What is Lumberyard?

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Amazon Lumberyard is a free, cross-platform, 3D game engine that allows you to create high-quality games, connect your games to the compute and storage of the AWS Cloud, and engage fans on Twitch. With Lumberyard, you can spend more time creating great gameplay and building communities of fans, and less time on the heavy lifting of building a game engine and managing servers.

Lumberyard offers everything a professional game developer can expect, such as a full-featured editor, native code performance, and stunning visuals. It also includes hundreds of other ready-to-use features like networking, cinematics, the Script Canvas editor, the Animation Editor, audio tools, and more.

Interested? Want to get started?

- Download the latest version of the Lumberyard beta
- Kickstart your learning by watching tutorial videos
- Sign up for and participate in the Amazon Lumberyard forums

Image from Starter Game. For more sample projects and levels, see Using Lumberyard sample projects and levels (p. 142).

Professional-Grade AAA Engine

Lumberyard helps you build rich, engaging, world-class games through its comprehensive and proven toolset and highly optimized runtime performance.
Beautiful Worlds

The visuals technology of Lumberyard can bring to life any virtual environment. Your artists get a powerful toolbox to create high quality visual elements, such as physically based shaders, dynamic global illumination, particle effects, lifelike vegetation, real-time dynamic water caustics, and volumetric fog. They can also produce cinematic features like color grading, motion blur, depth of field, and integrated HDR lens flares.

For more information, see the following topics:

- Creating levels and adding environment effects (p. 1219)
- Adding particle effects (p. 1504)
- Create screen effects (p. 1811)

Asset Changes

With the Lumberyard's Asset Processor, you can quickly get assets into the engine. Save a file (for example, from Maya or Photoshop) into a directory, and the Asset Processor automatically processes that file from source art into game-ready assets. If you edit an asset, Lumberyard detects the change and automatically updates it in the background.

For more information, see Using Asset Processor (p. 248).

Component Entities

The component entity system helps you compose complex entities out of simpler entities. Content creators can drag and drop components to build behaviors, edit component settings live in the editor, and create Lua scripts to quickly change or extend an entity's behavior. To build and iterate for complex scenes, entities can be grouped together into slices. Those slices can in turn be used to create more complex slices, resulting in a fully cascading prefab system. If you change a slice, you can share your changes to all the slice instances, or keep your changes exclusive to just that instance.

For more information, see the following topics:

- Working with component entities (p. 462)
- Working with Slices (p. 510)

Compelling Characters

Artists can use Lumberyard to create believable characters and high-fidelity performances. Lumberyard's character tool, Animation Editor, combines animation, attachments, and physics simulations with blend shape, blend space, and animation layering.

For more information, see Create and animate characters (p. 1340).

Robust Networking

Lumberyard introduces GridMate, a robust and flexible networking solution designed for efficient bandwidth usage and low-latency communications. You can synchronize objects over the network with GridMate's replica framework. GridMate's session management can be integrated with major online console services and helps you handle peer-to-peer and client–server topologies with host migration.

For more information, see Using Lumberyard Networking (p. 1990).
Real-Time Gameplay Editing

Real-time gameplay editing helps you iterate on gameplay and immediately see your results without waiting for builds or leaving the editor. Lumberyard's Asset Processor automatically converts and optimizes your game assets in real time so that you can import game objects, fine-tune behavior, and play the game that you created.

Modular Gems

Lumberyard's Modular Gems system gives you a library of prebuilt features with which you can start new projects or prototype ideas quickly. Modular Gems offer increased control over which technologies to include in your game project. Create your own modular Gems or use the Gems included with Lumberyard, such as physics, multiplayer, "white box" rapid prototyping tools, and more.

For more information, see Add modular features and assets with Gems (p. 1064).

Wwise LTX

Lumberyard includes a version of Audiokinetic's advanced, feature-rich sound engine. Sound designers and composers can author rich soundscapes for your games.

For more information, see Adding Audio and Sound Effects (p. 3140).

Integrated with AWS

Lumberyard is deeply integrated with AWS so you can build live and multiplayer games with dramatically less cost, time, and technical risk. AWS integrations include:

Amazon GameLift

Amazon GameLift is an AWS service for deploying, operating, and scaling session-based multiplayer games. You can scale high-performance game servers up and down to meet player demand without additional engineering effort.

For more information, see the Amazon GameLift Developer Guide.

Cloud Canvas

Cloud Canvas is Lumberyard's technology for connecting your game to Amazon Web Services. With Cloud Canvas, you can use AWS to implement cloud-hosted features and create asynchronous multiplayer games. Using cloud gems, you can build gameplay that connects to AWS services, such as Amazon DynamoDB, AWS Lambda, and Amazon S3.

For more information, see Implementing Connected Features with Cloud Canvas (p. 2106).

AWS SDK for C++

The AWS SDK for C++ provides C++ API operations for numerous AWS services including Amazon S3, Amazon EC2, Amazon DynamoDB, and more, with support for all major native platforms. You can use the SDK to integrate AWS components into your game.
For more information, see the AWS SDK for C++.

Integrated with Twitch

Lumberyard is integrated with Twitch so that you can build games that engage with more than 1.7 million monthly broadcasters and more than 100 million monthly viewers on Twitch.

Twitch ChatPlay

The Twitch ChatPlay feature within Lumberyard helps you build gameplay that interacts in real time with Twitch viewers. For example, you can build a game where viewers can vote on game outcomes, gift power-ups to their favorite players, or change the level based on the number of viewers watching the player.

For more information, see Twitch ChatPlay System (p. 2096).

Free with Source

Lumberyard is free, including source code. You can customize Lumberyard for your team and vision for your project today, and for future projects. There are no seat fees, subscription fees, or requirements to share revenue. Only pay for the AWS services that you choose to use.

For more information, see the Lumberyard Licensing FAQ.

Lumberyard Systems

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard consists of the following major systems that help you develop levels within the editor:

- Adding Audio and Sound Effects (p. 3140)
  
  The audio translation layer (ATL) provides an interface between Lumberyard and third-party audio middleware so you can change your audio implementation without affecting the game logic.

- Create and animate characters (p. 1340)
  
  The character animation system combines skeletal-based deformation of meshes with morph-based vertex deformation to facilitate complex animation. You can create realistic character movements by playing and blending animation sequences, controlling facial expressions, and applying damage effects. Characters can play scripted movements, employ AI navigation.

- Create cinematic sequences (p. 1583)
  
  Cinematics are interactive movie animations. You can use Lumberyard to add cutscenes to your game. You can also add scripted events so that a sequence of objects, animations, and sounds are triggered in the game. The players can view these from their own (first person) or another's (third person) perspective.
• **Working with component entities (p. 462)**

The component entity system provides a modular and intuitive construction of game elements, such as lights, cameras, trigger areas, and objects. The component entity system works at both the system level and the entity level. It employs reflection, serialization, event bus (EBus) messaging, fully cascading slices, and the ability to drag and drop and edit entities and their components in Lumberyard Editor.

• **Add modular features and assets with Gems (p. 1064)**

Gems are packages that contain code and assets to augment your game projects, such as the ChatPlay and Woodland Asset Collection gems. You can select gems to include in your project through the Lumberyard Project Configurator (p. 43) and from the command line.

• **Creating levels and adding environment effects (p. 1219)**

A level, also known as world or map, represents the space or area available to the player while completing a game objective. A level's environment includes lighting, terrain, bodies of water, vegetation, sky, and weather effects.

• **Materials (p. 1636)**

You can use the **Material Editor** to create and apply materials, map textures, set opacity and lighting effects, set shader parameters, create vertex deformations, tessellation, and more.

• **Adding particle effects (p. 1504)**

The particle effects system simulates explosions, fire, smoke, sparks, water spray, fog, snow, rain, and other effects.

• **Script Canvas (p. 2420)**

Create game logic and behaviors with Lumberyard's new visual scripting environment.

• **Shader Rendering System (p. 1639)**

Lumberyard's physically based rendering (PBR) shaders use real-world physical rules and properties to describe how incoming light interacts with objects. This means that object materials look more convincing under different lighting conditions.

• **Twitch ChatPlay System (p. 2096)**

The Twitch ChatPlay Gem provides a flexible framework to create customized game interactions between broadcasters and spectators on Twitch, the world's leading social video platform and community for gamers. Twitch ChatPlay includes support for chat commands, polls, and surveys that can be triggered by Twitch viewers through the Twitch chat channel.
• **Creating and Customizing Project User Interfaces (p. 2874)**

With the **UI Editor**, you can create and customize various parts of the game user interface, such as images, text, buttons, menus, scroll boxes, and heads-up displays (HUDs).

• **Create virtual reality projects in Lumberyard (p. 3248)**

Virtual reality (VR) is a technology that replicates the gaming environment and simulates a user's presence in it. With virtual reality players, feel as if they are in the game world as they interact with the environment, characters, and objects. Lumberyard's virtual reality system integrates the use of the Oculus Rift and HTC Vive head-mounted displays (HMD) on PC gaming systems.

The following Lumberyard tools are outside of the main editor and are used for project and game development:

• **Working with the Asset Pipeline and asset files (p. 247)**

The Asset Pipeline converts source art and other assets into platform-specific, game ready data.

• **Managing Game Projects with Lmbr.exe (p. 56)**

Lmbr.exe is a command-line tool for managing capabilities, game projects, and gems.

• **Developing for Android and iOS with Lumberyard (p. 3166)**

You can use Lumberyard to build your games for Android devices such as the NVIDIA Shield, Samsung Galaxy Note 5, and Motorola Nexus 6, and iOS devices that use the A8 GPUs or later. See Apple's GPU list for a list of these devices.

• **Create macOS projects in Lumberyard (p. 3263)**

You can use Lumberyard to build macOS applications.

• **Creating Lumberyard Executables for Linux (p. 3269)**

Lumberyard supports compiling and deploying the Windows client for a multiplayer project on a Linux dedicated server.

• **Project Configurator (p. 43)**

The Project Configurator is a standalone application that allows you to specify to the Waf build system which game projects and assets (gems) to include in a game build. With it, you can create new projects, save active projects, configure advanced settings, and enable, disable, or create new gems.

• **Profiling, Testing, and Debugging Game Projects (p. 1920)**

Lumberyard includes a number of tools for testing builds, profiling performance, and debugging.
Using the Waf Build System (p. 63)

With the Waf build system, you can switch between various build pipelines and ensure that you build only what is needed. You can use extensions, such as automatic project generation, or a simple GUI to modify the command line base system for your project requirements.

Supported platforms

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use Lumberyard to develop games for the following platforms:

- Microsoft Windows PC
- Android
- iOS
- macOS
- PlayStation
- Xbox
- Linux (dedicated server only)

Some platforms have additional requirements.

- For console support, see Developing Games for Xbox One and PlayStation Partners portals.
- For mobile devices, see Developing for Android and iOS with Lumberyard (p. 3166).
- For macOS, see Create macOS projects in Lumberyard (p. 3263).
- For Linux dedicated servers, see Creating Lumberyard Executables for Linux (p. 3269).

Setting up Amazon Lumberyard

Amazon Lumberyard has a two-part installation process:

1. The installer application downloads, extracts, and installs Lumberyard.
2. Setup Assistant configures and installs additional software based on your development needs. Jump right in to the Lumberyard Editor with an Express Install or customize Lumberyard's features for your development needs with a Custom Install.

   **Note**
   To create and build new projects, or add gems to existing projects, either select Custom Install or run Setup Assistant again later to enable this functionality.

After Lumberyard is installed, use Project Configurator to select a project or create a new project. The following sections detail the minimum requirements for Lumberyard and guide you through the installation process.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard has a minimum set of system requirements for development, as outlined in the following sections. Disk space and RAM requirements are dependent on the options that you choose during installation. If you have already installed Lumberyard, you can use Lumberyard Setup Assistant to see the requirements for the tools and features that you want for your Lumberyard development environment. Lumberyard Setup Assistant provides information about installing third-party software and SDKs on your computer. For more information, see Using Lumberyard Setup Assistant to Set Up Your Development Environment (p. 16).

If your system is capable of running a modern real-time 3D game with good performance you should be set, however, review these detailed requirements to be certain.

Lumberyard requires Windows 10.

**Lumberyard minimum hardware requirements:**

- 3 GHz quad-core processor
- 8 GB RAM
- 2 GB VRAM DirectX 11 or later compatible video card
  - NVIDIA GeForce GTX 660 Ti with driver version 368.81 or later
  - AMD Radeon HD 8730M with driver version 16.15.2211 or later
- 1366 x 768 px screen resolution
- 60 GB of free disk space

**Note**

If you select options to build the engine, editor, or tools in **Setup Assistant**, 14 GB RAM is required for compilation.

Some advanced graphics features require a DirectX 12 or later compatible video card. Required free disk space is dependent on the options that you select when installing Lumberyard.
Developer tools

You can use the Lumberyard Editor and tools without installing additional software. To create new projects or use advanced development features in Lumberyard, you need a developer environment that includes Microsoft Visual Studio. The following versions are supported:

- (Recommended) Microsoft Visual Studio 2019 version 16.2.4 thru version 16.9.x.
  
  **Important**
  There are some issues that arise when using the MSVC compiler shipped with Visual Studio 2019 versions 16.8, 16.8.1, and 16.8.2. For more details, check out the Lumberyard 1.28 Known Issues.
  

  **Note**
  The definitive source for the minimum version of Visual Studio for any particular release of Lumberyard is set in the file `dev\_WAF\settings\platforms\platform.win_x64_vs2019.json`. Look for the `vswhere-args` settings. The minimum version is the first value in the `default_value` range.

Microsoft offers Visual Studio Community edition free to individual developers. For more information and to download and install Visual Studio Community, visit the Visual Studio Community portal.

Visual Studio 2017 and 2019 required features

The default Visual Studio installation might not include all of the features that are required by Lumberyard. Ensure that the following Visual Studio features are enabled:

1. Launch the Visual Studio Installer from your download directory or the Start Menu if you've already installed Visual Studio.
2. If you've installed Visual Studio, choose More - Modify on the version of Visual Studio you'll use with Lumberyard.
3. On the Workloads tab:
   - Select Game development with C++.
   - In the Installation details panel on the right, select at least one Windows 10 SDK.
   - Select Desktop development with C++.
4. On the Individual components tab, under Compilers, build tools, and runtime, make sure that a VC++ toolset that corresponds to the installed version of Visual Studio has been selected:
   - If using Visual Studio 2017: Select at least one version of the VC++ 2017 toolset.
   - If using Visual Studio 2019: Select at least one version of the MSVC v142 - VS 2019 C++ x64/x86 build tool.
   - (Optional) To build with the Visual Studio 2017 toolset in Visual Studio 2019, select MSVC v141 - VS 2017 C++ x64/x86 build tools.

  **Note**
  Incredibuild users: Installing, reinstalling, or upgrading Visual Studio may cause the Incredibuild Agent to lose its settings or require an update. After modifying Visual Studio, be sure to confirm your Incredibuild Agent is active. For instructions on configuring the agent properly, see Compiling with IncrediBuild (p. 118).

  **Note**
  Beginning with Visual Studio 2017, Microsoft now releases updates on a more frequent cadence (in some cases weekly). Lumberyard is tested with the latest version of Visual Studio available during the release cycle.
Visual C++ redistributable packages

Lumberyard Installer will attempt to download and install the required Visual C++ Redistributable packages during the installation process. Under some circumstances, the installation of these redistributable packages may fail. If you receive a missing Visual C++ runtime .dll error while running Lumberyard Installer, Lumberyard Setup Assistant, or Project Configurator, do the following:

1. Check that the Visual C++ redistributable installers for Visual Studio 2012 and Visual Studio 2019 have been successfully downloaded. The installers are located in the corresponding Visual Studio directories in the \lumberyard_version\dev\Tools\Redistributables\ directory.
2. If the Visual C++ redistributable installers for Visual Studio 2012 and Visual Studio 2019 have not been downloaded by Lumberyard Installer, manually download the installers from Microsoft.
   • Visual C++ Redistributable for Visual Studio 2012
   • Visual C++ Redistributable for Visual Studio 2019
3. Run both Visual C++ redistributable installers.
4. Retry the Lumberyard installation after the Visual Studio redistributables have successfully installed.

Note

Installing Lumberyard

Download the latest version of Lumberyard Installer

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can also download earlier versions of Lumberyard and assets from the Amazon Lumberyard Downloads page.

Note
Verify that you have the required hardware and software for Lumberyard. For more information, see System requirements (p. 8).

For an in-depth tutorial about downloading and installing Lumberyard, watch the following video:

How to Install the Amazon Lumberyard Game Engine

Topics
• Using the Lumberyard Installer (p. 10)
• Using GitHub to Download Lumberyard (p. 11)
• Lumberyard Directories and Files (p. 12)

Using the Lumberyard Installer

The Lumberyard Installer extracts the Lumberyard files and adds shortcuts to your desktop and start menu for the following:
• Lumberyard Setup Assistant
• Project Configurator
• Lumberyard Editor

If you have an existing Lumberyard project and you want to upgrade, see Upgrading Lumberyard (p. 12).

Note
If you get file errors during extraction about AssetProcessor.exe, AssetProcessor_temp.exe, or CrySystem.dll, verify if your antivirus software is placing these files in quarantine. If needed, grant exceptions for the affected files.

To use the Lumberyard installer

1. Navigate to your download directory and run the Lumberyard Installer executable file: LumberyardInstaller.exe

2. (Optional) Change the location of the installation by selecting Options. The default installation location is C:\Amazon.

3. On the Welcome page of the installer, choose Install.

Note
In some situations, the Lumberyard Installer can stop responding and refuse to progress. The only known remedy at this time is to forcibly terminate the installer through the Windows Task Manager, or reboot, then retry the installation.

4. Follow the instructions to complete your installation.

5. On the Installation Successfully Completed page, click Launch Lumberyard Setup Assistant to install required third-party software and SDKs. For more information, see Running Lumberyard Setup Assistant (p. 16).

Using GitHub to Download Lumberyard

Each Lumberyard release exists as a separate branch in GitHub. To download Lumberyard, see the Amazon Lumberyard page on GitHub.
Lumberyard Directories and Files

After you install Lumberyard, the Lumberyard root directory includes the following folders and files:

- dev
  - _WAF_ – Waf build system files.
  - Bin64 – Binaries directory and configuration files for the Resource Compiler.
  - Bin64vc141 – Binaries directory and configuration files for Visual Studio 2017.
- Code – Source files directory and solution files.
- Editor – Editor assets.
- Engine – Engine assets.
- Gems – Optional systems and assets.
- MultiplayerSample – Multiplayer sample project that demonstrates how to build a multiplayer game with the new component entity system. For more information, see Multiplayer Sample (p. 155).
- ProjectTemplates – Configuration files, libraries, and scripts for the empty template.
- SamplesProject – Sample project. For more information, see Samples Project (p. 146).
- Tools – Third-party tools and plugins.
- engineroot.txt – System file required by Lumberyard Setup Assistant.
- 3rdParty
  - Third-party software required to use or compile Lumberyard
  - 3rdParty.txt – System file used by other third-party tools to verify the directory.

Upgrading Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

If you have an existing version of Lumberyard installed on your computer, you have several options for upgrading:

- Upgrade Lumberyard with an existing version in source control
- Upgrade Lumberyard without an existing version in source control
- Upgrade Lumberyard without source control

We recommend using source control, which allows relationships to be created between the installed versions of Lumberyard and the changes you make to your projects, among other benefits like revision history.

**Note**
When choosing a source control solution, keep in mind that Lumberyard provides plugins and tools for working with Perforce.

Topics

- Upgrading Lumberyard with an Existing Version in Source Control (p. 13)
- Upgrading Lumberyard without an Existing Version in Source Control (p. 13)
- Upgrading Lumberyard without Source Control (p. 13)
To set up Lumberyard in source control

1. Download and install Lumberyard. For information, see Installing Lumberyard (p. 10).
2. Check into source control a pristine, unmodified version of Lumberyard. For information about file types to ignore, see Files to Exclude When Upgrading Lumberyard (p. 15). For information about the Lumberyard directory structure, see Installing Lumberyard (p. 10).
3. In source control, create a new branch off the pristine Lumberyard branch to use for development.
4. Make changes to the new development branch only.

Upgrading Lumberyard with an Existing Version in Source Control

Before you begin upgrading, check into source control the previous pristine version of Lumberyard.

To upgrade Lumberyard with an existing version in source control

1. In Windows Explorer, locate the directory where you installed the previous pristine version of Lumberyard. Delete the contents of this directory to remove the files from source control.
2. Download and install the new version of Lumberyard to the empty directory. Ensure the directory structure is identical to the previous version.
3. Using source control, reconcile the files in the directory with the files in the pristine Lumberyard branch. For example, if you use Perforce, click Actions, Reconcile Offline Work.
4. Build and test the reconciled version locally to ensure it works.
5. Submit the reconciled version to the pristine Lumberyard branch as the new version of Lumberyard.
6. Integrate the updated, pristine Lumberyard branch into your development branch.

Upgrading Lumberyard without an Existing Version in Source Control

Follow these steps to prepare your source control to upgrade Lumberyard.

To upgrade Lumberyard without an existing version in source control

1. Check into source control the pristine version of Lumberyard that you used to create your game project.
2. Create a new branch off the pristine Lumberyard branch to use for development.
3. In Windows Explorer, locate the directory for the new development branch and delete the contents.
4. Copy the files from your existing game project to the empty directory.
5. Using source control, reconcile the files in the development branch directory with the files in source control. Accept your changes.
6. Follow the steps in Upgrading Lumberyard with an Existing Version in Source Control (p. 13).

Upgrading Lumberyard without Source Control

You can upgrade Lumberyard without using source control; however, we do not recommend this method.
To upgrade Lumberyard without source control

1. Download and install the latest version of Lumberyard to a location that will not overwrite any previous versions. For information, see Installing Lumberyard (p. 10).
2. Use Lumberyard Setup Assistant to install the third-party software and SDKs required to run Lumberyard. For information, see Running Lumberyard Setup Assistant (p. 16).
3. Configure and compile the Samples Project to test your build environment.

Upgrading Your Game Projects

Once you have upgraded Lumberyard, you can upgrade each of your game projects.

To upgrade your game project

1. Copy your project's code (located in the \lumberyard_version\dev\Code\project_name directory) and game folder (located in the \lumberyard_version\dev\project_name directory) to the new Lumberyard directory.
2. Create a project.json file for your project with the following:

   ```json
   {
     "project_name": "project_name",
     "product_name": "project_name",
     "executable_name": "project_nameLauncher",
     "code_folder": "Code/project_name",
     "modules": ["project_name"]
   }
   ``

   Replace all instances of project_name with your project's name.

   For example, if your project was called MyProject, the project.json file would include the following:

   ```json
   {
     "project_name": "MyProject",
     "product_name": "MyProject",
     "executable_name": "MyProjectLauncher",
     "code_folder": "Code/MyProject",
     "modules": ["MyProject"]
   }
   ``

3. Save the project.json file in the \lumberyard_version\dev\project_name directory.
4. Run the Project Configurator (located in the \lumberyard_version\dev\Bin64 directory) and set your game project as the default project. When finished, close the Project Configurator.
5. Edit the wscript file (located in the \lumberyard_version\dev\Code\project_name\Game directory) to ensure the includes under #Common appear as follows:

   ```
   #===============================================================================
   # Common
   #===============================================================================
   includes = [ '.', 
                bld.Path('Code/CryEngine/CryCommon'),
                bld.Path('Code/CryEngine/CryAction')],
   ```

6. In a command line window, locate the new dev directory and enter the following build command for your version of Visual Studio:
Files to Exclude When Upgrading Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When adding Lumberyard to source control, there are various files that you should exclude because they are generated, temporary, or programming-specific.

File types and folders in the entire repository to exclude

- *.ilk
- *.suo
- *.user
- *.o
- *.temp
- *.bootstrap.digests
- *.log
- *.exp
- *.vssettings
- *.exportlog
- *.mayaSwatches
- *.ma.swatches
- *.dds
- *.bak
- *.bak2
- *.options
- *.pyc
- *.db
- Solutions
- BinTemp
- Cache

File types and folders in the \dev\Code directory to exclude.

- SDKs

File types and folders in each game folder (SamplesProject, MultiplayerProject, and so on) to exclude.

- Compiled assets
  - *.dds
  - *.caf
  - *.animsettings
- Editor backup files – *.bak*
Set Up a Development Environment

- Pak files that are exported from level files in the editor – *.pak

Using Lumberyard Setup Assistant to Set Up Your Development Environment

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Lumberyard Setup Assistant application to validate that you have installed the third-party software required to run Lumberyard.

Lumberyard Setup Assistant offers the following benefits:

- Ensures you have the required runtime software installed
- Ensures you have the required SDKs located in the source tree
- Provides plugins for certain programs detected
- Validates registry settings, paths, and libraries

You should run this application periodically and after you make any changes to your environment, to validate and repair settings and paths. You can also customize the application with a configuration file to easily integrate your specific directory structure.

**Note**
Certain third-party software may require a license. Please consult the terms of service before installing the software.

Prerequisites

- Lumberyard Setup Assistant is supported on the Windows operating system.
- Certain options require an installation of Microsoft Visual Studio. For more information, see System requirements (p. 8).

Topics

- Running Lumberyard Setup Assistant (p. 16)
- Using Lumberyard Setup Assistant Batch (p. 18)
- Customizing Lumberyard Setup Assistant (p. 20)

Running Lumberyard Setup Assistant

To learn about configuring Lumberyard Setup Assistant, watch the following video tutorial.

Note
Before you run Lumberyard Setup Assistant, verify the following:
• 3rdParty.txt file appears in the `lumberyard_version\3rdParty` directory
• engineroot.txt appears in the `lumberyard_version\dev` directory

Lumberyard Setup Assistant requires these files to properly detect third-party software and SDKs.

**To use Lumberyard Setup Assistant**

1. Open Lumberyard Setup Assistant with your preferred method:
   - From the desktop, double-click the **Setup Assistant** icon
   - Navigate to the `lumberyard_version\dev\Tools\LmbrSetup\Win` directory and double-click `SetupAssistant.exe`

2. In the **Full Install** box, choose **Start a Full Installation**.

3. Verify that the engine root path is correct.

4. On the **Get started** page, select what you want to do:
   - **Create, Modify and Build projects** – Select this option if you intend to create and build new projects with Lumberyard on the **Windows platform**, or make changes to the engine, asset pipeline, or other tools.
   - **Compile for Android devices**
   - **Setup for Linux Dedicated Server**

You can also create, enable, and disable these capabilities from the command line. For more information, see Using Lumberyard Setup Assistant Batch (p. 18) and Lmbr.exe (p. 56).

5. Select **Visual Studio 2017** or **Visual Studio 2019**.

**Note**

We recommend that you select only **one** version of Visual Studio - the one that you will use to compile your projects. If both are enabled, you will be asked which compiler to use when you rebuild your project in Project Configurator.
**Set Up a Development Environment**

**Note**
Selecting a version of Visual Studio here will enable it as a build platform and enable a Visual Studio solution to be generated for that version. For more information about build settings specific to Visual Studio, see Waf User Options and Settings (p. 78).

**Note**
For more information about installing and configuring Visual Studio for Lumberyard, see Developer tools (p. 9).

6. Click **Next**.
7. Follow the instructions on each page.
8. When you have completed installing software and SDKs, the **Summary** page displays information about your Lumberyard environment. From the **Summary** page, you can launch the Lumberyard Editor by choosing **Launch Editor**. If you’d like to choose an existing project or create a new project, choose **Configure project** to launch Project Configurator. For more information about configuring your project, see Creating Lumberyard projects (p. 43).

### Using Lumberyard Setup Assistant Batch

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The command line version of Lumberyard Setup Assistant is useful for server and build administrators who want to create a batch file to run the same configuration on multiple machines.

You can find the executable file `SetupAssistantBatch.exe` in the `lumberyard_version\dev\Tools\LmbrSetup\Win` directory. This executable uses the `SetupAssistantConfig.json` file to complete its tasks.

You can also use the batch file to create, enable, and disable capabilities, and to modify your projects and gems. For more information, see `Lmbr.exe` (p. 56).

**To use Lumberyard Setup Assistant Batch**

1. Open a command line window.
2. Navigate to the `Win` directory for your Lumberyard installation.
   ```bash
cd lumberyard_version\dev\Tools\LmbrSetup\Win
   ```
3. Run the `SetupAssistantBatch.exe` and modify the commands as needed. See the following list of commands.

**Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--help</code></td>
<td>Lists all commands and descriptions.</td>
</tr>
<tr>
<td><code>--3rdpartypath</code></td>
<td>Sets the third-party directory to the specified parameter. The default is the <code>lumberyard_version\3rdParty</code> directory. If you change the third-party directory, ensure that you also move the <code>3rdParty.txt</code> file.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>--sdkpath</td>
<td>Sets the location of the Lumberyard SDK to the specified parameter.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>This command expects a root where Lumberyardroot.txt is located.</td>
</tr>
<tr>
<td>--disablecapability</td>
<td>Disables the specified capabilities.</td>
</tr>
<tr>
<td></td>
<td>• Run your game project.</td>
</tr>
<tr>
<td></td>
<td>• Run Lumberyard Editor and tools.</td>
</tr>
<tr>
<td></td>
<td>• Compile the game code.</td>
</tr>
<tr>
<td></td>
<td>• Compile the engine and asset pipeline.</td>
</tr>
<tr>
<td></td>
<td>• Compile Lumberyard Editor and tools.</td>
</tr>
<tr>
<td></td>
<td>• Compile for Android devices.</td>
</tr>
<tr>
<td></td>
<td>• Compile for iOS devices.</td>
</tr>
<tr>
<td>--enablecapability</td>
<td>Enables the specified capabilities:</td>
</tr>
<tr>
<td></td>
<td>• Run your game project.</td>
</tr>
<tr>
<td></td>
<td>• Run Lumberyard Editor and tools.</td>
</tr>
<tr>
<td></td>
<td>• Compile the game code.</td>
</tr>
<tr>
<td></td>
<td>• Compile the engine and asset pipeline.</td>
</tr>
<tr>
<td></td>
<td>• Compile Lumberyard Editor and tools.</td>
</tr>
<tr>
<td></td>
<td>• Compile for Android devices.</td>
</tr>
<tr>
<td></td>
<td>• Compile for iOS devices.</td>
</tr>
<tr>
<td>--all</td>
<td>Enables all capabilities.</td>
</tr>
<tr>
<td>--none</td>
<td>Disables all capabilities.</td>
</tr>
<tr>
<td>--no-modify-environment</td>
<td>Prevents Lumberyard Setup Assistant from changing your environment variables.</td>
</tr>
</tbody>
</table>

**Example Commands**

The following example sets the paths, clears all selected capabilities, and then enables the capability rungame.

```bash
setupassistantbatch.exe --3rdpartypath "d:\lumberyard_version\3rdParty" --sdkpath "d:\lumberyard_version\dev" --none --enablecapability rungame
```

**Note**

To examine the values for each capability, see the SetupAssistantConfig.json file in the lumberyard_version\dev directory.

If the command runs correctly, this program returns the exit code 0.

The following example disables all capabilities and enables only the compilation tasks. This command is commonly used for hosting a build server:

```bash
setupassistantbatch.exe --none --enablecapability compilegame --enablecapability compileLumberyard --enablecapability compilesandbox
```
Customizing Lumberyard Setup Assistant

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the SetupAssistantConfig.json configuration file (located in the \lumberyard_version\dev\Tools\LmbrSetup directory) to customize Lumberyard Setup Assistant for your project. The settings in this file are prioritized above internal default settings.

For example configuration data that you can copy and paste into your own .json file, refer to the SetupAssistantConfig.json.example file (located in the \lumberyard_version\dev\Tools \LmbrSetup directory).

Save your changes to the SetupAssistantConfig.json configuration file in the \lumberyard_version\dev\Tools\LmbrSetup directory. To validate your changes and ensure there are no syntax errors (such as a missing comma), run the SetupAssistantBatch.exe file (located in the \lumberyard_version\dev\Tools\LmbrSetup\Win directory) from a command line window.

Enabling and Disabling Features

You can enable or disable software and third-party SDKs based on your project requirements. In the SetupAssistantConfig.ini file (located in the \lumberyard_version\dev\Tools\LmbrSetup directory), uncomment the lines (delete the semicolon) to disable specific features.

Adding New Third-Party SDKs

In addition to enabling or disabling software and third-party SDKs, you can edit the SetupAssistantConfig.json file (located in the \lumberyard_version\dev\Tools\LmbrSetup directory) to add new, third-party SDKs to your project configuration.

When you add third-party SDKs to the SetupAssistantConfig.json file, which is loaded after the internal configuration file, the .json file removes and replaces entries in the internal configuration. This allows you to customize your project configuration without having to recompile.

To add new tasks (capabilities)

1. If currently running, close the Lumberyard Setup Assistant.
2. Navigate to the \lumberyard_version\dev\Tools\LmbrSetup directory.
3. Edit the SetupAssistantConfig.json file to do the following:
   a. Add the task(s) to the Capabilities section.
   b. Update the third-party SDKs to include the appropriate tags.
Set Up a Development Environment

4. Open the Lumberyard Setup Assistant to see your changes.

To add third-party SDKs

1. If currently running, close the Lumberyard Setup Assistant.
2. Navigate to the \lumberyard_version\dev\Tools\LmbrSetup directory.
3. Edit the SetupAssistantConfig.json file to add information for your third-party SDKs. See SDK Fields (p. 21).
   
   Note
   For an example of how to add configuration data, refer to the SetupAssistantConfig.json.example file (located in the \lumberyard_version\dev\Tools\LmbrSetup directory).

4. Open the Lumberyard Setup Assistant to see your changes.

To remove existing third-party SDKs

1. If currently running, close the Lumberyard Setup Assistant.
2. Navigate to the \lumberyard_version\dev\Tools\LmbrSetup directory.
3. Edit the SetupAssistantConfig.json file to create a remove entry with the same identifier.
   
   Note
   For an example of how to add configuration data, refer to the SetupAssistantConfig.json.example file (located in the \lumberyard_version\dev\Tools\LmbrSetup directory).

4. Open the Lumberyard Setup Assistant to see your changes.

Note
When you specify the destination of your code directory, you can use $CODEFOLDERNAME$ or specify the actual name. The code directory is the location where third-party SDKs are expected and is relative to the SDK root. For example, you can change CodeFolderName to myGame/A/b/c.

SDK Fields

You may need to provide information for the following SDK fields.

identifier

Unique string identifier that refers to the SDK. The identifier must be one word and use only lowercase letters.

remove

If true, eliminates an existing entry. The remove and identifier fields are required to remove an entry.

name

Display name of the SDK. Custom SDKs can use any name without language restrictions.
Lumberyard User Guide Lumberyard User Guide
Set Up a Development Environment

version
Version of the SDK.
description
Brief description of the SDK. Custom SDKs can use any description. UTF-8 is supported.
detailedInstructions
(Optional) Detailed instructions to obtain and install the SDK.
tags
Tags to which the SDK applies. For example, to have the SDK run the game, add the rungame tag.
symlinks
List of symlink dictionaries for all junctions (symbolic links) to establish between the 3rdParty directory and the code base. Each symlink uses the following form:
• source – Source directory, relative to the 3rdParty directory.
• destination – Destination directory, relative to the SDK root.
• exampleFile – File that is located in the source and destination folders and that validates the established link.

Configuring Advanced Settings
The SetupAssistantConfig.json file (located in the \lumberyard_version\dev\Tools\LmbrSetup directory) has the following configuration settings in the root element (dictionary):

CodeFolderName
Location of the code directory, relative to the Lumberyardroot.txt file. You can specify relative paths such as .. and ../.. (use forward slash marks) or relative paths with multiple components such as code/mycode/stuff.

ToolsFolderName
Location of the tools directory, relative to the Lumberyardroot.txt file. The default directory is Tools, but you can specify relative folders such as ../tools.

RememberLumberyardRootFolder
If true, saves the Lumberyard root that the user browsed between sessions. If false, automatically detects the Lumberyard root based on the executable location. The default value is false.

Remember3rdPartyFolder
If true, saves the third-party directory that the user browsed between sessions. If false, automatically detects the third-party directory based on the executable location. The default value is false.

Customizing the Maya Environment
The \Tools\Maya\Plugins directory includes the Lumberyard Maya plugin, and the \Tools\Maya\script directory includes the MEL and Python scripts. To enable the Maya plugin functionality, Lumberyard Setup Assistant modifies Maya.ENV to add the required variables to your Maya configuration.

If you use your own Maya tools in addition to the exporter and pipeline tools that Lumberyard provides, you can use the SetupAssistantConfig.json file to add your project-specific paths to the MayaEnvironments tag.

For example configuration data, refer to the SetupAssistantConfig.json.example file (located in the \lumberyard_version\dev\Tools\LmbrSetup directory).
In the following example, #$TOOLSFOLDER#$ is a macro that is substituted with the appropriate tools directory. However, you can also use relative paths, relative to the game project’s root directory that includes Lumberyardroot.txt:

```
"MayaEnvironments" : 
  [ 
    "comment" : "an example entry showing how you can add a path to MAYA_PLUG_IN_PATH in maya.env",
    "identifier" : "MAYA_PLUG_IN_PATH",
    "paths" : ['$TOOLSFOLDER$/maya/plugins']
  ],
  [ 
    "comment" : "an example entry showing how you can add paths to MAYA_SCRIPT_PATH in maya.env",
    "identifier" : "MAYA_SCRIPT_PATH",
    "paths" : [ "%DHTECH_SCRIPT_PATH%\%DHTECH_GAME_PATH%", "%DHTECH_SCRIPT_PATH%\animation" ]
  ],
],
```

### Updating the Code or Tools Location

If your project requires moving the Lumberyard code or tools directory so that it's no longer located in a subfolder called Code or Tools relative to the Lumberyard root, you can edit the SetupAssistantConfig.json file (located in the \lumberyard_version\dev\Tools \LmbrSetup directory) to update the directory location. Ensure the updated directory includes the Lumberyardroot.txt file.

### Enabling a Firewall

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.
Download O3DE or visit the AWS Game Tech blog to learn more.

You can help protect your environment by enabling the firewall settings on all computers running the Asset Processor or Lumberyard Editor to do the following:

- Exclude external connections to ports 4600, 9432, 9433, and 45643 from untrusted IP addresses.
- Exclude connections from every address except 127.0.0.1.
- If you have multiple computers that work together (e.g. a PC and a Mac), you must allow connections to ports 4600, 9432, 9433, and 45643 from the IP addresses for these computers, but exclude all other connections.

Refer to the documentation for your operating system for how to manage your firewall settings.

### Using the Perforce Plugin with Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.
Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard integrates with Perforce as a source control solution. The engine uses the `p4 set` command to configure settings, and the Perforce visual client (P4V) to selectively sync and submit changed assets.
You can use the **Perforce Settings** dialog box to configure how Lumberyard connects to Perforce. The following settings are cached and populated when the dialog box opens:

- **Server** (P4PORT)
- **User** (P4USER)
- **Workspace** (P4CLIENT)
- **Charset** (P4CHARSET)

  **Note**
  
P4_<P4PORT>_CHARSET is also cached. This value is used if it matches your current P4PORT value; otherwise, the value for P4CHARSET is used. For example, if P4PORT is set to my.perforce.server.com:1666, the value P4_my.perforce.server.com:1666 would be used.

Certain values may not be modifiable if your Perforce connection settings are configured using a method that overrides the p4 set command. The following connection methods may override the ability to modify a setting:

- **Config** – A configuration file overrides this connection setting. If detected, the path to the configuration file is displayed. If undetected, you can check the setting for P4CONFIG.
- **Environment** – Your system environment overrides this connection setting. You can check your system's control panel to remove these overrides.

**To use the Perforce plugin menu**

1. In Lumberyard Editor, click the P4 icon in the bottom toolbar.

   **Note**
   
   Hover over the icon to display the connection status.

2. In the drop-down menu, you can do the following:

   - Click **Enable** or **Disable** to toggle the plugin. The **Enable** setting allows you to work online. The **Disable** setting forces you to work offline.

     **Note**
     
     Changes are not tracked in offline mode. If you work offline, you must manually reconcile your work when you reconnect to Perforce.

   - Click **Settings** to view or modify your Perforce settings.

   To restore default settings, click **Reset** for each value. When finished, click **OK** to apply your changes.

---

**Uninstalling Amazon Lumberyard**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

If you want to uninstall Lumberyard, you can remove it with Windows Control Panel. The uninstall removes the Lumberyard Setup Assistant, Project Configurator, and Lumberyard Editor.

**To uninstall Lumberyard**

1. Go to the **Control Panel** and navigate to the list of programs on your computer.
2. Click Lumberyard_**your_version** and then choose Uninstall.
3. In the Lumberyard Setup prompt, choose Uninstall.
   
   After the process is done, the **Uninstall Successfully Completed** message appears.

---

## Lumberyard Programming Concepts and Resources

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This topic provides brief explanations of some important Lumberyard programming concepts and resources. More information links are provided.

**Topics**
- Asset System (p. 25)
- AZ Code Generator (p. 25)
- Building (p. 26)
- Cloud Canvas (p. 26)
- Debugging (p. 26)
- EBuses (p. 26)
- Entities and Components (p. 26)
- Gems and AZ Modules (p. 27)
- Input (p. 27)
- Lua (p. 28)
- Networking (p. 28)
- Reflection System (p. 28)
- Script Canvas (p. 28)
- Slices (p. 28)
- C++ Best Practices for Amazon Lumberyard (p. 28)

### Asset System

The Lumberyard Editor and Lumberyard runtime code use the Lumberyard asset system (p. 247) to asynchronously stream and activate assets.

For information on using the runtime asset system to load already-built assets into a running instance of the engine, see Programming the Lumberyard AZCore Runtime Asset System (p. 304).

For information on adding a custom asset type to Lumberyard, see Adding an Asset Type to Lumberyard (p. 308).

For information on creating a builder for custom assets, see Creating a Custom Asset Builder (p. 318).

### AZ Code Generator

You can use the AZ Code Generator command line utility to generate boilerplate code when the structure of the intended code is known in advance. AZ Code Generator generates source code (or any data or text) from source code that is specially tagged.
Building

You can build your Lumberyard projects in profile mode, debug mode, or release mode.

For more information, see Building Lumberyard projects (p. 61).

Cloud Canvas

Lumberyard's Cloud Canvas (p. 2106) enables connected game features that use AWS cloud computing. You can use the cloud gems (p. 2127) that are included with Lumberyard to provide prepackaged cloud-connected game features. You can use the Cloud Gem Framework (p. 2257) to create your own cloud gems (p. 2259).

For more information about programming with Cloud Canvas, see Getting Started with the Cloud Gem Framework (p. 2258).

Debugging

Lumberyard includes a number of programming tools for testing, profiling, and debugging.

For more information, see Profiling, Testing, and Debugging Game Projects (p. 1920).

EBuses

EBuses (event buses) are Lumberyard's general-purpose messaging system. They dispatch notifications and receive requests.

Components commonly use EBuses in two ways: to dispatch events from a notification bus or to handle requests using a request bus. Some components provide one type of bus, and some components provide both types. You use the EBus class for both EBus types. Some components do not provide an EBus at all.

To interact with the engine or other components in Lumberyard, include the component or system's EBus or API header in your code. Then make calls to the exposed EBuses. With this approach you can replace engine level system APIs with implementations that you define in a gem. For example, you could replace Lumberyard’s audio system with your own EBus handler. This would give you complete control over audio without having to recompile the engine.

For information about EBuses, see Working with the Event Bus (EBus) system (p. 1851).

For information about using EBuses in Lua, see Using EBuses in Lua (p. 2693).

Entities and Components

Lumberyard uses a lightweight entity/component model called the component entity system for both game objects and systems. Lumberyard entities are simply an ID and a container of components. They have no functionality associated with them. Lumberyard's component model is granular: It expects each component to provide independent functionality. It expects game objects to be made up of one or more entities with many components attached to each entity. Lumberyard components communicate with each other using a messaging system called EBuses (explained later). Lumberyard expects you to use EBuses instead of holding references to other entities or their components.

Lumberyard's components have a simple lifecycle. When an entity is activated, it calls Activate() on all of its components. When the entity is deactivated, it calls Deactivate() on all of its components. In the Activate() function a component sets itself up, connects to EBuses, and allocates resources.
or requests assets. In the `Deactivate()` function, a component should release all resources and disconnect from all EBuses. Components should be completely dormant after deactivation, and they should be in more or less the same state that they are in after `Init()` is called. The `Init()` function is only called once and allows a component to initialize its internal state. Note that a component can be activated and deactivated many times before it is deleted. For example, it might be deactivated temporarily while it is being streamed out.

The remaining API operations of a component should be established by the EBus that it implements.

Components can depend on services. Such services usually have a one-to-one relationship with EBuses. If a component declares that it depends on (requires) a service, any entity that uses the component must also contain a component that provides the required services.

Components are always activated in order of their dependency. For this reason, a component can always assume that the services that it requires are available when the component is activated.

Entities are never allowed to be in a state in which one of their component dependencies is missing, even during authoring. In Lumberyard's editing tools, this means that components whose dependencies are missing are actually removed from the entity and stored in a temporary list. When all of the component's dependencies become available, the component is restored to the entity.

For more information about entities and components, see Programmer's Guide to Entities and Components (p. 973).

## Gems and AZ Modules

Lumberyard is designed to create applications that are small executables. A Lumberyard application has a simple application class (`AZ::ComponentApplication`). The application class reads a manifest (a `gems.json` file) and loads modules that provide functionality for your game. Lumberyard calls these modules gems. Lumberyard's goal is to have you choose a set of gems that match the requirements of your game and only compile what you need. Lumberyard includes a variety of prebuilt gems that add functionality to the game engine, such as VR, cloud connectivity, and the EMotion FX animation system.

Cloud gems (p. 2127) are gems that add AWS cloud-connected functionality to your game.

When you create a game, your game code and assets go into one or more gems. Each code gem contains an `AZ::Module` (p. 1090). An AZ module is a collection of C++ code built as a static or dynamic library (.lib or .dll file) that implements specific initialization functions. The AZ module is the interface that Lumberyard uses to extract the contents of your gem into the global environment.

Each application has a single entity associated with it that is referred to as the **system entity** (p. 1104). AZ modules can add components to this entity before it is activated.

Components that are added to the system entity are called **system components** (p. 1098). System components are often singleton/manager-type objects that aggregate or provide resources to game components or other systems. Like other entities, a system entity must have its dependencies present. You can assume that any systems that you depend on are booted and available when your system component is activated.

For information on programming with gems, see Programming with Gems (p. 1073).

For information on creating system components, see Creating System Components (p. 987).

## Input

Lumberyard provides independent, extensible, and efficient access to input data from supported operating systems and devices. Lumberyard's AZ framework input interface provides abstracted interfaces for OS-specific features like file I/O and application lifecycle management.

For more information, see Input in Amazon Lumberyard (p. 1902).
Lua

Lua is a powerful, fast, lightweight, scripting language. You can use Lua in Lumberyard to facilitate quick iteration of your game project. When you construct new gameplay and game systems, you can run your changes immediately, without compiling your source code.

For more information on using Lua in Lumberyard, see Writing Lua Scripts (p. 2683).

Networking

Lumberyard's networking system is designed for efficient bandwidth usage and low-latency communications. It uses a replica framework to synchronize objects over the network, and its session management integrates with major online console services. Lumberyard networking lets you handle peer-to-peer and client-server topologies with host migration and supports in-game achievements, leaderboards, and cloud-based saved games.

For more information, see Using Lumberyard Networking (p. 1990).

Reflection System

You can use Lumberyard's reflection system to expose runtime code for C++-based objects, for Lumberyard Editor, and for scripting (Lua and Script Canvas). Lumberyard provides three reflection contexts for this purpose: a serialization context (p. 1033), a behavior context (p. 1053), and an edit context (p. 1052).

For more information, see Reflecting Lumberyard Classes, Methods, and EBus Interfaces (p. 1032).

Script Canvas

Script Canvas (p. 2420) is Lumberyard's visual scripting environment.

For information on creating your own nodes in Script Canvas, see Creating Custom Nodes in Script Canvas (p. 2553).

For information on using the behavior context to expose runtime code to Script Canvas, see Script Canvas and the Behavior Context (p. 2543).

Slices

Slices are practical and powerful way to create units of content in Lumberyard and manage them. A slice is a collection of one or more entities. You can instantiate a slice as many times as you require. Many game engines use levels and/or sublevels for their content, but Lumberyard loads content into its engine in the form of slices. Because slices can inherit from each other and be nested, they are powerful tools for managing content.

Like most systems that use prefabs or archetypes, you can use inheritance to override properties in Lumberyard. However, you can use Lumberyard's slices to add or remove components or even entire entity hierarchies.

For more information, see Working with Slices (p. 510).

C++ Best Practices for Amazon Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The following topics present some best practice coding patterns that Lumberyard engineers have found helpful for writing high quality code. Because of the complexity of C++ and the variety of ways it is used in Lumberyard, consider these guidelines as suggestions rather than a formal standard.

**Topics**

- Memory Management (p. 29)
- Use AzCore Standard Containers (p. 31)
- Tracing (p. 31)

## Memory Management

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When managing memory in Lumberyard, use AZ memory management calls and avoid static variables whose constructors allocate memory or connect to EBuses.

### Memory Allocations

When allocating memory, use the following recommended practices:

- **Do not use** `new`, `malloc`, and similar allocators directly. Instead, use AZ memory manager calls to `aznew`, `azmalloc`, `azfree`, `azcreate`, and `azdestroy`.
- **Specify the allocator in each class.**
- **Use child allocators.** To tag and track resource usage, new gems and subsystems should create their own allocator or create a `ChildAllocator` that references an existing allocator. For an example of creating a child allocator, see Creating an Allocator (p. 1911).

**Reason:** Lumberyard's core AZ systems provide a memory managed environment, not a raw system allocator like the managed memory in C# or Java. In Lumberyard, the core AZ systems provide speed, safety, and facilities for tracking memory usage.

For information about Lumberyard's scheme for allocators and new allocators, see Manually Allocating Memory (p. 1907).

### Memory Issues Caused by Static Variables

In constructors and destructors for static variables, avoid the following:

- Allocating memory with the AZ memory allocator system.
- Deallocating memory with the AZ memory allocator system.
- Connecting to EBuses
- Disconnecting from EBuses.

These rules apply to global static variables, function local static variables, and containers.

**Reason:** Lumberyard manages the memory of its classes and container types using the AZ memory allocator system. However, class static variables and containers can attempt to use the AZ memory allocator system before it is created or after it no longer exists. Keep in mind the following:

- On application startup or when a gem is loaded, if a static variable attempts to use the AZ system allocator before the AZ system allocator has been created, a crash can occur.
• On shutdown, if a static variable attempts to deallocate from the AZ system heap when the AZ system allocator no longer exists, a crash can occur.

Remember that the lifetime of a static variable lasts until the module in which the variable is declared is unloaded. In static linked libraries, the duration of static variables is the entire duration of the application.

Static Local Variable Example

The following example code from the Lumberyard version 1.17 AzFramework (\dev\Code\Framework\AzFramework\AzFramework\Physics\DefaultDebugDrawSettings.h) uses function static container variables whose destructors rely on AZ::SystemAllocator.

```
namespace Physics
{
    AZ_INLINE void GetDefaultDebugDrawSettings(DebugDrawSettings& settings)
    {
        static AZStd::vector<Vec3> cryVerts;      // These function static container variables use AZ::SystemAllocator.
        static AZStd::vector<ColorB> cryColors;
        // ...
    }
}
```

By default, the AZStd::vector class uses the SystemAllocator. Invoking this function on application shutdown, when SystemAllocator no longer exists, causes a deletion from a destroyed heap.

Global Static Variable Example

On startup, the following code attempts to create a global static variable whose constructor connects to an EBus:

```
// Example of a global static variable that connects to an EBus.
namespace LmbrCentral
{
    // Wraps an IMaterial pointer so that BehaviorContext can use it.
    class MaterialHandle : public AZ::RenderNotificationsBus::Handler
    {
        public:
            AZ_CLASS_ALLOCATOR(MaterialHandle, AZ::SystemAllocator, 0);
            AZ_TYPE_INFO(MaterialHandle, "{BF659DC6-ACDD-4062-A52E-4EC053286F4F}");
            MaterialHandle()
            {
                AZ::RenderNotificationsBus::Handler::BusConnect();
            }
            // ...

    // Later in the code, a MaterialHandle in global space is declared:
    MaterialHandle g_defaultMaterialHandle;
```

The code crashes the engine as soon as the module that contains the global variable definition is loaded. The constructor of the global variable attempts to connect to the EBus, but the EBus system is not ready because it uses an environment variable from a module that has not yet been initialized.
Use AzCore Standard Containers

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

**Recommended:** Instead of writing your own containers, use the full range of AzCore standard containers in Lumberyard. Because these containers provide AZ memory allocators by default, they work with AZ memory manager out of the box. These containers include the following:

- array
- bitset
- deque
- fix_unordered_set
- fixed_forward_list
- fixed_unordered_map
- fixed_vector
- fixed_list
- forward_list
- list
- map
- multimap
- multiset
- queue
- ring_buffer
- set
- stack
- unordered_map
- unordered_multimap
- unordered_multiset
- vector

For multithreaded environments, Lumberyard has concurrent versions of `vector`, `map`, `set`, and `fixed`. For the source code, see `lumberyard_version\dev\Code\Framework\AzCore\AzCore\std\containers`.

**Recommended:** Create containers by value. Because none of the AZStd containers allocate memory when they are empty, creating containers with `new` on the heap is usually not necessary.

**Recommended:** Store container contents by value. If the container is the owner of dynamically allocated contents, store the contents in AZStd smart pointers.

### Tracing

**Recommended:** For code tracing needs, use `AZ_*` tracing macros.

**Reason:** Error handling and tracing functions provide useful messages formatted for readability about errors that occur. To facilitate debugging, `AZ_*` tracing functions indicate where in code the errors occurred.

The following table describes the `AZ_Tracing` macros and their uses.
<table>
<thead>
<tr>
<th>AZ Tracing Macro</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AZ_Assert</td>
<td>Use for critical errors when the program cannot continue. AZ_Assert macros print an error message, the file name and line number where the error occurred, and then break program execution.</td>
</tr>
<tr>
<td>AZ_Error</td>
<td>Use when an obvious error has occurred but the program can continue safely. AZ_Error macros print an error message and the file name and line number where the error occurred. In some environments, AZ_Error notifies the user that an error has occurred (for example, in a message box or onscreen message).</td>
</tr>
<tr>
<td>AZ_Warning</td>
<td>Use when an error might have occurred. AZ_Warning macros print an error message and the file name and line number of the possible error, but take no other action.</td>
</tr>
<tr>
<td>AZ_TracePrintf</td>
<td>Use for informational purposes only. AZ_TracePrintf macros print a message but take no other action.</td>
</tr>
</tbody>
</table>

For source code, see `lumberyard_version\dev\Code\Framework\AzCore\AzCore\Debug\Trace.*`.

**Suppressing AZ Trace Messages in Unit Tests**

You can use macros to suppress AZ trace messages. Starting in Lumberyard version 1.21, the following macros for suppressing AZ Trace messages in the AZ Unit Test framework have equivalent macros with new names. The old macros will be removed in a future release.

<table>
<thead>
<tr>
<th>Old Macro Name</th>
<th>New Macro Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>AZ_TEST_START_ASSERTTEST</td>
<td>AZ_TEST_START_TRACE_SUPPRESSION</td>
</tr>
<tr>
<td>AZ_TEST_STOP_ASSERTTEST</td>
<td>AZ_TEST_STOP_TRACE_SUPPRESSION</td>
</tr>
</tbody>
</table>

The old macros only suppressed the AZ_Error and AZ_Assert trace messages, but their names implied application termination. The new macros are equivalent in functionality to the old macros but have names that more accurately reflect their functionality.

For source code, see `lumberyard_version\dev\Code\Framework\AzCore\AzCore\UnitTest\UnitTest.h`.

### Lumberyard Editors and Tools

This topic references tools and features that are *legacy*. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the [AWS Game Tech blog](https://aws.amazon.com/pt/blogs/gaming/) to learn more.
Lumberyard provides the following suite of applications, editors, and tools for game development.

Animation Editor (p. 1340)

Manages character animations, attachments, and physics simulations along with blendspace and animation layering.

Asset Browser (p. 296)

Displays all game assets available for use.

Asset Processor (p. 248)

Runs in the background when you launch Lumberyard Editor, monitoring input directories for changes in source files and automatically generating platform-specific game assets as they change.

Audio Controls Editor (p. 3142)

Manages audio translation layer (ATL) controls and events for the audio system.

Animation Editor (Legacy)

Manages character animations, attachments, and physics simulations along with blendspace and animation layering.

Console (p. 210)

Runs editor commands and lists available console variables.

Database View (p. 1264)

Displays various object libraries such as entities, particles, and prefabs.

Entity Inspector (p. 475)

Displays the ID and name for component entity system objects.

Entity Outliner (p. 462)

Displays all component entities used for a level.

FBX Settings (p. 409)

Imports single static meshes and materials from FBX.

Layers (p. 469)

Organizes level data into discrete files.

Lens Flare Editor

Creates and manages camera lens flare effects.

Sun Trajectory Tool (p. 1265)

Creates and manages dynamic sky lighting effects.

LOD Generator

Generates geometry and material level of detail (LOD).

Lumberyard Editor (p. 182)

Acts as the main workspace editor and game viewport; loads the Rollup Bar and console by default.

Lumberyard Setup Assistant (p. 16)

Ensures that you have the necessary runtime software and SDKs installed to successfully run Lumberyard.
Material Editor (p. 1636)
Applies final material setup, texture mapping, and shader parameters.
Measurement System Tool
Measures the length of segmented objects like roads, rivers, and paths.
Missing Asset Resolver
Searches for assets that have moved and references their new locations (legacy).
Gems System (p. 1064)
Provides a library of prebuilt features that you can use to quickly start new projects or prototype ideas.
Particle Editor (p. 1504)
Creates and simulates explosions, fire, sparks, and other visual effects.
Project Configurator (p. 43)
Standalone application used to tell the Waf build system which Gems to include in the game build.
Resource Compiler (p. 248)
Compresses and processes source game asset files and creates package files.
Script Canvas (p. 2420)
Create game logic and behaviors with Lumberyard's new visual scripting environment.
Script Terminal
Runs various scripts in a terminal window.
Smart Objects Editor
Creates and manages smart objects, which can interact with other objects according to complex rules.
Substance Editor
Imports substance .sbsar files, edits material properties, and exports them as textures.
Terrain Editor (p. 1220)
Generates terrain and sculpts terrain elements in your level.
Terrain Texture Layers (p. 1232)
Creates and paints terrain texture layers in your level.
Time of Day Editor (p. 1265)
Creates and manages day–night cycles and other dynamic sky effects.
Track View Editor (p. 1584)
Creates and manages cinematic scenes and sequences; consists of the Track View and Curves Editor.
UI Editor (p. 2874)
Creates, manages, and simulates user interface elements for your game, such as menus and heads-up displays (HUD).
Universal Remote Console (p. 3209)
Used to connect to a remote instance of Lumberyard running on mobile devices.
Lumberyard Asset File Types

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

See the following tables for supported asset data file types in Lumberyard.

Lumberyard supports the .xml file format and the following image file formats:

- .bmp
- .jpg
- .pgm
- .png
- .raw
- .r16
- .tga
- .tif

3D Art Asset File Types

The following file formats are used for static geometry:

<table>
<thead>
<tr>
<th>File Type</th>
<th>Where Created</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*.cgf (Static Geometry File)</td>
<td>DCC tool</td>
<td>Contains static geometry data, such as grouped triangles, tangent spaces, vertex colors, physics data, and spherical harmonics data.</td>
</tr>
<tr>
<td>*.chr (Character Asset File)</td>
<td>DCC tool</td>
<td>The base character used for animations.</td>
</tr>
<tr>
<td>*.cdf (Character Definition File)</td>
<td>Lumberyard</td>
<td>Defines the base character and associated attachments. This file is created with Geppetto and contains a reference to the .chr file.</td>
</tr>
<tr>
<td>*skin (Character Skinned Render Mesh)</td>
<td>DCC tool</td>
<td>Contains skinned character data, including the mesh, vertex weighting, vertex colors, and morph targets.</td>
</tr>
<tr>
<td>*.fbx (Filmbox File)</td>
<td>DCC Tool</td>
<td>Contains mesh, material, camera, and animation data. Provides interoperability between DCC tools.</td>
</tr>
<tr>
<td>*.scenesettings (Scene Settings File)</td>
<td>Lumberyard</td>
<td>Contains configuration and rules settings from an *.fbx file.</td>
</tr>
<tr>
<td>*.abc (Alembic Cache File)</td>
<td>DCC tool</td>
<td>Contains non-procedural, application-independent set of baked geometric data such as baked meshes and their materials.</td>
</tr>
<tr>
<td>*.cax (CAD/CAE Exchange File)</td>
<td>Lumberyard</td>
<td>Contains compressed game assets read from the .abc file and streamed in-game on demand from disk.</td>
</tr>
</tbody>
</table>

**Lumberyard Blog, Forums, and Feedback**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

As we continue to improve Lumberyard, we want to thank everyone in our game developer community. Without your participation in the forums, your messages, and your bug reports, Lumberyard wouldn’t be as strong as it is.

- Keep sending your feedback to <lumberyard-feedback@amazon.com>.
- You can also keep up with new changes on our blog and leave comments to let us know what you think.
- Learn how to use Lumberyard our Getting Started video series. This series covers all the basics of working with Lumberyard and is a terrific foundation for moving on to intermediate and advanced topics.

**Getting Started with Amazon Lumberyard**

- Lumberyard also has an ever-growing YouTube channel that’s loaded with additional tutorial videos and presentations. Subscribe and enable notifications so you always know when new videos are released.

**Amazon Lumberyard on YouTube**

- Dive deeper into the features and usage of Lumberyard with the Amazon Lumberyard documentation.

**Amazon Lumberyard documentation home**

- Join the online community in the Lumberyard forums to learn from Lumberyard staff and users, and share your projects.

**Amazon Lumberyard forums**

- Lumberyard users have created an unofficial Discord. Join the conversation to share tips and get help from Lumberyard users.

**Amazon Lumberyard on Discord**

---

**Key Lumberyard Terminology**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

If you are new to working with Lumberyard, see the following list to learn about key terms and concepts for Lumberyard. For more information, see the additional topics for in-depth descriptions and procedures.
**Actor**

An actor is an entity that you create for characters in your game. You can then add the Anim Graph, Character Physics, Lua Script, and Actor components to the entity to control your actor’s movements. An Actor component exposes nodes that Lumberyard uses for animation. You work with the nodes in the Animation Editor to create motion sets that determine the motions for the characters (run, walk, idle, and so on).

**Example Actor**

The entity in the Lumberyard Editor viewport has an Actor component attached.

For more information, see Create and animate characters (p. 1340).

**Asset Builder API**

The Asset Builder API is an interface for creating custom types of assets. With the Asset Builder API, you create a custom asset, and register the asset in the asset pipeline. Asset Processor processes the asset like any other file (for example, .tif file to a .dds file), so that you can use it in Lumberyard. The Asset Builder API lets you leverage all the benefits of the asset pipeline, such as Asset Processor and the Asset Browser.

For more information, see Creating a Custom Asset Builder (p. 318).
**Asset Processor**

This utility is a background service that monitors changes to your source files and updates the cache with any changes. For example, if you replace an existing mesh asset with a new version of the asset, Asset Processor detects and processes the change for you.

**Example Importing Assets**

When you import assets into your game project, Asset Processor automatically detects the change and processes them.

For more information, see [Working with the Asset Pipeline and asset files](p. 247).

**AZ Code Generator**

This command line utility accepts a tagged source code file and creates a text, data, or code file. AZ Code Generator parses through a list of existing C++ source files and/or header files and generates the intermediate data in JSON format. It passes the intermediate data to a series of templates, which provide the format for the code that is generated.

For example, you can use the AZ Code Generator feature to create a component that you can use in the **Entity Inspector**.

**Example AZ Code Generator Process**

For more information, see [Automating boilerplate with AZ Code Generator](p. 1869).
Behavior Context

You can use the Behavior Context (p. 1053) to reflect runtime code to make it accessible to scripting languages like Lua or scripting environments like Lumberyard's Script Canvas editor. The behavior context provides bindings that invoke runtime C++ code.

Dedicated Server Build

This Lumberyard build option is a minimal Waf build of your Lumberyard project for gameplay only. This configuration can be deployed to act as a server locally or hosted on AWS. Your Lumberyard dedicated server can use the Amazon GameLift to manage your multiplayer queues.

For more information, see Creating Dedicated Servers (p. 2076).

Entity

An entity is a game object with a unique ID and a container. An entity contains one or more components that provide functionality. For example, you can add a Mesh component to an entity to add visual geometry, such as creating a door or tree for your game.

Example Entities and Components

You can see entities in the Entity Outliner and the components attached to that entity in the Entity Inspector.

For more information about entities and components, see Working with component entities (p. 462).

Event Bus System

Event buses (EBuses) are a general-purpose communication system that Lumberyard uses to dispatch notifications and receive requests. EBuses are configurable and support many different use cases. For example, you can use EBuses to notify other parts of the engine about an event, such as changes to a component's configuration.

You can use the event bus system by adding a component to an entity, as a call in C++, or by including the API header.

For more information, see Working with the Event Bus (EBus) system (p. 1851).
GameLift

Amazon GameLift is an AWS service that you can use to host server-based games, scale servers up and down, allow players to connect, and provide matchmaking services. You can enable the GameLift gem for Lumberyard.

For more information, see Using Amazon GameLift (p. 2088) and GameLift Gem (p. 1130).

Gem

Gems are reusable packages of code and assets that can be added, modified, or removed from a Lumberyard game. A gem is a module based on the AZ Module system (p. 1090). You can enable gems for your game for additional assets and code. For example, you can enable the Rain gem so that you can add the Rain and Snow components to your entities. Gems can be enabled in other game projects or distributed to other game developers. Lumberyard builds gems with the Waf build system. Some gems are required for Lumberyard.

Cloud gems are Lumberyard gems that provide AWS cloud-connected functionality for a game. For more information, see Cloud Gems (p. 2127).

For more information, see Creating a Gem (p. 1064).

Example Gems

You can enable gems for your game project with the Project Configurator.

GridMate Networking System

GridMate is the Lumberyard networking library for hosting multiplayer gameplay on client-server or peer-to-peer architectures. You can enable the Multiplayer gem to include this library and the NetBindable interface for your project.

For more information, see Using Lumberyard Networking (p. 1990) and Multiplayer Gem (p. 1171).

Slice

A slice is a collection of configured entities that are stored as a single unit in a reusable asset. You can use slices to group entities and other slices for reuse. With slices, you can edit, create, and spawn
multiple entities as a set. Your project can use a slice in a similar way that you used prefabs and layers in previous versions of Lumberyard.

Slices contain entities, including their components and properties, and may also contain instances of other slices. This ability to nest slices without flattening the hierarchy is a feature unique to Lumberyard.

**Example Slice**

*Simple_JackLocomotion* is a slice that contains two entities – *Jack* and *Camera*. You can find this slice in the Samples Project (p. 146).

For more information, see Working with Slices (p. 510).

**Virtual File System (VFS)**

This system is designed for non-PC platforms to handle game assets for live reloading. The virtual file system streams and loads your assets from your development machine as needed. You do not have to load your entire level or game to the device ahead of time and you can avoid deploying assets to a target device. When you make a change on your development machine, live reloading automatically updates the asset in Lumberyard Editor and for the target device.

For example, if you want to run your game on an iOS device and you change an asset, Asset Processor uses the virtual file system to stream the updated asset from your development machine to the iOS device.

For more information, see Live Reloading and VFS (p. 291) and Serving assets over the Virtual File System (VFS) (p. 3174).
Working with Lumberyard projects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Working with projects in Lumberyard

Creating Lumberyard projects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Project Configurator is a standalone application that allows you to specify to the Waf build system which game projects and assets (Gems (p. 1064)) to include in a game build. With it, you can create new projects, save active projects, configure advanced settings, and enable, disable, or create new Gems (p. 1064). You can also use Lmbr.exe (p. 56) to perform these functions in a command line environment.

For information about Waf build system, see Using the Waf Build System (p. 63). For information about Gems, see Add modular features and assets with Gems (p. 1064).

Note
Before you can run the Project Configurator, you must first run Lumberyard Setup Assistant (p. 16) and close Lumberyard Editor.
Creating and Switching Game Projects

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Project Configurator to create and change the settings that affect building and editing of a game project. You can use the Project Configurator to do the following:

- Create a game project
- Enable or disable gems (code and assets files) from your game project
- Switch game projects

To learn about creating and compiling a new game project for Lumberyard, watch the following video tutorial.

How to Create and Compile a New Project for Amazon Lumberyard

Topics

- Project Templates (p. 44)
- Creating a Game Project in Lumberyard (p. 45)
- Choosing a Game Project to Open (p. 47)
- Switching Game Projects (p. 48)

Project Templates

When you create your game project with the Project Configurator, you can use the following templates:
Empty Template

The Empty template has the minimum features required for the editor to load and run a game project:

- **CryLegacy** – Enables the editor and launcher to load a game project that contains legacy code
- **Legacy Game Interface** – Enables the editor and launcher to load a game project that contains legacy game interface code
- **LyShine gem** – Provides access to the in-game UI system for Lumberyard
- **Maestro gem** – Provides access to cinematics features

Default Template

The Default template builds on the Empty template and enables the following gems to provide basic features for game development:

- **Amazon GameLift** – Provides capabilities to use this service and create game sessions
- **Camera** – Includes a basic camera component for runtime rendering
- **ChatPlay** – Includes the interface for triggering events based on Twitch chat activity
- **Cloud Canvas** – Provides visual scripting capabilities to power your game backend with AWS services
- **Gestures** – Allows gesture-based input, including click/tap, drag, hold, pinch, rotate, and swipe
- **Http Requestor** – Adds support to handle HTTP and HTTPS requests
- **In-App Purchases** – Provides the in-app purchasing API for Android and iOS
- **Input Management Framework** – Converts input to user-defined gameplay events
- **LyShine** – Provides access to the in-game UI system for Lumberyard
- **PBS Reference Materials** – Includes a set of physically based shading reference materials and texture assets
- **Physics Entities** (Legacy) – Provides physics entity modifiers to simulate physical events
- **Primitive Assets** – Provides primitive objects to manipulate in your level

To see the gems that enabled for the Default template, create a project from that template and choose Enable Gems.

The Default template also includes a simple level for you to manipulate components and entities in the editor and experiment with other assets in a neutral, gray environment. The simple level includes a camera, a single light, an environment probe for reflections, and primitive objects with physics enabled. The objects are provided by the Primitive Assets Gem (p. 1190).

**Note**

- When you create your game project, we recommend the Default template and its set of gems. This template helps you start designing and developing quickly. Some of the gems in the template are optional.
- To create a base project without optional gems, use the Empty template. This template creates a basic project using the minimum features to start a game.

Creating a Game Project in Lumberyard

You can create a game project using the Project Configurator or command line. When you create a game project, the following are also created:

- A game gem that includes your game-specific code. The gem is named after your game project and is located in the MyNewProject\Gem directory.
• A Visual Studio solution file specific to your game.

**Project Configurator**

**To create a game project in the Project Configurator**

1. Open the Project Configurator with your preferred method:
   - Open Lumberyard Setup Assistant and, on the **Summary** page, click **Configure project**
   - Open the Lumberyard Project Configurator, located at `lumberyard-version\dev\Bin64\BuildPlatform\ProjectConfigurator.exe`. For example, when using Visual Studio 2019 as your build platform, the Project Configurator is located at `lumberyard-version\dev\Bin64vc142\ProjectConfigurator.exe`.

2. In the Project Configurator, click **Create new**.

3. In the **Create a new project** window, do the following:
   a. Enter a name for your project.
      Only alphanumeric characters are allowed. Don't use special characters or spaces in the name. Don't use single C++ keywords such as if, while, break, new, and virtual.
   b. Choose one of the following: **Default** or **Empty**.
   c. Click **Create project**.

4. When your project is created, click **Continue**.

5. In the Project Configurator, select the new project and click **Set as default** to make it the default project that Lumberyard Editor loads.

6. **(Optional)** Click **Enable Gems** to add gems to your project.

   **Note**
   If you selected **Code & Assets** gems, you must build your project.
   a. At a command-line prompt, navigate to the `lumberyard_version\dev\` directory.
   b. To configure Lumberyard, enter the following command.

   ```
   lmbr_waf configure
   ```
   c. Build the game project.
Note
In Lumberyard version 1.23, the initial build time for a new project can be lengthy. It can take approximately one hour on higher end systems.

For more information, see Building Lumberyard projects (p. 61).

7. Close the Project Configurator.
8. Open Lumberyard Editor with your preferred method:
   • Open Lumberyard Setup Assistant and, on the Summary page, click Launch editor
   • Start Editor.exe from one of the following directories:
     • For Visual Studio 2017: lumberyard_version\dev\Bin64vc141
     • For Visual Studio 2019: lumberyard_version\dev\Bin64vc142

Command Line
When you create a game project from a command line, you can enter lmbr for a list of all possible commands that you can use with Lmbr.exe (p. 56).

To create a game project from a command line
1. At a command-line prompt, navigate to the following directory:

   lumberyard_version\dev\Tools\LmbrSetup\Win\n
2. To create your project, enter the following command.

   lmbr projects create MyNewProject

3. To set your new project as the default or active project, enter the following command.

   lmbr projects set-active MyNewProject

4. To configure Lumberyard to run this project, navigate to the following directory:

   lumberyard_version\dev\n
5. Enter the following command.

   lmbr_waf configure

6. Build the game project.

   For more information, see Building Lumberyard projects (p. 61).

Choosing a Game Project to Open
Use the Project Configurator to set default game project that opens in Lumberyard Editor.

To open a game project
1. Open the Project Configurator with your preferred method:
   • From the desktop, double-click the Project Configurator icon
   • Open the Lumberyard Project Configurator, located at lumberyard-version\dev\Bin64\BuildPlatform\ProjectConfigurator.exe. For example, when using Visual Studio 2017 as your build platform, the Project Configurator is located at lumberyard-version\dev\Bin64vc141\ProjectConfigurator.exe.
Creating and Switching Game Projects

2. On the Summary page, select the project and click Set as default.

3. (Optional) Click Enable Gems and select the additional features and assets that you want available to design your game. If you select a gem labeled with Code & Assets, you must build your project from a command line.

   For more information, see Building Lumberyard projects (p. 61).

4. (Optional) Choose Advanced Settings and verify that the System entity and Memory settings are appropriate for your project.

5. Close the Project Configurator.

6. After setting the default project, open Lumberyard Editor with your preferred method:

   • From the desktop, double-click the Lumberyard Editor icon
   • For Visual Studio 2017, navigate to the \lumberyard_version\dev\Bin64\vc141 directory and double-click Editor.exe
   • For Visual Studio 2019, navigate to the \lumberyard_version\dev\Bin64\vc142 directory and double-click Editor.exe

   After the first launch and each time you change projects, Asset Processor runs in the background. Asset Processor manages your assets and project files. While Lumberyard Editor opens, you can see messages appear with status information.

   For more information, see Using Asset Processor (p. 248).

Switching Game Projects

To switch projects, you must close Lumberyard Editor. With the Project Configurator, you then specify a different project and its gems and system settings for the editor to open.

When you switch projects, you can specify the following:

• Name of the project to open
• (Optional) Gems enabled for the project
• (Optional) System settings for the editor to use

To switch game projects

1. In Lumberyard Editor, choose File, Project Settings, Switch Projects.
2. You must close Lumberyard Editor before you can open the Project Configurator. In the dialog box, choose Save.

3. Follow the procedure in Choosing a Game Project to Open (p. 47).

Configuring Advanced Settings

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To configure advanced settings for your selected project, click Advanced Settings in the Project Configurator.

Upon launch, the System Entity Editor detects any required system components that are missing and adds them. System Entity Editor displays a dialog that lists all of the components that it added to your project.
The System Entity Editor interface has the following tabs:

- System Entity
- Memory Settings

**System Entity Editor**

A single entity, shown in the following picture as SystemEntity, makes up the core of every Lumberyard application. This entity’s components, known as system components (p. 1098), power major systems within Lumberyard. Using the System Entity Editor, game developers can customize the project’s components and configuration settings.
To add a system component, click **Add Component**.

**Memory Settings**

Click the **Memory Settings** tab to configure and manage your project's memory settings.
Understanding the Project Configurator

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Project Configurator is an application for specifying the settings that affect building and editing of your game project. When you work with the Project Configurator, note the following changes.

Topics
Set Default (Active) Project

When you set the default (active) project, the Project Configurator modifies the following files with the following information:

```
lumberyard_version\dev\bootstrap.cfg
```

The `sys_game_folder` property specifies the project that the editor and PC launcher attempts to load (for example, `sys_game_folder=SamplesProject`).

```
lumberyard_version\dev\WAF\user_settings.options
```

The property `enabled_game_projects` is a comma-separated list of one or more projects to include in a build.

Create a New Project

When you create a new project in the Project Configurator, several things happen:

- The Project Configurator uses the EmptyTemplate to create a new project. This template is located in the `lumberyard_version\dev\ProjectTemplates\EmptyTemplate` directory.
- The contents of `lumberyard_version\dev\ProjectTemplates\EmptyTemplate\code\EmptyTemplate` are copied to the following directory:
  
  `lumberyard_version\dev\code\NewProjectName`

- The contents of `lumberyard_version\dev\ProjectTemplates\EmptyTemplate` are copied to the following directory:
  
  `lumberyard_version\dev\NewProjectName`

- The EmptyTemplate is replaced in both new directories with the name of your new project, including file names and file contents.

For more information about templates, see Project Templates (p. 44).

Enable or Disable Gems

When you enable or disable a gem in a project, the Project Configurator updates the list of enabled gems that is maintained in `lumberyard_version\dev\Game_Project\gems.json`.

For more information, see Enabling Gems (p. 1064).

- Enabling a gem adds that gem name to the list in `gems.json`.
- Disabling a gem removes that gem name from the list in `gems.json`.
- Enabling or disabling a gem updates the `Editor.xml` and `Game.xml` files. You can find these files in the `lumberyard_version\dev\Game_Project\Config` directory. These files tell Lumberyard to load the required `.dll` files for the gems that you specify.
**Note**
The Editor.xml and Game.xml files are only updated when you enable or disable gems where "LinkType": "Dynamic" in the gem.json file. For more information, see Gem JSON File (p. 1074).

**Create a New Gem**

When you use the Project Configurator to create a gem, the following takes place:

- The content of the gem template (which is part of the Project Configurator resources and is not directly accessible) is copied into the `lumberyard_version\dev\Gems\Gem_Name` directory.
- Strings with the gem name in the copied content are replaced with the name of your gem to make it a valid gem.

For more information, see Creating a Gem (p. 1066).

**Troubleshooting**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Review the following if you experience issues when using the Project Configurator.

**Perforce integration**

If you have enabled Perforce integration with the tooling, then the Project Configurator automatically checks the following files out of Perforce. If not, then update the read only flag manually:

- `project_asset_folder\gems.json`
- `project_asset_folder\game.cfg`
- `lumberyard_version\bootstrap.cfg`
- `lumberyard_version\dev\game_project_folder\project.json`

**Cannot create a new project**

Make sure that the `lumberyard_version\dev\game_project_folder\project.json` file is editable.

Ensure that the name entered is valid and does not contain special characters or whitespaces.

**Cannot enable or disable a gem**

Make sure that the `project_asset_folder\gems.json` file is editable before trying to save changes made to gems being enabled or disabled.

**New project or gem does not appear in Visual Studio**

Make sure that you have run `lmbr_waf configure` from a command line, which regenerates the Visual Studio solution to include the new project or gem.
If the project or gem still does not show up in Visual Studio, ensure that the `enabled_game_projects` field in the `lumberyard_version\dev\_WAF\_\user_settings.options` file is set to the name of your project.

**Wrong project gets loaded in Lumberyard Editor**

Ensure that the `lumberyard_version\dev\bootstrap.cfg` is editable. Then, open the Project Configurator, select the project to open, and choose **Set as default**.

Also ensure that the `sys_game_folder` field in the `lumberyard_version\dev\bootstrap.cfg` file is set to the name of your project.

