWS Service</th>
<th>Limit</th>
<th>Information Link</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon S3</td>
<td>100 buckets per account.</td>
<td>Amazon Simple Storage Service (Amazon S3) Limits</td>
</tr>
<tr>
<td>Amazon API Gateway</td>
<td>60 APIs per account per region.</td>
<td>Amazon API Gateway Limits, Pricing and Known Issues</td>
</tr>
<tr>
<td>Amazon DynamoDB</td>
<td>Initially, 256 tables per region.</td>
<td>Limits in DynamoDB</td>
</tr>
</tbody>
</table>
For more information on the resource limits of individual AWS services, see the AWS Service Limits in the AWS General Reference.

If necessary, you can contact AWS customer service to increase the resource limits for some services. However, if you have resources that you no longer require, it might be easier to simply remove them from your account.

To remove unused resources from AWS, the following tools are available:

- The Cloud Canvas Cleanup Tool (p. 2363)
- The AWS Command Line Interface (CLI) (p. 2366)
- The AWS Management Console (p. 2369)

Of these, the Cloud Canvas cleanup tool provides the quickest way to delete resources.

The Cloud Canvas Cleanup Tool

The Lumberyard installation includes the Cloud Canvas cleanup tool. You can use the Cloud Canvas cleanup tool to delete AWS resources from your account that have the prefix that you specify. The tool is located in the \lumberyard_version\dev\Tools\lmbr_aws\test directory.

Prerequisites

To use the cleanup tool, you must complete the following:

- Have access to a Windows computer.
- Install Lumberyard on your computer.
- Set up and configure an AWS admininstrator IAM profile and set an admininstrator profile name as default on your computer.

For more information, see Step 2: Create an IAM User to Administer the Cloud Canvas Project (p. 2117) and Step 4: Add Administrator Credentials to Lumberyard (p. 2119) in the Cloud Canvas tutorial (p. 2116).

- Install the AWS CLI, configure it with an admininstrator IAM profile, and set it to your preferred region.

For instructions on how to install the AWS CLI on Windows, see Installing the AWS Command Line Interface. The AWS CLI requires Python. You may use the version of Python distributed as part of Lumberyard, provided that it's available in your system's PATH.

- Use Cloud Canvas Resource Manager or the lmbr_aws tool to create a Cloud Canvas project stack.

  **Note**
  If you are using a fresh installation of Lumberyard and need to clean up resources before you can create a project stack, perform the following steps.

  **To use the cleanup tool without creating a project stack**

  1. In Project Configurator, set the default project to a project that has the Cloud Canvas Common gem enabled.
  2. Determine the name of the AWS profile that you want to use. To discover existing profiles, you can examine either the credentials or config file in the %SystemDrive% \Users\user_name\.aws\ directory.
  3. Enter the following command to configure the AWS CLI to use the profile.

```bash
aws configure --profile profile_name
```

  4. In the lumberyard_installation\dev directory, run the following command.
lmbr_aws profile default --set profile_name

This adds the profile to the DefaultProfile section of the user-settings.json (p. 2237) file. As of Lumberyard version 1.15, the Cloud Canvas cleanup tool requires that a default profile be set in the user-settings.json file.

Example

The following example command sets the default Cloud Canvas profile to CloudCanvasAdmin for the CloudGemDefectReportSample project in the Lumberyard installation location C:\Lumberyard\.

C:\Lumberyard\dev>lmbr_aws profile default --set CloudCanvasAdmin

The command produces the following output.

[WAF] Engine Root: C:\Lumberyard\dev\ Saving C:\Lumberyard\dev\Cache\CloudGemDefectReportSample\pc\User\AWS\user-settings.json Default Profile: CloudCanvasAdmin

Using the Cloud Canvas Cleanup Tool

Before you use the cleanup tool, be aware of the following points:

- Do not use the cleanup tool if you have a project stack name that begins with an IAM user name that you do not want to delete. Doing so can result in the deletion of the IAM user, its roles, and its profiles.
- When you delete an AWS resource, you permanently delete any objects that are stored in that resource. For example, if you delete an S3 bucket, all objects inside the bucket are also deleted.

To use the Cloud Canvas cleanup tool

1. Open a command prompt window.
2. Navigate to the lumberyard_version\dev directory.
3. Determine the string prefix (full or partial) that you want to specify to delete resources. For more information, see Identifying Cloud Canvas Prefixes (p. 2364).
4. Enter the following command:
   
   `lmbr_aws --cleanup --prefix prefix_string`

   For example, the following command removes AWS resources that begin with the prefix cloudgemssamples.

   `lmbr_aws --cleanup --prefix cloudgemssamples`

   Depending on the number of resources, the command might take some time to complete.
5. Repeat the command until the cleanup tool no longer finds items to delete. Multiple runs can be required. The cleanup tool attempts to delete resources as they become available for deletion. However, because the cleanup tool attempts to delete resources in type order, some resources are not available for deletion until after the script finishes.
The `--cleanup` argument will take priority over other `lmbr_aws` arguments.

**Note**
The `lmbr_aws --cleanup` command runs the same script as the `cleanup` command script found in the `lumberyard_version\dev\Tools\lmbr_aws` directory. Either one can be used with the same list of optional arguments described in the list that follows.

### Optional Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--aws-access-key</code></td>
<td>The AWS access key to use.</td>
</tr>
<tr>
<td><code>--aws-secret-key</code></td>
<td>The AWS secret access key to use.</td>
</tr>
<tr>
<td><code>--delete-global-resources</code></td>
<td>If the <code>--region</code> argument is specified, deletes global resources such as IAM roles and Amazon S3 buckets. If the <code>--region</code> argument is not specified, the <code>--delete-global-resources</code> argument is ignored. This argument is new in Lumberyard version 1.16.</td>
</tr>
<tr>
<td><code>--except</code> <code>exception [exception ...]</code></td>
<td>Do not delete resources that start with the prefixes specified.</td>
</tr>
<tr>
<td><code>-h, --help</code></td>
<td>Shows a help message and exits.</td>
</tr>
<tr>
<td><code>--prefix</code> <code>prefix [prefix ...]</code></td>
<td>Deletes stacks and Amazon S3 buckets in AWS that have the specified prefixes.</td>
</tr>
<tr>
<td><code>--profile</code> <code>profile</code></td>
<td>The AWS profile to use. Defaults to the default AWS profile.</td>
</tr>
<tr>
<td><code>--region</code> <code>region</code></td>
<td>The AWS region to use. Defaults to <code>us-east-1</code>.</td>
</tr>
</tbody>
</table>

### Identifying Cloud Canvas Prefixes

Use the Cloud Canvas resource naming conventions in this section to identify the resources that you want to delete. In general, the AWS Management Console uses the names that you provided for your resources when you created them in Cloud Canvas Resource Manager or `lmbr_aws`.

#### Project Stacks

In Cloud Canvas, project stack names correspond to AWS CloudFormation stack names. For example, if you create a Cloud Canvas project stack called `CloudGemSamples`, the project stack appears in the AWS CloudFormation Console as `CloudGemSamples`.

#### Project Stack Resources

Resources in a Cloud Canvas project stack have the following form.

```
ProjectStackName-ResourceName
```

For example, if a `CloudGemSamples` Cloud Canvas project stack has an Amazon S3 bucket named `Storage`, the bucket appears in the Amazon S3 Console as `CloudGemSamples-Storage`.

#### Deployment Stacks

A deployment stack name in AWS has the following form.

```
ProjectStackName-DeploymentStackName
```
For example, if a CloudGemSamples Cloud Canvas project stack has a deployment stack named TestDeployment, the deployment stack appears in the AWS CloudFormation Console as CloudGemSamples-TestDeployment.

**Deployment Stack Resources**

Cloud Canvas deployment stack resource names have the following form.

```
ProjectStackName-DeploymentName-ResourceGroupOrGemName-ResourceName
```

For example, suppose a CloudGemSamples Cloud Canvas project stack has a deployment stack named TestDeployment. If TestDeployment has a cloud gem named TestGem that uses an Amazon S3 bucket named GemResourceBucket, the bucket appears in the Amazon S3 Console as CloudGemSamples-TestDeployment-TestGem-GemResourceBucket.

**Viewing Prefixes in the AWS Management Console**

You can use the AWS Management Console to identify resources to delete.

To view AWS CloudFormation stacks

2. In the upper-right corner of the management console, choose the AWS region from which you want to delete resources.
3. Identify the AWS CloudFormation stack(s) that you no longer require.
4. Use the Cloud Canvas resource naming rules to determine the prefix to use with the Cloud Canvas cleanup tool.

To identify orphaned resource(s)

1. Open the AWS Console for the resource that you believe is orphaned (for example, the Amazon S3 Console or the Amazon API Gateway Console).
2. In the upper-right corner of the management console, choose the AWS region from which you want to delete resources.
3. Identify a resource that you no longer require.
4. Use the Cloud Canvas resource naming rules to determine the prefix to use with the Cloud Canvas cleanup tool.

**Notes Regarding the Cleanup Tool**

When you use the Cloud Canvas cleanup tool, note the following.

- You do not have to specify a complete prefix. The cleanup tool takes the string that you specify and matches it with all resources that have names that start with that string. For example, if you specify the prefix Cloud, all resources that start with Cloud (like CloudGemSamples) are deleted, including resources that AWS CloudFormation created.
- An Amazon S3 bucket/aws_resource can seem to fail to delete even though it is empty and visible in the management console.

A resource that has been removed can have an obsolete (ghost) reference to it in the AWS Management Console. If you attempt to use the cleanup tool or AWS CLI to delete the resource, you receive an error that the resource does not exist. For example, when you try to delete an S3 bucket that has already been deleted, an error message like the following occurs:
ERROR An error occurred (NoSuchBucket) when calling the ListObjectVersion operation: The specified bucket does not exist.

This error confirms that the resource has been deleted. The resource will no longer count against your resource limits or costs. AWS automatically cleans up the ghost reference in 24 to 72 hours.

- Errors can occur when you delete a Cloud Canvas project stack prefix for your current Lumberyard project and then use Cloud Canvas Resource Manager or \lmbr_aws\ commands. This is because the resources that the project expects no longer exist in AWS.

To resolve this issue, you can delete the \lumberyard_version\dev\project_name\AWS\local-project-settings.json file, which is automatically regenerated by Cloud Canvas Resource Manager and \lmbr_aws\ commands. Alternatively, you can edit the ProjectStackId section of the local-project-settings.json file to remove the resources listed that have been deleted. You should also edit the Mappings section of the \lumberyard_version\dev\Cache\game\OS\user\AWS\user-settings.json file to remove references to resources that have been deleted.

AWS Command Line Interface (CLI)

You can use the AWS Command Line Interface to remove resources from specific AWS services in your account. This section lists some useful commands for the following AWS services that are commonly used with Cloud Canvas:

- Amazon DynamoDB (p. 2366)
- AWS Lambda (p. 2367)
- Amazon API Gateway (p. 2368)
- Amazon S3 (p. 2368)

Prerequisites

To use the AWS CLI, you must complete the following:

- Set up and configure an AWS administrator IAM profile and set an admininstrator profile name as default on your computer.

  For more information, see Step 2: Create an IAM User to Administer the Cloud Canvas Project (p. 2117) and Step 4: Add Administrator Credentials to Lumberyard (p. 2119) in the Cloud Canvas tutorial (p. 2116).

- Install the AWS CLI, configure it with an admininstrator IAM profile, and set it to your preferred region.

  For instructions on how to install the AWS CLI on Windows, Linux, macOS, or Unix, see Installing the AWS Command Line Interface. The AWS CLI requires Python. You may use the version of Python distributed as part of Lumberyard, provided that it's available in your system's PATH.

Creating Script Files for Batch Deletion

A generally useful ad hoc strategy is to use a service-specific AWS CLI command to redirect a list of the resources into a text file. You can then use the text file programatically or convert the file into a shell script of AWS CLI deletion commands. The next few sections illustrate this technique.

Amazon DynamoDB

To show list of the DynamoDB tables in the current region in a command prompt window, enter the following command.
aws dynamodb list-tables

To specify a different region, use the --region region_name argument, as in the following example.

aws --region us-west-2 dynamodb list-tables

To redirect the list of tables into a text file, enter a command like the following.

aws dynamodb list-tables >ddb_table_list.txt

The example command redirects the output into a text file called ddb_table_list.txt.

The AWS CLI command to delete a DynamoDB table uses the following syntax.

aws dynamodb delete-table --table-name table_name

To create a shell script that deletes many or all tables at once, you can edit the text file that has the list-tables output. Use a search and replace operation to precede each table name with the aws dynamodb delete-table command. Do another search and replace to remove the double quote and comma at the end of each line. The result looks like the following example.

aws dynamodb delete-table --table-name CloudGemSamples-CGSamplesDeployment-CloudGemDynamicContent-hash-StagingSettingsTable
aws dynamodb delete-table --table-name CloudGemSamples-CGSamplesDeployment-CloudGemInGameSurvey-hash-AnswerAggregations
aws dynamodb delete-table --table-name CloudGemSamples-CGSamplesDeployment-CloudGemInGameSurvey-hash-Questions
aws dynamodb delete-table --table-name CloudGemSamples-CGSamplesDeployment-CloudGemInGameSurvey-hash-Surveys
aws dynamodb delete-table --table-name CloudGemSamples-CGSamplesDeployment-CloudGemLeaderboard-hash-BannedPlayerTable

After you rename the file with a .cmd or .bat extension (Windows), you can run the script to delete all the tables in one go.

For more information on the DynamoDB CLI commands, see dynamodb.

AWS Lambda

To list AWS Lambda functions, enter the following command.

aws lambda list-functions

The following syntax deletes a Lambda function.

aws lambda delete-function --function-name function_name

The deletion syntax requires only the function name, so to create a script, filter the JSON output of the list-functions command on FunctionName. In Windows, you can use the following syntax to pipe the output of list-functions into the findstr command and redirect the result into a text file.

aws lambda list-functions | findstr /C:FunctionName >lambdafns.txt
The resulting file looks like this:

```
"FunctionName": "CloudGemSamples-CGSamplesDep-Clo-ServiceLambda-hash",
"FunctionName": "CloudGemSamples-AH-CoreResourceTypes-AWS_SQS_Queue",
"FunctionName": "CloudGemSamples-AH-CoreResourceTypes-Custom_ServiceApi",
"FunctionName": "CloudGemSamples-CRH-CoreResourceTypes-Custom_Helper",
"FunctionName": "CloudGemSamples-CRH-CoreResourceTypes-Custom_Interface-hash",
"FunctionName": "CloudGemSamples-CGSamplesDep-PackageVoiceLines-hash",
```

As before, use search and replace operations to turn the file into a deletion script, as in the following example.

```
aws lambda delete-function --function-name CloudGemSamples-CGSamplesDep13-Clo-ServiceLambda-hash
aws lambda delete-function --function-name CloudGemSamples-AH-CoreResourceTypes-AWS_SQS_Queue
aws lambda delete-function --function-name CloudGemSamples-AH-CoreResourceTypes-Custom_ServiceApi
aws lambda delete-function --function-name CloudGemSamples-CRH-CoreResourceTypes-Custom_Helper
aws lambda delete-function --function-name CloudGemSamples-CRH-CoreResourceTypes-Custom_Interface-hash
aws lambda delete-function --function-name CloudGemSamples-CGSamplesDep13-PackageVoiceLines-hash
```

For more information on the AWS Lambda CLI commands, see `lambda`

**Amazon API Gateway**

To delete a REST API from API Gateway, you must specify the ID of the REST API.

```
aws apigateway delete-rest-api --rest-api-id rest_api_id
```

To list the APIs in API Gateway, use the `get-rest-apis` command.

```
aws apigateway get-rest-apis
```

In Windows, you can filter the output of the `get-rest-apis` command by ID as in the following example.

```
aws apigateway get-rest-apis | findstr /C:id >gatewayapis.txt
```

For more information on the API Gateway CLI commands, see `apigateway`

**Amazon S3**

In Amazon S3, you can **delete** empty buckets but must **remove** non-empty buckets.

**Note**
The commands presented here work only on unversioned buckets. Amazon S3 buckets are unversioned by default. For more information, see **Using Versioning** in the **Amazon Simple Storage Service User Guide**.

**Getting a List of Bucket Names**

To obtain a list of S3 bucket names, use the following command.
aws s3api list-buckets --query Buckets[].Name

Deleting a Bucket

The following syntax deletes an empty S3 bucket:

aws s3api delete-bucket --bucket bucket_name

Removing a Bucket

To remove a non-empty bucket, use the `rb` (remove bucket) command with `--force` parameter.

aws s3 rb s3://bucket_name --force

The following example command deletes all objects in the `cloudgemsamples-cloudgemportal-hash` bucket and then deletes the bucket itself.

aws s3 rb s3://cloudgemsamples-cloudgemportal-hash --force

For more information on the Amazon S3 CLI high-level commands, see s3. For more information on the more detailed Amazon S3 CLI commands, see s3api.

Using the AWS Management Console

You can use the AWS Management Console to manually delete individual AWS resources from your account. However, if you have many resources to delete, the Cloud Canvas cleanup tool or the AWS CLI are faster alternatives.

To delete an Amazon S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.
2. Identify a bucket that you no longer require.
3. Select the identified bucket’s line entry.
4. Click the Empty Bucket button.
5. Follow modal instructions to empty bucket and confirm.
6. Click the Delete Bucket button.
7. Follow the modal instructions to delete the bucket and confirm.

To delete an API from API Gateway

1. Sign in to the AWS Management Console and open the API Gateway console at https://console.aws.amazon.com/apigateway/.
2. In the upper-right corner of the management console, choose the AWS region from which you want to delete resources.
3. Identify an API that you no longer require.
4. Click the API.
5. Click the Actions menu.
6. Select Delete API from the menu.
7. Follow the instructions in the DeleteRestApi dialog box to confirm the deletion of the API.

To delete AWS CloudFormation stacks

2. In the upper-right corner of the management console, choose the AWS region from which you want to delete resources.
3. Identify a AWS CloudFormation stack that you no longer require.
4. Select the stack.
5. Click the Actions menu.
6. Choose Delete Stack from the drop-down list.

   **Note**
   If termination protection is enabled for the stack, you must remove the protection before you can delete the stack.
7. Follow the instructions to confirm the deletion of the stack.

Understanding the Resource Manager Security System

Cloud Canvas Resource Manager provides a robust set of features for securing your Amazon Lumberyard project and its cloud-connected resources. You can control the access to project resources of team members, players, Lambda functions, and specify other custom access control configuration for your project.

**Topics**

- Controlling Access to Resources (p. 2370)
- Cloud Canvas Built-In Roles and Policies (p. 2373)
- Player Identity (p. 2379)
- Using the Cloud Canvas Command Line to Manage Roles and Permissions (p. 2381)
- Improve Security with a Custom Domain Name (p. 2386)

Controlling Access to Resources

Setting access permissions correctly is key to ensuring that Cloud Canvas Resource Manager manages your project's cloud-connected features securely.

Access Scenarios and ProjectResourceHandler

Cloud Canvas Resource Manager requires that the following access scenarios be supported. Additional roles with more nuanced permissions can be created, but the table below describes the core access requirements.
A project team member must be able to create resource group stacks that contain arbitrary resources, but not be able to create or modify roles and policies. This introduces a significant complexity. Some resources like Lambda functions require that the game developer also provide a role that is assumed by the resource. The game developer must be able to create such roles and manage their policies. However, granting IAM permissions such as these directly to team members would effectively make them administrators.

To enable the required functionality while still limiting what a project team member can do directly, Cloud Canvas Resource Manager uses AWS CloudFormation custom resources. The custom resource handlers for Cloud Canvas Resource Manager are implemented in the `ProjectResourceHandler` Lambda function in the project stack. The Lambda function's execution role (`ProjectResourceHandlerExecution`) grants permissions that Cloud Canvas Resource Manager requires. These permissions are not granted to project team members.

For example, the `Custom::AccessControl` resource, described in detail later in this document, is responsible for managing inline policies on various roles. It can perform these actions on the project team member's behalf. However, the `Custom::AccessControl` handler also must know what to put into these policies. It can't trust the project team member to provide this information directly. Instead, it must construct the information from trusted sources. To do this, `AccessControl` uses metadata on resource definitions from AWS CloudFormation. It also constructs ARNs for the stack's resources identified by AWS CloudFormation. In this way, only a user with permission to update the stack can influence the policies that are constructed for the resources in that stack.

<table>
<thead>
<tr>
<th>Project Stack</th>
<th>Project Team Member</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full Access</td>
<td>Read</td>
</tr>
<tr>
<td>Full Access</td>
<td>Read/Update</td>
</tr>
<tr>
<td>Full Access</td>
<td>Read</td>
</tr>
<tr>
<td>Full Access</td>
<td>Create/Update/Delete</td>
</tr>
<tr>
<td>Full Access</td>
<td>Assume</td>
</tr>
</tbody>
</table>

A project team member must be able to create resource group stacks that contain arbitrary resources, but not be able to create or modify roles and policies. This introduces a significant complexity. Some resources like Lambda functions require that the game developer also provide a role that is assumed by the resource. The game developer must be able to create such roles and manage their policies. However, granting IAM permissions such as these directly to team members would effectively make them administrators.

To enable the required functionality while still limiting what a project team member can do directly, Cloud Canvas Resource Manager uses AWS CloudFormation custom resources. The custom resource handlers for Cloud Canvas Resource Manager are implemented in the `ProjectResourceHandler` Lambda function in the project stack. The Lambda function's execution role (`ProjectResourceHandlerExecution`) grants permissions that Cloud Canvas Resource Manager requires. These permissions are not granted to project team members.

For example, the `Custom::AccessControl` resource, described in detail later in this document, is responsible for managing inline policies on various roles. It can perform these actions on the project team member's behalf. However, the `Custom::AccessControl` handler also must know what to put into these policies. It can't trust the project team member to provide this information directly. Instead, it must construct the information from trusted sources. To do this, `AccessControl` uses metadata on resource definitions from AWS CloudFormation. It also constructs ARNs for the stack's resources identified by AWS CloudFormation. In this way, only a user with permission to update the stack can influence the policies that are constructed for the resources in that stack.
Using the Custom::AccessControl Resource

As described above, Cloud Canvas Resource Manager security depends on IAM roles and the credentials used from assuming such roles. The Access Scenarios and ProjectResourceHandler (p. 2370) section earlier in this topic explains why Cloud Canvas Resource Manager has the responsibility of managing the inline policies attached to these roles.

This section describes the data used by the Custom::AccessControl resource handler to configure the project's roles. A Custom::AccessControl resource must be defined in the following templates:

<table>
<thead>
<tr>
<th>Template</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>project-template.json</td>
<td>Causes policies on the roles defined in the project-template.json file to be updated. These roles can provide access to any resource defined in any resource groups across all deployments.</td>
</tr>
<tr>
<td>deployment-access-template.json</td>
<td>Causes policies on the roles defined in the deployment-access-template.json file to be updated. These roles can provide access to any resource in any resource of a given deployment.</td>
</tr>
<tr>
<td>resource-group-template.json</td>
<td>Causes policies on the roles defined in the project-template.json and deployment-access-template.json files to be updated. Only permissions for the resource defined in the resource-group-template.json file are updated. For roles defined in the deployment-access-template.json file, only the instances of those roles for the deployment that contains the resource group stack are updated.</td>
</tr>
</tbody>
</table>

This process is illustrated in the following diagram. The diagram shows the metadata that is read and roles that are updated when a resource group stack, deployment access stack, or project stack is updated.
Custom::AccessControl Resource Definitions

The Custom::AccessControl resource supports the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConfigurationBucket</td>
<td>The name of the project’s configuration bucket. This property must be provided.</td>
</tr>
<tr>
<td>ConfigurationKey</td>
<td>Identifies the location in the configuration bucket where data for the stack operation is stored. However, the custom resource handler depends on this value changing on each update. Property changes such as this cause AWS CloudFormation to invoke the custom resource handler on each stack operation.</td>
</tr>
<tr>
<td>ServiceToken</td>
<td>Identifies the Lambda function that is invoked for the custom resource. This should be the project global ProjectResourceHandler Lambda function that is defined in the project-template.json file.</td>
</tr>
</tbody>
</table>

The DependsOn attribute of the Custom::AccessControl resource definition must list the following resources.

- All the resources in the project-template.json, deployment-access-template.json, or resource-group-template.json files that provide permissions metadata.

- All the AWS::IAM::Role resources that have RoleMapping metadata.

- Any custom resources that create implicit roles, such as Custom::LambdaConfiguration and Custom::ServiceApi resources.

When you use the AWS CLI to manage roles and permissions, these resources are listed for you. However, if you edit these files yourself, it is important that you maintain these dependencies. Without these dependencies, the Custom::AccessControl resource might be updated before the other resources have been updated. If this occurs, the Custom::AccessControl no longer has access to the latest metadata from the resources, and the changes that were intended might not be made.

Setting Access Permissions

For information on setting Custom::AccessControl permissions, see Permissions Metadata for Resource Definitions (p. 2240).

Cloud Canvas Built-In Roles and Policies

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the built-in Cloud Canvas roles and policies to manage resource and deployment permissions for your project.
**Built-In Roles**

You can use the `AWS::IAM:Role` resource to define roles in your `project-template.json` or `deployment-access-template.json` files. Cloud Canvas Resource Manager defines the following roles for you.

**DeploymentAdmin**

Grants restricted access to the deployment. Similar to the `DeploymentOwner` role, but cannot create or delete resource group stacks. This is a convenience role that is safer than `DeploymentOwner`. To add additional restrictions to the `DeploymentAdmin` role, edit the `DeploymentAdminRestrictions` policy definition.

<table>
<thead>
<tr>
<th>Policy Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assume role</td>
<td>Can be assumed by principles defined in the same AWS account, as allowed by their permissions.</td>
</tr>
<tr>
<td>Attached</td>
<td><code>DeploymentAccess, DeploymentOwnerAccess, and DeploymentAdminRestrictions</code></td>
</tr>
<tr>
<td>Inline</td>
<td>Added and removed by the <code>Custom::AccessControl</code> resource handler based on abstract role mappings.</td>
</tr>
</tbody>
</table>

File location: `\project_name\deployment_name\deployment-access-template.json`.

**DeploymentOwner**

Grants full access to all the resources in a deployment. To modify the default permissions granted by this role, edit the `DeploymentOwnerAccess` policy definition.

<table>
<thead>
<tr>
<th>Policy Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assume role</td>
<td>Can be assumed by principles defined in the same AWS account, as allowed by their permissions.</td>
</tr>
<tr>
<td>Attached</td>
<td><code>DeploymentAccess and DeploymentOwnerAccess</code></td>
</tr>
<tr>
<td>Inline</td>
<td>Added and removed by the <code>Custom::AccessControl</code> resource handler based on abstract role mappings.</td>
</tr>
</tbody>
</table>

File location: `\project_name\deployment_name\deployment-access-template.json`.

**Note**

Permissions added to `DeploymentOwnerAccess` are also granted to `DeploymentAdmin` unless they are denied by `DeploymentAdminRestrictions`.

**Player**

Grants players limited access to specific resources in a deployment as determined by permissions metadata on those resources.

<table>
<thead>
<tr>
<th>Policy Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assume role</td>
<td>Can be assumed by <code>cognito-identity.amazonaws.com</code>.</td>
</tr>
<tr>
<td>Attached</td>
<td>None.</td>
</tr>
</tbody>
</table>
## Administering Cloud Canvas

### Policy Type

<table>
<thead>
<tr>
<th>Policy Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inline</td>
<td>Added and removed by the <code>Custom::AccessControl</code> resource handler based on abstract role mappings.</td>
</tr>
</tbody>
</table>

File location: `\project_name\deployment_name\deployment-access-template.json`.

### ProjectAdmin

Grants project administrators restricted access to all the project's deployments. Similar to the `ProjectOwner` role, but cannot create, update, or delete deployments with names that start with "Release." This is a convenience role that is safer than `ProjectOwner`. To add additional restrictions to the `ProjectAdmin` role, edit the `ProjectAdminRestrictions` definition.

<table>
<thead>
<tr>
<th>Policy Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assume role</td>
<td>Can be assumed by principals defined in the same AWS account, as allowed by their permissions.</td>
</tr>
<tr>
<td>Attached</td>
<td><code>ProjectAccess</code>, <code>ProjectOwnerAccess</code>, and <code>ProjectAdminRestrictions</code>.</td>
</tr>
<tr>
<td>Inline</td>
<td>Added and removed by the <code>Custom::AccessControl</code> resource handler based on abstract role mappings.</td>
</tr>
</tbody>
</table>

File location: `\project_name\project-template.json`.

**Warning**
The intent of this role is to securely "sandbox" user actions so that they don't accidentally impact other projects. However, anyone who can assume the `ProjectAdmin` role can grant themselves additional permissions. Because a `ProjectAdmin` user can escalate the privilege for the role, the `ProjectAdmin` role should still be considered an account administrator role and therefore a potential security concern.

### ProjectOwner

Grants project administrators full access to all the project's resources. To modify the default permissions granted by this role, edit the `ProjectOwnerAccess` policy definition.

<table>
<thead>
<tr>
<th>Policy Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assume role</td>
<td>Can be assumed by principals defined in the same AWS account, as allowed by their permissions.</td>
</tr>
<tr>
<td>Attached</td>
<td><code>ProjectAccess</code> and <code>ProjectOwnerAccess</code>.</td>
</tr>
<tr>
<td>Inline</td>
<td>Added and removed by the <code>Custom::AccessControl</code> resource handler based on abstract role mappings.</td>
</tr>
</tbody>
</table>

File location: `\project_name\project-template.json`.

**Warning**
- The intent of this role is to securely "sandbox" user actions so that they don't accidentally impact other projects. However, anyone who can assume the `ProjectOwner` role can grant themselves additional permissions. Because a `ProjectOwner` user can escalate the privilege for the role, the `ProjectOwner` role should still be considered an account administrator role and therefore a potential security concern.
for the role, the ProjectOwner role should still be considered an account administrator role and therefore a potential security concern.

- Permissions added to ProjectOwnerAccess are also granted to ProjectAdmin unless they are denied by ProjectAdminRestrictions.

**ProjectResourceHandlerExecution**

Grants the ProjectResourceHandler Lambda function runtime execution permissions. This role grants permissions for Cloud Canvas Resource Manager to use AWS CloudFormation custom resources for stack operations. For more information, see Access Scenarios and the ProjectResourceHandler (p. 2370).

<table>
<thead>
<tr>
<th>Policy Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assume role</td>
<td>Can be assumed by the AWS Lambda service.</td>
</tr>
<tr>
<td>Attached</td>
<td>None.</td>
</tr>
<tr>
<td>Inline</td>
<td>ProjectAccess.</td>
</tr>
</tbody>
</table>

File location: `\project_name\project-template.json`.

**Server**

Grants Lumberyard dedicated server builds access to select deployment resources, as determined by permissions metadata on those resources.

<table>
<thead>
<tr>
<th>Policy Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assume role</td>
<td>Can be assumed by cognito-identity.amazonaws.com.</td>
</tr>
<tr>
<td>Attached</td>
<td>None.</td>
</tr>
<tr>
<td>Inline</td>
<td>Added and removed by the Custom::AccessControl resource handler based on abstract role mappings.</td>
</tr>
</tbody>
</table>

File location: `\project_name\deployment_name\deployment-access-template.json`.

**Role Scope**

The configuration file in which you define a role determines the resources to which the role provides access.

<table>
<thead>
<tr>
<th>File</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>project-template.json</td>
<td>Applies to all resources in all resource groups for all deployments. Only a single instance of the role is created for the entire project.</td>
</tr>
<tr>
<td>deployment-template.json</td>
<td>Applies to all resources in all resource groups for a specific deployment. A separate instance of the role is created for each deployment.</td>
</tr>
</tbody>
</table>

You can use the `lmbr_aws` command line tool to manage the role definitions in the `project-template.json` and `deployment-access-template.json` files. For more information, see Using the Cloud Canvas Command Line to Manage Roles and Permissions (p. 2381).
**Implicit Roles**

Some Cloud Canvas custom resources also create roles. For example, when a Lambda function is executed, it assumes the role that the `Custom::LambdaConfiguration` resource creates. When API Gateway invokes a Lambda function or accesses other resources, it assumes the role that the `Custom::ServiceApi` resource creates. Including these custom resources in a `resource-group-template.json` file causes these implicit roles to be created (and deleted when the resource is deleted). For information on implicit role names, see Implicit Role Mappings (p. 2379).

**Managed Policies**

You can use `AWS::IAM::ManagedPolicy` resources to define permissions that are shared across any number of roles. Cloud Canvas defines the following managed policies for you:

<table>
<thead>
<tr>
<th>Policy</th>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ProjectAccess</td>
<td><code>project-template.json</code></td>
<td>Defines the permissions needed to access the project and deployment configuration that must be read before a project-wide role can be assumed. For more information, see Assuming a Role (p. 2381).</td>
</tr>
<tr>
<td>ProjectOwnerAccess</td>
<td><code>project-template.json</code></td>
<td>Defines the default permissions granted to the ProjectOwner and ProjectAdmin roles.</td>
</tr>
<tr>
<td>ProjectAdminRestrictions</td>
<td><code>project-template.json</code></td>
<td>Defines restrictions to the ProjectOwnerAccess policy that apply only to the ProjectAdmin role.</td>
</tr>
<tr>
<td>DeploymentAccess</td>
<td><code>deployment-access-template.json</code></td>
<td>Defines the permissions needed to access project and deployment configuration that must be read before a deployment-specific role can be assumed. For more information, see Assuming a Role (p. 2381).</td>
</tr>
<tr>
<td>DeploymentOwnerAccess</td>
<td><code>deployment-access-template.json</code></td>
<td>Defines the default permissions granted to the DeploymentOwner and DeploymentAdmin roles.</td>
</tr>
<tr>
<td>DeploymentAdminRestrictions</td>
<td><code>deployment-access-template.json</code></td>
<td>Defines restrictions to the DeploymentOwnerAccess policy that apply only to the DeploymentAdmin role.</td>
</tr>
</tbody>
</table>

The `ProjectAdmin` and `DeploymentAdmin` roles are granted the same permissions as the `ProjectOwner` and `DeploymentOwner` roles, minus any permissions specifically denied by the `ProjectAdminRestrictions` and `DeploymentAdminRestrictions` managed policies, respectively. In effect, an "admin" is granted all the permissions of an "owner" minus any special actions that the "admin" should not be able to perform.

**Role Mapping Metadata**

The `AbstractRole` property in the `Permission` metadata object does not directly specify the actual role that receives the described permission. These values must be mapped to actual IAM roles. This makes it possible to setup roles in whatever way makes sense for your project. It also removes the need to modify the permissions defined by individual resource groups.

The ability to map abstract roles to actual IAM roles is important when you use a cloud gem across multiple projects or from a third party. Cloud gems acquired from a third party might have roles that are different from the roles that you use in your organization. (A cloud gem is a Lumberyard gem (p. 1064) that uses the AWS resources defined by a Cloud Canvas Resource Group. For more information, see Cloud Gems (p. 2127).)
The Custom::AccessControl resource looks for CloudCanvas RoleMappings metadata on AWS::IAM::Role resources to determine which abstract roles map to that physical role. In the following example, the CustomerSupport abstract role from all resource groups is mapped to the DevOps physical role.

```
... 

"DevOps": { 
  "Type": "AWS::IAM::Role",
  "Properties": { 
    "Path": "Fn::Join": [ "", [ "/", { "Ref": "ProjectStack" }, "/", { "Ref": "DeploymentName" } ] ]
  },
  "Metadata": { 
    "CloudCanvas": { 
      "RoleMappings": [ 
        { 
          "AbstractRole": [ "*.CustomerSupport" ],
          "Effect": "Allow"
        }
      ]
    }
  },
},
... 
```

Each Cloud Canvas RoleMapping metadata object can have the following properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AbstractRole</td>
<td>Required string or list of strings of the form <code>&lt;resource-group-name&gt;.&lt;abstract-role-name&gt;</code>. To match abstract roles defined in any resource group, use * for the <code>&lt;resource-group-name&gt;</code>. To match abstract roles defined only in a specific resource group, use an actual resource group name.</td>
</tr>
<tr>
<td>Effect</td>
<td>Required string. Must be either <code>Allow</code>, to allow an action defined by permission metadata, or <code>Deny</code> to deny an action. This is used as the Effect property in a statement in the policy.</td>
</tr>
</tbody>
</table>

You can use the `lmbr_aws` command line tool to manage RoleMappings metadata on role resource definitions in the `project-template.json` and `deployment-access-template.json` files. For more information, see Using the Cloud Canvas Command Line to Manage Roles and Permissions.

**Default Role Mappings**

Cloud Canvas defines role mappings for the following roles:

<table>
<thead>
<tr>
<th>Role</th>
<th>File</th>
<th>Default Role Mapping</th>
</tr>
</thead>
<tbody>
<tr>
<td>ProjectResourceHandlerExecution</td>
<td>project-template.json</td>
<td>none</td>
</tr>
<tr>
<td>ProjectOwner</td>
<td>project-template.json</td>
<td>*.ProjectAdmin</td>
</tr>
<tr>
<td></td>
<td></td>
<td>*.ProjectOwner</td>
</tr>
<tr>
<td>ProjectAdmin</td>
<td>project-template.json</td>
<td>*.ProjectAdmin</td>
</tr>
<tr>
<td>DeploymentOwner</td>
<td>deployment-access-template.json</td>
<td>*.DeploymentAdmin</td>
</tr>
<tr>
<td></td>
<td></td>
<td>*.DeploymentOwner</td>
</tr>
</tbody>
</table>
Implicit Role Mappings

As mentioned in Implicit Roles (p. 2377), role mappings are automatically defined for the implicit roles created by Cloud Canvas resources like Custom::LambdaConfiguration. These mappings are only used with permission metadata in the same resource-group-template.json file as the custom resource that creates the role. The name of the abstract role used in permission metadata to reference an implicit role depends on the custom resource type.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Implicit Role Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Custom::LambdaConfiguration</td>
<td>The name of the Lambda function, as specified by the Function property in the Custom::LambdaConfiguration resource definition. This is also the logical ID of the AWS::Lambda::Function resource.</td>
</tr>
<tr>
<td>Custom::ServiceApi</td>
<td>The logical ID of the Custom::ServiceApi resource.</td>
</tr>
</tbody>
</table>

Player Identity

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the AWS Game Tech blog to learn more.