**Managing Game Projects with Lmbr.exe**

This feature is in **preview** release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/gameengine/) or visit the [AWS Game Tech blog](https://aws.amazon.com/developer/game-tech/) to learn more.
Lmbr.exe is a command-line tool for managing capabilities, game projects, and Gems.

To find the Lmbr.exe file

1. Navigate to one of the following directories:
   - For Visual Studio 2017: `lumberyard_version\dev\Bin64\vc141`
   - For Visual Studio 2019: `lumberyard_version\dev\Bin64\vc142`
2. In a command line prompt, enter the following command to see the commands that you can run.
   
   ```
   lmb -help
   ```

   The list of possible commands appears.

   ![Available Commands](image)

   You can also use `-help` on other commands. For example, to see more information about Lumberyard capabilities, you can enter the following commands:

   ```
   lmb capabilities -help
   lmb capabilities list -help
   ```

   Topics
   - Projects Commands (p. 58)
   - Gems Commands (p. 58)
   - Capabilities Commands (p. 59)
   - ThirdPartySDKs Commands (p. 60)
   - Packages Commands (p. 60)
Projects Commands

Use the following commands to create and modify game projects.

**list**

Lists all projects in the current engine directory.

```
lmbr projects list
```

**create**

Creates a new project using EmptyTemplate, which is located at `dev\ProjectTemplates\EmptyTemplate`, as a template.

```
lmbr projects create project_name
```

**get-active**

Displays the name of the active project.

```
lmbr projects get-active
```

**set-active**

Sets the active project for building and executing Lumberyard. This command modifies `_WAF_\user_settings.options` and `bootstrap.cfg` to reference the specified project.

```
lmbr projects set-active project_name
```

**populate-appdescriptors**

Populates the appdescriptors files from the gems list. If you use the Project Configurator to change gems, Lumberyard automatically updates the application descriptor files. If you manually edit a `gems.json` file, run this command to update these two application descriptor files in a project's asset directory:

- `dev/project_asset_directory/Config/Game.xml`
- `dev/project_asset_directory/Config/Editor.xml`

```
lmbr projects populate-appdescriptors
```

Gems Commands

Use the following commands to create gems and modify a project's use of gems.

**list**

Lists all gems that are installed or enabled in the specified project.

```
lmbr gems list (-project project_name)
```
disable

Disables the specified gem in the specified project. If -disable-deps is specified, all dependencies of the gem are also disabled.

```
lmbr gems disable project_name gem_name (-disable-deps)
```

enable

Enables the specified gem in the specified project. If a version is specified, it's used, otherwise the latest version installed is used.

```
lmbr gems enable project_name gem_name (-version version)
```

create

Creates a gem with the given name. If you specify id or version, those values are used. If you do not specify -out-folder, name is used.

```
lmbr gems create gem_name (-version version) (-out-folder gems\relative_folder)
```

Capabilities Commands

Use the following commands to create and modify Lumberyard capabilities.

list

Lists all of the Lumberyard capabilities.

```
lmbr capabilities list
```

create

Creates a new Lumberyard capability. Include the ID, description, and tooltip.

```
lmbr capabilities create new_capability_name "This is the description." "This is the tooltip."
```

You can also specify the following arguments:

- -help (bool): Displays help descriptions of available commands and options.
- -tag (list): String tags associated with the capability.
- -default (bool): True if capability is default; otherwise false.
- -enable (bool): True if you want to enable the capability right away.

disable

Disables a Lumberyard capability.

```
lmbr capabilities disable lumberyard_capability
```

enable

Enables a Lumberyard capability.
**ThirdPartySDKs Commands**

Before you can use `thirdpartysdk` commands, you must set up your workspace. To do this, run Lumberyard Setup Assistant and perform each step of the setup process.

The `thirdpartysdk` module manages the installation states of third party SDKs. These are specified by default in the `\3rdParty\` directory. If you have defined a different third party SDKs path in the `SetupAssistantUserPreferences.ini` configuration file, then this module manages the SDKs in that path.

The `thirdpartysdk` module has dependencies on the following:

- **Engines module**
- **Capabilities (p. 59) module** – Downloads only the SDKs that are required based on the user-enabled capabilities.
- **Packages (p. 60) module**
- `SetupAssistantUserPreferences.ini` – Path specified for the SDKSearch3rdParty property.
- `SetupAssistantConfig.json` – Parses the SDK required for the engine

Use the following commands to manage Lumberyard third party SDKs.

**list**

Prints out a list of SDKs specified by `SetupAssistantConfig.json` and their available state.

```
lmbr thirdpartysdk list (-help)
```

**setup**

Downloads and sets up all Lumberyard third party SDKs based on your current selected capabilities (p. 59). Does not support software installation such as FBX or Android SDK.

```
lmbr thirdpartysdk setup (-only <sdk1,sdk2,sdk3>) (-3rdpartypath <path>) (-help)
```

- `- (only) (list): Specify name(s) of specific SDKs to set up (comma separated).
- `- (3rdpartypath) (string): Path to your third party folder. Defaults to path in `SetupAssistantUserPreferences.ini`.
- `- (optionals) (flag): Flag to include optional sdks. Does not work if specifying specific sdks.
- `- (help): Print help describing available commands/options.

**Packages Commands**

Before you can use `packages` commands, you must set up your workspace. To do this, run Lumberyard Setup Assistant and perform each step of the setup process.
The packages module downloads third party packages from S3.

The packages module has dependencies on the Engines module.

Use the following command to download a resource packages from S3.

```
dlmb packages download [name] [version] [platform] [uri] [destination] (-help)
```

- `[name]` (positional argument): The name of the package you want to download.
- `[version]` (positional argument): the version of the package you want to download.
- `[platform]` (positional argument): The platform of the package you want to download.
- `[uri]` (positional argument): Where to look for package on remote file system.
- `[destination]` (positional argument): Where to unpack the package.
- `(-help)`: Print help describing available commands/options.

Building Lumberyard projects

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Building your Amazon Lumberyard game is the most important part of the development process - it's how you debug, test, and distribute. In this section of the guide, you'll learn how to configure your Lumberyard builds, get started with your first build, see which build types are available and what they offer, and how to use the Waf build system.

For instructions on bundling assets and distributing them with a release build, see Build and bundle assets for release in Lumberyard (p. 344).

**Your First Lumberyard Build**

One of the first things you'll want to do with Lumberyard is configure the build system and see your configured game project (p. 43) running as a stand-alone executable or Visual Studio Solution.

**Configure and build a Lumberyard game**

1. Open a command line window and navigate to the `Lumberyard_version\dev` directory.
2. Configure the build system:

   ```
   lmbr_waf configure
   ```

3. Build your game project in profiling mode:

   ```
   lmbr_waf build_win_x64_vs2019_profile -p game_and_engine
   ```

   Depending on your hardware, the build may take a while to complete.

To learn the general steps for creating a release build in Lumberyard, see Build and bundle assets for release in Lumberyard (p. 344). For more information about creating release builds for Android and iOS, see Developing for Android and iOS with Lumberyard (p. 3166).

### Game Build Types in Amazon Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Amazon Lumberyard lets you create different types of game builds for each step in your development process:

**Profile mode builds for game developers, designers, and artists**

- Provides an optimized build meant for game development.
- Contains performance instrumentation and debugging output.
- Compiles shaders at run time, which may require the remote shader compiler.
- Communicates with Asset Processor and compiles as needed.
- Has logging, crash reporting, metrics, and other troubleshooting features.

**Debug mode builds for programmers**

- Provides a non-optimized version of the game engine that provides the same features as the profile version.
- Has additional memory checks and tests.
- Provides step-by-step code that programmers can use to debug the execution.

**Release mode builds for customer previews, demos, and launches**

- Loads assets and data only from .pak files.
- Loads shaders from .pak files for better performance but may compile shaders for DirectX at run time if a shader is not found in the .pak files.
- Can't use virtual file system (VFS) or remote asset access.
- Doesn't communicate with Asset Processor because Asset Processor doesn't ship with the game.
- Removes most logging, instrumentation, profiling, and other measurement metrics.
• Removes all game developer and programmer features such as console usage, cheat commands, command line parsing, and batch mode processing.
• Combines everything into a single executable file instead of DLLs.

To learn how to perform each type of build and about build configuration, see Waf Commands and Options (p. 90)

Using the Waf Build System

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard uses the Waf build system to allow you to switch between various build pipelines and to ensure you build only what is needed. You can use extensions, such as automatic project generation, or a simple GUI to modify the command line base system for your project requirements.

You can run Waf using the following methods:

• Command line window

• Waf-generated, Visual Studio solution file. Waf creates a Visual Studio solution file along with the projects specified in the selected project specs. If more than one spec file includes the same project, only one project file is created to prevent duplicates. Waf uses the project specs to determine the projects, project filters, and possible build configurations. Waf uses the wscript files to identify individual project definitions.

Note
Waf is compatible with the version of Python 3 that comes bundled with Lumberyard.

Lumberyard includes the Project Configurator (p. 43), a standalone application that allows you to specify to Waf which game templates and assets (Gems) to include in the game build.

Waf File System

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can find global configurations and project specs in the _WAF_ directory at the root project path. Three subfolders represent settings specific to the following build systems: android, apple, and msbuild. Defined specs are located in the specs directory.

In addition to the configurations specified in the _WAF_ directory, you can find other Waf settings in the waf_branch_spec.py file in the root directory. You can modify this file if you need to include support for additional platforms or configurations.

The Waf build file system can be grouped into three categories:

- Waf Module files (wscript)
- Waf file list (*.waf_files)
- Project and compilation files such as *.h, *.cpp, and so on

Topics

- Waf File Lists (*.waf_files) (p. 64)
- Waf Branch Spec (waf_branch_spec.py) (p. 67)
- Waf Projects File (project.json) (p. 69)
- Waf Spec Files (*.json) (p. 74)
- Waf Module Files (wscript) (p. 76)
- Waf User Options and Settings (p. 78)

Waf File Lists (*.waf_files)

In standard Waf, the source files to include for a build is specified directly as a list of files using the keyword Source. However, the list of source files does not provide support for the following features in Lumberyard:

- **Uber Files**

  Uber files provide a way to group files into a single compilable unit. This grouping offers the benefits of improving build speed and creating smaller binaries. However, it is not always possible to combine all files together successfully without changing the source code. The .waf_files file list provides a way to manually group files and avoid potential collisions.

- **Visual Studio Filters**

  The .waf_files mechanism also provides a way to declare the source files that are included in a Microsoft Visual Studio filter. Visual Studio's solution explorer does not always accurately represent the files and their directory hierarchy on disk, so it uses filters. Cases exist in Lumberyard where multiple projects share a subset of source code outside of individual project directories. The ability to manually specify filters lets Lumberyard maintain this file sharing.
Using the Waf Build System

The paths to the source files specified in a .waf_files file are relative to the location of the .waf_files file itself. It is also possible to use aliases (p. 113) to third-party directories for situations in which a third-party library consists of source code.

File Structure

A .waf_files file is organized into three levels:

- **Level 1 – Uber file grouping**
  
  When uber files are enabled for the build, Waf uses this dictionary of uber file name keys to generate the uber files. The uber files combine the files specified in the group. Because uber files are relevant only for C++ source, the names of the uber files must have a C++ source file extension (for example, .cpp or .cc) and must be unique within the list.

  Level 1 key names can also include the following special key words:
  
  - **none** – Files under the none grouping are not combined into any uber file, even if uber mode is enabled.
  - **auto** – Files are combined automatically into uber files based on a set uber file size limit.

- **Level 2 – Visual Studio filter specification**
  
  The key names for this dictionary represent the directory filters in the generated Visual Studio projects from Waf. The name supports a path-like definition that uses ‘/’ delimiters that you can use to specify directory structures for the filter. If the source files are intended to reside in the root level of the project in Visual Studio, the reserved key name Root is used.

- **Level 3 – List of source files**
  
  The list of source files relative to the location of the .waf_files file to be listed under the Visual Studio filter key name. Waf file lists also support file globbing. For more information, see the File Globbing section in this topic.

Using Uber Mode

Uber mode is specified in the user_settings.options file under the use_uber_files attribute, as shown in the following example:

```python
use_uber_files = False
```

When uber mode is enabled, Waf uses the Level 1 grouping information to create uber files to combine for compiling.

In deciding how to use uber mode, consider the following suggestions:

- If you do not want to create an uber file and want to compile the files individually, specify none for the group of files.
- If you want Waf to automatically place files into uber files, specify auto.
- If you want to specify an uber source file to group the source files, specify the name of that uber source file.

The following example shows this structure.

```json
{
    "none": {
        "Source Files": [
            ...
```
Limiting the Uber File Byte Size

When you specify `auto`, Waf limits the size of the uber file to the byte limit specified in the `user_settings.options` file `uber_file_size` attribute, as in the following example:

```
uber_file_size = 307200
```

File Globbing

The source file definitions support limited ant pattern-based file matching, or "globbing". This allows you to group related files together based on file extension instead of listing files individually. To enable globbing, use a globbing pattern instead of a file path in the source file. The following shows examples of file globbing.

```
{
  "none": {
    "Root": [
      "*.cpp"
    ],
    "Single": [
      "Single/*.cpp"
    ],
    "Nested": [
      "Nested/**/*.cpp"
    ]
  }
}
```

The example showcases the following globbing patterns:

<table>
<thead>
<tr>
<th>Globbing Pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>*.cpp</code></td>
<td>Add all files with the <code>.cpp</code> extension in the current directory only.</td>
</tr>
<tr>
<td><code>Single/*.cpp</code></td>
<td>Add all files with the <code>.cpp</code> extension in the <code>Source</code> directory only.</td>
</tr>
<tr>
<td><code>Nested/**/*.cpp</code></td>
<td>Recursively add all files with the <code>.cpp</code> extension in the <code>Source</code> directory.</td>
</tr>
</tbody>
</table>
**Custom Globbing Rules**

You can create some custom globbing rules by specifying a dictionary for the glob search. For example, the following dictionary includes all files in the directory except for files with a .res extension:

```plaintext
{
    "none": {
        "Root": [
            {
                "pattern": "**/.*",
                "excl": "*.res"
            }
        ]
    }
}
```

Dictionary specifications support the following keys:

- **pattern** – (Required) The globbing pattern to apply to the search.
- **excl** – An exclusion pattern to filter out of the results.
- **maxdepth** – For a recursive search, limit the depth of the search.
- **ignorecase** – Ignore case when using the globbing pattern.

**Globbing at Configure Time and Build Time**

Because globbing is an expensive operation, it is not recommended on large sets of files. Globbing can be done either at configure time, or at both configure and build time. Doing globbing only at configure time improves the build performance. It reuses the glob result that was created at the time of the last configure. The disadvantage is that it does not pick up any files that are added or removed until another configure is done. Doing globbing at both configure and build time picks up file additions and removals for every build, but can be expensive.

**Enabling Build Time Globbing**

To enable or disable build time globbing, set the `enable_dynamic_file_globbing` attribute in the `user_settings.options` file to `True` or `False`, as shown in the following example:

```plaintext
enable_dynamic_file_globbing = False
```

**Waf Branch Spec (waf_branch_spec.py)**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The `waf_branch_spec.py` is the topmost configuration level of the Waf build system. It specifies which operating systems and configurations are available for all projects and specs.

The following is an example `waf_branch_spec.py` file, with explanatory comments for each value moved and enhanced in the table that follows:

```plaintext
# Global constants
BINTEMP_FOLDER = 'BinTemp'
WAF_FILE_GLOB_WARNING_THRESHOLD = 1000
CACHE_FOLDER = 'Cache'
```
The `waf_branch_spec.py` file manages the following global values:

**Global values**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADDITIONAL_COPYRIGHT_TABLE</td>
<td>(Optional) To embed a company name and copyright in the generated binaries, add a name-value pair here. Example:</td>
</tr>
</tbody>
</table>
|                           | ADDITIONAL_COPYRIGHT_TABLE = {
|                           |     'MyCompany' : 'Copyright (c) MyCompany'
|                           | }
|                           | You must also add 'copyright_org' to either your `project.json` or `wscript` module definition file. |
|                           | Project.json example:                                                        |
|                           | "copyright_org": "MyCompany"                                                |
|                           | Wscript module example:                                                      |
|                           | bld.CryEngineModule(                                                         |
|                           |     ...                                                                    |
|                           |     copyright_org = 'MyCompany'                                              |
|                           |     ...                                                                    |
|                           | )                                                                        |
| ADDITIONAL_SEARCH_PATHS   | (Optional) Provide additional paths to search for the WAF build. You can use aliases such as @ENGINE@ and @PROJECT@ for the engine and project roots, respectively. |
| ADDITIONAL_WAF_MODULES    | (Optional) Specify a table of additional modules that will be loaded by WAF. |
|                           | The table format is:                                                        |
|                           | 'Key' : [ 'Module list' ]                                                  |
|                           | Where key is the path of the directory for a set of WAF modules, and the module list is a list of WAF python modules to load into the build system, separated by commas and relative to the path directory specified by the key. |
|                           | Example:                                                                   |
### Using the Waf Build System

**Value**

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
</table>
| ADDITIONAL_WAF_MODULES = {
  'Tools/Build/custom_build': [
    'custom_a.py',
    'custom_b.py:win32'
  ]
} |

The above example will load 'custom_a.py' for all platforms, and 'custom_b.py' only for win32 platforms. Note that the methods that are exposed in the modules must be decorated accordingly, as they are generally used based on the context of the command, and not through regular python imports.

**BINTEMP_FOLDER**

Subfolder under the base of the project where WAF stores all intermediate and temporary files.

**LMBR_WAF_VERSION_TAG**

Version stamp (GUID) of lmbrwaf that is used to signal that a clean of bintemp is necessary. Only update this number if there are changes in WAF handling where it is not possible to track stale intermediate files caused by the WAF changes. To ignore the bintemp cleaning check, set this value to `None`. Only update this value as a last resort. If there were WAF changes that do not affect the generation or tracking of intermediate of generated files, then there is no need to wipe out BinTemp.

**WAF_FILE_GLOB_WARNING_THRESHOLD**

Defines a warning threshold in number of files that were hit during `waf_file globbing (p. 66)`.

### Waf Projects File (project.json)

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/developerguides/3d-engine/) or visit the [AWS Game Tech blog](https://aws.amazon.com/blogs/gaming/) to learn more.

The `project.json` file (located in each game project directory) is used to store game project-specific data. The `enabled_game_projects` settings (`user_settings.options`) and the `--enable-game-projects` build parameter use the project names defined in this file.

The `project.json` file is structured as follows:

- **First level** – Represents the project based on its name
- **Second level** – Presents attributes that you can set for each game project

The following is an example `project.json` file:

```json
"project_name" : "SamplesProject",
"product_name" : "Samples Project",
"executable_name" : "SamplesProjectLauncher",
"code_folder" : "Code/SamplesProject",
"modules" : ["SamplesProject"],
"project_id": "{D882E365-54D6-586E-BD78-2650F3057D49}"
```

You can configure the following settings in the `project.json` file:
### General settings

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>executable_name</td>
<td>Name of the built executable file:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Dedicated server executables</strong> – '_Server' is appended to the name</td>
</tr>
<tr>
<td></td>
<td>• <strong>Unit test executables</strong> – '_UnitTest' is appended to the name</td>
</tr>
<tr>
<td>modules</td>
<td>(List) Base modules for the game</td>
</tr>
<tr>
<td>product_name</td>
<td>Externally-facing name of the product</td>
</tr>
</tbody>
</table>

The following values are only valid under the **android_settings** key:

### Android settings

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>package_name</td>
<td>Android application package identifier. Used for generating the project-specific Java activity class and in AndroidManifest.xml. Must be in dot separated format.</td>
</tr>
<tr>
<td></td>
<td>Default: &quot;com.lumberyard.sdk&quot;</td>
</tr>
<tr>
<td>version_number</td>
<td>Internal application version number. Used to set the android:versionCode tag in AndroidManifest.xml.</td>
</tr>
<tr>
<td></td>
<td>Default: 1</td>
</tr>
<tr>
<td>version_name</td>
<td>Human readable version number. Used to set the android:versionName tag in AndroidManifest.xml.</td>
</tr>
<tr>
<td></td>
<td>Example: &quot;1.2.3-beta&quot;</td>
</tr>
<tr>
<td></td>
<td>Default: &quot;1.0.0.0&quot;</td>
</tr>
<tr>
<td></td>
<td>Default: &quot;landscape&quot;</td>
</tr>
<tr>
<td>icons</td>
<td>A map of icon override path(s) for each screen DPI type. All entries require a path that is either relative to &lt;engine&gt;\Code&lt;project&gt;\Resources or an absolute resource path to the PNG image.</td>
</tr>
<tr>
<td></td>
<td>Available sub-options:</td>
</tr>
<tr>
<td></td>
<td>• default</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>---------------------------------------------------------------</td>
</tr>
<tr>
<td>• Default image used if a specific DPI is not specified</td>
<td></td>
</tr>
<tr>
<td>• mdpi</td>
<td>Medium ~160 dpi</td>
</tr>
<tr>
<td>• hdpi</td>
<td>High ~240 dpi</td>
</tr>
<tr>
<td>• xhdpi</td>
<td>Extra high ~320 dpi</td>
</tr>
<tr>
<td>• xxhdpi</td>
<td>Extra-extra high ~480 dpi</td>
</tr>
<tr>
<td>• xxxhdpi</td>
<td>Extra-extra-extra high ~640 dpi</td>
</tr>
</tbody>
</table>

For more information on Android screen DPI settings, consult the official Android documentation page [https://developer.android.com/guide/practices/screens_support.html](https://developer.android.com/guide/practices/screens_support.html)

Example:

```json
"icons" : {
  "default" : "AndroidLauncher/icon-xhdpi.png",
  "mdpi" : "AndroidLauncher/icon-mdpi.png",
  "hdpi" : "AndroidLauncher/icon-hdpi.png",
  "xhdpi" : "AndroidLauncher/icon-xhdpi.png",

Waf Spec Files (*.json)

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You use Waf spec files to specify which modules to include in a build configuration. All settings are mandatory if not explicitly stated otherwise.

A typical spec includes all modules that are required to build a game project. Lumberyard includes the following with the engine SDK:

- `game_and_engine.json` – Specs to build the sample game and engine
- `resource_compiler.json` – Specs to build the Resource Compiler
- `pipeline.json` – Specs to build the pipeline tools
- `all.json` – Specs to build all projects

The following is an example *.json file that illustrates a spec file layout:

```json
{
```

Version 1.28
74
```json
"description" : "Configuration to build the my game",
"visual_studio_name" : "My Game",
"comment"               : "This is meant to only compile tools on Windows.",
"disable_game_projects" : true,
"platforms" : ["win"],
"configurations" : ["debug","profile"],

"modules" :
[  
  "AzCore",
  "AzFramework",
  "AzToolsFramework",
  "GridMate",
  "LuaIDE",
  "Profiler"
]
}
```

**Note**

The `disable_game_projects` keyword does not compile the games specified in the `project.json` file. The default value is false, which means the specs compile the game projects by default.

**Platform-specific Entry Values**

You can apply the entry values in the table to targeted platforms and/or configurations. For example, a spec can build specific modules for win_x64 or a spec can build different modules in certain configurations.

- **modules** – Includes in the build all modules defined by this key, regardless of platform and configuration.
- **win_x64_modules** – Includes in the win_64 build all modules defined by this key, regardless of configuration.

Overlapping lists are combined into a single list based on the build command.

**Spec File Format Specification**

The general format of the JSON-based spec file is a dictionary of keyword values. The following table lists the possible keywords and their description.

<table>
<thead>
<tr>
<th>Keyword Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>comment</td>
<td>Additional comments to add to the spec file.</td>
</tr>
<tr>
<td>configurations</td>
<td>The list of configurations that this spec supports. In other words, the spec only builds the modules listed in the spec if the current configuration exists in the list of configurations. This is an AND condition with the platforms value.</td>
</tr>
<tr>
<td>description</td>
<td>Description of the spec file.</td>
</tr>
<tr>
<td>disable_game_projects</td>
<td>Flag that indicates that no game projects (as defined in project.json) are included in the build for this spec.</td>
</tr>
<tr>
<td>platforms</td>
<td>The list of platforms that this spec supports. In other words, the spec only builds the modules</td>
</tr>
</tbody>
</table>

Version 1.28
75
Using the Waf Build System

<table>
<thead>
<tr>
<th>Keyword Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>listed in the spec if the current target platform exists in this list of platforms.</td>
</tr>
<tr>
<td><strong>platform_configuration_defines</strong></td>
<td>•  <em>platform</em> and <em>configuration</em> are optional values.</td>
</tr>
<tr>
<td></td>
<td>•  Possible values for <em>platform</em> and <em>configuration</em> can be determined from the <em>waf_branch Spec</em> file.</td>
</tr>
<tr>
<td></td>
<td>•  The build uses the entry that matches the combination of these values and the build command.</td>
</tr>
<tr>
<td><strong>visual_studio_name</strong></td>
<td>Name of the generated Visual Studio solution that is used to distinguish this build spec from a build configuration.</td>
</tr>
</tbody>
</table>

**Waf Module Files (wscript)**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Wscript files are Python source files that have a fixed name and defined rules for the project folder. Waf picks up and processes the wscript file in each folder. Files can recurse into one or more subdirectories, define the build script for one or more modules, or both.

Wscript files are the main project script files for projects and can include the following:

- Specialized behavior for various Waf commands
- Different module types and entries
- Build rules for the folder
- Project- or target platform-specific definitions for compile, link, or other settings

Lumberyard includes a wscript file at the root folder that is used for the following:

- Loading all supported modules and tools relevant to a platform
- Importing all scripts necessary for configuring and building the engine
- Setting the available options that can be passed through the command line or in the default user options file located at _WAF_/user_settings.options
- Recursing into the Code and Engine folders at the root level

At the root is a compiled python script called *lmbr_waf.bat* that executes the Waf commands through the root wscript file.

**Lumberyard Engine Build Modules**

The Lumberyard Waf system includes the following predefined build modules that can help define the build rules for system modules:
<table>
<thead>
<tr>
<th>Build Module</th>
<th>Description</th>
<th>Consumers</th>
<th>Project Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CryConsoleApplication</td>
<td>Build module for generic console applications</td>
<td>ShaderCacheGen</td>
<td>Executable</td>
</tr>
<tr>
<td>CryDedicatedServer</td>
<td>Build module for dedicated (server) game project launchers</td>
<td>FeaturesTestsDedicatedLauncher</td>
<td>Executable</td>
</tr>
<tr>
<td>CryEditor</td>
<td>Build module for Lumberyard Editor project</td>
<td>Editor</td>
<td>Executable</td>
</tr>
<tr>
<td>CryEngineNonRCModule</td>
<td>Version of the CryEngineModule that does not attempt to create an RC file</td>
<td>CrySoundUnitTests, LyShine, AssetTaggingTools</td>
<td>Shared Library</td>
</tr>
<tr>
<td>CryEngineStaticModule</td>
<td>Build module to create static libraries</td>
<td>lua, md5, LZSS, Lzma, expat, DBAPI, zlib, lz4, PRT</td>
<td>Static Library</td>
</tr>
<tr>
<td>CryFileContainer</td>
<td>Build module that acts as a placeholder for source files</td>
<td>CryCommon, CryAudioCommon, EditorAudioControlsBrowser</td>
<td>Non</td>
</tr>
<tr>
<td>CryLauncher</td>
<td>Build module for game project launchers</td>
<td>FeaturesTestsLauncher</td>
<td>Executable</td>
</tr>
<tr>
<td>CryPipelineModule</td>
<td>Build module for pipeline components</td>
<td>CryExport2014, CryExport2015, CryExport2016, MayaCryExport22014, MayaCryExport22015, MayaCryExport22016</td>
<td>Custom</td>
</tr>
</tbody>
</table>
**Build Module** | **Description** | **Consumers** | **Project Type**  
---|---|---|---
CryPlugin | Build module for Lumberyard Editor plugins | AssetTagging, CryDesigner, EditorDesc, EditorAnimation, EditorFbxImport, EditorGameDatabase, SchematycPlugin | Shared Library  
CryPluginModule | Build module for Lumberyard Editor plugin modules | EditorCommon, PerforcePlugin | Shared Library  
CryResourceCompiler | Build module for the resource compiler application | ResourceCompiler | Executable  
CryStandAlonePlugin | Build module for Lumberyard Editor standalone plugins (does not link to any engine shared libraries) | EditorAudioControlsBrowser, EditorNoSound, EditorWwise, FBXPlugin, FFMPEGPlugin, MetricsPlugin, PrototypeEditorPlugin, StateMachineEditorPlugin, UiEditor | Shared Library  
CryUnitTestLauncher | Build module for unit test launchers | UnitTestLauncher | Executable

**Waf User Options and Settings**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In Lumberyard, the Waf options for configure and build time operations in are determined primarily by the following files in the *lumberyard_version*\dev\_WAF\_subdirectory:

- **default_settings.json** – Declares most of the configurable settings that control how Lumberyard and its game projects are built, including the default values.
- **Platform-specific settings** – Settings and defaults declared in the *settings* sections of *.json* files in the *lumberyard_version*\dev\_WAF\_settings\platforms subdirectory, including the following:
  - **common.android.json** – Options for Android.
  - **platform.darwin_x64.json** – Options for macOS.
  - **platform.ios.json** – Options for iOS.
Using the Waf Build System

- `user_settings.options` – Use this file to override default values defined in the `default_settings.json` file and platform-specific settings files.

**Topics**
- `default_settings.json` (p. 79)
- `user_settings.options` (p. 80)
- Waf User Settings (`user_settings.options`) (p. 80)

**default_settings.json**

The `default_settings.json` file and the `settings` sections of platform-specific `.json` files use the following format to organize related settings into groups:

```json
"Group Name": [
  {
    "long_form": "Command line form",
    "short_form": "Optional short form of the command line option",
    "attribute": "Waf option attribute",
    "default_value": "Default value",
    "description": "Brief description of the setting"
  },
  ...
],
```

Each option can have the following attributes:

- **long_form** – The long form of the command line argument that Waf accepts as a command-line override to the setting. This overrides both the default value and any override value in the `user_settings.options` file. The long form is usually preceded with a double hyphen (for example, `--enable-my-option`).
- **short_form** – (Optional) The short form of the command argument override option (for example, `-s`).
- **attribute** – The name of the attribute for configure and builds. The attribute is set to the Options WAF module object. This form of the attribute name is used in the `user_settings.options` override file.
- **default_value** – The default value if the setting is not overridden in the `user_settings.options` file or by the related command line argument.
- **description** – A brief description of the option.

The following example shows the `enabled_game_projects` attribute in the Game Projects section of the `default_settings.json` file.

```json
"Game Projects": [
  {
    "long_form": "--enabled-game-projects",
    "attribute": "enabled_game_projects",
    "default_value": "StarterGame,CloudGemSamples",
    "description": "Comma-separated list of game projects to enable for compiling"
  },
  ...
],
```

Version 1.28
user_settings.options

Use the user_settings.options file to override the default values specified in default_settings.json and platform-specific settings .json files. This configuration file is in a standard .cfg file format (not .json) with section names in brackets, as in the following example:

```
[Game Projects]
;enabled_game_projects = StarterGame,CloudGemSamples
```

The groupings are defined in the default_settings.json file and in the platform-specific settings .json files. The user_settings.options file uses the form of the attribute for each setting as it is defined in the corresponding .json file.

Overriding Default Values

The default values are commented out with a semi-colon ';' comment token at the beginning of each line in the user_settings.options file. To override a value, remove the semicolon from the beginning of the line and set the attribute to the value that you want. For example, the option to use IncrediBuild is off (False) by default. If you want to set it to True, modify the corresponding section of the user_settings.options file to resemble the following:

```
[IncrediBuild Options]
useIncrediBuild = True
;IncrediBuild_max_cores = 128
;auto_updateIncrediBuild_settings = False
;IncrediBuild_profile = Tools/build/waf-1.7.13/profile.xml
```

Overriding user_settings.options Changes

If you use the the user_settings.options file to override a default value like useIncrediBuild, you can override the change temporarily by using the command line argument defined for the setting, as shown in the following example:

```
lmbr_waf build_win_x64_vs2017_profile -p all --use-incredibuild=False
```

**Note**

Using the lmbr_waf command to override a value does not update the value in the user_settings.options file.

Waf User Settings (user_settings.options)

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Global Waf build system settings are specified in the user_settings.options file located in the lumberyard_version\dev\WAF_subdirectory. If the user_settings.options file does not exist, Lumberyard uses the default_settings.json and platform-specific .json files to create a new one automatically. Every build that runs refers to this file to get the option values specific to the build.

The settings listed can be modified in the file directly, or through the Lumberyard WAF settings dialog box. To invoke the settings dialog box, enter show_option_dialog command into Waf as follows:

```
lmbr_waf show_option_dialog
```
The tables in the following sections describe the options available for override in the user_settings.options file. To override any setting, you can use the Override Parameter for the attribute. For more information, see Overriding user_settings.options Changes (p. 80).

Topics
- default_settings.json Options (p. 81)
- Output Folder Options (p. 86)
- Platform-Specific Options (p. 87)

### default_settings.json Options

The following tables describe the options defined in the default_settings.json file.

#### Build Options

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Override Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>copy_3rd_party_pdbs</td>
<td>--copy-3rd-party-pdb</td>
<td>Copies .pdb files from third party libraries for debugging.</td>
<td>True</td>
</tr>
<tr>
<td>crash_handler_token</td>
<td>--crash-handler-token</td>
<td>Token that you use to submit crash reports.</td>
<td></td>
</tr>
<tr>
<td>crash_handler_url</td>
<td>--crash-handler-url</td>
<td>Endpoint where you submit crash reports.</td>
<td></td>
</tr>
</tbody>
</table>
## Attribute

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Override Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable_dynamic_file_globbing</td>
<td>--enable-dynamic-file-globbing</td>
<td>Enables globbing of files during all build operations, globbing only once during configure.</td>
<td>False</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong> Excessive usage of file globbing negatively impacts build performance.</td>
<td></td>
</tr>
<tr>
<td>enable_link_time_optimization</td>
<td>--enable-link-time-optimization</td>
<td>If true, link time optimizations and code generation are enabled in the performance and release configurations.</td>
<td>False</td>
</tr>
<tr>
<td>enable_memory_tracking</td>
<td>--enable-memory-tracking</td>
<td>Enable the AZCORE_ENABLE_MEMORY_TRACKING define, which allows the Memory Driller to run and track all allocations.</td>
<td>False</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong> This option severely impacts code execution times.</td>
<td></td>
</tr>
<tr>
<td>enable_msvc_timings</td>
<td>--enable-msvc-timings</td>
<td>Enable output timing information for msvc compile and link operations.</td>
<td>False</td>
</tr>

<thead>
<tr>
<th>Attribute</th>
<th>Override Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>specs_to_include_in_project_generation</td>
<td>--specs-to-include-in-project-generation</td>
<td>List of Waf spec files (p. 74) to include in the Visual Studio solution generation.</td>
<td>all, game, game_and_engine</td>
</tr>
<tr>
<td>visual_studio_solution_folder</td>
<td>--visual-studio-solution-folder</td>
<td>Name of the directory in which the generated Visual Studio solution should be stored.</td>
<td>Solutions</td>
</tr>
</tbody>
</table>

### Output Folder Options

Output folder options determine build output paths and folder name extensions for specific types of builds and environments.

The output path attributes in the Output Folder table can have configuration-based extensions from the Output Folder Name Extensions table. The output path attributes are autogenerated by Waf from the enabled platforms. The default values are defined by the default_folder_name attribute in each target's `lumberyard_version\dev\_WAF_\settings\platforms\platform.target.json` file.

#### Output Folder

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Override Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>out_folder_android_armv8_clang</td>
<td>--output-folder-android-armv8-clang</td>
<td>The base output folder name for the android_armv8_clang platform.</td>
<td>BinAndroidArmv8Clang</td>
</tr>
<tr>
<td>out_folder_ios</td>
<td>--output-folder-ios</td>
<td>Absolute or relative iOS target platform build output path.</td>
<td>BinIos</td>
</tr>
<tr>
<td>output_folder_darwin_x64</td>
<td>--output-darwin-x64</td>
<td>Absolute or relative macOS (Darwin) target platform build output path.</td>
<td>BinMac64</td>
</tr>
<tr>
<td>out_folder_win_x64_vs2017</td>
<td>--output-folder-win64-vs2017</td>
<td>The base output folder name for the win_x64_vs2017 platform.</td>
<td>Bin64vc141</td>
</tr>
<tr>
<td>out_folder_win_x64_vs2019</td>
<td>--output-folder-win64-vs2019</td>
<td>The base output folder name for the win_x64_vs2019 platform.</td>
<td>Bin64vc142</td>
</tr>
</tbody>
</table>

The following name extensions are appended to the output folder based on the target platform builds. These configuration extension options are autogenerated by Waf. The default values are defined by the default_output_ext attribute for each configuration in the `lumberyard_version\dev\_WAF_\settings\build_configurations.json` file.

#### Output Folder Name Extensions

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Override Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>output_folder_ext_debug</td>
<td>--output-folder-ext-debug</td>
<td>The output folder name extension for debug builds.</td>
<td>Debug</td>
</tr>
<tr>
<td>output_folder_ext_performance</td>
<td>--output-folder-ext-performance</td>
<td>The output folder name extension for performance builds.</td>
<td>Performance</td>
</tr>
</tbody>
</table>
## Attribute Override Parameter

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>output_folder_ext_profile</td>
<td>The output folder name extension for profile builds.</td>
</tr>
<tr>
<td>output_folder_ext_release</td>
<td>The output folder name extension for release builds.</td>
</tr>
</tbody>
</table>

## Platform-Specific Options

Specific settings for Android, iOS, macOS, and Windows are defined in files located in the `lumberyard_version\dev\_WAF\_settings\platforms\` directory as noted.

## All Platforms

The following settings define whether or not a platform is enabled to build. The default value comes from the value of the `enabled` key found in each platform-specific file in the `lumberyard_version\dev\_WAF\_settings\platforms\` directory.

### Enable Platform

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Override Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable_android_armv8_clang</td>
<td>--enable-android-armv8-clang</td>
<td>Enable the android_armv8_clang platform to build.</td>
<td>True</td>
</tr>
<tr>
<td>enable_win_x64_vs2017</td>
<td>--enable-win64-vs2017</td>
<td>Enable the win_x64_vs2017 platform to build.</td>
<td>True</td>
</tr>
<tr>
<td>enable_win_x64_vs2019</td>
<td>--enable-win64-vs2019</td>
<td>Enable the win_x64_vs2019 platform to build.</td>
<td>True</td>
</tr>
</tbody>
</table>

## Android

This section has been relocated to another part of the Lumberyard documentation, and is now part of the Reference for Android (p. 3187). See Waf settings (p. 3188).

## iOS

The following settings for iOS are defined in the `lumberyard_version\dev\_WAF\_settings\platforms\platform.ios.json` file.

### iOS Options

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Override Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>ios_paks</td>
<td>--ios-paks</td>
<td>Forces .pak files to be built in non-release builds.</td>
<td>False</td>
</tr>
</tbody>
</table>
iOS Project Generator

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Override Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>generate_ios_projects_automatically</td>
<td>--generate-ios-projects-automatically</td>
<td>Automatically generate an Xcode project for iOS.</td>
<td>True</td>
</tr>
<tr>
<td>ios_project_name</td>
<td>--ios-project-name</td>
<td>Name of the generated iOS project.</td>
<td>LumberyardiOSSDK</td>
</tr>
<tr>
<td>ios_project_folder</td>
<td>--ios-project-folder</td>
<td>Name of the directory in which the generated iOS projects should be stored.</td>
<td>Solutions</td>
</tr>
</tbody>
</table>

macOS

The following settings for macOS are defined in the `lumberyard_version\dev\WAF\settings\platforms\platform.darwin_x64.json` file.

Mac Options

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Override Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>mac_build_monolithic</td>
<td>--mac-build-monolithic</td>
<td>Boolean flag to generate a monolithic or a non-monolithic build for macOS.</td>
<td>False</td>
</tr>
<tr>
<td>darwin_paks</td>
<td>--darwin-paks</td>
<td>Forces .pak files to be built in non-release builds.</td>
<td>False</td>
</tr>
</tbody>
</table>

Mac Project Generator

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Override Parameter</th>
<th>Description</th>
<th>Default</th>

</thead>
<tbody>
<tr>
<td>generate_mac_projects_automatically</td>
<td>--generate-mac-projects-automatically</td>
<td>Automatically generate Xcode projects for macOS.</td>
<td>True</td>
</tr>
<tr>
<td>mac_project_name</td>
<td>--mac-project-name</td>
<td>Name of the generated project.</td>
<td>LumberyardSDK</td>
</tr>
<tr>
<td>mac_project_folder</td>
<td>--mac-project-folder</td>
<td>Name of the directory in which the generated macOS projects should be stored.</td>
<td>Solutions</td>
</tr>
</tbody>
</table>

Windows

The following settings for Visual Studio are defined in the `lumberyard_version\dev\WAF\settings\platforms\common.win_msvc.json` file.
Visual Studio Options

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Override Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>generate_vs_solution_automatically</td>
<td>--generate-vs-solution-automatically</td>
<td>Automatically generate Visual Studio solutions during every configure.</td>
<td>True</td>
</tr>
</tbody>
</table>

The following settings for Visual Studio 2017 are defined in the `lumberyard_version\dev\WAF\settings\platforms\platform.win_x64_vs2017.json` file.

Visual Studio 2017 Options

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Override Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>generate_vs2017_projects_automatically</td>
<td>--generate-vs2017-projects-automatically</td>
<td>Automatically generate Visual Studio 2017 projects and solutions during every configure if the Windows VS2017 platform is enabled.</td>
<td>True</td>
</tr>
<tr>
<td>vs2017_solution_name</td>
<td>--vs2017-solution-name</td>
<td>The name of the generated Visual Studio 2017 solution.</td>
<td>LumberyardSDK_vs2017</td>
</tr>
<tr>
<td>win_vs2017_vcvarsall_args</td>
<td>--win-vs2017-vcvarsall-args</td>
<td>Additional arguments to pass to the vcvarsall.bat file.</td>
<td></td>
</tr>
<tr>
<td>win_vs2017_vswhere_args</td>
<td>--win-vs2017-vswhere-args</td>
<td>The arguments to pass to vswhere when locating Visual Studio 2017 executables. The default maximum is up to but not including the next major version of Visual Studio. The default minimum is the last known ABI incompatibility for Lumberyard builds.</td>
<td>-version [15.9.28307.770,16.0)</td>
</tr>
<tr>
<td>win_vs2017_winkit</td>
<td>--win-vs2017-winkit</td>
<td>The windows kit that Visual Studio 2017 builds Windows targets against.</td>
<td></td>
</tr>
</tbody>
</table>

The following settings for Visual Studio 2019 are defined in the `lumberyard_version\dev\WAF\settings\platforms\platform.win_x64_vs2019.json` file.

Visual Studio 2019 Options

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Override Parameter</th>

<tr>
<td>win_vs2019_vswere_args</td>
<td>--win-vs2019-vswere-args</td>
<td>The arguments to pass to vswere when locating Visual Studio 2019 executables. The default maximum is up to but not including the next major version of Visual Studio. The default minimum is the last known ABI incompatibility for Lumberyard builds.</td>
<td>-version [16.2.29230.47,17.0]</td>
</tr>
</tbody>
</table>

**Waf Commands and Options**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

**Contents**

- Waf Configuration (p. 90)
- Build Configuration (p. 91)
- Multiplayer Configuration (p. 95)

Before building a project using Waf, you must run `configure` from the command line. The `configure` command recursively processes all of the wscript configuration files starting from the root directory and generates a Visual Studio solution file for the entire project. You can set an option to generate a solution file during the `configure` command.

**Note**

The Waf script automatically runs Lumberyard Setup Assistant to ensure the correct third-party libraries are available and the proper links are created to compile the game code, engine and asset pipeline, and editor and tools.

**Waf Configuration**

To run the Waf executable, run the following command at the `lumberyard_version\dev\` directory of your project:

`lmbr_waf configure`

This command iterates through all the Waf project configuration files and sets up the project-specific settings in the Waf cache, which is used in subsequent build commands. It also uses the host environment to determine which platforms are available to build.
Example

The following example shows the output of the `lmbr_waf configure` command:

```
[WAF] Executing 'configure'
Running SetupAssistant.exe...
---- Lumberyard Setup Assistant ----
SDK location: d:/lumberyard_engine/dev
Third party location: d:/lumberyard_engine/dev/3rdParty
Capabilities Available, [x] enabled - [ ] disabled:
[ ] rungame - Run your game project
[ ] runeditor - Run the Lumberyard Editor and tools
[X] compilegame - Compile the game code
[X] compileengine - Compile the engine and asset pipeline
[X] compileeditor - Compile the Lumberyard Editor and tools
[ ] compileandroid - Compile for Android devices
[ ] compileios - Compile for iOS devices
Successfully executed
[INFO] Configure "win_x64_vs2017 - [debug, profile, performance, release, debug_dedicated, performance_dedicated, release_dedicated]"
[INFO] Configure "win_x64_vs2019 - [debug, profile, performance, release, debug_dedicated, performance_dedicated, release_dedicated]"

[WAF] 'configure' finished successfully (10.335s)
[WAF] Executing 'generate_uber_files' in 'd:\ws\lyengine\dev\BinTemp'
[WAF] 'generate_uber_files' finished successfully (2.177s)
[WAF] Executing 'msvs' in 'd:\ws\lyengine\dev\BinTemp'
```

The `configure` command uses the settings defined in the `user_settings.options` file that is located in the `lumberyard_version\dev\_WAF_` subfolder. You can edit this file in a text editor or enter the following command to use the Lumberyard Waf settings tool:

```
lmbr_waf show_option_dialog
```

By default, whenever the `configure` command is run, Visual Studio solution and project files are created in the `dev\Solutions` directory. The name of the solution file includes the version of Visual Studio for which it has been generated, such as `LumberyardSDK_vs2017.sln`. You can change this behavior, the solution directory, and the solution name in the `user_settings.options` file.

You can also generate the solution files manually by running the command `lmbr_waf msvs`, or the version-specific `lmbr_waf msvs_2017`.

Build Configuration

After configuring Waf, you can run the `build` command.

The following example shows the syntax:

```
lmbr_waf build_platform_configuration -p spec
```

The following commands and options are available:

- `configure` – Must be run before any clean or build command. Loads all modules, configs, and project specs; validates and sets up the working cached build Python file.
- `build_*` – Builds the specified project spec for the specified platform and configuration.
- `package_*` – Creates a runnable package of the specified project spec for the specified platform and configuration for supported platforms. Supported operating systems and devices include Android, iOS, and macOS.
Using the Waf Build System

- **deploy_*** – Deploys the specified project spec for the specified platform and configuration to a remote device for supported platforms. Supported operating systems and devices include Android.
- **clean_*** – Cleans out intermediate and target files that were generated for the particular platform and configuration.

The following example shows how to build release for Windows x64 with Visual Studio 2017:

```
lmbr_waf build_win_x64_vs2017_release -p all
```

**Note**
Combining the `clean_*` and `build_*` commands is the equivalent of performing a rebuild.

**Configure command options**

<table>
<thead>
<tr>
<th>Command</th>
<th>Command Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>build_*</td>
<td><code>-p spec_name</code></td>
<td>The spec name to use to build or clean a project.</td>
</tr>
<tr>
<td>package_*</td>
<td><code>--project-spec=spec_name</code></td>
<td>Optional flag to filter on which targets to build. The targets must be included in the project spec above in order for this to work.</td>
</tr>
<tr>
<td>clean_*</td>
<td><code>--targets=target1,target2,...</code></td>
<td>Optional flag to filter on which targets to build. The targets must be included in the project spec above in order for this to work.</td>
</tr>
<tr>
<td>build_*</td>
<td>`--profile-execution=(True</td>
<td>False)`</td>
</tr>
<tr>
<td>clean_*</td>
<td><code>--execsolution=VS_solution_path</code></td>
<td>This internally-generated command line is a Visual Studio solution that provides a way to build Waf commands invoked from the VS IDE to apply additional overrides that can be defined in the .vcxproj files themselves.</td>
</tr>
<tr>
<td>config</td>
<td><code>--file-filter=source_files</code></td>
<td>An option to pass in a comma-separated list of absolute paths to source files to filter the build on. This option is useful to build specific files.</td>
</tr>
<tr>
<td>build_*</td>
<td>`--show-includes=(True</td>
<td>False)`</td>
</tr>
<tr>
<td>build_*</td>
<td>`--show-preprocessed-file=(True</td>
<td>False)`</td>
</tr>
<tr>
<td>build_*</td>
<td>`--show-disassembly=(True</td>
<td>False)`</td>
</tr>
</tbody>
</table>
Using the Waf Build System

<table>
<thead>
<tr>
<th>Command</th>
<th>Command Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure</td>
<td>--update-settings=(True</td>
<td>False)</td>
</tr>
</tbody>
</table>

You can set the command options at build time. These options override the values set in the user_settings.options file. For more information, see Project Configurator (p. 80).

Only modules that support each project configuration are built from the project spec. If a module is defined in the spec that only can be built in debug or profile, building in performance mode excludes that project from compilation.

Project configurations parameters

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Asserts</th>
<th>Profiling</th>
<th>Optimization</th>
<th>Logging</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<tr>
<td></td>
<td></td>
<td>The following example runs only the package command:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>lmbr_waf package_android_armv8_clang_profile --deploy-android=False</code></td>
</tr>
</tbody>
</table>
Using the Waf Build System

### Command Option Description

The following command ensures that all three commands (`build`, `package`, and `deploy`) run:

```
lmbr_waf -p all build_android_armv8_clang_profile --package-projects-automatically=True --deploy-android=True
```

### Multiplayer Configuration

Before you can build multiplayer information, you must build the dedicated server. This creates a directory called `Bin64.Dedicated` that includes the binaries directory and configuration files for the dedicated server.

To build the dedicated server, run the following build command for your version of Visual Studio:

```
lmbr_waf build_win_x64_vs2017_profile_dedicated -p dedicated_server
```

### Waf Supported Operating Systems and Compilers

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This topic provides information about the operating systems and compilers that Waf supports. For more information about supported configurations, see Waf Commands and Options (p. 90).

#### Supported operating systems

<table>

**Waf Project Settings**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

When defining a project's build settings (wscript), you can specify several different project settings for the build modules to configure the correct parameters for the project.

The following table provides the valid attributes for the different build modules.

**Build attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
<th>Target to Platform or Configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>additional_manifests</td>
<td>Additional manifests to add to MSVC applications</td>
<td>Y</td>
</tr>
</tbody>
</table>
| additional_settings         | Container that groups compile settings and acts upon them recursively; useful for specifying options for particular files in a project For example, you can disable precompiled headers for a specific file using the following: 
```... additional_settings = Settings ( files = 'my_file.cpp', disable_pch=True ) ``` | Y                                   |
<p>| build_in_dedicated          | True by default; if False, the module will not be built when building in dedicated server mode | N                                   |
| cflags                      | Additional C flags to pass to the compiler                                 | Y                                   |
| cxxflags                    | Additional CXX flags to pass to the compiler                               | Y                                   |
| defines                     | List of additional pre-processor defines for the project                   | Y                                   |
| enable_rtti                 | Enable RTTI for a particular module                                        | Y                                   |</p>
<table>

<td>Y</td>
</tr>
<tr>
<td>vs_filter</td>
<td>Folder filter in the generated solution file where this project exists</td>
<td>N</td>
</tr>
</tbody>
</table>

### Platform and Configuration Targeting

If allowed (refer to the third column in the table above), you can set an attribute value to apply only under certain target platforms and configurations. Each attribute can be universal for all builds or targeted specifically to a platform/configuration combination:

- `[Attribute]` – Applies to any target platform/configuration for the attribute
- `[target_platform]_[attribute]` – Applies to any configuration for a specific target platform for the attribute
- `[configuration]_[attribute]` – Applies to a specific configuration for any target platform for the attribute
- `[target_platform]_[configuration]_[attribute]` – Applies to a specific target platform and configuration for the attribute

### Features

The Lumberyard Waf system allows the use of custom features to add functionality to a project's build pipeline.

#### Build features

<table>
<thead>
<tr>

<td>Sets the following for building and linking against the AWS Native SDK library: environment, includes, libraries, and library paths</td>
</tr>
</tbody>
</table>
### Using the Waf Build System

#### AWSGameLift
Sets the following for building and linking against the AWS GameLift library: environment, includes, libraries, and library paths

#### GridMate
Sets the following for building and linking against the GridMate library: environment, includes, libraries, and library paths

### Using the Waf Artifacts Cache

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Waf artifacts cache is for Waf-generated files. The cache speeds up Waf build time by caching previously built artifacts and retrieving them when the task signature hasn't changed. To calculate the task signature, Lumberyard uses MD5 hashes of the task's run function, source file, dependencies, and build environment.

#### Improvements in Build Time

The Waf artifacts cache can significantly improve clean, non-incremental build time. The following table shows, in minutes, typical differences in build times for packaging jobs.

<table>
<thead>
<tr>
<th>Operating System or Device</th>
<th>Clean Build Time Without Cache</th>
<th>Clean Build Time with Cache</th>
</tr>
</thead>
<tbody>
<tr>
<td>PC</td>
<td>75</td>
<td>14</td>
</tr>
<tr>
<td>macOS</td>
<td>163</td>
<td>25</td>
</tr>
</tbody>
</table>

#### Supported File Types

Unlike the normal compiler cache, which caches only `.obj` files, the Waf artifacts cache caches all files that Waf generates. It supports the following file extensions: `.h`, `.cpp`, `.json`, `.o`, `.obj`, `.inl`, `.inline`, `.rc`, `.res`, `.moc`, `.lib`, `.dll`, `.exp`, `.pdb`, `.manifest`, and `.exe`.

#### Limitations and Notes

Keep in mind the following limitations and considerations about the Waf artifacts cache.

- The Waf artifacts cache can be used among multiple machines that have different build paths. However, to correctly retrieve files from the cache, all builds must use the same version compiler and linker.
- The Waf artifacts cache doesn't support the `/Zi` compiler flag. Use the `/Z7` compiler flag instead.

The Waf artifacts cache is implemented at the Waf level, not at the compiler/linker level. When you use the `/Zi` flag, the compiler generates a separate `.pdb` file for the `.obj` file. However, because Waf does not know the `.pdb` file name in advance, it cannot upload or retrieve the `.pdb` files. When you use the `/Z7` flag instead, the symbolic debugging information is stored in the `.obj` file itself.
• The compiler assumes the same compilation environment when you use a `.pch` file. Therefore, caching precompiled headers across different workspace paths is not supported. For more information, see Precompiled Header Consistency Rules in the Microsoft Visual Studio documentation.

• When caching for different workspace paths is enabled, builds with and without Waf artifacts caching have different task signatures. Thus, if you run a build with Waf cache and then run another build without Waf cache, all files are recompiled.

## Waf Options

The Waf artifacts cache feature has the following Waf options:

---artifacts-cache -- Specifies a string that represents the artifacts cache path. The cache path can be any directory path on local disk or on a net share. The default value is the empty string ("""). If the option is not set or empty, the artifacts cache is not used.

---artifacts-cache-restore -- If true, the task's target output files are copied from the artifacts cache before the task is run. The default value is false.

---artifacts-cache-upload -- If true, the task's target output files are uploaded to the artifacts cache after the task is finished. The default value is false.

### Example

The following command specifies the artifacts cache path as `E:\waf_artifacts_cache` and restores artifacts from cache on cache hit. On cache miss, the command uploads the task's target output files to the artifacts cache after the task is finished.

```
lmbr_Waf build_win_x64_vs2017_fullprofile -p all --artifacts-cache="E:\waf_artifacts_cache" --artifacts-cache-restore=True --artifacts-cache-upload=True
```

To build using Visual Studio, update the `dev/_WAF_/user_settings.options` file to enable the artifacts cache as in the following example:

```
artifacts_cache = E:/artifacts_cache
artifacts_cache_restore = True
artifacts_cache_upload = True
```

## Deleting State Artifacts

Use the `clean_stale_cached_artifacts` Waf command to delete stale artifacts from the cache. The command has the following options:

---artifacts-cache-days-to-keep -- Number of days to keep the artifacts before they are considered stale.

---artifacts-cache-wipeout -- If true, deletes all artifacts from the cache.

### Examples

The following example specifies that artifacts in the cache location `E:\waf_artifacts_cache` be kept for four days.

```
lmbr_waf clean_stale_cached_artifacts --artifacts-cache="E:\waf_artifacts_cache" --artifacts-cache-days-to-keep=4
```

The following example deletes all artifacts from the cache location `E:\waf_artifacts_cache`. 

Version 1.28

100
lmbr_waf clean_stale_cached_artifacts --artifacts-cache="E:\waf_artifacts_cache" --artifacts-cache-wipeout=True

How the Waf Artifacts Cache Works

The Waf cache feature helps ensure that the proper task uid and env signatures are used.

Waf Pickle File

The Waf pickle file stores information about Waf targets.

For a clean build, the Waf cache feature uses a signature calculated before run() is called to decide the task's runnable status. However, because of changes in node dependencies, outputs or build environment, the task's signature can change between the calls to run() and post_run(). Merging the cached Waf pickle file with the local Waf pickle file helps to ensure that Waf can get the right dependencies for a task. It also helps to ensure that Waf can get the signature that matches the task signature from cache.

The Waf pickle file has the following attributes.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>root</td>
<td>The node that represents the root of the file system.</td>
<td>Node.</td>
</tr>
<tr>
<td>node_deps</td>
<td>Implicit dependencies.</td>
<td>Dictionary mapping of a task-computed uid to nodes.</td>
</tr>
<tr>
<td>raw_deps</td>
<td>Implicit file dependencies that could not be resolved.</td>
<td>Dictionary mapping of a task-computed uid to any serializable type.</td>
</tr>
<tr>
<td>task_sigs</td>
<td>Signature of the tasks that are run.</td>
<td>Dictionary mapping of a task-computed uid to a hash that represents the task's signature.</td>
</tr>
<tr>
<td>azcg</td>
<td>Data for AzCodeGen tasks.</td>
<td>Dictionary mapping of a task-computed uid to a list of AzCodeGen saved data.</td>
</tr>
<tr>
<td>cached_engine</td>
<td>Engine path for the build that created the cached pickle file.</td>
<td>String</td>
</tr>
<tr>
<td>cached_tp_root</td>
<td>Third-party path for the build that created the cached pickle file.</td>
<td>String</td>
</tr>
</tbody>
</table>

Loading Data from a Waf Pickle File

To use the Waf artifacts cache, Waf must have the latest build pickle data from a cached pickle file. It then must merge that data with the local build pickle data. If an entry with the task uid key appears in both local data and cached data, then the local one is used. If the data merged from both pickle files contains node instances from the cached build which are unusable in current build, those node instances are recreated for the current build.

The following diagram shows this workflow.
Initiate BuildContext

Load build data from local pickle file if exists

Load build data from cached pickle file if exists, delete cache_sig from all nodes.

Merge two build data (like task signatures, task dependencies), if there is value conflict, then keep the value from local data.

Recursively find all the node instances that come from the cached build, and recreate the nodes for current build.

Task producer starts
Overriding the Task’s uid and env Signatures

When using the Waf artifacts cache feature across multiple machines with different paths, the task's uid and env signature shouldn't depend on an absolute path. When the Waf artifacts cache is enabled, the calculation of task's uid and env signatures is overridden and the absolute path is converted to a relative path.

Executing Tasks

When the Waf artifacts cache is enabled, it tries to retrieve the target files from the cache before it runs a task. If a cache miss or an error occurs during the file transfer, it runs the task and uploads the generated target files to the Waf artifacts cache after post_run() is called.

When the target files are successfully copied from the Waf artifacts cache, Waf skips the run function and calls post_run(). Because Lumberyard customizes the run and post_run functions for each task type, it can update a task's dependencies, outputs, or build environment. This changes the task's signature. When the run function is skipped, Lumberyard updates the task's dependencies, outputs, or build environment in the post_run function to keep the signature consistent.

For example, during the run function, the AzCodeGen task updates the task's INCPATHS and creates new linking tasks. If the AzCodeGen task's target output files are retrieved from cache successfully, the run function is skipped. Then Lumberyard uses the post_run function to update the task's INCPATHS and create new linking tasks.

The following diagram shows this workflow.
Adding Third-Party Libraries

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Gems (p. 1064) are Lumberyard extensions that can be enabled or disabled for any game project. This modularity is advantageous when you want to add a third-party library to specific games. You can add the third-party library to a new or existing gem, and then enable the gem for the projects that you want. This narrows the scope of the library to only the games that use the gem.

Adding a third-party library to a gem includes the following steps:

1. Determine the location of the library's content files, including its include headers, static libraries, and/or shared libraries.
2. Create a definition file for the library.
3. Configure other gems or modules to use the library.
4. Run `lmbr_waf configure` to process the library definition files.

In the following example, the steps add a fictional third-party library to a gem. The library is a static library called "SuperLibrary" that supports both Windows and macOS. The gem is called "MyGem".

**Step 1. Determine the Location of the Third-Party Library**

When you add a third-party library to a gem, you specify two locations: one for the library definition, and one for the library contents.

**Definition File**

The gem module expects the third-party SDK .json definition file (in this example, `superlibrary.json`) to reside in a subdirectory named `3rdParty`. The following gem directory structure shows the location of the `lumberyard_version\dev\Gems\gem_name\3rdParty` directory.

```
+---\3rdParty
+---\Assets
+---\Code
|   +---\wscript
+---\External
+---\gem.json
```

**Library Files**

The library code file location is not predetermined, but a best practice is to place them inside the gem's directory structure in an `External\SDK_name` directory, like this:

```
lumberyard_version\dev\Gems\gem_name\External\SDK_name
```

The following directory structure shows the `External` directory with the `SuperLibrary` directory inside.

```
+---\External
    +---\SuperLibrary
        +---\includes
            +---superlibrary.h
```
Step 2. Create a Third-Party Library Definition File

Create a .json definition file for the third-party library. Using the directory structure from the previous step, the third-party definition file superlibrary.json looks like this:

```json
{
    "name": "SUPERLIBRARY",
    "source": "@GEM@/External/SuperLibrary",
    "description": "My Super Library",
    "includes": [
        "Include"
    ],
    "defines": [],
    "lib_required": "True",
    "platform": {
        "win_x64_vs2017": {
            "libpath": [
                "lib/win32"
            ],
            "lib": [
                "superlibrary.lib"
            ]
        },
        "win_x64_vs2019": "@win_x64_vs2017",
        "darwin_x64": {
            "libpath": [
                "lib/osx"
            ],
            "lib": [
                "superlibrary.a"
            ]
        }
    }
}
```

Note

- The `source` key contains an alias called `@GEM@`. The `@GEM@` alias represents the root path of the current gem. The `source` key specifies the base of the third-party library directory on which the other paths specified by keys like `includes` and `libpath` are based.
- The `platform` key sections describe the locations of platform-specific library files based on the library identifier.

For more information, see Creating Third-Party Library Configuration Files for Waf (p. 108).

Step 3. Apply the Library to Modules or Gems That Require It

By default, after the third-party library definition is set in the gem, it is automatically available to that gem. In order for this gem to be available in other modules, those modules need to add `SUPERLIBRARY` to their `uselib` list.

Other gems (or the game gem) that require access to the gem-scoped third-party library must establish a dependency on the gem that has the library. For example, if you want a gem called `OurGem` to have...
access to the SuperLibrary library in MyGem, OurGem's gem.json file must define a dependency on MyGem.

**Example**

In the OurGem.gem.json file, OurGem declares a dependency on MyGem:

```json
{
    "Dependencies": [
        {
            "Uuid": "981435f1646a4ccfbd7733920c011b6",
            "VersionConstraints": [
                ">=0.1"
            ],
            "_comment": "MyGem"
        }
    ],
    "GemFormatVersion": 3,
    "Uuid": "1daafa0ea544f64befb74a1cc719a9c",
    "Name": "OurGem",
    "DisplayName": "Our Gem",
    "Version": "0.1.0",
    "LinkType": "Dynamic",
    "Summary": "Our Gem",
    "Tags": ["Animation"],
    "IconPath": "OurGem.png",
    "EditorModule" : true
}
```

In the lumberyard_version\dev\Gems\OurGem\Code\wscript file, the uselib key must specify SUPERLIBRARY:

```python
def build(bld):
    bld.DefineGem(
        uselib = ['SUPERLIBRARY'],
        file_list  = ['our_gem.waf_files']
    )
```

### Step 4. Configure and Validate the Library Definition

Now you can test your definitions by using the Waf configure command, which processes third-party definitions. Before you begin, use the Project Configurator to ensure that the gem that has the third-party library is enabled for the game project. For more information, see Enabling Gems (p. 1064).

From the engine root path, run the configure command:

```
lmbr_waf configure
```

After the configure command completes successfully, the configured values appear in the Waf variant cache files in the BinTemp\c4che directory.

The entries are similar to the following ones in the variant cache file for the Microsoft Visual Studio 2017 profile configuration lumberyard_version\dev\BinTemp\c4che\win_x64_vs2017_profile_cache.py:

```python
... INCLUDES_SUPERLIBRARY = ['C:\\MyProj\\Lumberyard-1.16\\Gems\\MyGem\\External\\Include'] ...
```
Updating a Third-Party Library in a Gem

To update a third-party library that is defined in a gem, you don't have to create a new third-party definition file. Instead, you can update the existing definition file. As a best practice, place the third-party library files in a version-named subfolder. To maintain good dependency tracking, we recommend that you update the gem version when you update a third-party library.

Creating Third-Party Library Configuration Files for Waf

Lumberyard's Waf build system has the ability to incorporate third-party libraries. Waf's uselib mechanism can apply the proper dependency injection of a third-party library into any project or module. In the wscript file, the uselib attribute specifies all-caps identifiers that represent the third-party libraries. The identifiers are defined in the .json configuration files that can exist either in the global _WAF_\3rdParty directory or in the gem-specific 3rdParty directory. These configuration files provide details for the library, including include paths, library paths, and linkage information. The files also specify whether the library is shared, dynamic, or header-only.

Topics
- Key Features (p. 108)
- Supported Library Types (p. 110)
- Using Aliases (p. 113)
- Creating Entries for Multiple Related Libraries (p. 114)
- Third-Party Library Configuration File Attributes (p. 116)
- Special Reserved Words (p. 117)

Key Features

Key features of the uselib mechanism include centralized management and an abstraction layer that makes it easy to use the same libraries across Lumberyard projects and modules.

Centralized Management

Encapsulating the build details within a single file helps centralize the management of third-party libraries. Centralized management in a single file is also beneficial when changes like different include paths or libraries to the third-party library occur. These configuration files can be global to the entire engine, or gem-specific based on the gems that are enabled for the game.

Abstraction

The third-party identifiers provide an abstraction layer between the third-party library details and the consuming project or module. This layer makes it unnecessary to explicitly inject the paths for the library and include headers for each project or module that uses the library. Instead, the uselib mechanism with the third-party identifier provides the necessary injection of paths, libraries, and custom rules.
For example, assume you have two third-party libraries, StaticLibA and DynamicLibB, that you want to link into test project ProjectOne. Without the uselib system, the wscript file for ProjectOne would look like the following:

**Example**

**ProjectOne\wscript**

```python
def build(bld):
    bld.LumberyardSharedLibrary(
        target = 'ProjectOne',
        ...
        includes = ['3rdParty/StaticLibA/includes',
                    '3rdParty/DynamicLibB/includes'],
        win_stlibpath = ['3rdParty/StaticLibA/win32/lib'],
        darwin_stlibpath = ['3rdParty/StaticLibA/osx/lib'],
        ...
        win_libpath = ['3rdParty/DynamicLibB/win32/bin'],
        darwin_libpath = ['3rdParty/DynamicLibB/osx/bin'],
        ...
        lib = ['staticliba', 'dynamiclibb'],
        ...
        win_copy_dependent_files = ['3rdParty/DynamicLibB/win32/bin/dynamiclibb.dll'],
        darwin_copy_dependent_files = ['3rdParty/DynamicLibB/win32/bin/
libdynamiclibb.dylib'],
        ...
    )
```

Instead, you could use the following third-party configuration files for the two libraries, as in the following examples:

**Example**

**StaticLibA.json**

```json
{
    "name": "STATIC_LIB_A",
    "source": "3rdParty",
    "description": "My Static Library A",
    "includes": "includes",
    "platform": {
        "win_x64_vs2017": {
            "libpath": [
                "win32/lib"
            ],
            "lib": ["staticliba.lib"],
        },
        "darwin_x64": {
            "libpath": [
                "osx/lib"
            ],
            "lib": ["libstaticlibb.a"],
        }
    }
}
```

**Example**

**DynamicLibB.json**

```json
{
    "name": "DYNAMIC_LIB_B",
   ...
```
"source": "3rdParty",
"description": "My Dynamic Library B",
"includes": 
"platform": { 
  "win_x64_vs2017": { 
    "importlibpath": [ 
      "win32/lib"
    ],
    "import": [ 
      "dynamiclibb.lib"
    ],
    "shared": [ 
      "dynamiclibb.dll"
    ]
  },
  "darwin_x64": { 
    "importlibpath": [ 
      "osx/lib"
    ],
    "import": [ 
      "libdynamiclibb.a"
    ],
    "shared": [ 
      "libdynamiclibb.dylib"
    ]
  }
}

This now simplifies the wscript declaration for ProjectOne to the following:

Example

```
ProjectOne\wscript
def build(bld):
    bld.LumberyardSharedLibrary(
        target = 'ProjectOne',
        ...
        uselib = ['STATIC_LIB_A', 'DYNAMIC_LIB_B'],
        ...
    )
```

After you have created these third-party configuration files, you can apply the same simplification to any project or module in Lumberyard.

**Supported Library Types**

Third-party configuration files support the following library types:

- **Header Only** (p. 110)
- **Static** (p. 111)
- **Shared/Dynamic** (p. 112)

**Note**

For simplicity, the rest of this topic refers to shared/dynamic libraries as 'shared'.

**Header-only Libraries**

Header-only libraries provide only the include paths to the dependent project or module. The following example third-party library configuration file contains a definition for a header-only library:
Example

rapidxml.json

```json
{
  "name": "rapidxml",
  "source": "@3P:rapidxml@",
  "description": "Rapid XML header only library",
  "header_only": "True",
  "includes": [
    "include"
  ],
  "defines": [],
  "lib_required": "False"
}
```

This simple declaration specifies only the includes header path which is a subdirectory of the source directory. The source directory is defined by the alias pattern @3P:XXX@. For descriptions of the other attributes in this file, see Third-Party Library Configuration File Attributes (p. 116).

Static Libraries

Static third-party library configuration files declare header include paths, library include paths, and library names for inclusion in a dependent project or module. The following example third-party library configuration file contains a declaration for a simple static library.

Example

lz4.json

```json
{
  "name": "lz4",
  "source": "@3P:lz4@",
  "description": "LZ4 Compression Library",
  "includes": [
    "lib"
  ],
  "defines": [],
  "lib_required": "True",
  "shared_required": "False",
  "platform": {
    "win_x64_vs2017": {
      "libpath_debug": [
        "build/win_x64/vc140/debug"
      ],
      "libpath_release": [
        "build/win_x64/vc140/release"
      ],
      "lib": [
        "lz4.lib"
      ],
      "win_x64_vs2019": "@win_x64_vs2017",
      ...
    }
  }
```

Platform-Specific Information

In addition to the attributes described for header-only library definition, the preceding example includes platform-specific values. The platform attribute contains a dictionary of target platform sections. Each target platform must be specified here. If a particular target platform is not listed, this third-party library definition will not apply for that platform when built. Static libraries must specify the library
path (`libpath`) and the names of the library file (`lib`) against which to link for each platform. The configuration extension for the `libpath` attribute in the preceding example will be described later in this topic.

**Shared Libraries**

Shared libraries are more complex than static libraries. Shared libraries must declare an include path, import library path, shared library path, shared library file names, and optionally, program database (.pdb) files. The following example third-party library configuration file contains a definition for a shared library.

**Example**

`boostpython.json`

```json
{
  "name": "boostpython",
  "source": "@3P:boost@",
  "description": "Boost header library including python support libraries",
  "defines": [],
  "lib_required": "False",
  "platform": {
    "win_x64_vs2017": {
      "includes": ["."],
      "importlibpath": ["lib/windows/x64"],
      "sharedlibpath": ["lib/windows/x64"],
      "import_debug": ["boost_python-vc140-mt-gd-1_61.lib"],
      "import_release": ["boost_python-vc140-mt-1_61.lib"],
      "shared_debug": ["boost_python-vc140-mt-gd-1_61.dll"],
      "shared_release": ["boost_python-vc140-mt-1_61.dll"],
      "pdb_debug": ["boost_python-vc140-mt-gd-1_61.pdb"
      
    }
  },
}
```

The following table describes the attributes for shared library configuration files.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>importlibpath</td>
<td>Path to the import library that declares the exported symbols against which the dependent project or module links.</td>
</tr>
<tr>
<td>sharedlibpath</td>
<td>Path to the binaries of the shared library (the .dll file).</td>
</tr>
<tr>
<td>import</td>
<td>File names of the import libraries against which the dependent project or modules will link to get the exported symbols.</td>
</tr>
</tbody>
</table>
### Attribute Description

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>shared</td>
<td>File names of the binaries of the shared libraries.</td>
</tr>
<tr>
<td>pdb</td>
<td>File names of any pdbs that can be optionally copied over with the .dll file.</td>
</tr>
</tbody>
</table>

Besides providing the paths for header inclusion and linking, Lumberyard Waf also copies the shared library and PDB files to the path where the dependent project or module is built.

**Mixed Shared and Static Libraries**

In some cases, the third-party library is static on some platforms but shared on others. For cases like these, it is possible to declare mixed static and shared libraries for each platform.

**Using Aliases**

The following sections describe how to simplify the configuration file by using aliases for libraries, platforms, and paths.

**Aliasing Library Lists**

The same list of libraries might be needed in different platform sections of the configuration file. To avoid repetition, you can define and use a list alias that expands to a list of other values. This is helpful for cases in which you have multiple shared libraries that import libraries of the exact same name.

You define an alias in the *aliases* node under the root node in the configuration file. Add the name of the alias to the *aliases* node and a list of strings that the alias represents under the alias name.

In the following example, the *all_foo_lib_names* alias represents the libraries *foo_library_A* through *foo_library_D*. The library names must not have any prefixes or extensions.

**Note**

For some platforms, the file name to library name convention is different. For example, Linux-based libraries prefix the file name with *lib*, but Windows-based libraries do not.

In the *platform* section, the shared library definitions for *import*, *shared*, and *pdb* use the notation `${<ALIAS>}` to form the entries, where `<ALIAS>` is the name of the alias that was defined in the *aliases* section.
Aliasing Platform Declarations

Some different target platforms are binary compatible. In these cases, you do not have to declare a copy of an existing configuration section. Instead, you can use the platform attribute string alias `@<platform_name>` instead of another attribute dictionary.

In the following example, the `win_x64_vs2017` and `win_x64_vs2019` platforms are binary compatible, so the alias `@win_x64_vs2017` is used.

```
"platform": {
    "win_x64_vs2017": {
        "libpath_debug": ["build/win_x64/vc141/debug"],
        "libpath_release": ["build/win_x64/vc141/release"],
        "lib": ["foo.lib"
    ],
    "win_x64_vs2019": 
        "@win_x64_vs2017",
    ...
```

Aliasing Paths

Path aliasing for the `source` attribute is common within the configuration file. The alias value is denoted by `@XXXX@`, where the `XXXX` value resolves to an absolute path. The third-party configuration file recognizes two different path alias types:

- `@3P:YYYY@` – This alias refers to a third-party library that is managed by the Lumberyard Setup Assistant. These third-party libraries are globally available to the engine. Lumberyard Setup Assistant manages the location and version of these libraries independently from the build system. `YYYY` refers to the SDK identifier used by Lumberyard Setup Assistant and is different from the third-party `uselib` identifier used by Waf.
- `@GEM@` – This alias is valid only for gem-defined third-party libraries and refers to the base path of the gem from which the third-party library is defined. For information about putting third-party libraries in gems, see Adding Third-Party Libraries (p. 105).

Creating Entries for Multiple Related Libraries

Your project might have multiple libraries under a shared root source directory that are related but have separate purposes. This section shows how your configuration files can handle these more complex cases so that you can still take advantage of the `uselib` mechanism.

Build Configuration Filtering

Attributes can be constrained by build configuration. For example, a debug library and a release library might have the same name but exist in two different directories, as in the following example file structure:

```
/StaticLibA/
   /Include
       static_a.h
```
Using the Waf Build System

```plaintext
/lib
d/ebg
    static_a.lib
/release
    static_a.lib
```

The following example shows the configuration file declaration for this file structure. Notice that the `lib` attribute is specified once, but the `libpath` attribute is specified twice.

```plaintext
"include": ["Include"],
"libpath_debug": ["lib/debug"],
"libpath_release": ["lib/release"],
"lib": ["static_a.lib"]
```

If the libraries are in the same directory, but named differently, the file structure might look like this:

```plaintext
/StaticLibA/
/Include
    static_a.h
/lib
    static_aD.lib
    static_a.lib
```

In this case, the value for `libpath` in the configuration file is the same, but there are two values for `lib`:

```plaintext
"include": ["Include"],
"lib": ["lib"],
"lib_Debug": ["static_aD.lib"],
"lib_Release": ["static_a.lib"]
```

### Specifying Multiple Identifiers

A third-party library might contain a suite of libraries and be organized by specific categories according to need. In these cases, the configuration file can define more than one identifier. As long as the library files are under the same directory that is specified for the `source` attribute, the configuration can specify multiple third-party identifiers.