A Lumberyard cloud-connected game must use AWS credentials that grant the desired access when calling AWS APIs (using either the C++ AWS SDK or the AWS flow nodes). Cloud Canvas uses an Amazon Cognito identity pool to get these credentials.

Using a Amazon Cognito identity pool has the benefit of providing the game with a unique identity for each individual player. This identity can be used to associate the player with their saved games, high scores, or any other data stored in DynamoDB tables, Amazon S3 buckets, or other locations. If you use the Player Account Cloud Gem, this identity is mapped to an account ID that can be used instead.

Amazon Cognito identity pools support both unauthenticated and authenticated identities. Unauthenticated identities are associated with a single device such as a PC, tablet, or phone, and have no associated user name or password.

Authenticated identities are associated with the identity of an player as determined by an external identity provider such as Amazon, Facebook, or Google, or an Amazon Cognito user pool. This allows Amazon Cognito to provide the game with the same player identity everywhere a player plays a game. The player’s saved games, high scores, and other data effectively follow the player from device to device.

Cloud Canvas supports both anonymous (unauthenticated) and authenticated player identities. The Player Account Cloud Gem is the easiest way to add authentication. Authenticated identity support for other providers is more complex and requires additional setup and coding.
Anonymous (Unauthenticated) Player Login

In Lumberyard version 1.11, the identity system that previously existed in an LmbrAWS CryEngine module (`dev\Code\CryEngine\CryCommon\LmbrAWS`) has been converted into a CloudCanvasPlayerIdentityComponent (`dev\Gems\CloudGemFramework\vN\Code\Source\PlayerIdentity.*`). This component is implemented as a required system component from the CloudGemFramework Gem. The Cloud Canvas client configuration system is automatically initialized by the following call:

```cpp
EBUS_EVENT_RESULT(appliedConfiguration, CloudGemFramework::CloudCanvasPlayerIdentityBus, ApplyConfiguration)
```

Alternatively, you can use a Cloud Canvas (AWS):Configuration:ApplyConfiguration flow node. An existing anonymous identity is loaded from the local identities cache. If an anonymous identity is not found in the cache, a new identity is acquired from the pool. The identity cache is stored in an .aws/.identities file in the user's home directory.

Authenticated Player Login

In order to understand how to use Cloud Canvas to implement authenticated player identities for your game, you must be familiar with Amazon Cognito's Enhanced (Simplified) Authflow. For information, see the article Authentication Flow in the Amazon Cognito Developer Guide.

The login process for authenticated player identities is more complex than the anonymous player login process. The Player Account Cloud Gem handles this for Amazon Cognito user pools. For other providers, this login process requires additional setup beyond what Cloud Canvas provides by default.

The authenticated player login process takes place automatically when the Cloud Canvas client configuration system is initialized by the following call:

```cpp
EBUS_EVENT_RESULT(appliedConfiguration, CloudGemFramework::CloudCanvasPlayerIdentityBus, ApplyConfiguration)
```

Alternatively, the process can occur by using a Cloud Canvas (AWS):Configuration:ApplyConfiguration flow node. If an authenticated identity is found in the local identities cache, it is loaded and the access token is refreshed if needed using the stored refresh token. If no existing identity is found, it falls back to using the anonymous identity for AWS calls.

The code that implements the authenticated login flow can be found in the `dev\Gems\CloudGemFramework\vN\Code\Source\Identity` directory. A description of the files follows.

- **ResourceManagementLambdaBasedTokenRetrievalStrategy.cpp** – Implements the token exchange process that calls the PlayerAccessTokenExchange Lambda function.

- **TokenRetrievingPersistentIdentityProvider.cpp** – An implementation of the PersistentCognitoIdentityProvider interface that is defined in the AWS SDK. The implementation uses ResourceManagementLambdaBasedTokenRetrievalStrategy instances to implement the token exchange process.

Configuring a Cognito Identity Provider (Cognito User Pool)

Cloud Canvas provides the `Custom::CognitoUserPool (p. 2253)` resource for adding the Amazon Cognito user pools and linking them to a Amazon Cognito identity pool. The Player Account Cloud Gem (p. 2188) uses this custom resource. It also provides an EBus interface so that you can work with the user pool and the sample level that has an in-game menu.
You can use the `lmbr_aws` command line tool to manage Cloud Canvas Resource Manager access control. For example, you can use the tool to assume a role when you run a command, or to manage roles, permissions, and role mappings.

### Assuming a Role

Most `lmbr_aws` commands support an `--assume-role <role-name>` argument. You can use this argument to assume a role when you run a command.

If specified, `<role-name>` must be the logical resource ID of an IAM role resource defined in either the `project-template.json` or `deployment-access-template.json` files.

**Note**

You should avoid defining roles that have the same name in both files. If you do, the role from the deployment file takes precedence.

If you specify a deployment access role, the actual role used depends on the deployment on which the command is operating. If the `--deployment` argument has been specified, then the specified deployment is used. If the `--deployment` argument has not been specified and the user has specified a default deployment, the default deployment is used. If a default deployment has not been specified, the project's default deployment is used.

`lmbr_aws` uses your configured AWS credentials to assume the specified role. See [Configuration](#) for a description of how the credentials are determined. The credentials must have permission to assume the role. For more information, see [Granting a User Permission to Switch Roles](#).

Before assuming the role, the `lmbr_aws` tool uses credentials to read project configuration data from AWS. The `ProjectAccess` managed policy in the `project-template.json` file and the `DeploymentAccess` managed policy in the `deployment-access-template.json` file grant the permissions necessary to read this information. You can attach the corresponding managed policy to any IAM user that works on a project or deployment.

Note that administrative users created for an AWS account normally have permissions to assume roles and read project configuration. Administrative users typically have permission to perform any action on any resource owned by an account.

### Role Management Commands

Role management commands manage the `AWS::IAM::Role` resource definitions in the `project-template.json` and `deployment-access-template.json` files. After you use these commands to make changes, you must update the project or deployment access stacks for the changes to take effect. For information about the permissions to perform this action, see [Controlling Access to Resources](#).

#### `lmbr_aws role add`

Adds an AWS IAM role resource definition to the `project-template.json` file or `deployment-access-template.json` file.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>role</code></td>
<td>Required. The name of the role resource definition.</td>
</tr>
</tbody>
</table>
**lmbr.aws role remove**

Removes an AWS IAM role resource definition from the `project-template.json` file or `deployment-access-template.json` file.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>##role <code>&lt;role-name&gt;</code></td>
<td>Required. The name of the role resource definition.</td>
</tr>
<tr>
<td>##project</td>
<td>Optional. When present, specifies that the role resource definition be removed from the <code>project-template.json</code> file. Otherwise, the role resource definition is removed from the <code>deployment-access-template.json</code> file.</td>
</tr>
</tbody>
</table>

**lmbr.aws role list**

Lists the AWS IAM role definitions in the `project-template.json` and/or `deployment-access-template.json` files.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>##deployment</td>
<td>Optional. Either --deployment or --project can be specified. If --deployment is specified, only the roles in the <code>deployment-access-template.json</code> file are listed.</td>
</tr>
<tr>
<td>##project</td>
<td>Optional. Either --deployment or --project can be specified. If --project is specified, only the roles in the <code>project-template.json</code> file are listed.</td>
</tr>
</tbody>
</table>

**Output**

The output is similar to the following example.

<table>
<thead>
<tr>
<th>Scope</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deployment</td>
<td>DeploymentAdmin</td>
</tr>
<tr>
<td>Deployment</td>
<td>DeploymentOwner</td>
</tr>
<tr>
<td>Deployment</td>
<td>Player</td>
</tr>
<tr>
<td>Deployment</td>
<td>PlayerLoginRole</td>
</tr>
<tr>
<td>Project</td>
<td>ProjectAdmin</td>
</tr>
<tr>
<td>Project</td>
<td>ProjectOwner</td>
</tr>
<tr>
<td>Project</td>
<td>PlayerAccessTokenExchangeExecution</td>
</tr>
<tr>
<td>Project</td>
<td>ProjectResourceHandlerExecution</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Indicates whether the role is defined in the <code>deployment-access-template.json</code> or <code>project-template.json</code> file.</td>
</tr>
<tr>
<td>Name</td>
<td>Shows the resource definition name. This is the &quot;logical&quot; resource name, not the &quot;physical&quot; resource name which identifies an actual instance of the role. To see the physical resource</td>
</tr>
</tbody>
</table>
Permission Metadata Management

The permission metadata management commands manage CloudCanvas Permissions metadata on resource definitions in the resource-group-template.json files. After you use these commands to make changes, you must update the project or deployment access stacks for the changes to take effect. For information about the permissions to perform this action, see Controlling Access to Resources.

lmbr_aws permission add

Adds Cloud Canvas Permissions metadata to an resource definition in a resource-group-template.json file.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>##resource#group &lt;resource-group-name&gt;</td>
<td>Required. The name of a resource group. The metadata will be added to a resource definition in that resource group's resource-group-template.json file.</td>
</tr>
<tr>
<td>##resource &lt;resource-name&gt;</td>
<td>Required. The name of the resource definition in the resource-group-template.json file.</td>
</tr>
<tr>
<td>##role &lt;abstract-role-name&gt;</td>
<td>Required. Identifies the role that is granted the permission.</td>
</tr>
<tr>
<td>##action &lt;action&gt; [&lt;action&gt; ...]</td>
<td>Required. The action that is allowed. You can specify more than one action.</td>
</tr>
<tr>
<td>##suffix &lt;suffix&gt; [&lt;suffix&gt; ...]</td>
<td>Optional. A string appended to the resource ARN. You can specify more than one suffix.</td>
</tr>
</tbody>
</table>

lmbr_aws permission remove

Removes Cloud Canvas Permissions metadata from a resource definition in a resource-group-template.json file.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>##resource#group &lt;resource-group-name&gt;</td>
<td>Required. The name of a resource group. The metadata is removed from a resource definition in the specified resource group's resource-group-template.json file.</td>
</tr>
<tr>
<td>##resource &lt;resource-name&gt;</td>
<td>Required. The name of the resource definition in the resource-group-template.json file.</td>
</tr>
<tr>
<td>##role &lt;abstract-role-name&gt;</td>
<td>Required. Identifies the roles from which permissions are removed.</td>
</tr>
<tr>
<td>##action &lt;action&gt;</td>
<td>Optional. The action that is removed. You can specify more than one action. If not specified, all permissions for the role are removed.</td>
</tr>
<tr>
<td>##suffix &lt;suffix&gt;</td>
<td>Optional. A string appended to the resource ARN, which is removed. You can specify more than one suffix.</td>
</tr>
</tbody>
</table>
Imbr/aws permission list

Removes Cloud Canvas Permissions metadata from an resource definition in a resource-group-template.json file.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>###resource#group &lt;resource-name&gt;</td>
<td>Optional. The name of the resource definition in the resource-group-template.json file. The default lists metadata from all resource definitions.</td>
</tr>
<tr>
<td>###role &lt;abstract-role-name&gt;</td>
<td>Optional. Lists metadata for the specified abstract role. The default lists metadata for all abstract roles.</td>
</tr>
</tbody>
</table>

Output

The output is similar to the following example.

<table>
<thead>
<tr>
<th>Resource Group</th>
<th>Resource</th>
<th>Resource Type</th>
<th>Roles</th>
<th>Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>DynamicContent</td>
<td>ContentBucket</td>
<td>AWS::S3::Bucket</td>
<td>ServiceLambda</td>
<td>s3:GetObject</td>
</tr>
<tr>
<td>DynamicContent</td>
<td>ContentBucket</td>
<td>AWS::S3::Bucket</td>
<td>ContentRequest</td>
<td>s3:*</td>
</tr>
<tr>
<td>DynamicContent</td>
<td>ContentRequest</td>
<td>AWS::Lambda::Function</td>
<td>Player</td>
<td></td>
</tr>
<tr>
<td>DynamicContent</td>
<td>ServiceLambda</td>
<td>AWS::Lambda::Function</td>
<td>ServiceApi</td>
<td></td>
</tr>
<tr>
<td>DynamicContent</td>
<td>StagingSettingsTable</td>
<td>AWS::DynamoDB::Table</td>
<td>ServiceLambda</td>
<td>dynamodb:GetItem, dynamodb:Scan, dynamodb:UpdateItem</td>
</tr>
<tr>
<td>DynamicContent</td>
<td>StagingSettingsTable</td>
<td>AWS::DynamoDB::Table</td>
<td>ContentRequest</td>
<td>dynamodb:GetItem</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource Group</td>
<td>Shows the resource group where the permission metadata was found.</td>
</tr>
<tr>
<td>Resource</td>
<td>Shows the name of the resource definition with the metadata.</td>
</tr>
<tr>
<td>Resource Type</td>
<td>Shows the type of the resource definition with the metadata.</td>
</tr>
<tr>
<td>Roles</td>
<td>Shows the abstract roles specified by the permission metadata.</td>
</tr>
<tr>
<td>Actions</td>
<td>Shows the actions specified by the permission metadata.</td>
</tr>
<tr>
<td>ARN Suffixes</td>
<td>Shows the suffix added to the resource ARN, as specified by the permission metadata.</td>
</tr>
</tbody>
</table>

Tip

To see all the resources players have access to through the game client, use the command:
Role Mapping Metadata Management

Role mapping metadata management commands manage CloudCanvas RoleMappings metadata on AWS::IAM::Role resource definitions in the project-template.json and deployment-access-template.json files. After you use these commands to make changes, you must update the project or deployment access stacks for the changes to take effect. For information about the permissions to perform this action, see Controlling Access to Resources (p. 2370).

**lmbr_aws role-mapping add**

Adds Cloud Canvas RoleMappings metadata to an AWS IAM role definition in the project-template.json or deployment-access-template.json file.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>##role &lt;role-name&gt;</td>
<td>Required. The name of the role resource definition.</td>
</tr>
</tbody>
</table>
| ##pattern <abstract-role-pattern> | Identifies the abstract roles mapped to the role. Has the form <resource-group-name>.<abstract-role-name>, where <resource-group-name> can be *.
| ##allow       | Either --allow or --deny must be specified. Indicates that the permissions requested for the abstract role are allowed. |
| ##deny        | Either --allow or --deny must be specified. Indicates that the permissions requested for the abstract role are denied. |
| ##project     | Optional. Indicates that the role definition is in the project-template.json file. The default is for the role definition to be in the deployment-access-template.json file. |

**lmbr_aws role-mapping remove**

Removes an AWS IAM role resource definition from the project-template.json file or deployment-access-template.json file.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>##role &lt;role-name&gt;</td>
<td>Required. The name of the role resource definition.</td>
</tr>
</tbody>
</table>
| ##pattern <abstract-role-pattern> | Identifies the abstract roles mapped to the role. Has the form <resource-group-name>.<abstract-role-name>, where <resource-group-name> can be *.
| ##project     | Optional. Indicates that the role definition is in the project-template.json file. The default is for the role definition to be in the deployment-access-template.json file. |

**lmbr_aws role-mapping list**

Lists the AWS IAM role definitions in the project-template.json and/or deployment-access-template.json files.
## Administering Cloud Canvas

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>##role &lt;role-name&gt;</code></td>
<td>Required. The role definition with the metadata to list. The default is to list metadata from all role definitions.</td>
</tr>
<tr>
<td><code>##pattern &lt;abstract-role-pattern&gt;</code></td>
<td>The abstract role pattern specified by the metadata listed. The default is to list metadata with any abstract role pattern.</td>
</tr>
<tr>
<td><code>##deployment</code></td>
<td>Optional. Either <code>--deployment</code> or <code>--project</code> can be specified. Lists metadata from role definitions in the <code>deployment-access-template.json</code> file. The default is to list metadata from role definitions in the <code>project-template.json</code> file and <code>deployment-access-template.json</code> files.</td>
</tr>
<tr>
<td><code>##project</code></td>
<td>Optional. Either <code>--deployment</code> or <code>--project</code> can be specified. Lists metadata from role definitions in the <code>project-template.json</code> file. The default is to list metadata from role definitions in the <code>project-template.json</code> file and <code>deployment-access-template.json</code> files.</td>
</tr>
</tbody>
</table>

**Output**

The output is similar to the following example.

<table>
<thead>
<tr>
<th>Scope</th>
<th>Actual Role</th>
<th>Abstract Role</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deployment</td>
<td>DeploymentAdmin</td>
<td>*.DeploymentAdmin</td>
<td>Allow</td>
</tr>
<tr>
<td>Deployment</td>
<td>DeploymentOwner</td>
<td>*.DeploymentAdmin</td>
<td>Allow</td>
</tr>
<tr>
<td>Deployment</td>
<td>Player</td>
<td>*.Player</td>
<td>Allow</td>
</tr>
<tr>
<td>Project</td>
<td>ProjectAdmin</td>
<td>*.ProjectAdmin</td>
<td>Allow</td>
</tr>
<tr>
<td>Project</td>
<td>ProjectOwner</td>
<td>*.ProjectOwner</td>
<td>Allow</td>
</tr>
</tbody>
</table>

**Column Description**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Shows whether the role mapping came from the <code>project-template.json</code> or <code>deployment-access-template.json</code> files.</td>
</tr>
<tr>
<td>Actual Role</td>
<td>Shows the name of the role resource definition with the mapping metadata.</td>
</tr>
<tr>
<td>Abstract Role</td>
<td>Shows the abstract roles (as specified on permission metadata) that map to the role.</td>
</tr>
<tr>
<td>Effect</td>
<td>Shows whether the permissions requested for the abstract role are allowed or denied.</td>
</tr>
</tbody>
</table>

### Improve Security with a Custom Domain Name

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. 
[Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

To improve security when connecting to the Cloud Canvas APIs, you can enforce a minimum Transport Layer Security (TLS) version and cipher suites. This can be achieved by creating a custom domain name through Amazon API Gateway and establishing TLS handshakes to Cloud Canvas APIs via service URLs that are generated with this custom domain.
Create a Custom Domain Name

For a video tutorial of these steps, see How do I define a custom domain name for my Amazon API Gateway API?

To create a custom domain name in API Gateway

1. Register an internet domain name.

You can register an internet domain using Amazon Route 53 or using a third-party domain registrar of your choice. An API's custom domain name can be the name of a subdomain or the root domain of a registered internet domain.

2. Request or import an SSL/TLS certificate.

Request an SSL/TLS certificate from AWS Certificate Manager (ACM), or import an SSL/TLS certificate into ACM. For more information, see Get Certificates Ready in AWS Certificate Manager.

3. Use the API Gateway console to create an edge-optimized custom domain name.

Select Edge-optimized for the endpoint type, and choose the appropriate TLS version. Then choose the ACM certificate you just requested. For more information, see How to Create an Edge-Optimized Custom Domain Name.

4. Create or update your DNS provider’s resource record.

After creating a custom domain name, you can check its details by choosing the domain name in the API Gateway console. Take note of the API Gateway domain name field, which is the default API endpoint. It has a format of name.cloudfront.net. Then create or update your DNS provider’s resource record to map your custom domain name to the default API endpoint. Without such a mapping, API requests bound for the custom domain name cannot reach API Gateway.

Create New Cloud Canvas Stacks Using the Custom Domain Name

Use the following steps to create new project and deployment stacks using your custom domain name.

To create new project and deployment stacks

1. To use the custom domain name for all service URLs in your Cloud Canvas project, specify the custom-domain-name argument when you create a new project stack using CLI commands.

The following command is an example.

```
lmbr_aws project create --stack-name SampleProject --region us-east-1 --custom-domain-name example.com
```
When the new project stack is created, you can create multiple deployments using normal CLI commands, without any additional change. All ServiceApi resources created within the project and deployment stacks generate a unique base path under the custom domain name, which is mapped to the actual API stage. Base paths have the format of `{region}.{stage}.{rest_api_id}`. You can find all these mappings in the API Gateway console.

<table>
<thead>
<tr>
<th>API</th>
<th>Stage</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>customdomain-ServiceApi</td>
<td>api</td>
<td>us-east-1-api/quxwH7y12</td>
</tr>
</tbody>
</table>

2. Verify local mappings files.

Service URLs generated from your project and deployment stacks have the format of `https://{custom_domain_name}/{region}.{stage}.{rest-api-id}`, which is also reflected in your local mappings files (`deploymentName.server.awsLogicalMappings.json`, `deploymentName.player.awsLogicalMappings.json`, and `user-settings.json`). To verify the correctness of the local mapping files, look for the URL for your service API. If the feature is enabled successfully, the service API URL should contain the custom domain name.

Clients can then use these custom service URLs to make their requests.

**Update Existing Cloud Canvas Stacks Using the Custom Domain Name**

Updating your old project and deployment stacks to use the custom domain name requires manual inputs and exposes the stacks to risk of rollback failure. New versions of custom resource handlers are created when you update the custom domain name, but they are not be used to process events because custom resources are locked by default to the version of the code that you used to create the resources. For more information, see Versioning of Custom Resources (p. 2303).

If necessary, you can override the locking of a custom resource to the version of the code with which it was created using the following steps.

**To update your existing project and deployment stacks**

1. Update your existing project stack using the `project update` command and the `custom-domain-name` argument.

   ```bash
lmbr_aws project update --custom-domain-name example.com
   ```

2. Set the `CustomResourceVersion` in your project template.

   a. Open the AWS Lambda console and find the custom resource handler for ServiceApi resources, which has a name like `SampleProject-CRH-CoreResourceTypes-Custom_ServiceApi`. Make a note of the new Lambda version number after the update.
b. Edit the definition of ServiceApi resource in `dev\Gems\CloudGemFramework\v1\ResourceManager\resource_manager\templates\project-template.json`. Add the metadata field and specify the custom resource version number.

```
"ServiceApi": {
  "Metadata": {
    "CloudCanvas": {
      "CustomResourceVersion": "2"
    }
  },
  "Properties": {
    ...
  },
  "Type": "Custom::ServiceApi",
  "DependsOn": [
    "CoreResourceTypes"
  ]
}
```

3. Update your project stack again using the same CLI command that you used in step 1, with the custom-domain-name argument specified. The specified version of the Lambda functions processes the resources this time and the custom domain name is used to generate service URLs.

Alternatively, you could have set CustomResourceVersion in the template to $LATEST before the first update to your project stack and only updated the project stack once. This practice is not recommended for environments where failed stack updates cannot be tolerated. Using $LATEST replicates the unsafe behavior in previous versions of Lumberyard where the most recent Lambda code version is used to process custom resource instance events.

4. Update your deployment stacks using the normal CLI commands without any additional change.

5. Update the resource templates defined in each enabled cloud gem. ServiceApi resources might be defined in each of these gems. Check the definition in `resource-template.json` under each gem and specify the same custom resource version number as you did for the project ServiceApi resource. You need to do something similar for any custom resource defined in your project or deployment stacks that uses service URLs directly, such as CrossGemCommunicationInterfaceResolver (defined in `dev\Gems\CloudGemFramework\v1\ResourceManager\resource_manager\config.py`). Find the custom resource handlers in the AWS Lambda console and update the resource definitions with CustomResourceVersion.

6. Update your deployment stacks again after the template updates. To do this, re-process the resources with the specified version of Lambda functions.

You can set CustomResourceVersion to $LATEST in the templates before updating the deployment stacks to avoid updating them twice as well, but this practice is not recommended for environments where failed stack updates cannot be tolerated.

7. Verify local mappings files.

Service URLs generated from your project and deployment stacks have the format of `https://{custom_domain_name}/{region}.{stage}.{rest-api-id}`, which is also be reflected in your local mappings files (`deploymentName.server.awsLogicalMappings.json`, `deploymentName.player.awsLogicalMappings.json`, and `user-settings.json`).

To verify the correctness of the local mapping files, look for the URL for your service API. If the feature is enabled successfully, the service API URL should contain the custom domain name.

Clients can then take advantage of these custom service URLs to make their requests.
Using the Cloud Canvas Command Line

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Cloud Canvas provides the `\dev\lmbr_aws\.cmd` command line tool for working with AWS resources. The tool invokes Python code that is located in the `\dev\Tools\lmbr_aws` directory.

Notes

- Lumberyard 1.9 renamed some `lmbr_aws` commands. For a list of the older commands and their newer equivalents, see Command Reorganization (p. 2412).
- For information on using Dynamic Content Cloud Gem `lmbr_aws` commands to update dynamic content, see Using the Dynamic Content CLI (p. 2169).
- For information on `lmbr_aws` commands for the cloud gem framework, see Using the Cloud Gem Framework Command Line (p. 2339).
- For information on `lmbr_aws` commands that manage roles and permissions, see Using the Cloud Canvas Command Line to Manage Roles and Permissions (p. 2381).

Syntax

```
lmbr_aws {command} {command-arguments}
```

{command} is one of commands in the command summary section that follows. {command-arguments} are the arguments accepted by the command. Arguments common to most commands are listed in the Common Arguments (p. 2391) section. Arguments unique to a command are listed in the detail section for the command.

Configuration

The tool gets its default AWS configuration from the same `~/.aws/credentials` and `~/.aws/config` files as the AWS command line tools (for information, see Configuring the AWS Command Line Interface). The `lmbr_aws` tool does not require that the AWS command line interface be installed.

Environment Variables

As with the AWS command line tools, the default AWS configuration can be overridden by using the following environment variables.

- AWS_ACCESS_KEY_ID The access key for your AWS account.
- AWS_SECRET_ACCESS_KEY The secret key for your AWS account.
- AWS_DEFAULT_REGION The default region to use; for example, `us-east-2`.
- AWS_PROFILE The default credential and configuration profile to use, if any.

Configuration Arguments

The following arguments can be used to override the AWS configuration from all other sources:

- `--assume-role role-name` or `-R role-name` – Specifies the IAM role to assume to perform the requested actions. The credentials in the `~/.aws/credentials` file must be able to assume the specified role.
• --aws-access-key \{access-key\} – The AWS access key that is used.
• --aws-secret-key \{secret-key\} – The AWS secret key that is used.
• --profile \{profile-name\} or -P \{profile-name\} – The AWS command line tool profile that is used.

Common Arguments

Most of the lmbr_aws commands accept the following arguments, in addition to their own individual arguments:

• --aws-directory \{aws\} – Identifies the \{game\}\AWS directory to use. The default is the value of the sys_game_folder property from \{root\}\bootstrap.cfg with AWS appended.
• --game-directory \{directory\} – Location of the game project directory. The default is \{root\}\{game\} where \{game\} is determined by the sys_game_folder setting in the \{root\}\bootstrap.cfg file.
• --help or -h – Display help for the command.
• --no-prompt – Suppresses calls that request input from the command prompt window.
• --region-override \{AWS_region\} – Specify a non-default AWS region to use in your local-project-settings.json file.
• --root-directory \{root\} – Identifies the lumberyard_installation\dev directory. The default is the current working directory.
• --user-directory \{user\} – Location of the user cache directory. The default is \{root\}\Cache \{game\}\AWS where \{game\} is determined by the sys_game_folder setting in the \{root\}\bootstrap.cfg file.
• --verbose – Shows additional output when executing commands.

Commands

Following are the lmbr_aws commands.

**cleanup Command**

The lmbr_aws --cleanup command deletes resources that you no longer need from your account in AWS.

**Warning**

Before you use the cleanup tool, be aware of the following points:

- Do not use the cleanup tool if you have a project stack name that begins with an IAM user name that you do not want to delete. Doing so can result in the deletion of the IAM user, its roles, and its profiles.
- When you delete an AWS resource, you permanently delete any objects that are stored in that resource. For example, if you delete an S3 bucket, all objects inside the bucket are also deleted.

--cleanup

Note that unlike other lmbr_aws commands, the cleanup command begins like a command argument, with two '--'. In the following example, replace \{cleanup-command-parameters\} with any of the valid cleanup arguments shown in the list that follows.

```
lmbr_aws --cleanup \{cleanup-command-parameters\}
```
In addition to the Common Arguments (p. 2391), the cleanup command accepts the following arguments:

- **--aws-access-key** `{aws-access-key}`
  The AWS access key to use.
- **--aws-secret-key** `{aws-secret-key}`
  The AWS secret key to use.
- **--delete-global-resources**
  Optional. If the --region argument is specified, deletes global resources such as IAM roles and Amazon S3 buckets. Ignored if --region is unspecified.
- **--confirm-deletion**
  Optional. Used with the --delete-global-resources command to confirm you understand that AWS resources will be deleted. Can be useful for automation.
- **--prefix** `{prefix [prefix...]}`
  Optional. Deletes stacks and Amazon S3 buckets in AWS that have the specified prefixes.
- **--except** `{exception [exception...]}`
  Optional. Do not delete resources that start with the specified exceptions. Can be useful, for example, when cleaning up old results while a test in progress.
- **--profile** `{profile}`
  Optional. The AWS profile to use. Defaults to the default AWS profile. AWS access and secret key take precedence over profile if set.
- **--region** `{region}`
  Optional. The AWS region to use. Defaults to us-east-1.

For more information on the cleanup tool, see Freeing Up AWS Resources (p. 2361).

**cloud-gem Commands**

The `lmbr_aws cloud-gem` commands create, enable, and disable cloud gems.

**cloud-gem create**

Create a cloud gem. This command is new in Lumberyard 1.11.

In addition to the Common Arguments (p. 2391), the `cloud-gem create` command accepts the following arguments:

- **--directory** `{path}`
  Optional. The directory where the gem is created. The default is `\dev\Gems\{name}\v{N}`, where `{name}` is the name that was specified by the --gem option and `{N}` is the major part of the gem version number as specified by the --version option.
- **--enable**
  Optional. Enable the gem for the current project when the gem is created. By default, the gem is not enabled when it is created.
- **--gem** `{name}`
  Required. The name of the gem to create.
Using the Command Line

• **--initial-content** *{initial-content-type}*

   Optional. Initialize the cloud gem's AWS directory with the contents specified by *{initial-content-type}*.

   Following are possible values for *{initial-content-type}***.

   **Note**
   Before you can use the api content options, do one of the following:
   • In Lumberyard Setup Assistant, choose **Compile the game code**
   • From a command prompt window on the \dev\Tools\LmbrSetup\Win directory, enter the following command:

   ```
   lmbr capabilities enable compilegame
   ```

• **api-lambda**

   Define a resource group with Amazon API Gateway and AWS Lambda function resources that conform to the Cloud Gem Framework's Service API pattern. You can add AWS resources as needed.

• **api-lambda-bucket**

   Define a resource group with API Gateway and Lambda function resources that conform to the Cloud Gem Framework's Service API pattern. Also creates an Amazon S3 bucket resource.

• **api-lambda-dynamodb**

   Define a resource group with API Gateway and Lambda function resources that conform to the Cloud Gem Framework's Service API pattern. Also creates an Amazon DynamoDB table resource.

• **bucket**

   Define a resource group that has an Amazon S3 bucket resource.

• **lambda**

   Define a resource group that has a Lambda function resource.

• **no-resources**

   Define a resource group that has no resources (except AccessControl (p. 2372), which is required). This is the default value.

• **resource-manager-plugin**

   Define a resource manager plugin.

• **--no-cpp-code**

   Optional. Define a gem that contains no C++ code and does not build as a .dll file. The gem can contain resource group definitions and/or resource manager plugins.

• **--version** *{version}*

   Optional. Set the gem version to the number specified by *{version}*. The default is 1.0.0. The version number must be in the format *{number}.{number}.{number}***.

**cloud-gem disable**

Disable a cloud gem that is in the current project. This command is new in Lumberyard 1.11.

In addition to the **Common Arguments (p. 2391)**, the cloud-gem disable command accepts the following arguments:

• **--gem** *{name}***
Required. The name of the gem to disable.

**cloud-gem enable**

Enable a cloud gem that is in the current project. This command is new in Lumberyard 1.11.

In addition to the Common Arguments (p. 2391), the `cloud-gem enable` command accepts the following arguments:

- `--gem {name}`

  Required. The name of the gem to enable.

### deployment Commands

The `lmbr_aws deployment` commands manage Cloud Canvas deployments.

**Note**

In Lumberyard 1.16 and later versions, the `deployment` commands install, modify, or remove gems in series rather than in parallel. This prevents issues that can occur in AWS when multiple resource groups are created, updated, or deleted at the same time. This default behavior can be overridden with the `--parallel` option, as in the following examples:

```shell
lmbr_aws deployment create --deployment deployment_name --parallel
lmbr_aws deployment update --parallel
lmbr_aws deployment delete --deployment deployment_name --parallel
```

**Warning**

Because it greatly increases the risk of errors when you modify your deployment, use of the `--parallel` option is not recommended.

**deployment create**

Create a complete and independent copy of all the resources needed by the Lumberyard project.

In addition to the Common Arguments (p. 2391), the `deployment create` command accepts the following arguments:

- `--deployment {deployment-name}` or `-d {deployment-name}`

  Required. The name of the deployment to create.

- `--confirm-aws-usage` or `-C`

  Optional. Confirms that you know that the `deployment create` command will create AWS resources for which you may be charged and that may perform actions that can affect permissions in your AWS account. Specify this argument to disable the related confirmation prompt.

**deployment default**

Set or show the default user and project deployments.

In addition to the Common Arguments (p. 2391), the `deployment default` command accepts the following arguments:

- `--set {deployment}`
Optional. Sets the default to the provided deployment name.

- **--clear**
  Optional. Clears the defaults.

- **--show**
  Optional. Shows the defaults.

- **--project**
  Optional. Applies --set and --clear to the project default instead of the user default. Ignored for --show.

Only one of the --set, --clear, and --show arguments is allowed.

If --set or --clear is specified, this command updates the `{root}\user\AWS\user-settings.json` file. If --project is provided, the `{root}\{game}\AWS\project-settings.json` file is updated.

deployment delete

Delete a complete and independent copy of all the resources needed by the Lumberyard project.

In addition to the Common Arguments (p. 2391), the deployment delete command accepts the following arguments:

- **--deployment {deployment-name}** or **-d {deployment-name}**
  Required. The name of the deployment to delete.

- **--confirm-resource-deletion**
  Optional. Acknowledges that the command will permanently delete the resources for the specified deployment. If this argument is not specified, a confirmation prompt is issued.

**Note**

AWS CloudFormation cannot delete stacks that define Amazon S3 buckets that contain data. To allow project stacks to be deleted, the project-template.json file specifies a DeletionPolicy of Retain for the configuration bucket. This causes AWS CloudFormation to not delete the bucket when the project stack is deleted. After the project stack has been deleted, the command removes all the objects from the configuration bucket and then deletes the bucket.

deployment list

List all deployments in the local project.

Example output:

<table>
<thead>
<tr>
<th>Name</th>
<th>Status</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>AnotherDeployment</td>
<td>CREATE_PENDING</td>
<td>Resource is defined in the local project template but does not exist in AWS.</td>
</tr>
<tr>
<td>Development</td>
<td>CREATE_COMPLETE</td>
<td></td>
</tr>
<tr>
<td></td>
<td>03/04/16 18:43:11</td>
<td>arn:aws:cloudformation:us-</td>
</tr>
</tbody>
</table>
Using the Command Line

deployment list-resources

List all of the resources associated with the project.

In addition to the Common Arguments (p. 2391), the deployment list-resources command accepts the following arguments:

• --deployment {deployment-name} or -d {deployment-name}
  Optional. The name of the deployment to list resources for. If not specified, lists all the project's resources.

deployment protect

Marks a deployment as protected and issues a warning when a user (for example, a game developer, programmer, or tester) attempts to connected a development game client to live resources. For more information, see Using Protected Deployments (p. 2359).

In addition to the Common Arguments (p. 2391), the deployment protect command accepts the following arguments:

• --set {deployment-name}
  Optional. Specifies that the deployment is protected.

• --clear {deployment-name}
  Optional. Specifies that the deployment is not protected.

• --show
  Optional. Displays a list of the deployments that are currently protected.

  Note
  To display the protected status of deployments, you can also use either the deployment list (p. 2395) or mappings list (p. 2401) command.

deployment release

Sets, shows, or removes the release deployment.

In addition to the Common Arguments (p. 2391), the deployment release command accepts the following arguments:

• --set {deployment-name}
  Required. The name of the deployment to set as the release.

• --clear
  Removes the release designation from the current release deployment.

• --show
Shows the deployment that is currently configured as the release deployment.

**deployment tags**

Manages the tags for a deployment. Deployment tags specify resource group overrides for a deployment.

In addition to the Common Arguments (p. 2391), the `deployment tags` command accepts the following arguments:

- `--add {tag} [{tag} ...]`
  
  Optional. Specifies the tags to add to a deployment. The tags are saved in the `lumberyard_version\dev\project_name\AWS\local-project-settings.json` file.
- `--clear`
  
  Optional. Clears all tags for a deployment.
- `--delete {tag} [{tag} ...]`
  
  Optional. Specifies the tags to delete from a deployment.
- `--deployment {deployment-name} or -d {deployment-name}`
  
  Optional. The name of the deployment.
- `--list`
  
  Optional. Lists all the tags for a deployment.

**deployment update-access**

Sets, shows, or removes the release deployment.

In addition to the Common Arguments (p. 2391), the `deployment update-access` command accepts the following arguments:

- `--confirm-aws-usage or -C`
  
  Optional. Confirms that you know this command creates AWS resources for which you can be charged and that it may perform actions that can affect permissions in your AWS account. Specify this argument to disable the related confirmation prompt.
- `--confirm-resource-deletion`
  
  Optional. If the operation will delete resources permanently, confirms your acknowledgement and approval. If this argument is not specified, you are prompted to confirm completion of the operation. Specify this argument to disable the related confirmation prompt.
- `--confirm-security-change`
  
  Optional. Confirms that you know that this command may make security-related changes. Specify this argument to disable the related confirmation prompt.
- `--deployment {deployment-name} or -d {deployment-name}`
  
  Optional. The name of the deployment whose access stack is updated. If omitted, the default deployment is updated. Use * to update all deployments.

**deployment update, deployment upload, deployment upload-resources**

Updates a deployment. `deployment upload` or `deployment upload-resources` can be used instead of `deployment update`.
In addition to the Common Arguments (p. 2391), the deployment update command accepts the following arguments:

- **--confirm-aws-usage or -C**
  
  Optional. Confirms that you know this command creates AWS resources for which you can be charged and that it may perform actions that can affect permissions in your AWS account. Specify this argument to disable the related confirmation prompt.

- **--confirm-resource-deletion**
  
  Optional. If the operation will delete resources permanently, confirms your acknowledgement and approval. If this argument is not specified, you are prompted to confirm completion of the operation. Specify this argument to disable the related confirmation prompt.

- **--confirm-security-change**
  
  Optional. Confirms that you know that this command may make security-related changes. Specify this argument to disable the related confirmation prompt.