The following example configuration file defines two third-party identifiers that `uselib` will point to: `water_lib` and `air_lib`. The `lib` attribute is prefixed with the name of the third-party identifier. Both libraries are under the same elements library directory and exist individually as `water_lib.lib` and `air_lib.lib`. Both `water_lib` and `air_lib` require the same base `element_base.lib` library.

```plaintext
{
    "name": [
        "water_lib",
        "air_lib"
    ],
    "source": "elements",
    ...
    "platform": {
        "win_x64_vs2017": {
            "libpath": [
                "lib"
            ],
            "water_lib/lib": [
                "element_base.lib",
                "water_lib.lib"
            ],
            "air_lib/lib": [
```
"element_base.lib",
"air_lib.lib"
]

...}
%

...}

**Third-Party Library Configuration File Attributes**

The following attributes are used in third-party library definition files.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>string/ [string]</td>
<td>Name of the third-party identifier. The value for the identifier set here is represented in Lumberyard in all caps. If the definition file defines multiple third-party identifiers, the name attribute contains a list of names.</td>
</tr>
<tr>
<td>source</td>
<td>string (aliasable)</td>
<td>Base directory upon which all library paths defined in the configuration file are based.</td>
</tr>
<tr>
<td>description</td>
<td>string</td>
<td>Description for the third-party definition.</td>
</tr>
<tr>
<td>header_only</td>
<td>Boolean</td>
<td>Flag that indicates that the file specifies a header-only library definition.</td>
</tr>
<tr>
<td>includes</td>
<td>[string]</td>
<td>List of include paths to apply to any dependent project or module.</td>
</tr>
<tr>
<td>defines</td>
<td>[string]</td>
<td>List of additional defines to apply to any dependent project or module.</td>
</tr>
<tr>
<td>engine_configs</td>
<td>Boolean</td>
<td>When false, specifies that the library's debug configuration maps to the engine debug configuration and that release maps to profile, performance and release. The default is false. When true, accepts custom rules for each engine configuration. For example, if you want to use specific libraries for profile builds, you can specify values for libpath_profile and lib_profile. To copy specific binaries per configuration, you can also use attributes like copy_extra_debug, copy_extra_profile, and copy_extra_performance.</td>
</tr>
<tr>
<td>lib_required</td>
<td>Boolean</td>
<td>Flag that instructs the third-party configuration file parser whether to verify the existence of the declared static library files on disk.</td>
</tr>
<tr>
<td>shared_required</td>
<td>Boolean</td>
<td>Flag that instructs the third-party configuration file parser whether to verify the existence of the declared shared library files on disk.</td>
</tr>
<tr>
<td>suppress_warning</td>
<td>Boolean</td>
<td>Flag that disables warnings related to invalid third-party configurations. It is recommended that this flag be set to true for libraries that are optional.</td>
</tr>
<tr>
<td>platform</td>
<td>{ platform_def }</td>
<td>Dictionary of platform-specific settings (platform_def) that is keyed by the target platform name.</td>
</tr>
</tbody>
</table>
### Attribute Description

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>linkflags</td>
<td>[ string ]</td>
<td>List of linker flags to pass to the linker.</td>
</tr>
<tr>
<td>libpath</td>
<td>[ string ]</td>
<td>List of static library search paths to add to the consumers of this library. The paths are relative to the location specified by the source attribute.</td>
</tr>
<tr>
<td>lib</td>
<td>[ string ]</td>
<td>List of full static library file names (including file extensions) to add to the consumers of this library. The system validates the existence of the files by searching the locations defined in the libpath attribute.</td>
</tr>
<tr>
<td>sharedlibpath</td>
<td>[ string ]</td>
<td>List of paths that contain the shared libraries for this uselib definition. The paths are relative to the location specified by the source attribute.</td>
</tr>
<tr>
<td>shared</td>
<td>[ string ]</td>
<td>List of the shared library file names for this uselib definition. These shared libraries are copied to the output directory of the target of the consumer module.</td>
</tr>
<tr>
<td>importlibpath</td>
<td>[ string ]</td>
<td>Applies to Windows-based platforms only. A list of paths that contain import libraries for linking DLLs for this uselib definition. The paths are relative to the location specified by the source attribute.</td>
</tr>
<tr>
<td>import</td>
<td>[ string ]</td>
<td>Applies to Windows-based platforms only. A list of import library file names that represent this uselib definition. These libraries are used in the linker command.</td>
</tr>
<tr>
<td>frameworkpath</td>
<td>[ string ]</td>
<td>Applies to OSx-based platforms only. A list of framework paths that contain frameworks for this uselib definition. The paths are relative to the location specified by the source attribute.</td>
</tr>
<tr>
<td>framework</td>
<td>[ string ]</td>
<td>Applies to OSx-based platforms only. A list of frameworks that represent this uselib definition.</td>
</tr>
<tr>
<td>copy_extra</td>
<td>[ string ]</td>
<td>List of additional files to copy from the source to the target directory where the executables that consume this uselib definition reside. Each item in the list is a colon-delimited source-destination pair in the format <code>&lt;source&gt;:&lt;destination&gt;</code>. <code>&lt;source&gt;</code> specifies the source directory that contains the files relative to the location specified by the source attribute. <code>&lt;destination&gt;</code> is the directory to which the files are copied relative to the destination directory of the consuming target executable.</td>
</tr>
</tbody>
</table>

### Special Reserved Words

The following special reserved words are used in third-party library configuration files.

<table>
<thead>
<tr>
<th>Reserved Word</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@GEM@</td>
<td>Alias that represents the base directory of the gem. This is used for third-party configurations that reside within the gem.</td>
</tr>
<tr>
<td>%LIBPATH(&lt;libname&gt;)</td>
<td>Specifies a macro that resolves to the full path of <code>&lt;libname&gt;</code>. <code>&lt;libname&gt;</code> must be defined within the scope of the platform for which the macro is used.</td>
</tr>
</tbody>
</table>
Reserved Word | Description
--- | ---
| | is used. For example, if there is a library called libmath.lib whose absolute path is C:\libs, %LIBPATH(libmath.lib) resolves to C:\libs\libmath.lib. This is useful for linker flags like --force-load <libfullpath> that can be added as a link flag parameter. In the following example, libtomcrypt requires a force load on its library through its linker flags. The definition that achieves this is as follows:

```json
"linkflags": [
  "-force_load",
  "%LIBPATH(libtomcrypt.a)"
]
```

Waf Extensions

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Compiling with IncrediBuild

Waf supports IncrediBuild 8.0.1 or later, and allows for distributed network builds for compiling larger projects.

You must have the appropriate package for your operating system:

- **Windows** or **Android** – IncrediBuild for Make and Build or Accelerated Dev Tools

To verify which package is configured for your machine, run the following command (located in C:\Program Files (x86)\Xoreax\IncrediBuild): xgConsole.exe /QUERYLICENSE

The following is output:

```plaintext
> xgConsole.exe /QUERYLICENSE
License details:
----------------
Registered to: My Game Company
Up to XX Agents allowed
Maintenance expires on XX/XX/XXXX
Packages installed:
-------------------
- IncrediBuild for Make & Build Tools
```

<table>
<thead>
<tr>
<th>To do this</th>
<th>Run this at a command line</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable or disable IncrediBuild builds</td>
<td>use_incredibuild</td>
</tr>
<tr>
<td>Adjust the maximum number of parallel tasks</td>
<td>incredibuild_max_cores</td>
</tr>
</tbody>
</table>
Using the Waf Build System

To do this

Determine which IncrediBuild package is configured for your machine

Run this at a command line

xgConsole.exe /QUERYLICENSE

Waf requires certain packages and the Windows registry key settings below to run IncrediBuild. Run lmb\_\_waf\_\_\_waf.bat in Administrator mode to edit the registry.

Modify the settings in the Windows registry under the following key:

HKEY\_LOCAL\_MACHINE\Software\Wow6432Node\Xoreax\Incredibuild\Builder

Registry Settings

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxConcurrentPDBs</td>
<td>0</td>
<td>Controls how many files can be processed in parallel. This optimization is also useful for MSBuild.</td>
</tr>
</tbody>
</table>

To enable IncrediBuild

1. Open the user\_settings\_options file located in //_WAF_._
2. In the user\_settings\_options file, under [IncrediBuild Options], do the following:
   * Set the use\_incrdibuild flag to True.
3. Save your changes.

Note

Installing, reinstalling, or upgrading Visual Studio may cause the Incredibuild Agent to lose its settings or require an update. After modifying Visual Studio, be sure to confirm your Incredibuild Agent is active.

Compiling with QT

Waf supports compiling QT5 .moc Meta-Object-Compiler files. To enable or disable compiling of particular files, add the qt5 feature to your Waf Module (wscript) file and then add the list of files to be compiled.

The following example shows a Waf Module (wscript) file:

```python
# wscript relative path
QT\_TO\_MOC\_FILES = [ 
  'MyQTFile.h',
  'MyOtherQTFile.h',
  ...
]
def build(bld):
  bld.CryPlugin(
    target = 'MyQTPlugin',
    vs_filter = 'Plugins',
    file_list = 'file_list.waf_files',
    features = ['qt5'], # add the QT5 moc feature to this Waf module
  )
```

Version 1.28

119
Using Waf

Adding a Game Project

The simplest and recommended method to add a game project to the Lumberyard Waf build system is to use the Project Configurator. The Project Configurator is a standalone application for telling the Waf build system which game projects and assets to include in a game build. For more information, see Creating Lumberyard projects (p. 43).

You can also add a game project with the following steps:

- Create the project definition
- Create a game module
- Update the user settings to include the game

**Note**
You can build your game project by creating a game project first (see steps below) and then creating a spec for just the game (no modules, just basic spec values):

```
{
    "description": "Configuration to build the My Game",
    "visual_studio_name": "My Game"
}
```

When the project is properly defined and all source files are in the correct locations, you can set the enabled_game_projects value in the user_settings.options file. Configuring this value limits the Visual Studio solution to the launcher projects and your game project.

**Topics**
- Creating the Project Definition (p. 120)
- Creating a Game Module (p. 121)
- Updating the User Settings (p. 122)
the game-specific assets. You can define any number of game projects in this file and you can configure which ones to build.

**To create the project definition**

1. Navigate to the SDK root and locate the Code folder and project directory. Typically your game code folder should reside under these locations.
2. Determine the name for your project. For this example, use **My Game**.
3. Add the definitions for the new game project to the `project.json` file (located in the game project folder under the `lumberyard_version\dev` directory). For this example, add **My Game** to the SDK:

```
"project_name" : "SamplesProject",
"product_name" : "Samples Project",
"executable_name" : "SamplesProjectLauncher",
"code_folder" : "Code/SamplesProject",
"modules" : ["SamplesProject"],
"project_id": "{D882E365-54D6-586E-BD78-2650F3057D49}",
"sys_game_folder" : "SamplesProject",
"sys_dll_game" : "SamplesProject",
```

**Creating a Game Module**

You can create a game module after setting the game project definition. Game modules include wscript files, source files, and a waf_files configuration file. You must create separate folders for the game source code and for the resources. Both should reside under the `code_folder` specified earlier. For this example you create folders called **GameSource** and **Resources** under the `Code/MyGame` directory.

**Create a wscript file**

Because Waf searches for and discovers wscript files recursively through other wscript files, you must include a simple wscript file in the `Code/MyGame` folder that recurses to the `GameSource` folder.

Create a file with the following:

```python
SUBFOLDERS = ['GameSource']

def build(bld):
    bld.recurse(SUBFOLDERS)
```

Next you must create the source code in the **GameSource** folder. Include in this folder all of your source files and the corresponding Waf source file configuration (for example, **MyGame.waf_files**) to include your game files.

Create a wscript in the **GameSource** folder to define the build configuration for your game:

```python
def build(bld):
    bld.CryEngineModule(
        target = 'MyGame',
        vs_filter = 'Game/MyGame',
        file_list = 'MyGame.waf_files',
        pch = 'StdAfx.cpp',
    )
```
Create source files

All game projects first need a source file. If you intend to use pre-compiled headers you must create standard `StdAfx.h` and `StdAfx.cpp` files. For this example you create a single C++ file and a corresponding header file (`MyGameMain.cpp` and `MyGameMain.h`).

Create a waf_files configuration file

You use the waf_files configuration file to include the source files into the game module. For this example you create a file called `MyGame.waf_files` and specify it for the project. This file includes the four files you created from the previous step.

Create a waf_files configuration file called `MyGame.waf_files` with the following:

```json
{
  "auto": {
    "Source Files": ["MyGameMain.cpp"],
    "Header Files": ["MyGameMain.h"
  },
  "none": {"Root": [
    "StdAfx.h",
    "StdAfx.cpp"
  ]
}
}
```

Updating the User Settings

The final step is to update enabled_game_projects to include or exclusively set the new game project. You can do this one of the following ways:

- In a text editor, edit the `user_settings.options` file (in the `lumberyard_version\dev\WAF_\` directory) to set the value for the `enabled_game_projects`. The following example sets `MyGame` as the only game project generated. You can use a comma-separated list to include multiple game projects in the final solution.

  ```
  [Game Projects]
  enabled_game_projects = MyGame
  ```

- Update game projects with the Lumberyard Waf GUI.

  To run the GUI, in a command line window, navigate to the `lumberyard_version\dev\` directory and enter the following command:

  ```
  lmbr_waf show_option_dialog
  ```

  Click **Game Projects** in the Lumberyard Waf window, and select your new project. You can select more than one project.
• Build the project with the following command for your version of Visual Studio. Use `--enabled-game-projects=MyGame` to override every build command. This does not include the project in the generated solution, but it sets specific game projects to build during the build commands.

```bash
lmbr_waf build_win_x64_vs2017_debug -p game_and_engine --enabled-game-projects=MyGame
```

**Adding a Spec**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Waf spec system provides a template to create Visual Studio solutions and describes a build filter that determines which modules to build for particular platforms and configurations. The nature of the generic Waf build system is to be all projects that are defined through the wscript system, which acts recursively on the root directory structure. If no spec is specified when you execute a build or clean command, the Waf build system system attempts to build all modules that are supported by the selected target platform and configuration. The platform and configuration support is defined in each of the module's wscript definitions. For more information, see Adding a Build Module (p. 125).

Project spec files are a collection of modules and definitions for a specific build pipeline. These files are useful for including existing modules or adding new ones as part of the build dependencies for your game project.

When you build in debug or profile configurations and their _dedicated counterparts, a spec file is not required. This is because these two configurations build out of Lumberyard as modular shared components. In performance and release configurations, however, all the modules that are marked as CryEngineModules are built monolithically, which means that they are built into a single executable. This causes problems with similar modules that support the same platform and configuration. Currently, the spec file is required for this scenario in order to target specific modules to build into the monolithic .exe files.

Adding a project requires these steps:

• Creating a New Project Spec JSON File (p. 123)
• Adding the Spec File to the Visual Studio Solution Generator (p. 124)
• Building the Spec (p. 125)

**Topics**

• Creating a New Project Spec JSON File (p. 123)
• Adding the Spec File to the Visual Studio Solution Generator (p. 124)
• Building the Spec (p. 125)

**Creating a New Project Spec JSON File**

In the following example a spec file called `my_game` includes the game engine modules as a base as well as custom modules for Windows. The spec file also sets a custom #define for Windows builds.

You need to configure the values for the modules that you want to include in the spec file (and optionally the target platform and configuration). The spec file can isolate target_platform modules for multiplatform builds.

Create a spec file called `my-game.json` with the following:

```json
{
```

Version 1.28

123
Using the Waf Build System

The spec files are located in the `lumberyard_version\dev\WAF\specs` directory and have the `.json` file extension. For more information about Waf spec files, see Waf Spec Files (*.json) (p. 74).

<table>
<thead>
<tr>
<th>Spec</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>all.json</td>
<td>Configuration for all targets.</td>
</tr>
<tr>
<td>dedicated_server.json</td>
<td>Configuration to build dedicated servers for the enabled projects.</td>
</tr>
<tr>
<td>external_sdks.json</td>
<td>Configuration to build externally distributed binary-only libraries.</td>
</tr>
<tr>
<td>game_and_engine.json</td>
<td>Configuration to build the engine and game projects.</td>
</tr>
<tr>
<td>pipeline.json</td>
<td>Configuration to build Pipeline Only for building Resource Compiler, and also Maya, 3ds Max, and Photoshop plugins if Visual Studio 2010 and 2012 are installed. Build only in Profile or Debug mode (Release mode is only for the 3ds Max plugin)</td>
</tr>
<tr>
<td>resource_compiler.json</td>
<td>Configuration to build only the Resource Compiler.</td>
</tr>
<tr>
<td>shadercachegen.json</td>
<td>Configuration to build only the shadercache generator.</td>
</tr>
<tr>
<td>tools.json</td>
<td>Configuration to build nonessential tools.</td>
</tr>
</tbody>
</table>

Adding the Spec File to the Visual Studio Solution Generator

Adding the spec file to the Visual Studio solution is optional.

To add the spec file to the Visual Studio solution

1. In a text editor, edit the `specs_to_include_in_project_generation` value in the `user_settings.options` file to add your spec file to the Visual Studio solution:

   ```
   [Visual Studio Project Generator]
   generate_vs_projects_automatically = True
   visual_studio_solution_name = LumberyardSDK
   visual_studio_solution_folder = Solutions
   specs_to_include_in_project_generation = MySpec1, MySpec2, MySpec3
   ```

2. Enter the following command to regenerate the Visual Studio solution:
Building the Spec

After saving the new spec, do one of the following:

- Build the spec using Visual Studio (if you followed the steps above to add the spec to Visual Studio).
- Build the spec from the command line by entering the following command for your version of Visual Studio:

```
lmbr_waf build_win_x64_vs2017_profile -p MySpec
```

The `build` command builds the game project specified in the `user_settings`, even if the module is not defined in the spec. The exception is if the option `disable_game_projects` is set to `True`.

Adding a Build Module

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can create a custom build module in the Lumberyard Waf build system. You can use predefined build modules to add any shared library or plugin into the Lumberyard engine SDK.

The default Waf system defines modules and methods that will take various keywords into Waf commands to build applications and shared and static libraries as well as serving as a project container for files. There `cryengine_modules.py` file defines functions that wrap these modules with additional keywords and logic to extend the behavior of standard Waf into a system that supports the requirements of Lumberyard. In addition to providing standard Waf build functionality, the functions in the various modules add support for precompiled headers (`pch`), content file support (`.waf_files`), monolithic build capability, uber file support, and Microsoft Visual Studio (msvs) generation.

Creating a module requires the following steps:

1. Create the source folder and script
2. Create a basic `wscript` module
3. Create the `.waf_files` content file
4. Specify additional include paths and external library linking
5. Add a project dependency

Creating a New Module

You can create and add the following types of modules to the Lumberyard Waf build system:

<table>
<thead>
<tr>
<th>Build Module</th>
<th>Description</th>
<th>Project Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CryEngineModule</td>
<td>Modules that are dynamically loaded at runtime as part of the lumberyard engine module system. For Performance and Release configurations, all projects that are built using</td>
<td>Shared Library (Non-Release), Static Library</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Performance (Performance, Release)</td>
</tr>
</tbody>
</table>

Version 1.28

## Using the Waf Build System

<table>
<thead>
<tr>
<th>Build Module</th>
<th>Description</th>
<th>Project Type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>These modules are included monolithically to the final build output. If the libraries are not linked in, the source from these modules is included in the build.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For Debug and Profile configurations, these modules are built as shared libraries. For the Windows platform, versioning information is injected as defined in the waf_branch_spec.py file located in the root folder. As such, a Windows resource (.rc) file as needed as part of the waf_files content.</td>
<td></td>
</tr>
<tr>
<td>CryEngineSharedLibrary</td>
<td>Used to define a shared library that any other module can use inside Waf. Provided they are located in the same directory path as the dependent project, these modules are included as a dependency to other modules by use of the <code>use</code> keyword.</td>
<td>Shared Library</td>
</tr>
<tr>
<td>CryEngineStaticLibrary</td>
<td>Used to define a static library that can be used by any other module inside Waf. Provided they are located in the same folder path as the dependent project, these modules are included as a dependency to other modules by use of the <code>use</code> keyword.</td>
<td>Static Library</td>
</tr>
<tr>
<td>CryLauncher</td>
<td>Used to define the build definition for launchers, which are created for each game project defined per supported platform. All supported launchers that can be generated based on availability against the current platform are located in the \Code\Launcher subfolder. If an additional platform is included, a new launcher project would be added in this subfolder and use the CryLauncher build module.</td>
<td>Executable</td>
</tr>
<tr>
<td>CryDedicatedServer</td>
<td>Similar to the CryLauncher module, except used for dedicated server projects.</td>
<td>Executable</td>
</tr>
<tr>
<td><strong>Build Module</strong></td>
<td><strong>Description</strong></td>
<td><strong>Project Type</strong></td>
</tr>
<tr>
<td>------------------</td>
<td>----------------</td>
<td>-----------------</td>
</tr>
<tr>
<td><strong>CryConsoleApplication</strong></td>
<td>Used to build console applications. On the Windows platform, it builds a console application instead of a Windows application.</td>
<td>Executable</td>
</tr>
<tr>
<td><strong>CryBuildUtility</strong></td>
<td>Used to define build utility projects, such as AZCodeGenerator. Build utilities are separated into a build_utilities group that are built before the regular build group.</td>
<td>Executable</td>
</tr>
<tr>
<td><strong>CryFileContainer</strong></td>
<td>Used to set a file container for projects.</td>
<td>None</td>
</tr>
<tr>
<td><strong>CryEditor</strong></td>
<td>Used by Lumberyard Editor projects.</td>
<td>Executable</td>
</tr>
<tr>
<td><strong>LumberyardApp</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>CryEditorUiQt</strong></td>
<td>Used by the CryEditorUI_QT plugin.</td>
<td></td>
</tr>
<tr>
<td><strong>CryPlugin</strong></td>
<td>Used by Lumberyard Editor plugin projects. It is automatically placed in the EditorPlugins subfolder and automatically loaded by Lumberyard Editor at runtime.</td>
<td>Shared Library</td>
</tr>
<tr>
<td><strong>CryStandAlonePlugin</strong></td>
<td>Used by Lumberyard Editor plugin projects. The difference between this module and CryPlugin is that it does not import any SANDBOX or EDITOR_COMMON imports, RTTI is enabled, and nodefaultlib:/ is set to libcmt.</td>
<td>Shared Library</td>
</tr>
<tr>
<td><strong>CryPluginModule</strong></td>
<td>Used to define shared libraries that can be used by a Lumberyard Editor plugin. Plugins that need to link to a Cryengine plugin module use the use feature of Waf.</td>
<td>Shared Library</td>
</tr>
<tr>
<td><strong>CryResourceCompiler</strong></td>
<td>Used by the Resource Compiler to implicitly set the target name to rc and the subfolder to rc under the configure output folder.</td>
<td>Executable</td>
</tr>
</tbody>
</table>
Using the Waf Build System

Build Module | Description | Project Type
--- | --- | ---
CryResourceCompiler | Used by the Resource Compiler to implicitly set the target name to rc and the subfolder to rc under the \configure output folder. | Shared Library
CryPipelineModule | Used to define pipeline modules such as for the 3ds Max and Maya exporters. | Custom
CryQtApplication | Used to define Qt 5 applications that can be launched by Lumberyard Editor, such as the Asset Processor. | Executable
CryQtConsoleApplication | Used to define Qt 5 console applications that can be launched by Lumberyard Editor, such as the Asset Processor batch file. | Executable

In this topic's example you create a CryEngineModule.

**Build Module Keywords**

The following describes the general keywords that are supported by the build modules. The listed targetable keywords can be specific to a platform or a configuration. The keyword by itself is used for all supported platforms and configurations, but if you need keywords that are specific to a platform or configuration, you must include the name of the platform or configuration in the name.

**Other things to consider:**

- The general pattern for platform plus configuration-specific values is `<platform>_<configuration>_<keyword>`.
- The general pattern for platform-specific values is `<platform>_<keyword>`
- The general pattern for configuration-specific values is `<configuration>_<keyword>`

You can use the following keyword macros to reduce the verboseness of `wscript` files:

**<platform>_nddebug_<keyword>**

This macro eliminates the need to repeatedly specify certain non-debug flags. Lumberyard has one debug configuration and three non-debug configurations.

| Keyword | Description | Targetable?
--- | --- | ---
| target | Name of the target project. | No
| platforms | The list of platforms to restrict this module to. If not specified, then defaults to all, which assumes all supported target platforms on the current host. | No

Version 1.28
128
<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
<th>Targetable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>configurations</td>
<td>The list of configurations to restrict this module to. If not specified, then defaults to all. In addition to the standard configurations (debug, profile, and release), configurations can be specific to a particular platform. This is done by appending the platform name with a colon separator in front of the configuration. For example, if a module supports only debug and profile for the iOS platform, then the configuration list would include the values <code>ios:debug</code> and <code>ios:profile</code>.</td>
<td></td>
</tr>
<tr>
<td>file_list</td>
<td>The <code>.waf_files</code> JSON file that contains the file list definition for the project.</td>
<td>Yes</td>
</tr>
<tr>
<td>pch</td>
<td>The name of the precompiled header. If present, then precompiled headers are enabled.</td>
<td></td>
</tr>
<tr>
<td>use</td>
<td>Additional projects to link as a use dependency.</td>
<td>Yes</td>
</tr>
<tr>
<td>uselib</td>
<td>Additional libraries to use.</td>
<td>Yes</td>
</tr>
<tr>
<td>defines</td>
<td>Additional preprocessor defines for the project.</td>
<td>Yes</td>
</tr>
<tr>
<td>includes</td>
<td>Additional include paths.</td>
<td>Yes</td>
</tr>
<tr>
<td>cflags</td>
<td>Additional C flags.</td>
<td>Yes</td>
</tr>
<tr>
<td>cxxflags</td>
<td>Additional C++ flags.</td>
<td>Yes</td>
</tr>
<tr>
<td>lib</td>
<td>Additional libraries to link to.</td>
<td>Yes</td>
</tr>
<tr>
<td>libpath</td>
<td>Additional library include path.</td>
<td>Yes</td>
</tr>
<tr>
<td>stlib</td>
<td>Boolean flag that indicates a static library module.</td>
<td>Yes</td>
</tr>
<tr>
<td>stlibpath</td>
<td>Lib path for static libs (generally the same for any lib).</td>
<td>Yes</td>
</tr>
<tr>
<td>linkflags</td>
<td>Additional link flags during the linker phase.</td>
<td>Yes</td>
</tr>
<tr>
<td>export_definition</td>
<td>Export definition filename (.def file).</td>
<td>Yes</td>
</tr>
</tbody>
</table>
## Creating a Basic Wscript Module

The `wscript` file specifies the name of the module (`target`), `.waf_files` content file (`file_list`), Visual Studio filter (`vs_filter`), and precompiled headers (`pch`).

Create a `wscript` module with the following:

```python
def build(bld):
    bld.CryEngineModule(
        target      = 'MyEngineModule',
        vs_filter   = 'LyEngine',
        file_list   = 'myenginemodule.waf_files',
        pch         = 'StdAfx.cpp'
    )
```

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
<th>Targetable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>features</td>
<td>Any additional features to tag this project to.</td>
<td>Yes</td>
</tr>
<tr>
<td>output_file_name</td>
<td>An output file name used to override the default output file based on the target.</td>
<td>Yes</td>
</tr>
<tr>
<td>framework</td>
<td>Additional frameworks (Darwin).</td>
<td>No</td>
</tr>
<tr>
<td>frameworkpath</td>
<td>Additional framework paths (darwin).</td>
<td>No</td>
</tr>
<tr>
<td>export_defines</td>
<td>Additional preprocessor defines that are added to any module that uses the current module as a project dependency.</td>
<td>No</td>
</tr>
<tr>
<td>export_includes</td>
<td>Additional library include paths that are added to any module that uses the current module as a project dependency.</td>
<td>No</td>
</tr>
<tr>
<td>additional_settings</td>
<td>Additional settings added for specific files.</td>
<td>Yes</td>
</tr>
<tr>
<td>meta_includes</td>
<td>Meta includes for WinRT.</td>
<td>Yes</td>
</tr>
<tr>
<td>files</td>
<td>Another way to pass in files for processing a build project.</td>
<td>Yes</td>
</tr>
<tr>
<td>winres_includes</td>
<td>Additional include paths for the winres compiler.</td>
<td>No</td>
</tr>
<tr>
<td>winres_defines</td>
<td>Additional defines for the winres compiler.</td>
<td>No</td>
</tr>
<tr>
<td>enable_rtti</td>
<td>Flag to enable rtti settings for a project.</td>
<td>Yes</td>
</tr>
<tr>
<td>rpath</td>
<td>Additional relative library paths (Darwin).</td>
<td>No</td>
</tr>
</tbody>
</table>

Version 1.28
130
In order for the Lumberyard Waf build system to pick up the new folder and script, you must add the new folder to the list of subfolders to recurse. Because you are adding this project under `lumberyard_version/Code/CryEngine/MyEngineModule`, you need to update the wscript located in the parent `lumberyard_version/Code/CryEngine` folder.

Update the wscript located in the `lumberyard_version/Code/CryEngine` folder with the following:

```python
SUBFOLDERS = ['CryInput', 'Cry3DEngine', ...
              'MyEngineModule',
              ]

def build(bld):
    # Recursive into all sub projects
    bld.recurse(SUBFOLDERS)

Creating the .waf_files Content File

In the example wscript, you specified a file called `myenginemodule.waf_files` as the project content file. The project content file can be one of the following:

- A single file that defines the source files for the project
- A list of files that define the source files for the project
- Platform/configuration, where certain files are included only for a particular platform (for example, console-specific files)

The following `myenginemodule.waf_files` example demonstrates a simple module with six files:

```json
{
    "NoUberFile":
    {
        "Root":
        [
            "StdAfx.cpp",
            "StdAfx.h"
        ],
    },
    "myenginemodule_uber_0.cpp":
    {
        "Root":
        [
            "myenginecore.cpp",
            "myenginecore.h",
            "myengineextras.cpp",
            "myengineextras.h"
        ]
    }
}
```

Specifying Additional Include Paths and External Library Linking

To configure the module to link to external modules, you need to update the wscript to specify the include path and link related project settings flags such as includes, lib, libpath, and linkflags.

In this example, you add the following to your module:

1. Google mock libraries for Win x64
2. Preprocessor DEFINE called `USE_GMOCK` to inject into the compile based on the platform Win x64
3. Link-time code generation flag to enable instrumentation (\`/LTCG:PGOPTIMIZE\`)

Add the following to your wscript module:

```python
def build(bld):
    bld.CryEngineModule(
        target          = 'MyEngineModule',
        vs_filter       = 'LyEngine',
        file_list       = 'myenginemodule.waf_files',
        pch             = 'StdAfx.cpp',
        win_includes    = [Path('Code/SDKs/GoogleMock/include')],
        win_lib         = ['gmock'],
        win_linkflags   = ['/LTCG:PGOPTIMIZE'],
        win_defines     = ['USE_GMOCK'],
        win_x64_debug_libpath       = [Path('Code/SDKs/GoogleMock/bin/x64/Debug')],
        win_x64_profile_libpath     = [Path('Code/SDKs/GoogleMock/bin/x64/Release')],
        win_x64_performance_libpath = [Path('Code/SDKs/GoogleMock/bin/x64/Release')],
        win_x64_release_libpath     = [Path('Code/SDKs/GoogleMock/bin/x64/Release')]
    )
```

**Note**

The following are duplicated to cover all possible configurations that you specified in the `waf_branch_spec`: `win_x64_profile_libpath`, `win_x64_profile_performance`, and `win_x64_release_libpath`.

### Adding and Linking to a Project Dependency

If you want to link to another module that is built within the system, you can use the `use` parameter for the build.

Update your wscript module to link to the CryPerforce module:

```python
def build(bld):
    bld.CryEngineModule(
        target          = 'MyEngineModule',
        vs_filter       = 'LyEngine',
        file_list       = 'myenginemodule.waf_files',
        pch             = 'StdAfx.cpp',
        use             = ['CryPerforce'],
        win_includes    = [Path('Code/SDKs/GoogleMock/include')],
        win_lib         = ['gmock'],
        win_defines     = ['USE_GMOCK'],
        win_x64_debug_libpath       = [Path('Code/SDKs/GoogleMock/bin/x64/Debug')],
        win_x64_profile_libpath     = [Path('Code/SDKs/GoogleMock/bin/x64/Release')],
        win_x64_performance_libpath = [Path('Code/SDKs/GoogleMock/bin/x64/Release')],
        win_x64_release_libpath     = [Path('Code/SDKs/GoogleMock/bin/x64/Release')]
    )
```

### Launching the Game Project

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Building your game project produces an `.exe` file in Lumberyard's file system.

To launch your project, open the executable file. The directory and file name are named according to the following conventions:

```
/dev/Bin64compiler.build mode/executable name.exe
```

Where:

- `compiler`
- `build mode` (p. 61)
  - `Debug` – Built in debug mode.
  - `(None)` – Built in profile mode.
  - `Performance` – Built in performance mode.
  - `Release` – Built in release mode.
- `executable name` – The `executable_name` specified in your `project.json` (p. 69) file. The file name typically mirrors the project name.

For example, if your project was configured with the following:

- Compiler: Visual Studio 2017
- Build mode: `debug`
- Executable name: `SampleProjectLauncher`

Then your directory and file name would be the following:

```
{lumberyard_version}/dev/Bin64vc141.Debug/SampleProjectLauncher.exe
```

### Adding User Settings to Waf

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add a new user setting to the `default_settings.json` file in the `Waf` folder located at the root. Use the standards established in this file and customize as needed. After you have added a user setting, you need to add a minimum of three utility functions for the GUI and console to validate your new setting.

To define utility functions, add the following to `default_settings.py`:

- **Getter** – Retrieves the value of your new setting and performs necessary transformations
- **Validator** (optional) – Validates new values
- **Hinter** (optional) – Tells GUI the available options

See the sections below for more information about these functions.

You can also add these functions to any new `.py` file as long as you add the module during build and configure. Be sure to load the file using the following command:
Using the Waf Build System

Getter Function

Waf calls the getter function to retrieve the value of your new setting and perform any necessary transformations.

Follow these guidelines:

• Implement the \texttt{@register\_attribute\_callback} function for your type.
• Use the same name for your function as your property name that's defined in the \texttt{default\_settings} file. For example, if your property name is called \texttt{my\_setting}, the function must be called \texttt{my\_setting()}.
• Choose attribute names that are unlikely to conflict.

In the example below of a getter/setter function, the current value is the input and the return value is the value with any validation and transformations applied. We expect a list of comma-separated values. The first half of the function returns the value quickly and the second half is where Waf runs in interactive or GUI mode.

```python
@register_attribute_callback
def enabled_game_projects(ctx, section_name, option_name, value):
    """Configure all Game Projects enabled by user""
    if ctx.options.execsolution or not ctx.is_option_true('ask_for_user_input'):
        return value
    if LOADED_OPTIONS.get('enabled_game_projects', 'False') == 'False':
        return ''

    info_str = ['Specify which game projects to include when compiling and generating project files.]
    info_str.append('Comma separated list of Game names, from the project.json root (SamplesProject, MultiplayerProject) for example')
    # GUI
    if not ctx.is_option_true('console_mode'):
        return ctx.gui_get_attribute(section_name, option_name, value, '\n'.join(info_str))
    # Console
    info_str.append("\nQuick option(s) (separate by comma):")
    project_list = ctx.game_projects()
    project_list.sort()
    for idx, project in enumerate(project_list):
        output = '   %d: %s: ' % (idx, project)
        while len(output) < 25:
            output += ' '  
        output += ctx.get_launcher_product_name(project)
        info_str.append(output)
    info_str.append("(Press ENTER to keep the current default value shown in [])")
    Logs.info(''.join(info_str))
    while True:
        projects = _get_string_value(ctx, 'Comma separated project list', value)
        projects_input_list = projects.replace(' ', '').split(',')
        # Replace quick options
        options_valid = True
        for proj_idx, proj_name in enumerate(projects_input_list):
            if proj_name.isdigit():
                option_idx = int(proj_name)
                try:
                    projects_input_list[proj_idx] = project_list[option_idx]
                except:
                    options_valid = False
        if not options_valid:
            Logs.error('Quick option(s) invalid. Try again or consult the manual for more information.')
        else:
            return projects_input_list
```
Logs.warn('[WARNING] - Invalid option: "%s" % option_idx)
options_valid = False
if not options_valid:
    continue
projects_enabled = ','.join(projects_input_list)
(res, warning, error) = ATTRIBUTE_VERIFICATION_CALLBACKS['verify_enabled_game_projects'](ctx, option_name, projects_enabled)
if error:
    Logs.warn(error)
    continue
return projects_enabled

In the example below, the function is simpler because it's a simple string entry and there are no enumerations like bool and no validation.

@register_attribute_callback
def out_folder_linux64(ctx, section_name, option_name, value):
    """ Configure output folder for linux x64 ""
    if not _is_user_input_allowed(ctx, option_name, value):
        Logs.info('User Input disabled.
Using default value "%s" for option: "%s" % (value, option_name))
        return value
    # GUI / console mode
    if not ctx.is_option_true('console_mode'):
        return ctx.gui_get_attribute(section_name, option_name, value)
    return _get_string_value(ctx, 'Linux x64 Output Folder', value)

Validator Function

Waf only requires the getter function; however, to validate input or provide the GUI with more than raw strings, you'll need to implement other functions like the validator.

Follow these guidelines:

- Implement the @register_verify_attribute_callback function and name it verify(_your_option_name_).
- Pass into the function the value parameter, which is the current raw value.
- Return a tuple of Bool, String, ErrorString. The first bool specifies whether or not validation is okay.

In the example below of a validator function, we make sure not to trigger the duplicate check (for example with a list like "SamplesProject,SamplesProject,SamplesProject") or provide a list that won't be accepted (for example with a list like "ASDJASUIDIASJDA").

@register_verify_attribute_callback
def verify_enabled_game_projects(ctx, option_name, value):
    """ Configure all Game Projects which should be included in Visual Studio ""
    if not value:
        return True, "", "" # its okay to have no game project
    if (len(value) == 0):
        return True, "", ""
    if (value[0] == ' ' and len(value) == 1):
        return True, "", ""
Hinter Function

Waf uses the optional hinter function to provide the GUI with a list of available options. For example, you might want to use the hinter function if you have a string list that can have multiple or single values that must be specific (enums).

Follow these guidelines:

- Implement the `@register_hint_attribute_callback` function and name it `hint_(your_option_name)`.
- Ignore the value parameter passed, which is the current value.
- Return a tuple of display value list, actual value list, help text list, multi or single. All three input lists should be the same length. The values in these lists are what's displayed in the GUI, the values to set if selected, and the text to display as extra information for an option, respectively.

The example below is for a hinter function.

```python
@register_hint_attribute_callback
def hint_enabled_game_projects(ctx, section_name, option_name, value):
    """ Hint list of specs for projection generation """
    project_list = ctx.game_projects()
    project_list.sort()
    desc_list = []
    for gameproj in project_list:
        desc_list.append(ctx.get_launcher_product_name(gameproj))
    return (project_list, project_list, desc_list, "multi")
```

You can also see how Waf uses hinting by engaging Waf in GUI mode and entering the following command: `lmbr_waf.bat show_option_dialog`

This displays an options dialog box that you can review to determine hinting.

Adding Qt 5 Content to Waf

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
You can add Qt 5 content into the Waf build system. Typically you use an IDE (integrated development environment) tool such as Qt Designer to create and edit the Qt source file. As with all files that are processed through the Waf build system, the Qt source file must be included in the corresponding *.waf_files file for each project.

Intermediate files that need additional compilation such as the .rcc file from the .qrc compiler do not need to be specified explicitly in these files or any other source file. In addition, intermediate .rcc files are never included in any uber files (if the uber file option is enabled) since they are not compatible with uber files in general.

To enable Qt for a particular module, you must define it as a feature. Each module's configuration is in a wscript file that is in each module's directory. For example, the EditorUI_QT module has a wscript file located at dev\Code\Sandbox\Plugins\EditorUI_QT\. To enable Qt, edit this file and add ['qt5'] to the features line, as shown in the following example.

```wscript
bld.CryEditorUiQt(
    # Settings
    target = 'EditorUI_QT',
    vs_filter = 'Sandbox/Plugins',
    file_list = 'editorui_qt.waf_files',
    platforms = ['win'],
    configurations = ['debug', 'debug_test', 'profile', 'profile_test'],
    features = ['qt5'],
)
```

**MOC (Meta-Object Compiler) Files**

When header files need to be processed by the Meta-Object Compiler (MOC) as part of the build process, the build system identifies them by including their MOC output file inside the source .cpp file. For example, if foo.h is a file that is to be processed by MOC, then the source foo.cpp file also needs to include the corresponding #include for the .moc file that is generated.

For example:

```cpp
...
#include "foo.h"
...
#include <foo.moc>
```

The #include for the .moc file requires angled brackets because the generated .moc file does not reside in the local project directory but rather is located in an intermediate directory. Also, the include path that is added to the project is based on the mirrored project base in the intermediate directory. If the header file exists in a relative subdirectory, that subdirectory needs to be included in the #include for the .moc, regardless of where the .cpp file is located.

For example, if foo.h and foo.cpp are moved into the \test subdirectory, the result looks like the following:

```cpp
...
#include "foo.h"  // This can still be relative to the current source file
...
#include <test/foo.moc>  // This needs to be relative to the base path for the project in the intermediate directory.
```
QRC (QT Resource Collection) files

Qt resource collection (.qrc) files are processed by the Qt .qrc compiler. The output file has the same source name but with an .rcc extension. The resulting .rcc file is stored in the projects intermediate directory relative to any subdirectory that it exists in.

For example, if the file foo.qrc is located in the \test subdirectory, the generated .rcc file is stored in the \test subdirectory under the project's intermediate directory structure. There is no need to explicitly include the generated .rcc file into any source file as it is added as a build task for the project.

The following is an example of the contents in an ObjectPanel.qrc file:

```xml
<RCC>
  <qresource prefix="/Panels/ObjectPanel">
    <file alias="icon_layers.png">res/icon_layers.png</file>
  </qresource>
</RCC>
```

For more information, see The Qt Resource System documentation.

UI Files

Designer UI files are processed by the Qt UIC (user interface compiler). The output file has an .h header extension to it, and ui_ is also added to the name of the source. The resulting header file is created in the project's intermediate directory relative to its location in the project.

For example, if the file foo.ui is located in a \test subfolder, the generated ui_test.h file will be located in the \test subfolder under the project's intermediate folder structure.

When including the generated header file, using the same rule as the moc include applies as follows:

```c
#include "foo.h"
...  
#include <test/ui_foo.h>  // Path is relative to the project root
```

Qt Linguist (TS) files

Qt Linguist files (.ts) are processed by Qt and output as .qm files. The .qm files are automatically included into a single .qrc file specified by the langname attribute in the wscript file. The .qrc file is automatically added as a build task like other .qrc files for the project.

The following example demonstrates adding the required langname attribute to a wscript file:

```python
...  
def build(bld):
    bld.YourPlugin(
        ...  
        langname = 'en-us',
        ...
```

The .qm files are loaded using the QTranslator module, and the Qt resource directory is the same relative to the source directory. For example, if there a foo_en-us.ts file in a \test subdirectory, then that is the same directory that you use when loading the resource, as shown in the following example:

```c
...  
#include <QTranslator>
```
Using Uber Files

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Uber files combine multiple C and CPP files into a single compilation unit, which is intended to reduce input/output impact on compilation time and help accelerate build time.

The code in uber files must meet the following coding standards:

- No global statics in the global namespace
- No global 'using namespace' declarations

Waf compile jobs include files from the *.waf_files lists. These files have the following format:

```json
{
    "<uber_file>": {
        "<source_filter_name>": [
            "file1.h",
            "file1.cpp"
        ]
    }
}
```

Valid values for `<uber_file>` are:

- **none** – Files in this list are banned from uber files. If you want your module to use precompiled headers, you must include them in this list.
- **auto** – Files in this list are combined into modules that are optimized for compile time by Waf. Files that are automatically combined are sorted by absolute path and then combined until the file size path is reached. The combination must be deterministic given the same input files and file size limit.

File size limits vary depending on the compilation:

- 200K – Suggested for compiling remotely using Incredibuild
- 300K – Default setting and suggested for compiling locally using an SSD
- 400-500K – Suggested for compiling using an HDD

You can specify the file size by updating the `uber_file_size` value in the `user_settings` file or by running the following command: `--uber-file-size <filename>.cpp`

- **somefilename.cpp** – Files in this list are combined into `somefilename.cpp`. This action is useful when certain files can only be combined together or when you want to combine platform-specific code.
Using the Waf Build System

Most waf_files lists should include one none section with the precompiled header and an auto section with everything else.

**Configuring Waf**

To help obtain the most optimal compile times, use the following:

- `use_uber_files = True`
- `max_parallel_link = 4`
- `use_incredibuild = True`
- `incredibuild_max_cores = 128`

**Debugging Waf**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

If you encounter issues that are not related to configuration, it is important to debug the internal Waf library. For a Python callstack, you typically must debug in `\dev\Tools\Build \waf-version\waflib`.

Using PyCharm, an IDE for Python development, you can browse to a file where you are having problems, set a breakpoint, and click the bug icon to start debugging. Execution time may be slower when running PyCharm.

Opening the root directory creates file indexing. You can use PyCharm to specify folders to exclude from the project structure, as shown in the example image.
You can also debug the way you would any native Visual Studio solution-based project. Right-click the project you want to debug and select **Set as Startup Project**. Continue the debugging process as you normally would. If you receive a warning that the _WAF_ project is outdated but your project is already up-to-date, click **No** to build.

**Troubleshooting**

When using multiple jobs (for example, `--jobs=12`), Waf can be difficult to debug. Try using `--jobs=1` to disable multi-threading.

When using IncrediBuild, the debugger won't properly execute all break points. Try disabling IncrediBuild when debugging Waf.

**Adding Custom Game Icons**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add a custom icon that appears in the top left title bar window of your game.
To add a custom game icon

1. Create an icon and name it `default_icon`. You can save it in `.tif`, `.png`, `.tga`, or `.bmp` format.
2. Save the icon file to your game's `\textures` directory.

Using Lumberyard sample projects and levels

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard provides a variety of sample projects, levels, and assets, which are located in the `\lumberyard_version\dev` directory.

Use the Project Configurator to set or change your default project. For more information, see Creating Lumberyard projects (p. 43).

Samples Project

The Samples Project includes many sample levels that demonstrate various Lumberyard features, such as the Fur Shader (p. 1661), Rin Locomotion (p. 151), UI samples (p. 2923), and more. For a complete list and descriptions of levels, see Samples Project (p. 146).

Multiplayer Sample

You can use the Multiplayer Sample game to test the Lumberyard GridMate (p. 2080) networking features.
Sample projects and levels

In-App Purchases
The In-App Purchases sample (p. 175) demonstrates how to use the In-App Purchases (IAP) gem for a Lumberyard application that runs on a mobile device.

**Cloud Gem Samples Project**

The Cloud Gem Samples Project includes sample levels that demonstrate the use of cloud gems that can add cloud-connected functionality to your game.

Use of the following levels is covered in the associated gem's topic found in the Cloud Gems (p. 2127) documentation.

- **DynamicContentTest** – Found under CloudGemTests, this level provides a test of the Dynamic Content (p. 2155) Gem, which enables you to upload new or updated game assets to the cloud, that can be automatically downloaded to game clients.
- **PlayerAccountSample** – Demonstrates the use of the Player Account (p. 2188) Gem, which provides a standalone player authentication and management solution for your game.
- **CommunicatorSample** – Demonstrates the use of the Web Communicator (p. 2204) Gem, which can send AWS cloud service events to your game's connected editors or clients. Your editors or game clients can use this information to update themselves without having to poll AWS for updates.

**Virtual Reality Project Sample**

The Virtual Reality Project sample is a template that you can use to build VR applications for any supported device. You can download this content separately.

Legacy Sample Projects

The following sample projects and assets are available as a separate download from the Lumberyard Legacy Downloads page.

- **Woodland Asset Collection** (p. 177) – Free assets for you to use to create your levels.
• **Beach City Night Asset Collection** (p. 178) – Collection of free assets that you can use to try Lumberyard or make your own games.

• **Legacy Project (GameSDK)** (p. 180) – Enables you to use GameSDK functionality.
Samples Project

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Samples Project includes two collections of sample levels and code that demonstrates how to use various Lumberyard features.
The Samples Project's level files are located in the `lumberyard_version\dev\SamplesProject\Levels` directory.

The `Samples` subdirectory contains the following levels:

- Advanced Rin Locomotion (p. 151)
- Audio Sample (p. 147)
- Fur Technical Sample (p. 1661)
- Metastream Sample (p. 1164)
- Script Canvas Sample (p. 149)
- Scripted Entity Tweener Sample (p. 3011)
- Simple Jack Locomotion (p. 153)

The `UI` subdirectory contains the following levels:

- UI Features – Demonstrates UI components (p. 2923), UI animation (p. 3023), font rendering (p. 2999), language support and localization (p. 2415), and C++ canvases and custom components.
- UI in 3D World (p. 2897) – Demonstrates placing game UI on 3D objects.
- UI Main Menu Lua Sample (p. 2897) – Demonstrates loading a UI canvas using Lua.
- UI Main Menu Script Canvas Sample – Demonstrates loading a UI canvas using the Script Canvas editor (p. 2420).

**Audio Sample**

This sample demonstrates how to use the Audio Trigger (p. 559) and Audio Rtpc (p. 557) components with Lua scripts to associate sounds of a door opening and closing.

This example is fully annotated within the Lua script of the level file. The following sounds are associated:

- Sounds
  - Door open
  - Door creak
  - Door creak stop
  - Door slam
- Rtpc
  - Creak volume
  - Creak pitch

To play the example, do the following:

- Press W/S to swing the door.
- Press Q to open the door.
- Press E to open the door.
- Press the `spacebar` to open or close the door.

To see the Lua script, select the Door entity (a child of DoorTest) and then click the `{ }` button next to the script property to open the Lua IDE.
For more information about audio, setting up sounds and using Wwise LTX, see Adding Audio and Sound Effects (p. 3140).

**Starter Game Sample**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Starter Game sample to see how Lumberyard systems work together to make a game. Starter Game is a small, third-person game that is built with the Lumberyard component entity system. In addition to component entities, Starter Game demonstrates bipedal locomotion, the Dynamic Vegetation system, the Script Canvas visual scripting system, use of PhysX as the physics system, and more. In this sample, you play as Valena, a human who has crashed on a distant planet. Valena can explore the world and must defend herself against enemy robots that occupy the planet.

Starter Game is included in the Lumberyard installation package. It runs on PC and supported consoles, but is not supported for MacOS and mobile devices.

All reusable assets and scripts have been placed into the following Asset Gems, so you can easily add them to your own projects. You'll find these under `dev\Gems\StarterGame`:

- Starter Game Audio
- Starter Game Characters (includes animations)
- Starter Game Environment
- Starter Game User Interface
- Starter Game Weapons

**To run the Starter Game sample**

1. Set Starter Game as the default project:
a. Double-click the Project Configurator desktop icon.
b. In the Project Configurator, select **Starter Game**.
c. Choose **Set as default** and close the Project Configurator.

2. Run Lumberyard Editor.

3. In the **Welcome to Lumberyard Editor** dialog box, choose **Open level**.

4. In the **Open a Level** dialog box, open the **Game** folder, select the **SinglePlayer** level, and choose **Open**.

5. To start the game, press **Ctrl+G**.

6. Use the following keyboard keys and mouse controls:

<table>
<thead>
<tr>
<th>Input</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>W, A, S, D</td>
<td>Move Valena either parallel or orthogonal to camera.</td>
</tr>
<tr>
<td>Shift</td>
<td>Hold this key to walk instead of run.</td>
</tr>
<tr>
<td>Spacebar</td>
<td>Jump.</td>
</tr>
<tr>
<td>Mouse</td>
<td>Orbit camera.</td>
</tr>
<tr>
<td>Primary mouse button</td>
<td>Fire weapon.</td>
</tr>
<tr>
<td>Secondary mouse button</td>
<td>Aim weapon.</td>
</tr>
<tr>
<td>Esc</td>
<td>Exit the game.</td>
</tr>
</tbody>
</table>

If you're running Starter Game in the editor and Valena dies, press **Esc** to exit the game.

**Note**
To toggle debugging information on and off in the viewport when you're in gameplay mode, press the tilde (~) key. For more information, see **Using Console Debug Views** (p. 1967).

## Script Canvas Basic Sample

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Script Canvas Basic Sample contains a collection of five Script Canvas scripts that demonstrate the following gameplay functions:

- Basic player controller
- Ballistic projectile
- Door that opens based on a trigger volume
- Light that toggles based on a trigger volume
- Flickering light
To see the Script Canvas graphs

1. In Lumberyard Editor, choose Tools, Script Canvas.
2. In the Script Canvas editor, choose File, Open.
3. Navigate to the `lumberyard_version\dev\SamplesProject\Levels\Samples\ScriptCanvas_Sample\ScriptCanvas_Basic_Sample\ScriptCanvas` directory.
4. Open one of the Script Canvas scripts:
   - doortriggerarea.scriptcanvas
   - flickerlight.scriptcanvas
   - lumbertankcontrols.scriptcanvas
   - projectile.scriptcanvas
   - tooglelight.scriptcanvas

To play the game

Do the following:

- To start the level, press Ctrl+G.
- To control the tank, do the following:
  - To move forward and backward, press the W and S keys, respectively.
  - To turn left and right, press the A and D keys, respectively.
  - To control the camera, move the mouse pointer.
  - To fire the tank's gun, use the left mouse button.
- To open the door, drive up to it or shoot it.
- To turn off the light, drive up to the light.
- To turn the light on, drive away from the light.
- To exit the level, press Esc.
Advanced_RinLocomotion Sample

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This sample level showcases the Rin character in a simplified environment and demonstrates how the Animation Editor uses actors, motion sets, and animation graphs to control character behavior. Playable animations include idle, walk, run, turn, and multiple attacks.

The Advanced_RinLocomotion sample level is located in the \dev\SamplesProject\Samples \Advanced_RinLocomotion directory. The assets are located in the \dev\SamplesProject \AnimationSamples\Advanced_RinLocomotion directory.

Once the sample level is open, in the Perspective viewport in Lumberyard Editor, use the following keyboard keys and mouse controls:

- To start the level, press Ctrl+6.
- To move forward, left, backward, and right, press the W, A, S, and D keys, respectively.
- To look around, move the pointer.
- To attack, press the left mouse button.
- To jump, press the Space key.
• To exit game mode, press Esc.

You can also use a controller connected to your computer:
• To control the movement direction, use the left joystick.
• To control the camera navigation around the character, use the right joystick.
• To attack, press X.
• To jump or dive roll, press A.
• To zoom in the camera, press the right trigger.
• To zoom out the camera, press the left trigger.
• To snap the camera to the back of the character, press the right joystick.
Simple_JackLocomotion Sample

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This sample level showcases Jack the robot in a basic environment and demonstrates how the Animation Editor uses actors, motion sets, and animation graphs to control character behavior. Playable animations include idle, walk, run, and navigate.

The Simple_JackLocomotion sample level is located in the \dev\SamplesProject\AnimationSamples directory. The assets are located in the \dev\SamplesProject\AnimationSamples\Simple_JackLocomotion directory.

Once the sample level is open, in the Perspective viewport in Lumberyard Editor, use the following keyboard keys and mouse controls:

- To start the level, press Ctrl+G.
- To move forward, left, backward, and right, press the W, A, S, and D keys, respectively.
- To look around, move the pointer.
- To toggle the LookAt node on and off during the idle animation, press Tab.
- To aim, hold the left mouse button.
- To exit game mode, press Esc.

You can also use a controller connected to your computer:

- To control the movement direction, use the left joystick.
- To control the camera navigation around the character, use the right joystick.
- To toggle the character aim on and off, press the right trigger.
- To toggle the LookAt node on and off during the idle animation, press the left trigger.
Multiplayer Sample

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Multiplayer sample shows you how to build and structure multiplayer games that use the various features of the GridMate networking (p. 1990) library. The new preview attempts to incorporate as many GridMate features as possible but is not comprehensive. Instead it is intended as a living snapshot of the current state of the networking library. Consequently, as the sample evolves, features might be added to enhance functionality or removed to keep the sample concise.

Building and Running the Sample

Follow these steps to build and run the sample.

To build and run the Multiplayer sample

1. In the Project Configurator set MultiplayerSample as the active project.
2. Run the following command:
   ```
   lmbr_waf configure
   ```
3. Run the following command which builds everything in the profile, for your version of Visual Studio.
   ```
   lmbr_waf build_win_x64_vs2017_profile -p all
   ```
4. Run the MultiplayerSampleLauncher.exe file from your default bin directory.
   - For Visual Studio 2017, use the Bin64vc141.Dedicated directory.
   - For Visual Studio 2019, use the Bin64vc142.Dedicated directory.

MultiplayerLobby

This level demonstrates a multiplayer lobby that uses GridMate networking. Currently, the level performs the following tasks:

- Creates a server
- Displays a list of servers on the local LAN
- Connects to a server

To create a server

1. Enter the server name in the Create a Server form.
2. Click Create Server.

   The game starts hosting and loads the selected map.

To connect to a server

1. Find your server in the server browser list. If your server doesn't appear, click Refresh.
2. To select your server, click the row that contains your server name.
3. Click **Connect**.

**Game Overview**

The Multiplayer sample is an arcade space shooter. Each player controls a ship in a giant field of asteroids. Each player must fly through the asteroids and destroy as many of them as possible in an effort to achieve the highest score. Additional points are awarded when other players are killed. Points are deducted every time the player dies. In addition to the threats posed by asteroids and other players, gravity wells scattered around the map can draw players in and trap them. Players who become trapped in a gravity well die instantly.

When a ship is spawned, three kinds of ships are assigned randomly:

- **Fighter** – An average space ship.
- **Speeder** – A faster and more maneuverable space ship but less sturdy as a result.
- **Rammer** – A sturdier ship that is weaponless but designed to smash into asteroids and destroy them. The ship is fast but has poor maneuverability.

When destroyed, some asteroids spawn collectibles that award a short-time power-up bonus. These power-ups include extra damage against certain targets, a longer power-up time, and extra protection against certain sources of damage.

**Game Controls**

The following tables list controls for keyboards, controllers, and touch interfaces.

**Keyboard**

<table>
<thead>
<tr>
<th>Key</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>WASD keys</td>
<td>Move the ship relative to the screen (W is always up, S is always down, and so forth).</td>
</tr>
<tr>
<td>Arrow left, arrow right</td>
<td>Rotate the ship clockwise or counterclockwise.</td>
</tr>
<tr>
<td>Spacebar</td>
<td>Fire the ship's weapon (if applicable).</td>
</tr>
<tr>
<td>Tab (hold)</td>
<td>Open the <strong>Player Stats</strong> window.</td>
</tr>
</tbody>
</table>

**Controller**

<table>
<thead>
<tr>
<th>Control</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Left joystick</td>
<td>Move the ship in absolute terms relative to the screen.</td>
</tr>
<tr>
<td>Right joystick</td>
<td>Rotate the ship clockwise or counterclockwise.</td>
</tr>
<tr>
<td>Right shoulder button</td>
<td>Fire the ship's weapon (if applicable).</td>
</tr>
<tr>
<td>Back button (hold)</td>
<td>Open the <strong>Player Stats</strong> window.</td>
</tr>
</tbody>
</table>
Touch interface

<table>
<thead>
<tr>
<th>Control</th>
<th>Action</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual joystick (left side of screen, no visual indication)</td>
<td>Move the ship in absolute terms relative to the screen.</td>
<td></td>
</tr>
<tr>
<td>Virtual joystick (right side of screen, no visual indication)</td>
<td>Rotate the ship clockwise or counterclockwise.</td>
<td></td>
</tr>
</tbody>
</table>

Notes

• As soon as you begin moving with either virtual joystick, the ship begins firing (if applicable).
• These controls can also be accessed by using the mouse (click to touch).
• If you fire manually, the automatic firing stops until the next input from one of the virtual joysticks.

Game CVars

The following console variables can be used with the game.

mps_AISteeringDebug

Specifies whether the debug drawing information for the bot is drawn.

mps_ControllerType number

Controls the type of PlayerController that the client uses to control the assigned ship. The following table shows the possible values for number:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Specifies manual control. A user controls a single ship.</td>
</tr>
<tr>
<td>1</td>
<td>A bot that plays the game.</td>
</tr>
</tbody>
</table>

mps_DrawBucketSystem

Specifies whether the debug information for the bucket system is drawn.

mps_SpawnTag

Controls what ship is spawned for a player when the player spawns a ship. Possible values are shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Random</td>
<td>Chooses an available ship at random. This is the default value.</td>
</tr>
<tr>
<td>Fighter</td>
<td>Spawns a fighter ship.</td>
</tr>
<tr>
<td>Speeder</td>
<td>Spawns a speeder ship.</td>
</tr>
<tr>
<td>Rammer</td>
<td>Spawns a rammer ship.</td>
</tr>
</tbody>
</table>
mps_User\textit{Name}

Specifies the name for the client in game elements such as the scoreboard or action notification.

**Creating a Dedicated Server**

To create a dedicated server for the game, perform the following steps.

**To create a dedicated server**

1. In the Project Configurator set \textit{MultiplayerSample} as the active project.
2. Enter the following command:
   
   \texttt{lmbr\_waf configure}

3. Enter the following command which builds everything in the profile, for your version of Visual Studio:
   
   \texttt{lmbr\_waf build\_win\_x64\_vs2017\_profile -p all}

4. Enter the following command which builds \texttt{game\_and\_engine} in \texttt{profile\_dedicated}, for your version of Visual Studio:
   
   \texttt{lmbr\_waf build\_win\_x64\_vs2017\_profile\_dedicated -p game\_and\_engine}

5. Run the \texttt{MultiplayerSampleLauncher\_Server.exe} file from your default bin directory.
   
   • For Visual Studio 2017, use the \texttt{Bin64vc141.Dedicated} directory.
   • For Visual Studio 2019, use the \texttt{Bin64vc142.Dedicated} directory.

**Supported Platforms**

The Multiplayer sample is currently supported on a variety of client and server platforms.

**Clients**

The following playable client platforms are supported:

• Windows (Visual Studio 2017 or Visual Studio 2019)
• Android
• iOS

**Dedicated Server Platforms**

The following dedicated server platforms are supported:

• Windows (Visual Studio 2017 or Visual Studio 2019)
• Linux (Ubuntu)

**About Self-Signed Certificates in the Multiplayer Sample**

In Windows, the Multiplayer sample enables client-side self authentication that uses a \texttt{self-signed certificate}, which the build script generates for each user. Regarding this certificate, keep in mind the following points:
• The self-signed certificate is not an official certificate. If you want to ship a publically available game, you must replace it with a public key certificate.

• On the macOS and Linux platforms, you must generate self-signed certificates manually.

• On the macOS and Linux platforms, the Multiplayer sample has the following limitations:
  • macOS: Only iOS client builds can be made.
  • Linux: Only dedicated server builds can be made.

Troubleshooting

The following are some connection troubleshooting tips.

• If clients are unable to discover a server, ensure that the server and client are on the same subnet in order to allow for UDP discovery.

• If clients are unable to connect to a server, ensure that the server and client are using the same key and certificate files.

• When trying to host or join a session, you might receive one of the following error messages:

  Invalid Secure Socket configuration given for hosting a session.
  Ensure that a Public and Private key are being supplied.

  Invalid Secure Socket configuration given for joining an encrypted session.
  Ensure that a Certificate Authority is being supplied.

To resolve these issues, perform one of the following tasks:

• Run the command `lmbr_waf configure` to generate a set of certificates.

• In the `MultiplayerSample/certificates` directory, provide your own appropriately named certificates.

For more information about self-signed certificates, see Encryption in the Multiplayer Sample Network Features (p. 162) section and About Self-Signed Certificates in the Multiplayer Sample (p. 158).

Topics

• Multiplayer Sample Gameplay Architecture (p. 159)
• Multiplayer Sample Network Features (p. 162)

Multiplayer Sample Gameplay Architecture

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Multiplayer sample consists of five main entities and an equal number of supporting gameplay systems. The following overview provides a conceptual introduction to the architecture of the Multiplayer sample.

Principal Entities in the Multiplayer Sample

The principal entities in the Multiplayer sample are ships, asteroids, gravity wells, bullets, and collectibles. These entities also have some common components.
Common Components

The principal entities in the game share the following components:

- **SimpleSpacePhysicsComponent** – This component enables objects to move around in space and be affected by gravity.
- **CollisionSystemComponent** – These components enable objects to interact with each other in the world.
- **NetBindingComponent** – Activates the net binding code of other components on an entity and signals the game that the entity should be replicated across the network.

Ships

The Multiplayer sample uses a variety of ships that demonstrate how a selectable game state can be synchronized from a client to a session when the player first joins the game. Different types of ships also provide a variety of game experiences. Some ships have long range weapons, and others are short range and have no weapons. The following components are related to ships:

- **ShipComponent** – Identifies an object as a ship to Lumberyard. It also takes commands from the player and converts them on the host into the motion required to move the ship.
- **ShipGunComponent** – Handles the firing of bullets.
- **ActiveModifiersComponent** – Manages the modifiers that affect the ship.
- **CollectibleInterpreterComponent** – Enables a layer of interpretation between a collectible and the actual modifier that is granted. This enables implementations of a collectible according to the ship type. For example, ships with guns that receive a collectible get a special laser, while weaponless ships get a nonweapons-related buff.
- **HealthComponent** – Determines the relative health of the ship as long as it remains operational.

Asteroids

Asteroids are the most common slice in the Multiplayer sample. They exist in three sizes (small, medium, and large). These asteroid types are functionally the same while they exist. When destroyed, they react differently by spawning varying amounts of asteroids and collectibles. Blanketing the playfield with these objects allows for optimization techniques to be implemented that create a reasonable visual experience without overusing bandwidth. The following components are related to asteroids:

- **AsteroidComponent** – Identifies an object as an asteroid to the game engine.
- **DeathActionComponent** – Allows for actions to be taken upon the destruction of the object. In the sample, the DeathActionComponent spawns additional asteroids and collectibles.
- **DamageComponent** – Determines how much damage the asteroid does when it collides with a ship.
- **HealthComponent** – Determines how much damage an asteroid can take before it is destroyed.

Gravity Wells

Gravity wells create action inside the game by causing objects to be destroyed and spawned even in the absence of user interaction. This prevents the game state from falling into stasis. The following components are related to gravity wells:

- **GravityWellComponent** – Identifies an object as a gravity well.
- **GravitySourceComponent** – Applies gravity to physical objects and draws them towards the source object.
Bullets

Ships use bullets to damage asteroids and each other. The use of bullets drives gameplay and generates points. The following components are related to bullets.

- BulletComponent – Identifies an object as a bullet.
- DamageComponent – Determines how much damage a bullet does when it hits a ship or asteroid.

Collectibles

Collectibles add fun and excitement to the game and provide a way to enable and test dynamic in-game changes to otherwise static systems. The sample uses collectibles to test the handling of constantly shifting objects to find the right balance between natural appearance and controllability. The following component is related to collectibles.

- CollectibleComponent – Identifies an object as a collectible.

Multiplayer Sample Gameplay Systems

The gameplay systems in the Multiplayer sample handle the game logic essential to game operations.

Game Manager

The GameManagerComponent handles all of the general game logic, such as controlling game start and end, managing the results screens, and other tasks not performed by individual game modes. The GameManagerComponent functions as a server-only component. A component like this would normally be reserved for use in a dedicated server and not be shipped in a player version of the game. The component synchronizes no data and is not replicated across the network.

Score Attack Game Mode

The ScoreAttackGameModeComponent works with the GameManagerComponent to provide the rules for play and synchronize data to players for score attack mode.

Asteroid Manager

The AsteroidManagerComponent creates new asteroids and manages asteroid lifespans. It decides where, how, and how many asteroids are spawned into the game. Although it is exported with the level, this component synchronizes no data and should not be included in a player version of the game.

Collectible Manager

The CollectibleManagerComponent spawns collectibles in response to the destruction of asteroids. Although it is exported with the level, this component synchronizes no data and should not be included in a player version of the game.

Spawn Manager

The SpawnManagerComponent is a wrapper for the Spawner (p. 859) that allows the sample to spawn objects in complex ways without requiring the use of multiple spawner components. The spawn manager facilitates the automation of variation among spawned entities. For example, when an asteroid is spawned, a general type can be specified and the specific type randomly selected in the spawn manager from the supported types. This removes the need to manually specify a type with each spawn request.

This approach also promotes ease of maintenance because it enables a single object to handle all objects of a single type. For example, all asteroids are defined in a single place and are identified by a specific tag (SmallAsteroid, MediumAsteroid, or LargeAsteroid). This limits the number of interactions required among the objects and the amount of information that must be exchanged.
In the sample, only one object manager (for example, asteroid or collectible) is aware of the location of the spawner for an object. This location is usually on the object itself.

**Multiplayer Sample Network Architecture**

The sample uses a server-authoritative architecture. In the sample, client-side input is processed on the player and converted into RPCs that are processed by the server.

**Player Object**

When each client joins the session, it creates an object on the server that represents the player. The object provides information relevant to player configuration. The client maintains full control over player configuration, which the server reads from the object. The player object consists of a `GamePlayerComponent` and a related `GamePlayerChunk`.

- **GamePlayerComponent** – The `GamePlayerComponent` represents the player on the server. The component is owned by the client and replicated to the server. This component handles local player configuration such as the player's name and the ship to spawn. The user can change this information during gameplay. These changes must be reflected to the server.

- **GamePlayerChunk** – The Replica Chunks (p. 2037) that represents player information on the server. The `GamePlayerChunk` specifies the display name of the player and the ship that the player wants to spawn.

**Ship Object**

The ship object consists of a `ShipComponent` and a related `ShipComponentReplicaChunk`.

- **ShipComponent** – Manages the overall ship logic, controls, and ship configurations.

- **ShipComponentReplicaChunk** – Contains the RPCs that are invoked on the client and passed to the server. The server then validates, sanitizes, and applies the results to the game state.

**See Also**

For more information about networking in the Multiplayer sample, see Multiplayer Sample Network Features (p. 162).

**Multiplayer Sample Network Features**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Multiplayer sample offers the following features.

- **Dedicated Server Split (Partial)** – Because the clients can also host game sessions for LAN play, a true split is never done even when the client has no server code. However, the code itself is compartmentalized in such a way that the split can be done easily. A dedicated server split is used in the following component:

  - **GameManagerComponent** – Designed to be available only on the server. It relies on the GameModeBus to synchronize the state to display (for example, whether the game is ready to start a round, or whether the current round is complete). For details, see the source code files in the `\dev\Code\MultiplayerSample\Modules\MultiplayerSampleModule\Source\Components\GameLogic` directory.

- **Client Authoritative Control** – Enables the client to maintain exclusive control of an object whose actions are processed on the server. Client authoritative control is used in the following components:
• **ShipComponent** – Client commands that control a ship trigger a series of RPCs that the ShipComponent exposes. The RPCs are then processed on the server. The commands are restricted to the owner of the object. For details, see the source code files in the `dev\Code\MultiplayerSample\Modules\MultiplayerSampleModule\Source\Components\Ship` directory.

• **ManualPlayerControllerComponent** – Represents the human-controllable player. For details, see the source code files in the `dev\Code\MultiplayerSample\Modules\MultiplayerSampleModule\Source\Components\ShipController` directory.

• **BaseAutomatedPlayerControllerComponent** – Represents an AI-controllable player. It maps computer-generated input to the RPC calls. For details, see the source code files in the `dev\Code\MultiplayerSample\Modules\MultiplayerSampleModule\Source\Components\ShipController` directory.

• **Encryption** – Encryption is performed using `FileDataSource` with self-signed certificates and certificate pinning. The files expected are a set of X.509 PEM files, which are split into a nonpassword-protected key (`multiplayersample.key.pem`) and a cert file (`multiplayer.cert.pem`). These are located in the `MultiplayerSample\certificates` directory. If either of these files is missing, a set of certificates is generated using RSA2048 and some default answers that can be customized from the `wscript` file. For more information, see How To Generate a Private Key and Public Certificate (p. 2072). For important information about self-signed certificates in the Multiplayer sample, see About Self-Signed Certificates in the Multiplayer Sample (p. 158). In the Multiplayer sample, encryption is used in the following features:

• **GameManager** – Exposes a function called `SetupEncryption`, which handles the configuration of certificates for the game. For details, see the source code files in the `dev\Code\MultiplayerSample\Game\Game` directory.

• **MultiplayerUtils** (in Multiplayer Gem) – Has utility functions that handle configuration of the carrier description (p. 2014) for hosting and joining. The code shows how to configure the `SecureSocketDriver` (p. 2070) and use an EBus event to signal its use for the connection. For details, see the source code files in the `dev\Gems\Multiplayer\Code\Include\Multiplayer` directory.

• **RPC Traits** – In Lumberyard, RPCs allow games to send events or requests to remote nodes through GridMate replicas (p. 2034) that synchronize the state of the session. In the Multiplayer sample, RPC traits are used to control ships, manage the HUD state, and manage audio controllers. To see how they are attached to RPCs, see the source code files in the following locations.

<table>
<thead>
<tr>
<th>Component</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>ShipComponent</td>
<td><code>dev\Code\MultiplayerSample\Modules\MultiplayerSampleModule\Source\Components\Ship</code></td>
</tr>
<tr>
<td>CoreGameHUDControllerComponent</td>
<td><code>dev\Code\MultiplayerSample\Modules\MultiplayerSampleModule\Source\Components\GameLogic</code></td>
</tr>
<tr>
<td>ShipAudioControllerComponent</td>
<td><code>dev\Code\MultiplayerSample\Modules\MultiplayerSampleModule\Source\Components\Audio</code></td>
</tr>
</tbody>
</table>

• **Custom Component Net Binding** – For a Lumberyard component to share data on the network, it must include the `NetBindingComponent` (p. 2055). A number of Multiplayer sample components demonstrate custom component net binding.

• **CoreGameHUDController** – An illustrative example that has datasets, RPCs, RPC traits, and callbacks. For details, see the source code files in the `dev\Code\MultiplayerSample\Modules\MultiplayerSampleModule\Source\Components\GameLogic` directory.

• **Custom Type Marshalling** – In GridMate, all data marshalling (p. 2022), whether for a dataset or an RPC, is written using a specialized `Marshaler` type. If the type is a complex type like a class or container, then that marshaler marshals each of its fields with nested marshalers. Custom marshalers...
can be implemented to support custom types. Custom type marshalling is used in the following component:

- **ScoreAttackGameModeComponent** – The `PlayerRoundInfo` struct demonstrates the simplest way of defining a custom marshaler for a custom type without needing to specifically override it in the dataset definition. For details, see the source code files in the `\dev\Code\MultiplayerSample\Modules\MultiplayerSampleModule\Source\Components\GameLogic` directory.

## Virtual Reality Samples Project

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Virtual Reality Samples Project is a template that you can use to build virtual reality (VR) applications for any supported device. The sample is configured with the base set of gems (HMD Framework, Oculus, and OpenVR) that you need for VR and demonstrates the following essential VR features:

- Room-scale VR setup
- Tracked controller input system
- Spatialized audio playback
- Stereo 360 video playback

To install the Virtual Reality Samples Project

1. Download the `vrproject.zip` package at Lumberyard Downloads and extract it in your Lumberyard directory, such as `lumberyard_version\`
2. Open Lumberyard Setup Assistant (p. 16) and on the Summary page, click Configure project.
Note
To ensure that the VR project launches, you must use Lumberyard Setup Assistant to open the Project Configurator. Lumberyard Setup Assistant copies required SDKs from the 3rdParty directory into the dev\VirtualRealityProject directory.

3. In the Project Configurator, select VirtualRealityProject and then click Set as default.
5. Open Lumberyard Setup Assistant.
6. Download the required SDKs to view video playback for the Virtual Reality Samples Project.

Important
The video playback on the TV in the VR_TVRoom_Sample level must be enabled before you can view video playback. For instructions on setting up video playback, see Setting Up Video Playback (p. 907).

7. Close Lumberyard Setup Assistant.
8. After completing video playback setup, you must also build (p. 61) the virtual reality project.
9. Start Editor.exe from one of the following directories:
   - For Visual Studio 2017, use the lumberyard_version\dev\Bin64vc141 directory.
   - For Visual Studio 2019, use the lumberyard_version\dev\Bin64vc142 directory.

Topics
- VR Islands Level (p. 165)
- VR TV Room Level (p. 167)
- VR Xylophone Level (p. 169)
- VR Box Garden Level (p. 172)

VR Islands Level

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The VR Islands level (VR_Islands_Sample) shows you how to create a simple VR level with the instantvr entity and physics collision on controllers. This level features floating islands between which a player can teleport with the trigger button on the Oculus or Vive motion controllers. The player can hold the trigger button to pick the location and then release the button to initiate the teleport.

Note
This level uses Script Canvas and Lua for game logic. Legacy systems have been replaced or removed, with the exception of the navigation mesh. The VR Preview (p. 924) component generates the navigation mesh, which is required for teleporting in gameplay.

This level uses an instantvr slice that has the following child entities:

- Controller_One – Represents the player's right hand.
- Controller_Zero – Represents the player's left hand.
- Camera – Represents the player's head.
- InvalidLocationSpawner – Spawns an invalid location marker when the player teleports within the terrain or navigation mesh.
• **ValidLocationSpawner** – Spawns a valid location marker when the player teleports within the terrain or navigation mesh.
• **InputConfiguration** – Contains the input bindings for teleportation events.

For more information about installing the project that includes the VR Islands level, see Virtual Reality Samples Project (p. 164).

**Using the InstantVR Entity**

The VR Islands level is created with the `instantvr` entity, which has the following components:

- **Lua Script (p. 683)** – This component uses the `instantvr.lua` script for VR device tracking and teleportation functionality. You can find the script in the `lumberyard_version\dev\VirtualRealityProject\Scripts\vr` directory.

- **VR Preview (p. 924)** – This component automatically generates a 50x50 meter navigation area, and a navigation mesh within the navigation area. The navigation mesh is required for the `instantvr.lua` script to detect valid teleportation locations.
Note
You must select the Static check box on the Transform (p. 878) component for all entities in the navigation area. This ensures that the navigation mesh generates correctly. The Static check box is cleared by default.

Using the HideOcean Entity

The VR Islands level includes a HideOcean entity that allows you to hide the ocean when the level runs in VR mode.

To hide the ocean

1. Open the Console Variables window. For instructions, see Viewing the Console Window (p. 210).
2. In the Console Variables window, search for the e_WaterOcean console variable.
3. Set the e_WaterOcean console variable to 0.

VR TV Room Level

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The VR TV Room level demonstrates a simple VR level that is set up to play 2D video, 3D video, and 360 video on a VR device. This level contains the following:

- 2D video
- 3D video
- Input Configurator entity – Initiates an input event when you press the trigger button.
- VideoPlayback_Toggle entity – Contains a Script Canvas (p. 818) component that listens for the input event and then toggles visibility.
- Screen_Toggle_Sphere entity – Contains a Lua script that enables the 3D video sphere to follow the VR camera.

For more information about installing the project that includes the VR TV Room level, see Virtual Reality Samples Project (p. 164).

Using Components in the VR TV Room Level

You can use the Video Playback (p. 906) component to assign a diffuse texture to the specified video. You can then assign the material that uses the diffuse texture to any mesh.

You can use the Script Canvas component and graph to set the playback to loop mode and to start playing immediately.
Cycling Through Video Playback Options

The TV Room level shows you how to cycle through video playback options. When you use the trigger button in-game, the television cycles through 2D video, 3D video, 360 video, and an off state. In Lumberyard, this is achieved with four entities, one for each video playback option. You can toggle the visibility of each entity to reflect the playback on the television in the level.

The 2D and 3D videos were created with the same static mesh, but different materials. The 360 video was created by attaching a sphere to a camera with a 3D video material.

VR Xylophone Level

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The VR Xylophone level shows you how to create basic VR gameplay with the Lumberyard component entity system. You use Script Canvas and Lua for VR device tracking, input events, and corresponding gameplay events.

For more information about installing the project that includes the VR Xylophone level, see Virtual Reality Samples Project (p. 164).
VR Device Tracking

The VR Xylophone level uses the following:

- **Input Configurator** entity – Handles VR device tracking and input events.
- **Input (p. 642)** component – Defines two input events (**FireLargeBox** and **FireSmallBox**) that are initiated when you use the trigger button on the Oculus or Vive motion controllers.
- **Lua Script (p. 683)** component – Uses the `vrdevice_tracking.lua` script to track the movement and orientation of the VR controllers. Passes the transforms to specific controller entities.
**VR Controllers and Projectiles**

The VR Xylophone level uses a controller_right.slice for the right controller and a controller_left.slice for the left controller. You can find these slices in the lumberyard_version\dev\VirtualRealityProject\slices directory.

The right and left controllers are set up similarly, except that they spawn different projectiles and use different materials. The following image shows the entities for the left controller (green) and right controller (red), as well as their respective projectile entities.

![VR Controllers and Projectiles](image)

The projectile entities are also set up similarly, except for size and color. They use the Rigid Body component, Primitive Collider and Box Shape (p. 820) components to collide and interact with the domino entities in a physically realistic way. Upon spawning, the projectile entities use the Script Canvas (p. 818) component to move forward.

You can find the projectile_largebox.slice and projectile_smallBox.slice files in the lumberyard_version\dev\VirtualRealityProject\slices directory.

The VR Xylophone level uses the following scripts:

- **vrdevice_tracking Lua script** – Matches the in-game movement and orientation of the controller entities with the physical controllers.
- **Script Canvas graph** – Spawns a projectile and plays a spawning sound when an input event is triggered. This graph is on the controller entity.
  - In the **Input Handler** node, the **Event Name** is the event that is defined in the **Input Configurator**.
  - The **Audio Trigger** component specifies the sound to play.
• The **Spawner** component specifies the dynamic slice to spawn.

![Diagram showing Spawner component](image)

**Domino Tiles**

The projectile entities interact with the domino tiles. These tiles are instances of eight slices, each differing in color, letter, and sound pitch. The sound pitch occurs when the tile's trigger makes contact with another collider.

Each domino tile slice has a child entity with the **Trigger Area** and **Lua Script** components. The **Trigger Area** component triggers an event to play the sound that's specified in the `triggerarea_play_sound.lua` script.

![Domino tiles image](image)

**VR Box Garden Level**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The VR Box Garden level shows you how to use the Lumberyard component entity system to set up a VR playspace, basic VR gameplay, and controller tracking. You use Script Canvas and Lua for VR device tracking, input events, and corresponding gameplay events.
For more information about installing the project that includes the VR Box Garden level, see Virtual Reality Samples Project (p. 164).

**VR Device Tracking and Controller Gameplay**

The VR Box Garden level uses the following:

- **Input Configurator** entity – Handles VR device tracking and input events.
- **Input (p. 642)** component – Defines input events that are initiated when you use the trigger button on the Oculus or Vive motion controllers.
- **Lua Script (p. 683)** component – Uses the vrdevice_tracking.lua script to track the movement and orientation of the VR controllers. Passes the transforms to specific controller entities.

The level uses a `controller_right.slice` for the right controller and a `controller_left.slice` for the left controller. These controllers listen for input events and spawn projectiles when an event is detected. The projectile entities use the Script Canvas (p. 818) component to move forward.

All slices for the VR Box Garden level are located in the `lumberyard_version\dev\VirtualRealityProject\slices` directory.

The VR Box Garden level uses the following scripts:

- **vrdevice_tracking** Lua script – Matches the in-game movement and orientation of the controller entities with the physical controllers.
- **input_play_sound** Lua script – Plays a spawning sound when an input event is triggered. The Lua Script component specifies the sound to play.
  
  **Note**
  
  To play sound correctly, you must add both the Audio Proxy (p. 557) component and the Audio Trigger (p. 559) component on the entity.

- **Script Canvas graph** – Spawns a projectile. The Spawner (p. 859) component specifies the dynamic slice to spawn. This graph is on the controller entity. In the Input Handler node, the Event Name is the event that is defined in the Input Configurator.

**VR Playspace**

The level's playspace includes the following:

- **Base** – Uses the Playspace_Base entity that has a vrplayspace_base.lua script. The Lua script adjusts the scale of the static mesh to match the dimension of the VR playspace. The dimension is derived from the position of four corners of the playspace from the VR device.
- **Posts** – Spawns at runtime from the Playspace_Posts entity. This entity uses a Lua script to calculate the number and position of posts, and spawn the posts along the playspace edges at a fixed interval.
- **Corners** – Uses a Lua script to locate the corner position and move to the correct position. There are four entities, one for each corner. You can use the Lua script to assign a number for each corner.
Procedurally-Spawned Stacking Boxes

The level uses six Box Spawner entities with the random_spawner.lua script to demonstrate how to procedurally generate a specified number of boxes at runtime. These boxes are used in-game as shooting targets.

You can modify the following parameters in the Spawner component to affect random generation.

For more information, see Spawner Component Properties (p. 859).
To enable triggering spawn events, you can add a Lua Script component to the entity with the Spawner component attached. The spawned box uses a dynamic slice called greybox.slice.

In-App Purchases Sample

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The In-App Purchases sample demonstrates how to use the In-App Purchases (IAP) Gem for a Lumberyard application that runs on a mobile device. For more information about this gem, see In-App Purchases Gem (p. 1147).

Topics

- Prerequisites (p. 175)
- Testing the In-App Purchases Sample on Android (p. 175)
- Testing the In-App Purchases Sample on iOS (p. 176)

Prerequisites

To use the In-App Purchases sample, you must have the following:

- An understanding of how to build a Lumberyard application and deploy to a mobile device. For more information, see Developing for Android and iOS with Lumberyard (p. 3166).
- Access to iTunes Connect to properly configure the sample for an iOS device.
- Access to the Google Play Developer Console to properly configure the sample for an Android device.

To load the In-App Purchases sample, you must edit the autoexec.cfg file (located in the \dev\SamplesProject directory) to include the following:

```
map Gems_InAppPurchases_Sample
```

You must also update the product IDs in the product_ids.json file to match the product IDs in iTunes Connect or the Google Play Developer Console. This file is located in the \dev\SamplesProject\IAP_ProductIds directory.

Testing the In-App Purchases Sample on Android

You can test the In-App Purchase samples on an Android device.
To test the In-App Purchases sample on an Android device

1. In a command line window, build the SamplesProject application.
2. Go to the Google Play Developer Console.
3. In the left pane, click **All Applications**.
4. In the right pane, click **Create Application**.
5. Follow the steps to create a new application. The package name for your application must match the package name under **android_settings** in the **project.json** file. This file is located in the \dev\SamplesProject directory.
6. Once the application is created, it appears on the **All Applications** tab in the Google Play Developer Console. Click the application. In the left pane, navigate to **In-app Products**.
7. On the **In-app Products** page, click **Add new product** to add products that can be purchased through the application.
8. In the left pane of the application page, click **APK** to upload the APK that you built in step 1.
9. Create a closed beta test and add test accounts for testing.
10. Deploy the application to your device. The in-app products that you created in the Google Play Developer Console appear when you select **Available Products** in the application.

You can now buy products, view purchased products, and consume purchased products in the application.

Testing the In-App Purchases Sample on iOS

You can test the In-App Purchases sample on an iOS device.

To test the In-App Purchases sample on an iOS device

1. Go to **iTunes Connect**.
   
   You must have an admin account to create applications.
2. Click **My Apps**.
3. In the top left of the page, click + to create a new application.
4. On the **My Apps** page, click your newly created application.
5. In the top pane of the application page, click **Features**.
6. In the left pane of the **Features** page, click **In-App Purchases**.
7. On the **In-App Purchases** page, click + to add products that can be purchased through the application.
8. When you finish adding products for in-app purchases, go to the iTunes Connect home page.
9. In iTunes Connect, click **Users and Roles**.
10. On the **Users and Roles** page, click **Sandbox Testers**.
11. On the **Sandbox Testers** page, click + to add sandbox tester accounts.

   **Important**
   
   Do not log in using this account on your device. This will deactivate the sandbox testing account and you'll need to create a new account.
12. On your device, choose **Settings**, **iTunes**. Log out of any accounts that are logged in.
13. Deploy and run the application from Xcode. When prompted, sign in with your sandbox tester account on the device.

You can now view available products, buy products, view purchased products, and more. When you buy a product, a note appears that indicates you are in the sandbox environment and will not be charged for the purchase.

**Woodland Asset Package – Legacy**

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Woodland asset package includes free wilderness assets that you can use to create a forest scene or populate your own levels with vegetation and other natural features that might be found in a woodlands scene. The Woodland assets are static art assets; therefore, you will not need to recompile your project after adding these assets.

**Note**
This package is compatible with Lumberyard 1.9 and earlier.

**To install the Woodland asset package**

1. Download the Woodland Asset Package at Lumberyard Previous Versions and extract it in the `\dev\Gems\AssetCollection_Woodland` directory at the root of your Lumberyard installation. You may need to create this folder or rename the extracted folder.
2. Open the Project Configurator.
3. In the Project Configurator, under your project, click Enable Gems.
4. On the Gems (extensions) page, select Woodland Asset Collection.
5. Click Save.
6. Open Lumberyard Editor and do the following:
   - In the Rollup Bar, click Geom Entity and select your meshes.
   - Click Tools, Material Editor and select your materials and textures.
   - Click Tools, Geppetto and select your animations.

Sample images from the Woodland asset collection:
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Beach City sample project includes free assets that you can use to create your own levels. Although the Beach City sample project is intended to be a visual demo and is not a playable demo, you can add player controls to the level if you wish to make it playable.
Note
This package is compatible with Lumberyard 1.9 and earlier.

To install the Beach City sample project

1. Download the BeachCity.zip package at Lumberyard Previous Versions and extract it in your Lumberyard directory. For example, \Lumberyard\1.x.0.0.

2. Open the Lumberyard Setup Assistant (p. 16). On the Summary page, click Project Configurator.

   Note
   To ensure that the Beach City project launches, you must use Lumberyard Setup Assistant to open the Project Configurator. Lumberyard Setup Assistant copies required SDKs from the 3rdParty directory into the dev\BeachCity directory.

3. In the Project Configurator, select BeachCity.

4. Click Set as default. Close the Project Configurator.

Sample images from the Beach City sample project:
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard provides a package named Legacy Game Sample that demonstrates how to use Lumberyard features such as CryAction and CryAISystem. The fully functional game implements the necessary pieces that allow a game to communicate with some of Lumberyard's low-level systems. If you are familiar with CryEngine, the legacy game sample is a repurposed version of the GameSDK project.

You can use the legacy game sample to evaluate changes you make to the engine core and ensure your changes do not have unintended side effects. The legacy game sample is intended to be used as a reference for how to communicate with various systems of the Lumberyard engine. We do not recommend using the legacy game sample as the starting point of a new game.

**Note**
The legacy game sample is Windows only and is not supported on console or mobile devices. This sample is compatible with Lumberyard 1.9 and earlier.

**To download and access GameSDK**

1. Download the GameSDK.zip package at Lumberyard Previous Versions and extract it in your Lumberyard directory. For example, \lumberyard\1.10.0.
2. Open Lumberyard Setup Assistant (p. 16) and on the Summary page, click Project Configurator.

   **Note**
   To ensure that the GameSDK project launches, you must use Lumberyard Setup Assistant to open the Project Configurator. Lumberyard Setup Assistant copies required SDKs from the 3rdParty directory into the dev\GameSDK directory.

3. In the Project Configurator, select GameSDK.
4. Click Set as default and then close the Project Configurator.
5. Rebuild (p. 1064) the GameSDK project.
6. Open Lumberyard Setup Assistant. On the **Summary** page, click **Launch editor**.

**Note**
Audiokinetic Wave Works Interactive Sound Engine (Wwise) version 2014.1.14 or later is required to access audio for this project.
Lumberyard Editor is your primary workplace for game development. The editor provides access to the tools to create, design, and deploy your game project. You can also play the game to test your changes.

**Note**
If you receive errors from the `AssetProcessor.exe` or `AssetProcessor_temp.exe`, check for the quarantined file in your antivirus software. You can grant exceptions for the affected files.

**To open Lumberyard Editor**
- After installation, launch Lumberyard Editor with your preferred method:
  - From the desktop, double-click the Lumberyard Editor icon.
    
    **Note**
    The Lumberyard Editor desktop shortcut points to the `lumberyard_installation\dev\Bin64vc\xxx\Editor.exe` file that corresponds to the version of Visual Studio that you chose in Lumberyard Setup Assistant during setup. If you later change the version of Visual Studio that you use with Lumberyard, this desktop shortcut may no longer be valid.
  - From Lumberyard Setup Assistant, on the **Summary** page, click **Launch Editor**.
  - For Visual Studio 2017, navigate to the `lumberyard_version\dev\Bin64vc141` directory and double-click `Editor.exe`.
  - For Visual Studio 2019, navigate to the `lumberyard_version\dev\Bin64vc142` directory and double-click `Editor.exe`.

After the first launch and each time you change projects, Asset Processor runs in the background using the project configuration settings to populate the **Asset Browser**. Messages appear with status information before the editor opens. For more information about Asset Processor, see Using Asset Processor (p. 248).

Lumberyard User Guide

Lumberyard Editor Interface

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard Editor has the following panels and toolbars in the default layout:

A. Entity Outliner – The Entity Outliner lists the component entities that are included in the current level. For more information, see Entity Outliner (p. 462).

B. Asset Browser – The Asset Browser displays your assets in a tree view that mirrors your assets directory. For more information, see Asset Browser (p. 296).

C. Perspective – The 3D viewport window displays the game environment and allows you to view, create, and interact with assets. For more information, see Using the Viewport (p. 207).

D. Entity Inspector – The right pane defaults to the Entity Inspector view, which allows you to add component and entities and modify their settings and properties. For more information, see Entity Inspector (p. 475).

E. Top Toolbar – The top toolbar provides quick access to the most commonly used functions and features. You can customize the toolbar. For more information, see Using the Top Toolbar (p. 200).

F. Console – The console window allows you to enter commands to change settings for your game or execute functionality, such as connecting to a server or banning a player. The console window also displays warnings and errors for your game level, such as missing textures and models. You can access the console while in-game by pressing the tilde (~) key. For more information, see Using the Console Window (p. 210).

G. Bottom Toolbar – Use the Go to position button in the bottom toolbar to navigate to a precise X, Y, and Z location in the viewport. To transport to a point above the terrain, you can change the X, Y, and Z values to 1024, 1024, and 34, respectively. For more information, see Using the Bottom Toolbar (p. 202).

Using the Menu Bar

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The main menu bar in Lumberyard Editor provides access to the features and tools to design, run, and deploy your game, as well as, work with external tools and find online information. To access the available features and tools, you can use the menu, the buttons on the toolbars, or the keyboard. You can pause on the buttons to see tool tips. Some editors and tools have keyboard shortcuts. For a comprehensive list, see Using Keyboard Shortcuts (p. 205).

The main menu bar has the following categories of features and functionality.

<table>
<thead>
<tr>
<th>Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File</td>
<td>Manage your resource files for your level, project, and other file management tools.</td>
</tr>
<tr>
<td>Edit</td>
<td>Select objects in your level and make changes.</td>
</tr>
<tr>
<td>Game</td>
<td>Perform operations that affect the whole game.</td>
</tr>
<tr>
<td>Tools</td>
<td>Launch a variety of editors and specialty tools.</td>
</tr>
<tr>
<td>AWS</td>
<td>Set and configure Amazon Web Services and manage your profile.</td>
</tr>
<tr>
<td>Help</td>
<td>Get information about this version of Lumberyard and how to use it.</td>
</tr>
</tbody>
</table>

File

In the File menu, you can manage your game project such as opening and saving level files, show a log file, and modify your project's settings.
<table>
<thead>
<tr>
<th>File Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>New</td>
<td>Create a new level. For more information, see Creating a New Level (p. 1219).</td>
</tr>
<tr>
<td>Open</td>
<td>Switch to another level in your project.</td>
</tr>
<tr>
<td>Open Recent</td>
<td>Open a recently opened level.</td>
</tr>
<tr>
<td>Save</td>
<td>Update the level file with your changes.</td>
</tr>
<tr>
<td>Save as</td>
<td>Create a copy of the open level with a new name.</td>
</tr>
<tr>
<td>Save Level Resources</td>
<td>Update all of the assets with changes made in the open level.</td>
</tr>
<tr>
<td>Save Level Statistics</td>
<td>Save statistics for the open level to an .xml file.</td>
</tr>
<tr>
<td>Save Modified External Layers</td>
<td>Save only the external layers that have been modified since the last save.</td>
</tr>
<tr>
<td>Project Settings</td>
<td>Launch other file management tools:</td>
</tr>
<tr>
<td></td>
<td>• Switch Projects – Opens the Project Configurator</td>
</tr>
<tr>
<td></td>
<td>• Configure Gems – Opens the Project Configurator</td>
</tr>
<tr>
<td></td>
<td>• Deployment Tool – Opens the editor and console for selecting a deployment platform and to use a console.</td>
</tr>
<tr>
<td>Show Log File</td>
<td>Show the log file that contains all text printed in the console to a .log file in the project's directory.</td>
</tr>
<tr>
<td>Upgrade Legacy Entities</td>
<td>Launch the Legacy Converter tool to convert your legacy entities to components that you can edit in Lumberyard Editor. For more information, see Converting Entities with the Legacy Converter (p. 963).</td>
</tr>
<tr>
<td>Exit</td>
<td>Close Lumberyard Editor. At the prompt, you can save any changes made since the last save was performed.</td>
</tr>
</tbody>
</table>

**Edit**

In the **Edit** menu, you can select and manipulate objects, such as undo and redo actions, and select and hide objects.
<table>
<thead>
<tr>
<th>Edit Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undo</td>
<td>Revert the last action.</td>
</tr>
<tr>
<td>Redo</td>
<td>Apply the last action.</td>
</tr>
<tr>
<td>Duplicate</td>
<td>Create a copy of the selected object</td>
</tr>
<tr>
<td>Delete</td>
<td>Remove the selected object from the level and its base object remains available in the Asset Browser.</td>
</tr>
<tr>
<td>Select All</td>
<td>Specify that all visible, unlocked objects are selected for changing or applying settings.</td>
</tr>
<tr>
<td>Deselect All</td>
<td>Remove focus from the objects that are currently selected.</td>
</tr>
<tr>
<td>Next Selection Mask</td>
<td>Select the next selection mask.</td>
</tr>
<tr>
<td>Invert Selection</td>
<td>Swap the selection set from the currently, selected set of objects to the other available objects.</td>
</tr>
<tr>
<td>Hide Selection</td>
<td>Set the selected object as invisible.</td>
</tr>
<tr>
<td>Show Selection</td>
<td>Set the selected object as visible.</td>
</tr>
<tr>
<td>Show Last Hidden</td>
<td>Reverse the visibility setting of the hidden object last modified.</td>
</tr>
<tr>
<td>Unhide All</td>
<td>Set all invisible objects as visible.</td>
</tr>
</tbody>
</table>
### Edit Menu Item

<table>
<thead>
<tr>
<th>Group</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group</td>
<td>Specify multiple selected objects as a set to manipulate and modify. The viewport displays a green box around the objects.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Modify</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modify</td>
<td>Show a submenu of actions. See the Modify (p. 188) section.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Lock Selection</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lock Selection</td>
<td>Set the selected object as frozen. Frozen objects are uneditable.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Unlock All</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unlock All</td>
<td>Set all frozen objects as editable.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Rename Object(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rename Object(s)</td>
<td>Opens a dialog box to specify a new name. If you rename multiple objects at once, each object is appended with a number.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Set Object(s) Height</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set Object(s) Height</td>
<td>Opens a dialog box to specify a specified height (in meters) above the terrain.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Editor Settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Editor Settings</td>
<td>See the Editor Settings (p. 189) section.</td>
</tr>
</tbody>
</table>

### Group

In the **Group** menu, you can apply changes to multiple objects as a set, such as grouping and ungrouping objects.

<table>
<thead>
<tr>
<th>Group Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group</td>
<td>Specify multiple objects as a set to manipulate.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Ungroup</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ungroup</td>
<td>Separate all of the objects that are in the selected group.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Open Group</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open Group</td>
<td>Allow an object within a set to be selected and manipulated independently of the group.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Attach to Group</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach to Group</td>
<td>Add selected objects to a group.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Detach from Group</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Detach from Group</td>
<td>Remove selected objects from a group.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Hold</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hold</td>
<td>Save the current state for the group temporarily, so that you can test and experiment with alternative settings. You can keep the new settings or click <strong>Fetch</strong> to undo them.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Fetch</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fetch</td>
<td>Restores the state of the group to the saved state specified with <strong>Hold</strong>. This option is only available if you placed a <strong>Hold</strong> at some point.</td>
</tr>
</tbody>
</table>
Modify

In the Modify menu, you can manipulate attributes and properties of objects and entities, such as height, alignment, and material.

<table>
<thead>
<tr>
<th>Modify Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Link</td>
<td>Create hierarchies between objects.</td>
</tr>
<tr>
<td>Unlink</td>
<td>Remove the connection between linked objects.</td>
</tr>
<tr>
<td>Align</td>
<td>Display a submenu with options for placing an object in relationship to the grid, to another object, or to the selected surface, which moves the pivot point of the object.</td>
</tr>
<tr>
<td></td>
<td>If you align an object to another object that has modified scale or rotation, the original object will use the modified settings along with the position data. To override this action, use the following keys (single or combination) when you select the original object:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Ctrl</strong> – Align the object to the bounding box.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Alt</strong> – Use the object’s existing rotation.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Shift</strong> – Use the object’s existing scale.</td>
</tr>
<tr>
<td>Constrain</td>
<td>Limit the movement of an object to the XYZ axes, XY planes, or to the surface of the terrain and objects.</td>
</tr>
<tr>
<td>Snap</td>
<td>Place an object on the grid or a rotational increment.</td>
</tr>
<tr>
<td>Transform Mode</td>
<td>Displays a submenu to apply the following changes to an object:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Select Mode</strong> – Select an object to modify.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Move</strong> – Change the location of an object along the axes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Rotate</strong> – Select and spin an object on the selected axis.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Scale</strong> – Select and resize an object proportionally.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Select Terrain</strong> – Switch from the selected object to the terrain.</td>
</tr>
<tr>
<td>Convert to</td>
<td>Change the selected object to another type of entity: brush, geometry entity, designer object, static entity, game volume,</td>
</tr>
</tbody>
</table>
Modify Menu Item | Description
--- | ---
| or component entity. For more information, see the Converting Entities with the Legacy Converter (p. 963). |

Fast Rotate | Quickly spin the selected object on the specified axis or with the degree value that you set for Rotate Angle. |

Sub Object Mode | If the Edit Mesh function is enabled, select and edit the geometry components of the object. |

Save Object(s) | Update the file with the changes made to the selected objects. |

Load Object(s) | Open the dialog box to browse and select objects from the game directory. |

Update Procedural Vegetation | Reapply settings in the .sbsar files. |

**Editor Settings**

In the Editor Settings menu, you can customize your editing experience.

---

<table>
<thead>
<tr>
<th>Editor Settings Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global Preferences</td>
<td>Modify the global settings for Lumberyard Editor and its tools. For more information, see Changing Preferences (p. 238).</td>
</tr>
<tr>
<td>Graphics Performance</td>
<td>Select your preferred display setting:</td>
</tr>
<tr>
<td></td>
<td>• PC – Enable specific resolution display settings (Note: Some values are DX11 specific):</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• OSX GL osx-gl.cfg – same OSX Metal osx-metal.cfg.</td>
</tr>
<tr>
<td></td>
<td>• OSX Metal – Emulate the macOS display settings that use OpenGL graphics.</td>
</tr>
<tr>
<td></td>
<td>• Android – Enable specific resolution display settings.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• iOS – Enable specific resolution display settings.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Apple TV – Emulate the Apple TV display settings.</td>
</tr>
<tr>
<td>Keyboard Customization</td>
<td>Configure toolbars, menus, and keyboard shortcuts. You can customize your keyboard settings, with the option to import or export saved custom keyboard settings.</td>
</tr>
</tbody>
</table>
Game

In the Game menu, you can add and test enhancements to your game project.

<table>
<thead>
<tr>
<th>Game Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Play Game</strong></td>
<td>Switch to game mode (runtime). To return to edit mode, press Esc.</td>

**AI**

In the **AI** menu, you can manage AI settings such as generating AI navigation and updating the AI system within a level. For more information, see the [Navigation Area (p. 693)](p.693) component.

<table>
<thead>
<tr>
<th>AI Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate All AI</td>
<td>Generates the AI navigation to include triangulation, 3D navigation volumes, flight navigation, and waypoints.</td>
</tr>
<tr>
<td>Generate Triangulation</td>
<td>Generates only the triangulation of the navigation mesh that is used for outdoor levels.</td>
</tr>
<tr>
<td>Generate 3D Navigation Volumes</td>
<td>Generates only the 3D navigation data for 3D volumes that are used by alien AI agents; volumes are defined by AINavigationModifier and a Volume navigation type.</td>
</tr>
<tr>
<td>AI Menu Item</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Generate Flight Navigation</td>
<td>Generates only the 2.5D navigation data for volumes used by flying AI agents; volumes are defined by AINavigationModifier and a Flight navigation type.</td>
</tr>
<tr>
<td>Generate Waypoints</td>
<td>Generates only the links for indoor waypoints.</td>
</tr>
<tr>
<td>Validate Navigation</td>
<td>Check the generated data for various problems and display warnings if any problems are found (for example, bad object placement, overlapping forbidden areas, or corruptions).</td>
</tr>
<tr>
<td>Clear All Navigation</td>
<td>Remove the triangulation, 3D navigation volumes, flight navigation, and waypoint data from the level.</td>
</tr>
<tr>
<td>Generate Spawner Entity Code</td>
<td>Search for AI entity classes and generate an .ent file for each; associate an entity class name with the Lua base file for that entity.</td>
</tr>
<tr>
<td>Generate 3D Debug Voxels</td>
<td>Generate debugging information for volume navigation regions when the ai_DebugDraw console variable is enabled.</td>
</tr>
<tr>
<td>Create New Navigation Area</td>
<td>Create a navigation area.</td>
</tr>
<tr>
<td>Request a full MNM rebuild</td>
<td>Perform a full rebuild of all multi-layer navigation mesh (MNM) data. Use this periodically if the Continuous Update feature is off (see below).</td>
</tr>
<tr>
<td>Show Navigation Areas</td>
<td>Enable blue areas to highlight MNM areas on the terrain in the viewport.</td>
</tr>
<tr>
<td>Add Navigation Seed</td>
<td>Add an entity designated as points of off-mesh accessibility of an MNM.</td>
</tr>
<tr>
<td>Continuous Update</td>
<td>Enable automatic updates to the MNM data. If disabled, you need to select Request a full MNM rebuild in order for the mesh data to update.</td>
</tr>
<tr>
<td>Visualize Navigation Accessibility</td>
<td>Display areas that are inaccessible to the AI agent in red and accessible areas in blue in the viewport.</td>
</tr>
<tr>
<td>View Agent Type</td>
<td>Select from a submenu of agent types such as MediumSizedCharacters. You can add agent types to the navigation.xml file in the lumberyard_version\dev \your_project\scripts directory.</td>
</tr>
<tr>
<td>Generate Cover Surfaces</td>
<td>Generate the data specifying areas available for hiding and avoiding danger.</td>
</tr>
<tr>
<td>AIPoint Pick Link</td>
<td>Combine AI navigation modifier points.</td>
</tr>
<tr>
<td>AIPoint Pick Impass Link</td>
<td>Restricts AI navigation modifier points to prevent AI from walking on the points.</td>
</tr>
</tbody>
</table>

**Audio**

In the **Audio** menu, you can stop all sounds or refresh the audio.
### Audio Menu Item

<table>
<thead>
<tr>
<th>Audio Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stop All Sounds</td>
<td>Silence all sounds in the level.</td>
</tr>
<tr>
<td>Refresh Audio</td>
<td>Reapply settings to all of the sounds in the level.</td>
</tr>
</tbody>
</table>

### Clouds

**Clouds**

In the **Clouds** menu, you can create, open, close, and delete your custom cloud assets. The project must have the *Sky Clouds Gem* (p. 1202) enabled. For more information, see *Sky Clouds Gem* (p. 1202).

<table>
<thead>
<tr>
<th>Clouds Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create</td>
<td>Create a new cloud asset.</td>

<tr>
<td>Destroy</td>
<td>Remove a custom cloud asset.</td>
</tr>
<tr>
<td>Open</td>
<td>Open the selected cloud asset.</td>
</tr>
<tr>
<td>Close</td>
<td>Close the selected cloud asset.</td>
</tr>
</tbody>
</table>

### Prefabs

**Prefabs**

In the **Prefabs** menu, you can modify CryEntities defined in the prefab library.

**Note**

We recommend that you use slices instead. For more information, see *Working with Slices* (p. 510).

<table>
<thead>
<tr>
<th>Prefabs Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Prefab from Selected Object(s)</td>
<td>Create a prefab from selected objects.</td>
</tr>
<tr>
<td>Add Selected Object(s) to Prefab</td>
<td>Add the selected objects to the prefab.</td>
</tr>
<tr>
<td>Clone Selected Object(s)</td>
<td>Clone the selected objects.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Prefabs Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Prefab from Selected Object(s)</td>
<td>Create a prefab from selected objects.</td>
</tr>
<tr>
<td>Add Selected Object(s) to Prefab</td>
<td>Add the selected objects to the prefab.</td>
</tr>
<tr>
<td>Clone Selected Object(s)</td>
<td>Clone the selected objects.</td>
</tr>
<tr>
<td>Prefabs Menu Item</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Extract Selected Object(s)</td>
<td>Extract the selected objects from the prefab.</td>
</tr>
<tr>
<td>Open All</td>
<td>Open all prefabs.</td>
</tr>
<tr>
<td>Close All</td>
<td>Close all prefabs.</td>
</tr>
<tr>
<td>Reload All</td>
<td>Reload all prefabs.</td>
</tr>
</tbody>
</table>

### Terrain

In the **Terrain** menu, you can specify changes that affect the game world and terrain appearance.

<table>
<thead>
<tr>
<th>Terrain Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate Terrain Texture</td>
<td>Generate the terrain surface texture in a compressed format into the <code>terraintexture.pak</code> file; you must do this in order for changes made by the terrain painter to be visible in game mode.</td>
</tr>
<tr>
<td>Generate Terrain</td>
<td>Open the <strong>Terrain Editor</strong> to generate terrain for the level.</td>
</tr>
<tr>
<td>Edit Terrain</td>
<td>Open the <strong>Terrain Editor</strong> to modify the terrain settings.</td>
</tr>
<tr>
<td>Export/Import Megaterrain Texture</td>
<td>Save or include a megaterrain texture, which is a diffuse texture that provides changes in detail as the camera moves closer to the terrain.</td>
</tr>
<tr>
<td>Export Terrain Block</td>
<td>Save a section of the terrain to a terrain block <code>.trb</code> file.</td>
</tr>
<tr>
<td>Import Terrain Block</td>
<td>Include terrain from a saved <code>.trb</code> file.</td>
</tr>
<tr>
<td>Resize Terrain</td>
<td>Open the <strong>Terrain Resize</strong> tool to modify the terrain size.</td>
</tr>
<tr>
<td>Terrain Modify</td>
<td>Flatten or smooth the terrain.</td>
</tr>
<tr>
<td>Edit Vegetation</td>
<td>Open the <strong>Vegetation</strong> section on the <strong>Terrain</strong> tab in the <strong>Rollup Bar</strong> in order to modify the vegetation.</td>
</tr>
</tbody>
</table>
### Terrain Menu Item

<table>
<thead>
<tr>
<th>Terrain Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paint Layers</td>
<td>Open the <strong>Layer Painter</strong> section on the <strong>Terrain</strong> tab in the <strong>Rollup Bar</strong> in order to modify settings on the layer.</td>
</tr>
<tr>
<td>Refine Terrain Texture Tiles</td>
<td>Divide the terrain tiles into smaller sections.</td>
</tr>
<tr>
<td>Export Terrain Area</td>
<td>Save the selected terrain area to an <code>.obj</code> or <code>.fbx</code> file.</td>
</tr>
<tr>
<td>Export Terrain Area with Objects</td>
<td>Save the selected terrain area and all objects within to an <code>.obj</code> or <code>.fbx</code> file.</td>
</tr>
</tbody>
</table>

### Debugging

In the **Debugging** menu, you can reload scripts, textures, geometry, and terrain. Other debugging options include configuring user commands and checking the level for errors.

#### Debugging Menu Item

<table>
<thead>
<tr>
<th>Debugging Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reload Scripts (LEGACY)</td>
<td>Reapply all scripts or apply scripts separately for actor, AI, entity, item, and UI.</td>
</tr>
<tr>
<td>Reload Textures/Shaders</td>
<td>Reapply the settings for all of the textures and shaders used in the level.</td>
</tr>
<tr>
<td>Reload Geometry</td>
<td>Reapply the settings for all of the geometry used in the level.</td>
</tr>
<tr>
<td>Reload Terrain</td>
<td>Reapply the settings for the selected terrain.</td>
</tr>
<tr>
<td>Resolve Missing Objects/Materials...</td>
<td>Check the level and resolve all object and material issues.</td>
</tr>
<tr>
<td>Enable File Change Monitoring</td>
<td>Enable tracking to detect changes to files.</td>
</tr>
<tr>
<td>Check Object Positions</td>
<td>Check the position of all objects in the level.</td>
</tr>
<tr>
<td>Debugging Menu Item</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Clear Registry Data</td>
<td>Remove the registry data stored for all custom toolbars.</td>
</tr>
<tr>
<td>Check Level for Errors</td>
<td>Compile a list of errors within the level (such as duplicate objects and missing assets) and display it in the console window.</td>
</tr>
<tr>
<td>Save Level Statistics</td>
<td>Update the <code>your_level_name.xml</code> file in the <code>C:\Amazon\Lumberyard\your_version\dev\Cache\your_game\pc\your_game\testresults</code> directory with current data.</td>
</tr>
<tr>
<td>Compile Script</td>
<td>Compile an entity script.</td>
</tr>
<tr>
<td>Reduce Working Set</td>
<td>Reduce memory consumption.</td>
</tr>
<tr>
<td>Update Procedural Vegetation</td>
<td>Apply modifications made to the procedural vegetation.</td>
</tr>
<tr>
<td>Configure Toolbox Macros</td>
<td>Open the <code>Tools Configuration</code> window to create shortcuts for the console commands.</td>
</tr>
<tr>
<td>Toolbox Macros</td>
<td>Display the shortcuts in the console and Lumberyard Editor commands that you created.</td>
</tr>
<tr>
<td>Script Help</td>
<td>Open the <code>Script Help</code> window to view a list of commands, descriptions, and examples.</td>
</tr>
</tbody>
</table>

**Tools**

In the **Tools** menu, you can access Lumberyard Editor tools and plugins. For more information, see [Lumberyard Editors and Tools (p. 32)](p. 32).
In the **View** menu, you can customize the layout and the viewport of Lumberyard Editor.

<table>
<thead>
<tr>
<th>View Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Center on Selection</strong></td>
<td>Select an object to zoom to its boundaries. You can then press <strong>Alt</strong> and use the mouse to pan around the object, which remains centered on the screen.</td>
</tr>
<tr>
<td><strong>Show Quick Access Bar</strong></td>
<td>Show or hide the quick access bar.</td>
</tr>
<tr>
<td><strong>Error report</strong></td>
<td>Open the file with details about errors.</td>
</tr>
</tbody>
</table>
### View Menu Item

<table>
<thead>
<tr>
<th>View Menu Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Layouts</strong></td>
<td>Choose or save the pane layout shown in Lumberyard Editor:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Component Entity Layout</strong> – Display the <strong>Entity Outliner</strong>, <strong>Entity Inspector</strong>, and <strong>Asset Browser</strong> with the viewport,</td>
</tr>
<tr>
<td></td>
<td>• <strong>Legacy Layout</strong> – Display the <strong>Rollup Bar</strong> and viewport only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Save Layout</strong> – Save your current layout.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Restore Default Layout</strong> – Restore the layout to the default (<strong>Component Entity Layout</strong>).</td>
</tr>
<tr>
<td></td>
<td>For more information, see <a href="#">Restoring the Default Layout for Lumberyard Editor</a> (p. 244).</td>
</tr>
</tbody>
</table>

| **Viewport**   | Submenu for the **Perspective** panel. See the [Viewport](#) (p. 198) section. |

<table>
<thead>
<tr>
<th><strong>Viewport Menu Item</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Wireframe</strong></td>
<td>Enable or disable the wireframe view.</td>
</tr>
<tr>
<td><strong>Ruler</strong></td>
<td>Add a tool measure the distance from one point to another.</td>
</tr>
<tr>
<td><strong>Grid Settings</strong></td>
<td>Set grid line spacing, angle snapping, and rotation and translation settings.</td>
</tr>
<tr>
<td><strong>Configure Layout</strong></td>
<td>Select a preconfigured layout.</td>
</tr>
<tr>
<td><strong>Goto Coordinates</strong></td>
<td>Specify the camera position in XYZ coordinates and move the camera to that position.</td>
</tr>
<tr>
<td><strong>Center on Selection</strong></td>
<td>Go to the currently selected object in the viewport.</td>
</tr>
</tbody>
</table>
Viewport Menu Item | Description
--- | ---
Goto Location | Go to one of 10 predefined locations in the viewport.
Remember Location | Save up to 10 locations in the viewport.
Change Move Speed | Change the movement speed for all objects in the level.
Switch Camera | Change the camera for the viewport:
  - Default Camera – Select the default camera.
  - Sequence Camera – Select the camera that is used in a track view sequence.
  - Selected Camera Object – Select the camera entity.
  - Cycle Camera – Select the next camera.
Show/Hide Helpers | Show or hide all helper objects.

AWS

In the AWS menu, you can sign up for an Amazon Web Services (AWS) account and set up services using Cloud Canvas and Amazon GameLift.

AWS Menu Item | Description
--- | ---
Credentials manager | Add or edit an AWS profile.
Cloud Canvas | Select a deployment or see more information in Understanding Cloud Canvas Resource Manager (p. 2110) or Using Dynamic Content Manager (p. 2155).
Commerce | Learn how to submit your game to Amazon's Digital Software store using Merch by Amazon or Publishing on Amazon.
GameLift | Access the Amazon GameLift console or learn more about the game server hosting and matchmaking solution built on AWS.
Open AWS Console | Open the AWS Management Console and access Amazon Cognito, user management services; Amazon DynamoDB, NoSQL database service; Amazon S3, cloud storage; and AWS Lambda, serverless computing.

Help

In the Help menu, you can search the Lumberyard documentation, open Lumberyard tutorials and resources, and view information about Lumberyard Editor.
Using the Top Toolbar

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Lumberyard Editor provides a toolbar that allows you to easily access various editor tools and features. The toolbar is docked at the top of the editor by default, but you can also dock it vertically on the edges of the editor or undock it from the editor. To customize the toolbar, right-click anywhere on the toolbar and select Customize from the context menu. You can choose which toolbars, views, or modes to include. You can also add commands to a toolbar.

You can access Lumberyard tools and features using one of the following methods:

- Toolbar buttons
- Tools menu
- Keyboard shortcuts (p. 205)

For information about the bottom toolbar, see Using the Bottom Toolbar (p. 202).

**EditMode Toolbar**

The **EditMode** toolbar includes various tools for general level editing:

- A – Revert or apply the last command
- B – Link or unlink the selected object
- C – Filter what you can select in the viewport: all, brushes, no brushes, entities, prefabs, areas, shapes, AI points, decals, solids, or no solids
- D – Use the translation tools to select, move, rotate, or scale an object or object type; and select or rotate a terrain area
- E – Select the reference coordinate system
- F – Specify the axis constraint by locking on the x-, y-, or z-axis or xy-plane
- G – Use the object placement tools to follow the terrain, snap to objects, snap to grid, snap to angle, or show the ruler
- H – Use the asset organization tools to open the object selector, create a selection, delete a selection, save selected objects, or load selected objects
- I – Select the current layer

**Object Toolbar**

The **Object** toolbar includes various tools for object alignment and manipulation:

- A – Go to the selected object
- B – Align the selection to an object by choosing the source object, clicking the tool, and then clicking the target object
- C – Align the object to the grid
- D – Set the object's height
- E – Align the object to the terrain surface normal (press and hold Ctrl for object surface normal alignment)
- F – Freeze or unfreeze the selected object
- G – Apply vertex snapping for the selected object
Editors Toolbar

The Editors toolbar allows you to access various editor tools:

- **A** – Open the Asset Browser
- **B** – Open the Layer Editor
- **C** – Open the LOD Generator
- **D** – Open the Material Editor
- **E** – Opens Geppetto
- **F** – Open the Mannequin Editor
- **H** – Open the AI Debugger
- **I** – Open the Track View
- **J** – Open the Audio Controls Editor
- **K** – Open the Terrain Editor
- **L** – Open the Terrain Texture Layers editor
- **M** – Open the Particle Editor
- **N** – Open the Time of Day editor
- **O** – Open the Sun Trajectory Tool
- **P** – Open the Database View
- **Q** – Open the UI Editor

Substance Toolbar

The Substance toolbar includes a button that opens the Substance Editor.

Using the Bottom Toolbar

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Lumberyard Editor includes a bottom toolbar that provides status as well as the features below.

**Status**

The *status* bar (A) displays the number of selected entities and provides functional hints for buttons or menu items in Lumberyard Editor.

**Coordinates/Transforms**

The *coordinates/transform* area (B) shows the position of the cursor or the status of a transform, and allows you to enter new transform values. The information in these fields vary based on your tasks:

- When creating an entity or moving the mouse in the viewport, these fields show the cursor location in absolute world coordinates.
- When translating an entity by dragging it in the viewport, these fields show entity's location in absolute world coordinates.
- While transforming an entity, these fields change to spinners in which you can directly type values, or modify by scrolling the mouse wheel.
- While a transform button is active and multiple entities are selected, these fields show the first selection's transform values.

**Set Vector**

The *Set Vector* button (C) allows you to set the position, rotation or scale for the selected entities.

**Goto Position**

The *Goto Position* button (D) opens the *Go to position* dialog box to set a world position and rotation for the perspective view. You can enter floating point coordinates and rotation, or use the spinners to specify values. Clicking the *Go To* button immediately moves the viewport to the specified coordinates and rotates the view.
Lock Selection

The Lock Selection button (E) toggles selection locking, preventing you from inadvertently selecting something else in a level.

When your selection is locked, you can click or drag the mouse anywhere in the viewport without losing your selection. To deselect or alter your selection, click Lock Selection again to unlock the selection.

Lock Axis Vectors

The Lock Axis Vectors button (F) makes scale operations uniform.

Speed Control

The Speed button (G) allows you to change the speed of viewport movement. Select a preset speed from the list, enter a value into the field, or use the spinners to adjust the speed up or down.

Terrain Collision

The Enable Terrain Camera Collision button (H) toggles terrain collision to inhibit camera movement below the terrain surface.

Move Player and Camera Separately

The Move Player and Camera Separately button (I) allows the viewport camera to be moved separately from the player entity.

Simulate

The Simulate button (J) toggles physics simulation and AI, allowing you to test physics and AI behavior directly in the editor without entering game mode.
Mute Audio

The Mute Audio button (K) mutes audio in both editor and play mode.

VR Preview

The VR Preview button (L) previews your project in virtual reality mode (p. 3258) when a virtual reality (p. 3248) gem is enabled.

Using Keyboard Shortcuts

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard supports the following keyboard shortcuts.

File Menu

<table>
<thead>
<tr>
<th>Keyboard shortcut</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl+O</td>
<td>Open a level</td>
</tr>
<tr>
<td>Ctrl+S</td>
<td>Save the level</td>
</tr>
<tr>
<td>Ctrl+Alt+F</td>
<td>Restore the saved state</td>
</tr>
<tr>
<td>Ctrl+Alt+H</td>
<td>Save the current state</td>
</tr>
<tr>
<td>Ctrl+Shift+S</td>
<td>Save the selected object</td>
</tr>
</tbody>
</table>

Edit Menu

<table>
<thead>
<tr>
<th>Keyboard shortcut</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>G</td>
<td>Toggle snap-to-grid</td>
</tr>
<tr>
<td>Ctrl+D</td>
<td>Duplicate the selected object</td>
</tr>
<tr>
<td>Ctrl+Z</td>
<td>Undo the last operation</td>
</tr>
<tr>
<td>Ctrl+Shift+Z</td>
<td>Redo the last operation</td>
</tr>
<tr>
<td>Ctrl+Shift+Space</td>
<td>Lock the selection</td>
</tr>
</tbody>
</table>

Game Menu

<table>
<thead>
<tr>
<th>Keyboard shortcut</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl+E</td>
<td>Export the level</td>
</tr>
<tr>
<td>Ctrl+G</td>
<td>Enter game mode (Esc to exit)</td>
</tr>
</tbody>
</table>
Using Keyboard Shortcuts

<table>
<thead>
<tr>
<th>Keyboard shortcut</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl+P</td>
<td>Enable AI or physics</td>
</tr>
</tbody>
</table>

**Tools Menu**

<table>
<thead>
<tr>
<th>Keyboard shortcut</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>Open the Material Editor</td>
</tr>
<tr>
<td>`</td>
<td>Open the console window</td>
</tr>
<tr>
<td>[</td>
<td>Increase the brush radius size</td>
</tr>
<tr>
<td>]</td>
<td>Decrease the brush radius size</td>
</tr>
<tr>
<td>Shift+[</td>
<td>Decrease the hardness shape of the fall-off curve between the inner and outer radius of the brush</td>
</tr>
<tr>
<td>Shift+]</td>
<td>Increase the hardness shape of the fall-off curve between the inner and outer radius of the brush</td>
</tr>
</tbody>
</table>

**Select Toolbar**

<table>
<thead>
<tr>
<th>Keyboard shortcut</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Select the object</td>
</tr>
<tr>
<td>2</td>
<td>Select and move the object</td>
</tr>
<tr>
<td>3</td>
<td>Select and rotate the object</td>
</tr>
<tr>
<td>4</td>
<td>Select and scale the object</td>
</tr>
<tr>
<td>5</td>
<td>Select the terrain area</td>
</tr>
</tbody>
</table>

**Hide Toolbar**

<table>
<thead>
<tr>
<th>Keyboard shortcut</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>Freeze the selected object</td>
</tr>
<tr>
<td>H</td>
<td>Hide the selected object</td>
</tr>
<tr>
<td>Ctrl+F</td>
<td>Unfreeze all objects</td>
</tr>
<tr>
<td>Ctrl+H</td>
<td>Unhide all hidden objects</td>
</tr>
</tbody>
</table>

**Constraint Toolbar**

<table>
<thead>
<tr>
<th>Keyboard shortcut</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl+1</td>
<td>Follow the terrain</td>
</tr>
<tr>
<td>Ctrl+2</td>
<td>Lock on the xy-plane</td>
</tr>
<tr>
<td>Ctrl+3</td>
<td>Lock on the x-axis</td>
</tr>
</tbody>
</table>
Using the Viewport

<table>
<thead>
<tr>
<th>Keyboard shortcut</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl+4</td>
<td>Lock on the y-axis</td>
</tr>
<tr>
<td>Ctrl+5</td>
<td>Lock on the z-axis</td>
</tr>
</tbody>
</table>

### Perspective Viewport

<table>
<thead>
<tr>
<th>Keyboard shortcut</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>W</td>
<td>Move forward in the viewport</td>
</tr>
<tr>
<td>A</td>
<td>Move backward in the viewport</td>
</tr>
<tr>
<td>S</td>
<td>Move left in the viewport</td>
</tr>
<tr>
<td>D</td>
<td>Move right in the viewport</td>
</tr>
<tr>
<td>Q</td>
<td>Move up in the viewport</td>
</tr>
<tr>
<td>E</td>
<td>Move down in the viewport</td>
</tr>
<tr>
<td>Z</td>
<td>Focus the camera to the selected object in the viewport</td>
</tr>
<tr>
<td>F3</td>
<td>Toggle the wireframe view</td>
</tr>
<tr>
<td>Alt+middle mouse button</td>
<td>Rotate around the selected object</td>
</tr>
<tr>
<td>Alt+right click</td>
<td>Zoom in and out</td>
</tr>
<tr>
<td>Ctrl+F1 (or F2, F3, F4, F5, F6, F7, F8, F9, F10, F11, F12)</td>
<td>Save the viewport location</td>
</tr>
<tr>
<td>Shift+F1 (or F2, F3, F4, F5, F6, F7, F8, F9, F10, F11, F12)</td>
<td>Move to the saved viewport location</td>
</tr>
<tr>
<td>Shift+Spacebar</td>
<td>Show or hide helpers</td>
</tr>
</tbody>
</table>

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com玩游戏/3DE) or visit the [AWS Game Tech blog](https://aws.amazon.com/game-tech/) to learn more.

The viewport window (called Perspective in Lumberyard Editor) displays the scene that is rendered by the engine. The majority of level design occurs in the viewport, including object placement, terrain editing, in-editor play testing, and asset creation and interaction. You can also use dynamic and flexible tools to understand the 3D relationships among objects in a level.

The Perspective header includes a search box, field of view (FOV), screen ratio information, and options to show or hide debug information.

**Topics**
- Changing the Field of View (FOV) (p. 208)
- Changing the Camera View (p. 209)
To customize the viewport

1. In Lumberyard Editor, in the viewport title bar, right-click **Perspective** and choose **Configure Layout**.
2. In the **Layout Configuration** dialog box, select your preferred layout.
3. Click **OK** to save your changes.

### Changing the Field of View (FOV)

You can change the default camera's FOV for the Lumberyard Editor viewport or the FOV for your game's camera. Follow the steps to change the default camera's FOV. To change the FOV for your game's camera, see **Camera** (p. 566).

#### To change the default camera's FOV

1. In Lumberyard Editor, choose **Edit, Editor Settings, Global Preferences**.
2. In the **Preferences** window, under **Viewports**, click **General**.
3. In the right pane, under **General Viewport Settings**, for **Perspective View FOV**, set the desired value in degrees.
4. Click **OK** to save your changes.
Changing the Camera View

You can use the Viewport Camera Selector to quickly position and orient a camera in your game. You can choose between all in-game cameras and the editor camera. When you possess the camera, you can use the editor controls to manipulate the camera.

To possess the camera and move around

1. In Lumberyard Editor, in the Perspective viewport, select an entity with a Camera component or create one if it doesn't exist.
2. In the Entity Inspector, under Camera, choose Be this camera. This allows the editor to use the selected camera as its view.

Note
After choosing Be this camera, moving the view in the editor changes the transform for the camera entity. As you look around in the viewport while possessing a camera, the corresponding position and orientation for the transform is updated accordingly.
3. Do any of the following:
   - Change to the default view: In the Entity Inspector, under Camera, choose Return to default editor camera.
   - Choose another camera to possess in the Viewport Camera Selector.
   - Disable the Viewport Camera Selector controls by entering game mode (Ctrl+G).

Using the Console Window

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In Lumberyard Editor, the console window shows a running list of all editor commands, processes, and output. For example, when you delete an entity, the console shows the action and the output. You can use the console to enter or modify console variables (CVARs). Console variables are a type of variable that you can manipulate in Lumberyard Editor.

**Topics**
- Viewing the Console Window (p. 210)
- Exporting All Console Commands and Variables (p. 211)
- Configuring Console Variables (p. 212)
- Console in Depth (p. 213)
- Console Variable Tutorial (p. 216)

**Viewing the Console Window**

You can enter commands directly in the console window or search and edit console variables.

**To view the console window**

1. In Lumberyard Editor, choose Tools, Console.
2. Click the X icon in the left corner to open the Console Variables window. The Console Variables window lists all available console variables.
3. Enter a name to search for a specific console variable. To learn more about the console variable, pause on the name.

Exporting All Console Commands and Variables

You can retrieve a complete list of console commands and variables, including their descriptions and assigned values.

To export a list of all console commands and variables

1. In the Console window, enter the following command: DumpCommandsVars
2. Navigate to the lumberyard_version\dev\ directory and then open the consolecommandandvars.txt file.

Example

You can see the available commands and variables in the file.
3. You can specify a sub-string parameter to restrict the results that you want. For example, the `DumpCommandsVars i_` command exports all commands and variables that begin with the prefix `i_`, such as `i_giveallitems` and `i_debug_projectiles`.

### Configuring Console Variables

Console variables can also be set in code or specified in configuration files. Console variables are executed in the following order:

1. Configuration files:
   - The `game.cfg` file in your project directory
   - The `lumberyard_version\dev\system_gamesystem.cfg` file for your game system
   - The `lumberyard_version\dev\engine\config\user.cfg` file
   - The `level.cfg` file in your project's level directory

2. Code

3. Console variables typed directly into the console

The order of execution is also the override order. For example, console variables set in code override those set in configuration files (and `level.cfg` overrides `user.cfg`, and so on). Console variables set in flow graphs override any identical console variables set in code. Finally, console variables typed directly into the console override all the other console variable settings.

### Configuring Console Variables in the Console

You can specify values for console variables in the console to apply changes to your level.

**To configure console variables in the console**

- Do one of the following:
  - In the Console Variables window, search for the variable name, double-click the value, and then enter the value that you want.
  - In the Console command line, enter the console variable and its value, and then press Enter. For example, enter the `r_DisplayInfo=1` command to display debugging information in the viewport.
Configuring Console Variables in Configuration Files

You can specify values for console variables in the configuration files, such as the level configuration file (level.cfg).

**To configure console variables with a configuration file**

1. Navigate to the directory that has the configuration file. For example, if you want to configure the level.cfg file, navigate to the `lumberyard_version\dev\ProjectName\Levels\level_name` directory.
2. Use a text editor to edit the file or to create one.
3. Specify the console variable name and the value. For example: `r_DisplayInfo=1` shows debugging information in the viewport.
4. Save the file.

Console in Depth

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The console is a user interface system which handles console commands and console variables. It also outputs log messages and stores the input and output history.

Color coding

The game console supports color coding by using the color indices 0..9 with a leading $ character. The code is hidden in the text outputted on the console. Simple log messages through the ILog interface can be used to send text to the console.

```
This is normal $1one$2two$3three and so on
```

In the preceding example, one renders in red, two in green, and three (and the remaining text) in blue.

Console Variables

Console variables provide a convenient way to expose variables which can be modified easily by the user either by being entered in the console during runtime or by passing it as command-line argument before launching the application.

More information on how to use command-line arguments can be found in the Command Line Arguments article.

Console variables are commonly referred to as `CVar` in the code base.

Registering new console variables

For an integer or float based console variable, it is recommended to use the `IConsole::Register()` function to expose a C++ variable as a console variable.

To declare a new string console variable, use the `IConsole::RegisterString()` function.

Accessing console variables from C++

Console variables are exposed using the `ICVar` interface. To retrieve this interface, use the `IConsole::GetCVar()` function.
The most efficient way to read the console variable value is to access directly the C++ variable bound to the console variable proxy.

Adding New Console Commands

The console can easily be extended with new console commands. A new console command can be implemented in C++ as a static function which follows the `ConsoleCommandFunc` type. Arguments for this console command are passed using the `IConsoleCmdArgs` interface.

The following code shows the skeleton implementation of a console command:

```cpp
static void RequestLoadMod(IConsoleCmdArgs* pCmdArgs);

void RequestLoadMod(IConsoleCmdArgs* pCmdArgs)
{
    if (pCmdArgs->GetArgCount() == 2)
    {
        const char* pName = pCmdArgs->GetArg(1);
        // ...
    }
    else
    {
        CryLog("Error, correct syntax is: g_loadMod modname");
    }
}
```

The following code will register the command with the console system:

```cpp
IConsole* pConsole = gEnv->pSystem->GetIConsole();
pConsole->AddCommand("g_loadMod", RequestLoadMod);
```

Console Variable Groups

Console variable groups provide a convenient way to apply predefined settings to multiple console variables at once.

Console variables are commonly referred to as `CVarGroup` in the code base. Console variable groups can modify other console variables to build bigger hierarchies.

Warning
Cycles in the assignments are not detected and can cause crashes.

Registering a new variable group

To register a new variable group, add a new `.cfg` text file to the `GameSDK(config\CVarGroups` directory.

```cfg
sys_spec_Particles.cfg

[default]
; default of this CVarGroup
= 4
e_particles_lod=1
e_particles_max_emitter_draw_screen=64

[1]
e_particles_lod=0.75
e_particles_max_emitter_draw_screen=1

[2]
```

Version 1.28
214
This creates a new console variable group named `sys_spec_Particles` that behaves like an integer console variable. By default, this variable has the state 4 (set in the line following the comment in the example).

On changing the variable, the new state is applied. Console variables not specified in the `.cfg` file are not set. All console variables need to be part of the default section. An error message is output in case of violation of this rule.

If a console variable is not specified in a custom section, the value specified in the default section is applied.

**Console variable group documentation**

The documentation of the console variable group is generated automatically.

### `sys_spec_Particles`

Console variable group to apply settings to multiple variables

```plaintext
sys_spec_Particles [1/2/3/4/x]:
... e_particles_lod = 0.75/1/1/1/1
... e_particles_max_screen_fill = 16/32/64/128/128
... e_particles_object_collisions = 0/1/1/1/1
... e_water_ocean_soft_particles = 0/1/1/1/1
... r_UseSoftParticles = 0/1/1/1/1
```

Checking if a console variable group value represents the state of the variables it controls

**From the console**

In the console you can enter in the console variable group name and press tab. If the variable value is not represented, it will print the value of `RealState`.

```plaintext
sys_spec_Particles=2 [REQUIRE_NET_SYNC] RealState=3
sys_spec_Sound=1 [REQUIRE_NET_SYNC] RealState=CUSTOM
sys_spec_Texture=1 [REQUIRE_NET_SYNC]
```

By calling the console command `sys_RestoreSpec` you can check why the `sys_spec_` variables don't represent the right states.

**From C++ code**

From the code you can use the member function `GetRealIVal()` and compare its return value against the result of `GetIVal()` in `ICVar`.

**Deferred execution of command line console commands**

The commands that are passed via the command line by using the `+` prefix are stored in a separate list as opposed to the rest of the console commands.

This list allows the application to distribute the execution of those commands over several frames rather than executing everything at once.
Example

Consider the following example.

```bash
--- autotest.cfg --
hud_startPaused = "0"
wait_frames 100
screenshot autotestFrames
wait_seconds 5.0
screenshot autotestTime

-- console --
StarterGameLauncher.exe -devmode +map SinglePlayer +exec autotest +quit
```

In the example, the following operations were performed:

- Load the SinglePlayer map.
- Wait for 100 frames.
- Take a screenshot called autotestFrames.
- Wait for 5 seconds.
- Take a screenshot called autotestTime.
- Quit the application.

Details

Two categories of commands are defined: blocker and normal.

For each frame, the deferred command list is processed as a fifo. Elements of this list are consumed as long as normal commands are encountered.

When a blocker is consumed from the list and executed, the process is delayed until the next frame. For instance, commands like `map` and `screenshot` are blockers.

A console command (either command or variable) can be tagged as a blocker during its declaration using the `VF_BLOCKFRAME` flag.

The following synchronization commands are supported.

### Optional Title

<table>
<thead>
<tr>
<th>Command</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait_frames</td>
<td>num:</td>
<td>&lt;int&gt; Wait for <code>num</code> frames before the execution of the list is resumed.</td>
</tr>
<tr>
<td>wait_seconds</td>
<td>sec:</td>
<td>&lt;float&gt; Wait for <code>sec</code> seconds before the execution of the list is resumed.</td>
</tr>
</tbody>
</table>

Console Variable Tutorial

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This tutorial shows you how to modify existing and create console variables (CVARs). CVARs can be used to control many configurable behaviors in Lumberyard. You can also use them in your game.
Note
This brief tutorial is intended for programmers. Most of the content uses code.

Creating CVars

To create a console variable

1. In your code editor, open the Code\GameSDK\GameDll\GameCVars.h file, which declares all game-specific CVars.
2. Locate the SCVars struct. Inside the struct, declare a new variable, as in the following example.

```c
struct SCVars
{
    int g_tutorialVar; //add this line

    //... pre-existing code ...
};
```

The variable you added will be used to store the current value of the variable. If you need to store fractional numbers, you can also add a variable of the type float.

Next, you will register the CVar with the game engine so that its value can be changed by using the console.

3. In the same Code\GameSDK\GameDll\GameCVars.cpp file, locate and use the InitCVars function.

```c
void SCVars::InitCVars(IConsole *pConsole)
{
    m_releaseConstants.Init( pConsole );

    REGISTER_CVAR(g_tutorialVar, 42, VF_NULL, "This CVar was added using the tutorial on CVars"); //add this line

    //... pre-existing code ...
}
```

Specify a default value and help text for the variable. You can initialize the variable with any value that is valid for the type with which the variable was declared in the header file. The preceeding example specifies 42 as the default value and some help text that will be shown to users.

4. When your game unloads, be sure to un-register the variable. In the Code\GameSDK\GameDll\GameCVars.cpp file, locate and use the ReleaseCVars function, as shown in the following example.

```c
void SCVars::ReleaseCVars()
{
    IConsole* pConsole = gEnv->pConsole;

    pConsole->UnregisterVariable("g_tutorialVar", true); //add this line

    //... pre-existing code ...
}
```

6. After you finish making changes, don't forget to compile your code.

Using the CVar

You can now change the value of the CVar that you created by using code, the console, and .cfg files.

From code

Version 1.28

217
To access the value of the variable in your game code, use the `g_pGameCVars` pointer, as shown in the following example.

```cpp
int myTutorialVar = g_pGameCVars->g_tutorialVar;
```

**From the console**

To change the value of the cvar from the console, use the syntax `cvar_name=cvar_value`. The following example sets the value of the `g_tutorialVar` console variable to 1337.

```plaintext
g_tutorialVar = 1337
```

**From .cfg files**

It's also possible to change the default CVar value from one of the `.cfg` files. Whenever a CVar is assigned a value, its previous value is discarded. Therefore, the last assignment is the one that is current.

The following list shows the order of initialization for console variables.

1. The value specified in the `GameCVars.cpp` file when `REGISTER_CVAR` is used. (A change here requires compiling.)
2. The value specified in the `system.cfg` file.
3. The value specified in the user's `user.cfg` file.
4. Any value assigned at game runtime.

**Tip**

To change the default value of an existing CVar without having to compile, add a line to the `system.cfg` file to override the default.

---

**Automating the Lumberyard Editor with the Python Editor Bindings gem**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Some tasks in the Lumberyard Editor are tedious or could easily be automated, and to support that, Lumberyard has support for scripting the editor through Python bindings to the underlying editor implementation. These bindings are enabled with the `PythonEditorBindings` gem, and interacted with through a Python 3 library embedded within the editor. You can access a Python REPL through an in-editor console, or launch the editor with an argument that loads and runs a Python script on boot.

**Enable editor automation**

Editor automation is enabled by selecting the `PythonEditorBindings` gem for your project, and then rebuilding the editor. No specific configuration (debug, profile, release) is required to enable the Python bindings. Because the bindings are enabled through a gem that you select for your project, you’ll need to make sure that this gem is enabled for all projects that you intend to use automation with.

**Important**

In order to use the editor bindings, your Lumberyard installation needs to be configured to be able to build the editor and tools. See Running Lumberyard Setup Assistant (p. 16) for details.
Use editor automation

The easiest way to get started with editor automation is to use the REPL that's available from within the Lumberyard Editor and try out some commands. Open this REPL by selecting **Tools > Other > Python Console**. The Python console opens in a new editor view, which gives you access to a console that displays output from Python, the REPL input, and a full reference of available commands. To get access to the reference, select the ? icon in the lower-right corner of the console.

You can also access a set of available scripts, including some samples for common tasks in the editor, by selecting **Tools > Other > Python Scripts**. These scripts are stored in a directory depending on their scope. Scripts only for your project are stored in the `lumberyard_install\dev\Editor\Scripts` directory, and scripts meant to be used along with a gem are stored at `lumberyard_install\dev\Gems\gem\Gemname\Editor\Scripts`.

Editor automation is driven primarily through the event bus (EBus) system. Before working with the editor bindings, you should become familiar with the basics of EBus from Working with the Event Bus (EBus) system (p. 1851). To learn about some of the specific busses used by the editor automation system, take a look at the Python Editor Bindings gem examples (p. 219).

Python Editor Bindings gem examples

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Python Editor Bindings are driven by an API that connects through to the Editor's C++ implementation, using the Lumberyard event bus (Ebus) to send messages between scripts and the editor. This reference covers the use of the editor bindings API to perform tasks like interacting with components, entities, and and properties.

Contents

- Level management (p. 219)
- Editor timing (p. 220)
- Entities (p. 220)
  - Entity IDs (p. 220)
  - Entity operations and Ebus interfaces (p. 220)
  - Entity search (p. 221)
  - Entity notifications (p. 222)
- Component management (p. 223)
  - Component type events (p. 223)
  - Component usage events (p. 224)
  - Component control events (p. 225)
- Component property events (p. 226)
- Editing properties (p. 227)
  - Property containers (p. 228)
- Asset management (p. 229)

Level management

Use these functions to load, create, and save levels. In order to use other editor binding APIs, a level needs to be loaded in the editor.
Examples

# opens a level with a user prompt
azlmbr.legacy.general.open_level(strLevelName)

# opens a level without prompting the user (better for automation)
azlmbr.legacy.general.open_level_no_prompt(strLevelName)

# creates a level with the parameters of 'levelName', 'resolution', 'unitSize' and 'bUseTerrain'
azlmbr.legacy.general.create_level(levelName, resolution, unitSize, bUseTerrain)

# same as create_level() but no prompts
azlmbr.legacy.general.create_level_no_prompt(levelName, resolution, unitSize, bUseTerrain)

# saves the current level
azlmbr.legacy.general.save_level()

Editor timing

Occasionally a script will need to introduce a delay in actions to be performed in the editor while another action completes, such as loading a level. Rather than use the built-in Python delay methods, use these editor binding APIs.

# enables/disables idle processing for the Editor
azlmbr.legacy.general.idle_enable(boolValue)

# Returns whether or not idle processing is enabled for the Editor
azlmbr.legacy.general.is_idle_enabled()

# waits idling for a given seconds
azlmbr.legacy.general.idle_wait(floatSeconds)

Entities

The API allows you to add and remove entities to the root entity of a level, retrieve and compare entity IDs, and search for entities.

Entity IDs

The azlmbr.entity.EntityId class is used to refer to entity instances, properties, and the entity tree.

# returns True if the entity ID is valid
entityId.IsValid()

# returns string representation of an entity ID
entityId.ToString()

# returns True if both entity IDs
entityId.Equal(otherEntityId)

Entity operations and Ebus interfaces

There are three main EBus interfaces used to manage Editor entities:

- azlmbr.editor.ToolsApplicationRequestBus: Used to create and delete Editor entities
- azlmbr.editor.EditorEntityInfoRequestBus: Used to access Entity values
- azlmbr.editor.EditorEntityAPIBus: Used to mutate Entity values
Example usage:

```python
# Create a new Entity at the root level
rootEntityId = azlmbr.editor.ToolsApplicationRequestBus(azlmbr.bus.Broadcast, 'CreateNewEntity', EntityId())

# Create a new Entity parented to the parent Entity
childEntityId = azlmbr.editor.ToolsApplicationRequestBus(azlmbr.bus.Broadcast, 'CreateNewEntity', rootEntityId)

# Delete the entity
azlmbr.editor.ToolsApplicationRequestBus(azlmbr.bus.Broadcast, 'DeleteEntityById', childEntityId)

# Delete the root Entity we created and all its children
azlmbr.editor.ToolsApplicationRequestBus(azlmbr.bus.Broadcast, 'DeleteEntityAndAllDescendants', rootEntityId)

# Get current name
name = azlmbr.editor.EditorEntityInfoRequestBus(azlmbr.bus.Event, 'GetName', entityId);

# Set a new name
azlmbr.editor.EditorEntityAPIBus(azlmbr.bus.Event, 'SetName', entityId, "MyName")

# get the parent ID of this EntityID
getId = azlmbr.editor.EditorEntityInfoRequestBus(azlmbr.bus.Event, 'GetParent', childId);
```

**Entity search**

The entity search API is based around setting up filters using azlmbr.entity.SearchFilter to set up the search parameters, and then conduct the search over the Ebus represented by azlmbr.entity.SearchBus.

**azlmbr.entity.SearchFilter usage:**

```python
searchFilter = azlmbr.entity.SearchFilter()
searchFilter.names = [] # List of names (matches if any match); can contain wildcards in the name.
searchFilter.names_case_sensitive = False # Determines if the name matching should be case sensitive.
searchFilter.components = {} # Dictionary keyed on component type IDs (matches if anymatch).
searchFilter.components_match_all = False # Determines if the filter should match all component type ids (AND).
ssearchFilter.roots = [] # Specifies the entity IDs that act as roots of the search
searchFilter.names_are_root_based = False # Determines if the names are relative to the root or should be searched in children too.
```

**azlmbr.entity.SearchBus usage:**

```python
# The SearchBus interface
busType = azlmbr.bus.Broadcast

# Iterates through all entities in the current level, and returns a list of the ones that match the conditions
entityIdList = azlmbr.entity.SearchBus(busType, 'SearchEntities', searchFilter)

# Returns a list of all editor entities at the root level in the current level
entityIdList = azlmbr.entity.SearchBus(busType, 'GetRootEditorEntities', searchFilter)
```

Searching with wildcards:
Entities are addressable by a 'name path' using strings separated by the pipe character | such as root name|my entity|my child for a name path. Entity search also supports the use of ? and * wildcards.

**Example usage:**

```python
import azlmbr.bus as bus
import azlmbr.entity as entity

searchFilter = entity.SearchFilter()
searchFilter.names = ['TestName']

# Search by name
entityIdList = entity.SearchBus(bus.Broadcast, 'SearchEntities', searchFilter)

# Search by name path (DAG)
searchFilter = entity.SearchFilter()
searchFilter.names = ['TestParent|TestChild']
entityIdList = entity.SearchBus(bus.Broadcast, 'SearchEntities', searchFilter)

# Search using wildcard
searchFilter = azlmbr.entity.SearchFilter()
searchFilter.names = ['Test*|?estChild']
entityIdList = entity.SearchBus(bus.Broadcast, 'SearchEntities', searchFilter)

# Filter with roots
searchFilter = entity.SearchFilter()
searchFilter.names = ['TestChild']
searchFilter.roots = [rootId]
searchFilter.names_are_root_based = False # default
entityIdList = entity.SearchBus(bus.Broadcast, 'SearchEntities', searchFilter)

# Filter with roots using the names, only get the kids realtive from the root nodes
searchFilter = entity.SearchFilter()
searchFilter.names = ['TestParent|TestChild']
searchFilter.roots = [rootId]
searchFilter.names_are_root_based = True # search from roots for these names
entityIdList = entity.SearchBus(bus.Broadcast, 'SearchEntities', searchFilter)
```

**Entity notifications**

You can capture editor entity events using the `EditorEntityContextNotificationBus` handler. Callbacks can be assigned to entity management event names: `OnEditorEntityCreated` and `OnEditorEntityDeleted` where the callback will be called with a tuple of data coming from the events.

```python
# The events
"OnEditorEntityCreated" # returns when an entity is created in the Editor
"OnEditorEntityDeleted" # returns when an entity is destroyed in the Editor
```

**Example usage:**

```python
# assumes a level has been opened or created
import azlmbr.bus as bus
import azlmbr.editor as editor
from azlmbr.entity import EntityId
```
createdEntityIds = [] # to capture created entites

def onEditorEntityCreated(parameters):
    global createdEntityIds
    entityId = parameters[0]
    createdEntityIds.append(entityId)

def onEditorEntityDeleted(parameters):
    global createdEntityIds
    deletedEntityId = parameters[0]
    for entityId in createdEntityIds:
        if (entityId.Equal(deletedEntityId)):
            createdEntityIds.remove(entityId)
        break

# Listen for notifications when entities are created/deleted
handler = editor.EditorEntityContextNotificationBusHandler()
handler.connect() # connects to a Singleton bus handler
handler.add_callback('OnEditorEntityCreated', onEditorEntityCreated)
handler.add_callback('OnEditorEntityDeleted', onEditorEntityDeleted)

# Create new Editor Entity
editor.ToolsApplicationRequestBus(bus.Broadcast, 'CreateNewEntity', EntityId())

Component management

The component system is used to add and removes components to existing entities with the azlmbr.editor.EditorComponentAPIBus bus.

Note
Components are not active when in editing mode. They only become active when the game is being played within the editor.

Component type events

The API requires IDs to create, use, or control component instances. To get a component IDs, use the following Ebus events:

# azlmbr.editor.EditorComponentAPIBus Broadcast events

# Finds the component ids from their type names
# input: list of strings of type names
# output: (list of component type IDs)
'FindComponentTypeIds'

# Finds the component names from their type ids
# input: list of component type IDs
# output: (list of strings) of type names
'FindComponentTypeNameList'

Example usage:

import azlmbr.bus as bus
Component usage events

The API can add components to an existing entity, test for component existence, counts components by type, and enumerate the components on an entity.

Example usage:

```python
import azlmbr.bus as bus

# adding a Mesh component
meshComponentOutcome = azlmbr.editor.EditorComponentAPIBus(bus.Broadcast,'AddComponentsOfType', entityID, [meshComponentTypeId])
if (meshComponentOutcome.IsSuccess()):
    print("Mesh component added to entity.")
```
```python
meshComponents = meshComponentOutcome.GetValue()
meshComponent = meshComponents[0]

# test for a mesh component exists on the entity
hasComponent = azlmbr.editor.EditorComponentAPIBus(bus.Broadcast, 'HasComponentOfType', entityId, meshComponentTypeId)
if (hasComponent):
    print("Entity has a Mesh component.")

# find the number of Mesh components on the entity
commentsCount = azlmbr.editor.EditorComponentAPIBus(bus.Broadcast, 'CountComponentsOfType', entityId, meshComponentTypeId)
if(commentsCount == 1):
    print("Entity has one Mesh component")

# returns the first mesh component ID, if any
meshSingleComponentOutcome = azlmbr.editor.EditorComponentAPIBus(bus.Broadcast, 'GetComponentOfType', entityId, meshComponentTypeId)
if (meshSingleComponentOutcome.IsSuccess()):
    print("GetComponentOfType mesh works.")
    firstMeshComponentId = meshSingleComponentOutcome.GetValue()

# returns a list of component IDs for a component type
meshMultipleComponentOutcome = azlmbr.editor.EditorComponentAPIBus(bus.Broadcast, 'GetComponentsOfType', entityId, meshComponentTypeId)
if (meshMultipleComponentOutcome.IsSuccess()):
    print("GetComponentsOfType mesh works.")
    firstMeshComponentId = meshMultipleComponentOutcome.GetValue()[0]

Component control events

The API offers events to validate, enable or disable, and remove components.

```
'RemoveComponents'

Example usage:

```python
import azlmbr.bus as bus

# test a component is valid
isValid = azlmbr.editor.EditorComponentAPIBus(bus.Broadcast, 'IsValid', meshComponent)
if (isValid is True):
    print("Mesh component is valid.")

# test if the component is enabled
isEnabled = azlmbr.editor.EditorComponentAPIBus(bus.Broadcast, 'IsComponentEnabled', meshComponent)
if (isEnabled is True):
    print("Mesh component is enabled.")

# enable this mesh component
isEnabled = azlmbr.editor.EditorComponentAPIBus(bus.Broadcast, 'EnableComponents', [meshComponent])
if (isEnabled is True):
    print("Mesh component set to enabled.")

# disable this mesh component
didDisable = azlmbr.editor.EditorComponentAPIBus(bus.Broadcast, 'DisableComponents', [meshComponent])
if (didDisable is True):
    print("Mesh component set to disabled.")

# remove only this mesh component
didRemove = azlmbr.editor.EditorComponentAPIBus(bus.Broadcast, 'RemoveComponents', [meshComponent])
if (didRemove is True):
    print("Mesh component has been removed.")
```

Component property events

Component properties can be accessed and modified using a string that indicates a direct path to a property value. The pipe character | is used as the separator between the property path elements.

The azlmbr.editor.EditorComponentAPIBus bus is used to access or modify component property values.

```python
# azlmbr.editor.EditorComponentAPIBus Broadcast events

# Get value of a property on a component
# input: component ID
# input: property path
# output: (Outcome<object>) the current value of the property
'GetComponentProperty'

# Set value of a property on a component
# input: component ID
# input: property path
# input: object value
# output: (Outcome<object>) the new value of the property
'SetComponentProperty'

# Get a full list of properties in a component
# input: component ID
# output: (list of strings) property paths
'BuildComponentPropertyList'
```
Example usage:

```python
import azlmbr.bus as bus

# Get current value of the mesh asset property of the MeshComponentRenderNode
propertyPath = "MeshComponentRenderNode|Mesh asset"
valueOutcome = azlmbr.editor.EditorComponentAPIBus(bus.Broadcast, 'GetComponentProperty', componentId, propertyPath)

if (valueOutcome.IsSuccess()):
    meshAssetId = valueOutcome.GetValue()
    print ('Old mesh asset is {}'.format(meshAssetId))

# Set the mesh asset
outcome = None
if (meshAssetId is not None):
    outcome = azlmbr.editor.EditorComponentAPIBus(bus.Broadcast, 'SetComponentProperty', componentId, propertyPath, meshAssetId)

if(outcome.IsSuccess()):
    result = outcome.GetValue()
    print ('New mesh asset is {}'.format(result))

# Read the properties of this MeshComponentRenderNode
propertyPaths = azlmbr.editor.EditorComponentAPIBus(bus.Broadcast, 'BuildComponentPropertyList', componentId)
for path in propertyPaths:
    print ('ComponentId path has {}'.format(path))
```

Editing properties

To access this API a script needs access to a property tree editor instance. This object accesses the properties on a component, in the style of the property editing view inside of the editor. Properties are accessed starting from the root of the component, and follow the chain of labels until a property value is encountered.

A common way to create a property tree editor instance is during content creation when a component is created via the EditorComponentAPIBus.AddComponentsOfType event.

```python
componentOutcome = editor.EditorComponentAPIBus(bus.Broadcast, 'AddComponentsOfType', entityId, typeIdsList)
if (!componentOutcome.IsSuccess()):
    raise Exception('FAILURE FATAL: AddComponentsOfType')

components = componentOutcome.GetValue()
pteObj = editor.EditorComponentAPIBus(bus.Broadcast, 'BuildComponentPropertyTreeEditor', components[0])
if(pteObj.IsSuccess()):
    pte = pteObj.GetValue()

azlmbr.property.PropertyTreeEditor API:

# type: azlmbr.property.PropertyTreeEditor
# - method: build_paths_list() -> string List
#     Get a complete list of all property paths in the tree.
# - method: build_paths_list_with_types() -> string List
#     Get a complete list of all property paths in the tree with (typename)s.
# - method: set_visible_enforcement() -> string List
```
Limits the properties using the visibility flags such as ShowChildrenOnly.
- method: has_attribute(str: path, str: attribute) -> bool
  Detects if a property has an attribute.
- method: get_value(str: path) -> Object
  Gets a property value.
- method: set_value(str: path, object: value)
  Sets a property value.
- method: compare_value(str: path, object: value) -> Boolean
  Compares a property value.
- method: is_container(str: path) -> Boolean
  True if property path points to a container.
- method: get_container_count(str: path) -> Outcome Integer
  Returns the size of the container.
- method: reset_container(str: path) -> Outcome Boolean
  Clears the items in a container.
- method: add_container_item(str: path, object key, object value) -> Outcome Boolean
  Add an item in a container.
- method: append_container_item(str: path, object value) -> Outcome Boolean
  Appends an item in an non-associative container.
- method: remove_container_item(str: path, object key) -> Outcome Boolean
  Removes a single item from a container.
- method: update_container_item(str: path, object key, object value) -> Outcome
  Updates an existing the item's value in a container.
- method: get_container_item(str: path, object: key) -> Outcome Object
  Retrieves an item value from a container.

Property containers

The Editor automaton API exposes a number of special methods to handle container component property types. If the property tree editor points to a component that has container properties these methods give access to the items in the container.

To determine if the property is a container type use the azlmbr.PropertyTreeEditor.is_container() method.

Example usage:

```python
# the path to the 'Extended Tags' property
tagListPropertyPath = 'm_template|Extended Tags'

# get current item count of the the container
outcome = pte.get_container_count(path)
if(outcome.IsSuccess()):
    count = outcome.GetValue()

# clear the container
outcome = pte.reset_container(path)
if(outcome.IsSuccess()):
    print('cleared item')

# if this is a Dictionary type make sure to have a valid key
key = 'tag_1'
value = pte.add_container_item(path, key, value)
if(outcome.IsSuccess()):
    print('added item')

# an update needs a key such as an index or a Dictionary key
value = 'tag_2'
outcome = pte.update_container_item(path, key, value)
if(outcome.IsSuccess()):
    print('updated item')
```
Examples

```python
print('updated an item')

# the 'append' can be used for properties that are Lists
value = 'tag_3'
ooutcome = pte.append_container_item(path, value)
if(outcome.IsSuccess()):
    print('appended an item')

# get an item using a key such as an index or a Dictionary key
key = 0
outcome = pte.get_container_item(path, key)
if(outcome.IsSuccess()):
    print('got the value {} from index 0'.format(outcome.GetValue()))

# remove an item using a key,
# even in List types give an index for the key
key = 0
outcome = pte.remove_container_item(path, key)
if(outcome.IsSuccess()):
    print('removed an item')
```

Asset management

The editor automation API exposes a few methods to manage assets via the `azlmbr.asset.AssetCatalogRequestBus` bus.