- **--deployment {deployment-name} or -d {deployment-name}**
  
  Optional. The name of the deployment to update. If omitted, the default deployment is updated.

**function Commands**

The lmbr_aws function commands manage folders, CloudWatch logs, and code for Lambda functions.

**function create-folder**

Recreates the default function folder for a Lambda function resource.

In addition to the Common Arguments (p. 2391), the function create-folder command accepts the following arguments:

- **--function {function-name} or -f {function-name}**
  
  Required. The logical name of a Lambda function resource.

- **--resource-group {resource-group-name} or -r {resource-group-name}**
  
  Required. The name of a resource group.

- **--force**
  
  Optional. Skips checks for existence of resource and type of resource. Used when creating folders for functions not yet created.

**function get-log**

Retrieves data from a CloudWatch Logs log file.

In addition to the Common Arguments (p. 2391), the function get-log command accepts the following arguments:

- **--deployment {deployment-name} or -d {deployment-name}**
  
  Optional. The name of a deployment. If this argument is specified, the --resource-group argument must also be specified. If this argument is omitted, then the function must exist in the project stack.

- **--function {function-name} or -f {function-name}**
Required. The logical name of a Lambda function resource.

- **--resource-group** `{resource-group-name}` or `-r` `{resource-group-name}`
  
  Optional. The name of a resource group. If specified, the `--deployment` argument must also be specified.

- **--log-stream-name** `{log-stream-name}` or `-l` `{log-stream-name}`
  
  Optional. The log stream name or partial log stream name. If omitted, the most recent log stream is shown.

**function upload-code**

Updates Lambda functions for a deployment or project.

In addition to the Common Arguments (p. 2391), the `function upload-code` command accepts the following arguments:

- **--deployment** `{deployment-name}` or `-d` `{deployment-name}`
  
  Optional. The name of a deployment to update. If neither this argument nor the `--project` argument is specified, the default deployment is updated. If the `--project` argument is specified, the `--deployment` argument is ignored.

- **--function** `{function-name}`
  
  Optional. The name of the Lambda function to update. If not specified, all Lambda functions in the resource group are updated.

- **--keep**
  
  Optional. Keep the generated `.zip` file instead of deleting it after it is uploaded.

- **--project**
  
  Optional. Updates the project. Overrides the `--deployment` argument.

- **--resource-group** `{resource-group-name}` or `-r` `{resource-group-name}`
  
  Optional. The name of a resource group that has the function to update.

**login-provider Commands**

The `lmbr_aws login-provider` commands add, remove, and update social network login providers in Amazon Cognito identity pool configuration.

**login-provider add**

Add a player login provider to the Amazon Cognito identity pool configuration. Login providers allow your game's players to log in using their social network identity, such as Facebook or using their Amazon identity. For more information, see Controlling Access to Resources (p. 2370).

In addition to the Common Arguments (p. 2391), the `login-provider add` command accepts the following arguments:

- **--provider** `{provider-name}`
  
  Required. The name of the provider. The name must be `amazon`, `google` or `facebook`, or, if you are using a generic OpenID provider, a name that you choose.

- **--app-id** `{application-id}`
Using the Command Line

Required. The application id from your login provider (this is usually different from your client ID).

• --client-id {client-id}

Required. The unique application client ID for the login provider.

• --client-secret {client-secret}

Required. The secret key to use with your login provider.

• --redirect-uri {redirect-uri}

Required. The redirect URI to use with your login provider.

• --provider-uri {provider-uri}

Optional. The URI for a generic open ID connect provider. This is only used for generic OpenID providers.

• --provider-port {provider-port}

Optional. The port your provider listens on for its API. This is only used for generic OpenID providers.

• --provider-path {provider-path}

Optional. The path portion of your provider's URI. This is only used for generic OpenID providers.

This command saves its configuration in a `player-access/auth-settings.json` object in the project's configuration bucket so that the `PlayerAccessTokenExchange` Lambda function can access it.

**Note**
You must run `project upload` after running this command so that the `PlayerAccessIdentityPool` configuration is updated to reflect the change.

**login-provider remove**

Remove a player login provider from the Amazon Cognito identity pool configuration.

In addition to the Common Arguments (p. 2391), the `login-provider remove` command accepts the following argument:

• --provider {provider-name}

Required. The name of the provider.

The `login-provider remove` command saves the configuration in a `/player-access/auth-settings.json` object in the project's configuration bucket so that the `PlayerAccessTokenExchange` Lambda function can access it.

**Note**
You must run `lmbr_aws project upload` after running this command so that the `PlayerAccessIdentityPool` configuration is updated to reflect the change.

**login-provider update**

Update a player login provider in the Amazon Cognito identity pool configuration. Login providers allow your game's players to log in using their social network identity, such as Facebook, or using their Amazon identity. For more information, see Controlling Access to Resources (p. 2370).

In addition to the Common Arguments (p. 2391), the `login-provider update` command accepts the following arguments:

• --provider {provider-name}
Required. The name of the updated provider. The name must be `amazon`, `google` or `facebook`, or, if you are using a generic OpenID provider, the name that you chose when the provider was added.

- `--app-id {application-id}`

Optional. The application ID from your login provider (this is usually different from your client ID).

- `--client-id {client-id}`

Optional. The unique application client ID for the login provider.

- `--client-secret {client-secret}`

Optional. The secret key to use with your login provider.

- `--redirect-uri {redirect-uri}`

Optional. The redirect URI to use with your login provider.

- `--provider-uri {provider-uri}`

Optional. The URI for a generic open id connect provider. This argument is used only for generic OpenID providers.

- `--provider-port {provider-port}`

Optional. The port the provider listens on for the provider's API. This argument is used only for generic OpenID providers.

- `--provider-path {provider-path}`

Optional. The path portion of the provider's URI. This argument is used only for generic OpenID providers.

The `login-provider update` command saves its configuration in a `/player-access/auth-settings.json` object in the project’s configuration bucket so that the `PlayerAccessTokenExchange` Lambda function can access it.

**Note**

You must run `lmbr_aws project upload` after running this command so that the `PlayerAccessIdentityPool (p. 2239)` configuration is updated to reflect the change.

**mappings Commands**

The `lmbr_aws mappings` commands manage the mappings of logical to physical resource names in a Cloud Canvas deployment.

**mappings list**

Show the logical to physical resource name mappings.

**Example output:**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Id</th>
</tr>
</thead>
<tbody>
<tr>
<td>HelloWorld.SayHello</td>
<td>AWS::Lambda::Function</td>
<td>foo-hw-Development-</td>
</tr>
<tr>
<td>ZDLXUB7FK94-HelloWo-SayHello-1FADMNE5MCO</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PlayerAccessIdentityPool</td>
<td>Custom::CognitoIdentityPool</td>

</table>
**mappings update**

Update the friendly name to physical resource ID mappings for the current default deployment or the release deployment.

In addition to the Common Arguments (p. 2391), the `mappings update` command accepts the following arguments:

- **--release**
  
  Optional. Causes the release mappings to be updated. By default, only the mappings used when launching the game from inside the editor are updated.

  The command looks in the `resource-template.json` file for `Metadata.CloudCanvas.PlayerAccess` properties on resource definitions. It then queries AWS CloudFormation for the physical names of those resources in the current default deployment. If the `--release` argument is specified, the release deployment is queried.

- **--deployment** `{deployment-name}` or `-d` `{deployment-name}`

  Optional. Exports client and server mapping files for the specified deployment to the `\dev\project_name\Config` directory in the format `{deployment_name}.player.awsLogicalMappings.json` and `{deployment_name}.server.awsLogicalMappings.json`. The `{deployment-name}` argument is required and is case-sensitive.

  When you run a game launcher such as the one at `\Bin64\NNN\CloudGemSamplesLauncher.exe`, you can use the `-cc_override_resource_map `{mappings-name}` argument to choose the mapping. For more information, see Selecting a Deployment with a PC Launcher (p. 2358).

**parameter Commands**

The `lmbr_aws parameter` commands manage parameters for Cloud Canvas deployments and resource groups.

**parameter clear**

Clears the specified parameter configuration for your project. The project must be initialized (a project stack must have been created) before you can clear parameters.

In addition to the Common Arguments (p. 2391), the `parameter clear` command accepts the following arguments:

- **--deployment** `{deployment-name}` or `-d` `{deployment-name}`

  Optional. Clears the parameter value for the specified deployment. `{deployment-name}` can be *, in which case the parameter value used for all deployments that do not override the value is cleared. If omitted, the parameter value is cleared for all deployments, including *.

- **--resource-group** `{resource-group-name}` or `-r` `{resource-group-name}`

  Optional. Clears the parameter value for the specified resource-group. `{resource-group-name}` can be *, in which case the parameter value used for all resource groups that do not override the value is cleared. If omitted, the parameter value is cleared for all resource groups, including *.

- **--parameter** `{parameter-name}` or `-p` `{parameter-name}`

  Required. The parameter to clear.
parameter list

Lists the parameters currently configured for your project. The project must be initialized (a project stack must have been created) before you can list parameters.

In addition to the Common Arguments (p. 2391), the parameter list command accepts the following arguments:

- `--deployment {deployment-name}` or `-d {deployment-name}`
  Required. Limits the list to the specified deployment. `{deployment-name}` can be *, in which case parameters that apply to all deployments are listed.
- `--resource-group {resource-group-name}` or `-r {resource-group-name}`
  Required. Limits the list to the specified resource group. `{resource-group-name}` can be *, in which case parameters that apply to all resource groups are listed.
- `--parameter {parameter-name}` or `-p {parameter-name}`
  Optional. Limits the list to the specified parameter.

parameter set

Sets parameter configuration for your project. The project must be initialized (a project stack must have been created) before you can set parameters.

In addition to the Common Arguments (p. 2391), the parameter set command accepts the following arguments:

- `--deployment {deployment-name}` or `-d {deployment-name}`
  Required. Sets the parameter value for the specified deployment. `{deployment-name}` can be *, in which case the parameter value is used for all deployments that do not override the value.
- `--resource-group {resource-group-name}` or `-r {resource-group-name}`
  Required. Sets the parameter value for the specified resource group. `{resource-group-name}` can be *, in which case the parameter value is used for all resource groups that do not override the value.
- `--parameter {parameter-name}` or `-p {parameter-name}`
  Required. Specifies the parameter whose value will be set.
- `--value {parameter-value}` or `-v {parameter-value}`
  Required. Specifies the value to set.

profile Commands

The lmb_aws profile commands manage the AWS profiles that you use for Cloud Canvas.

profile add

Add an AWS profile to the AWS command line tool configuration.

In addition to the Common Arguments (p. 2391), the profile add command accepts the following arguments:

- `--aws-access-key {accesskey}`
  Required. The AWS access key associated with the added profile.
• --aws-secret-key \(\text{secretkey}\)
  Required. The AWS secret key associated with the added profile.
• --profile \(\text{profile-name}\) or -P \(\text{profile-name}\)
  Required. The name of the AWS profile to add.
• --make-default
  Optional. Make the new profile the default profile.

profile default

Set, clear, or show the default AWS profile. The profile default command modifies the DefaultProfile section of the user-settings.json (p. 2237) file. As of Lumberyard 1.15, the Cloud Canvas cleanup tool (p. 2362) uses this setting to determine the AWS profile to use.

In addition to the Common Arguments (p. 2391), the profile default command accepts the following arguments:
• --set \(\text{profile-name}\)
  Optional. Set the default profile for the current deployment to the provided AWS profile name.
• --clear
  Optional. Clear the default profile.
• --show
  Optional. Show the default profile.

profile list

List the AWS profiles that have been configured.

profile remove

Remove an AWS profile from the AWS command line configuration.

In addition to the Common Arguments (p. 2391), the profile remove command accepts the following argument:
• --profile \(\text{profile-name}\) or -P \(\text{profile-name}\)
  Required. The name of the AWS profile to remove.

profile rename

Rename an AWS profile in the AWS command line tool configuration.

In addition to the Common Arguments (p. 2391), the profile rename command accepts the following arguments:
• --old \(\text{old-profile-name}\)
  Required. The name of the AWS profile to change.
• --new \(\text{new-profile-name}\)
  Required. The new name of the AWS profile.
profile update

Update an AWS profile.

In addition to the Common Arguments (p. 2391), the profile update command accepts the following arguments:

• `--aws-access-key {accesskey}`
  Optional. The AWS access key associated with the updated profile. The default is to not change the AWS access key associated with the profile.

• `--aws-secret-key {secretkey}`
  Optional. The AWS secret key associated with the updated profile. The default is to not change the AWS secret key associated with the profile.

• `--profile {profilename}` or `-P {profile-name}`
  Required. The name of the AWS profile to update.

Note

To make an existing profile the default profile, use the profile default --set {profile-name} (p. 2404) command.

project Commands

The lmbr_aws project commands manage Cloud Canvas projects in Lumberyard.

project create

Initialize Cloud Canvas resource management for a Lumberyard project. This includes creating a set of default Resource Definitions (p. 2236) in the dev\game\AWS directory and a AWS CloudFormation stack that contains the resources that the Cloud Canvas resource manager uses to manage your game resources.

In addition to the Common Arguments (p. 2391), the project create command accepts the following arguments:

• `--stack-name {stack-name}`
  Optional. The name used for the project's AWS CloudFormation stack. The default is the name of the {game} directory.

• `--confirm-aws-usage` or `-C`  
  Optional. Confirms that you know this command will create AWS resources for which you may be charged and that it may perform actions that can affect permissions in your AWS account. Specify this argument to disable the related confirmation prompt.

• `--files-only`
  Optional. Writes the default configuration data to the {game}\AWS directory and exits. The directory must be empty or must not exist.

• `--region {region}`
  Required. The AWS region in which the project stack will be created.

Note

The region argument can be used only with the project create and resource-importer list-importable-resources commands. To manually override the AWS region in other lmbr_aws commands, use the --region-override argument.
• `--admin-roles`
  
  Optional. Creates the ProjectOwner and ProjectAdmin roles. The default is to create these roles unless `--no-admin-roles` argument is used. For more information about these roles, see Cloud Canvas Built-In Roles and Policies (p. 2373).

• `--no-admin-roles`
  
  Optional. Turns off the creation of the ProjectOwner and ProjectAdmin roles. This is recommended unless you have a need for these roles.

How `project create` Works

The `project create` command performs the following tasks:

1. Creates the project's AWS CloudFormation stack using a bootstrap template that defines only the Configuration Bucket (p. 2248) resource.
2. Uploads the `project-template.json` (p. 2238) file and the zipped up contents of the `project-code` subdirectory (p. 2240) to the Configuration Bucket (p. 2248).
3. Uses the uploaded `project-template.json` file to perform an AWS CloudFormation stack update operation. The `project-code.zip` file is used to create the Lambda function resources defined by the `project-template.json` file.

Note

• If the `{root}\{game}\AWS` directory is empty or does not exist, `project create` creates the directory if necessary and copies the contents of the `dev\Tools\lmbr_aws\AWSResourceManager\default-project-content` directory to that directory.
• `project create` fails if a stack with the specified name already exists in the configured AWS account and region. In this case you can use the `--stack` argument to specify a different name for the project stack.
• `project create` fails if the `dev\{game\}AWS\local-project-settings.json` file has a non-empty ProjectStackId property. Initially, the ProjectStackId property is not present in the `local-project-settings.json` file. After the project stack is created in step 1, the ProjectStackId property is written to the file and is the project's AWS CloudFormation stack ID.
• If the stack update process in step 2 fails on the first attempt, you can retry by using the `project upload` command.

`project create-extension-template`

Creates an extension template for adding project, deployment, or deployment access resources that complement the existing `project-template.json`, `deployment-template.json`, or `deployment-access-template.json` files.

In addition to the Common Arguments (p. 2391), the `project create-extension-template` command accepts the following arguments:

• `--project`
  
  Optional. Creates a `project-template-extensions.json` file in the project directory.
• `--deployment`
  
  Optional. Creates a `deployment-template-extensions.json` file in the project directory.
• `--deployment-access`
Optional. Creates a deployment-access-template-extensions.json file in the project directory.

**project delete**

Delete the AWS CloudFormation stack that contains your project's resources. You must delete all of the project's deployments before deleting the project stack. After deleting the project stack, you must create a new project stack before you can use AWS CloudFormation resource manager for your project.

In addition to the Common Arguments (p. 2391), the `project delete` command accepts the following argument:

- `--confirm-resource-deletion`

Optional. Confirms your acknowledgement and approval that the operation will delete resources permanently. If this argument is not specified, you will be prompted to confirm completion of the operation. Specify this argument to disable the related confirmation prompt.

AWS CloudFormation cannot delete stacks that define Amazon S3 buckets that contain data. To allow project stacks to be deleted, the `project-template.json` file specifies a `DeletionPolicy` of `Retain` for the configuration bucket. This causes AWS CloudFormation to not delete the bucket when the project stack is deleted. After the project stack has been deleted, the command removes all the objects from the configuration bucket and then deletes the bucket.

**Note**

Before you use the `project delete` command, ensure that the default AWS credentials specified by the `~/.aws/credentials` file on the local file system are the same as the credentials that are specified in the Cloud Canvas Credentials Manager. If the credentials are not the same, the project might not delete properly. You can use the Cloud Canvas Cleanup Tool (p. 2363) to remove orphaned resources after a failed project stack deletion.

**project list-resources**

List all of the resources associated with the project.

**project update, project upload**

Update the project's AWS CloudFormation stack. `project upload` can be used instead of `project update`.

In addition to the Common Arguments (p. 2391), the `project update` command accepts the following arguments:

- `--confirm-aws-usage` or `-C`

Optional. Confirms that you know this command will create AWS resources for which you may be charged and that it may perform actions that can affect permission in your AWS account. Specify this argument to disable the related confirmation prompt.

- `--confirm-resource-deletion`

Optional. If the operation will delete resources permanently, confirms your acknowledgement and approval. If this argument is not specified, you are prompted to confirm completion of the operation. Specify this argument to disable the related confirmation prompt.

**How project update works**

The project update command performs the following tasks:
1. Uploads the `project-template.json` file and the zipped up contents of the `project-code subdirectory` to the Configuration Bucket.

2. Uses the uploaded `project-template.json` file to perform an AWS CloudFormation stack update operation. The `project-code.zip` file is used to create the Lambda function resources defined by the `project-template.json` file.

**Note**

The `project update` command fails if the `dev\{game}\AWS\local-project-settings.json` file does not exist or does not have a valid `ProjectStackId` property.

### project update-framework-version

Updates the Cloud Gem framework version for a project.

In addition to the Common Arguments (p. 2391), the `project update-code` command accepts the following arguments:

- `--confirm-aws-usage` or `-C` (Optional. Confirms that you know that the deployment create command will create AWS resources for which you may be charged and that may perform actions that can affect permissions in your AWS account. Specify this argument to disable the related confirmation prompt.)
- `--confirm-resource-deletion` (Optional. Acknowledges that the command will permanently delete the resources belonging to the specified deployment. If this argument is not specified, a confirmation prompt is issued.)
- `--confirm-security-change` (Optional. Confirms that you know that this command may make security-related changes. Specify this argument to disable the related confirmation prompt.)

For more information, see Applying Framework Updates to a Project (p. 2343).

### resource-group Commands

The `lmbr_aws resource-group` commands manage the resource groups in your Cloud Canvas project.