```python
import azlmbr.bus as bus
import azlmbr.math
emptyTypeId = azlmbr.math.Uuid()

# get the cube asset ID
bRegisterType = False
cubeAssetId = azlmbr.asset.AssetCatalogRequestBus(bus.Broadcast, 'GetAssetIdByPath',
        'objects/default/primitive_cube.cgf', emptyTypeId, bRegisterType)
print ('cube asset ID validity is {}'.format(cubeAssetId.IsValid()))

cubePath = azlmbr.asset.AssetCatalogRequestBus(bus.Broadcast, 'GetAssetPathById',
        cubeAssetId)
print ('cube asset path is {}'.format(cubePath))
```
Demo and Video Capture

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This section contains information about recording videos for benchmarking. Capturing audio and video is also discussed, using either the Perspective viewport in Lumberyard Editor or in game mode using the launcher.

Topics
- Capturing Video and Audio (p. 230)
- Recording Time Demos (p. 233)

Capturing Video and Audio

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This tutorial explains how to set up Lumberyard editor (or game) to capture video. Lumberyard outputs video as single frames. If required, it can also output stereo or 5.1 surround sound audio in .wav file format. You can edit the output with commonly available video editing software.

Preparation

Before you can start video and audio streams in preparation for capture, you must configure some settings that determine how the video will be captured. You configure these settings by using console commands. To save time, you can create configuration files that execute the necessary commands for you instead of entering the commands directly into the console. Example configuration files are presented later in this topic.

The next sections describe the settings and the console commands that configure them.

Video Settings

Frame Size and Resolution

The height and width of the captured frames in the editor is normally set to the exact view size of your rendered perspective window. To resize the view size, re-scale the perspective window, or right click in the top right of the perspective viewport where the frame size is displayed.

You can also capture higher than rendered images from Lumberyard Editor and Launcher.

The console variables that are now used in conjunction with Capture Frames are:

- r_CustomResHeight=N - Specifies the desired frame height in N pixels.
- r_CustomResWidth=M - Specifies the desired frame width in M pixels.
- r_CustomResMaxSize=P - Specifies the maximum resolution at which the engine will render the frames in P pixels.
- r_CustomResPreview=R - Specifies whether or how the preview is displayed in the viewport. Possible values for R are:
Frames Per Second

When deciding the number of frames per second to specify, keep in mind the following:

- NTSC standard video is approximately 30 frames per second, which is a good compromise between quality and file size.
- High quality video can have up to 60 frames per second, but the difference in quality of the increased number of frames is barely noticeable and can take up a lot of file space.
- Video at less than 24 FPS (a cinema standard) will not look smooth.

To specify a fixed frame rate, use the command:

```
t_fixedstep N
```

$N$ specifies the time step. Time step is calculated by using the formula

```
step = 1 second/<number of frames>
```

A table of common time step values follows.

<table>
<thead>
<tr>
<th>FPS</th>
<th>Time Step</th>
</tr>
</thead>
<tbody>
<tr>
<td>25 (PAL)</td>
<td>0.04</td>
</tr>
<tr>
<td>30</td>
<td>0.0333333333</td>
</tr>
<tr>
<td>60</td>

Video Capture File Format

You can capture pictures in several different file formats. A good choice for average quality is the `.jpeg` file format. The `.tga` or `.bmp` file formats are better for higher quality, and `.hdr` for pictures that use high-dynamic-range imaging.

To specify the capture file format, use the console command

```
capture_file_format N
```

$N$ is jpg, bmp, tga or hdr.

Video Capture File Location

By default, recorded frames are stored in the directory $<root>\CaptureOutput$. To specify a custom directory, use the command:
**Lumberyard User Guide**

### Capturing Video and Audio

- **capture_folder** \(N\)

\(N\) is the name of the custom directory.

**Warning**

When you start a recording, the captured frames are placed in the currently specified directory and will overwrite existing files with the same name. To avoid losing work, create a directory for each recording, or move the existing files to another directory before you start.

### Starting and Ending the Video Recording

After you have specified the values mentioned in the previous sections, you can start the recording by using the command:

- **capture_frames** \(N\)

Setting \(N\) to 1 starts the recording, and setting \(N\) to 0 stops it.

### Audio Settings

Before you begin, decide if you require audio in stereo or in 5.1 surround format, and then change your audio settings accordingly in the Windows control panel.

### Deactivating the Sound System

After loading the level of your game that you want to capture, you must deactivate the sound system so that you can redirect the sound output to a file. To deactivate the sound system, use the command:

- \#Sound.DeactivateAudioDevice()

This redirects the sound output to a `.wav` file in the root directory of the game. The sound will not run in realtime, but be linked precisely to the time step that you set previously.

To write the sound capture, use the command:

- `s_OutputConfig N`

Setting \(N\) to 3 activates the non-realtime writing of sound to the `.wav` file. Setting \(N\) to 0 specifies auto-detection (the default).

### Reactivating the Sound System

To reset the sound system use the command:

- \#Sound.ActivateAudioDevice()

This creates a `.wav` file in the root directory of the game. The file will continue to be written to until you run the following combination of commands to deactivate the audio device:

- \#Sound.DeactivateAudioDevice()

- `s_OutputConfig 0`

- \#Sound.ActivateAudioDevice()
Tip
Although these commands reset the sound system, some sounds won’t start until they are correctly triggered again. This applies particularly to looped sounds. To get looped sounds to play, start the recording of video and sound first, and then enter any area that triggers the looped sounds that you want to record.

Configuration Files

Creating Configuration Files

- To ensure that multiple recordings use exactly the same settings, create a configuration file that you can use for each of them. This will ensure that all of your captured files have the same format.

An example configuration file:

```
sys_spec = 4
Fixed_time_step 0.0333333333
Capture_file_format jpg
Capture_folder myrecording
r_width 1280
r_height 800
```

The command `sys_spec = 4` sets the game graphic settings to "very high" to generate the best appearance.

- To speed up the process of starting and stopping the recording, you can create two configuration files: one to start the video, and one to stop it.

- To start recording, use a config file like the following:

```
#Sound.DeactivateAudioDevice()
s_OutputConfig 3
#Sound.ActivateAudioDevice()
Capture_frames 1
```

- To stop recording, use a config file like the following:

```
Capture_frames 0
#Sound.DeactivateAudioDevice()
s_OutputConfig 0
#Sound.ActivateAudioDevice()
```

Executing the Config Files

To run the config file, open the console and enter the following command:

```
Exec N
```

`N` is the name of the config file.

Recording Time Demos

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Overview

Lumberyard Editor can record and play back player input and camera movement.

**Note**
Recording of some player actions such as vehicle movement are not supported.

To use the feature, you must start game mode in Lumberyard Editor and then record in it. To start game mode, press `Ctrl+G` after a level has fully loaded, or load the level in pure-game mode.

Output like the following appears both in the console and in the `timedemo.log` file in the directory corresponding to the level used:

```
TimeDemo Run 131 Finished.
Play Time: 3.96s, Average FPS: 50.48
Min FPS: 0.63 at frame 117, Max FPS: 69.84 at frame 189
Average Tri/Sec: 14037316, Tri/Frame: 278071
Recorded/Played Tris ratio: 0.99
```

Recording Controls

<table>
<thead>
<tr>
<th>Command</th>
<th>Keystroke</th>
<th>Console Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start Recording</td>
<td><code>Ctrl + PrintScreen</code></td>
<td>record</td>
</tr>
<tr>
<td>End Recording</td>
<td><code>Ctrl + Break</code></td>
<td>stoprecording</td>
</tr>
<tr>
<td>Start Playback</td>
<td><code>Shift + PrintScreen</code></td>
<td>demo</td>
</tr>
<tr>
<td>Stop Playback</td>
<td><code>Ctrl + Break</code></td>
<td>stopdemo</td>
</tr>
</tbody>
</table>

Related Console Variables

- `stopdemo` – Stops playing a time demo.
- `demo demoname` – Plays the time demo from the specified file.
- `demo_fixed_timestep` – Specifies the number of updates per second.
- `demo_panoramic` – Uses a panoramic view when playing back the demo.
- `demo_restart_level N` – Repeats the level after each loop. Possible values for `N`: 0 = Off; 1 = use quicksave on first playback; 2 = load level start.
- `demo_ai` – Enables or disables AI during the demo.
- `demo_savestats` – Saves level stats at the end of the loop.
- `demo_max_frames` – Specifies the maximum number of frames to save.
- `demo_screenshot_frame N` – Makes a screenshot of the specified frame during demo playback. If a negative value for `N` is supplied, takes a screenshot every `N` frame.
- `demo_quit` – Quits the game after the demo run is finished.
- `demo_noinfo` – Disables the information display during the demo playback.
- `demo_scroll_pause` – Enables the use of the ScrollLock key to pause demo play and record.
- `demo_num_runs` – Specifies the number of times to loop the demo.
- `demo_profile` – Enables demo profiling.
- `demo_file` – Specifies the time demo file name.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can customize your workspace by adjusting how the windows and tools are docked, customizing which toolbars and menus display, and updating the global editor settings.

**Note**

To change the size setting for the toolbar icon, open the `Editor.cfg` file and enter a value for the `ed_toolbarIconSize` parameter. By default, the toolbar icon size is set to 0 (32 pixels).

**Topics**

- Docking Windows and Toolbars (p. 235)
- Customizing Toolbars and Menus (p. 237)
- Changing Preferences (p. 238)

### Docking Windows and Toolbars

When you drag a window or toolbar over an interface element or the edges of the editor, docking targets appear to show you where you can dock them. These targets appear for the top, bottom, left, and right quadrants of the pane. You can dock windows relative to any open pane, whether it is already docked, floating as a tab, or split in a column or row.

**To split a row or column**

To split a row or column, drop the window or toolbar on a docking target.

**To dock a window or toolbar as a tab**
To dock a window or toolbar as a tab, drop it on the docking target in the middle of a pane.

To dock a window or toolbar to the editor window, drop it on the outer docking target. This creates a new column next to the existing column.

To undock a window or toolbar, drag the title bar and move the selection window away. Avoid the docking targets to prevent from accidentally redocking the window. To help prevent accidental docking,
a brief delay occurs before a docking target becomes active. You can also undock a window by right-clicking the title bar and choosing **Undock**.

To prevent a window from docking

To prevent a window from docking, press and hold **Ctrl** while moving the window.

**To snap windows**

To snap a window in place, move the window close to a stationary window. Snapping works on the top, bottom, left, and right borders of the pane.

**Customizing Toolbars and Menus**

You can also give toolbars and menus your own personal touch.

**To customize preset toolbars or create custom toolbars and menus**

1. Right-click the top toolbar and choose **Customize**.
2. In the **Customize** window, for **Toolbars**, create, rename, and delete any custom toolbars and menus, or reset them to the default settings.
Changing Preferences

You can change the default settings to customize the look and functionality of the editor.

To customize the look and features of Lumberyard Editor

- In Lumberyard Editor, choose **Edit, Editor Settings, Global Preferences**.
General Settings

You can change the general Lumberyard Editor settings and file settings.

Restoring the Default Layout for Lumberyard Editor

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

If you customized your workspace, you can reset Lumberyard Editor to use the default layout. This restores your editors, tools, and windows to the default view that you see when you open Lumberyard Editor for the first time. You can restore the default layout at any time.
Contents

- Restoring the Component Entity Layout (p. 245)
- Restoring the Legacy Layout (p. 245)

Restoring the Component Entity Layout

The component entity layout is the default view for Lumberyard Editor. If you customize your settings and tools, you can restore the default layout for Lumberyard Editor.

To use the component entity layout (default)

- In Lumberyard Editor, do one of the following:
  - Click View, Layouts, Component Entity Layout.
  - Click View, Layouts, Restore Default Layout.

The following example shows the component entity layout in Lumberyard Editor:

Note

- Resetting Lumberyard Editor to the default layout does not reset the layout for individual tools, such as the Script Canvas editor or the Particle Editor.
- You can enable the CryEntity Removal gem to disable all legacy features from Lumberyard Editor. Legacy features will eventually be removed. If you enable this gem, the legacy layout view is removed from Lumberyard Editor. For more information, see CryEntity Removal Gem (p. 1123).

Restoring the Legacy Layout

If you don't enable the CryEntity Removal gem, you can switch back to the legacy layout.
To use the legacy layout

- In Lumberyard Editor, click View, Layouts, Legacy Layout.

The following example shows the legacy layout in Lumberyard Editor:

If you require more granular control to restore Lumberyard Editor settings, you can delete the relevant keys in the Windows registry.

**Important**
Exercise caution when editing the Windows registry. Not following the instructions carefully can result in a corrupt Windows installation.

**To edit the Windows registry**

1. On your Windows desktop, click Start and enter regedit in the search box.
2. In the Registry Editor, go to HKEY_CURRENT_USER\Software\Amazon\Lumberyard\Editor.
3. Right-click the `fancyWindowLayouts` and `mainWindowLayouts` folder icons and choose Delete. This deletes custom layout settings that you have for Lumberyard Editor.

The default settings are restored the next time you start Lumberyard Editor.
## Working with assets in Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

## Working with assets in Lumberyard

Learn how to manage, process, and package the assets for your Lumberyard game. This documentation covers the Lumberyard Asset Browser tool, the asset pipeline, managing and organizing game assets, and packaging (bundling) game assets for delivery.

### In this section:

<table>

</tbody>
</table>

## Working with the Asset Pipeline and asset files

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Asset Pipeline converts source art and other assets into OS-specific, game ready data. To prepare your game to ship, build all your game assets with the Asset Pipeline and package them with your game for your supported operating systems.

The Asset Processor (AP) is a service that runs in the background and monitors a configurable set of input directories for changes in files. When it detects changes, it uses configurable rules to determine its next action. The objective is to end up with game-ready versions of all assets for each OS and each game directory in a location called the asset cache. The asset cache is kept separate from your input directory and can be automatically rebuilt entirely from your source assets by the Asset Processor.
Using Asset Processor

Note
The asset cache should not be added to your source control.

The Asset Processor detects changes in the directories that contain input assets, with the game directory being the highest priority. Therefore, if you put assets in the game directory, those assets override assets with the same path in Lumberyard or other directories with lower priority.

Each output directory in the asset cache represents a full image of all files (except for executables and related files) needed to run the game. The Asset Processor curates the directory to keep it up to date, ensuring that new files are ready to use in the game and Lumberyard Editor as soon as possible. Game runtimes load assets only from the asset cache and never directly from your input source folders.

Topics
- Using Asset Processor (p. 248)
- Configuring the Asset Pipeline (p. 269)
- Configuring Image Processing (p. 278)
- Live Reloading and VFS (p. 291)
- Compiling Shaders for Release Builds (p. 291)
- Shader Compiler Proxy (p. 292)
- Shader Cache and Generation (p. 293)
- Game Startup Sequence (p. 296)
- Asset Browser (p. 296)
- Programming the Lumberyard AZCore Runtime Asset System (p. 304)

Using Asset Processor

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Asset Processor is a utility that runs in the background to detect changes to your asset files. When Asset Processor detects new or updated asset files, it launches the Resource Compiler (rc.exe for FBX and ABC files, AssetBuilder.exe for all other types), processes the assets, and then places them in the cache. Asset Processor then notifies all running game or tool instances that the assets are updated. The game can then reload the updated assets.
As part of Asset Processing, the Asset Processor generates and stores product and source dependencies. In this context, a dependency defines how a one product or source asset depends on another asset. A given asset may have 0 or more dependencies, and these dependencies are used by features such as the Asset Bundler (p. 334) in order to determine which assets must be included when you bundle your game for release.

**Topics**
- Modifying the Asset Processor Configuration File (p. 250)
- Using the Asset Processor Batch Program (p. 250)
- Asset Processor Interface (p. 250)
- Enabling Asset Processor's Faster Scanning Mode (p. 261)
- Importing Assets into Lumberyard (p. 263)
- Using Resource Compiler (p. 264)
- Debugging Asset Processor (p. 265)

Asset Processor enables games to run on other platforms without deploying assets to that platform. Instead, the assets are accessed from the asset cache on a connected Windows or macOS system. With Asset Processor, you can also run games that use someone else's assets.

By proxying requests through itself, Asset Processor communicates with an iOS or Android shader compiler server through a USB cable on iOS and Android.

In Windows, Asset Processor starts automatically if you run Lumberyard Editor with automatically maintained connections. Asset Processor also restarts automatically if you modify any of the data files that it needs to operate or if you retrieve a new version.

In macOS, you must manually start Asset Processor from a command line window. Asset Processor is located in the `lumberyard_version/dev/BinMac64` directory.

**Note**
Symbolic links are not supported when using Asset Processor in macOS. To ensure that Asset Processor works properly in macOS, follow these guidelines:

- Do not use a symbolic link for your cache directory when you store compiled assets in a central location.
- Do not store your source project assets in a symbolic link directory.
- Use a unique cache directory. Do not share the cache directory with a Windows system that is also running Asset Processor.

You can open the Asset Processor options from the notification area on the taskbar.
You don't need to close Asset Processor when you get the latest updates from source control. You can start Lumberyard Editor while Asset Processor is still processing your assets.

However, if you aren't using the game or Lumberyard Editor, you can exit Asset Processor by right-clicking its icon in the notification area on the Windows taskbar or the macOS menu bar.

Asset Processor can also serve files directly to running console games so that the assets aren't required to be present on the game device. This is called virtual file system (VFS) and is required for live reloading to work on those platforms. For more information, see Live Reloading and VFS (p. 291).

Modifying the Asset Processor Configuration File

Use the `AssetProcessorPlatformConfig.ini` configuration file (located in the `lumberyard_version/dev/` directory) to perform the following tasks:

- Add new file types for Asset Processor to feed to the Resource Compiler, copy into the cache, or update existing file type rules.
- Update the ignore list.
- Specify which platforms are currently enabled. The default value is the host platform that Asset Processor runs on. Asset Processor automatically builds assets for the host platform. For example, if Asset Processor is running on Windows, Asset Processor builds Windows assets even if `pc` is not enabled in the `.ini` file. If Asset Processor is running on macOS, Asset Processor builds macOS assets even if `osx_gl` is not enabled in the `.ini` file. To build assets for other platforms, update the `.ini` file and specify the platforms that you want.
- Add additional folders for Asset Processor to watch. For example, you can specify folders such as shared particle libraries and associated textures between projects.
- Specify which files trigger related files to be rebuilt. This is called metafile fingerprinting.

To add game-specific overrides, you can add a file named `AssetProcessorGamePlatformConfig.ini` to your game assets directory. This file is read after the root configuration file and can have additional game-specific settings for the ignore list, platforms, and file types.

For more information about these configuration files, see Configuring the Asset Pipeline (p. 269).

Using the Asset Processor Batch Program

The `AssetProcessorBatch.exe` application compiles all assets for the current project and enabled platforms. If the process succeeds without errors, it exits with a 0 code. You can use the Asset Processor Batch program as part of your build system for automation.

The `AssetProcessorBatch.exe` file accepts the following command line parameters for overriding the default behavior:

- `/platforms=` comma separated list
- `/gamefolder=` name of game folder

Example:

```
AssetProcessorBatch.exe /platforms=pc,ios /gamefolder=SamplesProject
```

Asset Processor Interface

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The Asset Processor interface provides areas containing detailed information about the assets that it processes. These areas are shown in the following example.

A – Processing status

Displays asset processing status, the project name, its root location, and the processor port.

B – Tabs

Displays scoped views of Asset Processor functionality. Tabs are described in detail in the following sections.

C – Asset Status

Displays the asset status and details about the source asset in a sortable table.

D – Asset status search with filter

Filters your search by keyword, regular expressions, or status.

E – Event log details

Provides additional information for the selected row in the asset status table.

F – Event log details filter

Filters by warnings and errors.

G – Context details

When enabled, shows specific debugging information for the asset. This setting is disabled by default.
H – Event log line details table

Displays debugging values set in the program for the selected line in the Event log details. These values are emitted during processing.

I – Asset processing timer

After asset processing completes, displays information about the time that it took to perform scans, analyze assets, and produce a build.

Jobs

The Jobs tab displays information about the current state of asset processor jobs. This includes information on the state of jobs, events that occurred during processing, and detailed logging information from the asset processor.

Asset Status

The Asset Status table displays the status of assets that Lumberyard is processing. Select a row to display contextual asset processing information in the Event Log Details table.

The columns in the Asset Status table display the following information about each asset:

- **Source** – Asset's file name and location
- **Completed** – Timestamp of the process completion
- **Platform** – Game platform
- **Job Key** – Specific job process

![Asset Status Table]

Status Column

In the Status column, you can sort by status types.

The column headers display the following information about each asset:

- **Completed** – Completely processed and converted for use in the game
- **Failed** – Failed and needs investigation and debugging
- **In Process** – Currently processing and will display Completed or Failed when complete
- **Pending** – Awaiting processing

Filtering by Keyword and Status

In the filter box, you can filter the table view by entering keywords and regular expressions. The regular expressions are standard `std::regex` in extended format. The standard `std::regex` rules apply.
Example

A regular expression (regex) to search for all files ending with .png:

\*\..png

The asterisk (*) indicates any character 0 or more times.

Example

A regex to search for any files under a \Slices subdirectory:

/\Slices/\.+ 

The dot plus (+) indicates any character 1 or more times.

To view all assets with a particular status, do one of the following:

- Type the status keyword (for example, "failed").
- Click the filter icon and select the status types that you want to see.

Filters that you apply remain active until you remove them. You can either clear the status type box, or click the X next to the filter’s label.

Using a Row’s Context Menu

You can perform actions on each row in the Asset Status table. Right-click on the row to expose a context menu with the following actions:

Show in Asset Browser

Highlights the asset in the Editor's Asset Browser. The Editor must be open and running.

Open in Explorer

Opens the asset in Windows Explorer.

Copy

Copies the asset name.

Open log file

Opens the most recent log file for the asset, if one has been made. File copies and other simple asset processing steps don’t generate logs.

Open folder with log file

Opens the directory with the log file for the asset.
Event Log Details

In the Event Log Details table, you can view asset processing information for an asset that you select in the Asset Status table. This table provides an activity log that shows how the asset was processed and any errors or warnings generated during processing.

The Status column displays icons for the following message types:

- **Information**
  Additional supporting messages are available about the processing of the asset.

- **Warning**
  See the Message column for information about a potential processing issue for this asset.

- **Error**
  The location of the asset and the specific error generated by attempting to process that asset.

The Source column indicates the subsystem that generated the message (such as AssetBuilder) or a generic type, such as Warning or Error.

The Message column displays information related to the processing details of the selected asset.

**Note**
The Message column occasionally prefixes Errors with E: and warnings with W:.

The Event Log Details table also features a context menu to perform copy actions. You can copy the following to the clipboard:

- **Copy Line** – Selected line of the log
- **Copy Line With Details** – Selected line and any related details that appear in the **Event log line details** table
- **Copy All** – All log lines and any hidden details for each item

**Event Log Line Details**

The **Event Log Line Details** table displays when you enable the **Context Details** option. This table displays any additional information about the selected line in the **Event Log Details** table. These details and additional information is generally useful only when debugging issues with a particular asset.

The **Event Log Line Details** table also features a context menu to perform copy actions. You can copy the following to the clipboard:
• **Copy Selected Key** – Text in the **Key** column of the selected row
• **Copy Selected Value** – Text in the **Value** column of the selected row
• **Copy All Values** – All keys and values in the table

Assets

The **Assets** tab displays information about the assets associated with your active project. The data you get includes things like the name of the asset, what files are produced by the resource compiler, and dependencies. In addition to seeing information on source assets, you can also look through generated assets and try to locate missing dependencies.

Source assets

Using the **Source Assets** view of the **Assets** tab shows you the assets picked up during asset processing and lets you investigate their dependencies, products, associated jobs, and force asset rebuilds.
Using Asset Processor

A – Search bar

Search for assets. The search bar is visible in both the Source Assets and Product Assets views. The search will match partial file names and supports regular expressions. Search bar functionality is the same between Source Assets and Product Assets views.

B – Source asset list

The list of all source assets which match the current search filter. When the search is empty, shows all of the source assets used by the project.

C – Asset information

Detailed information about the asset currently selected in the asset list. This includes the name of the asset, the containing folder on the filesystem, and the GUID associated with the asset in the Lumberyard asset system.

D – Products

The compiled asset products that are produced from the source asset. Selecting the popout icon ( ) next to a product name takes you to that asset within the Product Assets view.

E – Outgoing source dependencies

The list of source assets which require an output from this source asset to process. See Why define product dependencies? (p. 337) for more information on product dependencies.

F – Incoming source dependencies

The list of source assets which must have their jobs completed before the processing of this asset. See Why define product dependencies? (p. 337) for more information on product dependencies.
Product assets

A – Product asset list

The list of all product assets which match the current search filter. When the search is empty, shows all of the available products.

B – Asset information

The information for the product asset. Includes the asset GUID, the last time the product was generated, which type of job generated the asset, which platform the asset was produced for, and which source asset is the primary input for the product.

C – Outgoing product dependencies

The list of product assets which depend on this product. In order for your project to function and be distributed properly, all of these assets need to be in the final bundle. See Why define product dependencies? (p. 337) for more information on product dependencies.

D – Outgoing unmet path product dependencies

The list of product assets which are hardcoded paths to be loaded by the Lumberyard runtime that this asset depends upon. Because these products aren’t necessarily generated by the asset processor, they’re placed into a separate category of dependencies. See Hardcoded File Loads (p. 364) for information on resolving path product dependency issues.

E – Incoming product dependencies

The list of product assets which this product depends on. In order for your project to function and be distributed properly, all of these assets need to be in the final bundle. See Why define product dependencies? (p. 337) for more information on product dependencies.
F – Missing dependency scanner

Run the missing dependency scanner from inside the Asset Processor. See Using the Missing Dependency Scanner (p. 366) for more information.

Logs

The Logs tab displays events for the internal operation of the Asset Processor. This area doesn’t display logs for the processing of individual assets. The information in these logs is helpful for troubleshooting the Asset Processor if an issue occurs.

Right-click to access the Logs context menu.

Shaders

The Shaders tab displays a table with information related to shader compiler proxies. Shader failures appear in this table. For more information, see Shader Compiler Proxy (p. 292).
Connections

The Connections tab displays devices and programs that the Asset Processor is connected to and the platform they are running on. You can add approved connections in the White Listed Connections box and disapproved connections in Rejected Connections.

In the Active Connections table's Enabled column, automatic connections are labeled as Auto. This means that it's a connection that the Asset Processor created. One example of such a connection is Asset Builder connections. User-created connections show a check box. If you select the check box, the Asset Processor continually attempts to reconnect to those connections. You can use these custom connections for specialized cases, such as when connecting to mobile devices outside of a company's internal network.

You can edit or remove a user-created connection, or add a connection.
Tools

On the Tools tab, you control how your assets are scanned. Use Faster Scanning Mode when you don't need to perform a full asset scan. For more information, see Enabling Asset Processor's Faster Scanning Mode (p. 261).

Enabling Asset Processor's Faster Scanning Mode

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Asset Processor's Faster Scanning Mode speeds up Lumberyard's startup scan by disabling checking for cache changes that occurred while Asset Processor was not running. This can save you time when processing many assets in your project.

By default, Faster Scanning Mode is enabled. You can enable or disable this mode any time without restarting the Asset Processor, including during the scan. Asset Processor saves your preference between sessions.

To disable Faster Scanning Mode

1. Open Asset Processor (p. 248).
2. Select Tools and clear Faster Scanning Mode.
To perform a full scan

- Click Start Scan. This starts a full scan immediately, which checks for files missing from the cache and rebuilds the appropriate source files.

Asset Processor's batch version also supports a command line parameter for Faster Scanning Mode.

```
AssetProcessorBatch.exe --zeroAnalysisMode
```

When you enable the feature you can also use console mode stdout as well as open GUI log windows that indicate the effectiveness of Faster Scanning Mode. The output message displays the number of files that required full analysis and the total number of files.

**Example**

```
--Debug--5303 files reported from scanner. 2903 unchanged files skipped, 2400 files processed
```

For more information, see Configuring the Asset Pipeline (p. 269).

**Performing a Full Scan**

When you choose a full scan, Asset Processor performs the following actions. Low cost actions contribute to less than 1% of the total time.

- (Low) Determines which builders are responsible for building a file. Asset Processor examines builder patterns, such as *.tif or *.fbx when they register.
- (Low) Lookup the file in the database to determine what happened to it the previous time.
- (Low) Compares the new job fingerprints to the previously emitted jobs to check for differences.
- (Moderate) Generates a job fingerprint that includes modtimes of source files and dependencies and the versions of the involved builders.
- (High) Checks the cache directory and ensures that every product that was emitted last time for this source file is still present.
- (Very high) Sends the file to the registered builders so that they can spawn jobs for the job queue.

If all of the following are true for a given source file found during the scan, then that file can be excluded from reanalysis.

- The source file hasn't changed on disk (it has the same modtime as previously).
- The files on which the source file depends haven't changed on disk (it has the same modtime as previously).
- The builders assigned to that source file successfully processed it last time. This means there were no failures or errors.
- The builders assigned to that source file didn't get a new version or a new analysis fingerprint.
- There are no new builders that may operate on that source file.
- There are no builders that were previously enabled which could have operated on that source file but have since been removed.
- There are no builders that have changed the set of source files.

Asset Processor performs a check at the beginning of the scan and does the following actions. These actions are low cost.
Using Asset Processor

• (Very low) Collects modtime information for every file scanned as part of Asset Processor startup.
• (Very low) Checks whether the source file in question had any builders version change or analysis fingerprint by comparing the data from the previous time.
• (Very low) Compares the modtime with the previously recorded time in the database.
• (Low) Queries the database files table to get a list of every file and its modtime from previous runs.
• (Low) Queries the database sources table to get a list of every source asset and its builder-fingerprint signature.

If any of these checks fail, the source goes through the normal, unchanged analysis pipeline. This means that Faster Scanning Mode makes no changes to the actual analysis.

Importing Assets into Lumberyard

You can import assets into your Lumberyard game project directory with one of the following.

Importing Assets Manually into Lumberyard

You can import assets even if Lumberyard isn't running. You can do this at any time.

To import assets manually
1. Navigate to your game project directory, such as `lumberyard_version/dev/My_Game_Project/Objects`.
2. Copy or move the assets to your game project directory. For example, you can add your `.cgf` files to the specified directory.
   • If Asset Processor is running, it detects the new files and converts them for use in Lumberyard Editor.
   • If Asset Processor isn't running, Asset Processor automatically detects the new files the next time you start Lumberyard Editor.

Importing Assets from Lumberyard Editor

To import assets from Lumberyard Editor
1. In Lumberyard Editor, choose File and then Import.
2. Navigate to your assets and select the files to add to your game project directory. Then click OK.
3. In the Import Asset(s) dialog box, the Destination Folder path automatically shows the root of your game project directory. You can click Browse to specify a subdirectory in your game project directory.
   
   Note
   You can import assets to a directory only in the current game project.
4. Select whether you want to Copy Files from their original location or Move Files and then click Import. If you copy the files, Asset Processor doesn't monitor changes to the original files.
5. In the **Processing asset** dialog box, click **View status** to check the status of your assets.

**Tutorials: Importing Assets into Lumberyard**

To learn more about importing your assets, see the following video tutorials:

- Tutorials: Importing FBX Files as Actors and Motions (p. 1497)
- FBX Settings mesh export (p. 436)

**Using Resource Compiler**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Resource Compiler converts certain assets into a format that Lumberyard can use. Resource Compiler stores the converted, game-ready assets in a cache that mirrors your project directory. This cache is located in the \lumberyard_version\dev\Cache directory. Resource Compiler can also create PAK files.
Asset Processor calls Resource Compiler to automatically convert new or modified assets in your Lumberyard directory. The Resource Compiler application, `rc.exe`, is located in the `\lumberyard_version\dev\Bin64vc141\rc` directory.

Resource Compiler converts the following file types.

**ABC**
- Alembic files

**CGF**
- Legacy geometry format

**I_CAF**
- Legacy animation format

**TIF, BMP, JPG, PNG**
- Image files (p. 278)

**FBX**
- Geometry (static mesh) only. Doesn't convert new EMotion FX characters or animations.

**Note**
All other types, such as characters and animation, are converted by the BuilderSDK system. For more information, see Creating a Custom Asset Builder (p. 318).

You can customize how resources are converted by modifying the `AssetProcessorPlatformConfig.ini`. For more information, see Configuring the Asset Pipeline (p. 269).

You can access a full list of arguments available for use in `AssetProcessorPlatformConfig.ini`. To access a full list of arguments available for the `rc.exe` command line tool:

1. Open a command line.
2. Navigate to the `\lumberyard_version\dev\Bin64vc141\rc` directory.
3. Enter the following command:
   
   ```
   rc /help
   ```

   To output the help text to a file, enter the following command:

   ```
   rc /help >file.txt
   ```

**Debugging Asset Processor**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. **Download O3DE** or visit the **AWS Game Tech blog** to learn more.

Use the following options to help debug Asset Processor issues.
Topics

- Viewing Asset Processor Log Files (p. 266)
- Restarting Asset Processor (p. 267)
- Using Asset Builder (p. 267)
- Using the Microsoft Child Process Debugging Power Tool (p. 268)
- Debug Asset Builders from Asset Processor (p. 269)
- Clearing the Cache (p. 269)

Viewing Asset Processor Log Files

You can view logs for internal operations of Asset Processor. If Asset Processor isn’t processing or working as expected, use the information in the logs to debug the issue. This doesn’t include logs for the processing of individual assets.

To view the Asset Processor log files

1. In Asset Processor, choose Logs.
2. In the Logs section, you can view the following:
   - Status – The date and time stamp of the log
   - Source – Where the log came from (for example, Asset Processor)
   - Message – The description of the log

Example

3. To create another log report, click Add.
4. In the Create New Logging Tab, you can specify the following settings.
   - Filter name – Enter the name of your filter (for example, All logs).
   - Text filter (optional) – Enter text to filter the log results.
   - Show messages – Displays messages about each log.
   - Show warnings – Displays logs that have warnings.
   - Show errors – Displays logs that have errors.
   - Show debug – Displays logs that have debug issues.
5. Click OK. Your log report appears as another tab in Asset Processor.
6. You can click Copy all and paste the raw logs into a text file.
7. You can also click Open log files to open \lumberyard_version\dev\Bin64vc141\logs\JobLogs directory.
8. In a text editor, open the example.log file.

### Restarting Asset Processor

You can restart Lumberyard Editor and Asset Processor. Verify that only one instance of Asset Processor runs at the same time.

**To restart Asset Processor**

1. Close Lumberyard Editor.
2. In the Windows taskbar, right-click Asset Processor, and choose Quit or press Ctrl+Q.
3. Restart the project or branch that you are working on. Asset Processor automatically starts.

### Using Asset Builder

You can also debug Asset Processor using Asset Builder. This is a standalone AzToolsFramework application that lets you run BuilderSDK modules in isolation. You can run AssetBuilder in debug mode to develop new features for a builder. In debug mode, Asset Builder creates a test job or processes jobs for specified files.

**Note**

You must start Asset Processor before you can enter a -debug command.

**To debug Asset Processor using Asset Builder**

1. Navigate to the \lumberyard_version\dev\Bin64vc141 directory.
2. In a command line prompt, enter the following command to get a list of possible options.

   ![AssetBuilder.exe -help](AssetBuilder.exe -help)

3. You can use the following debug options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-debug</td>
<td>Creates and processes jobs for the specified file.</td>
</tr>
</tbody>
</table>
Using Asset Processor

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-debug_create</td>
<td>Creates, but doesn't process jobs for the specified file.</td>
</tr>
<tr>
<td>-debug_process</td>
<td>Processes, but doesn't create jobs for the specified file.</td>
</tr>
<tr>
<td>-output</td>
<td>The directory to write the result to. If you don't specify the directory,</td>
</tr>
<tr>
<td></td>
<td>the default directory is Debug*filename in the builders binary directory.</td>
</tr>
<tr>
<td>-input</td>
<td>If you enable debug mode using the -task option, you must use -input with</td>
</tr>
<tr>
<td></td>
<td>the specified file.</td>
</tr>
<tr>
<td>-tags</td>
<td>The list of additional tags to append to the platform tag list. You can use</td>
</tr>
<tr>
<td></td>
<td>tags to replicate the same list of platform tags that the source asset uses</td>
</tr>
<tr>
<td></td>
<td>in the normal Asset Processor workflow.</td>
</tr>
</tbody>
</table>

**Example**

To debug a specified file, run the following command.

```
AssetBuilder.exe -debug Objects\Tutorials\Fbx\shapes.fbx
```

**Example**

To create a job without processing a specified file, run the following command.

```
AssetBuilder.exe -debug_create "Objects\Tutorials\Fbx\shapes.fbx" -module "C:\lumberyard_version\dev\Bin64vc141.Debug\Builders\ExampleBuilder.dll" -output "C:\lumberyard_version\dev\Logs\Shapes\"
```

**Example**

To process without creating a job for a specified file, run the following command.

```
AssetBuilder.exe -debug_process "Objects\Tutorials\Fbx\shapes.fbx"
```

**Using the Microsoft Child Process Debugging Power Tool**

Use this tool to automatically attach the debugger to spawned child processes.

**To use the Microsoft Child Process Debugging Power Tool**

1. Go to the download page, and click Download.
2. Install the tool for Visual Studio.
**Debug Asset Builders from Asset Processor**

Use the following procedure to debug in the following scenarios:

- Debug intermittent failures that are difficult to reproduce in a single run of Asset Builder using the –debug option
- Debug failures that only occur in multiple process job requests

**To debug Asset Builders from Asset Processor**

1. Navigate to the `lumberyard_version\dev` directory.
2. In a text editor, open the `AssetProcessorPlatformConfig.ini` file and set `maxjobs=1`. This limits Asset Processor to run one job at a time.
3. Run Asset Processor so that it spawns the Asset Builder process.
4. To debug, attach the `AssetBuilder.exe` in Visual Studio. There is only one Asset Builder.
   
   The next time that you modify your source file, `AssetBuilder.exe` builds that asset.

**Tip**

You can spawn multiple instances of `AssetBuilder.exe` and attach them to Visual Studio.

**Clearing the Cache**

If you're a game artist and you're having issues running Asset Processor, this might be the result of a corrupt cache. In this case, you can delete your `Cache` directory. When you delete your cache, you can restart Asset Processor to rebuild all of your assets.

**Note**

- If you're an engineer making new BuilderSDK-based builders, we recommend that you don't delete your cache.

**To delete the Asset Processor cache**

1. Quit Asset Processor.
2. Navigate to the `lumberyard_version/dev/Bin` directory.
3. Delete the `Cache` directory.
4. Restart Asset Processor to rebuild all assets.

**Configuring the Asset Pipeline**

**Important**

The Asset Builder SDK is now preferred over the legacy `rc.exe` program for adding asset types to the pipeline. Instead of using the `rc.exe` program, make a builder module that you derive from the BuilderSDK. These modules are self configuring. For instructions and examples on how to write builders that process your own asset types, see the [Creating a Custom Asset Builder (p. 318)](#). We recommend that you do not rely on the old `rc.exe` pipeline, although it's still available if you have legacy code.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.
You can configure the Lumberyard asset pipeline by editing the `\dev\AssetProcessorPlatformConfig.ini` file that rc.exe program uses. You can add your own asset types to it by modifying the sections of the file described in this document. When you check in your changes to the config file, the version of the assets on your collaborators’ computers is updated automatically. This removes the need for you to manually refresh the cache on each coworker’s computer.

The `AssetProcessorPlatformConfig.ini` consists of six sections. The `.ini` file uses standard Qt/Windows `.ini` file formatting rules. Comments are preceded by a semicolon, and named sections are designated by square brackets.

**Important**

Backslashes in `.ini` files have a special meaning. To use a regular backslash character, you must prefix it with another backslash. To avoid problems with file paths, the asset processor and asset pipeline use forward slashes for path names. However, if you need to use backslashes in regular expressions, you must also escape them so that they can be recognized by the regex system. For example, you must specify the regular expression `.*/\Levels\).* like this:

```
.*\/\Levels\\/\.*
```

In addition to the `AssetProcessorPlatformConfig.ini` file (located in the `/lumberyard_version/dev` directory), you can also add the following:

- `AssetProcessorGamePlatformConfig.ini` – Add this file to your game project folder to override any configurations that are specific to a project. The final configuration is the result of merging both files. The `AssetProcessorGamePlatformConfig.ini` file is read last and therefore takes priority.
- `AssetProcessorGemConfig.ini` – Add this file to the gem folder to allow your enabled gem to affect the asset processor configuration. The impact is similar to editing the root file but without making permanent changes to the root file. For example, you can add an `AssetProcessorGemConfig.ini` file for the Cloud gem to the `/lumberyard_version/dev/Gems/Clouds` directory.

The final configuration is the result of merging the following files in order:

- `dev/AssetProcessorPlatformConfig.ini`
- `dev/Gems/GEM_NAME1/AssetProcessorGemConfig.ini`
- `dev/Gems/GEM_NAME2/AssetProcessorGemConfig.ini`
- `dev/Gems/GEM_NAME3/AssetProcessorGemConfig.ini`
- `your_project_folder/AssetProcessorGamePlatformConfig.ini`

**Platforms Section**

The `Platforms` section contains two subsections:

- **Platform Definition** – Defines which platforms exist when you use the `[Platform platformName]` section header.
- **Platforms** – Defines which of the platforms are enabled by default in your project.

**Platform Definition Subsection**

Use the following subsections to define an operating system and its attributes. The name of the operating system appears in the section header, for example, `pc` or `ios`.

```
[Platform pc]
tagstoools,renderer
```
You can define the tags attribute and assign tags to an operating system. This allows you to control behavior based on the tags. For example, you can choose to compile textures on all operating systems with the mobile tag rather than naming operating systems individually. Should you add mobile operating systems to your configuration, you can use the mobile tag to include them when modifying behavior. This removes the necessity of recompiling and modifying all rules and builders to include the new operating systems.

**Platforms Subsection**

Use the Platforms subsection to enable and disable operating systems for the entire project. Note that "disabling" means that the game project does not use the specified operating system. When you disable an operating system, the related assets are removed, and the associated space on your hard drive is freed up.

In the following example, PC is enabled and other operating systems are commented out.

```
[Platforms]
pc=enabled ;es3=enabled ;ios=enabled ;osx_gl=enabled
```

Because the default value for an operating system is disabled, the operating systems in the example that are commented out are not enabled.

If you want to enable an operating system that is already listed in the [Platforms] subsection, remove the semicolon to uncomment the corresponding line.

If an entry for a game operating system that you want is not in the list, you can add it. However, you must also handle OS-related differences like image formats. To do so, you must change the code in the asset processor (and possibly the image compiler and other builders).

If you are using the rc.exe pipeline, specified operating systems are passed as parameters to the rc.exe program.

The operating system that Lumberyard runs on is enabled by default, so you can leave that line commented out. For example, if Lumberyard runs on Mac, you can leave the osx_gl=enabled line commented out.

If you run AssetProcessor.exe or AssetProcessorBatch.exe on a build server, you can use the following command line parameter to specify which operating systems to enable: /platforms=comma-separated-list

Using this command line parameter enables only the specified operating systems, regardless of the host platform that runs the tools.

You can specify tags for the platforms command line parameter, for example:

```
AssetProcessorBatch.exe /platforms=tools,es3
```

**Jobs Section**

Use the Jobs section to control how many parallel jobs to run, as in the following example.

```
; ---- The number of worker jobs, 0 means use the number of logical cores
[Jobs]
```
minJobs=1
maxJobs=0

Setting `maxJobs` to zero specifies using as many cores as are available. A number other than zero limits the cores used to no more than the number that you specify.

**MetaDataTypes Section**

Use the `MetaDataTypes` section to tell the asset system that certain file types are associated with other files in the same folder. These specifications control the compilation of side-by-side assets, as in the following example.

```plaintext
[MetaDataTypes]
eventsettings=
animsettings=i_caf
Animations/SkeletonList.xml=i_caf
cbc=abc
fbx.assetinfo=fbx
```

Entries on the left and right sides of the equals sign specify file extensions of asset files in the same folder. If a file with the extension on the left changes, then the file with the extension on the right must also be rebuilt if it has the same filename. For example, the line `animsettings=i_caf` means that if a file called `example.animsettings` changes, `example.i_caf` will be recompiled.

The line `exportsettings=` means that when any file with the extension `.exportsettings` changes, any asset file that has the same filename as the file with the `.exportsettings` extension is invalidated. For example, a change in the `MyImage.TIF.exportsettings` file invalidates the `MyImage.TIF` file.

In the example `Animations/SkeletonList.xml=i_caf`, the left side specifies not an extension, but a specific file. Whenever the `Animations/SkeletonList.xml` file changes (note that the forward slash indicates a directory path), all files with the extension `.i_caf` are invalidated.

**Note**

If you use the Asset Builder SDK, you can declare your dependencies on other files explicitly. This makes the `[MetaDataTypes]` section less important.

**ScanFolder Section**

Use the `ScanFolder` section to direct the Asset Processor to monitor the assets in specific folders. The following example directs the Asset Processor to monitor the `Editor` folder.

```plaintext
[ScanFolder Editor]
watch=@ROOT@/Editor
output=editor
recursive=1
order=30000
```

You can add as many scan folders as you want, but each folder must have a unique name. Because the scan folders are stored in a hash table using the name specified in square brackets, make sure that the name following `ScanFolder` is unique.

You can use the aliases `@root@` and `@gamename@` as placeholders to enable portability to the computers of other users who are working on the same project.

To make the scan folder OS-specific, use the keywords `include` and `exclude`. Both keywords can contain platform tags and/or platform identifiers. If you do not specify a keyword, all enabled operating systems are included by default.

The `ScanFolder` section has the following parameters.
### Configuring the Asset Pipeline

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>watch=&lt;foldername&gt;</td>
<td>Watch this specific folder for assets.</td>
</tr>
<tr>
<td>output=&lt;foldername&gt;</td>
<td>Put the contents of this watch folder into the subfolder of the @assets@ folder called &lt;foldername&gt;.</td>
</tr>
<tr>
<td>recursive=1</td>
<td>Recurse into subfolders.</td>
</tr>
<tr>
<td>order=30000</td>
<td>Declares a priority order. The lower the number, the more &quot;important&quot; a folder is. The game folder for your project is always considered 0, the most important.</td>
</tr>
</tbody>
</table>

**Note**

The *order* parameter affects only assets with the same name. For example, suppose you have an asset called MyTexture.TIF in two separate scan folders. If both asset files map to the same output file, then the asset file with the lower order number overrides the one with the higher.

| include=<comma-separated platform tags or identifiers> | Contains the list of platforms or platform tags to include for the scan folder. Only enabled platforms are included. If you include a disabled platform, it will not be considered for the scan folder. |
| exclude=<comma-separated platform tags or identifiers> | Contains the list of platforms or platform tags to exclude for the scan folder. |

### Notes

- In most cases, you do not need to specify an output folder. The output folder remaps source folders into subfolders of the cache. Usually folders that contain assets go into the cache directly, without requiring a subfolder.
- It is not considered an error if a scan folder is missing. This behavior is by design because it lets you have optional folders for assets. For example, this might be useful for test cases.
- Removing folders from the ScanFolder sections removes any corresponding assets from the cache. If the assets specified were overriding other assets, the overridden assets are reinstated and become primary assets again.

### Exclude Section

Use the Exclude section to add file path patterns to ignore. As in the rest of the ini file, backslashes must be prefixed with an extra backslash to escape them from .ini file processing.

The following example excludes alembic compression templates and temporary animation compression files.

```ini
[Exclude AlembicCompressionTemplates]
pattern=.*Presets\/GeomCache\/.*

[Exclude TmpAnimationCompression]
pattern=.*Editor\/Tmp\/AnimationCompression\/.*
```

### Notes
- The regular expressions are standard `STD::regex` in extended format. Standard `STD::regex` rules apply.
- The input paths are always absolute paths. If you don't want to filter by absolute path, start your regular expressions with `.*`, as in the example.
- If you want to add new exclude rules, give them a unique name. The actual name does not matter as long as each is unique.

**RC Section**

Use the RC section to specify files to be processed by the `rc.exe` program or to be copied as-is into the asset cache without processing. The RC section is only for use by legacy RC modules and for specifying simple file copies to cache.

The RC section consists of a series of recognizer descriptors. Each descriptor specifies a set of files (by glob or by pattern) and what to do with the specified files. Changing the fields of the recognizer invalidates assets according to the change made.

**Important**

Because they do not use the legacy `rc.exe` program, builders implemented as builder modules do not use the RC section. Instead, they derive their configuration programmatically or read it from a custom config file. If you create your own BuilderSDK builder, do not add anything to the RC section.

The following code block shows the syntax of the RC section.

```
[RC (recognizer name)]
; ---- Choose either pattern or glob. You cannot choose both.
pattern=(pattern to use to recognize these files)
glob=(glob to use to recognize these files)
(params)=command line params/copy/skip
(platformname)=(params)
lockSource=(true/false)
priority=(0...n); Higher numbers are more important.
critical=(true, false)
version=(0...n)
```

The following table describes each parameter and its options.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pattern</td>
<td>A regular expression that specifies the files to process. When you use regular expressions, remember to escape any backslashes.</td>
</tr>
<tr>
<td>glob</td>
<td>A wildcard expression like <code>*.tif</code> that specifies binary glob files to process.</td>
</tr>
<tr>
<td>params</td>
<td>The <code>params</code> parameter can take one of the following three options.</td>
</tr>
<tr>
<td></td>
<td>1. The default parameters to pass to the <code>rc.exe</code> program to process the kind of asset specified.</td>
</tr>
<tr>
<td></td>
<td>2. <code>copy</code> – Copies the file as-is into the cache. It does not invoke <code>rc.exe</code>.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> Copy jobs are the most common type of job. For example, in the <code>dev \assetprocessorplatformconfig.ini</code> file that is included with Lumberyard, most <code>[RC]</code> sections specify <code>params=copy</code>.</td>
</tr>
<tr>
<td></td>
<td>3. <code>skip</code> – Skips the specified file type entirely. The <code>skip</code> option is typically more useful in the <code>platformname</code> parameter.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>If you omit the params, platform params, or tag params sections, the <code>rc.exe</code> program processes the file using default options. To process the file on specific operating systems, set the <code>params</code> parameter to <code>skip</code> and then specify the desired platforms.</td>
<td></td>
</tr>
<tr>
<td>If you pass parameters to the <code>rc.exe</code> program, you can pass <code>p</code> (as in <code>/p=pc</code>) to force the program to process the asset as if it were the PC. You can pass the appropriate parameter for the desired platform.</td>
<td></td>
</tr>
<tr>
<td><code>(platformname)=(params)</code></td>
<td>Specifies OS-specific parameters. You can use the <code>params</code> parameter to specify default parameters, and then override them for specific operating systems when required by using <code>platformname=params</code>. For example, the statement <code>pc=/TEST</code> overrides the default parameters for PC and passes the parameter <code>/TEST</code> to the <code>rc.exe</code> program. Can be <code>true</code> or <code>false</code>. When <code>true</code>, causes the job to wait until it can gain an exclusive read/write lock on the source file.</td>
</tr>
<tr>
<td><code>(tagname)=(params)</code></td>
<td>Specifies tag-specific parameters, which are generally better than platform-specific parameters. For example, the following statement causes all platforms to use the default parameters when processing <code>.tiff</code> files. However, a platform with the <code>server</code> tag is skipped.</td>
</tr>
<tr>
<td><code>server=/p=pc</code></td>
<td>The following statement passes <code>/p=pc</code> to invocations of the <code>rc.exe</code> program: <code>server=/p=pc</code>. This allows the program to process assets (such as textures) as if it were the PC, even on the server. The default behavior is to pass <code>/p=server</code>, which the <code>rc.exe</code> program may not understand. The <code>lockSource</code> parameter is useful for dealing with applications that hold onto a file and then slowly stream data into it. For example, if a program creates very large files over a long period of time, you can set <code>lockSource=true</code> to avoid processing an asset until the other application releases it. Use of this parameter is relatively rare and is generally expensive, so you should avoid using it unless absolutely required.</td>
</tr>
<tr>
<td><code>priority</code></td>
<td>Specifies job priority. A larger number gives a job greater priority in the queue. Normally, you should assign a larger number to assets that are likely to be needed from the start or that affect gameplay. This ensures that they get compiled sooner. Note params copy jobs have an default priority of 1.</td>
</tr>
</tbody>
</table>
### Configuring the Asset Pipeline

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| critical  | Can be true or false. Critical jobs cause the editor splash screen to continue displaying and pause the startup of the runtime until every critical job has been completed. Marking jobs as critical ensures they are complete before the editor is allowed to start. You can specify entire types of assets as critical. This can be useful for files that are used during startup, cause bad behavior if they are not ready during bootstrap, or cannot be reloaded live. **Important** Because critical jobs can delay the startup of the editor for the first time, not having critical jobs is always the preferred choice. Alternative approaches include:  
  • Making the editor or runtime capable of reloading the asset live after it is compiled.  
  • Making a call to compile the asset on demand using the asset system bus. You can use the public function CompileAssetSync to do this. See the Lumberyard source code for examples.  

  **Note** params copy jobs are critical by default.  
| version   | An arbitrary versioning number. The default is 0. Changing the version number invalidates the assets specified and causes them to be rebuilt. The version parameter provides a convenient way to cause a rebuild of all assets of a particular kind. For example, you might make changes to the compiler that builds a particular kind of asset. Then, when you check in your changes to the .ini file, local assets of workers receiving the update are rebuilt for them automatically.  

The following example specifies how .tiff files are to be processed.

```ini
[RC tif]
pattern=.*\.tiff?
params=/imagecompressor=CTSquish /streaming=1
es3=/imagecompressor=CTSquish /streaming=0
ios=/imagecompressor=CTSquish /streaming=0
; Streaming = 1 splits files.
lockSource=true
```

The example has the following characteristics.

- It declares a recognizer called tif (because [RC tif] is the name).
- The pattern specifies all files which match the regex expression .*/\.tiff?. Note that the example escapes the backslash.
- The params parameter specifies the default parameters with which to invoke rc.exe. In the example, .tiff files will be compiled into the /imagecompressor=CTSquish /streaming=1 format.
- For ES3 and iOS, streaming is turned off, overriding the default that was specified in the params parameter.
- lockSource is set to true to avoid conflict with external tools that create a zero byte file, pause for many seconds, and then fill it with data.
The following example specifies how .tiff files in the GoldenImages subfolder are to be processed.

```ini
; Feature tests use the raw .tif files for the golden image comparison.
[RC goldenimages]
pattern=.*GoldenImages\/*.\*.tif
params=copy
```

The example has the following characteristics.

- It declares a recognizer called goldenimages which applies to any .tiff file in the GoldenImages subfolder.
- The params parameter specifies copy, so any .tiff file in the GoldenImages subfolder is copied to the cache without processing.

**Notes**

The two example RC sections are both in the same file. This has the following important consequences:

- The multiple rules that match the files all apply simultaneously. They are not exclusive. If you have two rules that apply to the same file, both rules are run. For example, the rules in the two examples would both apply to a file called \dev\SamplesProject\textures\GoldenImages\myfile.tif. The rules would produce both a .dds compressed version of myfile.tif and an uncompressed myfile.tif file that is copied into the cache.
- If you want to specify an exclusive subfolder rule, you must use inverse regex selectors to create exclusion patterns.

The following example shows a set of rules that apply exclusively to .png files. The two rules are written so that any .png file matches only one of the rules.

```ini
;Example: Use the specified parameters to process all .png files except those in the libs/ui folder.
[RC png-normal]
pattern=(?!.*libs\/ui\/).*\.png
params=/imagecompressor=CTSquish /streaming=0
lockSource=true

;Example: Process all .png files in the libs/ui folder using linear color space.
[RC png-ui]
pattern=(.*libs\/ui\/).*\.png
params=/imagecompressor=CTSquish /streaming=0 /colorspace=linear,linear
lockSource=true
```

For more examples, see the default \dev\AssetProcessorPlatformConfig.ini file.

**Common Problems**

When troubleshooting, be aware of the following pitfalls.

- Not escaping your regular expressions with two backslashes. Remember that one of the slashes is removed when the .ini file is processed.
- Duplicating a rule without changing its name. The rule [RC png] has a name of png. These names are inserted into an unordered hash. If you specify another section with the name of png, the second section overwrites the other in random order. This behavior is by design. For example, you can use it to allow your game version of the .ini file to override particular sections or specify skip to skip them. Otherwise, if you want to add new rules, give them a unique name. The actual name does not matter.
as long as each is unique. This is especially true for named sections like the Exclude and ScanFolder sections.

- Not understanding that all recognizers that match apply, not just the first one.
- Forgetting to prefix your regular expressions with .*. By default, the input files that you specify are considered absolute paths. This behavior is by design because it lets you exclude or include files based on absolute paths, if that is your intent. Use the .* prefix if you want to use relative paths.

### Configuring Image Processing

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Images or textures are automatically processed by Asset Processor, which makes them ready for Lumberyard game creation. When you place an image file anywhere within your Lumberyard directory, Asset Processor detects and converts the file to a game-ready asset. Lumberyard has several configuration files that specify settings for the conversion process, such as the colorspace to use, texture size, whether to generate mip maps (p. 286), and so on.

You can edit the configuration files (p. 280) to create your own image processing presets. To use these presets, you append existing or customized suffixes to your image file names. Based on these file name suffixes, Asset Processor automatically uses the appropriate preset to convert the image.

After Asset Processor successfully converts the image, the resulting .dds asset is placed in the appropriate lumberyard_version\dev\Cache directory. The image source file remains in its original form and location.

Asset Processor calls the Resource Compiler, rc.exe (located in lumberyard_version\dev\Bin64vc141\rc), to convert the image files. Resource Compiler also has an image tool (p. 283), which you can use to manually select image presets, mip maps, and so on. The Resource Compiler image tool can also output an imagefilename.exportsettings, which you must check in if your project uses source control such as Perforce. Checking in the .exportsettings file ensures that the texture renders similarly for each person working on the project.

Lumberyard supports the following image file types:

- TIFF – No grayscale
- TGA – Indexed or true color only; no grayscale
- PNG – RGB or RGBA only; no grayscale
- BMP – Any format
- GIF – Supported, but not an ideal texture format
- JPG – Any format

The following diagram represents the general workflow for converting images.
Topics
• Creating Image Processing Presets (p. 280)
Creating Image Processing Presets

Lumberyard contains an existing set of image processing presets. You apply these presets on your source image file names before you add them in your Lumberyard directory for processing. Based on the appended suffix for the file name, Asset Processor converts them into .dds files with specific settings and adds them to the `lumberyard_version\dev\Cache` directory.

You can define presets in two ways:

(Recommended method) **ImageCompiler.cpp and rc.ini**

The `ImageCompiler.cpp` file contains the code that finds a file name suffix match, and points to another file for the specific settings. The `rc.ini` file defines those specific settings for the matched suffix.

**AssetProcessorPlatformConfig.ini**

The `AssetProcessorPlatformConfig.ini` file matches file name suffix patterns and then calls functions to process the file based on its matches.

Topics

- Creating Presets with ImageCompiler.cpp and rc.ini (p. 280)
- Creating Presets with AssetProcessorPlatformConfig.ini (p. 282)

Creating Presets with ImageCompiler.cpp and rc.ini

The following snippet is from `ImageCompiler.cpp`, located in the `lumberyard_version\dev\Code\Tools\RC\ResourceCompilerImage` directory. Part of this code finds file names appended with `_bump`, and then calls the `presetName` function `defaultBump`, which derives its settings from `NormalsFromDisplacement` (defined in `rc.ini`).

```cpp
... static string AutoselectPreset(const ConvertContext& CC, const uint32 width, const uint32 height, const bool hasAlpha) {
    const char* const defaultColorchart = "ColorChart";
    const char* const defaultBump = "NormalsFromDisplacement";
    const char* const defaultNormalmap = "Normals";
    ...
    const string fileName = CC.config->GetAsString("overwritefilename", CC.sourceFileNameOnly, CC.sourceFileNameOnly);
    string presetName;
    if (SuffixUtil::HasSuffix(fileName.c_str(), '_', "cch"))
    {
        presetName = defaultColorchart;
    }
    else if (SuffixUtil::HasSuffix(fileName.c_str(), '_', "bump"))
    {
        presetName = defaultBump;
    }
...```
Configuring Image Processing

```cpp
else if (SuffixUtil::HasSuffix(fileName.c_str(), '_','ddn'))
{
    presetName = defaultNormalmap;
}
...
```

The `rc.ini` file (located in the `lumberyard_version\dev\Bin64vc141\rc` directory) contains the following setup information:

- Asset presets for operating systems.
- Image preset aliases (profile mapping from a legacy preset).
- Image format settings, such as compression method, pixel format, and so on.
- Mip map settings.
- Naming convention presets: Image suffixes such as `_diff`, `spec/refl`, `_disp`, `_ddna`, `_ddn`, `_bump`, `cm/cubemap`, `detail`, and so on.

**Example**

The following snippet from the `rc.ini` file defines `NormalsFromDisplacement`. It includes pixel formats for each operating system, maximum texture size, mip map settings (p. 286), colorspace, and so on.

```ini
... ; converts greyscale texture to normal map, normal map textures (signed BC5)
[NormalsFromDisplacement]
pixelformat=BC5s
;pixelformat:es3=ASTC_5x5
;pixelformat:es3=EAC_RG11
;pixelformat:ios=PVRTC4
pixelformat:ios=EAC_RG11
maxtexturesize:es3=1024
maxtexturesize:ios=1024
bumpertype=1
powof2=1
mipnormalize=1
mipmaps=1
mipgentype=average
colorspace=linear,linear
filemasks=_bump*
...
```

You can edit `ImageCompiler.cpp` and `rc.ini` to add your own image presets.

**To add your own image processing presets**

1. In a text editor, open `ImageCompiler.cpp`, located in the `lumberyard_version\dev\Code\Tools\RC\ResourceCompilerImage` directory.
2. Specify the appropriate lines of code to define your new preset.
3. Save and close `ImageCompiler.cpp`.
4. In a text editor, open `rc.ini`, located in the `lumberyard_version\dev\Bin64vc141\rc` directory.
5. Add your new definition.
6. Specify the settings for the new definition.
7. Save and close `rc.ini`. 

Version 1.28
281
Example

If you want to add a line of code that searches for file names that end in `_awesome`, you might add the following lines to your `ImageCompiler.cpp`.

```c++
const char* const defaultAwesomeSuffix = "AwesomeImage";
```

Example

```c++
else if (SuffixUtil::HasSuffix(fileName.c_str(), '\', "awesome"))
{
    presetName = defaultAwesomeSuffix;
}
```

You would also add to a definition of `AwesomeImage` to the `rc.ini` file.

Example

```
[AwesomeImage]
pixelformat=BC1
pixelformat:es3=ETC2
pixelformat:ios=FVRTC2
;pixelformat:es3=ASTC_4x4
;pixelformat:ios=ASTC_6x6
rgbweights=ciexyz
pwof2=1
mipmaps=1
colorspace=sRGB,auto
discardalpha=1
filemasks=_*_awesome*
```

Creating Presets with `AssetProcessorPlatformConfig.ini`

You can also add presets in the `AssetProcessorPlatformConfig.ini` file, located in the `lumberyard_version\dev` directory.

Example

The following snippet from `AssetProcessorPlatformConfig.ini` shows two rules, both of which match a file that ends in `_awesome.tif`. The image is processed for each rule that it matches. In this example, multiple results (assets) would be produced for each image.

```ini
...[RC uitextures]
pattern=.*\.(bmp|gif|jpg|jpeg|tga|png)
params=/imagecompressor=CTSquish /streaming=0
lockSource=false
server=skip
...

...[RC special images]
pattern=.*(_awesome)\.tif?
...
```

To add image processing presets

1. In a text editor, open the `AssetProcessorPlatformConfig.ini` file, located in the `lumberyard_version\dev` directory.
2. Specify the appropriate lines of code to define your new preset.
3. Save and close the file.

Using Image Naming Conventions

You can use any existing or created image processing presets (p. 280). To do this, append the suffix to the end of the file name before you add it to your Lumberyard directory.

Example

If you create an image that you want to use as a decal, add the _decal suffix to the file name before the extension. For example, to convert scorchmark.tif as a decal, rename it to scorchmark_decal.tif. You then add it to your Lumberyard directory, so that Asset Processor automatically processes the file.

There are a number of existing presets that you can use. For a full list, see the rc.ini file in the lumberyard_version\dev\Bin64\vc141\rc directory.

Some of the existing presets include the following:

- _diff – Albedo
- _spec, _refl – Specular textures
- _ddn – Normal map texture
- _ddna – Normal map texture with smoothness in alpha
- _bump – Converts grayscale texture to normal map
- _displ – Displacement map
- _decal – Decal
- _detail – Merged detail maps
- _cm, _cubemap – HDR reflection textures
- _cch – Color chart
- _mask – Grayscale mask
- _sss, _trans, _opac – Opacity

Using the Resource Compiler Image Tool

Before you can use the Resource Compiler image tool, you must install RC Shell Commands.

Note
You can also use the Texture Settings Editor to manage your texture settings for image files. For more information, see Texture Settings Editor (p. 1734).

To install RC Shell Commands

1. Open Lumberyard Setup Assistant (p. 16).
2. On the Install plugins page, click Install.
Once you install the RC Shell Commands, you can use the Resource Compiler image tool.

**To open the Resource Compiler image tool**

- Right-click an image file from within a file explorer and choose **RC Open Image**.

![RC Open Image](image)

The Resource Compiler image tool lists image processing presets defined in the `rc.ini` file, located in the `lumberyard_version\dev\Bin64vc141\rc` directory. Select a preset to create the `imagefilename.exportsettings` file that you can check in to your source control.

**To select an image processing preset and save it to an .exportsettings file**

1. In the Resource Compiler image tool, under **Preset**, select a preset from the drop-down menu.
2. (Optional) To see more information about the preset settings, click **Show preset info**.
3. Select other options you want to change, such as **MIP Control (p. 286)**.
4. Click **Generate Output**.

Your `imagefilename.exportsettings` file and the resulting `imagefilename.dds` output is saved in the same directory as your source image.
Generating Mip Maps

Mip maps are a sequence of optimized images made from one image. Each image is lower in resolution than the previous image by a power of two. Mip maps reduce the time and processing power it takes to render an image in a game. Lower resolution mip maps are used when the viewing distance is great enough that the loss of detail is not noticeable. Higher resolution mip maps are used when an object is close to the camera and needs to be displayed in detail.

When you enable mip maps in Lumberyard, Resource Compiler automatically generates six mip maps for that image. The largest mip map is the original size of your image, and each progressive mip map is smaller by a power of two.

Example

If your original image is 1024x1024, then you will have mip maps that are 1024x1024, 512x512, 256x256, 128x128, 64x64, and 32x32.
Example

If your original image is 4096x4096, then you will have mip maps that are 4096x4096, 2048x2048, 1024x1024, 512x512, 256x256, and 128x128.

Note

For most of the existing presets, mip maps are enabled by default. If you create your own presets, you must enable mip maps.

If mip maps are not enabled, then on the MIP Control tab, under Mip maps, none (0) appears.
To enable mip maps for an image processing preset

1. In a text editor, open the rc.ini file, located in the lumberyard_version\dev\Bin64vc141\rc directory.
For more information, see Creating Image Processing Presets (p. 280).

2. Add `mipmaps=1` to the definition.

**Example**

```xml
...[
    AwesomeImage]
    pixelformat=BC1
    pixelformat:es3=ETC2
    pixelformat:ios=PVRTC2
    ;pixelformat:es3=ASTC_4x4
    ;pixelformat:ios=ASTC_6x6
    rgbweights=ciexyz
    powof2=1
    mipmaps=1
    colorspace=sRGB,auto
    ;discardalpha=1
    filemasks=*_awesome*
...```

To disable mip maps, specify `mipmaps=0`.

**Adjusting Alpha Test on Mip Maps**

You can adjust the Alpha Test value for each mip map in the MIP Control tab of the Resource Compiler image tool.

**To adjust Alpha Test for each mip map**

1. For each mip map, adjust the sliders or enter a number in the box.
2. Select **Maintain alphatest coverage** to maintain shape and opacity from a distance when working with certain types of objects, such as leaves on a tree. If you don't select this option, the tree leaves may lose their silhouette in the lower resolution mip maps.
Configuring Image Processing

### MIP Control

- **Mip maps:**
  - Max, tiled (1)
- **AlphaTest adjustment:**
  - Mip1: 50
  - Mip2: 50
  - Mip3: 50
  - Mip4: 50
  - Mip5: 50
  - Mip6: 50
- **Filter scale:** 0

### Preset (defined in rc.ini)

- **List all presets:**
  - AlbedoWithGenericAlpha
- **Show preset info...**

### Preview

- **On**: Toggle preview mode.
- **Zoom In**, **Zoom Out**: Adjust zoom level.
- **Tiled**, **Bilinear**: Select preview mode.
- **RGB**: Normal RGB preview mode (no gamma correction).

### Resolution

- **1024x1024 Fmt:A8R8G8B8 Alpha:8**

Version 1.28

290
Live Reloading and VFS

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

On the PC platform, live reloading does not require virtual file system (VFS), since the PC that is running the game is presumably also running the Asset Processor.

On non-PC platforms, VFS is required for live reloading to work, because otherwise assets would need to be deployed onto the game device as part of live reloading, incurring platform-specific costs and different asset pipelines. VFS enables the same behavior across all platforms using the same workflow. For debugging purposes, you can also enable VFS on a PC and point it at a remote Asset Processor to serve assets.

To enable VFS, you use the `bootstrap.cfg` configuration file.

The game runtimes and all tools can communicate with the Asset Processor through simple interfaces. Communication involves the following:

- Notification when assets are built and change, so as to reload them if possible.
- Request an immediate compilation of an asset, blocking until processing has completed.
- Request asset status, blocking until the status is known.
- Query the location of an asset source file, given an asset ID.
- Query the destination asset ID, given an asset source file name and path.

Not all asset types can live reload. If you are developing new asset types, keep the following guidelines in mind:

- When an asset loads, be prepared to substitute it for a temporary asset while it is compiling.
- If an asset is missing, query the status of the asset from the Asset Processor. This can determine whether the asset really is missing or whether it is in the queue for processing. Querying also moves the asset to the front of the queue for processing.
- If your asset is essential and it cannot live reload, use the blocking synchronous asset build request to make it build immediately. This moves the asset to the front of the queue and prevents the call from returning until the asset is compiled.
- Do not discard the original requested name when an asset is missing.
- Connect to the notification bus to learn when assets change and reload them when that happens.

Compiling Shaders for Release Builds

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

If you build game projects with Lumberyard, shaders for release builds should be compiled and packaged into .pak files.

**Mobile devices** – On mobile devices, runtime shader compilation is not supported for release builds. Shaders will compile at run time only if you are running in profile mode or debug mode and can connect to a remote shader compiler server (p. 1645). For more information, see the following:
• Connect to the Shader Compiler (p. 3176)
• Creating a Release App (p. 3204)
• Running the Shader Compiler on Amazon EC2 (p. 3239)

**macOS** – On macOS, the shader compilation pipeline depends on the High-Level Shader Language (HLSL) optimizer. You must connect to a shader compiler on your PC or macOS when running a game on macOS during development. This compiles the required subset of shaders for your game, on demand. For more information, see Building Shaders for macOS Games (p. 3265).

**Windows DirectX** – On Windows builds that use the DirectX module, runtime shader compilation is supported for release builds. However, it is highly recommended that you compile shaders into .pak files for performance reasons. Compiling shaders at run time can cause unwanted frame rate fluctuations. In addition, objects that use shaders compiled at run time may fail to appear until the shaders are successfully compiled.

The following shader .pak files are required for release builds:

- **Shaders.pak** – Required only if you want to support runtime compilation. Source shaders are located in the `lumberyard_version\dev\Engine\Shaders\` directory.
- **ShaderCache.pak** – Compiled shaders of all possible combinations that Lumberyard uses.
- **ShaderCacheStartup.pak** – Compiled shaders that are used during start.

### Generating Shader .pak Files

To generate shader .pak files, use the following tools:

- **Shader Compiler** – The shader compiler server generates the ShaderList.txt file that contains the list of all shaders for your game. This server can run locally or on a remote PC.
  
  For more information, see Remote Shader Compiler (p. 1645).
- **ShaderCacheGen.exe** – File that populates the local shader cache folder with all the shaders contained in the ShaderList.txt file.
  
  For more information, see ShaderCache.pak File Generation (p. 293).
- **lmbr_pak_shaders.bat** – Batch file that generates the ShaderCache.pak files.
  
  For more information, see ShaderCache.pak File Generation (p. 293).

### Shader Compiler Proxy

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Some mobile devices may be connected via a USB TCP/IP tunnel and may not have direct network access to a shader compiler server. The shader compiler proxy component in Lumberyard allows such devices to forward shader compiler requests through the Asset Processor connection.

This proxy connection only works for connecting to the shader compiler server on that protocol. It is not a general purpose network bridge or tunnel. To use the shader compiler proxy, open the `system_assetsplatform.cfg` file and modify the following values:
Shader Cache and Generation

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This section discusses the shader cache and how to generate shader cache .pak files.

Shader Cache

The shader cache stores a collection of parsed and precompiled shaders. Since the shader code is written with multiple definitions, Lumberyard can generate an enormous number of different shaders. Compiling shaders on demand at run time is only possible on the PC. On-demand shader compiling can cause freezes during the game play and uses extra memory. To reduce this overhead, all required shader combinations for a game are parsed, compiled, and stored in the shader cache.

The shader cache generally refers to the following files:

- **Shaders.pak** – Contains the shader source files, which is everything inside the `lumberyard_version\dev\Engine\Shaders\` directory, excluding EngineAssets.
  
  **Note**
  
  The actual shader source code (*.cfi and *.cfx) can be removed from this file for the final released version, and is not required anymore when the binary shaders are valid and available.

- **ShadersBin.pak** – Contains the binary-parsed shader information of the shader source code.
- **ShaderCache.pak** – Contains compiled shaders for all possible combinations that have been submitted to the remote shader compiler.
- **ShaderCacheStartup.pak** – Contains a small subset of the shader cache that is used during game start. This file is loaded into memory for quicker start times, but is not required. This cache is often used to hold the minimum required set of shaders to show a loading screen so that the rest of the loading can occur.

ShaderCache.pak File Generation

Creating a ShaderCache.pak file consists of running the `lmbr_pak_shaders.bat` batch script, which in turn runs ShaderCacheGen.exe to ensure the local cache directory contains all the shaders that are listed in the ShaderList.txt file. The `lmbr_pak_shaders.bat` script packs the contents of the cache directory, creates a ShaderCache.zip file, and then renames the file to ShaderCache.pak.

You can find the ShaderList_platform.txt file either from the remote shader compiler server or from the Lumberyard Editor directory. This file contains the list of all shaders which ShaderCacheGen.exe uses to produce the shader combinations for your game.

When running Lumberyard Editor, individual shaders are created as you view them. As such, you do not strictly need a remote shader compiler server to test game release mode or test shader pack generation. You just need access to the ShaderList_platform.txt file that is created in the
Shader Cache and Generation

However, only the shaders you have viewed on your local computer while running Lumberyard Editor will be listed in the ShaderList_platform.txt file. For this reason, it is recommended that you use a remote shader compiler server if possible.

Note
During development time, when you run the game or Lumberyard Editor, and before the shaders are packed into shader cache .pak files, loose shader files are created in the following directory: lumberyard_version\Dev\Cache\your_game\platform\user\cache

The following sections detail the steps used to generate ShaderCache.pak files:

ShaderCacheGen.exe

Lumberyard ships with ShaderCacheGen.exe, which is located in the lumberyard_version\dev\Bin64 directory. For macOS, the file is located in the BinMac64 directory. ShaderCacheGen.exe is a stripped-down version of the Lumberyard game launcher without the render viewport, and is used to populate the local shader cache directory with all the shaders contained in the ShaderList.txt file.

Running the ShaderCacheGen.exe will load the ShaderCacheGen.cfg file. This configuration file includes the IP address and other settings for the remote shader compiler that generates the shaders. The ShaderCacheGen.exe must connect to the remote shader compiler that's specified in the configuration file. The ShaderCacheGen.exe will not use the IP address and other settings that are specified in the system configuration files.

If you customized Lumberyard in any way, you must build Lumberyard and your game using the all profile. This argument builds both ShaderCacheGen.exe (and ensures that it is up-to-date) and the game .dll files that are required.

Enter the following command for your version of Visual Studio.

```
lmbr_waf build_win_x64_vs2017_profile -p all --targets=CrySCompileServer
```

If you don't want to (or can't) build using the all profile, you can alternatively just build the game_and_engine spec and the shadercachegen spec.

Enter the following command for your version of Visual Studio.