#### resource-group add

**Note**

The functionality of this command has changed in Lumberyard 1.11. This command is deprecated in favor of the `resource-group enable (p. 2409)` and `cloud-gem create (p. 2392)` commands. As of Lumberyard 1.11, project local resource groups are deprecated in favor of cloud gems. Because cloud gems are reusable, we recommend that you use them instead of local resource groups.

As of Lumberyard 1.11, the `resource-group add` command has the following behavior:

- If the resource group specified in the `--resource-group` parameter exists but is disabled, the resource group is enabled. This is the equivalent of the `lmbr_aws resource-group enable` command.
- If the resource group does not exist, the `lmbr_aws cloud-gem create` command is called to create a new resource group in a cloud gem. The name of the cloud gem is specified by the `--resource-group {resource-group-name}` parameter.
- By default, the new gem has no resources. This corresponds to the `cloud-gem create` command's `--initial-content no-resources` option.
- If the `--include-example-resources` option is specified, the equivalent of the `cloud-gem create` command's `--initial-content api-lambda-dynamodb` option is called.
In addition to the Common Arguments (p. 2391), the `resource-group add` command accepts the following arguments:

- `--resource-group {resource-group-name} or -r {resource-group-name}`
  Required. The name of an existing resource group to enable. If no resource group with the specified name exists, specifies the name of the cloud gem and resource group to be created.
- `--gem {gem-path}`
  Optional. Looks for the resource group definition at `Gems\group\AWS` or `gem-path\AWS`.
- `--include-example-resources`
  Optional. The equivalent of the `--initial-content api-lambda-dynamodb` option of the `cloud-gem create (p. 2392)` command.

**resource-group disable**

Disable a resource group for debugging. This command is new in Lumberyard 1.11.

In addition to the Common Arguments (p. 2391), the `resource-group disable` command accepts the following argument:

- `--resource-group {resource-group-name} or -r {resource-group-name}`
  Required. The name of the resource group to disable.

By default, when a cloud gem is enabled for a project, all its resource groups are enabled. Disabling a resource group has the following consequences:

- When a deployment is created, the resources that the disabled resource group defines are not created in AWS.
- When a deployment is updated, the resources that were defined by the disabled resource group are removed.
- The resource group is added to a list of disabled resource groups in the project's `local-project-settings.json` file.

**Note**

Prior to Lumberyard 1.11, the `local-project-settings.json` file kept a list of enabled resource groups. By default, all of a cloud gem's resource groups are enabled when the cloud gem is enabled. Therefore, listing only the disabled resource groups makes it easier to identify them.

Usually it is better to disable the cloud gem that provides a resource group than to disable the resource group itself. Therefore, we recommend that you use the `resource-group disable` command only for debugging or testing. To reenable a resource group, you can use the `lmbr_aws resource-group enable` command.

**resource-group enable**

Enable a resource group. This command is new in Lumberyard 1.11.

In addition to the Common Arguments (p. 2391), the `resource-group disable` command accepts the following argument:

- `--resource-group {resource-group-name} or -r {resource-group-name}`
  Required. The name of the resource group to enable.
resource-group list

List all the resource groups found in the local deployment template and in the selected deployment in AWS.

In addition to the Common Arguments (p. 2391), the resource-group list command accepts the following argument:

• **--deployment** `{deployment-name}` or **-d** `{deployment-name}`
  
  Optional. The name of the deployment to list resource groups for. If not given, the default deployment is used.

Example output:

<table>
<thead>
<tr>
<th>Name</th>
<th>Status</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>AnotherResourceGroup</td>
<td>CREATE_PENDING</td>
<td>Resource is defined in the local deployment template but does not exist in AWS.</td>
</tr>
<tr>
<td>HelloWorld</td>
<td>CREATE_COMPLETE</td>
<td></td>
</tr>
</tbody>
</table>

resource-group list-resources

List all of the resources associated with the project.

In addition to the Common Arguments (p. 2391), the resource-group list-resources command accepts the following arguments:

• **--deployment** `{deployment-name}` or **-d** `{deployment-name}`
  
  Optional. The name of the deployment to list resources for. If not specified, lists all the project's resources.

• **--resource-group** `{resource-group-name}` or **-r** `{resource-group-name}`
  
  Optional. The name of the resource group to list resources for. If specified, deployment must also be specified. If not specified, all deployment or project resources are listed.

resource-group remove

**Note**

The functionality of this command has changed in Lumberyard 1.11. This command is deprecated in favor of the cloud-gem disable (p. 2393) and resource-group disable (p. 2409) commands.

As of Lumberyard 1.11, the resource-group remove command has the following behavior:

• If the resource group specified in the **--resource-group** parameter is provided by a cloud gem, disables the cloud gem. This is the equivalent of the lmbr_aws cloud-gem disable command.

• If the resource group is not provided by a cloud gem, disables the resource group. This is the equivalent of the lmbr_aws resource-group disable command.
In addition to the Common Arguments (p. 2391), the resource-group remove command accepts the following argument:

- `--resource-group {resource-group-name} or -r {resource-group-name}`

  Required. The name of the resource group or cloud gem to be disabled.

**resource-group upload-resources (upload, update)**

Update a resource group's AWS CloudFormation stack in a deployment. resource-group upload or resource-group update can be used instead of resource-group upload-resources.

In addition to the Common Arguments (p. 2391), the resource-group upload command accepts the following arguments:

- `--confirm-aws-usage or -C`

  Optional. Confirms that you know this command will create AWS resources for which you may be charged and that it may perform actions that can affect permissions in your AWS account. Specify this argument to disable the related confirmation prompt.

- `--confirm-resource-deletion`

  Optional. If the operation will delete resources permanently, confirms your acknowledgement and approval. Specify this argument to disable the related confirmation prompt.

- `--confirm-security-change`

  Optional. Confirms that you know that this command may make security-related changes. Specify this argument to disable the related confirmation prompt.

- `--deployment {deployment-name} or -d {deployment-name}`

  Optional. The name of the deployment to update. If not specified, the default deployment is updated.

- `--resource-group {resource-group-name}, or -r {resource-group-name}`

  Required. The name of the resource group to update. If not specified, all resource groups in the deployment are updated.

**resource-importer Commands**

The lmbr_aws resource-importer commands list and import AWS resource definitions to your Cloud Canvas project.

**resource-importer import-resource**

Import a resource to a resource group.

In addition to the Common Arguments (p. 2391), the resource-importer import-resource command accepts the following arguments:

- `--type {dynamodb|s3|lambda|sns|sqs}`

  Optional. The type of the AWS resource to import. Choose from dynamodb, s3, lambda, sns or sqs.

- `--arn ARN`

  Required. The ARN of the AWS resource to import.

- `--resource-name {resource-name}`

  Required. The name of the resource to import.
• **--resource-group** `{resource-group-name}` or `-r {resource-group-name}`
  Required. The name of the resource group to import.
• **--download**
  Optional. If specified, downloads the contents of the Amazon S3 bucket.

`resource-importer list-importable-resources`

List all supported resources currently existing on AWS.

In addition to the Common Arguments (p. 2391), the `resource-importer list-importable-resources` command accepts the following arguments:

• **--type** `{dynamodb|s3|lambda|sns|sqs}`
  Required. The type of the AWS resource to list. Choose from dynamodb, s3, lambda, sns or sqs.
• **--region** `{region}`
  Optional. The AWS region of the resources. The default value is the region of the project stack, if it exists.

  **Note**
  The region argument can be used only with the `resource-importer list-importable-resources` and `project create` commands. To manually override the AWS region in other `lmbr_aws` commands, use the --region-override argument.

### Command Reorganization

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

As of Lumberyard 1.9, the commands made available by the `lmbr_aws` command line tool have been reorganized. The previous commands are still functional but are subject to removal in a future release.

The following table shows how the previous commands map to the new commands. In a few cases single commands have been split into two or more commands for clarity and ease of use. These are commented accordingly. For information about the commands, see Using the Cloud Canvas Command Line (p. 2390).

<table>
<thead>
<tr>
<th>Previous Command</th>
<th>New Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>add#login#provider</td>
<td>login#provider add</td>
</tr>
<tr>
<td>add#profile</td>
<td>profile add</td>
</tr>
<tr>
<td>add#resource#group</td>
<td>resource#group add</td>
</tr>
<tr>
<td>clear#parameter</td>
<td>parameter clear</td>
</tr>
<tr>
<td>create#deployment</td>

<tr>
<td></td>
<td>deployment list#resources</td>
</tr>
<tr>
<td></td>
<td>resource#group list#resources</td>
</tr>
<tr>
<td>The list#resources command supported # deployment and # resource#group arguments.</td>
<td></td>
</tr>
<tr>
<td>The project list#resources command is the same as list#resources without the # deployment and # resource#group arguments.</td>
<td></td>
</tr>
<tr>
<td>The deployment list#resources command is the same as list#resources with only the # deployment argument.</td>
<td></td>
</tr>
<tr>
<td>The resource#group list#resources command is the same as list#resources with both the # deployment and # resource#group arguments.</td>
<td></td>
</tr>
<tr>
<td>protect#deployment</td>
<td>deployment protect</td>
</tr>
<tr>
<td>release#deployment</td>
<td>deployment release</td>
</tr>
<tr>
<td>remove#login#provider</td>
<td>provider remove</td>
</tr>
<tr>
<td>remove#profile</td>
<td>profile remove</td>
</tr>
<tr>
<td>remove#resource#group</td>
<td>resource#group remove</td>
</tr>
<tr>
<td>rename#profile</td>
<td>profile rename</td>
</tr>
<tr>
<td>set#parameter</td>
<td>parameter set</td>
</tr>
<tr>
<td>update#deployment#access</td>
<td>deployment update # access</td>
</tr>
<tr>
<td>update#login#provider</td>
<td>provider update</td>
</tr>
<tr>
<td>Previous Command</td>
<td>New Command</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>update#mappings</td>
<td>mappings update</td>
</tr>
<tr>
<td>update#profile</td>
<td>profile update</td>
</tr>
<tr>
<td>update#project#code</td>
<td>project code update</td>
</tr>
<tr>
<td>update#project</td>
<td>project upload</td>
</tr>
</tbody>
</table>

You can use `project update` instead of `project upload`.

<table>
<thead>
<tr>
<th>upload#lambda#code</th>
<th>function upload#code</th>
</tr>
</thead>
<tbody>
<tr>
<td>upload#resource</td>
<td>deployment upload</td>
</tr>
<tr>
<td>resource#group</td>
<td>upload#resources</td>
</tr>
</tbody>
</table>

The `upload#resources` command supported a `##resource#group` argument.

The `deployment upload` command is the same as `upload#resources` without the `##resource#group` argument.

The `resource#group upload` command is the same as `upload#resources` with the `##resource#group` argument.

You can use `deployment update` and `resource#group update` instead of `deployment upload` and `resource#group upload`.

**Argument Aliases**

As a convenience, aliases have been added for the following common arguments.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Alias Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>##assume#role</code></td>
<td><code>#R</code></td>
</tr>
<tr>
<td><code>##confirm#aws#usage</code></td>
<td><code>#C</code></td>
</tr>
<tr>
<td><code>##deployment</code></td>
<td><code>#d</code></td>
</tr>
<tr>
<td><code>##function</code></td>
<td><code>#f</code></td>
</tr>
<tr>
<td><code>##log#stream#name</code></td>
<td><code>#l</code></td>
</tr>
<tr>
<td><code>##parameter</code></td>
<td><code>#p</code></td>
</tr>
<tr>
<td><code>##profile</code></td>
<td><code>#P</code></td>
</tr>
<tr>
<td><code>##resource#group</code></td>
<td><code>#r</code></td>
</tr>
<tr>
<td><code>##value</code></td>
<td><code>#v</code></td>
</tr>
</tbody>
</table>
Localizing Game Projects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can create multiple-language, region-specific versions of your game using Lumberyard's localization system.

The localization system supports Unicode keyboard input support and language-specific loading of font assets.

With this system, you can do the following:

- Easily modify localization assets and definitions. These are stored in XML files.
- Load and unload localized text assets as you need them. Localized text assets are grouped with tags that you choose.
- Reference localized text using the UI system's text component.
- Use the UI Editor to rapidly preview your UI in multiple languages.
- Customize the font texture configuration. This makes it possible for the engine to render a large number of unique characters or glyphs.

Configuring and Loading Localization Data

Lumberyard has two main types of localization XML assets:

- Tag definition XML (p. 2415)
- Localized text XML (p. 2416)

After you prepare your assets and place them in the preferred location, see the Localization System (p. 2417) documentation to ensure that your game is ready to use your assets.

English is the default language for a game project. To change languages, see Console Variables (p. 2418).

Tag Definition XML

The Tag Definition XML file groups localized text XML files by tag name. It must be loaded in C++ at runtime (p. 2418), typically at startup.

The following is an example of how the tag definition XML file appears:

```
<localization>
  <init>
    <entry>text_ui_menus.xml</entry>
  </init>
  <singleplayer>
    <entry>text_ui_sp_dialog.xml</entry>
  </singleplayer>
  <multiplayer>
    <entry>text_ui_mp_dialog.xml</entry>
  </multiplayer>
</localization>
```
This file should reside within your game project directory. For example, in the Samples Project, this file is located at dev/SamplesProject/libs/Localization/localization.xml. However, its specific location is inconsequential as long as the localization manager can load it at runtime. For more information, see Localization Initialization (p. 2417).

Localized text XML

Localized text XML files contain the text resources for a specific language. This way, your game project can reference the localization keys. This causes the localization system to return the corresponding value for the currently configured language. For more information, see Localizing Text (p. 2418).

You can edit these files manually, in Microsoft Excel, or in most industry-standard CAT tools.

For an example of an English localized text XML, open dev/SamplesProject/Localization/English_xml/text_ui_menus.xml.

For an example of the same localized text XML in Korean, open dev/SamplesProject/Localization/Korean_xml/text_ui_menus.xml.

Localization Checklist

To use localization in your game, verify that you have done the following:

1. Created a tag definition XML (p. 2415) and placed it within your game project directory.
2. Created localized text XML (p. 2416) assets for at least one language, also located within your game project directory.
3. Configured the g_language and sys_localization_folder console variables (p. 2418) appropriately.
   • g_language defaults to English.
   • sys_localization_folder must point to a game project sub-directory where you store your localized text XML assets in language-specific sub-directories.
4. Initialized the Localization Manager (p. 2418) in your game's startup code.

After completing these steps, you can start localizing text by passing in the localized key string to the localization manager. Note that some Lumberyard systems, such as the UI System (p. 2416), already attempt to localize text for you (p. 2418).

UI System Localization Features

By default, all Text (p. 2943) component values are passed to the Localization Manager (p. 2418) for localizing. If the value of a Text (p. 2943) component matches a localization key for the currently loaded language, then the localized text is rendered.

For an example, open the Samples Project (p. 146). In the UI Editor (p. 2874), load the following UI canvas: dev/Gems/LyShineExamples/Assets/UI/Canvases/LyShineExamples/Localization/Text.uicanvas.

You can quickly test a UI canvas that contains localized text. To change the current language in the UI Editor (p. 2874), choose View, Set Current Language.
Font Features

Language-Specific Font Assets

You can group Font Family XML (p. 3000) definitions by using a lang attribute. This attribute tells the localization system to load font assets only for the currently actively language. To see an example, open the Samples Project (p. 146) and, in the UI Editor (p. 2874), open dev/Gems/LyShineExamples/Assets/UI/Fonts/LyShineExamples/NotoSans/NotoSans.fontfamily.

Unique Characters

Some languages feature a large variety of unique characters. Font XML files contain attributes for adjusting font texture resolution and number of slots for storing unique characters. For more information, see Configuring Font Quality (p. 3002).

For an example of unique character support in action, open the Samples Project (p. 146), then load the UiFeatures level. Press Ctrl+G to play the game. Choose Language Support, then choose either Unique Characters: 32px or Unique Characters: 64px.

Localization Initialization

Initializing the localization system requires the following:
Localization Initialization

- C++ call to initialize the Localization Manager at game startup
- Tag Definition XML
- Localized text XML

Localization Manager

At game startup, you must initialize the Localization Manager (ILocalizationManager) with the tag definition XML.

For example, the following code snippet is from dev/SamplesProject/Gem/Code/Source/Core/GameplaySampleGame.cpp within the Samples Project:

```cpp
void LoadLocalizationData()
{
    ILocalizationManager* pLocMan = GetISystem()->GetLocalizationManager();
    if (pLocMan)
    {
        AZStd::string localizationXml("libs/localization/localization.xml");
        if (pLocMan->InitLocalizationData(localizationXml.c_str()))
        {
            const bool initLocSuccess = pLocMan->LoadLocalizationDataByTag("init");
            AZ_Error("Localization", initLocSuccess, "LoadLocalizationData() failed to load localization file=%s", localizationXml.c_str());
        }
    }
}
```

The code sample above does the following:

- Initializes the localization manager with the tag definition XML.
- Loads all the localized text XML for the current language that is grouped by the init tag within the tag definition XML.

Console Variables

The following two console variables, or CVars, affect the localization system:

- **g_language**
  The name of the current language that the game uses. Is set to *English* by default.

- **sys_localization_folder**
  The directory used for finding localization assets. This directory contains either language PAK files or 'loose' localized text XML files.

For example, in the Samples Project, the game config file, /dev/SamplesProject/game.cfg, sets sys_localization_folder to Localization. In the game directory structure, this defines the location as dev/SamplesProject/Localization.

Localizing Text

After you properly initialize the localization manager, you can localize text to the current language. To do this, you pass in the localization key that you want to localize.

For example:
string locText;
gEnv->pSystem->GetLocalizationManager()->LocalizeString("@ui_Hello", locText);

Assuming the key @ui_Hello is localized for the current language, the contents of locText will contain the Unicode (UTF8) encoding for the localized value contained within the localized text XML.

**UiTextComponent**

Lumberyard's UI System (p. 2874), contained in the LyShine Gem and installed by default, features a text (p. 2943) component with built-in support for automatically localizing text for you. When you enter a valid localized text key (such as @ui_Hello as shown in the previous example (p. 2418)), the engine replaces the contents of the rendered string with the localized text. That key must be localized for the current language.

To see the source code for examples of calls to the localization manager, open ui/Gems/LyShine/Code/Source.UiTextComponent.cpp.
Scripting in Amazon Lumberyard

Lumberyard includes two scripting technologies for automating gameplay: Script Canvas and Lua.

**Script Canvas**

A visual scripting environment that you can use to create game logic and behaviors without writing code. In the Script Canvas editor, you create, connect, and rearrange graphical nodes that provide a visual representation of the logic flow.

For more information, see Creating Gameplay with Script Canvas (p. 2420).

**Lua**

A powerful, fast, lightweight, embeddable scripting language. Lua facilitates quick iteration in your game project because you can run your changes immediately without needing to recompile your source code.

For more information, see Writing Lua Scripts (p. 2683).

Lumberyard's functionality is exposed to Script Canvas and Lua by the behavior context. For more information, see Behavior Context (p. 1053).

**Topics**

- Creating Gameplay with Script Canvas (p. 2420)
- Writing Lua Scripts (p. 2683)
- Using Script Events (p. 2762)

Creating Gameplay with Script Canvas

Script Canvas is a visual scripting environment for Amazon Lumberyard that you can use to create game logic and behaviors. Integrated with Lumberyard's component entity system, Script Canvas offers an approachable and easy-to-read environment to author behaviors using the same framework as Lua and C++. With its visual scripting options, you can use Script Canvas to create scripts for game logic without needing to know how to code. Event-driven scripts let you produce small scripts that don't require complex logic to maintain states.

Script Canvas is also an extensible system. You can build your own reusable Script Canvas functions and, since Script Canvas is based on AzCore, you can create custom Script Canvas nodes that use the serialization, reflection, modularization, and EBus messaging systems.
To enable Script Canvas for Lumberyard, you must enable the Script Canvas (p. 1201) gem and its dependencies.

- Programmer Guide (p. 2543)
- Script Canvas Node Reference (p. 2567)

Learning Guide

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In this Learning Guide, we provide you with a tour of the Script Canvas interface, several tutorials to get you started using the visual scripting environment, and a guide to additional resources for learning Script Canvas. Additionally, there's a glossary of terms you can continue referring back to as you learn your way around.

Topics
- Script Canvas Editor Interface (p. 2421)
- Script Canvas Concepts and Terms (p. 2423)
- Script Canvas Tutorials (p. 2424)
- More Learning Opportunities with Script Canvas (p. 2466)

Script Canvas Editor Interface

You can open the Script Canvas editor from Lumberyard Editor.

To open the Script Canvas editor
1. In Lumberyard Editor, choose Tools, Script Canvas.
2. Choose File, New Script or drag a node from the Node Palette and drop it on the canvas.
In the **Script Canvas** editor, you can do the following:

A. Use the menu bar to do the following:
   - Create, save, and open your scripts.
   - Cut, copy, or undo actions.
   - Change the **Script Canvas** editor view.

B. Use the tabs to switch between scripts.

C. In the **Node Palette**, you can search for nodes.

D. You can drag a node from the **Node Palette** to the canvas or right-click the canvas for the menu to appear.

E. On a node, you can specify values for the parameters.

F. Drag to connect the input pin of a node to an output pin of another node. This line creates a connection between the nodes.

G. The **Variable Manager** shows the variables that are used in the script. You can add or delete variables and set their default values. To create **Get**, **Set**, or **OnValueChanged** nodes, you can drag a variable from the **Variable Manager** onto the script.

H. In the **Node Inspector**, you can view and modify the properties for a selected node.

### Additional Tools

**Script Canvas** editor has the following additional menus and tools.

**Bookmarks**

View and modify your saved bookmarks. You can use bookmarks to save locations on your script and then use keyboard shortcuts to move to that location. For more information, see Adding Bookmarks for Script Canvas (p. 2534).

**Comments**

You can create floating blocks of text on the Script Canvas editor canvas. For more information, see Commenting Nodes (p. 2524).
Script Canvas Concepts and Terms

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The following concepts and terms are used in **Script Canvas**:

**Script**

A script is a collection of nodes, node properties, and node connections that, when combined, create a visual script.

**Node**

Nodes represent the data, events, and actions that you use to create logic and behaviors in **Script Canvas**.

See the following node types:

**Event nodes**

Event nodes subscribe to event bus (EBus) handlers to listen for events to occur. Examples include entering a trigger area, colliding with an object, turning off a light, and when the game ticks.

For more information about using the EBus interface, see [Working with the Event Bus (EBus) system](p. 1851).

**Action nodes**

Action nodes are used to get or send data across an EBus. Examples of action nodes include getting the mass of an entity, turning on a light, setting the text of a UI element, and playing an animation.

For more information about using the EBus interface, see [Working with the Event Bus (EBus) system](p. 1851).

**Variable and data nodes**

Variable and data nodes represent the custom data that can be required to build game logic. You can use these nodes to make counters, store entity references, specify a direction, define a color, and so on. Variable nodes are added to a script to declare and initialize them. Use get and set nodes to retrieve or set the variable's value.

The following are the commonly used data types in **Script Canvas**:

- Boolean
- Color
- Entity
- Number
- String
- Transform
- Vector 2/3/4

**Logic**

Logic nodes include comparison and timing operations. You can use logic nodes to check whether two values are equal, control the execution of nodes, delay the execution of a node for a specific amount of time, and more.
Math

Math nodes enable math operations, such as arithmetic, geometry, algebra, calculus and so on.

Debugging

Debugging nodes verify whether a script is functioning as expected. You can use debugging nodes to print data to the console or viewport and check for errors. These nodes pass logic flow, but do not execute in release builds.

User defined

You can build your own nodes for your project’s specific needs. For more information, see Creating Custom Nodes in Script Canvas (p. 2553).

Node Palette

The Node Palette contains a searchable list of nodes. By default, the palette is docked to the left of the Script Canvas editor.

To display the Node Palette

1. From Lumberyard Editor, choose Tools, Script Canvas.
2. In the Script Canvas window, do one of the following:
   - Choose Tools, Node Palette.
   - Press Ctrl+Shift+L.

   Note
   If you have an existing script open, you can right-click the canvas for the menu to appear.

Node Inspector

The Node Inspector shows the properties of the node. You can edit each property in the inspector or directly in the node. By default, this window doesn’t appear in the editor.

To display the Node Inspector

1. Open Script Canvas (p. 2421).
2. Do one of the following:
   - Click Tools, Node Inspector.
   - Press Ctrl+Shift+I.

Script Canvas Tutorials

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the following Script Canvas tutorials to learn about the Lumberyard visual scripting system.

Prerequisites

- Set the Samples Project (p. 146) as the default project. For more information, see Choosing a Game Project to Open (p. 47).
• If your **Node Palette** is missing nodes, you can update your preferences to show hidden nodes. For more information, see *Script Canvas Node Reference* (p. 2567).

• To access diagnostic nodes, including the **Print** node, you must enable the **Script Canvas Diagnostic Library** gem and then build your game project. For more information, see *Enabling Gems* (p. 1064).

**Topics**

- *Script Canvas Tutorial: Creating a Controllable Entity* (p. 2425)
- *Script Canvas Tutorial: Opening and Closing a Door with Trigger Areas and Variables* (p. 2435)
- *Script Canvas Tutorial: Shooting a Target by Spawning Entities and Detecting Collisions* (p. 2446)

**Script Canvas Tutorial: Creating a Controllable Entity**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

This tutorial walks you through the steps to create a simple sphere that you can control with keyboard input.

**Example**

![Sphere](#)

In addition to node basics, input, movement, and logging, you learn the following key concepts:

• Adding nodes
• Creating execution and data connections
• Adding event nodes
• Adding action nodes
Prerequisites

- Set the Samples Project (p. 146) as the default project. For more information, see Choosing a Game Project to Open (p. 47).
- If your Node Palette is missing nodes, you can update your preferences to show hidden nodes. For more information, see Script Canvas Node Reference (p. 2567).
- To access diagnostic nodes, including the Print node, you must enable the Script Canvas Diagnostic Library gem and then build your game project. For more information, see Enabling Gems (p. 1064).

Topics

- Step 1: Create a Level (p. 2426)
- Step 2: Create an Entity and Add Components to Create a Controllable Entity (p. 2426)
- Step 3: Create an Input Script with Script Canvas (p. 2429)
- Step 4: Assign the Script to Your Entity and Test the Script (p. 2431)
- Step 5: Create a Script to Move Your Sphere (p. 2431)
- Step 6: Add Movement on the X-Axis for Your Sphere (p. 2432)

Step 1: Create a Level

Before you create a sphere that you can control with keyboard input, you need to create a level.

To create a level

1. In Lumberyard Editor, choose File, New.
2. In the New Level dialog box, enter firstscriptcanvas and then click OK.
3. In the Generate Terrain Texture dialog box, choose 512x512 and then click OK.

Step 2: Create an Entity and Add Components to Create a Controllable Entity

To create a sphere that you can control with keyboard input, you create an entity and add the Mesh (p. 684), Rigid Body component, Mesh Collider, and Input (p. 642) components. You also create an input mapping that converts WASD keyboard input into movement in the x and y directions.

To create a controllable entity

1. In Lumberyard Editor, right-click in the Perspective viewport and choose Create entity.
2. In the Entity Inspector, do the following:
   a. For Name, enter Player.
   b. Click Add Component and then choose the Mesh component.
   c. In the Mesh component, for Mesh asset, click the browse (...) button, select the \SamplesProject\Objects\default\primitive_sphere.cfg file and then click OK.
3. In the viewport, use the Move tool (p. 201) to select the z-axis and move the entity off the ground.

4. In the Entity Inspector, click Add Component and then add the following components:
   - Rigid Body Physics
   - Mesh Collider
   - Input

5. In the Input component, click the Input Bindings Editor icon. This opens the Asset Editor.

6. In the Asset Editor, choose File, New, Input Bindings and for File name, enter player and then click Save.

7. In the Edit Asset window, do the following:
   a. For Input Event Groups, click + to add a new input event group.
   b. Expand the input event group. For Event Name, enter move_x.
   c. For Event Generators, click + to add an event generator.
   d. In the Class to create dialog box, click OK to add an input class.
   e. Expand move_x, Event Generators, gamepad_button_a. For Input Device Type, select keyboard.
   f. For Input Name, select keyboard_key_alphanumeric_A.
   g. For Event value multiplier, enter -1.
   h. Repeat steps C – E. For Input Name, select keyboard_key_alphanumeric_D. For Event value multiplier, use the default value of 1.
   i. Expand the keyboard_key_alphanumeric_A event generator and verify that your settings appear like the following.
8. In the **Edit Asset** window, do the following:

   a. For **Input Event Groups**, click + to add a new input event group.

   b. Expand the input event group. For **Event Name**, enter *move_y*.

   c. For **Event Generators**, click + to add an event generator.

   d. In the **Class to create** dialog box, click OK to add an input class.

   e. Expand *move_y*, **Event Generators**, *gamepad_button_a*. For **Input Device Type**, select **keyboard**.

   f. For **Input Name**, select **keyboard_key_alphanumeric_W**. For **Event value multiplier**, use the default value of 1.

   g. Repeat steps C – E. For **Input Name**, select **keyboard_key_alphanumeric_S**. For **Event value multiplier**, enter -1.

   h. Expand **keyboard_key_alphanumeric_W** and verify that your settings appear like the following.
Step 3: Create an Input Script with Script Canvas

Now that you set up a sphere with physics and input mapping, you can create your first script with the Script Canvas editor.

To create an input script
1. In Lumberyard Editor, choose Tools, Script Canvas.
2. In the Script Canvas editor, choose File, New Script.
3. After the graph loads, choose File, Save As.
4. In the **Save As** dialog box, for **File name**, enter `player` and then click **Save**.

5. In the **Node Palette**, enter **input** in the search box.

   **Note**
   You can also access the list of nodes by right-clicking in an empty area on the graph.

6. Under **Gameplay, Input**, drag **Input Handler** from the **Node Palette** to the graph. **Input Handler** is an event node. When an event occurs, the event node sends a message to the graph.

7. For **Event Name**, enter `move_y`. This tells the node to listen for the input event.

![Input Handler](image)

8. In the **Node Palette**, enter **Print** in the search box.

9. Under **Utilities, Debug**, drag **Print** from the **Node Palette** to the graph. **Print** is an action node. When you execute an action node, it completes actions such as request data, set data, manipulate data, and trigger functions. Action nodes also print data to the editor console, allowing you to check values as the script is being executed.

10. From **Input Handler**, drag the **Held** pin to connect it to the **In** pin of the **Print** node. This connection tells the **Print** node to execute after the input handler receives a held event.

11. From **Input Handler**, drag the **Value** pin to connect it to the **Value** pin of the **Print** node. This connection tells the **Input Handler** node to pass the input event value from the input handler to the first argument on the **Print** node.

   **Note**
   - Node execution always flows from the left side to the right side of a node.
   - Data is always input on the left side of a node and output from the right side of the node.

   For more information, see **Inputs, Outputs, and Connection Types** (p. 2497).

12. Verify that your `player.scriptcanvas` file looks like the following.

![Print](image)

13. In the **Script Canvas** editor, choose **File, Save** or press **Ctrl+S**.
Step 4: Assign the Script to Your Entity and Test the Script

The script that you made outputs the value of the input event. Now you can assign the script to your entity and test the script.

Note
The tutorial's keyboard input doesn't work in a remote desktop session.

To assign and test your script

1. In Lumberyard Editor, select the Player entity that you created.
2. In the Entity Inspector, click Add Component, and then choose the Script Canvas component.
3. Under Script Canvas, click the browse (...) button, select the player.scriptcanvas file, and then click OK.
4. Press ` to open the console window or choose Tools, Console.
5. Press Ctrl+G to enter game mode.
6. To trigger your input event, press W and then press S. The Console pane in Lumberyard Editor outputs the value of the input event when the move_y event is triggered. In this case, the Console pane outputs 1 when you press W and outputs -1 when you press S.

7. When you are done testing your script, press Esc.

Step 5: Create a Script to Move Your Sphere

Now that you've successfully created your first script, you can add nodes to move your sphere. You also modify the input event value to control the movement speed.

To move your sphere

1. In the Script Canvas editor, in the Node Palette, enter multiply in the search box.
2. Under Math, drag Multiply from the Node Palette to the graph.
3. From Input Handler, drag the Held pin to connect it to the In pin of the Multiply node. This connection executes the Multiply node after the input handler receives a held event.
4. From Input Handler, drag the Value pin to connect it to the Value A pin of the Multiply node.
5. In the **Multiply** node, for **Value B**, enter **0.1**. This smaller value for the input event throttles the movement speed.

6. In the **Node Palette**, enter **move** in the search box.

7. Under **Entity, Transform**, drag **Move Entity** from the **Node Palette** to the graph.

8. In the **Node Palette**, enter **create from values** in the search box.

9. Under **Math, Vector3**, drag **Create From Values** from the **Node Palette** to the graph. You use this node to build a vector 3 from a number.

10. From **Multiply**, drag the **Out** pin to connect it to the **In** pin of the **Create From Values** node.

11. From **Multiply**, drag the **Result** pin to connect it to the **Y** pin of the **Create From Values** node. You only need a y direction, so use the default value (0) for **X** and **Z**.

12. From **Create From Values**, drag the **Out** pin to connect it to the **In** pin of the **Move Entity** node.

13. From **Create From Values**, drag the **Vector 3** pin to connect it to the **Direction** pin of the **Move Entity** node.

14. Verify that your **player.scriptcanvas** graph looks like the following.

15. Save your graph.

16. In Lumberyard Editor, press **Ctrl+G** to enter game mode and test your script.

17. To move the sphere forward, press **W**. To move the sphere backwards, press **S**.

18. When you are done testing your script, press **Esc**.

**Step 6: Add Movement on the X-Axis for Your Sphere**

Now that you've converted your input event value to a direction that moves the entity on the y-axis, you can add movement on the x-axis.

**To add movement on the x-axis**

1. In the **Script Canvas** editor, drag on the graph to select the **Input Handler, Multiply, Create From Values**, and **Move Entity** nodes. An orange outline appears around the selected nodes.
2. Press **Ctrl+C** to copy the selected nodes.
3. Press **Ctrl+V** to paste the copied nodes and their connections. This allows you to clone the existing script and modify the cloned version with the appropriate settings for movement on the x-axis.
4. While still selected, move the nodes so they don't overlap the copied nodes.
5. In the duplicate **Input Handler** node, for **Event Name**, enter `move_x`.

**Example**

Your *player.scriptcanvas* graph should look like the following.

6. For the duplicate **Multiply** node, move the connection from the Y pin to the X pin on the duplicate **Create From Values** node.

**Note**

To disconnect a connection, drag it to an empty part of the canvas. To delete a connection, press **Alt** and click the connection.
7. Verify that your `player.scriptcanvas` file graph looks like the following.

Example

8. Save your graph.

9. In Lumberyard Editor, press **Ctrl+G** to enter game mode and test your script.

10. Do the following:
    
    a. To move the sphere forward, press **W**.
    b. To move the sphere backwards, press **S**.
    c. To move the sphere from side to side, press **A** and **D**.

11. When you are done testing your script, press **Esc**.
Script Canvas Tutorial: Opening and Closing a Door with Trigger Areas and Variables

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In the following tutorial, you create a door that opens and closes when your controllable sphere enters and exits a trigger area.

Example

This involves several tasks:

- Create a trigger area
- Add event nodes
• Add variables

Prerequisites

• Complete the Script Canvas Tutorial: Creating a Controllable Entity (p. 2425).

Topics

• Step 1: Create a Door and Trigger Area (p. 2436)
• Step 2: Create a Script to Open and Close the Door (p. 2441)

Step 1: Create a Door and Trigger Area

To create a door and trigger area, create an entity with child entities and then add components to the child entities.

To create a door and trigger area

1. In Lumberyard Editor, right-click the Perspective viewport near your controllable sphere and choose Create entity.

2. In the Entity Inspector, for Name, enter Door Group.

3. Do the following to create a door:
   a. In the Entity Outliner, right-click Door Group and choose Create child entity. This child entity is your door.
   b. In the Entity Inspector, for Name, enter Door Mesh.
c. For the **Door Mesh** entity, click **Add Component** and then choose the **Mesh** (p. 684) component.

d. In the **Mesh** component, for **Mesh asset**, click the browse (…) icon and select the `SamplesProject\Objects\Primitives\box_1x1.cgf` file.

e. Click **Add Component** and then choose the **Static Physics** component.

f. Click **Add Component** and then choose the **Mesh Collider** component. This component defines the collision shape for the **Door Mesh** entity.

g. In the **Transform** (p. 878) component, for **Scale**, set X to **2.5**, Y to **0.5**, and Z to **4.0**.

h. Verify that your **Door Mesh** entity looks like the following.
Example

4. Do the following to create a trigger area:
   a. In the **Entity Outliner**, right-click **Door Group** and choose **Create child entity**. This child entity is your trigger area.
   b. In the **Entity Inspector**, for **Name**, enter **Door Trigger**.
   c. Click **Add Component** and then choose the **Trigger Area (p. 890)** component.
d. With the Move tool (p. 201), adjust the Door Trigger entity so that its Z position fits the Door Mesh entity.

e. In the Trigger Area component, click Add Required Component and choose Box Shape.

f. For the Box Shape component, for Dimensions, set X to 3.0, Y to 9.0, and Z to 6.0.

g. Click Add Component and then choose the Script Canvas (p. 818) component.

h. In Lumberyard Editor, choose Tools, Script Canvas.

i. In the Script Canvas editor, choose File, New Script.

j. After the new canvas loads, choose File, Save As.

k. For File name, enter door and then click Save.

l. In the Script Canvas component, click the browse (...) icon, select the door.scriptcanvas file, and then click OK.

5. Verify that your Door Trigger entity looks like the following.
Step 2: Create a Script to Open and Close the Door

Now that you've set up your door and trigger area, you can create a script that opens and closes the door when another entity enters or leaves the trigger area.

To create a script that opens and closes the door

1. In the Script Canvas editor, open the door.scriptcanvas file.
2. In the Node Palette, enter trigger in the search box and under Gameplay, Trigger Area, drag On Area Entered to the canvas.
   
   Note
   
   With this event node you can easily use the Lumberyard EBus messaging system. For more information, see Working with the Event Bus (EBus) system (p. 1851).

3. In the Trigger Area node, click Add/Remove Events and then select the On Area Exited check box. This exposes the entered and exited events from the Trigger Area EBus.

4. In the bottom-right pane, in the Variable Manager, click Create Variable.
   
   Note
   
   You can store and modify persistent values in your graph with variable nodes. For more information, see Managing Script Canvas Variables (p. 2482).