```
lmbr_waf build_win_x64_vs2017_profile -p game_and_engine
lmbr_waf build_win_x64_vs2017_profile -p shadercachegen
```

Packing the Shader Cache as Part of the Release Build

The ShaderCache.pak files are generated for release builds as part of the build process. To generate the files, the ShaderCacheGen.exe must be connected to the Remote Shader Compiler. This must be the same Remote Shader Compiler that you used to generate the shaders for your game. As long as this instance of the shader compiler is running, the release build process can generate the necessary .pak files for your release build. If the shader compiler isn't running or reachable for some reason, the release build process fails.

Packing the Shader Cache Using a Batch File

The lmbr_pak_shaders.bat file generates the ShaderCache.pak files, which are saved to the lumberyard_version\dev\build\platform\your_game directory. The batch file first calls the ShaderCacheGen.exe and then calls Tools\PakShaders\pak_shaders.py.

From a command line, navigate to the lumberyard_version\dev directory, and run the lmbr_pak_shaders.bat, and specify the location to the ShaderList_platform.txt file.
Example

\[F:\{lumberyard_version}\\dev\lmb\pak\shaders.bat game_project_name D3D11 pc C:\shader_compiler_server\ShaderList_DX11.txt]\]

Once the shader .pak files are created, you can move them as needed. For example, if you already built a release version of your game, you can place them with the rest of the .pak files.

**Packing the Shader Cache Manually**

If you want to use more complex build pipelines, you can pack the shader cache manually.

**To pack the shader cache manually**

1. Run ShaderCacheGen.exe to generate the shader cache so you can pack it later.
2. Zip all the shaders into a ShaderCache.zip file, then rename the file to ShaderCache.pak.

Each platform has different .pak files. See the following directory mapping for the PC platforms:

The PC platform should copy data from the following directory:

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\D3D11\] into the following destination directory:

\[shaders\cache\D3D11\]

ShaderCache.pak should contain everything from the previously listed subfolders.

ShaderBin.pak should contain only the *.cfxb and *.cfib files.

ShaderCacheStartup.pak should contain the following files:

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\\{platform\}\lookupdata.bin -> Shadercache\\{platform\}\lookupdata.bin\]

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\\{platform\}\CGPShader\FixedPipelineEmu* -> Shadercache\\{platform\}\CGPShader\FixedPipelineEmu*\]

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\\{platform\}\CGPShader\Scaleform* -> Shadercache\\{platform\}\CGPShader\Scaleform*\]

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\\{platform\}\CGPShader\Stereo* -> Shadercache\\{platform\}\CGPShader\Stereo*\]

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\\{platform\}\CGVShader\FixedPipelineEmu* -> Shadercache\\{platform\}\CGVShader\FixedPipelineEmu*\]

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\\{platform\}\CGVShader\Scaleform* -> Shadercache\\{platform\}\CGVShader\Scaleform*\]

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\\{platform\}\CGVShader\Stereo* -> Shadercache\\{platform\}\CGVShader\Stereo*\]

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\\{platform\}\lookupdata.bin -> Shadercache\\{platform\}\lookupdata.bin\]

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\\{platform\}\Common.cfib -> Shadercache\\{platform\}\Common.cfib\]

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\\{platform\}\fallback.cfxb -> Shadercache\\{platform\}\fallback.cfxb\]

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\\{platform\}\fixedpipelineemu.cfxb -> Shadercache\\{platform\}\fixedpipelineemu.cfxb\]

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\\{platform\}\FXConstantDefs.cfib -> Shadercache\\{platform\}\FXConstantDefs.cfib\]

\[\{lumberyard_version\}\\dev\cache\your_game\platform\user\shaders\cache\\{platform\}\FXSamplerDefs.cfib -> Shadercache\\{platform\}\FXSamplerDefs.cfib\]
Build Platforms

You can find the build platform subfolders listed in the following table in the `lumberyard_version\dev\Cache\your_game\platform\user\cache\shaders` directory.

<table>
<thead>
<tr>
<th>Build Platform</th>
<th>Build Platform Subfolder</th>
</tr>
</thead>
<tbody>
<tr>
<td>PC, DirectX 11</td>
<td><code>\D3D11</code></td>
</tr>
</tbody>
</table>

Game Startup Sequence

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Compiled Lumberyard games start up in the following sequence:

1. The game reads the `bootstrap.cfg` file, which must contain the following information at a minimum:
   - Name of the game, and optionally, the name of the game DLL, if it differs from the game name.
   - Whether or not to connect to the Asset Processor on startup or listen for an incoming connection instead.
   - Whether or not to wait for an established connection before proceeding.
   - Whether or not to enable the virtual file system (VFS), which allows you to read assets remotely from a connected computer instead of having to deploy them to the game device. This also is required for live reloading to function on non-PC operating systems.
   - Which kind of assets to load. For example, you could configure the Android runtime to load `es3` assets, or `pc` assets, or `metal` assets. This determines which directory the game looks in for the assets so that the appropriate directory is also used for VFS.

2. The `lyconfig_default.xml` file is read.

3. VFS is started and enabled. All file access then goes through the VFS system. Besides the `bootstrap.cfg` file, executable files, DLL files, and associated OS files, nothing else needs to be deployed to the device. Instead, they can all be accessed remotely.

4. The `system_game OS_assets.cfg` file is read, where `assets` are the assets specified in the `bootstrap.cfg` file.

Asset Browser

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The **Asset Browser** displays all project assets in a source folder and file view to enable quick access and interaction. You can use the **Asset Browser** with other editor components to improve your development workflow, such as the viewport and the **Entity Inspector**.

The **Asset Browser** shows all files inside your watch folders that are specified in the `lumberyard_version\dev\AssetProcessorPlatformConfig.ini` file. In the **Asset Browser**, usable files appear white. Non-usable files such as `.exe` or `.zip` appear gray.

**To open the Asset Browser**

1. From Lumberyard Editor, choose **Tools, Asset Browser**.

   ![Asset Browser](image)

   To open the Asset Browser

2. Dock the **Asset Browser** window in Lumberyard Editor as needed.

   The **Asset Browser** displays source assets along with their products. For example, an `.fbx` file appears with its meshes and animations. However, if the source and product asset have the same name and extension, then the products are hidden to save space.

**Example**

The `WombearActor.fbx` file has two products, an actor and mesh.

![Example](image)

Files that are unprocessed or not usable in Lumberyard Editor appear gray.
With the **Asset Browser**, you can do the following:

**Contents**
- Drag and Drop (p. 298)
- Context Menu Operations (p. 300)
- Finding a Slice in the Asset Browser from the Viewport (p. 302)
- Filtering (p. 302)

**Drag and Drop**

You can drag assets from the **Asset Browser** into the viewport or the **Entity Inspector**.

When you drag an asset from the **Asset Browser** into the viewport, Lumberyard Editor does the following:

- Creates a new entity at the cursor's location.
- Adds the associated component, which is indicated by the icon next to the asset in the **Asset Browser**.
- Assigns the asset for that component's property.

**Example**

You can drag the `brokenrobot05.cgf` file to the viewport, which creates a new entity, adds a **Mesh** (p. 684) component, and assigns the asset into the **Mesh asset** property in the **Entity Inspector**.
Example

You can select multiple entities in the **Entity Outliner** and then select and drag an asset into the **Entity Inspector**. This adds the **Mesh** component and the associated mesh asset to the selected entities.

You can also drag the appropriate file type into a component property's field.

**Example**

You can drag an asset file (.cfg) into the **Material asset** field on the **Mesh** component. The boulder in the viewport displays the new asset.
Context Menu Operations

In the Asset Browser, right-click an asset to display a context menu. The following menu options appear:

- **Open with associated application** – Opens the file with the default application that you specify. For example, if you specified Photoshop to open .tiff files, this opens the file in Photoshop.
- **Open in Explorer** – Opens the asset in Windows Explorer.
- **Copy Name To Clipboard** – Copies the asset name.
- **Copy Path To Clipboard** – Copies the path of the asset.
- **Edit Texture Settings** – Opens the asset in the Texture Settings Editor. For more information, see Texture Settings Editor (p. 1734).

**Note**
You can also open some files in their respective Lumberyard tool, such as the **Lua Editor** for .lua files.

**FBX Files**

Some files, such as .fbx files, have an additional **Edit Settings** option, which opens the **FBX Settings** tool. For more information, see Customize FBX asset export with FBX Settings (p. 409).
Slices

The following additional options appear for slices:

- **Set Dynamic Slice** – Create a runtime version of a slice. For more information, see Working with Dynamic Slices (p. 524).
- **Unset Dynamic Slice** – Remove a dynamic slice.
- **Open in Slice Relationship View** – Show the dependencies and dependent members of the slice in a hierarchical view.

**Example**

The following image shows the Slice Relationship View for the Maze_Decor_Interior slice from the Starter Game. For more information, see Working with Slices (p. 510).

**Source Control**

If source control is enabled, the following additional options appear:

- **Check Out** – Check out the file in source control.
- **Undo Check Out** – Undo check out for the file.
• **Get Latest Version** – Get the latest version of the file.
• **Add To Source Control** – Add the file to source control.

### Finding a Slice in the Asset Browser from the Viewport

In the viewport, right-click the slice or slice entity and choose **Find slice in Asset Browser**. The Asset Browser navigates to the corresponding slice.

### Filtering

You can filter what appears in the Asset Browser by file name, asset type, or both.

**To filter your assets**

1. In the Asset Browser, choose the filter icon in the upper right.
2. Select one or more asset types.
3. To filter by file name, type search terms into the search bar. The filtering process is dynamic, which means that search results update as you type.

4. To reset your selection, in the Filter by drop-down menu, click Reset or Clear.

The search function also has the following features:

- Recognizes multiple words and performs an and search on assets and directories that contain all of the search terms in any order.
- Is not case sensitive.
- Displays product assets that match the search string.
- Displays source assets that match the search string and contain at least one valid product.
- Displays directories that match the search string and contain at least one valid product. All products in each displayed directory and its subdirectories are displayed.
Programming the Lumberyard AZCore Runtime Asset System

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Lumberyard Editor and Lumberyard runtime code use the AZCore runtime asset system to asynchronously stream and activate assets. This topic describes the workflow of the classes in the asset system and shows how to load already-built assets into a running instance of the engine.

Note
For information on compiling and building assets, see Working with the Asset Pipeline and asset files (p. 247).

Asset System Classes

The Lumberyard asset system includes the following classes and class families:

- AZ::Data::AssetData Derived Classes (p. 304)
- AZ::Data::AssetManager (p. 306)
- AzFramework::AssetCatalog (p. 307)
- AZ::Data::AssetHandler Derived Classes (p. 308)

The following sections describe these classes in detail. For the source code, see the lumberyard_version\dev\Code\Framework\AzCore\AzCore\Asset directory.

AZ::Data::AssetData Derived Classes

An AssetData class represents the data of an asset that is loaded in memory. To describe a particular kind of asset, derive from the AssetData base class. The base class provides an AssetID and a reference count member variable for the asset.

The following Lumberyard classes derive from AssetData:

<table>
<thead>
<tr>
<th>AssetData Class</th>
<th>Source Code Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScriptAsset</td>
<td>lumberyard_version\dev\Code\Framework\NoteBeg\AzCore\AzCore\Script\ScriptAsset.h</td>
</tr>
<tr>
<td>SliceAsset</td>
<td>lumberyard_version\dev\Code\Framework\AzCore\AzCore\Slice\SliceAsset.h</td>
</tr>
<tr>
<td>MeshAsset</td>
<td>lumberyard_version\dev\Gems\LmbrCentral\Code\include\LmbrCentral\Rendering\MeshAsset.h</td>
</tr>
<tr>
<td>ParticleAsset</td>
<td>lumberyard_version\dev\Gems\LmbrCentral\Code\include\LmbrCentral\Rendering\ParticleAsset.h</td>
</tr>
</tbody>
</table>

Note
Adding your own asset type to Lumberyard includes the following high-level steps:
1. Derive your type from `AssetData`.
2. Declare an `AZ_RTTI` type for the asset to ensure that it has a UUID.
3. Add the member fields or structs that store your data in memory at run time.

For more information, see Adding an Asset Type to Lumberyard (p. 308).

**AZ::Data::Asset<T> Templated Class**

Typically, components which use assets directly or indirectly do not have a pointer to your `AssetData`-derived class; instead, they have a member of type `Asset<T>`. The `AZ::Data::Asset<T>` templated class is a wrapper that is similar to a smart pointer, and the `T` templated type is an `AssetData`-derived class.

The use of `Asset<T>` provides the following benefits:

- Automatic dependency tracking for components that are part of slices.
- Automatic reference counting.
- Automatic reloading of asset data when the asset changes on disk.
- Explicit lifecycle management functions like `IsLoaded()` and `QueueLoad()`.
- Reference count tracking to ensure correct behavior for copy operators.
- The ability to control how the `Asset<T>` class loads data. To specify how the asset loads, you pass flags to the constructor of the `Asset<T>` member variable.

The following options are possible:

- The class automatically starts loading its data. The class waits for the data to be ready before it activates the component for which the data is intended.
- The class queues the load of your asset data.
- The class waits for you to load the data explicitly.

**Note**

A loaded asset remains loaded as long as an active `Asset<T>` points to it. The asset manager does not reference count the asset. The asset is unloaded when the last system with a reference to the `Asset<T>` drops its reference and the reference count on the asset goes to 0.

**Integration with UI Property Grids**

The `Asset<T>` member fields of your component can appear in UI property grids like those in the Entity Inspector. To make a component's field available in Lumberyard Editor, make the `Asset<T>` field a member variable and reflect it into the editor. When you do so, game developers can drag an asset from the Asset Browser onto the property field to assign the asset to the component.

Note the following points:

- Reflect the `Asset<T>` member variable just as you reflect other member variables of your component.
- Lumberyard handles asset IDs for you automatically. You do not have to handle them explicitly.
- `Asset<T>` fields serialize the `AssetId` and other information such as the last known name of that `AssetId`.
- After an `AssetId` is assigned to a component, the `AssetId` is saved when the component is saved. The next time the component loads, the asset is automatically loaded if you specified the appropriate flag in the `Asset<T>` constructor.
AZ::Data::AssetManager

AZ::Data::AssetManager is the central hub for retrieving assets. If you configure the Asset<T> fields of a component to load their assets automatically, you do not need to communicate directly with the asset manager. The AssetManager class performs the following tasks:

- Maintains a hash table that maps asset IDs to the instances of Asset<T> that are currently loaded.
- Calls FindAsset to see if an asset is already loaded. If the asset is not currently loaded, FindAsset returns a null reference.
- Automatically reloads assets as they change on disk.
- Notifies listeners about asset lifecycle changes. Events like asset loading or unloading are signalled on the AssetBus. The callback-based adapter for this bus is called AssetBusCallbacks. For more information, see the AssetCommon.h file.

To get an asset, call GetAsset. If the reference count is greater than zero, GetAsset returns an Asset<T> that is already loaded. If no Asset<T> is currently loaded, GetAsset starts loading a new instance of Asset<T>.

Example: Loading an Asset Using Asset Manager

The following code example uses AssetManager to load a script asset.

```cpp
m_scriptAsset = 
AZ::Data::AssetManager::Instance().GetAsset<AZ::ScriptAsset>(assetIdToLoad);
AZ::Data::AssetBus::Handler::BusConnect(m_scriptAsset.GetId());
```

In the example, m_scriptAsset is a field of type Asset<ScriptAsset>.

For related code, see lumberyard_version\dev\Code\Framework\AzToolsFramework\AzToolsFramework\ToolsComponents\ScriptEditorComponent.cpp.

Note the following points:

- GetAsset loads the asset asynchronously. By assigning the asset to the member m_scriptAsset, you ensure that the reference count is at least 1.
- The code connects to the AssetBus to receive notifications when the script asset is loaded or becomes ready.
- If the asset is already loaded, the AssetBus delivers the OnAssetReady event as soon as the connection is made to the bus. Because the connection to the bus triggers a callback about the asset's state, you do not have to write code to check the state.

More About Automatic Reloading

An asset can change on disk after the asset has been loaded (and therefore has a reference count greater than zero). When this occurs, the asset manager creates an instance of the updated asset and loads it in the background. When the updated asset is finished loading, two Asset<T>'s temporarily exist. One Asset<T> points to the old AssetData instance in memory, and one to the new. Both instances have the same AssetId. However, now when you request the asset by AssetId, the asset manager returns the new instance and increases the reference count of the new instance. The asset manager also sends the OnAssetReloaded(Asset<T>) event to the AssetBus. This notifies other systems to reload the asset by replacing their current member Asset<T> with the new instance. It also keeps the reference count from reaching zero for the duration of the callback.

The following code shows a component that has a member variable of type Asset<T> that handles live reloading. First, the component connects to the bus to monitor for asset reloading events.
When the AssetManager notifies that a new script has been reloaded, the code for the
OnAssetReloaded method cleans up old pointers. The code also assigns the asset, which updates the
reference count for the new and old versions of the asset.

```cpp
void ScriptComponent::OnAssetReloaded(AZ::Data::Asset<AZ::Data::AssetData> asset)
{
    // Clean up any pointers to the old AssetData.
    UnloadScript();
    m_script = asset; // This assignment increments the reference count of the new asset.
    // The old asset reference count decrements.
    // Re-establish state into the new AssetData.
    LoadScript();
}
```

Because `m_script` is of type `Asset<ScriptAsset>`, it can simply use `Asset<T>`'s `operator=` to drop
the reference count on the old `Asset<T>` and replace it with the new `Asset<T>`.

This way of handling automatic reloading gives components the flexibility to decide how to deal with
changes to assets. For example, components might choose among the following options:

1. Save the new `Asset<T>` on a queue and for later processing.
2. Discard the new `Asset<T>` and keep the old data.
3. Swap the references to the old and new versions immediately, as the script component does.

Note the following points:

- Because `Asset<T>` instances are reference counted, the internal `AssetData` object that they wrap is
  not deleted until all classes that have a reference to it clear that reference.
- If `OnAssetReloaded` is called and the code does not store the new `Asset<T>`, the reference count
  becomes zero and the asset is unloaded. Existing `Asset<T>` instances that point at the old data
  remain valid until they are dropped.
- Because messages like `OnAssetReloaded` are always delivered in the main thread, mutexes are not
  required.

**AzFramework::AssetCatalog**

The asset catalog is a set of lookup tables that notifies the Lumberyard asset system when assets on
the file system change. The asset manager monitors the `AssetCatalogEventBus`. When the bus
delivers the `OnCatalogAssetChanged` event, the asset manager starts upgrading assets. This is how
live reloading is implemented.

To receive notifications about assets that change on disk, connect to the `AssetCatalogEventBus`. Then
use the `AssetCatalogRequestBus` to make requests to the `AssetCatalog` to resolve assets by ID. For details, see the `AssetManagerBus.h` file.

The `AssetCatalogRequestBus` contains other functions that look up asset dependencies, enumerate
assets, and perform other low-level tasks. In most cases you do not have to use these functions directly.

**Note**

You do not have to use the asset catalog directly unless you write low-level code that performs
custom file processing. If you use the higher level systems like `Asset<T>`, `AssetData`, and
`AssetManager`, these classes communicate with the catalog for you.
To look up asset file information manually, you can pass an AssetId to the AssetCatalog. AssetCatalog returns a struct that contains the file's type, size, canonical name, and location.

**AZ::Data::AssetHandler Derived Classes**

When you create a new type of asset (p. 308), you also create an AssetHandler for the new asset type. The role of the asset handler is to create, load, save, and destroy assets when the asset manager requests it. After your asset handler creates an empty instance of your asset type, it loads serialized data into the in-memory representation of AssetData.

To create a handler for a specific asset type, derive from the AssetHandler class and register an instance of the handler with the asset manager. Because asset handling functions can be called from multiple threads, the handlers must be thread-safe. The handler can block the calling thread while the asset is loading.

**Asset System Workflow**

Lumberyard loads assets in the following two ways:

- **Implicit** – When classes and structs contain Asset<T> members. When a structure deserializes, the serialization system checks whether the structure contains a member of type Asset<T>. If so, the serialization system calls GetAsset() to retrieve the asset from AssetManager.
- **Explicit** – When AssetManager::GetAsset() or Asset<T>::QueueLoad is called explicitly.

The following steps summarize the workflow of the asset system.

1. GetAsset(assetId) calls AssetManager implicitly (through the serialization system) or explicitly.
2. AssetManager calls GetAssetInfoById to retrieve the information about the asset file.
3. If the asset is already loaded in the m_assets asset map, AssetManager returns a new Asset<T> instance of the existing asset and increments the reference count.
4. If the asset is not already loaded, AssetManager uses the information returned by GetAssetInfoById to look up the AssetHandler for the asset type.
   a. AssetManager calls the asset handler's CreateAsset function to create a new empty instance for the data.
   b. AssetManager inserts the asset into the empty instance.
   c. AssetManager creates a loading job in a job worker thread pool. To load the asset data, the thread pool calls the loadAssetData function on the handler in the worker pool.
   d. If the AssetManager was told to block while the asset loads, it stops processing until the asset is loaded.
   e. AssetManager returns the Asset<T> member.

**Conclusion**

While AssetCatalog, AssetHandler, and AssetData are part of the asset system, consumers of an asset deal only with Asset<T> and AssetManager.

**Adding an Asset Type to Lumberyard**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
When you develop a game, you might need to add a new kind of asset to Lumberyard. The new asset could be a configuration file, a game-specific data asset, or structured data for which you created an editor. This topic guides you through the process of adding a custom asset type to Lumberyard.

For an overview of the Lumberyard asset system, see Programming the Lumberyard AZCore Runtime Asset System (p. 304).

Topics
- Overview (p. 309)
- A. Registering Your Asset with the Asset Pipeline (p. 310)
- B. Enabling the Engine to Load and Stream the Asset (p. 312)
- C. Customizing UI Interaction (p. 314)

Overview
At a high level, adding an asset type to Lumberyard involves three steps:

A. Registering the asset with the asset pipeline.
B. Enabling the Lumberyard engine to load and stream the asset.
C. Optionally customizing your asset's interaction with the Lumberyard Editor UI and the Asset Browser.

After this overview, each step is covered in more detail. Not all of the steps are required. The steps are arranged in order of increasing integration with the Lumberyard asset pipeline and editor.

A. Register the Asset with the Asset Pipeline
You register your asset with the asset pipeline for common operations like building, processing, copying, and deploying. This registration assigns an appropriate type ID to the asset type and enables the asset to be added to the cache and the asset database. Depending on your asset file type, you can register it by creating a copy rule or writing code.

Registering by Copying
You can deploy your asset file by copying if the following are true:

- The processed or compiled version of your asset is the same across all operating systems and devices.
- The asset declares no dependencies on other assets.
- The asset doesn't need to be rebuilt when other source files change.

Registering by Creating a Builder
If your asset requires processing, compiling, or optimizing at run time, you can do one of the following:

- Create a BuilderSDK builder (p. 318) to transform your source asset into its compiled form.
- If your asset is extracted from a scene file like FBX and you want to integrate with its corresponding pipeline, create a scene pipeline plug-in.

Copying Versus Creating a Builder
It might be inefficient to use your source assets in your game under the following circumstances:

- You have extraneous tool data inside your asset that is not necessary to ship for each operating system or device.
- You want to do verify or error check your files.
• You want to optimize your data.

In these cases, consider writing a BuilderSDK builder (p. 318) instead of just copying your raw assets, even if it only compresses or converts the assets into binary format.

B. Enable the Engine to Load and Stream the Asset

After you register your asset with the asset pipeline, you must enable the Lumberyard engine to load your asset type at run time and stream it asynchronously.

Enabling your asset for loading and streaming involves the following steps:

1. **Create an asset data type** – Create a class derived from `AZ::Data::AssetData` that represents your loaded asset data. This class must be registered with `AZ_RTTI`. The UUID of the class is also the UUID of your asset in the Asset Processor database.

2. **Create an asset handler** – Create a singleton class that derives from `AZ::Data::AssetHandler` that loads, saves, and reads your data from buffer.

3. **Register your asset type handler with the asset system** – To do this, implement a `RegisterHandler` function inside your handler.

4. **Use your custom asset** – Inside components, use `Asset<T>` members, which are reflected to the editor and for serialization, to refer to your asset.

C. Customize UI Interaction

Optionally, you can describe your asset to the UI (and other systems) and customize your asset's interaction with it, including with the **Asset Browser**.

1. **Describe your asset type to the UI** – Use the `AssetTypeInfoBus` to provide integration with UI features like the **Asset Browser**.

2. **Customize drag-and-drop behavior** – If you have components, you can add reflection to them to enable custom behavior. For example, when a game developer drags your asset to the viewport, you can make your component be the default component that is spawned.

3. **Customize the context menu** – You can add context menu actions to interact with your asset.

4. **Customize file open behavior** – Customize file open operations to create custom behaviors when interaction occurs with your asset. For example, you can make your asset type open in a custom editor or create custom entities.

In addition, you can use the thumbnail API to generate thumbnails for your asset for use in the **Asset Browser** and other UI contexts. Although not described here, the related source code is located in the `lumberyard_version\dev\Code\Framework\AzToolsFramework\AzToolsFramework\Thumbnails` directory.

A. Registering Your Asset with the Asset Pipeline

When you register your asset with the asset pipeline, you define your asset to the asset system and asset processor. Depending on your asset file type, you can register it by creating a copy rule or by writing a BuilderSDK builder (p. 318).

Copying Assets

To copy assets, you typically create a copy rule in a configuration file. The configuration file that you use depends on your implementation goals.

• To copy assets as-is into the cache, add a copy rule to your `lumberyard_version\dev\AssetProcessorPlatformConfig.ini` file.
If the asset type is specific to a gem, add it to your gem's root directory (the directory with the gem.json file) instead of to the AssetProcessorGemConfig.ini. This overrides the platform configuration file but is overridden by the game configuration file.

If the asset type is specific to the game project, add it to your game directory's AssetProcessorGamePlatformConfig.ini file instead of to the AssetProcessorPlatformConfig.ini file.

A copied asset uses a copy rule entry similar to the following example. Rule names must be unique. In the example, the *dba copy rule copies *.dba files and uses a UUID to register their type. The asset shows in the catalog as the type that you designate. The type maps the asset to the AssetHandler that you create. This enables the handler to load the asset.

```
[RC dba]
glob=*.dba
params=copy
productAssetType={511562BE-65A5-4538-A5F1-AC685366243E}
version=1
```

For more information, see Configuring the Asset Pipeline (p. 269).

**Custom-Built Assets**

For custom-built assets, you can write a BuilderSDK builder or a Scene API plug-in. If your asset is extracted from an .fbx file, you can write a Scene API plug-in. With either approach, you do not need to edit .ini files as you do when copying assets.

**Writing a BuilderSDK Builder**

When you write a BuilderSDK builder to create the asset, it should fill in the product info struct for each asset that it creates. The product info struct includes the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filename</td>
<td>The name of the asset file.</td>
</tr>
<tr>
<td>Asset type</td>
<td>The UUID of the class that you derived from Az::AssetData.</td>
</tr>
<tr>
<td>SubID</td>
<td>Any u32 integer that disambiguates different outputs from the same source.</td>
</tr>
<tr>
<td>Legacy SubIDs</td>
<td>SubIDs for backward compatibility.</td>
</tr>
</tbody>
</table>

For more information and examples, see the Asset Builder API (p. 318).

**Writing a Scene API Plug-in**

The Scene API provides boilerplate code so that you only have to write a few code hooks to create a plug-in. For an example Scene API plug-in, see the SceneLoggingExample gem in the lumberyard_version\dev\Gems directory. The SceneLoggingExample gem shows how logging can be added to the asset pipeline. The gem adds a scene plug-in that outputs logs for each node in the file. The gem is a good starting point for your own code. You can replace the log outputs with the data collection and/or compiling functions that you want.

**Registration Versus Integration**

After you register the asset with the asset system, you can use the AssetCatalogRequestBus to find the asset in the catalog by its ID or other attributes. The result of the lookup gives you the asset's path, size, and other information. You can use standard file handling (p. 329) to load the asset.
While simple registration of an asset can be useful in some circumstances, full integration with the Lumberyard asset system offers many advantages, including the following:

- Automatic live reloading
- Automatic asynchronous streaming
- Automatic drag-and-drop support in the Asset Browser
- Thumbnails

### B. Enabling the Engine to Load and Stream the Asset

The following sections describe the steps required for integration with Lumberyard's asset system.

#### 1. Create an AssetData Type

To represent an image that is usable in-memory for your asset, derive a class from `AZ::Data::AssetData`. You do not load the asset from the `AssetData-derived class. Instead, the class actually represents your asset in memory, and the game uses it directly for processing. When you request the asset from `AssetManager`, the asset manager reference counts it, and the asset class is shared by any consumer of the asset. When you create an asset class, keep in mind the following:

- You can place `AssetData-derived classes in gems.
- Your asset class must have an AZ_RTTI declaration, including a UUID for the class's type. The UUID that you use for this type is actually the asset type that it represents. The UUID matches the type that you use in your asset builder or your copy rule.
- While an `AssetData-derived class typically contains asset data that it stores in memory and that you use at run time, this is not a requirement. If you have special requirements (like third-party considerations), your class can simply provide a handle to a foreign system that contains the asset data.
- For an example class that derives from `Az::Data::AssetData`, see the `ScriptCanvasAsset` class in the Lumberyard code at `lumberyard_version\dev\Gems\ScriptCanvas\Code\Editor\Include\ScriptCanvas\Assets\ScriptCanvasAsset.h`.

#### Asset Instances and Asset Data

It is important to understand the difference between asset instances and asset data.

An `AssetData-derived class contains the asset data that is shared among instances that use that data. Data that is specific to an instance should live in the instance itself. For example, an animation asset usually contains actual animation curves and samples. Only one such asset is loaded even if many characters use the animation. However, each character instance has an additional block of data that keeps track of the frame that the animation is on for the instance.

`AssetData objects are not immutable, and often change over time. For example, textures can load higher level of detail (LOD) objects, and procedural meshes or textures can change over time. However, all instances that use an asset get the same pointer to the asset and therefore change when the asset changes. This is also true when instances have a pointer to an asset in a foreign system.

#### 2. Create an Asset Handler

You write an asset handler to read assets from buffer and convert them into your `AssetData type. Only one such handler generally exists for each type of asset. The asset handler class is your asset factory for that type of asset because it can create and destroy your `AssetData-derived class. The `AssetHandler is a singleton instance whose functions are called in asynchronous job threads.

**Note**

You can place asset handlers in gems. For information on adding code to gems, see Using Gems to Add C++ Code to a Lumberyard Game (p. 1086).
Using the Generic Asset Handler for Structured Data

If your asset is a serialized `AZ::Reflected::ObjectStream`, you can use `GenericAssetHandler`, located in the `lumberyard_version\dev\Code\Framework\AzFramework\AzFramework\Asset\GenericAssetHandler.h` file. `GenericAssetHandler` calls the usual `Serialize` and `Deserialize` functions in its callbacks that load assets and registers your types for you.

Because assets like classes, lists, vectors, and properties are structured data, they are suitable for handling by `GenericAssetHandler`.

Writing a Handler for Custom Assets

If you have a custom asset (like bytes or custom formats), you must write your own `AssetHandler`. To do so, implement the `CreateAsset`, `LoadAssetData`, and other functions in the following code:

```cpp
// AZ::Data::AssetHandler
// CreateAsset is almost always implemented in the form:
// return aznew (your assetData class type)(id)
AZ::Data::AssetPtr CreateAsset(const AZ::Data::AssetId& id, const AZ::Data::AssetType& type) override;

// LoadAssetData is the main loading function. The stream that you are given is // already attached to the file and ready to read into the 'asset' variable.
bool LoadAssetData(const AZ::Data::Asset<AZ::Data::AssetData>& asset, AZ::IO::GenericStream* stream, const AZ::Data::AssetFilterCB& assetLoadFilterCB) override;

// The following functions are for legacy compatibility. Most implementations of the functions // simply wrap the file in a GenericStream and pass it to the LoadAssetData function above.
bool LoadAssetData(const AZ::Data::Asset<AZ::Data::AssetData>& asset, const char* assetPath, const AZ::Data::AssetFilterCB& assetLoadFilterCB) override;

// Destroy your asset in case you need to do cleanup. DestroyAsset usually just calls delete.
void DestroyAsset(AZ::Data::AssetPtr ptr) override;

// The AZ_RTTI type UUID(s) of your AssetData-derived classes.
void GetHandledAssetTypes(AZStd::vector<AZ::Data::AssetType>& assetTypes) override;

// CanHandleAsset usually returns true. Only useful if more than one handler is present for a single type.
bool CanHandleAsset(const AZ::Data::AssetId& id) const override;
```

After you create your handler, install the class that you derived from `AssetHandler`.

To install your asset handler with the asset system

1. Create an instance of the handler class in your component.
2. Call `RegisterHandler` on the asset manager instance. For an example, see the `lumberyard_version\dev\Code\Framework\AzCore\AzCore\Script\ScriptSystemComponent.*` files.

   **Note**
   Your component does not have to be a system component, but the component must exist to handle load request calls.

Example Asset Handlers

For example asset handlers, see `MeshAssetHandler`, `ParticleAssetHandler`, and `ScriptAssetHandler` in the following locations:
3. Register Your Asset Type and Handler with the Asset System

In this step, register your handler to handle a specific asset type, which is the UUID of your asset data.

Typically, you implement the registration code inside your handler in a `RegisterHandler` function. You call the `RegisterHandler` function during initialization, as in the following example. The example code registers an `<AssetType>` (that is, the UUID of the `AssetData` class type) with the asset catalog.

```cpp
AZ::Data::AssetCatalogRequestBus::Broadcast(&AZ::Data::AssetCatalogRequests::EnableCatalogForAsset, AZ::AzTypeInfo<AssetType>::Uuid());
AZ::Data::AssetCatalogRequestBus::Broadcast(&AZ::Data::AssetCatalogRequests::AddExtension, m_extension.c_str()); // The extension of your type.

// Register your handler.
AZ_Assert(AZ::Data::AssetManager::IsReady(), "AssetManager isn't ready!");
AZ::Data::AssetManager::Instance().RegisterHandler(this, AZ::AzTypeInfo<AssetType>::Uuid());
```

After you describe your asset type to the Lumberyard engine in this way, your custom asset becomes available in the Asset Browser for dragging and dropping. The asset displays its information and automatically updates.

4. Use Your Custom Asset in the Editor and Engine

At this point, you can use your custom assets in your structures and components.

To create components in the component editor

1. Add fields of type `AZ::Data::Asset<T>` to your components. To do so, use the following syntax. In the following example, `MyAsset` is the class that you derived from `AssetData`.

   ```cpp
   AZ::Data::Asset<MyAsset> m_myAsset;
   ```

2. Reflect the fields that you added by using editor reflection. For more information, see Reflecting a Component for Serialization and Editing (p. 977).

3. (Optional) In the constructor of your class, override the `m_myAsset` constructor to implement the serializer's behavior. For more information, see `m_script` in the `lumberyard_version\dev\Code\Framework\AzFramework\AzFramework\Script\scriptcomponent.cpp` file.

After you perform these steps, your component appears in the component editor. The component has a field to which you can drag and drop the asset from the Asset Browser. When the asset is dragged on the socket, the component accepts it. At this point, runtime or editor code can call functions like `QueueLoad` on the asset.

C. Customizing UI Interaction

(Optional) You can describe your asset type to the UI and then use EBus listeners (p. 1851) to customize your asset's interaction with the Asset Browser.
1. Describing Your Asset Type to the UI

In addition to deriving your asset handler from `Az::Data::AssetHandler`, you can derive it from `AZ::AssetTypeInfoBus::Handler` for user interface purposes. AssetTypeInfoBus tells Lumberyard the friendly name of your asset type, enables it to appear in the **Asset Browser**, gives it icons, and provides other UI–related features.

```cpp
// AZ::AssetTypeInfoBus::Handler
// Return the AZ_RTTI typeid of your AssetData.
AZ::Data::AssetType GetAssetType() const override;

// Get a friendly display name for the Asset Browser and GUI.
const char* GetAssetTypeDisplayName() const override;

// Get a friendly group name ("textures", "Meshes"...) for Asset Browser filtering.
const char* GetGroup() const override;

// Get the name of the icon image file to use in the Asset Browser.
// For example, "Editor\Icons\Components\StaticMesh.png".
const char* GetBrowserIcon() const override;

// Specify the AZ_RTTI type of an editor component for GetComponentTypeId.
// After doing so, dragging this asset type to the viewport will:
// 1) Spawn an entity with the component
// 2) Assign the asset to the component for you.
AZ::Uuid GetComponentTypeId() const override;

void GetAssetTypeExtensions(AZStd::vector<AZStd::string>& extensions) override;
```

Use EBus Listeners to Implement Custom Behavior

To customize how your asset type interacts with the **Asset Browser** and viewport, use EBus listeners to override or supplement behaviors like the following:

1. Default drag-and-drop behavior for viewport operations.
2. Default context menu (right-click) behavior for the **Asset Browser**.
3. Default file open behavior.

**Note**

Because a double-click is a request to open a file, when you override file open behavior, you also override double-click behavior.

2. Customizing Drag-and-Drop Behavior

To customize the default drag-and-drop behavior, you can edit the existing code in the `AzAssetBrowserRequestHandler.cpp` file. A more modular approach is to add a handler with higher priority to your gem.

To customize the default drag-and-drop behavior, create code that listens on the `DragAndDropEventsBus`, as in the following example.

```cpp
AzQtComponents::DragAndDropEventsBus::Handler::BusConnect(AzQtComponents::DragAndDropContexts::EditorViewport);
```

Your component now receives the DragEnter, DragMove, DragLeave, and Drop events shown in the following code.

```cpp
DragEnter(QDragEnterEvent* event, AzQtComponents::DragAndDropContextBase& context)
DragMove(QDragMoveEvent* event, AzQtComponents::DragAndDropContextBase& context)
```
DragLeave(QDragLeaveEvent* event)
Drop(QDropEvent* event, AzQtComponents::DragAndDropContextBase& context)

The events are described in the following table.

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DragEnter</td>
<td>Called when your item is dragged over the viewport.</td>
</tr>
<tr>
<td>DragMove</td>
<td>Called repeatedly after your item accepts the event.</td>
</tr>
<tr>
<td>DragLeave</td>
<td>Called when the item leaves the viewport, provided DragEnter accepted the event earlier.</td>
</tr>
<tr>
<td>Drop</td>
<td>Called if the game developer drops the item into the viewport.</td>
</tr>
</tbody>
</table>

For more information, see lumberyard_version\dev\Code\Framework\AzQtComponents\AzQtComponents\Buses\DragAndDrop.h and lumberyard_version\dev\Code\Sandbox\Editor\AzAssetBrowser\AzAssetBrowserRequestHandler.h.

Priority of Handling

Bus handlers on the DragAndDropEventsBus are sorted by the return value of GetPriority(). Because the first handler to accept the event gets priority, you can override the default behavior by positioning your component before others.

When assets from the Asset Browser are dragged, the MimeData function in the drag event contains one or more AssetBrowserEntry pointers.

Several utility functions make it easier to implement your drag handlers. The following example is from lumberyard_version\dev\Code\Sandbox\Editor\AzAssetBrowser\AzAssetBrowserRequestHandler.cpp:

```cpp
AssetBrowserEntry::ForEachEntryInMimeData<SourceAssetBrowserEntry>(event->mimeData(),
    [&](const SourceAssetBrowserEntry* source) {
        SpawnEntityAtPoint(source, viewportDragContext, spawnedEntities, spawnTicket);
    });
```

ForEachEntryInMimeData<T> takes one of the types of AssetBrowser entries (SourceAssetBrowserEntry, ProductAssetBrowserEntry, FolderAssetBrowserEntry, RootAssetBrowserEntry) and calls your callback for each of the entries found. You can use these callbacks to detect events and react to them appropriately.

Checking Event Ownership

It is important to note that Asset Browser elements are not the only objects that go through this drag operations pipeline. Files and other objects of drag operations can produce drag events. For this reason, it is important to verify that a drag event that you received corresponds to your object before you take any action. Your code should not assume that your object is the one being dragged.

To perform the check, examine the event's isAccepted() Boolean property. If the event has already been accepted, do not take action. You can also check the status of the event by examining the mimeData attached in event->mimeData() to decide whether to accept it.

The following related code is from AzAssetBrowserRequestHandler.cpp:

```cpp
// If a listener with a higher priority has already claimed the event, do not touch it.
```
ViewportDragContext* viewportDragContext = azrtti_cast<ViewportDragContext*>(&context);
if ((!event) || (!event->mimeData()) || (event->isAccepted()) || (!viewportDragContext))
{
    return false;
}

The Lumberyard drag-and-drop system uses the same semantics as the Qt drag and drop system. For more information, see Drag and Drop in the Qt documentation.

3. Customizing the Context Menu

Whenever the context menu is requested, an EBus is invoked that listeners can use to register additional actions to it. To add items to the context menu, monitor the AssetBrowserInteractionNotificationsBus::Handler and implement AddContextMenuActions, as in the following example.

```cpp
// A notification that a context menu is about to be shown provides an opportunity to add actions to it.
virtual void AddContextMenuActions(QWidget* /*caller*/, QMenu* /*menu*/, const AZStd::vector<AssetBrowserEntry*>& /*entries*/) {};
```

4. Customizing File Open Behavior

Right or double-clicking an asset in the Asset Browser or elsewhere in the UI triggers the file open behavior. The default behavior passes the asset file to the operating system.

You can override this behavior by deriving from the AssetBrowserInteractionNotificationsBus::Handler and implementing AddSourceFileOpeners, as in the following code.

```cpp
virtual void AddSourceFileOpeners(const char* /*fullSourceFileName*/, const AZ::Uuid& /*sourceUUID*/, SourceFileOpenerList& /*openers*/) {};
```

A source file opener provides the Open with... feature in the UI. You can return multiple source file openers if you have more than one.

The following code shows how to add source file openers.

```cpp
void AssetBrowserContextProvider::AddSourceFileOpeners(const char* fullSourceFileName, const AZ::Uuid& sourceUUID, AzToolsFramework::AssetBrowser::SourceFileOpenerList& openers)
{
    using namespace AzToolsFramework;
    // Get the details of the source file based on its UUID.
    if (const SourceAssetBrowserEntry* source = SourceAssetBrowserEntry::GetSourceByAssetId(sourceUUID))
    {
        // Specify actions to take when the source file is not handled.
        if (!HandlesSource(source))
        {
            return;
        }
    }

    // Create as many openers as you want. For each opener, specify a unique identifier, an icon, and a Lambda function to call.
    openers.push_back({"Lumberyard_FBX_Settings_Edit", "Edit Settings...", QIcon(), [this](const char* fullSourceFileNameInCallback, const AZ::Uuid& sourceUUID*)
    {
        // sourceName must be an AZStd::string.
        AZStd::string sourceName(fullSourceFileNameInCallback);
        AssetImporterPlugin::GetInstance()->EditImportSettings(sourceName);
    }});
}```
If you implement an opener in this way, double-clicks and other file open gestures call your opener instead of the operating system.

**Preventing the OS from Opening a Custom File**

You can prevent a source file from being opened by the operating system even if you do not provide a file opener to replace it. For example, you might want to prevent the operating system from opening a file that is in a custom format that the OS cannot handle. To implement this, create an opener for the corresponding asset that has a `nullptr` for the callback.

**Creating a Custom Asset Builder**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Asset Builder SDK lets you develop an asset builder that processes your custom asset type source files into game-ready files. This topic shows you how to create your own asset builder by using the example asset builder that is included with Lumberyard.

To create a builder for a custom asset type:

1. **Create Builder Classes** (p. 319) – Create one or more builder classes that build the asset. The classes must implement the appropriate callbacks and handle shutdown messages from Asset Processor.

2. **Create a Lifecycle Component** (p. 324) – Create a lifecycle `AZ::Component` that registers all of your builder classes. The lifecycle component provides Asset Processor with information to ensure that the correct asset builder is invoked for a file.

3. **Tag Components for Builder Mode** (p. 324) – Tag your lifecycle component and any supporting `AZ::Component` instances with the `AssetBuilder` tag to ensure that they are activated in builder mode.

4. **(Optional) Implement Message Logging** (p. 325) – Use the `BuilderLog()` function and standard `AZ_Trace` macros to log builder-related messages or errors.

This topic describes how to create builder classes, register your builder, tag your components, and implement message logging for your builder.

**Builder Resources**

This topic draws on the following resources, which are included with Lumberyard:

- **Lumberyard Asset Builder SDK** – The Asset Builder SDK enables you to build custom asset processing tools. The source code is located in the following directory:

  `lumberyard_version\dev\Code\Tools\AssetProcessor\AssetBuilderSDK\AssetBuilderSDK`

- **CustomAssetExample gem** – Provides sample custom asset builder code. The builder-related source files for the gem are located in the following directory:

  `lumberyard_version\dev\Gems\CustomAssetExample\Code\Source\CustomAssetExample\Builder`
Prerequisites

This topic assumes that you have a working knowledge of Lumberyard Gems (p. 1073), AZ::Modules (p. 1093), and AZ::Components (p. 974). The next section includes a brief overview of asset builders inside gems.

Asset Builders Inside Gems

Gems contain two kinds of modules:

- A runtime module: `gem_name.dll`
- A tools module: `gem_name.Editor.dll`

These modules contain system components (p. 1098) and tool components. When Lumberyard starts, an AZ::ComponentApplication activates all required system components for the gems that are enabled for the project.

1. Create Builder Classes

To create an asset builder, you must implement one or more builder classes. You can create a builder class with the following steps:

A. Implement the CreateJobsFunction Callback Function (p. 319)

B. (Optional) Declare Source File Dependencies (p. 320)

C. (Optional) Declare Job Dependencies (p. 321)

D. (Optional) Handle Platform-Specific Cases (p. 321)

E. Implement the Callback for ProcessJobFunction (p. 322)

F. (Optional) Declare Product Dependencies (p. 322)

G. (Optional) Declare Product Path Dependencies (p. 323)

H. (Optional) Create a JobCancelListener (p. 323)

I. Shut Down Properly (p. 323)

Each builder class requires two callback functions: one for CreateJobFunction, and one for ProcessJobFunction. Asset Processor uses these callbacks to communicate with your builder class.

Example builder class code is located in the `lumberyard_version\dev\Gems\CustomAssetExample\Code\Source\Builder\CustomAssetExampleBuilderWorker.cpp` file.

A. Implement the CreateJobsFunction Callback Function

In most cases, you should build a JobDescriptor for each processing job for each enabled platform. Then, add the JobDescriptor to the CreateJobsResponse list in the callback for CreateJobsFunction.

Keep in mind the following:

- To ensure that critical files are included, Lumberyard Editor blocks on startup until all callbacks for CreateJobFunction have completed. Due to this startup constraint, we recommend that your code perform minimal work during the CreateJobsFunction callback. For heavy processing work, use the callback for the ProcessJobFunction.
• For extra configurability, you can place arbitrary key–value pairs into the JobDescriptor.m_jobParameters field. The key–value pairs are retained and sent to the callback for ProcessJobsFunction. You can store information gathered during the CreateJobsFunction callback in these key–value pairs and then pass the information as parameters to the callback for ProcessJobsFunction.

• To delete stale products, Asset Processor compares the JobDescriptor that you create with the JobDescriptors that were created in the last iteration. Asset Processor compares JobDescriptors that have the same input source files, PlatformInfo value, and job key.

• You don't need to check whether a JobDescriptor that you create needs to be processed later. Instead, create all possible jobs at every iteration for a particular input asset on each enabled platform.

For an example of a CreateJobsFunction callback, see the CustomAssetExample::ExampleBuilderWorker::CreateJobs() function in the CustomAssetExample gem.

B. (Optional) Declare Source File Dependencies

You can use the Asset Builder SDK to declare dependencies for a source file on other source files. These source files can be any file within the project directory or directories. They do not need to be source files consumed by a builder.

Declaring Asset Dependencies

To declare dependencies, add them in the CreateJobsFunction callback in your builder class to m_sourceFileDependencyList in the CreateJobsResponse structure.

Keep in mind the following:

• Declaring dependencies for a source file implies that the data in its output changes if the files that the source file depends on change. If any of the source dependency files are modified, Asset Processor calls the CreateJobsFunction and ProcessJobsFunction callbacks on the dependent files to reprocess them.

• Asset Processor automatically handles source file dependencies recursively. If the source files downstream emit their own dependencies when they are queried, you do not need to recursively traverse the full tree of dependencies. Emit your local dependencies for each node in the tree, and Asset Processor takes care of the rest.

• Because metafiles such as *.assetinfo files are special case files that cause your asset to rebuild automatically, you do not need to add them as dependencies.

Source File UUIDs versus Paths

The SourceFileDependency structure contains m_sourceFileDependencyPath and m_sourceFileDependencyUUID. Your builder class must supply a value for only one of these fields.

Keep in mind the following:

• If the UUID of the file to add as a dependency is known inside of the CreateJobs method, the builder can simply fill in the m_sourceFileDependencyUUID field. Otherwise, the builder must provide the appropriate source dependency file path for the m_sourceFileDependencyPath field.

• There are two types of path dependencies, indicated by m_sourceDependencyType. These two types are Absolute and Wildcard. Absolute dependencies process only the files that match the provided path exactly. Wildcard dependencies allow for the use of * and % characters in an asset path, which match any number of characters. The use of Wildcard can increase asset build times, so use it only when you must.

• The field m_sourceFileDependencyPath can take both absolute and relative file paths. If a relative path is specified, the appropriate overriding asset is used, if one exists.
• If the builder uses a relative file path for the m_sourceFileDependencyPath field, then the specified path must be relative to one of the watched directories. However, if both the source and the source dependency file exist in the same directory, you can provide the file name without a path.

For an example of adding dependencies inside of a CreateJobsFunction callback, see the CustomAssetExampleBuilderWorker::CreateJobs() function in the CustomAssetExample gem.

C. (Optional) Declare Job Dependencies

You can use the Asset Builder SDK to declare that your custom asset build depends on another job registered with the Asset Processor. Job dependencies are based on either the fingerprint of another job's changes, or the successful completion of a job.

Types of Job Dependencies

There are two types of job dependencies, indicated by the AssetBuilderSDK::JobDependencyType value passed to the constructor for AssetBuilderSDK::JobDependency objects. The dependency type is stored in the m_type member of the created object. These two types are:

• Fingerprint: The Fingerprint dependency causes a job to re-run when the job it's dependent on is reprocessed, and the artifacts generated by the dependent job change according to its fingerprint definition. Fingerprint definitions can include any information, but a fingerprint always includes the state of the source file. This makes fingerprint dependencies a superset of source file dependencies.
• Order: The Order dependency causes a job to be processed whenever the job it's dependent on completes, regardless of whether or not any artifacts or fingerprints have changed. Adding order dependencies reduces the ability to parallelize asset build tasks, so use order dependencies only where needed.

Declare Job Dependencies

Adding job dependencies is done by adding JobDependency objects to an existing JobDescriptor through the m_jobDependencyList member. For example, to add a Fingerprint dependency on the test.example source file for the ExamplePlatform platform, for the job key Example Job:

```cpp
AssetBuilderSDK::JobDescriptor descriptor;
descriptor.m_jobKey = "Example Job"; // Key for matching dependent jobs
descriptor.SetPlatformIdentifier("ExamplePlatform"); // Platform identifier for matching dependent jobs
AssetBuilderSDK::SourceFileDependency sourceFile;
sourceFile.m_sourceFileDependencyPath = "test.example"; // Source file processed by dependent jobs
AssetBuilderSDK::JobDependency jobDependency(
    descriptor.m_jobKey,
    "ExamplePlatform",
    AssetBuilderSDK::JobDependencyType::Fingerprint,
    sourceFile
);
descriptor.m_jobDependencyList.push_back(jobDependency);
response.m_createJobOutputs.push_back(descriptor);
```

D. (Optional) Handle Platform-Specific Cases

CreateJobsRequest provides helper functions for operations related to the enabled platforms. These helper functions can be useful for building the output JobDescriptor for a specific enabled platform.
For more information about declaring, enabling, or disabling platforms, see Configuring the Asset Pipeline (p. 269).

The following functions are available in the Asset Builder SDK. For source code, see
lumberyard_version\dev\Code\Tools\AssetProcessor\AssetBuilderSDK \AssetBuilderSDK\AssetBuilderSDK.*

- HasPlatform(const char* platformIdentifier) - For the specified platform identifier, returns whether that platform is enabled for this CreateJobsRequest. The platform identifier is data driven and user specified. It is usually a string representation of the platform name (for example, "pc" or "osx").
- HasPlatformWithTag(const char* platformTag) - For the specified platform tag, returns whether Lumberyard has any enabled platforms in the CreateJobRequest that contain that tag. Tags are data driven and user specified. They usually identify features that are not specific to a single platform (for example, "mobile" or "console").

E. Implement the Callback for ProcessJobFunction

Asset Processor calls the callback for the ProcessJobFunction when it has a job for the builder class to begin processing. The callback for your ProcessJobFunction should perform the following tasks:

1. Process the source file and perform all work inside the temporary directory.
2. Create at least one product file in the temporary directory.

Keep in mind the following:

- Because the callback occurs on a worker thread, do not spawn threads to do the work in your builder class.
- Do not interact with other threads during the callback. The JobDescriptor that the callback receives is the JobDescriptor that your builder class created in the CreateJobsFunction callback.
- During the callback, create, modify, or write files only in the temporary directory. You can use this temporary directory any way that you want. For example, you can use this directory to write intermediate files and the final products themselves.
- After your job succeeds, Asset Processor copies your registered products to the asset cache. Do not write to the cache directly.

For an example of a ProcessJobFunction callback, see the
CustomAssetExample::ExampleBuilderWorker::ProcessJob() function in the
CustomAssetExample gem in the lumberyard_version\dev\Gems\CustomAssetExample\Code \Source\CustomAssetExample\Builder\CustomAssetExampleBuilderWorker.cpp file.

F. (Optional) Declare Product Dependencies

Product dependencies are used to indicate product files needed at runtime. An example of this kind of dependency is a mesh file that depends on a material. Product dependencies can be referred to by AssetId, path to the source file, or the path to the product. This section describes adding product dependencies based on AssetId references. For information about path dependencies, see the next step, declare product path dependencies (p. 323).

Product dependencies based on AssetId are represented by ProductDependency objects, and may also have an associated 64-bit field flag for metadata. JobProduct objects are assigned dependencies by adding them to the JobProduct.m_dependencies member. If a job's dependencies have their own dependencies, they're correctly handled by the Asset Bundler.
Important
If a product generated by a custom builder is needed at runtime, it must be declared as a product dependency somewhere. The release packaging system relies on product dependencies to figure out what to include in the release build.

G. (Optional) Declare Product Path Dependencies

For situations where you can't use an AssetId to define a product dependency, use either the source or product path to define a product dependency. Where possible, use the AssetId reference system. Product dependencies defined by paths are intended for use with legacy systems and third party tools that don't integrate properly with the AssetId system.

Path dependencies are created as ProductPathDependency objects. These objects are constructed with the ProductPathDependencyType and the string representing the file's path. Path dependencies can be absolute or relative. They are identified either as ProductPathDependencyType::SourceFile for files located in the source folder, or ProductPathDependencyType::ProductFile for product files stored in the cache.

Paths can include the * wildcard character, which matches any number of characters. Wildcards can introduce performance penalties as the Asset Processor evaluates all files of the given ProductPathDependencyType to see if they match the pattern. Additionally, wildcard dependencies are never considered to be resolved and are re-evaluated on each run of the Asset Processor.

JobProduct objects are assigned path dependencies by adding them to the JobDescriptor.m_pathDependencies member.

You can check to see if path dependencies have been resolved by opening the sqlite database in the cache and examining the ProductDependencies table. Unresolved dependencies will have their path in the UnresolvedPath field.

Important
If a product generated by a custom builder is needed at runtime, it must be declared as a product dependency somewhere. The release packaging system relies on product dependencies to figure out what to include in the release build.

H. (Optional) Create a JobCancelListener

Builder classes can use the JobCancelListener function to listen for job cancellation requests in their processJob method. Your code should listen for cancellation requests and then cancel work, if possible, when a request is received. The address of this listener is the job ID of the job that is in processJobRequest. If additional processing like signaling a semaphore or other threading work is required, you can derive from the JobCancelListener and then reimplement Cancel().

For a basic example of JobCancelListener, see the CustomAssetExample::ExampleBuilderWorker::ProcessJob() function in the CustomAssetExample gem in the lumberyard_version\dev\Gems\CustomAssetExample\Code \Source\CustomAssetExample\Builder\CustomAssetExampleBuilderWorker.cpp file.

I. Shut Down Properly

When your asset builder application needs to shut down, Asset Processor uses the address of the registered builder's AZ::Uuid to broadcast the Shutdown() message on the AssetBuilderSDK::AssetBuilderBus. At this point, your builder must stop all tasks and return control to Asset Processor.

Important
Failure to terminate promptly when Asset Processor shuts down and then restarts can cause your system to stop responding. The shutdown message comes from a thread that is separate from the ProcessJob() thread.
2. Create a Lifecycle Component

In this step, create a lifecycle component that registers your builder class with Asset Processor in the Activate() function.

To register each of the builder classes, your lifecycle component must call the AssetBuilderSDK::AssetBuilderBus Event Bus (EBus). This registration allows Asset Processor to send requests to the two registered callback functions in your builder class.

For a code example of a lifecycle component, see the lumberyard_version\dev\Gems\CustomAssetExample\Code\Source\Builder\CustomAssetExampleBuilderComponent.cpp file.

3. Tag Components for Builder Mode

In this step, tag your lifecycle component and all the system components that must be active for your builder worker’s ProcessJobs and CreateJobs functions to work. The components that you tag can be any components that aid in processing your asset type. For example, you might tag a component that contains an implementation of an EBus handler that loads your asset type.

To tag components as mandatory in builder mode, you add an AZ::Edit::Attributes::SystemComponentTags attribute to the AZ::SerializeContext of each component’s Reflect() function. The Asset Builder creates and activates components that you tag as AssetBuilderSDK::ComponentTags::AssetBuilder.

Example

The following example is from the lifecycle component of the CustomAssetExample gem’s CustomAssetExample::ExampleBuilderComponent::Reflect() function.

```cpp
// Perform static reflection or type registration here of any types that you need the serializer to know about
void ExampleBuilderComponent::Reflect(AZ::ReflectContext* context)
{
    if (AZ::SerializeContext* serialize = azrtti_cast<AZ::SerializeContext*>(context))
    {
        serialize->Class<ExampleBuilderComponent, AZ::Component>()
            ->Version(0)
            ->Attribute(AZ::Edit::Attributes::SystemComponentTags,
                        AZStd::vector<AZ::Crc32>({ AssetBuilderSDK::ComponentTags::AssetBuilder }));
    }
}
```

The AZ::Edit::Attributes::SystemComponentTags attribute takes a single AZ::Crc32 value or a vector of AZ::Crc32 values. The example uses a vector. Using a vector makes it more efficient to add tags later in development.

For the source code, see the lumberyard_version\dev\Gems\CustomAssetExample\Code\Source\CustomAssetExample\Builder\CustomAssetExampleBuilderComponent.cpp file.

More About Tagging

Many system components contain logic and startup systems that can be detrimental to asset builds. For example, systems that simulate physics, render GUIs, or attempt to acquire device or network contexts can negatively impact asset builder performance. For this reason, Lumberyard’s Asset Processor loads the same set of gems that Lumberyard Editor loads from the lumberyard_version\dev\project_name\Config\Editor.xml file, but activates only the components that are tagged as mandatory in builder mode. This selective activation of tagged components also makes it possible for an arbitrary number of builder and non-builder components to reside together inside a gem.
4. (Optional) Implement Message Logging

To log builder registration in your lifecycle component, use the following syntax:

```
BuilderLog(AZ::Uuid builderId, const char* message, ...)
```

`BuilderLog` records messages at the application level. To log job-specific messages in the builder classes, use standard `AZ_Trace` macros like the following in the function callbacks in your builder class:

```
AZ_TracePrintf(window, msg)
AZ_Warning(...)
AZ_Error(...)
AZ_Assert(...)
```

This ensures that your messages are in the job’s log file and display in Asset Processor’s log view for that specific job.

Logging Resources

For `BuilderLog` source code, see `lumberyard_version\dev\Code\Tools\AssetProcessor\AssetBuilderSDK\AssetBuilderSDK\AssetBuilderSDK.*`. For trace-related source code, see `lumberyard_version\dev\Code\Framework\AzCore\AzCore\Debug\Trace.*`.

Asset IDs and File Paths

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Consult this section if you are a game engineer who needs to port older game code or develop new code or tools.

File Path Aliases versus Asset IDs

All files accessed for the game runtime go through an interface that supports aliasing of file paths by name. For example, the alias `@ROOT@` refers to the root directory where the `bootstrap.cfg` file is located. If you need to open a file in the root directory, do not go to the root directory or use the current working directory. Instead, use the file name, such as `@root@/filename.cfg`. The various Lumberyard subsystems correctly resolve the alias.

Other aliases available include the following:

- `@log@` – For storing forensic data, such as crashes, logs, traces, performance drops, and unit test output.
- `@cache@` – For storing data that can be cleaned out at any time and does not need to persist.
- `@user@` – For storing data that needs to persist between users. Note that some operating systems may back up this data to the cloud, such as for user preferences.
- `@assets@` – The location of the asset cache. If no alias is specified, this is assumed, so it is almost never necessary to specify this.
- `@devroot@` – The root of your development tree where the editable `engineroot.txt` file is located. This file is shared by many game projects and used by the editor and other tools.
- `@devassets@` – The root of your source asset directory for your game, which is used by the editor and tools.
The following are examples of asset IDs:

- textures/mytexture.dds
- objects/rain/droplet.cfgf
- gamedata.xml
- levels/mainlevel/mainlevel.xml

The following examples are file paths and not assets IDs:

- @assets@/textures/mytexture.dds
- @root@/system.cfg
- C:\dev\mystuff.txt
- \\networkdrive\somefile.dat

The following example is invalid as it mistakenly assumes that the asset cache has the same name as the game and that it is a child folder of the root directory. This isn't true on all operating systems:

- @root@/GameName/textures/mytexture.dds

When referring to assets during runtime, always use the asset ID. Do not prefix asset IDs with @assets@ or the game name, and do not concatenate them with custom strings. Treat asset IDs as immutable data that are not strings and that refer to specific assets. For example, store textures/mytexture.dds, not gems/rain/mytexture.tif.

You can use the FileIO interface, which is accessible through gEnv->pFileIO, to resolve aliased names to full paths if you want to point to an external disk loading tool such as Qt Qfile(). This should almost never be necessary during runtime. If you do use this, your system cannot use remote asset access or support live reloading.

### Converting Asset IDs to Full Paths

If you are writing a new editor tool or porting an existing one from a legacy system, keep in mind the separation between game code and editor code. Game code cannot manipulate asset IDs, and therefore it is invalid to retrieve the game path or concatenate game names with path names. The game code and game modules also have no access to source control, so relying on the game to find out where to save files will not work.

Instead, develop your editor code in such a way that the editor decides where files are saved, and optionally loaded from, and correctly interfaces with source control and the asset processing system. (Source control and asset processing are overhead that is governed by the editor tool, not the game.)

The following utilities and guidelines are provided to make this easier:

- Store only asset IDs for all source assets. For example, if you are writing a file that refers to other files, do not store C:\lumberyard_version\dev\MyGame\myasset.txt in the file's data, for example. Instead, just store myasset.txt, its asset ID.
- If you are in an editor tool, link to EditorCore, and then do the following:
  - #include <PathUtil.h>
  - Call Path::FullPathToGamePath(string) to convert any full path into a game asset ID automatically.
  - Call Path::GamePathToFullPath(string) to convert any asset ID into a full source asset name.
  - Call Path::GetEditingGameDataFolder to see where to save files that do not exist yet, such as for a File Save dialog.
• If you are working in a new system that does rely on legacy systems, you can use an EBus, which has the same functionality as described above. For more information about the EBus, see Event Bus (EBus) in the Amazon Lumberyard User Guide.

• #include <AzToolsFramework/API/EditorAssetSystemAPI.h>

• Call EBus messages ConvertFullPathToRelativeAssetPath and ConvertRelativeAssetPathToFullPath to convert back and forth.

• Call EBus messages GetAbsoluteDevGameFolderPath to get the game directory for File Save dialogs. Use this only when you do not have an asset ID already, such as in the case of new files.

As an example, the following steps code a tool that provides a list of all available assets of type sprite:

To make a list of available sprite assets

1. Use the gEnv->pCryPak file-finding functions to search for all asset IDs. Usually, since @assets@ is assumed, just the directory name or extensions are all that is required, but aliases are accepted.

2. Once you have the asset ID list, call GamePathToFullPath or ConvertRelativeAssetPathToFullPath to convert the list to full source names.

3. Display the appropriate name in the UI, either the real source name or the output name.

4. To edit the file, use the source name to check it out from source control.

5. To save the file, make sure to write it to the source name, not the target name.

6. When the asset compiler recompiles the asset, it notifies you using the asset ID. Make sure you compare the incoming name to this asset ID.

Live Update Messages

If you are on a PC or you are connected to VFS, you can listen for live update messages from the Asset Pipeline and reload your assets when you get them.

To do this, do the following:

• #include <IAssetSystem.h>

• Subscribe a listener to the AssetSystemBus. Subscribers connect through the CRC of the file extensions that they are interested in. Search for "AssetChanged" to see examples in various systems.

Here is an example: BusConnect(AZ_CRC("dds")); // Be notified of all DDS file changes.

Once you get your live reload notification, it contains an asset ID. Consider queueing the request for later if you are in a thread-sensitive module.

Job Dependency for Asset Pipeline

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Manage dependencies for assets so that Asset Pipeline processes them in the correct order.

In Asset Pipeline, you create asset builders using the Asset Builder SDK. The Asset Builder SDK processes your custom asset-type source files into game-ready files. The Asset Builder SDK is a separate executable from Asset Processor. For more information about the Asset Builder SDK, see Creating a Custom Asset Builder (p. 318).
For each asset builder that registered a particular source asset type:

1. The `CreateJobs` operation is invoked, which is where you can declare job dependencies.
2. The `ProcessJob` operation is invoked, which is where your source files are processed into game-ready assets.

A job is uniquely identified by a tuple that contains the following:

- **Job key** – The key that the builder emits for that kind of job in its own `CreateJobs` function.
- **Platform** – The platform identifier of the job. This is generally set to the same platform as the job that runs.
- **Source file** – The source file that the job operates on.

Use the job dependency feature to specify dependencies on jobs, and tell Asset Processor to process jobs for the following conditions:

1. When the fingerprint of another job changes. This is called a *fingerprint job dependency*.
2. When another job completes the processing. This is called *order job dependency*.

**Example 1: Fingerprint Job Dependency**

A fingerprint job dependency means that Asset Processor must process the job if the fingerprint of another job changes. You can specify any number of fingerprint job dependencies.

For **Job A**, specify a fingerprint on **Job B**. So if the fingerprint of **Job B** changes, Asset Processor must reprocess **Job A**.

**Example 2: Order Job Dependency**

An order job dependency means that Asset Processor must process the job only when all other order dependency jobs specified by this job are processed. You can specify any number of order job dependencies.

**Job A** has a specified order job dependency on **Job B**. This means that Asset Processor must process **Job B** first and then **Job A**.

**Example**

You might want a builder that operates on the output of the image compilation set of `example.tif` on the platform `pc`. If so, find the job key of that job (for example, "RC Image") and declare a dependency, like the following: ("RC Image," "pc", "example.tif")

```cpp
enum class JobDependencyType : AZ::u32
{
    //!< Asset Processor should process the dependent job, if there is a change to the fingerprint of the job that it depends on.
    Fingerprint,
    //!< The dependent job should only run after Asset Processor processes the job it depends on.
    Order,
};

//! Job dependency information that the builder will send to Asset Processor.
struct JobDependency
{
    AZ_CLASS_ALLOCATOR(JobDependency, AZ::SystemAllocator, 0);
    AZ_TYPE_INFO(JobDependency, "{93A9D915-8C9E-4588-8D86-578C01EEA388}");
};
```
SourceFileDependency m_sourceFile;
AZStd::string m_jobKey;
AZStd::string m_platformIdentifier;
JobDependencyType m_type;

JobDependency() = default;

JobDependency(const AZStd::string& jobKey, const AZStd::string& platformIdentifier,
const JobDependencyType& type, const SourceFileDependency& sourceFile);

static void Reflect(AZ::ReflectContext* context);

For example code, see the CustomAssetExample gem. For source files related to builders, see the
lumberyard_version\dev\Gems\CustomAssetExample\Code\Source\CustomAssetExample\Builder\CustomAssetExampleBuilderWorker.cpp file.

Example

To declare a job dependency inside a builder, see the following code example.

```cpp
for (const AssetBuilderSDK::PlatformInfo& platformInfo : request.m_enabledPlatforms)
{
    AssetBuilderSDK::JobDescriptor descriptor;
    descriptor.m_jobKey = "Compile Example";
    descriptor.SetPlatformIdentifier(platformInfo.m_identifier.c_str());
    AssetBuilderSDK::SourceFileDependency sourceFile;
    sourceFile.m_sourceFileDependencyPath = "test.examplesource";
    // We are declaring a fingerprint job dependency for this job on any job of
    "test.examplesource" which has job key "Compile Example " for every enabled platforms
    AssetBuilderSDK::JobDependency jobDependency("Compile Example",
    platformInfo.m_identifier.c_str(), AssetBuilderSDK::JobDependencyType::Fingerprint,
    sourceFile);
    descriptor.m_jobDependencyList.push_back(jobDependency);
    response.m_createJobOutputs.push_back(descriptor);
}
```

Note

If Asset Processor detects a cyclic job dependency, it displays a warning message and then
processes the first job to unblock the remaining jobs.

Raw File Access in Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.
Download O3DE or visit the AWS Game Tech blog to learn more.

This topic describes how to directly access files in Lumberyard for special use cases. However, it's
recommended that you use the Lumberyard Asset system to work with asset files. In most cases,
raw file access is not required. For more information see Working with the Asset Pipeline and asset
files (p. 247).

When you write an AssetHandler-derived class to load assets in Lumberyard, runtime file handling
is automatic. However, some cases might require lower levels of file access at run time. Scenarios that
might require low-level file access include:

- Loading raw configuration files from the deployment root during startup before .pak files are
  mounted and available.
• Direct access to the files in a .pak file.
• Direct access to files at arbitrary locations on disk.
• Streaming file formats (for example, audio or video) that do not load the entire file but play it back. This approach commonly uses middleware to play back or capture audio, video, or vertex data. Most such systems require that you implement file hooks to perform operations like read, seek, tell, open, and close. In these cases, direct file access might be easier than treating the files as assets and performing operations on them with AZ::Data systems.
• Other legacy systems or middleware that require direct file access for which AZ::DataAsset systems cannot be used. However, note that it is possible to write a file access shim that describes how to access files for most middleware.
• Loading raw source files from locations other than the asset cache. Loading source files from locations other than the asset cache is possible only for tools inside Lumberyard Editor. Only the asset cache ships with your game, so loading raw source files from locations other than the asset cache at run time is not possible.

The few cases where you need to work directly with files are covered by a small number of classes in the AZ::IO namespace such as FileIOBase and FileIOStream.

The FileIOBase Virtual Class

The pure-virtual base class FileIOBase (located in \dev\Code\Framework\AzCore\AzCore\IO AzCore\IO\FileIO.h) defines the API for accessing files. It is a basic blocking low-level file API, as the following code shows:

```cpp
class FileIOBase
{
    ...
    static FileIOBase* GetInstance();  ///< Use this to get a concrete instance of the API that follows.
    ...
    virtual Result Open(const char* filePath, OpenMode mode, HandleType& fileHandle) = 0;
    virtual Result Close(HandleType fileHandle) = 0;
    virtual Result Tell(HandleType fileHandle, AZ::u64& offset) = 0;
    virtual Result Seek(HandleType fileHandle, AZ::s64 offset, SeekType type) = 0;
    virtual Result Read(HandleType fileHandle, void* buffer, AZ::u64 size, bool failOnFewerThanSizeBytesRead = false, AZ::u64* bytesRead = nullptr) = 0;
    virtual Result Write(HandleType fileHandle, const void* buffer, AZ::u64 size, AZ::u64* bytesWritten = nullptr) = 0;
    virtual Result Flush(HandleType fileHandle) = 0;
    virtual bool Eof(HandleType fileHandle) = 0;
    ...
};
```

The FileIOBase class contains operations to find files, create or delete directories, and inspect attributes. In addition, the class contains a directory aliasing system that is covered later in this document.

Getting an Instance of the I/O Interface

For almost all file operations, you call the GetInstance function to retrieve an instance of the file I/O interface:

```cpp
AZ::IO::FileIOBase::GetInstance()
```

Notes

• All file operations in the FileIOBase class are blocking.
• FileIOBase file operations behave similarly to the C language API fopen, fread, and fclose operations, but are 64-bit aware and work with very large files.
• Because the FileIOBase instance is created and initialized when the engine initializes, it is generally always available. It can inspect .pak files and arbitrary files on disk. For more information, see The FileIO Stack (p. 333) later in this document.

Note
Because .pak files are initialized only after the application boots, attempting to access data inside .pak files before they are mounted will fail.

For more information, see the code comments in the FileIO.h file.

The Aliasing System

In addition to a set of file functions mentioned above, the FileIOBase class provides directory aliases. Directory aliases are prefixes that you add to a file name. An alias indicates a virtual directory for a .pak file or arbitrary location on disk.

Note
We recommend that you always use the aliasing system to refer to files that are in the cache. Never use absolute paths. Files in the cache might be inside .pak files or in unexpected locations on mobile devices. In these cases, the use of absolute path names can fail.

Getting the Path of an Alias

To retrieve the path associated with an alias, use the GetAlias function.

FileIOBase::GetAlias()

List of Aliases

This section describes the use of directory aliases.

@assets@

Refers to the asset cache. This is the default alias when no alias is specified. Note the following:
• Because @assets@ is the default alias, code can simply load files by name (for example, textures\MyTexture.dds) without using the asset system. This makes it unnecessary to have the @assets@ alias appear throughout the code.

Note
If you are loading files from the asset cache, do not prefix your file names with the @assets@ alias. The use of aliases is required only when you must alter the default behavior. This best practice makes your code easier to read and enhances compatibility.
• During development on a PC, @assets@ points to the dev\Cache \<game_name>\pc\<game_name> directory. After release, it points to the directory where your .pak files are stored (not the root of your cache where your configuration files are stored).
• Because the asset cache can be locked by asset processing operations, attempting to write to the asset cache can cause an assertion fail. Do not attempt to write files to the asset cache.

@root@

Specifies the location of the root configuration files like bootstrap.cfg. Note the following:
• The asset cache @assets@ can be a child directory of @root@, but that is not always the case. Therefore, do not make this assumption. If you want to load a root file, use @root@. If you want to load assets, either use no alias (because @assets@ is the default), or use @assets@.
During development, the @root@ directory maps to your dev\Cache\<game_name>\pc directory. In release, this directory is the root directory of your game distribution (where the bootstrap.cfg file is stored).

Attempting to write to the @assets@ location causes an assertion fail. You should change these files in your source dev\ directory, not in the cache.

@user@

Specifies a writable directory that stores data between gaming sessions. Note the following:

- It is not expected that the user will delete this directory.
- On a PC, @user@ is the dev\Cache\<game_name>\pc\user directory.
- On other operating systems and devices, the @user@ location can be different. Some mobile operating systems have restrictions on where applications can write files.

@cache@

Specifies a writable directory for storing temporary data. The user can delete this data at any time.

@log@

Specifies a writable directory for storing diagnostic logs.

**Code Examples**

A. The following code example opens a file in the assets directory.

```cpp
using namespace AZ::IO;
HandleType fileHandle = InvalidHandle;
// Because @assets@\config\myfile.xml is desired, an alias doesn't have to be specified. // All files in the @assets@ alias are always lowercase. This removes concerns about // case sensitive environments.
if (FileIOBase::GetInstance()->Open("config/myfile.xml", AOpenMode::ModeRead| AOpenMode::ModeBinary, fileHandle))
{
    // Open succeeded. Use other API operations of FileIOBase to perform operations with
    // the handle. Remember to close the file!
    FileIOBase::GetInstance()->Close(fileHandle);
}
```

Note that because aliases are used in the preceding example, the config\myfile.xml file would be found even if it is inside a .pak file.

B. The following code example opens a file in the log directory and appends log lines to it.

```cpp
using namespace AZ::IO;
HandleType fileHandle = InvalidHandle;
// In this rare case, you want to write to a file in the @log@ alias, // so the file name must be specified.
// Because you're writing a file to a non-@assets@ directory, it can contain case.
if (FileIOBase::GetInstance()->Open("@log@/gamelog.txt", AOpenMode::ModeAppend|AOpenMode::ModeText, fileHandle))
{
    // Open succeeded. Use other API operations of FileIOBase to perform operations with
    // the handle.
    FileIOBase::GetInstance()->Close(fileHandle);
}
```

The FileIOStream class in the AZ::IO namespace automatically closes a file when it goes out of scope and presents it as a GenericStream interface. This provides compatibility for systems such as the streamer system and serialization system that expect generic streams.
Tools-Only Aliases

The following aliases are applicable only for editor tools.

@devroot@

Specifies the \dev\ directory of your source tree where files like bootstrap.cfg are located. These files are consumed by the Asset Processor and deployed into the cache specified by @root@.

@devassets@

Specifies the location of your game project's assets directory in the source tree. This directory contains uncompiled source files like .tif or .fbx files. It does not contain compressed .dds files or other assets that a game normally uses. Note the following:

• @devassets@ is a good starting point for a file open dialog that asks a user where to save a new file.
• Because existing files might be in a gem, do not save them in @devassets@. Instead, when your editor opens a file, have your editor remember the file's location. Then have the editor save the file to the file's original location.
• Because not all source files are located in @devassets@ (many are located in gems), do not attempt to find all source files by searching its location.

The FileIO Stack

To service the needs of the game client and tools, more than one FileIO instance is created. These instances form a stack through which file requests flow, as the following diagram illustrates.

The behavior of the Either/Or branch depends on whether the virtual file system (VFS) feature (RemoteFileIO in the diagram) is enabled. VFS reads assets remotely from non-PC devices such as Android (p. 3174) and iOS (p. 3208). VFS is required for live reloading of assets (p. 291). Otherwise, assets would need to be deployed directly onto game devices. VFS is disabled by default. To enable VFS, edit the remote_filesystem entry of the \dev\bootstrap.cfg configuration file, as in the following example.
Because the VFS feature is at a low level, file access operations are transmitted transparently over the network through the Asset Processor to the layers above.

To send requests for files through other systems, you can implement your own version of FileIOBase (or one of the derived classes such as RemoteFileIO or LocalFileIO). If you replace the instance returned by either GetInstance or GetDirectInstance with your own instance, the FileIO system uses your layer instead. You can form a stack of additional filters by replacing the instance with your own. Then make your own instance call down into the previously installed instance.

**Asynchronous Streaming**

If you want to use asynchronous background streaming, consider using the AZ::IO::Streamer class instead of FileIOBase. The Streamer class uses FileIOBase internally, but it uses asynchronous semantics. To use the Streamer class, you pass data and a deadline to it. The Streamer class puts the data into a buffer and does its best to fulfill the request before the specified deadline.

For more information, see the code and comments in the \dev\Code\Framework\AzCore\AzCore\IO\Streamer.h file.

### Bundle game assets in Amazon Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Amazon Lumberyard provides a set of tools for intelligently bundling assets and managing your game's product and source dependencies. Use these tools to package only the assets currently used in your game project and reduce the deployment size and complexity of your product overall.

What is the Amazon Lumberyard Asset Bundler?

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Asset Bundler is a command-line tool, AssetBundlerBatch.exe, and a set of specific file formats generated and used by the tool.

Prerequisites to use the Asset Bundler

To use the Asset Bundler, your game project must meet the following criteria:

- You have Lumberyard version 1.22 or later installed.
- You have game project in Lumberyard version 1.22 or later. This is the project that you want to generate asset bundles for.
- The assets that you are bundling have been processed by the Asset Processor (p. 248).
- You have Visual Studio 2017 or Visual Studio 2019 (any edition) installed and configured for C++ development.

Why use the Asset Bundler?

With the Asset Bundler, you don't have to figure out which assets that you need to include in your game and which assets to exclude. This can help save you time. For example, you have a working folder with 10,000 assets, but your final game uses only 5,000 of those assets. You want to ship only those 5,000 assets. Tracking this manually can quickly become complicated and expensive.

The Lumberyard Asset Bundler helps make shipping the specific assets used for the release of your game more reliable and repeatable. The reliability is based on an underlying dependency system that informs Asset Bundler which assets to include. If you make changes to your game and add or remove assets, the next time that you run the Asset Bundler, it automatically includes or excludes these new assets for you. The repeatability is based on underlying configuration files that provides consistency across different runs of the Asset Bundler.

By using the Asset Bundler, because you have smaller release packages, less risk of shipping unused or inappropriate assets, and more effective asset management.
How do I use the Asset Bundler?

Generating a platform-specific (for an iOS-specific release, or a console-specific one) asset bundle using the Asset Bundler follows these general steps:

1. **Define your seeds.** A *seed* is generally a top-level asset, such as a .pak file that contains an entire game or game level. You must have one or more seeds defined in a seed list. A seed list is a file with the suffix .seed.

2. **Generate your asset lists.** The Asset Bundler evaluates each seed defined in your seed list. It then recursively evaluates each dependent asset for inclusion in a complete asset list. Generated asset lists have the suffix .assetlist.

3. **Configure your bundle settings.** Provide a configuration file, called the "bundle settings file," which has the suffix .bundlesettings. It contains all of the specific settings, such as the maximum bundle size, when creating a release bundle for your game.

4. **Bundle your assets.** The Asset Bundler utility, AssetBundlerBatch.exe, uses the asset list and bundle settings files to create a release bundle as a .pak file.

The following diagram illustrates the relationships and process for bundling assets with the Asset Bundler.

In this example, the seeds are the assets Level1.pak and Level2.pak. These .pak files reference Lumberyard slice files, which reference the entity meshes they contain, which in turn reference the material and texture files for those entities.

With those product dependency relationships in place, the Asset Bundler examines the hierarchies of each seed and generates an asset list. Asset lists, along with the bundle settings file that you create, are used to assemble the final bundle as a .pak file with all of the dependent assets. Any assets not associated with a seed are not included in the final release bundle.

The Asset Bundler runs whenever the Asset Processor starts, which includes any time you launch Lumberyard. You can also run it from the command line with the AssetBundlerBatch command. For more information on the latter, read the Asset Bundler Command Line Reference (p. 394).

To get started using the Asset Bundler, read the following tutorials:
• **Work with Asset Bundling and the Lumberyard Starter Game (p. 344).** This tutorial uses the Starter Game packaged with Lumberyard and walks you through the general asset bundling process.

• **Creating Basic Asset Bundles (p. 344).** This tutorial covers the most simple case for asset bundling and release, using a single seed. Once you've worked through this topic, read the extended tutorials for multiple packages (p. 349) and delta patches (p. 354).

### Why define product dependencies?

Many game projects restrict the content in their bundled builds. This is often done to hit target build sizes, such as the over-the-air download cap on iOS. It can also restrict content from builds that you really don't want in your release, such as content that would result in a negative ESRB rating for your game. The product dependency system provides tools to help you understand why assets are included in your asset bundles. This lets you debug the associated references and remove them if you don't want an asset.

There are two types of asset dependencies:

- **Product dependencies.** This type of dependency is between two product assets. It declares that there is a specific link between these two assets, and in most cases you'll want both available in your final packaged build of your game.

- **Source dependencies.** This type of dependency indicates that a source asset must be processed first, and that information from processing the source asset is required before the final product asset can be generated. For example, a process in an asset pipeline that runs on `Tree.fbx` has declared a source dependency on `Tree.mtl`. The `Tree.fbx` job won't run until the `Tree.mtl` job has completed, which guarantees that product details for `Tree.mtl` are available when the `Tree.fbx` job runs, and that information can be used in the generation of `Tree.fbx`'s product (in this example, a single CGF file, `Tree.cgf`).

In these topics, we are referring to **product dependencies** unless otherwise indicated.

The Asset Bundler also lets you exclude content that you don't want to release using the asset list comparison feature (p. 380).

### How product asset dependencies are used by Lumberyard

Product dependencies generate asset lists from seed lists. This simplifies the management of what goes into your packaged game content for your game releases. These dependencies are expressed as paths (either relative or absolute, and can optionally include the wildcard *) and are managed by an Asset Builder during processing. Within the Asset Builder, the `m_pathDependencies` variable contains the list of dependency paths.