5. Select Vector3, double-click Variable 1 and then rename the variable to opened_position.
6. In the Node Inspector, specify 2 for the Z value. A positive value for the z-axis slides the door up. Because the door entity is a child of Door Group, you can specify local relative positions to control the open and closed positions of the door.
7. Create another Vector3 variable and name it closed_position. Keep the default value of 0, 0, 0.
8. Create another Vector3 variable and name it current_position. Keep the default value of 0, 0, 0. This variable sets the door's current position.
9. Create another Vector3 variable and name it `destination_position`. Keep the default value of 0, 0, 0. This variable sets the door’s destination position when the entity enters and exits the trigger area.

**Example**

You should have four Vector3 variable nodes such as the following.

![Variable Manager](image)

10. In the **Variable Manager**, do the following:

   a. Select and drag the `open_position` node to the canvas and then click **Get opened_position**.
   b. Select and drag the `closed_position` node to the canvas and then click **Get closed_position**.
   c. Select and drag two `destination_position` nodes to the canvas and then click **Set destination_position**.

11. In the canvas, make the following connections:

   a. From **On Area Entered**, drag the Out pin to connect it to the In pin of a **Get opened_position** node.
   b. From **On Area Exited**, drag the Out pin to connect it to the In pin of the **Get closed_position** node.
   c. From **Get opened_position**, drag the Out pin to connect it to the In pin of the **Set destination_position** node.
   d. From **Get opened_position**, drag the Vector3 pin to connect it to the Vector3 pin of the **Set destination_position** node.
   e. From **Get closed_position**, drag the Out pin to connect it to the In pin of the other **Set destination_position** node.
   f. From **Get closed_position**, drag the Vector3 pin to connect it to the Vector3 pin of the other **Set destination_position** node.
   g. Verify that your `door.scriptcanvas` graph looks like the following.
Example

12. Do the following to get the Door Mesh entity's position and interpolate to the destination:

   a. In the Node Palette, enter `get local` in the search box.

   b. Under Entity, Transform, drag Get Local Translation to the canvas. You can use this node to get the current position of the Door Mesh entity and interpolate to the destination. A local translation applies to the translation of the entity relative to its parent.

   c. In the Get Local Translation node, pause on the Source text box and click the target button. When selected, the target button has an orange outline.

   d. In the Entity Outliner, select Door Mesh to assign the Door Mesh entity to the Source property in the Get Local Translation node.
Note
To reset an entity reference, right-click twice on the Source text box and choose Set to Self.

e. In the Script Canvas editor, from both Set destination_position nodes, drag the Out pins to connect it to the In pin for Get Local Translation.

Note
When multiple connections enter a single logic pin, the node is executed each time either execution is triggered. The node is executed more than once in the same game tick if multiple executions are triggered simultaneously.

13. Do the following to execute nodes for a specified amount of time, in seconds:

   a. In the Variable Manager, drag current_position to the canvas and click Set current_position.

   b. From Get Local Translation, drag the Out pin to connect it to the In pin of the Set current_position node.

   c. From Get Local Translation, drag the Translation pin to connect it to the Vector3 pin of the Set current_position node.

   d. In the Node Palette, enter duration in the search box and under Timing, drag Duration to the canvas.

   e. From Set current_position, drag the Out pin to connect it to the Start pin of the Duration node. Triggering the Duration node resets the time.

   f. In the Duration node, for Duration, enter 1.0 (seconds).
Example

14. Do the following to set up interpolation between the current position and the destination:

   a. In the Variable Manager, select and drag `current_position` to the canvas and then click Get `current_position`.

   b. In the Variable Manager, select and drag `destination_position` to the canvas and then click Get `destination_position`.

   c. In the Node Palette, enter `lerp` in the search box and under Math, Vector3, drag Lerp from the Node Palette to the canvas. This node blends two values based on the Percentage property.

   d. From Duration, drag the Out pin to connect it to the In pin of the Get `current_position` node.

   e. From Duration, drag the Elapsed pin to connect it to the Percentage pin of the Lerp node.

   f. From Get `current_position`, drag the Out pin to connect it to the In pin of the Get `destination_position` node.

   g. From Get `current_position`, drag the Vector3 pin to connect it to the Start pin of the Lerp node.

   h. From Get `destination_position`, drag the Out pin to connect it to the In pin of the Lerp node.

   i. From Get `destination_position`, drag the Vector3 pin to connect it to the End pin of the Lerp node.

Example
15. Do the following to set the position of the door when the **Duration** node blends between the current and destination positions:

   a. In the **Node Palette**, enter **set local translation** in the search box and under **Entity, Transform**, drag **Set Local Translation** to the canvas.

   b. From **Lerp**, drag the **Out** pin to connect it to the **In** pin of the **Set Local Translation** node.

   c. From **Lerp**, drag the **Vector3** pin to connect it to the **Translation** pin of the **Set Local Translation** node.

   d. In the **Set Local Translation** node, pause on the **Source** text box and click the target button.

   e. In the **Entity Outliner**, select **Door Mesh** to assign the **Door Mesh** entity to the **Source** property in the **Set Local Translation** node.

   f. Verify that your **door.scriptcanvas** graph looks like the following.

   **Example**

   ![Diagram of door scriptcanvas graph]

16. Save your graph.

17. In Lumberyard Editor, press **Ctrl+G** to enter game mode and test your script.

18. To move the sphere forward into the door trigger area and slide open the door, press the **W, A, D** keys.

19. To move the sphere backwards out of the trigger area and slide the door closed, press **S**.

20. When you are done testing your script, press **Esc**.

**Script Canvas Tutorial: Shooting a Target by Spawning Entities and Detecting Collisions**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://www.aws.amazon.com/about-aws/whats-new/) or visit the [AWS Game Tech blog](https://aws.amazon.com/en_game/tech/) to learn more.

This tutorial builds on what you learned in the previous two tutorials. In the following tutorial, you create a controllable sphere that shoots projectiles at a target.
Example

This involves several tasks:

- Spawn entities
- Add scripts that run on the spawned entities
- Set up collision
- Add tag filtering

Prerequisites

- Complete the Script Canvas Tutorial: Creating a Controllable Entity (p. 2425) and Script Canvas Tutorial: Opening and Closing a Door with Trigger Areas and Variables (p. 2435).

Topics

- Step 1: Set Up a Projectile Entity (p. 2448)
- Step 2: Create a Script to Propel the Projectile Forward (p. 2452)
- Step 3: Save the Projectile Entity as a Slice (p. 2454)
- Step 4: Set Up the Player Entity to Spawn the Slice (p. 2456)
- Step 5: Set Up the Input Binding for the Projectile (p. 2457)
- Step 6: Add Logic to the Player Script to Spawn the Projectile (p. 2458)
- Step 7: Create a Target Entity (p. 2460)
- Step 8: Add Logic to the Projectile to Destroy Target Entities (p. 2463)
Step 1: Set Up a Projectile Entity

To create a projectile entity, create an entity and then add the Mesh (p. 684), Rigid Body component, Mesh Collider, and Script Canvas (p. 818) components.

To create a projectile entity

1. In Lumberyard Editor, right-click in the Perspective viewport near your sphere and choose Create entity.
2. In the Entity Inspector, do the following:
   a. For Name, enter Projectile.
   b. In the Transform component, for Scale, set X to 0.25, Y to 0.25, and Z to 0.25.
   c. Click Add Component and then choose the Mesh component.
   d. In the Mesh component, for Mesh asset, click the browse (...) button, select the \SamplesProject\Objects\default\primitive_sphere.cgf file, and then click OK.
3. In the **Entity Inspector**, click **Add Component** and then choose the following components:
   - Rigid Body Physics
   - Mesh Collider
   - Script Canvas

4. In Lumberyard Editor, choose **Tools, Script Canvas**.

5. In the **Script Canvas** editor, choose **File, New Script**.

6. After the graph loads, choose **File, Save As**.

7. In the **Save As** dialog box, for **File name**, enter `projectile` and then click **Save**.

8. In the **Script Canvas** component, for **Script Canvas Asset**, click the browse (...) button, select the `projectile.scriptcanvas` file, and then click **OK**.
9. Verify that the **Projectile** entity looks like the following.
Example

![Image of Lumberyard User Guide](image-url)
Step 2: Create a Script to Propel the Projectile Forward

Now that you’ve set up a projectile, you can create a script to propel the projectile forward when it spawns.

To create a projectile script

1. In the Script Canvas editor, open the projectile.scriptcanvas file, if it’s not still open from Step 1: Set Up a Projectile Entity (p. 2448).
2. In the Node Palette, enter start in the search box.
3. Under Utilities, drag On Graph Start from the Node Palette to the graph. This event node executes only for the first tick after the entity has initialized.
4. In the Node Palette, enter Get Forward.
5. From Entity, Transform, drag the Get Forward node to the graph.
6. From On Graph Start, drag the Out pin to connect it to the In pin of the Get Forward node.

7. In the Get Forward node, for Scale, enter 200.
8. In the Node Palette, enter Set Velocity and drag the node to the graph.
9. From Get Forward, drag the Out pin to connect it to the In pin of the Set Velocity node.
10. From Get Forward, drag the Forward pin to the Velocity pin of the Set Velocity node.

11. To set a lifetime for the projectile, do the following:
a. In the **Node Palette**, enter **delay** in the search box.

![Delay node]

b. Under **Timing**, drag **Delay** from the **Node Palette** to the graph.

c. From **On Graph Start**, drag the **Out** pin to connect it to the **In** pin of the **Delay** node.

d. In the **Delay** node, for **Time**, enter **1.0**.

12. To destroy the projectile after the set time, do the following:

a. In the **Node Palette**, enter **destroy** in the search box.

b. Under **Entity, Game Entity**, drag **Destroy Game Entity and Descendants** from the **Node Palette** to the graph.

![Destroy Game Entity And Descendants node]

c. From **Delay**, drag the **Out** pin to connect it to the **In** pin of the **Destroy Game Entity and Descendants** node.
d. Verify that your projectile.scriptcanvas graph looks like the following.

Example

13. In the Script Canvas editor, choose File, Save. You can also press Ctrl+S.

Step 3: Save the Projectile Entity as a Slice

Now that you've created a projectile script, you can save the projectile entity as a slice.

To save the projectile entity as a slice

1. In Lumberyard Editor, in the Entity Outliner, right-click Projectile and choose Create slice.
2. In the Save As dialog box, for File name, enter projectile and then click Save.
3. To enable the projectile to spawn, do the following:
   a. In the Asset Browser, navigate to the projectile.slice file that you just created.
b. Right-click `projectile.slice` and choose **Set Dynamic Slice**. Scripts that run on a dynamic slice will properly remap source entity assignments to the entity that the graph runs on.

4. In the **Entity Outliner**, right-click `Projectile` and then click **Delete**. Because you will spawn the projectile entity dynamically from your player script, you no longer need the entity in your scene.
Step 4: Set Up the Player Entity to Spawn the Slice

Now that you've created a slice, you can set up your Player entity to spawn the slice.

To set up the player entity to spawn the slice

1. In Lumberyard Editor, in the Entity Outliner, right-click the Player entity and choose Create child entity.
2. Enter a name for the child entity such as spawner.
3. In the Transform component, for the Translate Y property, enter 1.0. This sets the spawn point 1 meter in front of the parent entity.
4. Select the child entity and in the Entity Inspector, click Add Component, and then choose the Spawner (p. 859) component.
5. In the Spawner component, for Dynamic slice, click the browse (...) icon, select the projectile.slice file, and then click OK.

6. Verify that the spawner entity looks like the following.
Step 5: Set Up the Input Binding for the Projectile

Now that you've added the Spawner component, you can set up the input binding to shoot the projectile when you press the Spacebar.

To set up the projectile input binding

1. In Lumberyard Editor, in the Entity Outliner, select the Player entity.
2. In the Entity Inspector, under Input, click the Input Bindings Editor icon.
3. In the Edit Asset window, do the following:
   a. For Input Event Groups, click + to add a new input event group.
   b. Expand the input event group. For Event Name, enter shoot.
   c. For Event Generators, click + to add an event generator.
   d. In the Class to create dialog box, click OK to add an input class.
   e. Expand shoot, Event Generators, gamepad_button_a. For Input Device Type, choose keyboard.
f. For **Input Name**, choose `keyboard_key_edit_space`.

g. Verify that your settings appear as shown in the following.

![Edit Asset: player.inputbindings](image)

h. In the **Edit Asset** window, choose **File, Save**.

**Step 6: Add Logic to the Player Script to Spawn the Projectile**

Now that you've set up the input binding, you can add logic to the **Player** script to spawn the projectile when you press the **Spacebar**.

**To add logic to the player script**

1. In Lumberyard Editor, choose **Tools, Script Canvas**.
2. In the **Script Canvas** editor, choose **File, Open**. Select `player.scriptcanvas` and then click **Open**.
3. Do the following to enable the event node to listen for the input event:
   a. In the **Node Palette**, enter **input** in the search box.
   b. Under **Gameplay, Input**, drag **Input Handler** from the **Node Palette** to the graph. **Input Handler** is an event node. When an event occurs, the event node sends a message to the script.
   c. For **Event Name**, enter **shoot**.

![Input Handler](image)

4. Do the following to control the firing rate for the shoot event:
   a. In the **Node Palette**, enter **once** in the search box.
   b. Under **Logic**, drag **Once** from the **Node Palette** to the graph.
c. From Input Handler, drag the Held pin to connect it to the In pin of the Once node.

d. In the Node Palette, enter `spawn` in the search box.

e. Under Gameplay, Spawner, drag Spawn from the Node Palette to the graph.

f. From Once, drag the Out pin to connect it to the In pin of the Spawn node.

g. In the Spawn node, for Source, enter the name of the child entity with the Spawner component attached from Step 4 (p. 2456).

h. In the Node Palette, enter `delay` in the search box.

i. Under Timing, drag Delay from the Node Palette to the graph.
j. From Spawn, drag the Out pin to connect it to the In pin of the Delay node.
k. In the Delay node, for Time, enter 0.25 (seconds).
l. From Delay, drag the Out pin to connect it to the Reset pin of the Once node.

**Note**
Node execution always flows from the left side to the right side of a node. For more information, see Inputs, Outputs, and Connection Types (p. 2497).

5. Verify that your player.scriptcanvas graph looks like the following.

**Example**

6. Choose File, Save. You can also press Ctrl+S.
7. In Lumberyard Editor, press Ctrl+G to enter game mode and test your script.
8. Do the following:
   - To move the sphere forward, press W.
   - To move the sphere backwards, press S.
   - To move the sphere from side to side, press A and D.
   - To spawn a projectile that propels forward, press the Spacebar.

     If you hold the Spacebar, the spawn fires once and the Delay node resets the Once node every 0.25 seconds.
9. When you are done testing your script, press Esc.

**Step 7: Create a Target Entity**

Now that the Player entity shoots projectiles, you can add a Target entity for the Player entity to destroy.
To create a target entity

1. In Lumberyard Editor, create an entity: Right-click in the Perspective viewport near your controllable sphere and choose Create entity.

2. In the Entity Inspector, for Name, enter Target.

3. Click Add Component and then choose the Mesh component.

4. In the Mesh component, for Mesh asset, click the browse (...) button, select the \SamplesProject\Objects\default\primitive_cylinder.cgf file, and then click OK.

5. Click Add Component and choose the following components:
   - Static Physics
   - Mesh Collider
   - Tag

6. In the Tag component, click + to add a tag and for [0], enter Target.
7. Verify that your **Target** entity appears like the following.

Example

![Image of Target entity settings](image-url)
Step 8: Add Logic to the Projectile to Destroy Target Entities

Now that you've set up the **Target** entity, you can add logic to the projectile to destroy entities that have the **Target** tag.

To add logic to destroy target entities

1. In the **Script Canvas** editor, open the `projectile.scriptcanvas` file.
2. Do the following to add collision nodes:
   a. In the **Node Palette**, enter `collision` in the search box.
   b. Under **Physics, Physics Component**, drag **On Collision** from the **Node Palette** to the graph. This node has a special data enter called `collision`.

3. Do the following to add a **Set hit** node:
   a. In the bottom-right pane, in the **Variable Manager**, click **Create Variable**. You can use variables to store and modify persistent values in your graph.
      For more information, see Managing Script Canvas Variables (p. 2482).
   b. Select **Collision**, double-click **Variable 1** and then rename the variable to **hit**.
   c. Right-click the **hit** variable and choose **Set hit**.
4. Select the **Out** pin for **On Collision** and drag to connect it to the **In** pin for the **Set hit** node.
5. From **On Collision**, drag the **Collision** pin to connect it to the **Collision** pin of the **Set hit** node.
6. Do the following to add tags:
   
a. In the **Node Palette**, enter **CRC32** in the search box.
   
b. Under **Math, CRC32**, drag **Create CRC32** from the **Node Palette** to the graph. The tag system uses CRC32s to store tag names.
   
c. From **Set hit**, drag the **Out** pin to connect it to the **In** pin of the **Create CRC32** node.
   
d. In the **Create CRC32** node, for **String**, enter **Target**.

![Create CRC32 Node]

   e. In the **Node Palette**, enter **tag** in the search box.
   
f. Under **Gameplay, Tag**, drag **Has Tag** from the **Node Palette** to the graph.

![Has Tag Node]

g. From **Create CRC32**, drag the **CRC32** pin to connect it to the **Tag** pin of the **Has Tag** node.

7. Do the following to add a **Get hit** node:

   a. In the **Variable Manager**, right-click the **hit** variable and choose **Get hit**.
   
   b. From **Get hit**, drag the **entity: EntityID** pin to connect it to the **Source** pin of the **Has Tag** node. This enables the **Has Tag** node to check the entity that the projectile collided with rather than itself.
   
   c. From **Create CRC32**, drag the **Out** pin to connect it to the **In** pin of the **Get hit** node.
   
   d. From **Get hit**, drag the **Out** pin to the **In** pin of the **Has Tag** node.
8. Do the following to add the **If** node:

   a. In the **Node Palette**, enter `if` in the search box.
   b. Under **Logic**, drag **If** from the **Node Palette** to the graph.
   c. From **Has Tag**, drag the **Out** pin to connect it to the **In** pin of the **If** node.
   d. From **Has Tag**, drag the **Result** pin to connect it to the **Condition** pin for the **If** node.

9. Do the following to add a **destroy** node:

   a. In the **Node Palette**, enter `destroy` in the search box.
   b. Under **Entity, Game Entity**, drag **Destroy Game Entity and Descendants** from the **Node Palette** to the graph.
c. From If, drag the True pin to connect it to the In pin of the Destroy Game Entity and Descendants node.

d. From Get hit, drag the entity: EntityID pin to connect it to the EntityID pin of the Destroy Game Entity and Descendants node.

e. Verify that your projectile.scriptcanvas graph looks like the following.

Example

![Diagram of projectile.scriptcanvas graph]

10. In the Script Canvas editor, choose File, Save. You can also press Ctrl+S.

11. In Lumberyard Editor, press Ctrl+G to enter game mode and test your script.

12. To aim and shoot at the target, do the following:

   • To move the sphere forward, press W.
   • To move the sphere backward, press S.
   • To move the sphere from side to side, press A and D.
   • To spawn a projectile that propels forward, press the Spacebar.

13. When you are done testing your script, press Esc.