For example, you have a game that has one level for your release build. Your game contains a single tree. You also have a separate test level that you don't need to ship, which contains a single rock.
Overview

In the asset bundling workflow in versions of Lumberyard prior to version 1.22, each file had to be tracked and added to the game package. This was generally done by specifying wildcards. It worked for simple builds. However, this process became hard to use when a game was split into multiple bundles. The multiple bundles accommodated content being downloaded on demand, or the hard upper limit on package size because of platform package restrictions. It also became difficult to safely manage excluded content, such as when your game project had assets that could not appear in your release build.

Based on the file layout in the previous example, here's a simple diagram of the workflow in Lumberyard versions prior to 1.22:

For more complex game projects, the asset bundling workflow can look more like this:
The bundling workflow in Lumberyard version 1.22 has fewer steps, fewer loopbacks, and less complex steps than prior versions.

The following example shows a basic workflow for a simple game with assets that emits dependencies correctly.

For more complex game projects, with file loads implemented in C++ and custom asset builders, the asset bundling workflow can look more like this:
New Bundling System
Package release assets only: full process

In the previous bundling method, it was necessary to learn how each asset worked to find asset references in Lumberyard's tools. With the new asset bundling workflow, you need only dig into the individual asset systems when a problem occurs using the missing asset scanning tools (p. 365). You also have opportunities earlier in development to verify that you are bundling the correct assets. This is unlike the previous method that offered verification tools only for a bundled release build.

Asset Builders and the Asset Bundler

An Asset Builder is a standalone application that primarily translates intermediate assets to a platform-native asset format. An Asset Builder also provides dependency tracking and tasks related to managing asset metadata.

Lumberyard ships with Asset Builders for many common asset types. The Asset Bundler relies on the information produced by the Asset Builders for your project to manage the dependencies. If you use custom asset types, you can create your own Asset Builders (p. 318) to support proper asset management and bundling with Lumberyard.

For example, Asset Builders for images can convert any portable image asset into a set of performance image formats. When the Asset Builder for the images run, they create the dependency tree for the performance-oriented image formats generated from the more general-use portable image formats, and define them as dependent on the respective portable image format. If you create the performance-oriented images manually or through a separate process, the dependencies are not defined and not available to the Asset Bundler.
In addition to processing your asset, Asset Builders also determine any product or source asset dependencies and store that information in an Asset Catalog (p. 308) for later use by the Asset Bundler. Specifically, “defining asset dependencies” means updating your custom Asset Builder to identify all of the other assets that the asset being processed depends on. It is important to define asset dependencies so that you can perform accurate Asset Bundling to ship your game. Without defined dependencies the Asset Bundler has no way to know which assets your game needs when it's time to prepare your asset bundles release—you could end up missing assets, or include too many, or ship undesirable ones. With asset dependencies defined in your Asset Builder(s), you can be assured that you are including exactly the assets you need for your game and nothing more.

You can use the Asset Builder APIs to develop your own Asset Builders, which can then process your custom asset type's source files and generate files that you can use in Lumberyard. Source code for a sample Asset Builder implementation is provided in the Games/CustomAssetExample/Code/Source/Builder directory under your Lumberyard installation root.

For more information, see the Asset Builder documentation (p. 318).

### Define dependencies in your Asset Builder

In addition to processing your asset, Asset Builders also define any product or source asset dependencies, and then store that information in a database for later use by the Asset Bundler. Specifically, defining an asset dependency means updating your custom Asset Builder to identify all of the other assets that the asset being processed depends on. It is important to define asset dependencies so that you can perform accurate Asset Bundling to ship your game. Without defined dependencies, the Asset Bundler cannot identify which assets your game needs when it's time to prepare your asset bundles release. As a result, you could end up missing assets, including too many, or shipping undesirable ones. With Asset Dependencies defined in your Asset Builders, you are including the exact assets that you need for your game.

### Asset bundling and source control

During the asset bundling process, you can generate multiple different types of artifacts. We recommend that you track some of these in source control, as per the suggested best practices in the following table.

#### Asset bundling artifact storage best practices

<table>
<thead>
<tr>
<th>File Extension</th>
<th>Source Control Details</th>
<th>File Storage Best Practices</th>
</tr>
</thead>
<tbody>
<tr>
<td>.seed</td>
<td>Keep your seed lists in source control.</td>
<td>If you have multiple builds and are patching bugs in older revisions of your game, consider keeping versioned seed lists that match each release. For example, you could keep seed lists for multiple releases on Steam, such as an unstable feature release and your stable release.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If your game has one release for a specific platform and your release pipeline is relatively uncomplicated, you can maintain one version of a seed list.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You can also track your game's seeds by splitting the contents</td>
</tr>
<tr>
<td>File Extension</td>
<td>Source Control Details</td>
<td>File Storage Best Practices</td>
</tr>
<tr>
<td>----------------</td>
<td>------------------------</td>
<td>----------------------------</td>
</tr>
<tr>
<td>.assetlist</td>
<td>Keep your asset lists in source control. This makes it more efficient to generate delta patches for your game. These are patches that contain only modified files since your last release.</td>
<td>You should store a separate asset list file in your source control for each release that you generate from them. Asset lists contain fingerprint information for each file. If you want to generate a delta patch and you don't have your asset list from the previous version of your game, you must sync your source control back to the exact time you generated that first asset list. Storing each asset list for a version separately can save you time later. For more information, see Asset Bundling &amp; Release Build Tutorial - Delta Bundles, Patching Content.</td>
</tr>
<tr>
<td>.comparisonrules</td>
<td>If you use comparison rules, keep them in source control.</td>
<td>Storing your comparison rules in a file is an optional step in the asset bundling workflow. Use comparison rule files to help make sure that you're generating your packaged game content in the same way across multiple releases.</td>
</tr>
<tr>
<td>.bundlesettings</td>
<td>If you use bundle settings, keep them in source control.</td>
<td>Storing your bundle settings in a file is an optional step in the asset bundling workflow. Use bundle settings files to help make sure that you're generating your packaged game content in the same way across multiple releases.</td>
</tr>
</tbody>
</table>
In the following example, there is a game that has two sets of bundled content: Assets loaded by the engine itself, and assets loaded by the game. In this scenario, the game has just release a version 2 update. Bundles have been created that upgrade existing version 1 players to version 2; and version 2 only bundles content for new players who don't have version 1 content.

The following table provides some examples of the artifacts generated and used in bundling for this example scenario and how they are used.

### Example file artifacts in an Asset Bundler workflow

<table>
<thead>
<tr>
<th>Files (Example)</th>
<th>Usage</th>
<th>Notes</th>
</tr>
</thead>
</table>
| • EngineContent_v1.assetlist  
• Game_engineRemoved_v1.assetlist | The asset lists used to generate the bundles for version 1 of the game. | You should keep these files in source control with the version in the file name. This lets you use these files to generate delta patches for future game releases. |
| • EngineContent_v1_to_v2.assetlist  
• EngineContent_v2.assetlist  
• Game_engineRemoved_v2.assetlist  
• Game_engineRemoved_v1_to_v2.assetlist | Asset lists used to generate bundles for version 2 of the game. | You should keep these files in source control with the version in the file name. This allows these files to be easily used to generate delta patches for future game releases. |
| • Game_all_v1.assetlist  
• Game_all_v2.assetlist | These are asset lists generated as an interim step in creating the game bundle. An asset list comparison that removes content in the engine asset list is used to trim these down to the "engineRemoved" asset lists in the previous row. | You may have asset lists that you generate as interim steps that aren't used to create bundles directly. These could go into source control as a historical record, but they won't be used in the future to generate delta patches. |
| • DeltaBetweenVersions.comparisonrules  
• Game_RemoveOverlappingEngineContent.comparisonrules | Comparison rules files should be stored in source control, so you can use the same bundle creation process each release. Versioning information is not stored in the file name, because | |

Don't store .pak files for your asset bundles in standard source control. Keep them in a separate secured file store.

Keeping track of your previously released content can help you debug problems. Asset bundles can be large, so diffing them isn't particularly useful. We recommend that you find an alternate place to store these files. If you're using Git as your source control solution, Git LFS can provide a useful home for these files. You can also use Amazon S3 to store your historical asset bundles.

**File Extension**
- .pak (asset bundles)

**Source Control Details**
- Don't store .pak files for your asset bundles in standard source control. Keep them in a separate secured file store.

**File Storage Best Practices**
- Keeping track of your previously released content can help you debug problems. Asset bundles can be large, so diffing them isn't particularly useful. We recommend that you find an alternate place to store these files. If you're using Git as your source control solution, Git LFS can provide a useful home for these files. You can also use Amazon S3 to store your historical asset bundles.
### Bundle assets for release

<table>

### Build and bundle assets for release in Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This tutorial guides you through the process of building the code and assets to release a Lumberyard project, using the Starter Game sample project (p. 148). You'll learn how to:
• Create a release build of your game's executable.
• Set up the directory structure of a release build.
• Compile shaders and generate shader paks.
• Compile auxiliary data, like configuration information and gem assets.
• Create bundled content using the asset bundling system.
• Run a stand-alone release build for your project.

Prerequisites

To complete the procedures in this tutorial, you need the following:

• Amazon Lumberyard. Download the latest version of Amazon Lumberyard.
• (Recommended) Some familiarity with the Asset Bundler concepts and terminology (p. 391). This tutorial uses seed lists and asset lists to generate bundles.

Configure Lumberyard to build the Starter Game project

1. Open the Amazon Lumberyard Project Configurator.
2. Select Starter Game and then select Set as default in the upper-right corner of the Project Configurator screen.
3. Open a command prompt and navigate to the Lumberyard root directory at `lumberyard_dir\dev`.
4. Configure the build system for Starter Game and generate configuration files:

```
lmbr_waf configure
```

### Create a release build

1. Open a command prompt and navigate to the Lumberyard install root directory.
2. Create a profile build using the `all` build spec. Depending on your hardware, this can take a while.

```
lmbr_waf build_win_x64_vs2019_profile -p all
```

   This step ensures that your editor, asset processor, asset builders, and other edit-time content is up to date. It’s also required for shader generation.

3. Make a release build with the `game_and_engine` build spec. Depending on your hardware, this can take a while, but should be faster than a full profile build.

```
lmbr_waf build_win_x64_vs2019_release -p game_and_engine
```
Create a directory structure for the game release

1. Open a command prompt and navigate to the Lumberyard install root directory.
2. Create a directory for your game release. The following command creates the release directory:
   ```
   mkdir %USERPROFILE%\StarterGameRelease
   ```
   **Note**
   You can create this directory anywhere you want, but the rest of this tutorial assumes the release directory is in this location. It’s not recommended that you create this directory anywhere inside of your Lumberyard install. If you do, detecting missing assets and diagnosing bundle problems becomes more difficult.
3. Create a subdirectory that will contain the game binaries and libraries:
   ```
   mkdir %USERPROFILE%\StarterGameRelease\release
   ```
4. Copy the contents of the release build into the StarterGameRelease\release directory:
   ```
   xcopy /s Bin64 vc142.Release %USERPROFILE%\StarterGameRelease\release
   ```
   If prompted **Does path specify a file name or directory name on the target?**, choose **Directory**.
   **Note**
   Release builds include some metadata like debug symbols in a .pdb file. When releasing your game, make sure to delete any compiler metadata that's copied over that isn't needed for launching or running your game.
5. Create a subdirectory that will contain the game data:
   ```
   mkdir %USERPROFILE%\StarterGameRelease\startergame
   ```
   The remaining steps in this tutorial show how to build and copy your game data to this directory.

Export level data

1. Open the Lumberyard Editor and load the Starter Game level by selecting **File > Open Level** (Ctrl+O) and selecting the **SinglePlayer** level.
2. Select **Game > Play Game** (Ctrl+G) from the Editor’s main menu to enter Game mode. Roam through the level to load the shader assets. Make sure that you view as much of the level as possible, in order to load them all.
   
   You can also load shaders by flying the camera through the editor’s viewport, but make sure that you load shaders around the player’s starting area. Otherwise, running the standalone game executable will show a black screen.
3. Select **Game > Export to Engine** (Ctrl+E) from the Editor’s main menu to export the level data to a .pak.

Generate shaders and auxiliary data

1. Open a command prompt and navigate to `lumberyard_dir\dev\Tools\CrySCompileServer\x64\profile`.
2. Start the shader compiler. **Don't close the command prompt.**
3. Open a second command prompt and navigate to the Lumberyard install root directory.

4. Compile and package the shaders:

   `lmbr_pak_shaders.bat StarterGame D3D11 pc`

   After building the shaders, close the command prompt window where `CrySCompileServer.exe` is running.

5. Copy the shader .pak files generated by the compiler into the game data folder:

   `copy build\pc\StarterGame\* %USERPROFILE%\StarterGameRelease\startergame`

6. Generate the game's auxiliary data:

   `Tools\Python\python3 BuildReleaseAuxiliaryContent.py --platforms pc --buildFolder Bin64vc142`

   The auxiliary data includes configuration information for the engine and game loading and level data.

7. Copy the auxiliary data to the release directory:

   `xcopy /s startergame_pc_paks %USERPROFILE%\StarterGameRelease`

---

**Generate game asset bundles**

1. Open a command prompt and navigate to the Lumberyard install root directory.

2. Bundle assets needed by the game engine:

   `Bin64vc142\AssetBundlerBatch.exe assetLists --addDefaultSeedListFiles --assetListFile engine.assetlist`

   `Bin64vc142\AssetBundlerBatch.exe bundles --assetListFile engine_pc.assetlist --outputBundlePath %USERPROFILE%\StarterGameRelease\startergame\engine.pak`

   This generates the `engine_pc.pak` file in your release folder. The engine pak contains the assets required by the engine and gems.

3. Bundle game content and level assets:

   `Bin64vc142\AssetBundlerBatch.exe assetLists ^ --addSeed Levels\Game\SinglePlayer\level.pak ^ --addSeed project.json ^ --addSeed gems.json ^ --addSeed scripts/ai/navigation.xml ^ --assetListFile startergame.assetlist`

   `Bin64vc142\AssetBundlerBatch.exe bundles --assetListFile startergame_pc.assetlist --outputBundlePath %USERPROFILE%\StarterGameRelease\startergame\ startergame.pak`

   This generates the `startergame_pc.pak` file in your release folder.

   **Important**

   `--addSeed` takes a path relative to your project folder (for source assets) or the asset cache (for product assets). For Starter Game, project source assets are located in
lumberyard_dir\dev\StarterGame. Don't use absolute paths or paths relative to the current directory when adding a seed.

Run your packaged release

1. Open a command prompt and navigate to your packaged release at %USERPROFILE%\StarterGameRelease.
2. Run the launcher executable for your game and load the map:

```
release\StarterGameLauncher.exe +map singleplayer
```

If your content bundles are correct, the starter game will load and be playable. Use Alt+F4 to exit the game.

If objects are displayed but textures are missing, it probably means you forgot to export the level before packaging assets or didn't add the level.pak file as a seed. You could also be missing some shaders - run through the level and build the shader package again.

If the test isn't successful, common issues may occur. For example, error messages may display, the launcher may shut down, or a black screen displays. For more information about troubleshooting common issues, see Resolving Missing Assets (p. 363) and Compiling Shaders for Release Builds (p. 291).

**Note**

When you run the release build, it creates a User subdirectory under your release build directory. Be sure to delete this directory before shipping the release build.

Next Steps

Now that you've learned the basics of bundling assets for release, go on to further reading:

- Learn about how bundles are mounted, so that you can load content dynamically. See Creating Multiple Asset Bundles (p. 349).
- Explore the asset bundler functionality. See Lumberyard Asset Bundler Command-Line Tool Reference (p. 394).
- Learn how to scan for missing dependencies in your bundles. See Using the Missing Dependency Scanner (p. 366).
- To ask questions about the Asset Bundler and get support, see the Amazon Lumberyard forums.

Creating Multiple Asset Bundles

This tutorial is out of date for the new Starter Game project that shipped as part of Lumberyard 1.25. We're working to revise it and provide better, more comprehensive instructions.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Build and bundle assets for release in Lumberyard (p. 344) tutorial gets you started with using the asset bundling system to produce a game release. However, it doesn't represent what most games
require. In this tutorial, you learn the bundling process for a common use case: Games that download additional content after the player launches the game. The tutorial shows you how to create a release build with multiple game levels in separate asset bundles that have the contents of the base game removed.

This topic covers the following points:

• Adding a new level and basic content to the Starter Game project.
• Creating multiple asset bundles separated by game level.
• Running the new build with and without the additional bundles.

Prerequisites

This tutorial requires completing Build and bundle assets for release in Lumberyard (p. 344). After finishing that tutorial, you should have:

• A bundled release of Starter Game located at %USERPROFILE%\StarterGameRelease
• The startergame_pc.assetlist and engine_pc.assetlist asset list files used to generate the starter game asset bundles.

It's also useful to be familiar with the Amazon Lumberyard Asset List Comparison Operations (p. 380) for this tutorial.

Create a second level

In this section of the tutorial, you'll create a new level for the Starter Game that displays a static scene containing a single entity.

1. Launch the editor, and create a second level. Name it level2.

2. Create a camera. Right-click on the viewport and choose Create camera entity from view.
3. Create an object in front of the camera. To make sure that the object you create is located correctly, you may need to pull the perspective in the viewport back a bit so that you can clearly see the view frustum of the camera and know where the place the object.

   a. Create a new entity in the level by right-clicking in the viewport somewhere within the camera frustum, and selecting Create entity.
Creating Multiple Bundles

b. In the Asset Browser view, search for the `am_rock_boulder_01.cgf` mesh.

![Asset Browser](image)

4. Make sure that the boulder is visible from the camera position by running your game in the editor. Select Game > Play Game (Ctrl-G). If you can't see the boulder, adjust its position with the editor's Move tool and make sure it appears within the camera's view.

5. Select File > Save (Ctrl-S) to save the level.

6. Select Game > Export to Engine (Ctrl-E) to export the level.

7. Exit the editor.

Generate the new content bundle

In the Build and bundle assets for release in Lumberyard (p. 344) tutorial, you created two `.pak` bundles for the game release. This new level you've created only uses the already-available assets that
are bundled with your game, making it easy to distribute only the content that you need. One important feature available in Lumberyard Beta v1.24 and later is the ability to distribute level data as part of its own .pak, rather than with the auxiliary game data.

This section of the tutorial walks you through creating a new asset list based on the level2.pak dependencies, removing duplicate entries that already appear in startergame_pc.pak, and bundling the level for distribution.

1. Create the seed list and asset list for level2.pak:

```
Bin64vc141\AssetBundlerBatch.exe seeds --addSeed levels\level2\level.pak --seedListFile dlc_level2.seed
Bin64vc141\AssetBundlerBatch.exe assetLists --seedListFile dlc_level2.seed --assetListFile dlc_level2_all.assetlist
```

2. Get the complement of the assets between startergame_pc.assetlist from the previous tutorial and dlc_level2_all_pc.assetlist. This generates a new asset list containing game content exclusive to level2.

```
Bin64vc141\AssetBundlerBatch.exe compare --comparisonType complement ^
   --firstAssetFile startergame_pc.assetlist ^
   --secondAssetFile dlc_level2_all_pc.assetlist ^
   --output dlc_level2.assetlist
```

**Important**
The ordering of `--firstAssetFile` and `--secondAssetFile` here is required. The compliment comparison works by taking content located in `secondAssetFile` which isn't referenced in `firstAssetFile` — not the other way around. See Amazon Lumberyard Asset List Comparison Operations (p. 380) for all of the details.

3. Get the complement of the assets between engine_pc.assetlist from the previous tutorial and dlc_level2_pc.assetlist. This removes engine-specific content from the level2 assets.

```
Bin64vc141\AssetBundlerBatch.exe compare --comparisonType complement ^
   --firstAssetFile engine_pc.assetlist ^
   --secondAssetFile dlc_level2_pc.assetlist ^
   --output dlc_level2.assetlist ^
   --allowOverwrites
```

4. Create the asset bundle for level2:

```
Bin64vc141\AssetBundlerBatch.exe bundles --assetListFile dlc_level2_pc.assetlist --outputBundlePath %USERPROFILE%\StarterGameRelease\startergame\dlc_level2.pak
```

**Test the new level in release**

1. Open a console and navigate to the release directory at %USERPROFILE%\StarterGameRelease
2. Launch the new map:

```
release\StarterGameLauncher.exe +map level2
```

If everything works, you should see a scene similar to the following:
Conclusion

You now have a working example of a release build of a PC game on Lumberyard that uses multiple asset bundles. These bundles do not contain duplicate files, and you've performed a workflow that matches how a downloadable content system would add new content to an already released game.

Next Steps

Learn how to bundle patch updates instead of all-new content with the next tutorial in this series: Create content patches with Lumberyard (p. 354).

Create content patches with Lumberyard

This tutorial is out of date for the new Starter Game project that shipped as part of Lumberyard 1.25. We're working to revise it and provide better, more comprehensive instructions.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This tutorial demonstrates a bundling process designed to simulate a patch update to existing content. In this tutorial, you create a set of bundles that simulates a content patch. These bundles include the patch itself, and a new version of the software to distribute with the patch already in place. The update bundle contains only content that changed since the first set of bundles was created. This topic covers:

- Modifying an asset reference to reference a new asset that was not bundled previously.
- Creating an updated asset bundle that contains only updated or new assets.
- Running the new release build with new bundles.
Prerequisites

To complete this tutorial, you should have completed the Build and bundle assets for release in Lumberyard (p. 344) and Creating Multiple Asset Bundles (p. 349) tutorials. You should have:

- A bundled release of Starter Game located at `%USERPROFILE%\StarterGameRelease`
- The startergame_pc.assetlist file used to generate the starter game content bundle.
- The dlc_level2.seed seed list file used to generate the asset list for the level content bundle.
- The dlc_level2_pc.assetlist file used to generate the additional level content bundle.

Add a gem and modify the level

For this tutorial you'll modify the level2 level created in the previous tutorial. You'll also be adding a new asset-only gem to the Starter Game project, to demonstrate how to update auxiliary content in addition to pushing direct changes to a bundle.

1. Launch the Project Configurator, make sure that the Starter Game is selected, and select Enable Gems.

![Lumberyard Project Configurator (PREVIEW)](image)

![Select a project](image)

2. Search for the term primitive in the search bar. The Primitive Assets gem should appear in the results list. Select the checkbox to include it as part of the Starter Game, and then select Save.
Create content patch bundles

Note

The Primitive Assets gem is an asset-only gem, so you aren't required to recompile any code for your game. If you were adding a gem with a code component, you would also need to rebuild both the profile and release portions of your game and distribute the new binaries as part of the patch. See the Build and bundle assets for release in Lumberyard (p. 344) for build instructions and where the release binaries need to be located.

3. Open the Lumberyard Editor and then open level2 that you created in the previous tutorial. (p. 349)

4. Create a new entity in the level and assign it the _box_1x1.fbx mesh.
   a. Right-click in the viewport, somewhere within the frustum of the camera, and select Create entity.
   b. Search for _box_1x1.fbx in the Asset Browser.
   c. Drag the _box_1x1.fbx mesh onto your newly created entity in the level.

If you need a visual refresher on the editor UI for these steps, see Creating Multiple Asset Bundles (p. 349).

5. Save the level by selecting File > Save (Ctrl-S) from the main menu.

6. Export the level by selecting Game > Export to engine (Ctrl-E) from the main menu.

7. Close the Lumberyard Editor.

Recreate the project bundles

In this step you'll version your old asset lists, generate new asset lists based on the changes to the level, and create two content packs: One for distributing to existing versions of the game as a patch, and one for directly downloading the latest version.

Note

For most game updates, only the content of your game assets will change. When upgrading to a new version of Lumberyard and pushing an update, you should regenerate all of the existing content to ensure it's properly updated, including the engine assets and auxiliary content.

1. Open a console and navigate to the Lumberyard root directory at lumberyard_dir\dev.

2. Add a version identifier to the existing dlc_level2_all_pc.assetlist asset list:

   move dlc_level2_all_pc.assetlist dlc_level2_v1_all_pc.assetlist

3. Generate a new asset list dlc_level2_v2_all_pc.assetlist from the dlc_level2.seed file:

   Bin64vc\AssetBundlerBatch.exe assetLists --seedListFile dlc_level2.seed --assetListFile dlc_level2_v2_all.assetlist

   Note

   You don't need to update the dlc_level2.seed file here because only the dependences of the level have changed - nothing about the asset itself that's used as the seed.

4. Get the delta of the assets between the v1 and v2 contents. Taking a delta gets everything that's changed between the two versions and generates a patch:

   Bin64vc\AssetBundlerBatch.exe compare --comparisonType delta ^
   --firstAssetFile dlc_level2_v1_all_pc.assetlist ^
   --secondAssetFile dlc_level2_v2_all_pc.assetlist ^
Create content patch bundles

--output dlc_level2_v1_to_v2_patch.assetlist

5. Remove starter game and engine assets from the dlc_level2_v2_all_pc.assetlist and generate a new asset list with only the latest required level2 assets:

```bash
Bin64vc\AssetBundlerBatch.exe compare --comparisonType complement ^
--firstAssetFile startergame_pc.assetlist ^
--secondAssetFile dlc_level2_v2_all_pc.assetlist ^
--output dlc_level2_v2.assetlist
```

```bash
Bin64vc\AssetBundlerBatch.exe compare --comparisonType complement ^
--firstAssetFile engine_pc.assetlist ^
--secondAssetFile dlc_level2_v2_pc.assetlist ^
--output dlc_level2_v2.assetlist ^
--allowOverwrites
```

6. Create two new bundles, one for the patch and one for the new full distribution:

```bash
Bin64vc\AssetBundlerBatch.exe bundles --assetListFile dlc_level2_v1_to_v2_patch.assetlist --outputBundlePath dlc_level2_v1_to_v2_patch.pak
```

```bash
Bin64vc\AssetBundlerBatch.exe bundles --assetListFile dlc_level2_v2_pc.assetlist --outputBundlePath dlc_level2_v2.pak
```

**Important**

Don't copy either of these files to the release folder yet. The next section will cover testing each bundle to make sure that it contains the correct content, and that they load correctly.

## Simulate user scenarios

Now you're ready to simulate two scenarios: users who have v1 of your game but upgrade to v2, and users who download v2 for the first time.

### Simulate the v1 to v2 patch experience

1. Open a console and navigate to the Lumberyard root directory.
2. Copy the content patch to your release:

```bash
copy dlc_level2_v1_to_v2_patch_pc.pak %USERPROFILE%\StarterGameRelease\startergame
```
3. Launch the starter game and check to see if the new 1x1 box appears in the level2 scene.

```bash
%USERPROFILE%\StarterGameRelease\release\StarterGameLauncher.exe +map level2
```

If the content patch was applied successfully, you should see a scene similar to the following:
Simulate the v2 download experience

1. Delete the content patch and v1 data from your game release:

   ```
   del %USERPROFILE%\StarterGameRelease\startergame\dlc_level2_v1_to_v2_patch_pc.pak
   del %USERPROFILE%\StarterGameRelease\startergame\dlc_level2_pc.pak
   ```

2. Copy the level2 v2 content to the release:

   ```
   copy dlc_level2_v2_pc.pak %USERPROFILE%\StarterGameRelease\startergame
   ```

3. Launch the starter game and check to see if the new 1x1 box appears in the level2 scene.

   ```
   %USERPROFILE%\StarterGameRelease\release\StarterGameLauncher.exe +map level2
   ```

**Conclusion**

You've learned how to generate a content patch to apply to an existing game. Now you know the general steps for distributing additional content and patches for your Lumberyard game:

- Create a complete asset list using your newly created or updated content as a seed.
- Take the *complement* of this asset list from the original game assets and engine assets, to get only the assets needed by your new content.
- When you patch existing content, take the *delta* of the patch asset list against the asset list for the content you're applying the patch to.
Migrating a Game Project to the Asset Bundler

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

If you already have an existing Lumberyard project, and you want to use the new Asset Bundler for your game assets, complete the following steps to update your project:

- Fix missing product dependencies.
- Create a release build using files that are generated with the Asset Bundler.

Fix Missing Dependencies

The Asset Bundler relies on accurate and complete product dependency information to ensure that all assets that are needed for runtime are included in the asset bundle. This procedure shows how to use new and existing Lumberyard tools to find and fix missing product dependencies.

1. Identify missing product dependencies in your project. The missing dependency scanner tool is useful for finding missing product dependencies in projects that don't currently use asset bundling.
   - Using the Missing Dependency Scanner (p. 366)
   - Resolving Missing Assets (p. 363)
2. Update your custom asset builders to output product dependencies. Be sure to add false positive results to the exclusion list using the file tagging system.
   - Implement the Callback for ProcessJobFunction (p. 322)
   - Using the File Tagging System to Include or Exclude Assets (p. 377)
3. Create a seed list and add your required assets as seeds. You can create a dependencies XML file (such as Check Engine/Engine_Dependencies.xml) to include optional assets or add multiple seeds using wildcards. Include the dependencies XML file in the seed list.
   - What is the Amazon Lumberyard Asset Bundler? (p. 335)
4. After you add missing product dependencies and create seed lists, check that product dependencies are being emitted correctly using the Asset Validation Gem with seed mode enabled.
   - Using the Asset Validation Gem to Verify Seeds (p. 371)
5. Generate asset bundles using the Asset Bundler command line tools.
   - Build and bundle assets for release in Lumberyard (p. 344)
   - Lumberyard Asset Bundler Command-Line Tool Reference (p. 394)
6. Have the system load up the bundles that you created in Step 5. Then, use bundle mode to identify any missing assets in the bundle. Ideally, you don't want to see any missing dependencies, but there is no requirement to resolve them all.
   - Using Bundle Mode to Test Bundles (p. 373)

Create Release Build with New Asset Bundling System

After you generate asset bundles to deliver with your game, switch your release build process to use the new asset bundling system. Use the following instructions to generate content including asset bundles for a release build.
1. Configure your game project and set it as the active project. Go to the starter game walkthrough (Build and bundle assets for release in Lumberyard (p. 344)) and follow Steps 1 through 4. Be sure to specify your own game project name instead of "StartGame." The instructions provided in the walkthrough are for PC builds. If your game uses another operating system, such as macOS, iOS, or Android, specify the correct profile in your lmbr_waf and lmbr_pak_shaders calls.

2. If your game runs on the PC operating system, you are ready to create the release build for your game. You can do this by using command line calls, as described in Steps 5 through 6 of the starter game walkthrough. Alternatively, create custom scripts to generate your asset bundles and make .pak files for your content. You can customize the samples described in the next section.

3. If your game runs on any operating system other than PC, follow these steps:
   a. Create a custom RC config file. You can use the file RCJob_Generic_MakeAuxiliaryContentPC.xml as a template and update the operating system and any OS-specific settings.
   b. Create a customized batch file. You can use the file Build_AssetBundler_AuxiliaryContent_PC.bat as a template and update the operating system. You also must update the reference to the RC config file to point to the file that you created in the previous step.
   c. Run the customized batch file to generate auxiliary data and the asset bundles.
   d. Add the new bundle files to the directory gamename_platform_paks/gamename. You can do this manually or create custom scripts based on the samples described in the next section.

Release Build Sample Scripts

The following sample scripts show how you can simplify and automate basic release build processes for your game projects.

- generate_bundle.py (p. 360) – This script uses the Lumberyard command line calls to generate asset bundle files.
- ProjectName_MakePaks.py (p. 362) – This script creates a folder titled gamename_pc_paks and copies the base bundle files to the subfolder gamename_platform_paks/gamename.

```python
import argparse
import subprocess
import os
import platform

class Args(object):
    '''An object that returns None for any undefined properties.'''

    def __init__(self, **kwargs):
        if kwargs:
            for k, v in kwargs.items():
                self.__dict__[k] = v

    def __str__(self):
        return str(self.__dict__)

    def __getattr__(self, name):
        if name in self.__dict__:
            return self.__dict__[name]
        else:
            return None
```

Version 1.28

360
def generate_bundle(args):
    pak_name = args.level
    seed_list_file = 'ProjectName/SeedAssetList.seed'
    asset_list_path = os.path.join('ProjectName', 'AssetLists', pak_name + '_' +
                                args.platform + '.assetlist')
    bundle_path = os.path.join('ProjectName', 'Bundles', pak_name + '_' + args.platform +
                                '.pak')

    if platform.system() == 'Windows':
        asset_bundler_batch = 'Bin64vc141/AssetBundlerBatch.exe'
    elif platform.system() == 'Darwin':

parser = argparse.ArgumentParser()
parser.add_argument('--platform', help='Specifies the platform that will be referenced when generating Bundles.')(args = parser.parse_args())

print(args)
main(context, [args.platform])
Resolving Missing Assets

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

After you build and package your Lumberyard game, you want to frequently verify that your packages contain every asset they require. For information about verifying your asset bundles, see Verifying that Bundles Contain Required Assets (p. 365).

When you identify a potential missing asset, you want to include it so that the asset is no longer missing in your next bundled game package.

An asset that is missing from a bundle might be one of the following:

- **A missing product dependency** – An asset that references another asset, but did not declare it as a product dependency, or the referenced asset was removed during the asset list comparison process (p. 380).
- **A hardcoded file load** – Assets loaded by path or by asset ID in C++.
- **A false positive** – The asset appeared to be missing from a bundle, but is not actually used. For example, you might have an editor-only asset that appears to be missing that is never loaded or used in your game’s launcher.

To resolve the missing asset, check each of these possibilities in turn.

### Missing Product Dependencies

A missing asset might have been loaded as a reference from Lumberyard or from your game code's interaction with another asset. In these cases, you can resolve the issue by emitting a new product dependency.

#### Finding the Asset Reference

To find the source of the asset reference, try the following approaches:

- Use the Asset Processor Batch's missing dependency scanner (p. 366).
- Debug the file load using the following methods:
  - Set breakpoints, if possible
  - Add extra print commands
  - Try interacting with your game in different ways to see what triggers the missing asset to load.

As a hint to where to start debugging, note that most file loading routes through `lumberyard_version\dev\Code\CryEngine\CrySystem\CryPak.cpp` in `CCryPak::FOpen` and `CCryPak::GetFileData`. Setting breakpoints or adding additional debugging logic (like printf statements) can help identify what is triggering the asset load that you are investigating.

#### Finding the Builder to Update

Track down the job that generates the asset that references your missing asset. Then you can update the generated asset to emit the missing asset as a product dependency. The source of the generated asset can be obvious if it has a file extension that is associated with a known builder.

If the source of the generated asset is not obvious, you can use the asset database to look up the information.
To look up a job that generates an asset

1. In the **Products** table, search for the asset that you want to update to emit a dependency. The following example search for a material uses **DB Browser for SQLite** to explore the asset database:

![DB Browser for SQLite screenshot](image1.png)

2. Look up the **JobPK** value in the **Jobs** table, as in the following example:

![DB Browser for SQLite screenshot](image2.png)

3. Look up the **JobKey** or **BuilderGuid** in your code base.

**Updating the Builder to Emit the Dependency**

After you've identified the builder which emits the product that is missing the dependency, update the builder. For more information, see Declare Product Dependencies (p. 322).

**Hardcoded File Loads**

To resolve missing assets from hardcoded file loads, find where in code the file is loaded and then choose a resolution strategy.

**Finding the File Load**

We recommend the following techniques for tracking down a hardcoded file load:

1. Using breakpoints in code.
2. Adding additional log messages to the code base.
3. Doing a “find in files” search for strings that refer to the missing asset.

For more information, see Finding the Asset Reference (p. 363) earlier in this topic.

**Resolving the Missing Asset**

To resolve the missing asset from a hardcoded file load, try the following options:

- **Remove the hardcoded load** – By emitting assets as product dependencies from relevant builders, you can use seed lists with fewer files that are easier to maintain.
- **Add as seed** – If you can't or don't want to replace the hard-coded asset load, you can add the referenced file as a seed to your game's seed list. Because adding the seed changes only data and
doesn't require recompiling your game, this approach can be useful later in development and 
minimizes code changes. For information about adding the referenced file as a seed to your game's 
seed list, see the Lumberyard Asset Bundler Command-Line Tool Reference (p. 394).

• **Use the Wildcard Dependency System** – If your project uses relative path loads or wildcard path 
loads, you can declare the dependencies in a dependencies file. This technique is explained in the 
following section.

### Using the Wildcard Dependency System to Resolve Path Loads

When you migrate (p. 359) a Lumberyard project to use seeds or emit dependencies for all referenced 
assets, two cases cannot be resolved as seeds: Optional relative path loads and wildcard path loads. If 
your bundle is missing an asset that is loaded in either style, try to resolve the missing asset by using 
wildcard dependencies.

To handle dependency tracking for runtime systems that use path manipulation or directory 
scanning to load product files, declare dependencies in a `_Dependencies.xml` file. For example, 
dependencies in the core engine are included in the `lumberyard_version\dev\Engine 
\Engine_Dependencies.xml` file. A dependencies file uses the following format.

```xml
<EngineDependencies versionnumber="1.0.0">
  <Dependency path="*.ent" />
</EngineDependencies>
```

The `path` value is a relative path to a product file that uses simple glob searching. Asterisk (*) characters 
match any number of characters. Glob searches do not support single character wildcards. The files listed 
are recorded as dependencies.

After you add a new `_Dependencies.xml` file, add an entry for the referenced file to a seed list to 
ensure full dependency tracking. The core `Engine_Dependencies.xml` file is already included in the 
default seed list.

### False Positives

Some assets and asset references are used only in the editor or in launchers during development. These 
assets aren't used in release builds. Therefore, you can consider any assets that are missing from bundles 
that aren't used in release builds to be false positives.

### Removing False Positives From Missing Asset Scanning Results

After you've verified that an asset is not used in your release builds, you can use the file tagging system 
to tag it so that it doesn't appear in future scans. For more information, see Using the File Tagging 
System to Include or Exclude Assets (p. 377).

### Verifying that Bundles Contain Required Assets

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. 
Download O3DE or visit the AWS Game Tech blog to learn more.

When your team generates a release build that has bundled game assets, you want to verify that the 
bundles contain everything required to ship your game. Use the tools of the Lumberyard asset bundling 
system throughout the game development process to verify that your asset bundles contain the required 
assets.

As a best practice, verify that your bundles contain their required assets during all game development 
phases:
1. When you start
2. While you develop
3. In development builds
4. In release builds

**When You Start**

As you start building your game, ensure that you create the references to assets that your product requires at runtime. For information about how to emit product dependencies for your custom asset types, see the Declare Product Dependencies (p. 322) section of the Creating a Custom Asset Builder (p. 318) page.

**While You Develop Your Game**

Errors can occur when assets are bundled later in the development process. To avoid errors, consider bundling earlier. However, even before you've defined your seed list or built bundles, you can take steps to avoid unwanted surprises later.

**Before You Build a Seed List**

Before you build a seed list, you can use the missing dependency scanner to look for asset references that might have missing dependencies. For more information, see Using the Missing Dependency Scanner (p. 366).

**After You Have a Seed List**

After you've built a seed list, but before you bundle your assets, you can use the Asset Validation Gem to verify that asset loads map back to seeds. For more information, see Using the Asset Validation Gem to Verify Seeds (p. 371).

**In Development Builds**

After you've generated bundles for your game, test your game in bundle mode with a development build of the editor or launcher. With bundle mode active, use the `sys_report_files_not_found_in_paks` console variable to find any asset files that are missing from your game .pak files. For more information, see Using Bundle Mode to Test Bundles (p. 373).

**In Release Builds**

As with development builds, you can use bundle mode and the `sys_report_files_not_found_in_paks` console variable to find missing asset files in release builds. For more information, see Using Bundle Mode to Test Bundles (p. 373).

**Topics**

- Using the Missing Dependency Scanner (p. 366)
- Using the Asset Validation Gem to Verify Seeds (p. 371)
- Using Bundle Mode to Test Bundles (p. 373)

**Using the Missing Dependency Scanner**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Use the **AssetProcessorBatch.exe** tool to scan your files for patterns that look like missing dependencies. To perform a scan, run the **AssetProcessorBatch.exe** command using the `dependencyScanPattern` (or `dsp`) flag. Because the command performs a SQL query, use search strings compatible with SQL syntax; for example, the wildcard character is `%`, not `*`.

The following command scans all files with the extension `.txt`.

```
AssetProcessorBatch.exe /dependencyScanPattern=%txt
```

The command scans the **ProductName** column in the **Products** table in the asset database. The scanner performs multiple passes so that it can present only results that are likely to be missing dependencies. It scans for patterns like paths, asset IDs, and UUIDs that map to existing products in your game. The results of the scan are stored in the **MissingProductDependencies** table of the asset database.

**Taking Action**

If a scan of assets in your project returns results, verify that they are true dependencies.

- If the results are false positives, use the asset tagging system to mark the files that can be safely ignored in future scans. Files tagged with the `editoronly` or `shader` flags in the file `exclude.filetag` are skipped by the scanner. For more information about file tagging, see Using the File Tagging System to Include or Exclude Assets (p. 377).
- If the dependencies reported are truly missing, update the builder for your asset to emit a dependency. For more information, see the Declare Product Dependencies (p. 322) section of the Creating a Custom Asset Builder (p. 318) page.

**Example**

The following procedures show you how to create an XML file that has a missing dependency. You then resolve the dependency by creating a new schema.

**To create a file with a missing dependency**

1. Create a new XML file in your project named `missingdependency.xml`.
2. Edit the file to include a reference to an asset in your project. In the following example, `missingDependency` refers to the `project.json` file in the game project.

   ```xml
   <missingDependency path="project.json"/>
   ````

3. Run the missing dependency scanner, which processes assets, using syntax, as shown in the following example. The command uses a wildcard to avoid including a platform or project name in the query.

   ```
   Bin64\vc141\AssetProcessorBatch /dsp=%missingdependency.xml
   ```

   The following example shows a query without a wildcard character. The query matches the sample project and operating system environment. Replace `<project_name>` with the name of your game project.

   ```
   Bin64\vc141\AssetProcessorBatch /dsp=pc/<project_name>/missingdependency.xml
   ```

4. Observe the log output. The UUID in the following sample might be different from what you see.

   ```
   AssetProcessor: Scanning for missing dependencies: I:\p4\lyengine\branches \<project_name>\dev\Cache\<project_name>\pc\<project_name>\missingdependency.xml
   ```
AssetProcessor: Missing dependency: String "project.json" matches asset: 
{B076CDDC-14DF-50F4-A5E9-7518ABB3E851}:0

The following image shows sample asset database output.

Next, create a schema to match this file and output, or emit, the dependency.

**To create a schema to emit the dependency**

1. In Lumberyard Editor, choose Tools, Asset Editor.
2. In the Asset Editor, choose File, New, XML Schema.
3. For Matching Rules, click the plus (+) icon to add a rule.
4. For File Path Pattern, enter missingdependency.xml.

Version 1.28
368
5. For **Dependency Search Rules**, add a dependency search rule and a search definition.
6. For **Search Rule Structure, Name**, enter the name `missingDependency`.
7. For **Attributes**, add an attribute with the following values.
   a. For **Name**, enter `path`.
   b. For **Expected Extension**, enter `.json`.
   c. For **Path Dependency Type**, choose `ProductFile`.
8. Save the file to the location `lumberyard_version\dev\Engine\Schema\missingdependency.xmlschema`.
9. Save the `missingdependency.xml` again to force it to reprocess.
10. Verify that the dependency now appears correctly in the asset database, as the following images show:
11. Run the missing dependency scanner again, using syntax, as shown in the following example:

```
Bin64vc14\AssetProcessorBatch /dsp=%missingdependency.xml
```

12. The scanner should now report no results, as shown in the following sample log entry:

```
AssetProcessor: Scanning for missing dependencies: I:\p4\lyengine\branches \<project_name>\dev\Cache\<project_name>\pc\<project_name>\missingdependency.xml
```
Custom Dependency Scanners

The missing dependency scanning system supports authoring specialized dependency scanners. To match specific data types, you can build a custom scanner by inheriting from `SpecializedDependencyScanner`. Implement the necessary functions and register your scanner with the `MissingDependencyScanner` by calling `RegisterSpecializedScanner`.

You can specify which scanners are run against which files by changing the call to `MissingDependencyScanner`'s `ScanFile` to use a different match type or force the usage of a particular scanner.

Using the Asset Validation Gem to Verify Seeds

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

After you've built a seed list but before you bundle, you can use the Asset Validation gem to verify that asset loads map back to seeds. The Asset Validation gem adds a set of seed-related commands to the Lumberyard console command window. You can use these commands to ensure that you have seeds for all assets that you want to bundle.

One of these commands, `seedmode`, makes a seed mode active. When seed mode is active and an asset file loads, Lumberyard traverses the dependency graph from the newly loaded asset until it finds a seed for the asset. If it doesn't find a seed for the asset, an error message displays. It warns you that the loaded file won't be bundled if you try to bundle using the seeds that you provided for the current validation session.

During development, use seed mode to ensure that as assets get added they're properly bundled and included in the shipping version of the game.

**Note**

If you already have bundles to test, you can use `bundle mode` instead of seed mode. For more information, see Using Bundle Mode to Test Bundles (p. 373).

Prerequisites

**Enable** (p. 1064) the Asset Validation gem in your game project, and then **build** (p. 61) your game project.

Seed Mode Commands

When you use Lumberyard Editor or the launcher to run your game, the following console commands are available:

- `seedmode` – Enables or disables the reporting system.
- `addseedpath <Relative cache path to an asset>` – Adds the specified asset and all of its dependencies as a seed to your dependency graph, so they no longer are reported as missing. The `addseedpath` command lets you test which assets should be added to your seed list for packaging.

**Example**

AssetProcessor: No assets remain in the build queue. Saving the catalog, and then shutting down.
Verifying Bundles

- **addseedpath** `<Relative cache path to an asset>` – Removes an asset from the dependency graph.
- **removeseedpath** `<Relative cache path to an asset>` – Removes an asset from the dependency graph.
- **listknownassets** – Lists all the assets in your current dependency graph.
- **addseedlist** `<Relative source path to a seed list>` – Adds all the seeds found in the specified seed list to your known dependency graph. Because the path is a source path, it is relative to the `lumberyard_version\dev` directory.

Example

```
addseedlist Engine\SeedAssetList.seed
```

- **removeseedlist** `<Relative source path to a seed list>` – Removes all the assets in a seed list from your graph.
- **printblacklisted** – Enables or disables the display of approved assets in the system. Some assets, like shaders, are loaded at runtime and do not appear in your dependency graph. By design, shaders are packaged in their own `.pak` file, are not found in the dependency graph, and do not need to be reported by the system. However, you can use the `printblacklisted` command to force shaders or other approved asset types to be included in the dependency graph.

Using Seed Mode

The following procedure shows how to use seed mode to troubleshoot a level that has missing assets.

**To test seed mode**

1. In the Lumberyard console, enter the command `seedmode`. Asset validation begins.

   ```
   seedmode
   [CONSOLE] Executing console command 'seedmode'
   (AssetValidation) - Asset Validation is now on
   ```

2. Enter game mode. In the console, seed mode reports multiple `Asset not found in seed graph` errors.

3. Exit game mode.

4. Enter the `addseedpath` command to add the missing asset file. This example uses the command `addseedpath levels\milestone2\level.pak`.

5. Enter game mode. The `Asset not found` errors no longer appear.
Handling Missing Asset Errors

If seed mode reports that an asset is missing, the asset might be one of the following:

- Part of a list that you haven't added to the graph yet.
- An asset that must be added as a dependency of another asset already found in the level.
- An asset that must be a seed itself.

For more information, see Find and Fix Missing Asset References.

Using Bundle Mode to Test Bundles

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Bundle mode is a process that lets you enable asset loading to prioritize bundles over loose cache assets. After you build the seed lists for packaging your game, you can use bundle mode and the `sys_report_files_not_found_in_paks` console variable to test your packaging rules. Bundle mode makes it easy for you to load and report on issues in all the bundles (game .pak files) from a location that you specify without creating a release build.

Using bundle mode involves two key tasks:

- Turning on missing asset reporting for assets not in bundles. This enables "bundle mode".
- Mounting and loading bundles for your game.

When reporting is enabled, the `sys_report_files_not_found_in_paks` console variable reports when an asset loads that isn't in any of your bundles. By selectively loading bundles and using the `sys_report_files_not_found_in_paks` command, you can find assets that need to be included in your bundles.

Enabling Bundle Mode

To enable bundle mode, use the `sys_report_files_not_found_in_paks` console variable and specify a value of 1, 2, or 3. A value of 1 writes missing files as log entries without issuing warning messages.
The following list shows valid arguments for the `sys_report_files_not_found_in_paks` console variable.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disabled</td>
</tr>
<tr>
<td>1</td>
<td>Log</td>
</tr>
<tr>
<td>2</td>
<td>Warning</td>
</tr>
<tr>
<td>3</td>
<td>Error</td>
</tr>
<tr>
<td>&lt;Every other value&gt;</td>
<td>Error</td>
</tr>
</tbody>
</table>

Log File Entries

Missing files are logged with entries similar to the following:

```
Missing from bundle: @assets\levels\milestone2\auto_resourcelist.txt
```

If you use the `sys_report_files_not_found_in_paks` console variable with the launcher, the error messages are written to a log file in your cache user directory. On a PC, these are located at `lumberyard_version\dev\Cache\project_name\pc\user\log\logs\pakmissingassets.log`.

Setting the Console Variable

Enabling the console variable before running the editor or launcher ensures that all missing assets are reported. To ensure that the console variable is always active when you run the editor or launcher, modify the following files:

Editor: `lumberyard_version\dev\editor.cfg`

Runtime: `lumberyard_version\dev\project_name\autoexec.cfg`

You can also enable the console variable at runtime by using the console (~) or remote console. For information about the remote console, see Universal Remote Console (p. 3209).

Bundle Mode Commands

Bundle mode has two commands:

- `loadbundles <bundle_directory> <extension>` – Loads all the bundles from the specified directory into the game. If no arguments are supplied, the directory defaults to Bundles and the extension to .pak.

  For example, if you run the Starter Game project and enter the command `loadbundles` without arguments, Lumberyard loads all source files in the `lumberyard_version\dev\StarterGame\Bundles` directory that have the extension .pak.

- `unloadbundles` – Unload any bundle that was loaded through the `loadbundles` command.

Using Bundle Mode Example

The following procedure shows how bundle mode works. In the example, game mode is entered when a bundle is missing.

To test bundle mode

1. In the console window, enter the following command:

```
sys_report_files_not_found_in_paks 1
```
The 1 argument specifies that missing files are reported as log entries rather than warnings or errors.

2. Enter game mode. A list of Missing from bundle errors displays.

```
[Warning] (Cloud Canvas) [Cloud Canvas] Resource manager was invoked but there are no deployments or resource groups.
Disable Accelerators
(CryPak) - Missing from bundle: @assets\scriptcanvas\move\tank\scriptcanvas\compiled
(CryPak) - Missing from bundle: @assets\scriptcanvas\look\scriptcanvas\compiled
(CryPak) - Missing from bundle: @assets\scriptcanvas\camera\scriptcanvas\compiled
(CryPak) - Missing from bundle: @assets\ui\milestone2\menu\ui\canvas
(CryPak) - Missing from bundle: @assets\ui\milestone2\menu\ui\canvas
(CryPak) - Missing from bundle: @assets\levels\milestone2\hardcode\assetref\luac
(CryPak) - Missing from bundle: @assets\ui\textures\prefab\button\disabled\sprite
(CryPak) - Missing from bundle: @assets\ui\textures\prefab\button\normal\sprite
(CryPak) - Missing from bundle: @assets\levels\milestone2\milestonescene\scriptevents
(CryPak) - Missing from bundle: @assets\levels\milestone2\milestonescene\scriptevents
(CryPak) - Missing from bundle: @assets\scriptcanvas\milestone2\button\scriptcanvas\compiled
(CryPak) - Missing from bundle: @assets\levels\milestone2\milestonescene\scriptevents
(CryPak) - Missing from bundle: @assets\levels\milestone2\milestonescene\scriptevents
(CryPak) - Missing from bundle: @assets\levels\milestone2\milestonescene\scriptevents
```

3. Enter the command `loadbundles` to load bundles for the level.

```
loadbundles

[CONSOLE] Executing console command 'loadbundles'
<table>
<thead>
<tr>
<th>BundlingSystem</th>
<th>Loading bundles from bundles of type .pak</th>
</tr>
</thead>
<tbody>
<tr>
<td>BundlingSystem</td>
<td>Opening bundle @assets\bundle\engine\dependencies.pak</td>
</tr>
<tr>
<td>BundlingSystem</td>
<td>Loaded bundle @assets\bundle\engine\dependencies.pak</td>
</tr>
<tr>
<td>BundlingSystem</td>
<td>Opening bundle @assets\bundle\milestone2.pak</td>
</tr>
<tr>
<td>BundlingSystem</td>
<td>Loaded bundle @assets\bundle\milestone2.pak</td>
</tr>
<tr>
<td>BundlingSystem</td>
<td>Opening bundle @assets\bundle\spying.pak</td>
</tr>
<tr>
<td>BundlingSystem</td>
<td>Loaded bundle @assets\bundle\spying.pak</td>
</tr>
<tr>
<td>general.enter_game_mode</td>
<td>general.enter_game_mode</td>
</tr>
</tbody>
</table>
```

There are fewer errors, but some assets are still missing. The Asset Validation Gem (p. 371) seed-related commands can help find the missing assets.

4. Use the Asset Validation gem `addseedpath` command to add a likely missing bundle.

```
addseedpath levels\milestone2\level.pak
```

5. Enter the `listknownassets` command.
6. Examine the output. In the following example, the output shows missing button assets. In the case of the button assets, the bundle was packaged a while ago and must be repackaged. However, other assets are also still missing.

7. Add the missing assets to the seed list for the level.

8. Run the bundling commands (p. 394) for the level.

9. Drop the bundles into the Bundles directory.

10. Enter an assetbundlerbatch assetlists command, as shown in the following example. Use the --print argument to check the output. In the example, the single-line command has been formatted for readability.

```
assetbundlerbatch assetlists
   --addseed levels\milestone2\level.pak
   --addseed levels\milestone2\milestonecutscene.scriptevents
   --addseed levels\milestone2\hardcodedassetreference.luac
   --print
```

11. Verify that the output displays as expected.

12. Enter the assetbundlerbatch assetlists command again to bundle the assets, but this time without the --print argument. The example command is single-line, but has been formatted for readability.

```
assetbundlerbatch assetlists
   --addseed levels\milestone2\level.pak
   --addseed levels\milestone2\milestonecutscene.scriptevents
   --addseed levels\milestone2\hardcodedassetreference.luac
   --platform pc
   --assetlistfile DemoLevelList.assetlist
```

Output:

```
Saving Asset List file to ( G:\P4\dev\DemoLevelList_pc.assetlist )...
Save successful! ( G:\P4\dev\DemoLevelList_pc.assetlist )
```

13. Enter an assetbundlerbatch bundles command, as shown in the following example.
Tagging Files

```bash
assetbundlerbatch bundles
   --assetlistfile DemoLevelList_pc.assetlist
   --platform pc
   --outputbundlepath G:\P4\dev\DemoProject\Bundles\milestone2.pak
```

Output:

```
Creating Bundle ( G:\P4\dev\DemoProject\Bundles\milestone2_pc.pak )...
Bundle ( G:\P4\dev\DemoProject\Bundles\milestone2_pc.pak ) created successfully!
```

14. Enter the `loadbundles` command to reload the bundles, and then enter game mode.

```console
loadbundles
(CONSOLE) Executing console command 'loadbundles'
(BundlingSystem) - Loading bundles from bundles of type .pak
(BundlingSystem) - Opening bundle @assets@bundles\engine\dependencies.pak
(BundlingSystem) - Loaded bundle @assets@bundles\engine\dependencies.pak
(BundlingSystem) - Opening bundle @assets@bundles\milestone2_pc.pak
(BundlingSystem) - Loaded bundle @assets@bundles\milestone2_pc.pak
(BundlingSystem) - Opening bundle @assets@bundle\epasing.pak
(BundlingSystem) - Loaded bundle @assets@bundle\epasing.pak
general进入game mode
Returned;
[Warning] [Cloud Canvas] [Cloud Canvas] Resource manager was invoked but there are no deployments or resource groups.
Disable Accelerators
general.exit_game_mode
Returned;
general.exit_game_mode
Returned;
Enable Accelerators
```

All the assets loaded when game mode was entered are now in bundles.

### Using the File Tagging System to Include or Exclude Assets

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard v1.22 and later use a file tagging system to include or exclude files at various stages of processing. This system employs file tag rules to select files that match specified patterns. File tags are associated with each rule to use as keys in file tag queries. This is done by using the Lumberyard FileTag API. You can create your own custom file tag rules using the Lumberyard Asset Editor. This is useful whenever you need additional control over which files should be included or excluded during a processing step. For example, as part of asset bundling, it is useful to eliminate “false positives” found after using the Missing Dependency Scanner.

**Topics**

- Creating File Tag Rules (p. 378)
- Using the FileTag API (p. 379)
Creating File Tag Rules

Use the Lumberyard Asset Editor to add custom file tag rules to either `exclude.filetag` or `include.filetag`, depending on whether you are excluding or including asset files. Both of these `.filetag` files are located in the `dev\Engine` directory. File tag rules consist of two required parts:

- **A File Pattern** that defines the files to match this rule. Supported patterns include:
  - **Exact** (for example, `readme.txt`)
  - **Wildcard** (for example, `*.cfxb`)
  - **Regex** (for example, `.*/gems?/?.*/gem.json`)
- One or more **File Tags** that are used by either Lumberyard or your own code as keys to refer to the file pattern matching defined by this rule.

You can use the **Comment** field to add more information about a file tag rule, for example to document its usage.

**Note**
Some file tags have designated uses within Lumberyard. Various tools may require that you use specific tags, such as `editoronly` and `shader`. You can find the full list of commonly used tags in the `FileTagsIndex` enum in `dev\Code\Framework\AzFramework\AzFramework\FileTag\FileTag.h`.

How to Create a File Tag Rule

1. In Lumberyard Editor, choose **Tools, Asset Editor**.
2. Choose **File, Open**, and select either `exclude.filetag` or `include.filetag` from the **Engine** directory.
3. Open **Definition**, find the line labeled **File Tag Map**, and click on the `'+' button to add a new child element.
4. Enter the desired file matching pattern in the **New Key** field.
5. Open your new file pattern key from the list and select the appropriate **File Pattern** type.
6. Add one or more **File Tags** to associate with your new file pattern.
7. Select **File, Save** to save your new file tag rule.

## Using the FileTag API

You can use the C++ FileTag API to write your own logic for determining whether to include or exclude files. The following example uses the file tagging system to ignore files that match patterns associated with the `ignore` and `shader` tags.

```cpp
bool IsIgnored(const char* szPath)
{
  using namespace AzFramework::FileTag;
  AZStd::vector<AZStd::string> tags{ "ignore", "shader" };

  bool shouldIgnore = false;
  QueryFileTagsEventBus::EventResult(shouldIgnore, FileTagType::exclude,
  &QueryFileTagsEventBus::Events::Match, szPath, tags);

  return shouldIgnore;
}
```

**Note**
In the previous example, it shows querying the `QueryFileTagsEventBus` on the ID `FileTagType::exclude`. This implies that this query is using the file tagging rules specified in the `exclude.filetag` file.
You can find the FileTag API in the \dev\Code\Framework\AzFramework\AzFramework\FileTag directory. In that directory, FileTag.h declares the Match method that was used in the previous example. There are other methods there, such as GetTags, which you can use to write more complex logic. You may find it useful to work with the excludeFileComponent helper class, found in FileTagComponent.h. This component class automatically loads the default exclusion file for you, sets the file tag type to FileTagType::exclude, and connects to the QueryFileTagsEventBus upon activation.

Amazon Lumberyard Asset List Comparison Operations

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Asset list comparisons are rules provided to the AssetBundlerBatch.exe tool to determine which files should be included or excluded from the final bundle asset list. The asset list files have the suffix .assetlist and contain a flat list of paths and names of asset files. The following operations are available to use from the Asset Bundler tool:

- Delta Comparison Operation (p. 380)
- Union Comparison Operation (p. 381)
- Intersection Comparison Operation (p. 381)
- Intersection Count Comparison Operation (p. 382)
- Complement Comparison Operation (p. 383)
- File Pattern Comparison Operation (p. 384)

Note:

While the comparison operations use terms from set theory, they are not exactly the same as the actual set operations. This is particularly true of the delta comparison operation (p. 380), which includes a file entry in both sets if one of those files has been modified in the second set. Additionally, file pattern matching is not a set operation.

Asset List Delta Comparison Operation

This operation takes two asset list files to create an asset list for a bundle with only the assets that you need to ship in your release bundle. Use this operation to create bundles for incremental updates, such as delta patches for levels. To use this operation, run AssetBundlerBatch.exe with a --comparisonType argument value of 0 or delta.

To perform a delta comparison operation, open a command prompt, and run the following command:

```
 AssetBundlerBatch.exe compare ^
 --comparisonType delta ^
 --firstAssetFile firstAssetList_pc.assetlist ^
 --secondAssetFile secondAssetList_pc.assetlist ^
 --output deltaAssetList.assetlist
```

The following diagram shows the delta comparison operation.
Comparison Operations

Asset List Union Comparison Operation

This operation takes two asset list files to create an asset list for a bundle that combines all the assets from both lists. It includes only the modified version of a file in the output asset list, not the original from the first asset list. Use this operation when you have two bundles that no longer need to be separate and should be combined into a single bundle. To use this operation, run `AssetBundlerBatch.exe` with a `--comparisonType` argument value of 1 or `union`.

To perform a union comparison operation, open a command prompt, and run the following command:

```
AssetBundlerBatch.exe compare ^
   --comparisonType union ^
   --firstAssetFile firstAssetList_pc.assetlist ^
   --secondAssetFile secondAssetList_pc.assetlist ^
   --output unionAssetList.assetlist
```

The following diagram shows the union comparison operation.

Asset List Intersection Comparison Operation

This operation takes two asset list files to create a bundle asset list with only items that are in both asset lists. To use this operation, run `AssetBundlerBatch.exe` with a `--comparisonType` argument value of 2 or `intersection`.

Version 1.28
To perform an intersection comparison operation, open a command prompt and run the following command:

```
AssetBundlerBatch.exe compare ^
--comparisonType intersection ^
--firstAssetFile firstAssetList_pc.assetlist ^
--secondAssetFile secondAssetList_pc.assetlist ^
--output intersectionAssetList.assetlist
```

The following diagram shows the intersection comparison operation.

![Intersection Comparison Operation Diagram]

**Asset List Intersection Count Comparison Operation**

This operation takes any number of asset files to create a bundle asset list with only items that appear a given number of times across all of the asset lists. This comparison type can't be used as part of a series of comparison rules, and requires the use of the `--intersectionCount` argument. To use this operation, run `AssetBundlerBatch.exe` with the `--comparisonType` value of 5 or `intersectionCount`.

To perform an intersection count comparison operation, open a command prompt and run the following command:

```
AssetBundlerBatch.exe intersectionCount ^
--comparisonType intersectionCount ^
--intersectionCount 3 ^
--firstAssetFile
  firstAssetList_pc.assetlist, secondAssetList_pc.assetlist, thirdAssetList_pc.assetlist ^
--output intersectionCountAssetList.assetlist
```

The following diagram shows the intersection comparison operation.
Comparison Operations

Asset List Complement Comparison Operation

This operation takes two asset list files to create a bundle asset list with each item in the second asset list that is not in the first list. It works like the delta comparison, except that it does not check the file hash and will not include modified versions of a file that is in both lists. To use this operation, run `AssetBundlerBatch.exe` with a `--comparisonType` argument value of 3 or `complement`.

To perform a complement comparison operation, open a command prompt, and run the following command:

```
AssetBundlerBatch.exe compare ^
--comparisonType complement ^
--firstAssetFile firstAssetList_pc.assetlist ^
--secondAssetFile secondAssetList_pc.assetlist ^
--output complementAssetList.assetlist
```

The following diagram shows the intersection comparison operation.

Intersection Count Comparison Operation

Asset List A

- FileA.txt
- FileB.txt

Asset List B

- FileA.txt
- FileB.txt
- FileC.txt

Result Asset List

- FileB.txt

count=3

Asset List C

- FileB.txt
- FileC.txt

Asset List Complement Comparison Operation

This operation takes two asset list files to create a bundle asset list with each item in the second asset list that is not in the first list. It works like the delta comparison, except that it does not check the file hash and will not include modified versions of a file that is in both lists. To use this operation, run `AssetBundlerBatch.exe` with a `--comparisonType` argument value of 3 or `complement`.

To perform a complement comparison operation, open a command prompt, and run the following command:

```
AssetBundlerBatch.exe compare ^
--comparisonType complement ^
--firstAssetFile firstAssetList_pc.assetlist ^
--secondAssetFile secondAssetList_pc.assetlist ^
--output complementAssetList.assetlist
```

The following diagram shows the intersection comparison operation.

Complement Comparison Operation

Asset List A

- FileA.txt
- FileB.txt

Asset List B

- FileA.txt
- FileB.txt
- FileC.txt
- FileC.txt

Result Asset List

- FileC.txt
Asset List File Pattern Operation

This operation takes an asset list file, and a file pattern to apply. Any files that match this pattern in the asset list will be included in the output asset list. To use this operation, run AssetBundlerBatch.exe with a --comparisonType argument value of 4 or filepattern.

To perform a file pattern comparison operation, open a command prompt and run the following command:

```
AssetBundlerBatch.exe compare ^
--comparisonType filepattern ^
--filePatternType 0 ^
--filePattern "*.xml" ^
--firstAssetFile assetList_pc.assetlist ^
--output filePatternAssetList.assetlist
```

Note:

The previous command looks for files that have the .xml suffix for inclusion. You can replace it with any wildcard- or regex-based file pattern that you want to use for comparison.

The following diagram shows the file pattern comparison operation.

File Pattern Operation

How to Perform Multiple Asset List Comparison Operations

The following guidance shows the process of creating an asset list for a game patch that only contains modified and updated text (.txt) file content. During the process, it also validates the asset list contents against an inclusion list generated as the result of an intersection comparison.

The following diagram shows the comparison process and the outputs for this example.
Prerequisites

To complete the procedures in this tutorial, make sure that you have the following set up:

- An installed and configured installation of Amazon Lumberyard v1.22 or later. Download the latest version of Amazon Lumberyard.
- A Lumberyard game project ready to build and compile. You can use the Starter Game sample if you don't have a game project. Learn more about the Starter Game sample project. (p. 148).

Setup

Create the files that you will use in this tutorial.

1. In your game project's root folder, create these empty files:
   - FileA.txt
   - FileB.txt
   - FileC.txt
   - FileD.txt
   - FileE.cfg
   - FileF.cfg
   - do-not-add-me.txt
2. Process the assets on your project by running the Asset Processor (p. 248).

Create asset list files for the comparison operation

Create the .seed and .assetlist files to use in your comparisons.

1. Open a command prompt, navigate to the directory where you output the asset list files, and run the following command to create your initial seed list:

   AssetBundlerBatch.exe seeds ^
Comparison Operations

2. Run this command to create your asset list from the seed list:

```
AssetBundlerBatch.exe assetlists ^
--seedListFile include-list.seed ^
--assetListFile include-list.assetlist
```

3. Run this command to create your v1 seed file:

```
AssetBundlerBatch.exe seeds ^
--addSeed FileA.txt,FileB.txt ^
--seedListFile mygame_v1.seed
```

4. Run this command to create your v1 asset list file:

```
AssetBundlerBatch.exe assetlists ^
--seedListFile mygame_v1.seed ^
--assetListFile mygame_v1.assetlist
```

5. Run this command to create your v2 seed file:

```
AssetBundlerBatch.exe seeds ^
--addSeed FileA.txt,FileB.txt,FileC.txt,fileE.cfg,fileF.cfg,do-not-add-me.txt ^
--seedListFile mygame_v2.seed
```

6. Run this command to create your v2 asset list file:

```
AssetBundlerBatch.exe assetlists ^
--seedListFile mygame_v2.seed ^
--assetListFile mygame_v2.assetlist --print
```

This last command should produce output that looks like this, enabled by the `--print` flag:

```
Printing assets for Platform ( pc ):  
- filea.txt 
- fileb.txt 
- filec.txt 
- filee.cfg 
- filef.cfg 
- do-not-add-me.txt 
Total number of assets for Platform ( pc ): 6.
```

You have now created the `.seed` and `.assetlist` files that you need to start the comparison operations and assemble a final bundle asset list.

**Note**

At this point, you can choose either one of the next two steps to complete the tutorial. To run each comparison command individually, see the steps in section 1.6.4. To run all of the comparison operations in one command, see the steps in section 1.6.5.

**Run the individual step comparison commands**

1. Open a command prompt and navigate to the directory where you output the asset list files. Run the following command:
AssetBundlerBatch.exe compare ^
--comparisonType delta ^
--firstAssetFile mygame_v1_pc.assetlist ^
--secondAssetFile mygame_v2_pc.assetlist ^
--output multistep_delta.assetlist ^
--print

In this step the files that are in the v1 asset list, fileA.txt and fileB.txt, are removed based on comparisonType 0, the delta comparison type. Your command output should look like this:

Printing assets from the comparison result {PATH TO YOUR LUMBERYARD ROOT HERE}\dev \multistep_delta_pc.assetlist.
---------------------------------------------------------------
- filee.cfg
- do-not-add-me.txt
- filec.txt
- filef.cfg
Total number of assets (4).
---------------------------------------------------------------
Saving results of comparison operation...
Save successful!

2. Remove any files from the asset list that aren’t in the inclusion list by running this command from the prompt:

AssetBundlerBatch.exe compare ^
--comparisonType intersection ^
--firstAssetFile include_pc.assetlist ^
--secondAssetFile multistep_delta_pc.assetlist ^
--output multistep_include.assetlist ^
--print

For this step, the file do-not-add-me.txt is removed because it isn’t in the generated inclusion list, based on specified the intersection comparison (comparisonType 2). Your command output should look like this:

Printing assets from the comparison result {PATH TO YOUR LUMBERYARD ROOT HERE}\dev \multistep_include_pc.assetlist.
---------------------------------------------------------------
- filec.txt
- filee.cfg
- filef.cfg
Total number of assets (3).
---------------------------------------------------------------
Saving results of comparison operation...
Save successful!

3. Run this command to remove anything that is not a text (.txt) file from the asset list:

AssetBundlerBatch.exe compare ^
--comparisonType filepattern ^
--filePatternType 0 ^
--filePattern *.txt ^
--firstAssetFile multistep_include_pc.assetlist ^
--output multistep_filepattern.assetlist ^
--print
Comparison Operations

For this step, the two .cfg files are removed because they don't match the file pattern, based on the file pattern comparison (comparisonType 4). Your command output should look like this:

```
Printing assets from the comparison result \{PATH TO YOUR LUMBERYARD ROOT HERE}\dev \multistep_filepattern_pc.assetlist.
- filec.txt
  Total number of assets (1).
Saving results of comparison operation...
Save successful!
```

Run the multiple step comparison command

You can also perform all of these commands in a single command. The multiple step command is equivalent to running all of the commands in the prior steps individually, and uses variables you specify to store the intermediate results of the comparisons.

In this example, the multiple step comparison command runs the 3 comparisons sequentially, storing the results in variables that are used in the next steps. The delta comparison between v1 and v2 is stored into the $delta_all variable, and then runs the intersection comparison on the inclusion list with the asset list $delta_all, storing the results in the $delta_include variable. Finally, the file pattern comparison is run against all text files stored in the $delta_include variable. The output of this final command is stored in the file, mygame_v1tov2_patch.assetlist.

To try this approach, open a command prompt, and navigate to the directory where you output the asset list files. Run the following command:

```
AssetBundlerBatch.exe compare ^
  --comparisonType delta,intersection,filepattern ^
  --filePatternType 0 ^
  --filePattern *.txt ^
  --firstAssetFile mygame_v1_pc.assetlist,include_pc.assetlist,$delta_include ^
  --secondAssetFile mygame_v2_pc.assetlist,$delta_all ^
  --output $delta_all,$delta_include,mygame_v1tov2_patch.assetlist ^
  --print
```

The command should produce output that looks like this:

```
Printing assets from the comparison result \{PATH TO YOUR LUMBERYARD ROOT HERE}\dev \mygame_v1tov2_patch_pc.assetlist.
- filec.txt
  Total number of assets (1).
Saving results of comparison operation...
Save successful!
```

You can also confirm that the operation was successful by opening mygame_v1tov2_patch.assetlist in a text editor and checking that it only contains the files you expect to see.

How multiple comparisons work

When running multiple step commands, use a comma-separated list for each relevant parameter. The individual steps in the command match up to their placement in this comma-separated parameter value list.
Default dependencies

The previous example uses three comparison operations. The first two comparisons reference a first and second asset list file, and the last comparison references a file pattern and the first asset file. The multiple step command broken down into its component parts looks like this:

**Breaking down the process of a single multiple comparison command**

<table>
<thead>
<tr>
<th>Command Parameter</th>
<th>Step 1</th>
<th>Step 2</th>
<th>Step 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>comparisonType</td>
<td>delta</td>
<td>intersection</td>
<td>filepattern</td>
</tr>
<tr>
<td>firstAssetFile</td>
<td>mygame_v1_pc.assetlist incluedelta_include (temp file)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>secondAssetFile</td>
<td>mygame_v2_pc.assetlist</td>
<td></td>
<td>$delta_all</td>
</tr>
<tr>
<td>filePatternType</td>
<td>N/A</td>
<td>N/A</td>
<td>Wildcard (parameter value 0)</td>
</tr>
<tr>
<td>filePattern</td>
<td>N/A</td>
<td>N/A</td>
<td>*.txt</td>
</tr>
<tr>
<td>output</td>
<td>$delta_all</td>
<td>$delta_include</td>
<td>mygame_v1tov2_patch.assetlist</td>
</tr>
</tbody>
</table>

Read this table horizontally to see the data supplied to each comparison during each step of the process. Read this table vertically to see the parameter used for each command for each step.

**Default dependencies for Lumberyard projects**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com) or visit the [AWS Game Tech blog](https://aws.amazon.com) to learn more.

Throughout your Lumberyard project you'll use assets across multiple levels, or find those that need to be included whether or not they're a strict dependency. To handle these use cases, Lumberyard supports **default dependency files** which define assets that are always required when bundling your project. Default dependencies are also used by Gems to make sure their own critical assets are always included.

Default dependencies give you a convenient way to list assets that should be bundled as part of your whole project, and can be applied when generating any asset list by using `--addDefaultSeedListFiles`. When you use this argument as part of an asset bundler command, it picks up the default dependencies for the Lumberyard engine, included gems, and your project.

**Default dependency file locations**

There are four levels of default dependency files available. All paths are relative to `lumberyard_install\dev`:

<table>
<thead>
<tr>
<th>Default dependency</th>
<th>File path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Engine</td>
<td>Engine\Engine_Dependencies.xml</td>
<td>The dependencies packaged for every Lumberyard project. Only edit this file when you use the same installation to create multiple projects that need to include a specific resource which even basic game functionality depends on.</td>
</tr>
</tbody>
</table>
Default dependencies

<table>
<thead>
<tr>
<th>Default depende</th>
<th>File path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gems</td>
<td>Gems\gem_name\Assets \gem_name_Dependencies.xml</td>
<td>The required dependencies for the named gem. When creating a new gem, include any resources that are required regardless of whether they’re used explicitly within a project here. Never edit the default dependency file for a gem which you aren’t writing or customizing.</td>
</tr>
<tr>
<td>Project</td>
<td>project_name\project_name_Dependencies.xml</td>
<td>Project-wide dependencies. This is the default dependency file that you'll be editing most frequently, and should include things like game-wide audio, configuration information for pre-loading resources at launch time, or other assets that must always be included with your project. When you create a new project, the dependency file is created from the ProjectTemplates \DefaultTemplate${ProjectName}${ProjectName}_Dependencies.xml template.</td>
</tr>
</tbody>
</table>

**Important**

These files are not seed lists, and can’t be manipulated with commands that modify seed lists. Default dependencies are built by the Asset Processor to create seed lists in the cache. These seed lists are then picked up by the Asset Bundler when you use the --addDefaultSeedListFiles flag.

Another important consequence of this is that every time you change a default dependencies file, it must be built by the Asset Processor to generate an updated seed list for the Asset Bundler.

Default dependencies file format

Default dependencies files are written in XML and consist of only two elements: EngineDependencies and Dependency. The root element of a default dependency file should always be <EngineDependencies version="1.0.0">, including this specific value for the version attribute.

Dependency elements are the only children of the EngineDependencies node, and require two attributes: path and optional. Dependency elements have no children, including no text content.

How each Dependency node is treated depends on the attribute values:

- optional – This value is either true or false, and describes whether or not the listed asset is absolutely required by the asset bundling process. Most often you’ll want to use true for asset paths without wildcards, and false for paths which contain a wildcard.
- path – This value is the path to the asset(s) to include, and accepts the use of the * wildcard character. Wildcards search all subdirectories recursively.

Because wildcard matching may catch files that you don’t want to include as default assets, you can add exclusion paths: Dependencies where the path starts with a : character. Assets in an exclusion path are not included as a default dependency.

The following is an example of a default dependency list for a project, commented to make it clear which dependencies are processed by each node:

```xml
<EngineDependencies versionnumber="1.0.0">
  <Dependency path="libs/particles/preloadlibs.txt" optional="true" /> <!-- Include particle pre-loads if present -->
</EngineDependencies>
```
Asset Bundler Concepts and Terms

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The following terms and concepts relate to the Lumberyard Asset Bundler:

Asset ID

All product assets are assigned an Asset ID. The asset ID consists of the source asset’s UUID plus a sub ID, which uniquely identifies a product. Sub IDs are usually generated by an asset builder. They must be stable for running in a build, and mutually exclusive. Each product should have a unique sub ID that does not change. The Asset ID data structure is defined in dev\Code\Framework\AzCore\AzCore\Asset\AssetCommon.h. See also Source GUID.

Asset Browser

The Asset Browser program, which is part of the Lumberyard Editor, shows the current state of your assets. You can use this program to navigate through a set of assets, such as tracking which assets have been processed and which will be processed.

Asset Bundle

An asset bundle consists of product assets grouped together in a single compressed file. The bundle is mounted in a Lumberyard game so that the assets can be loaded and used during runtime. Asset bundles are .pak files, which use the CryEngine .pak file format. This file format is similar to the .zip file format.

For more information, see Creating a Custom Asset Builder (p. 318).

Asset List

An asset list contains information for product assets. This file is generated using the Asset Bundler. The information includes a fingerprint for each asset in the list. The fingerprint includes a modification time and file hash. An asset list can be generated from seed lists, individual seeds, or by using comparison operations on other asset lists. Asset list files have the file extension .assetlist. See also Seed and Seed List.

Builder

An asset builder is a C++ module that is used to transform source assets into product assets. For example, a builder that handles textures might also transform a source asset PNG file to a product asset DDS file. Builders emit metadata about source and product assets, such as dependencies.

For more information, see Creating a Custom Asset Builder (p. 318).

Copy Job

A copy job is an asset processing task that copies a source asset to the cache without modifying it. There are two ways that copy jobs occur:

• When you are authoring a builder. If the builder emits a source asset as a product asset, the Asset Processor copies the source to the cache.
When using additional asset processing rules as defined in AssetProcessorPlatformConfig.ini. These additional rules can include copy jobs, and are used to copy many file types to the cache.

As a best practice, create an Asset Builder for your assets so you can add product dependencies. While it’s easy to add copy jobs to AssetProcessorPlatformConfig.ini, it can be easy to forget to update files for dependencies later.

### Leaf Asset

A "leaf" asset is a product asset that has no dependencies on other product assets. See also Product Dependency.

### Product Asset

A product asset is game content that is loaded and used in the runtime game. A product asset is generated from a source asset during asset processing using a builder. The product asset is often a modified version of the source asset, such as image content that is compressed and otherwise optimized for runtime. Product assets reference their product dependencies. See also Source Asset.

When running a game using the Lumberyard asset system, only product assets are available. The source assets are not available. This includes running the game in the Lumberyard Editor or in a platform-specific launcher. When packaging a game using the Asset Bundler, only product assets are bundled. Product assets are available only from the asset cache or from asset bundles.

**Note**

When working with slices, keep in mind that only dynamic slices can be used at run-time. Non-dynamic slices, even if they are product assets, should not be included in bundles.

For more information about the asset life cycle, see Working with the Asset Pipeline and asset files (p. 247).

### Product Dependency

A product dependency occurs when one product asset references another product asset. When bundling assets, both the referencing asset and the referenced asset should be included in the bundle. Dependencies are created by referencing the Asset ID of the product asset. See also Source Dependency.

Product dependencies are generally relevant during asset packaging and bundling. With product dependencies established, bundling becomes the task of "shipping game level 1 and everything it references". For example, you have a character that is spawned through a dynamic slice. This character has a model, and the model has a material, which has a texture. In this scenario, the material needs the texture loaded to work, so the material has a product dependency on the texture. The model needs the material loaded to work, so the model has a product dependency on the material. The character needs the model loaded to work, so the dynamic slice for the character has a product dependency on the model. When bundling, you can include the character and expect that all dependencies are included.

### Root Folder

The root folder concept is inherited from CryEngine. When a Lumberyard application starts, it loads and initializes a set of modules, or code libraries, to support the application’s gems. Legacy modules, such as bootstrap.cfg and engine.cfg, are loaded from the root folder. Newer AZ modules are loaded from the assets folder.

For more information, see Programming with Gems (p. 1073).

### Runtime

A standalone game is referred to as the runtime. It can be run through a platform-specific launcher, such as a console, or in the Lumberyard Editor. A runtime uses the Lumberyard asset system to access only those product assets that were bundled with the game.
Scan Folder

Scan folders are scanned for assets during game runtime. A set of scan folders are designated in the AssetProcessorPlatformConfig.ini file. Scan folders are defined when the Asset Processor starts. They cannot be added, removed, or renamed during runtime.

Seed

A seed is a product asset added to a seed list. Defining a product asset as a seed can make bundling assets or mounting into a game runtime more efficient. Seeds can also be useful when validating or debugging an asset bundle, such as using "seed mode" in the Asset Validation Gem to track asset dependencies. See also Seed List.

Seed List

A seed list is a .seed file containing a collection of seeds for the bundling system to place into an asset list. Seed lists are also used to build asset dependency charts. See also Asset List File.

For simple game packages, seed lists are commonly used with level files. For example, you have a game with three levels. Levels 1 and 2 are production levels, and the other is the development test level. You want to ship your game with the two production levels and all files referenced by them. You can use the Asset Bundler to create a MyGame.seed asset list file, and then add your Level 1 and Level 2 product assets as seeds to this file.

Source Asset

A source asset is an instance of an asset that is not associated with a specific product. When working with an asset, you edit the source asset and then use an asset builder to generate a product-specific instance of the asset. When authoring edit-time code, you may need to access editor-only product assets or source assets. If your logic is actually editing a file, use the source asset. If your logic is only reading the file, use the editor-only product asset in the asset cache. Source assets are stored in the source asset folder, usually under dev\ProjectName\.

Source Dependency

A source dependency occurs when one source asset references another source asset. Source assets list each dependency by referencing the ID of the source asset. See also Product Dependency.

In general, source dependencies are relevant during content creation at edit time and when developing tools pipelines. Source dependencies are used in the following scenarios:

- When an asset is changed, all assets that depend on the changed asset must be updated.

  An asset won't process until all of the source assets that it depends on finish processing.

  For example, you're working with models and materials. Model source assets depend on material source assets. However, the product asset for the model does not need a corresponding product asset for the material. In this scenario, the relevant material must be generated before processing the model source asset, which is an FBX file, to output the product asset as a CGF file.

Source GUID

A source GUID is used to identify assets. It is generated by hashing the path—relative to the scan folder—of the source asset file. It is technically a UUID value, but is commonly referred to as a GUID. See also Asset ID.

Source assets are associated with a gem, and source GUIDs are unique within a gem's set of assets. It is possible for source assets from different gems to have the same GUID, if they have the same relative path, file name, and extension. When referencing a source GUID, the file from the highest priority scan folder is returned for all queries and copied to the cache.

Relative Paths

Some of the Lumberyard tool operations take relative paths as inputs. There are two types of relative paths:
• **Cache-relative paths** – Tells various systems where to find pre-processed assets in your asset cache. Each Lumberyard tool that uses cache-relative paths will be relative to a different subdirectory of the asset cache. For example, a cache-relative path from the absolute path `C:\Lumberyard\dev\Cache\SamplesProject\pc\samplesproject\levels\samples\advanced_rinlocomotion\level.pak` that does not include the platform and project would be `levels\samples\advanced_rinlocomotion\level.pak`.

• **Engine-root-relative paths** – Specifies files located in directories under `C:\Lumberyard\dev\`. For example, an engine-root-relative path lets you represent the location `C:\Lumberyard\dev\SamplesProject\textures\UIEditor_Sample\ButtonNormal.tif` as `SamplesProject\textures\UIEditor_Sample\ButtonNormal.tif`.

For more information, see Asset IDs and File Paths (p. 325).

  - Options (p. 407)
  - Examples (p. 408)

The Amazon Lumberyard Asset Bundler is driven by a command-line tool called `AssetBundlerBatch`. This tool manages seed lists, asset lists, comparisons, and asset bundles. The asset bundler is **not used**
to compile assets into the format used by the bundler for distribution — that is the role of the Asset Processor. Before running the Asset Bundler, make sure that you:

- Enable each platform assets should be bundled for. Enabled platforms are managed by editing the `dev\AssetProcessorPlatformConfig.ini` file in your project.
- Run the Asset Processor to ensure that assets and their metadata are up to date.

**Note**

All example commands in this reference are executed from the `dev\` folder of a project and assume a build produced with Visual Studio 2017 on Windows. The executable path and path separators will be different on other platforms.

See the [Asset Bundler Concepts and Terms](p. 391) or [Glossary](p. 3281) for definitions of terms used in this reference.

## General Use

The format for `AssetBundlerBatch` commands is:

```
AssetBundlerBatch command --parameterWithArgs arg1,arg2 --flagParameter ... 
```

The `AssetBundlerBatch` executable is contained in the `dev\Bin64\HostPlatform` folder of your project. For example, when building on PC with Visual Studio 2017, the asset processor is located at `dev\Bin64\vc141`.

The elements in this example invocation break down to:

- **command** - The command for the asset bundler to run. Examples include `seeds` and `assetLists`.
- **--parameterWithArgs** - An argument which takes parameters. If a parameter can take more than one argument, you can either separate arguments with a `,` character without using whitespace, or by giving the parameter multiple times:
  - `--parameterWithArgs arg1,arg2`
  - `--parameterWithArgs="arg1,arg2"`
  - `--parameterWithArgs arg1 --parameterWithArgs arg2`
  - `--parameterWithArgs="arg1" --parameterWithArgs="arg2"

  These styles of writing parameters can be freely mixed and matched. Note that not all arguments take more than one input parameter.
- **--flagParameter** - A flag which doesn't take any arguments. Flags represent boolean values and turn features of the Asset Bundler on and off.

An example command is:

```
Bin64\vc141\AssetBundlerBatch seeds --seedFileList MyProject\AssetBundling\SeedLists\AllDependencies.seed ^
--addPlatformToSeeds ^
--platform ios,pc
```

## Options

The options in this section are valid for all Asset Bundler subcommands.
--help, -h

Without a command, prints out the help text for AssetBundlerBatch. When used with a command, prints the help information for that command.

_Type:_ Flag

_Required:_ No

--verbose

Enables more detailed output messages. _Error_ and _Warning_ messages will display the file name and line number which generated the message. This flag is intended for use when looking at source files or generating output for debugging purposes.

_Type:_ Flag

_Required:_ No

Seed lists - seeds

The _seeds_ command is used to manage seed lists, the first phase of the Asset Bundler workflow. Seed list files have the `.seed` extension.

This command requires an existing cache of assets for each provided platform. To make sure that the cache is up to date, update the supported platforms and run the Asset Processor.

Options

--seedListFile

The seed list to modify and save. This file must be writable and have the `.seed` extension. The file is created if it doesn't exist. The argument's value may be either an absolute or engine-root-relative path.

_Type:_ Single-value argument

_Required:_ Yes

--addSeed

Add seeds to the seed list for the _--platform_ values. If a seed does not exist for one of the specified platforms, then the invalid platforms are ignored. The argument's value may be any number of cache-relative paths to pre-processed assets.

_Important_

Although `.slice` files are built and present in the asset cache, they aren't product assets and don't generate dependencies when added to a seed list. Avoid using them as seeds.

_Type:_ Multi-value argument

_Required:_ No

--removeSeed

Remove the _--platform_ values for the provided seeds. If a seed is not available for a platform, it's ignored. A seed is not completely removed from the seed list until it has no associated platforms.

_Type:_ Multi-value argument

_Required:_ No
--addPlatformToSeeds

Adds the --platform values to all seeds in the seed list. If a seed isn't valid for a provided platform, a warning is printed indicating the affected seed and the platform which caused the warning. The seed is updated for all other valid platforms.

Type: Flag
Required: No

--removePlatformFromSeeds

Removes the --platform values from all seeds in the seed list. If this would remove all platforms for an existing seed, the seed is unchanged and a warning is printed. Use --removeSeed to remove a seed from a seed list.

Type: Flag
Required: No

--print

Prints the contents of the seed list after performing operations.

Type: Flag
Required: No

--platform

The platforms used for this command. Defaults to all supported platforms for the current project. Supported platforms can be changed by modifying AssetProcessorPlatformConfig.ini.

Platform names can be found in the AssetProcessorPlatformConfig.ini file, or as folder names found under dev\Cache\ProjectName.

Type: Multi-value argument
Required: No

--updateSeedPath

Updates the relative paths for every seed in the seed list.

Type: Flag
Required: No

--removeSeedPath

Removes the relative path hints for every seed in the seed list. This argument is useful when you want to share your seed list with a third party.

Type: Flag
Required: No

Examples

In the following examples, assume that the current project has enabled the platforms pc, ios, and es3.

Example Add seed

Create the seed list testFile.seed if it doesn't exist, and adds the asset1.pak and asset2.pak assets as seeds for the PC platform:
Example Add platforms

Add the ios and es3 platforms for all seeds in the testFile.seed seed list:

```
Bin64vc141\AssetBundlerBatch.exe seeds --seedListFile testFile.seed --addPlatformToSeeds --platform ios,es3
```

Example Display seed list contents

Show the contents of the testFile.seed file, including the absolute and relative paths of all assets used as seeds:

```
Bin64vc141\AssetBundlerBatch.exe seeds --seedListFile testFile.seed --print
```

Asset Lists - assetLists

The assetLists command is used to manage and create asset lists. See the --assetListFile argument for how platform information is encoded in asset list file names. Asset list files have the .assetlist extension.

This command requires an existing cache of assets for each provided platform. To make sure that the cache is up to date, update the supported platforms and run the Asset Processor.

Options

--assetListFile

The base name of the platform-specific asset list files to be generated. This file's path must be writable, and the file name must have the .assetlist extension. The argument's value may be either an absolute or engine-root-relative path.

The asset list files generated are named based on the value of this argument and the provided platforms. For an argument value of path\assetFile.assetlist, each platform gets an asset file created as path\assetFile_Platform.assetlist. For example, assetFile.assetlist for the platform pc is named assetFile_pc.assetlist.

assetLists invocations must contain either the --assetListFile argument or --print flag.

_Type: Single-value argument

_Required: No_

--seedListFile

The seed list used to generate the asset list. This argument can be used along with other arguments that provide seeds.

_Type: Single-value argument

_Required: No_

--addSeed

Individual seeds used to generate the asset list. This argument can be used along with other arguments that provide seeds.

_Type: Single-value argument

_Required: No_
Important
Although \textit{.slice} files are built and present in the asset cache, they aren't product assets and don't generate dependencies when used as seeds. Avoid using them as seeds.

\textit{Type}: Multi-value argument

\textit{Required}: No

\texttt{--addDefaultSeedListFiles}

Automatically include the default seed lists for the Lumberyard Engine, default project, and all enabled Gems. As paths relative to \texttt{lumberyard\_dev}, the files that define default assets are:

- \textbf{Engine} – \texttt{Engine\Engine\_Dependencies\.xml}
- \textbf{Gems} – \texttt{Gems\gem\_name\Assets\gem\_name\_Dependencies\.xml}
- \textbf{Project} – \texttt{project\_name\project\_name\_Dependencies\.xml}

By default, the project dependencies includes pre-loaded particle libraries and game-wide audio, excluding level-specific audio.

This argument can be used along with other arguments that provide seeds.

\textit{Type}: Flag

\textit{Required}: No

\texttt{--skip}

A list of assets to ignore. This can include both seed assets and any dependencies that were picked up by the asset processor. The argument value is a comma-separated list of cache-relative paths to assets that have already been pre-processed.

\textit{Type}: Multi-value argument

\textit{Required}: No

\texttt{--platform}

The platforms used for this command. Defaults to all supported platforms for the current project. Supported platforms can be changed by modifying \texttt{AssetProcessorPlatformConfig.ini}.

Enabled platform names can be found in the \texttt{AssetProcessorPlatformConfig.ini} file, or as directories under \texttt{dev\Cache\ProjectName}. 

\textit{Type}: Multi-value argument

\textit{Required}: No

\texttt{--print}

Output a list of all product dependencies. The behavior of this argument depends on which other arguments are provided to the \texttt{AssetBundlerBatch argumentList} command:

- \texttt{--assetListFile} without operations: Read an existing asset list from disk and display its contents.
- \texttt{--assetListFile} with operations: Generate a new asset list and display its contents.
- Without \texttt{--assetListFile}: Display the contents of the asset list that would be generated.

Each of these behaviors is illustrated in the \texttt{assetList examples} (p. 400).

\texttt{AssetBundlerBatch assetLists} commands must contain either the \texttt{--assetListFile} argument to generate new asset lists, or the \texttt{--print} flag to write information to the console.

\textit{Type}: Flag
Required: No
--dryRun

Run without generating new asset lists.

Type: Flag

Required: No
--generateDebugFile

Generate a file that contains additional information about asset inclusion for debugging purposes. This file contains a hierarchical list of every asset contained within the asset list file, as well as information about which seeds marked each specific asset as a product dependency. The debug file is stored in the same path as the --assetListFile, with the extension .assetlistdebug.

This argument requires the use of --assetListFile. If you use the --print argument, the output of the generated files is displayed in the console, not the output of the debug file.

Type: Flag

Required: No
--allowOverwrites

Allow overwriting of existing asset files. By default, existing asset lists will not be regenerated.

Type: Flag

Required: No

Examples

In the following examples, assume that the seed list testFile.seed exists and that the pc, ios, and es3 platforms are enabled.

Example Display default assets

Display which asset lists would be generated from the seed lists for the Lumberyard Engine and enabled Gems for a project's default platforms:

Bin64vc141\AssetBundlerBatch.exe assetLists --addDefaultSeedListFiles --print

Example Display asset lists for default platforms

Use an input asset list and the project's default platforms to display that asset list's contents:

Bin64vc141\AssetBundlerBatch.exe assetLists --assetListFile assetListFile.assetlist --print

Example Create an asset list and debug file from a seed list

Generate an asset list testList_pc.assetlist and debug information testList_pc.assetlistdebug from the testFile.seed seed list:

Bin64vc141\AssetBundlerBatch.exe assetLists --assetListFile testList.assetlist ^
--seedListFile testFile.seed ^
--platform pc ^
--generateDebugFile
Example Display asset list contents for a platform

Display the contents of the testList_pc.assetlist file:

```bash
Bin64vc141\AssetBundlerBatch.exe assetLists --assetListFile testList.assetlist --platform pc --print
```

Example Regenerate asset lists from a seed list

Regenerate all asset lists from the testFile.seed seed list, overwriting the testList_pc.assetlist file if it exists:

```bash
Bin64vc141\AssetBundlerBatch.exe assetLists --assetListFile testList.assetlist --seedListFile testFile.seed --allowOverwrites
```

Comparison rules - comparisonRules

The comparisonRules command is used to generate comparison rules files. Comparison rules files are used as inputs for the compare (p. 402) subcommand. Comparison rules files are pre-built descriptions of which operations to perform and in what order. For more information on comparison rules, see Amazon Lumberyard Asset List Comparison Operations (p. 380).

Options

--comparisonRulesFile

The comparison rules file to generate.

Type: Single-value argument

Required: Yes

--comparisonType

The comparison types to apply, in the given order. Valid values are:

- 0 or delta: Delta comparison
- 1 or union: Union
- 2 or intersection: Intersection
- 3 or complement: Complement
- 4 or filePattern: FilePattern
- 5 or intersectionCount: IntersectionCount

For more information about how each of these rules operate on input files, see Amazon Lumberyard Asset List Comparison Operations (p. 380).

Note

The intersectionCount comparison type can't be combined with any other comparison type as part of a rule list.

Type: Multi-value argument

Required: Yes

--filePatternType

The type of file pattern matching to use on the provided file patterns. Valid values are:

- 0: Perform wildcard matching - the * character will match any number of characters
- 1: Perform regular expression matching
Type: Multi-value argument. The number of parameters for the --filePatternType argument must match the number of FilePattern arguments to the --comparisonType argument.

Required: No

--filePattern

The file patterns to use for building the list of files that will be compared by the corresponding --comparisonType. The patterns are interpreted according to the corresponding --filePatternType parameter.

Type: Multi-value argument. The number of parameters for the --filePattern argument must match the number of FilePattern arguments to the --comparisonType argument.

Required: No

--allowOverwrites

Allow overwriting of existing comparison rules files. By default, existing files will not be overwritten.

Type: Flag

Required: No

Examples

Example Generate a delta and filter for XML files

Generate a comparison rules file which produces a delta comparison, and then filters the results to include only XML files:

```
Bin64\vc141\AssetBundlerBatch.exe comparisonRules --comparisonRulesFile deltaFilterXML.rules
^  --comparisonType delta,filePattern ^
  --filePatternType 0 ^
  --filePattern "*xml"
```

Comparisons - compare

The compare command is used to take pairs of asset lists as input, perform a comparison operation, and write the result of the comparison as a new asset list. See Amazon Lumberyard Asset List Comparison Operations (p. 380) for details on comparison operations.

Options

--comparisonRulesFile

The comparison rules file to load rules from. Comparisons from the rules file will be performed before any other comparisons given as arguments, and are evaluated in the order that the rules file was created with.

Type: Single-value argument

Required: No

--comparisonType

The comparison types to apply to the input files. The first --comparisonType parameter is applied to the first arguments of --firstAssetListFile and --secondAssetListFile, the second comparison is applied to the second parameters of those arguments, and so on.
Valid values are:
• 0 or `delta`: Delta comparison
• 1 or `union`: Union
• 2 or `intersection`: Intersection
• 3 or `complement`: Complement
• 4 or `filePattern`: FilePattern
• 5 or `intersectionCount`: IntersectionCount

For more information about how each of these rules operate on input files, see Amazon Lumberyard Asset List Comparison Operations (p. 380).

**Note**
The `intersectionCount` comparison type can't be combined with any other comparison type.

*Type:* Multi-value argument  
*Required:* Yes

---

**--filePatternType**

The type of file pattern matching to use on the provided file patterns. Valid values for this argument are:
• 0: Perform wildcard matching - the `*` character will match any number of characters
• 1: Perform regular expression matching

*Type:* Multi-value argument. The number of parameters for the `filePatternType` argument must match the number of `FilePattern` comparison arguments to the `comparisonType` argument.  
*Required:* No

---

**--filePattern**

The file patterns to use for matching asset file paths from inputs. The patterns are interpreted according to the corresponding `filePatternType` parameter. The first pattern is used with the first occurrence of the `FilePattern` comparison type, the second with the second occurrence, and so on.

*Type:* Multi-value argument. The number of parameters for the `filePattern` argument must match the number of `FilePattern` comparison arguments to the `comparisonType` argument.  
*Required:* No

---

**--firstAssetListFile**

The files to use as the first set of inputs for comparison.

*Type:* Multi-value argument. The number of parameters for the `firstAssetListFile` argument must match the number of arguments to the `comparisonType` argument.  
*Required:* No

---

**--secondAssetListFile**

The files to use as the second set of inputs for comparisons which require a second input file. This argument isn't used for the `FilePattern` or `intersectionCount` comparison types.

*Type:* Multi-value argument. The number of parameters for the `secondAssetListFile` argument must match the number of non-`FilePattern` arguments to the `comparisonType` argument.
--output

The output files for the result of each performed comparison. Output files can be a file, or a variable passed from another comparison. Variables start with the $ character. For more about variables, see Amazon Lumberyard Asset List Comparison Operations (p. 380).

Required: No

--print

This argument behaves differently depending on whether it's given as a flag or has a parameter list.

- **Flag (no arguments):** Prints the final comparison result to the console.
- **With arguments:** Prints the contents of each argument to the console after comparisons complete. Arguments can either be files or variables.

Required: No

--allowOverwrites

Allow overwriting of existing output files. By default, existing files will not be overwritten.

Type: Flag

Required: No

Examples

Example Compare to generate a delta

Generate a new asset list `deltaAssetList.assetlist` by taking the files which appear in either `firstAssetList_pc.assetlist` and `secondAssetList_pc.assetlist`, but not both:

```
Bin64vc141\AssetBundlerBatch.exe compare --comparisonType delta ^
   --firstAssetFile firstAssetList_pc.assetlist ^
   --secondAssetFile secondAssetList_pc.assetlist ^
   --output deltaAssetList.assetlist
```

Example Compare based on file path matching

Generate a new asset list `filePatternAssetList.assetlist` that contains only XML files from the `assetList_pc.assetlist` file:

```
Bin64vc141\AssetBundlerBatch.exe compare --comparisonType filePattern ^
   --filePatternType 0 ^
   --filePattern "*.xml" ^
   --firstAssetFile assetList_pc.assetlist ^
   --output filePatternAssetList.assetlist
```

Example Count intersection across multiple asset lists

Use `intersectionCount` on `engine_pc.assetlist`, `game_pc.assetlist`, and `patch_pc.assetlist` to print out assets which appear 2 times or more between any of these asset lists:
Bin64\vc141\AssetBundlerBatch.exe compare --comparisonType intersectionCount ^
--firstAssetFile engine_pc.assetlist,game_pc.assetlist,patch_pc.assetlist ^
--print

**Bundle settings - bundleSettings**

The `bundleSettings` command is used to manage bundle settings file, configuration files that let you store commonly-used bundle configurations for easy reuse and automation.

**Options**

--- `bundleSettingsFile`

The bundle settings file to be modified when running this command. If this file already exists, only those settings which are specified by the command invocation are changed.

*Type:* Single-value argument

*Required:* Yes

--- `assetListFile`

Sets the asset list file to use in bundle generation.

*Type:* Single-value argument

*Required:* No

--- `outputBundlePath`

Sets the location where the generated asset bundle is written to. Asset bundles use the `.pak` file extension.

*Type:* Single-value argument

*Required:* No

--- `bundleVersion`

Sets the bundle format version to use in generation. The only allowed value is 1.

*Type:* Single-value argument

*Required:* No

--- `maxSize`

Sets the maximum allowed size for individual bundles, in MB. If any generated bundle is larger than the maximum size, it will be split into smaller bundles and named accordingly.

*Type:* Single-value argument

*Required:* No

--- `platform`

The platforms to update the bundle settings for. Defaults to the project's enabled platforms, defined in `AssetProcessorPlatformConfig.ini`. Valid platform names can be found in the platform configuration file or as folder names under `dev\Cache\ProjectName`.

*Type:* Multi-value argument

*Required:* No
**--print**

Prints the contents of the bundle settings file to the console after modifying all values.

*Type: Flag*

*Required: No*

### Examples

The following examples assume that these platforms are enabled for the project: pc

#### Example Set default max bundle size and asset list for PC

Create a bundler settings file `defaults_pc.bundlesettings` for PC with the maximum bundle size set to 1024MB and the `allAssets_pc.assetlist` asset list as its input:

```
Bin64vc141\AssetBundlerBatch.exe bundleSettings --bundleSettingsFile defaults.bundlesettings ^
  --maxSize 1024 ^
  --assetListFile allAssets.assetlist ^
  --platforms pc
```

### Asset bundles - bundles

The `bundles` command is used to generate the final bundle (.pak) files that contain all of the assets from an asset list. Bundles can't be modified once created, only regenerated.

#### Options

**--bundleSettingsFile**

The bundle settings file to be loaded. If arguments are provided which would override the settings file, the arguments override the settings file.

*Type: Single-value argument*

*Required: No*

**--assetListFile**

The asset list file to use in bundle generation.

*Type: Single-value argument*

*Required: No*

**--outputBundlePath**

The location where the generated asset bundle is written to. Asset bundles use the .pak file extension.

*Type: Single-value argument*

*Required: No*

**--bundleVersion**

The bundle format version to use in generation. The only allowed value is 1.

*Type: Single-value argument*
Required: No

--maxSize

The maximum allowed size for individual bundles, in MB. If any generated bundle is larger than the maximum size, it will be split into smaller bundles and named accordingly.

Type: Single-value argument

Required: No

--platform

The platforms to generate bundles for. Defaults to the project's enabled platforms, defined in AssetProcessorPlatformConfig.ini. Valid platform names can be found in the platform configuration file or as folder names under dev\Cache\ProjectName.

Type: Multi-value argument

Required: No

--allowOverwrites

Allow overwriting of existing bundle files. By default, bundles are not overwritten.

Type: Flag

Required: No

Examples

In the following examples, assume that the current project has enabled the platforms pc, ios, and es3.

Example Create a bundle for PC using a settings file

Create a assets_pc.pak bundle for PC, using the defaults_pc.bundlesettings file:

Bin64vc141\AssetBundlerBatch.exe bundles --outputBundlePath assets.pak --bundleSettingsFile defaults.bundlesettings --platform pc

Example Create bundles for all platforms

Create bundles for all of a project's enabled platforms, using the allAssets_pc.assetlist, allAssets_ios.assetlist, and allAssets_es3.assetlist files:

Bin64vc141\AssetBundlerBatch.exe bundles --outputBundlePath assets.pak --maxSize 512 -- assetListFile allAssets.assetlist

Bundle from seed - bundleSeed

The bundleSeed command is used to generate bundles directly from seeds and their dependencies, without the use of an intermediate asset list. No other files besides the required seeds are used as input, and only bundle files are produced as output.

Options

--addSeed

The seeds to be used in bundle file generation. All asset dependencies of these seeds are included in the bundle as well. Argument parameters should be given as cache-relative paths to pre-processed assets.
Type: Multi-value argument

Required: Yes

--bundleSettingsFile

The bundle settings file to be loaded. If arguments are provided which would override the settings file, the arguments override the settings file.

Type: Single-value argument

Required: No

--outputBundlePath

The location where the generated asset bundle is written to. Asset bundles use the .pak file extension.

Type: Single-value argument

Required: No

--bundleVersion

The bundle format version to use in generation. The only allowed value is 1.

Type: Single-value argument

Required: No

--maxSize

The maximum allowed size for individual bundles, in MB. If any generated bundle is larger than the maximum size, it will be split into smaller bundles and named accordingly.

Type: Single-value argument

Required: No

--platform

The platforms to update the bundle settings for. Defaults to the project's enabled platforms, defined in AssetProcessorPlatformConfig.ini. Valid platform names can be found in the platform configuration file or as folder names under dev\Cache\ProjectName.

Type: Multi-value argument

Required: No

--allowOverwrites

Allow overwriting of existing bundle files. By default, bundles are not overwritten.

Type: Flag

Required: No

Examples

Example Regenerate bundle for a seed

Regenerate the bundle processed.pak for the example.cgf asset and all of its dependencies, with a maximum size of 512MB.

Bin64vc141\AssetBundlerBatch.exe bundleSeed --addSeed example.cgf --outputBundlePath processed.pak --maxSize 512 --allowOverwrites
Customize FBX asset export with FBX Settings

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Meshes, actors, PhysX colliders, and motions created in third-party content creation tools must be exported to a runtime format for your project. To export your assets to Lumberyard, save the assets from your content application as .fbx files. Then, place the .fbx files in one of the asset directories of your project. Lumberyard uses .fbx as an intermediate file format because most modeling and animation applications can read and create .fbx files.

Topics
- FBX Settings introduction (p. 409)
- FBX Settings export properties (p. 409)
- FBX Settings mesh export (p. 436)
- FBX Settings actor export (p. 437)
- FBX Settings motion export (p. 438)
- FBX Settings PhysX export (p. 439)
- Multiple UV sets for meshes and actors (p. 441)
- FBX soft naming conventions (p. 443)

FBX Settings introduction

When you place .fbx files in an asset directory in your project, Asset Processor detects the new or modified files, determines the contents of the files, and then exports the data using basic settings. However, .fbx files can be complex and might contain data that is necessary for an artist, animator, or designer, but not necessary for a runtime asset. Data in the .fbx file might require special handling such as higher precision vertex data or a coordinate space change. With FBX Settings, you can specify what data in the .fbx file to export, and how the data should be processed by Asset Processor.

When you customize export properties and add modifiers with FBX Settings, a corresponding .assetinfo file containing the settings is created for the .fbx file. The .fbx file is not changed. When Asset Processor exports the .fbx file, it uses the settings in the .assetinfo file to generate the runtime asset.

You can find a sample .fbx files in the lumberyard_version\dev\SamplesProject\Objects\Tutorials\Fbx directory, or type fbx into the search field at the top of Asset Browser to show .fbx files in your current project.

FBX Settings export properties

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

- FBX Settings Meshes tab (p. 413)
- FBX Settings Actors tab (p. 419)
- FBX Settings Motions tab (p. 426)
- FBX Settings PhysX tab (p. 429)

FBX Settings overview

With FBX Settings you can customize how Asset Processor exports your .fbx files as runtime assets. FBX Settings presents options based on the contents of the selected .fbx file.

Your .fbx files can contain any number of assets. You can create a single .fbx file that contains multiple characters, with LoDs, and animations, or a single .fbx file containing all the vegetation assets.
required for a level. When these assets are processed they appear as children of the .fbx file in Asset Browser.

### Modify FBX Settings

1. In Lumberyard Editor, in Asset Browser, select the .fbx file to modify.

   **Tip**
   
   Enter `fbx` into Asset Browser's search bar to find .fbx files.

2. Right-click the .fbx file and then choose Edit Settings.
3. There are four possible tabs in **FBX Settings**. The available tabs depend on the contents of the `.fbx` file:

- **Meshes** - In the **Meshes** tab, you can create groups and modify export settings for meshes. Exported mesh data is stored in a `.cgf` file.

  The **Meshes** tab is available if the `.fbx` file contains meshes.

- **Actors** - In the **Actors** tab, you can create groups and modify export settings for actors. An actor has a skeleton and a skinned mesh, but is not necessarily a character. Any asset containing at least one bone is an actor. Actor data is stored in a `.actor` file.

  The **Actors** tab is available if the `.fbx` file contains at least one bone.

- **Motions** - In the **Motions** tab, you can modify export settings for animation. Animation data is stored in a `.motion` file.

  The **Motions** tab is available if the `.fbx` file contains at least one bone with animated channels.

- **PhysX** - In the **PhysX** tab, you can create groups and modify export settings for PhysX collider assets. You set properties to automatically fit primitive or generate convex collider assets based on meshes contained in the `.fbx` file. PhysX collider data is stored in a `.pxmesh` file.

  The **PhysX** tab is available if the `.fbx` file contains meshes.

  **Note**

  To use PhysX collider assets, you must have the PhysX Gem enabled in your project.

4. The **Meshes**, **Actors**, and **PhysX** tabs can have multiple groups, each with their own modifiers. Each group creates separate runtime asset files. To add groups, choose the **Add another...** button at the top of the tab. To add a modifier to a group, choose the **Add Modifier** button in the **Modifiers** section of the group and select a modifier from the list.

5. The **Motions** tab exports animations individually and creates a `.motion` file for each animation. To add motions, choose the **Add another motion** button at the top of the tab. To add a modifier to a motion, choose the **Add Modifier** button in the **Modifiers** section of the motion, and select a modifier from the list.

6. To remove a modifier, motion, or group, choose the **X** button for the entry.

7. Choose **Update** to apply your changes. A `.assetinfo` file containing your modified FBX settings is generated or the existing `.assetinfo` file is updated. **Asset Processor** automatically exports the data from your `.fbx` files. Some `.fbx` files might take longer to process depending on file size, complexity, and selected options and modifiers.
8. Review the status for errors or a success message. To return to the settings, choose OK.

The exported runtime assets appear as children of the .fbx file in Asset Browser.

**FBX Settings Meshes tab**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

All meshes in the .fbx file are processed to a single runtime asset (.cgf) by default. In the Meshes tab, you can create mesh groups containing specific meshes from the .fbx file. Each Mesh group produces its own .cgf file. The processed runtime assets appear in Asset Browser as children of the .fbx file.

**Contents**

- Meshes tab properties (p. 414)
- Cloth modifier (p. 415)
- Comment modifier (p. 416)
- Level of Detail modifier (p. 416)
- Material modifier (p. 416)
- Mesh (Advanced) modifier (p. 417)
- Origin modifier (p. 418)
- Touch Bending modifier (p. 418)
- CryPhysics Proxy modifier (p. 419)
Meshes tab properties

Add another mesh

Add a mesh group to process. Each mesh group can contain one or more meshes from the .fbx file. Each mesh group produces a .cgf file.

Name mesh

Enter a name for the mesh group. This is the name of the .cgf file containing the processed meshes. The .cgf file appears in Asset Browser as a child of the .fbx file.

Select meshes

Specify the meshes to process from the .fbx file for this mesh group. Choose the Hierarchy icon to see a list of meshes found in the .fbx file. Select meshes from the list to include them in the mesh group and process as visible render meshes. If the .fbx contains meshes that are intended to be used as PhysX collider assets, you should exclude them from the Mesh group by deselecting them in this list.

Add Modifier

Modifiers add specialized options for processing assets. Choose the Add Modifier button to see a list of available modifiers:

- Cloth
- Comment
- CryPhysics Proxy
- Level of Detail
- Material
- Mesh (Advanced)
- Origin
- Touch Bending
Note
Some modifiers are not available unless the gem that provides the modifier is enabled in your project.

Cloth modifier

Add NVIDIA Cloth data to a selected mesh to simulate cloth physics.

Note
Each mesh in the Mesh group to simulate as cloth requires its own Cloth modifier. When a Cloth modifier is added to a mesh group, the Merge Meshes property in the Mesh (Advanced) modifier will be ignored and treated as disabled. A cloth mesh needs to be processed independently and cannot be merged with other meshes.

For more information, see Simulate cloth with NVIDIA Cloth (p. 2857).

Select Cloth Mesh

Select the mesh to have cloth data applied and simulate as a cloth object.

Note
For information on the Inverse Masses, Motion Constraints, and Backstop properties below, see Per vertex properties for cloth (p. 2866).

Inverse Masses

Select a vertex color stream to apply per vertex inverse mass data for cloth simulation. If no vertex color stream is selected, an inverse mass value of 1.0 is assigned to all vertices in the cloth mesh.

Inverse Masses Channel

Select the channel in the vertex color stream that contains inverse mass data.

Motion Constraints

Select a vertex color stream to apply per vertex motion constraints data for cloth simulation. If no vertex color stream is selected, a motion constraint value of 1.0 is assigned to all vertices in the cloth mesh.

Motion Constraints Channel

Select the channel in the vertex color stream that contains motion constraints data.

Backstop

Select a vertex color stream to apply per vertex backstop data for cloth simulation. If no vertex color stream is selected, backstop is disabled for the cloth mesh.
Backstop Offset Channel

Select the channel in the vertex color stream that contains backstop offset data.

Backstop Radius Channel

Select the channel in the vertex color stream that contains backstop radius data.

Comment modifier

Add a comment to the file. You can add a comment about changes made to the .fbx file for tracking purposes or notes on export options, for example. Comments don't affect how files are processed. Multiple comment modifiers can be added to a mesh group.

Level of Detail modifier

Add level of detail (LoD) meshes to the Mesh group.

1. Choose the + button to add an LoD.
2. Choose the Trash Can button to remove an LoD.
3. Choose the Hierarchy button to specify the meshes to include in the LoD.

LoDs are optimized meshes with progressively lower polygon counts, fewer and smaller textures, and simplified materials. The farther an entity is from the camera, the less detail is required from the meshes that make up the entity. As the entity moves farther from the camera, it swaps to a lower LoD.

In addition to the base static mesh, you can specify up to five LoDs which are numbered [1] to [5], with [1] being the highest level of detail. As the entity moves further from the camera, it will transition from the base mesh to LoD 1, and progressively through the LoDs the further it moves from the camera. LoDs are not required. Creating LoDs, however, is recommended because they help get the best performance and visual fidelity across a range of platforms with different hardware capabilities.

Note

When you author the mesh in your 3D application, you can add _lod1, _lod2, _lod3, _lod4, _lod5 as suffixes to your mesh names to automatically add a Level of Detail modifier and assign the meshes to appropriate LoDs. _lod1 is mapped to [0], _lod2 is mapped to [1], and so on.

Material modifier

The Material modifier helps automatically manage the contents of the .mtl file that corresponds to the mesh group when mesh assets are updated.
A material is a combination of shaders and properties that define the surface of a mesh. Materials contain shader and texture assignments, settings for shader properties such as smoothness, opacity, emissive color, etc., and if necessary, a physics material assignment that defines physical properties such as friction. A mesh group processed with a file named `myfile.cgf` has a corresponding material file named `myfile.mtl`.

When a mesh group is processed, **Asset Processor** generates a material file (.mtl) containing a list of materials and their properties for the mesh group. A mesh can have multiple materials, and a mesh group can have multiple meshes, so the .mtl file might contain several materials even if the asset seems simplistic visually.

**Update materials**

When enabled, updates the texture map file names in the .mtl file to match the texture map names in defined in the .fbx file.

**Remove unused materials**

When enabled, removes materials that are present in the .mtl file that are not defined in the .fbx file.

**Mesh (Advanced) modifier**

![Mesh Modifier](image)

The **Mesh (Advanced)** modifier adds advanced mesh processing features such as a setting for vertex precision, which can save memory, and a setting to choose a vertex color stream to include in the processed mesh.

**Vertex Precision**

Select the precision of the vertex data for the mesh group. **16-bit** floats have a range of -65,500 to 65,500 and 3 significant decimal places. Using **16-bit** precision results in a much smaller file size for processed meshes, but vertices in the resulting .cgf file might shift slightly from their positions in the .fbx file. This position shift might be noticeable on large meshes, meshes with precise detail, or meshes that are placed far from the origin. Choose **32-bit** precision for larger maximum values and more significant decimal places if the vertices appear to have shifted in the runtime asset.

**Important**

32-bit precision vertices consume more resources and might result in a loss of performance on some platforms. Some platforms have native support for 16-bit precision which can offer improved performance. Check the capabilities of your target platform to determine which precision offers the best results.

**Merge Meshes**

When enabled, combines all sub-meshes in the mesh group into a single mesh for optimization.

**Use Custom Normals**

Enable this property to use custom normals, otherwise, **Asset Processor** generates averaged normals.

Normals are vertex attributes that define the surface direction of your meshes. Normals can be customized in third-party modeling tools to make a mesh appear faceted, create hard edges.
between surfaces, or smooth the appearance of a surface. Custom normals can be included in .fbx files.

**Vertex color stream**

If the mesh for this **Mesh group** contains a vertex color stream, it can be selected from this list to be processed.

Vertex color streams contain per vertex color data that can be referenced by materials. Vertex color streams are also often used for tagging meshes with arbitrary data such as the inverse mass value used in cloth simulation. Because of this, a mesh might have multiple vertex color streams. Be sure to select a vertex color stream intended to be referenced by materials if multiple streams exist.

**Origin modifier**

<table>
<thead>
<tr>
<th>Origin</th>
<th>Relative Origin Node</th>
<th>X 0.0</th>
<th>Y 0.0</th>
<th>Z 0.0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Translation</td>
<td>P 0.0</td>
<td>R 0.0</td>
<td>Y 0.0</td>
</tr>
<tr>
<td></td>
<td>Scale</td>
<td>1.0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Change the position (translation), orientation (rotation), and scale of a mesh relative to how it was authored.

**Relative Origin Node**

Select the transform relative to which the mesh is processed. By default, the mesh origin is placed at the scene position 0, 0, 0 in the .fbx file.

**Translation**

Sets the position offset of the processed mesh.

**Rotation**

Sets the orientation offset of the processed mesh in degrees.

**Scale**

Sets the scale offset of the processed mesh.

**Touch Bending modifier**

**TouchBending**

- Select root bone
- Proximity Trigger Mesh(es) 0 of 4 proximity meshes selected
- Stiffness 0.5
- Damping 0.5
- Thickness[m] 0.01

The **Touch Bending** modifier sets up mesh assets for touch bending. Touch bending is a collision effect, typically used on vegetation assets such as plants or tall grass, that causes the asset to bend away from an entity that brushes against it. You can use this modifier to create a field of wheat, for example, where the wheat parts and bends as a player character passes through.
Touch bendable assets require a rig similar to an actor. For more information on creating touch bendable assets, see Adding Touch (Collision) Bending Effects (p. 1302).

**Select root bone**

Specify the root bone of the touch bendable mesh.

**Proximity Trigger Mesh(es)**

Choose the Hierarchy button to select collision meshes that trigger the touch bending effect. Multiple trigger meshes can be selected, however, each additional trigger mesh decreases performance. A new PhysicsNoDraw material with a NoCollide type is created for the mesh(es).

**Stiffness**

Set a stiffness value between 0.0 and 1.0 for all branches to define how easily the asset bends.

**Damping**

Set a damping value between 0.0 and 1.0 for all branches to define how quickly the asset returns to its rest position after a collision.

**Thickness**

Set a thickness value for all branches to define the amount of bending. Thickness is determined as the radius of a cylinder in meters. Most often a small decimal number less than 1.0 is required. Valid values range from 0.00001 to infinity.

**CryPhysics Proxy modifier**

![CryPhysics Proxy](image)

**Important**

The legacy physics system will be deprecated in a future Lumberyard release. Use the PhysX system instead.

Select meshes to use as proxy physics meshes for the legacy physics system.

**Physics meshes**

Choose the Hierarchy icon to specify the meshes to use for physics proxies from the .fbx file. Physics proxies are meshes that encapsulate render geometry (for example, hit detection or physics collision) and are optimized with a low polygon count for better performance. Primitives such as a cube, sphere or capsule are best for optimal physics performance.

**Note**

If your .fbx file includes a mesh node with the suffix _phys, the mesh node automatically adds a new Physics Proxy modifier.

**FBX Settings Actors tab**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Actors are assets with at least one bone and can contain one or more skinned meshes. By default, all actors in the `.fbx` file are processed. However, you can manually exclude individual actors within your `.fbx` file. You can also process multiple actors from a single `.fbx` file. Each Actor group produces its own `.actor` file. The processed runtime assets appear in Asset Browser as children of the `.fbx` file.

Contents

- Actors tab properties (p. 420)
- Cloth modifier (p. 421)
- Comment modifier (p. 422)
- Coordinate system change modifier (p. 422)
- Level of Detail modifier (p. 423)
- Material modifier (p. 423)
- Mesh modifier (p. 424)
- Scale actor modifier (p. 424)
- Skeleton optimization modifier (p. 424)
- Skin modifier (p. 425)
- Tangents modifier (p. 425)

Actors tab properties

Add another actor

Add an Actor group to process. Each Actor group produces a `.actor` file.

Name actor

Enter a name for the Actor. This is the name of the `.actor` file that appears in Asset Browser as a child of the `.fbx` file.
Select root bone

Select the root bone of the skeleton hierarchy. The top parent bone of the skeleton is automatically selected as the default bone. All descendant bones of the root bone are processed.

Select base meshes

Specify the meshes to process from the .fbx file for this Actor group. Choose the Hierarchy icon to see a list of meshes found in the .fbx file. Select meshes from the list to include them in the Actor group and process as visible render meshes. If the .fbx contains meshes that are intended to be used as PhysX collider meshes, or meshes that are not skinned to the skeleton hierarchy being processed, you should exclude them from the Actor group by deselecting them in this list.

Note

If you have defined level of detail meshes for your actor by appending _lod0 through _lod5 to meshes in the .fbx file, the _lod0 meshes are automatically selected for the Select base meshes property.

Add Modifier

Modifiers add additional specialized options for processing assets. Choose the Add Modifier button to see a list of available modifiers:

- Cloth
- Comment
- Coordinate system change
- Material
- Mesh
- Scale actor
- Skeleton optimization
- Skin
- Tangents

Note

Some modifiers are not be available unless the gem that provides the modifier is enabled in your project.

Cloth modifier

Add NVIDIA Cloth data to a selected mesh to simulate cloth physics.

Note

Each mesh in the Actor group to simulate as cloth requires its own Cloth modifier.

For more information, see Simulate cloth with NVIDIA Cloth (p. 2857).
Select Cloth Mesh

Select the mesh to have cloth data applied and simulate as a cloth object.

**Note**
For information on the Inverse Masses, Motion Constraints, and Backstop properties below see Per vertex properties for cloth (p. 2866).

**Inverse Masses**

Select a vertex color stream to apply per vertex inverse mass data for cloth simulation. If no vertex color stream is selected, an inverse mass value of 1.0 is assigned to all vertices in the cloth mesh.

**Inverse Masses Channel**

Select the channel in the vertex color stream that contains inverse mass data.

**Motion Constraints**

Select a vertex color stream to apply per vertex motion constraints data for cloth simulation. If no vertex color stream is selected, a motion constraint value of 1.0 is assigned to all vertices in the cloth mesh.

**Motion Constraints Channel**

Select the channel in the vertex color stream that contains motion constraints data.

**Backstop**

Select a vertex color stream to apply per vertex backstop data for cloth simulation. If no vertex color stream is selected, backstop will be disabled for the cloth mesh.

**Backstop Offset Channel**

Select the channel in the vertex color stream that contains backstop offset data.

**Backstop Radius Channel**

Select the channel in the vertex color stream that contains backstop radius data.

**Comment modifier**

Add a comment to the file. You can add a comment about changes made to the .fbx file for tracking purposes or notes on export options, for example. Comments don't affect how files are processed and multiple comment modifiers can be added to a mesh group.

**Coordinate system change modifier**

Modify the coordinate system of the actor. Third-party content creation applications use varying coordinate systems with content applications often rotating the direction of the forward axis. The Facing direction property can be set to rotate the actor 180 degrees around its up axis to account for this difference. The rotation is applied when the asset is processed and the .fbx file remains unchanged.
Level of Detail modifier

The Level of detail (LoD) modifier is added to the Actor group automatically when LoDs are found in the .fbx file. Choose the Hierarchy button to verify or modify the meshes and bones assigned to each LoD. Actors support up to 5 levels of detail in addition to the base mesh(es).

Note
The Level of detail modifier for Actor groups cannot be added or removed manually and does not appear in the modifier list. The Level of detail modifier is automatically added and configured when actor LoDs are found in an .fbx file.

LoDs are optimized assets with progressively lower polygon counts, fewer and smaller textures, and simplified materials. An Actor LoD can also have a simplified skeleton where some leaf bones have been removed from the skeleton. The farther an entity is from the camera, the less detail is required from the actor contained in the entity. As the entity moves farther from the camera, it swaps to a lower actor LoD.

In addition to the base actor mesh, you can create up to five LoDs for actors which are numbered [1] to [5], with [1] being the highest level of detail. As the actor moves away from the camera, it will transition from the base mesh to LoD 1, and then progressively through the LoDs the further it moves from the camera. LoDs are not required. Creating LoDs, however, is recommended because they help get the best performance and visual fidelity across a range of platforms with different hardware capabilities.

Note
When you author the actor in your 3D application, you must add _lod1, _lod2, _lod3, _lod4, _lod5 as suffixes to your mesh names to automatically add a Level of Detail modifier and assign the meshes to appropriate LoDs. _lod1 is mapped to LOD 1, _lod2 is mapped to LOD 2, and so on.

Important
The meshes for the base mesh, and the corresponding skeleton are assigned in the Select base meshes and Select root bone properties of the Actor group automatically. Meshes labeled _lod1 through _lod5 and their skeleton hierarchies are assigned to corresponding LoDs in the Level of Detail modifier.

For more information, see Using Actor LODs to Optimize Game Performance (p. 1498).

Material modifier

The Material modifier helps automatically manage the contents of the .mtl file that corresponds to the Actor group when actor assets are updated.

A material is a combination of shaders and properties that define the surface of a mesh. Materials contain shader and texture assignments, settings for shader properties such as smoothness, opacity, emissive color, etc., and if necessary, a physics material assignment that defines physical properties such as friction. An Actor group processed with a file named myfile.actor has a corresponding material file named myfile.mtl.
When an **Actor group** is processed, **Asset Browser** generates a material file (.mtl) containing a list of materials and their property settings for the mesh group. A mesh can have multiple materials, and an **Actor group** can have multiple meshes, so the .mtl file might contain several materials even if the asset seems simplistic visually.

**Update materials**

When enabled, updates the texture map file names in the .mtl file to match the texture map names defined in the .fbx file.

**Remove unused materials**

When enabled, removes materials that are present in the .mtl file that are not defined in the .fbx file.

**Mesh modifier**

<table>
<thead>
<tr>
<th>Mesh</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Vertex color stream</td>
<td>No vertex colors</td>
</tr>
<tr>
<td>Vertex color mode</td>
<td>32 bit (8 bits per channel)</td>
</tr>
</tbody>
</table>

Set a vertex color stream and its precision for the Actor's visible render mesh.

**Vertex color stream**

If the mesh for this **Actor group** contains a vertex color stream, it can be selected from this list to be processed.

Vertex color streams contain per vertex color data that can be referenced by materials. Vertex color streams are also often used for tagging meshes with arbitrary data such as the inverse mass value used in cloth simulation. Because of this, a mesh might have multiple vertex color streams. Be sure to select a vertex color stream intended to be referenced by materials if multiple streams exist.

**Vertex color mode**

Set the vertex color precision to either 32 bit (8 bits per channel) or 128 bit (32 bits per channel).

Vertex color streams contain four channels: red, green, blue, and alpha. Setting the mode to 32 bit vertex color precision saves significant memory over 128 bit vertex color precision at a loss of dynamic range. If you are targeting a platform with memory constraints, using 32 bit precision is a very useful optimization. If you are targeting a platform that supports high dynamic range (HDR) display, 128 bit precision offers much greater color fidelity.

**Scale actor modifier**

<table>
<thead>
<tr>
<th>Scale actor</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scale factor</td>
<td>1.0</td>
</tr>
</tbody>
</table>

The **Scale factor** modifier sets a uniform scale for the **Actor group**. This setting is useful if your assets are created in an application that uses a different base standard unit of measurement than Lumberyard.

**Skeleton optimization modifier**

<table>
<thead>
<tr>
<th>Skeleton Optimization</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto Skeleton LOD</td>
<td></td>
</tr>
<tr>
<td>Server Skeleton Optimize</td>
<td></td>
</tr>
<tr>
<td>Critical bones</td>
<td>0 of 35 bones selected</td>
</tr>
</tbody>
</table>
The **Skeleton optimization** modifier automatically optimizes Actor skeletons for client and server scenarios.

**Auto Skeleton LoD**

When enabled, unskinned bones (bones not weighted to any vertices), are optimized out of the client side skeleton hierarchy.

**Server Skeleton Optimize**

When enabled, bones that do not have colliders attached are optimized out of the server side skeleton hierarchy.

**Critical bones**

Choose the **Hierarchy** button to select bones that should not be optimized out of the hierarchy. Your actor might have bones that have no skin weights such as attachment bones for weapons and accessories, for example, that you do not want optimized out of the hierarchy.

---

**Skin modifier**

<table>
<thead>
<tr>
<th>Max weights per vertex</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weight threshold</td>
<td>0.001</td>
</tr>
</tbody>
</table>

The **Skin** modifier sets the maximum bones and minimum weight per vertex.

**Max weights per vertex**

The maximum number of bones that can influence a vertex. Values range from a minimum of 1 to a maximum of 4.

**Weight threshold**

The minimum bone weight per vertex. Weight values beneath this threshold are ignored during export. Values range from a minimum of 0 to a maximum of 0.01.

---

**Tangents modifier**

<table>
<thead>
<tr>
<th>Tangent space</th>
<th>MikkT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bitangents</td>
<td>Orthogonal</td>
</tr>
<tr>
<td>Normalize</td>
<td>On</td>
</tr>
<tr>
<td>Uv set</td>
<td>0</td>
</tr>
</tbody>
</table>

The **Tangents** modifier generates or exports tangents and bitangents from your .fbx file. You should use the same tangent space you use to generate normal maps to achieve the desired appearance in Lumberyard.

Normal maps can make a surface appear as though it has more geometric surface detail than exists in the mesh. The normals in the map are in tangent space which points in the positive Z direction. Tangent space is local to the surface and is used to transform the normals in the normal map into world space so the material can be lit and rendered correctly on a deforming surface such as a character mesh. You can create tangents and bitangents in your third-party content application and save them as vertex attributes, then export the tangents with the **Tangents** modifier, or use the **Tangents** modifier to generate tangents when the mesh for this **Actor group** is processed.
Tangent space

Defines the tangent space that Lumberyard uses for an actor. Choose from the following options:

- **MikkT** – Uses MikkT to generate the tangents. MikkT is a widely used solution for generating tangent space that strives for consistency regardless of changes and optimizations to the source mesh. This is the default setting.
- **From FBX** – Export the tangents from the FBX file.
- **EMotion FX** – Use EMotion FX to calculate the tangents.

**Warning**
The **EMotion FX** option is for backward compatibility only and is not recommended.

Bitangents

Defines how to generate or read the bitangents.

- **Use from source** – Use the bitangents from the FBX file or the output from the tangent generator used (MikkT).
- **Orthogonal** – Generates the bitangents orthogonal to the tangent and normal. This is the default setting.

**Normalize**

When enabled, tangents and bitangents are normalized. **Normalize** is enabled by default.

UV set

The index of the UV set to generate tangents from. The default setting is 0, the first UV set.

FBX Settings Motions tab

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can process animation sequences from a single .fbx file as **Motions**. Each **Motion** produces its own .motion file. The processed runtime assets appear in **Asset Browser** as children of the .fbx file.

**Important**

Animation in your .fbx should be baked, that is, each animated channel should be keyed at every frame. Third-party animation applications might use functions and simulations to interpolate between keyframes and the results are not exported from your .fbx file unless the animation is baked into the animation channels.

For more information, see Animation Editor File Types (p. 1352).

Contents

- Motions tab properties (p. 427)
- Additive motion modifier (p. 427)
- Comment modifier (p. 428)
- Compression Settings modifier (p. 428)
- Coordinate system change modifier (p. 428)
- Motion range modifier (p. 429)
- Scale motion modifier (p. 429)

**Motions tab properties**

![Image of FBX export properties settings](image)

**Add another motion**

Add an animation to export as a .motion from the .fbx file.

**Name motion**

Enter a name for the motion. This is the name of the .motion file that appears in **Asset Browse** as a child of the .fbx file.

**Select root bone**

Select the root bone of the animated skeleton hierarchy. By default the top parent bone of the skeleton is selected as the root bone.

**Add Modifier**

Modifiers add specialized options for processing assets. Choose the **Add Modifier** button to see a list of available modifiers:

- Additive motion
- Comment
- Compression settings
- Coordinate system change
- Motion range
- Scale motion

**Additive motion modifier**

![Image of Additive motion modifier](image)
Export the animation as an additive motion. Additive motions can be layered on top of base motions without affecting the base motion functionality.

**Base Frame**

Specifies the number of the base frame that contains the reference pose.

For more information, see

**Comment modifier**

Add a comment to the file. You can add a comment about changes made to the .fbx file for tracking purposes or notes on export options, for example. Comments don't affect how files are processed and multiple comment modifiers can be added to a mesh group.

**Compression Settings modifier**

Reduce asset size by compressing animation. The **Compression settings** modifier sets tolerances for keyframe values on each transform type. If the change in a keyframe's value from the preceding keyframe is smaller than the tolerance value set in this modifier, the keyframe is removed.

**Max translation error tolerance**

Specify the maximum error tolerance allowed in translation. Valid values range from a minimum of 0 to a maximum of 0.1.

**Max rotation error tolerance**

Specify the maximum error tolerance allowed in rotation. Valid values range from a minimum of 0 to a maximum of 0.001.

**Max scale error tolerance**

Specify the maximum error tolerance allowed in scale. Valid values range from a minimum of 0 to a maximum of 0.01.

**Coordinate system change modifier**

Modify the coordinate system of the motion. Third-party content creation applications and game engines use varying coordinate systems with content applications often rotating the direction of the forward axis. The **Facing direction** property can be set to rotate the motion 180 degrees around its up axis to account for this difference. The rotation is applied when the asset is processed and the .fbx file remains unchanged.
Motion range modifier

Set the range of the animation to be exported from the .fbx file.

**Start frame**

Specify the start keyframe of the animation to export.

**End frame**

Specify the end keyframe of the animation to export.

Scale motion modifier

The **Scale factor** modifier sets a uniform scale for the **Motion**. This setting is useful if your assets are created in an application that uses a different base standard unit of measurement than Lumberyard.

FBX Settings PhysX tab

This feature is in **preview** release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

In the PhysX tab, you can create **PhysX Mesh groups** to process collider assets for PhysX. Collider assets can be triangle meshes, or generated as primitives or convex meshes based on meshes contained in the .fbx file. Multiple **PhysX Mesh groups** can be processed from a single .fbx file. Each **PhysX Mesh group** produces its own .pxmesh file. The processed runtime assets appear in Asset Browser as children of the .fbx file.

**Important**

There are many options for creating PhysX collider assets. The best options in a scenario depend on many factors including mesh complexity, how the collider asset is used, and whether the entity containing the collider is static (doesn't move), kinematic (animated), or dynamic (has a rigid body component). In general, primitive colliders offer the best simulation performance, but you might consider trading performance for precision in situations where collider assets that closely match a visible render mesh are desirable.

Contents

- PhysX tab properties (p. 430)
- Triangle mesh asset properties (p. 431)
- Convex asset properties (p. 432)
- Primitive asset properties (p. 433)
- Decomposition properties (p. 434)
• PhysX modifiers (p. 435)
• Comment modifier (p. 435)
• Origin modifier (p. 436)

PhysX tab properties

Add another PhysX mesh group to process as a PhysX collider asset (.pxmesh) from the .fbx file.

Name PhysX Mesh

Enter a name for the PhysX mesh. This is the name of the .pxmesh file that appears in Asset Browser as a child of the .fbx file.

Select meshes

Specify the meshes to process from the .fbx file for this PhysX mesh group. Choose the Hierarchy icon to see a list of meshes found in the .fbx file. Select meshes from the list to include them in the PhysX mesh group and process as PhysX collider assets.

Note
If your .fbx file includes mesh nodes with the suffix _phys, the meshes are automatically selected for processing in the PhysX mesh group.

Export As

The cooking method to apply to this PhysX mesh group. This setting exposes properties for the selected cooking method. The three options are:
• Triangle - Generate colliders composed of triangles based on the selected meshes.
• Convex - Generate convex hull colliders based on the selected meshes.
• Primitive - Fit primitive colliders based on the selected meshes.

Note
Triangle mesh colliders can only be used with static and kinematic entities. To use the PhysX collider asset with dynamic entities (entities that have a PhysX Rigid Body component), choose Convex or Primitive for the Export as property.
Triangle mesh asset properties

Triangle mesh colliders accurately reproduce the shape of the selected meshes, but cannot be used on dynamic entities. Triangle mesh colliders are most suitable for static environment entities that have complex shapes and require colliders that accurately resemble the visible render mesh shape.

<table>
<thead>

</tr>
</tbody>
</table>

**Merge Meshes**

When enabled, all selected mesh nodes are merged into a single collider mesh. Otherwise, the selected mesh nodes are exported as separate shapes. It is usually more efficient to have a single collider mesh.

**Weld Vertices**

When enabled, mesh vertex welding is performed. **Disable clean mesh** must be disabled when **Weld Vertices** is enabled or vertex welding is not performed.

**Disable Clean Mesh**

When enabled, mesh cleaning is disabled. This makes cooking faster. **Disable clean mesh** must be disabled when **Weld Vertices** is enabled or vertex welding is not performed.

**Force 32-bit Indices**

When enabled, 32-bit indices are created for the collider asset regardless of triangle count.

**Suppress Triangle Mesh Remap Table**

When enabled, the face remap table is not created. This saves a significant amount of memory, but the SDK won’t be able to provide the remap information for internal mesh triangles returned by collisions, sweeps, or raycast hits.

**Build Triangle Adjacencies**

When enabled, triangle adjacency information is created. You can get the adjacency triangles for a given triangle from `getTriangle`.

**Mesh Weld Tolerance**

When **Weld Vertices** is enabled, this value is the distance within which vertices are welded. When **Weld Vertices** is disabled, this value defines the acceptance distance for mesh validation.

Having a clean, welded mesh is required to achieve the best possible performance. **Weld Vertices** uses a snap-to-grid approach. This approach truncates each vertex to an integer value using **Mesh Weld Tolerance**. Once these snapped vertices are produced, all vertices that snap to a given vertex on the grid are remapped to reference a single vertex. Following this, all triangle indices are remapped to reference this subset of clean vertices. Vertices do not have their positions modified; the snap-to-grid is only performed to identify nearby vertices.

The mesh validation approach uses the same snap-to-grid approach to identify nearby vertices. If more than one vertex snaps to a given grid coordinate, the distance between the vertices is checked.
to ensure it is greater than **Mesh Weld Tolerance**. If the vertices are within **Mesh Weld Tolerance**, a warning is emitted.

**Number of Triangles Per Leaf**

Set the mesh cooking hint for max triangles per leaf. Fewer triangles per leaf results in slower cooking speed and produces larger mesh sizes with better runtime performance. More triangles per leaf results in faster cooking speed and produces smaller mesh sizes with decreased runtime performance.

**Convex asset properties**

Convex hulls are generated colliders that can approximate the shape of the selected meshes. Convex hulls can be used with static, kinematic, and dynamic entities, and are often used on interactive entities such as weapons that require rigid body physics and a collider mesh that resembles the shape of the visible render mesh.

**Area Test Epsilon**

If the area of a triangle in the hull is below this value, the triangle is rejected. This test is performed only if **Check Zero Area Triangles** is set. Valid values range from a minimum of 0 to a maximum value of 100.

**Plane Tolerance**

This value is used during hull construction. When a new point is added to the hull, it is rejected when the point is closer to the hull than the **Plane Tolerance** value. The **Plane Tolerance** value is increased according to the hull size.

If the **Plane Tolerance** value is 0.0, all points are accepted when the convex hull is created. This can lead to edge cases where the new points are merged into an existing polygon, changing the polygon's plane equation slightly, resulting in failures during polygon merging phase in the hull computation.

We recommend the default value. However, if all points must be accepted, or large, thin convex hulls must be created, you can specify a lower value. Valid values range from a minimum of 0 to a maximum value of 100.

**Use 16-bit Indices**

When enabled, 16-bit triangle or polygon indices are generated. Otherwise, 32-bit vertex indices are generated.

**Check Zero Area Triangles**

Checks and removes triangles that are have a smaller area than the area value specified in **Area Test Epsilon**.
Quantize Input

Quantizes the input vertices using k-means clustering (p. 3283).

Use Plane Shifting

Enables plane shifting vertex limit algorithm. For more information, see the NVIDIA PhysX Geometry documentation.

Shift Vertices

When enabled, convex hull input vertices are shifted to be around the origin to provide better computation stability. It is recommended to provide input vertices around the origin; otherwise, use this property to improve numerical stability.

Gauss Map Limit

Specifies the vertex limit beyond which additional acceleration structures are computed for each convex mesh. Increase the limit to reduce memory usage. Computing the extra structures doesn't guarantee optimal performance. There is a per-platform break-even point below which the extra structures can negatively impact performance. Valid values range from a minimum of 0 to infinity.

Build GPU Data

When enabled, additional information required for GPU accelerated rigid body simulation is generated. This can increase memory usage and cooking time for convex meshes and triangle meshes. Convex hulls are generated with respect to GPU simulation limitations. The vertex limit is set to 64 and the per face vertex limit is set to 32.

Decompose Meshes

When enabled, the V-HACD algorithm is applied to split each node into approximately convex parts. Each part is exported as a convex collider using the properties configured above. Decompose Meshes enables Decomposition Properties which determine how the selected meshes are decomposed into approximately convex parts.

Primitive asset properties

Primitive colliders are simple parametric primitives (box, capsule, sphere) fit to the selected meshes and can be used with static, kinematic, and dynamic entities. Primitive colliders generally provide the best simulation performance, but might not closely match the shape of the visible render mesh. They are best suited for dynamic entities with simple meshes such as crates and barrels, as well as projectiles, triggers, and entities where colliders that accurately represent shape of the visible render mesh are not necessary.

Target Shape

Select a target shape to fit to the mesh: Box, Capsule, or Sphere. If Automatic is selected, then the algorithm determines which shape fits best.

Volume Term Coefficient

Specifies how aggressively the primitive fitting algorithm minimizes the volume of the fitted primitive. Valid values range from a minimum of 0 to a maximum of 0.002.

A value of 0 performs no volume minimization and is recommended for most meshes, especially meshes with moderate to high vertex counts.
For meshes that have low vertex counts, or vertices that are distributed mainly along the edges, the algorithm can sometimes produce sub-optimal results where the primitive touches the edges of the mesh, but not the faces. In these cases, the fitting can be improved by increasing the Volume Term Coefficient so that the fitting algorithm shrinks the volume of the primitive while minimizing its deviation from the mesh. A Volume Term Coefficient that is too high can shrink the primitive collider so that it’s occluded by the mesh.

**Decompose Meshes**

When enabled, the V-HACD algorithm is applied to split each node into approximately convex parts. Each part is exported as a primitive collider using the properties configured above. Decompose Meshes enables Decomposition Properties which determine how the selected meshes are decomposed into approximately convex parts.

**Decomposition properties**

Exporting a PhysX mesh as a convex or a primitive collider might not produce good results if the mesh’s shape is concave or doesn’t closely fit one of the primitive shapes. Exporting a PhysX mesh as a triangle mesh collider creates a collider that accurately resembles the original mesh, but won’t work with a dynamic entity. For these scenarios, Lumberyard supports approximate convex decomposition. Arbitrary meshes are broken down into approximately convex parts before processing each part through the asset pipeline individually.

Decomposing meshes has the advantage that each individual, nearly convex part, can be more accurately exported as a convex or primitive. Since the resulting asset doesn’t contain any triangle meshes, it can be used on dynamic entities.

For more information and illustrated examples of results, see the V-HACD library on GitHub.

**Maximum Hulls**

Specify the maximum number of hulls to generate. Valid values range from a minimum of 1 to a maximum value of 1024.

**Maximum Vertices Per Hull**

Defines the maximum number of triangles per convex hull. Valid values range from a minimum of 4 to a maximum value of 1024.

**Concavity**

Specify the maximum concavity of each approximate convex hull. Valid values range from a minimum of 0 to a maximum value of 1.
Resolution

Maximum number of voxels generated during the voxelization stage. Valid values range from a minimum of 10000 to a maximum value of 6400000.

Mode

Select voxel-based approximate convex decomposition or tetrahedron-based approximate convex decomposition.

Alpha

Specify the bias toward clipping along symmetry planes. Valid values range from a minimum of 0 to a maximum value of 1.

Beta

Specify the bias toward clipping along revolution axes. Valid values range from a minimum of 0 to a maximum value of 1.

Minimum Volume Per Hull

Specify the adaptive sampling of the generated convex hulls. Valid values range from a minimum of 0 to a maximum value of 0.01.

Plane Downsampling

Specify the granularity of the search for the best clipping plane. Valid values range from a minimum of 1 to a maximum value of 16.

Hull Downsampling

Specify the precision of the convex hull generation process during the clipping plane selection stage. Valid values range from a minimum of 1 to a maximum value of 16.

Enable PCA

When enabled, the mesh is normalized before applying the convex decomposition.

Project Hull Vertices

When enabled, the output convex hull vertices are projected onto the original source mesh to increase the floating point accuracy of the results.

PhysX modifiers

Modifiers can be added to a PhysX mesh group by choosing the Add Modifier button, and selecting a modifier from the list.

Comment modifier

Add a comment to the file. You can add a comment about changes made to the .fbx file for tracking purposes or notes on export options, for example. Comments don't affect how files are processed and multiple comment modifiers can be added to a mesh group.
**Origin modifier**

![Origin modifier interface](image)

Change the position (translation), orientation (rotation), and scale of a mesh relative to how it was authored.

**Relative Origin Node**

Select the transform relative to which the mesh is processed. By default, the mesh origin is placed at the scene position 0, 0, 0 in the .fbx file.

**Translation**

Sets the position offset of the processed mesh.

**Rotation**

Sets the orientation offset of the processed mesh in degrees.

**Scale**

Sets the scale offset of the processed mesh.

**FBX Settings mesh export**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Meshes contain geometry that doesn't have a skeleton and skinning data. These assets are also called static Meshes. Static meshes are most often used as props and environment objects, but can be used as interactive objects and even player avatars. Entities containing static meshes can be animated through scripts (kinematics) or PhysX simulation (dynamics).

**Contents**

- Export a mesh (p. 436)
- Mesh export video tutorial (p. 437)
- Mesh export tips (p. 437)

**Export a mesh**

1. Copy your .fbx file to a sub directory in your project located at `lumberyard_version\dev\your_project`.
Alternatively, choose Import from the File menu in Lumberyard Editor to copy or move the .fbx file into your project.

2. Locate the .fbx in Asset Browser.

3. Right click the .fbx in Asset Browser and choose Edit Settings to open FBX Settings.

4. In FBX Settings, in the Meshes tab, choose the Hierarchy button to the right of Select meshes and ensure only the meshes required for the Mesh group are selected in the mesh list.

   You can choose Add another mesh to create additional mesh groups. A runtime .cfg asset will be produced for each mesh group. A mesh group can contain any number of meshes from the Select meshes list.

5. Set the properties for each mesh group and add modifiers to each mesh group as required. For information on Mesh group properties and modifiers, see FBX Settings Meshes tab (p. 413).

6. Optional - Set up PhysX colliders for your meshes. For more information, see FBX Settings PhysX export (p. 439).

7. Choose the Update button at the bottom right of the FBX Settings window. A File progress window opens to display information about asset processing. Choose OK to close the File progress window. This step creates or updates the .assetinfo file. Asset Processor automatically processes the .fbx file and generates the runtime .cfg files for meshes, .pxmesh files for PhysX, and .mtl files for materials.

8. Close the FBX Settings window.

Note
When you close FBX Settings after making changes, you might see a pop-up window warning of unsaved changes. This is a known issue and can be disregarded.

Mesh export video tutorial

To learn about exporting static meshes to Lumberyard, watch the following video tutorial.

Exporting static meshes to Lumberyard – Static Meshes

Mesh export tips

- Ensure that each object that needs to perform runtime collision has a PhysX mesh. Low-resolution PhysX meshes work better than high-resolution meshes. Primitives such as a cube, sphere, or capsule are best for optimal physics performance.
- The maximum number of vertices for any static geometry is 65,536. You can export a scene where the total number of vertices exceeds 65,536, but each static geometry piece can't exceed 65,536.

If the combined mesh has more than 65,536 vertices, make the following changes in the FBX Settings tool:

1. In Lumberyard Editor, in the Asset Browser, right-click the .fbx file and choose Edit Settings.
2. In the FBX Settings tool, on the Meshes tab, click Add Modifier and then choose Mesh (Advanced).
3. Clear the Merge Meshes setting. This prevents Asset Processor from merging the meshes, which allows Asset Processor to process the geometry.

FBX Settings actor export

This feature is in preview release and is subject to change.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

**Actors** contain geometry that has a skeleton and skinning data. An **Actor** is not necessarily a character. Assets that use a skeleton and skinning data to drive animation such as weapons, machines, and foliage, are **Actors**. **Actors** can be animated through keyframe animation imported as **Motions** or through PhysX simulation and other dynamic solvers such as **Touch Bending**.

**Export an actor**

1. Copy your `.fbx` file to a sub directory in your project located at `lumberyard_version\dev\your_project`.

   Alternatively, choose **Import** from the **File** menu in Lumberyard Editor to copy or move the `.fbx` file into your project.

2. Locate the `.fbx` in **Asset Browser**.

3. Right click the `.fbx` in **Asset Browser** and choose **Edit Settings** to open **FBX Settings**.

4. In **FBX Settings**, in the **Actors** tab, ensure the desired root bone of the actor’s skeleton is selected in the **Select root bone** property.

   An **Actor group** may contain only one skeleton hierarchy, and will only export bones that are part of the selected hierarchy.

5. In **FBX Settings**, in the **Actors** tab, choose the **Hierarchy** button to the right of **Select base meshes** and ensure only the meshes required for the **Actor group** are selected in the mesh list.

   You can choose **Add another actor** to create additional actor groups. A runtime `.actor` asset will be produced for each actor group. An actor group can contain any number of meshes from the **Select meshes** list and a single skeleton hierarchy.

6. Set the properties for each actor group. Add modifiers to each actor group as required. For information on **Actor group** properties and modifiers, see **FBX Settings Actors tab** (p. 419).

7. **Optional** - Set up PhysX colliders for your meshes. For more information, see **FBX Settings PhysX export** (p. 439)

8. Choose the **Update** button at the bottom right of the **FBX Settings** window. A **File progress** window opens to display information about asset processing. Choose **OK** to close the **File progress** window. This step creates or updates the `.assetinfo` file. **Asset Processor** automatically processes the `.fbx` file and generates the runtime `.actor` files, `.pxmesh` files for PhysX, and `.mtl` files for materials.

9. Close the **FBX Settings** window.

   **Note**
   When you close **FBX Settings** after making changes, you might see a pop-up window warning of unsaved changes. This is a known issue and can be disregarded.

---

**FBX Settings motion export**

This feature is in **preview** release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
**Motions** contain keyframe animated sequences that can be sequenced and blended in **Animation Editor** and applied to actors to create behaviors. Motions must use identical skeleton hierarchies as their actor counterparts.

**Export a motion**

1. Copy your `.fbx` file to a sub directory in your project located at `lumberyard_version\dev\your_project`.
   Alternatively, choose **Import** from the **File** menu in Lumberyard Editor to copy or move the `.fbx` file into your project.
2. Locate the `.fbx` in **Asset Browser**.
3. Right click the `.fbx` in **Asset Browser** and choose **Edit Settings** to open **FBX Settings**.
4. In **FBX Settings**, in the **Motions** tab, ensure the desired root bone of the actor’s skeleton is selected in the **Select root bone** property.
   A Motion may contain only one skeleton hierarchy, and will only export bones that are part of the selected heirarchy.
   A Motion exports a single animation sequence. If the `.fbx` contains multiple animation sequences, additional motions can be added by choosing **Add another motion**.
5. Set the properties for each motion. Add modifiers to each motion as required. For information on Motion properties and modifiers, see FBX Settings Motions tab (p. 426).
6. Choose the **Update** button at the bottom right of the **FBX Settings** window. A **File progress** window opens to display information about asset processing. Choose **OK** to close the **File progress** window.
   This step creates or updates the `.assetinfo` file. **Asset Processor** automatically processes the `.fbx` file and generates the runtime `.motion` files.
7. Close the **FBX Settings** window.
   **Note**
   When you close **FBX Settings** after making changes, you might see a pop-up window warning of unsaved changes. This is a known issue and can be disregarded.

**FBX Settings PhysX export**

This feature is in **preview** release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

PhysX colliders are required by **Actors** and **Meshes** to perform collision detection, raycast hit detection, overlap testing, and PhysX simulation. It's possible to use simple parametric primitive shapes in the **PhysX collider** component to create PhysX colliders, but many situations require colliders that more closely resemble the render mesh than simple shapes.

The **PhysX** tab in **FBX Settings** has many options to generate PhysX colliders that offer the best resolution and performance for any use scenario.

**Export PhysX colliders**

1. Copy your `.fbx` file to a sub directory in your project located at `lumberyard_version\dev\your_project`. The `.fbx` file can contain a mesh or an actor.
Alternatively, choose **Import** from the **File** menu in Lumberyard Editor to copy or move the `.fbx` file into your project.

2. Locate the `.fbx` in **Asset Browser**.

3. Right click the `.fbx` in **Asset Browser** and choose **Edit Settings** to open **FBX Settings**.

4. In **FBX Settings**, in the **PhysX** tab, choose the **Hierarchy** button to the right of **Select meshes** and ensure only the meshes required for the **PhysX group** are selected in the mesh list.

The selected meshes can be the visible meshes, or meshes that have been created in a content creation application as physics colliders.

You can choose **Add another physxmesh** to create additional PhysX mesh groups. At least one runtime `.pxmesh` asset is produced for each mesh group. A PhysX mesh group can contain any number of meshes from the **Select meshes** list.

5. Set the properties for each PhysX mesh group, Add modifiers to each PhysX mesh group as required.

Use the **Export as** property to generate the appropriate type of PhysX colliders for your use scenario. **Export as** has three options and one property that are important to understand:

**Triangle mesh**

Triangle mesh generates a triangle mesh collider from the selected meshes. Triangle mesh colliders can offer high precision collisions because they can accurately represent the shape of the visible render mesh. Because triangle meshes can be complex and non-convex, they might carry a performance penalty compared to convex and primitive colliders. Triangle mesh colliders can only be used with static and kinematic entities.

**Primitive**

Primitive either uses the selected primitive shape or determines the most appropriate primitive shape for the collider based on the selected meshes. The primitive shape is automatically fit over the selected meshes. Primitive shapes include box, sphere, and capsule. Primitive shapes offer the highest simulation performance, but might not closely represent the shape of the visible render mesh. Primitives can be used for static, kinematic, and, dynamic entities.

**Convex**

Convex generates a convex hull that encompasses the selected meshes. A convex collider can more accurately represent the shape of the visible render mesh than a primitive collider, at a slight performance cost. Convex colliders can be used for static, kinematic, and dynamic entities.

**Decompose Meshes**

When generating **Primitive** or **Convex** colliders, you have the option to decompose meshes. When enabled, **Decompose Meshes** breaks the selected meshes down into approximately convex parts. Primitives or convex hulls are generated and fit to each decomposed mesh part. Many small colliders that more accurately resemble the shape of the visible render mesh are generated. This option is useful for automatically generating colliders for characters and other complex meshes without authoring colliders in a content creation application or fitting primitive colliders manually.

For further information on **PhysX mesh group** properties and modifiers, see **FBX Settings PhysX tab** (p. 429).

6. Choose the **Update** button at the bottom right of the **FBX Settings** window. A **File progress** window opens to display information about issues encountered during asset processing. Choose **OK** to close the **File progress** window. This step creates or updates the `.assetinfo` file. **Asset Processor** automatically processes the `.fbx` file and generates the runtime `.cfg` files for meshes, `.pxmesh` files for PhysX, and `.mtl` files for materials.
7. Close the **FBX Settings** window.

**Note**
When you close **FBX Settings** after making changes, you might see a pop-up window warning of unsaved changes. This is a known issue and can be disregarded.

### Multiple UV sets for meshes and actors

This feature is in **preview** release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

You can use **FBX Settings** to import multiple UV sets. With multiple UV sets, you can apply a detail or blend layer map to your geometry using UV sets that are independent of the diffuse, normal, and spec UV sets. With multiple UV sets, you can also apply an animated glow that is independent of other texture maps on a mesh.

---

**Topics**
- Processing multiple UV sets (p. 442)
Multiple UV sets

• Materials and multiple UV sets (p. 442)
• Independent tiling and UV sets (p. 442)

Processing multiple UV sets

Lumberyard supports two UV sets per mesh. Asset Processor follows these rules when processing UV sets:

• If the .fbx file contains one or two UV sets, the UV sets are automatically exported.
• If the .fbx file contains three or more UV sets, the first two sets are automatically exported, and the remaining sets are ignored.

Materials and multiple UV sets

By default, FBX Settings creates materials for your exported mesh. You must use the Shader Generation Parameters in the Material Editor to specify how the material should use the second UV set.

Follow these steps to apply the second UV set:
1. In Lumberyard Editor, choose Tools and then Material Editor.
2. In the left pane, navigate to and select the material to use.
3. In the right pane, under Shader Generation Params, do the following to apply the second UV set to one of these features:
   • Blend Layer – Select Blendlayer and Use UV set 2 for blendlayer maps to apply the second UV set to the Second Diffuse Map, Specular, Height, Bump, and Blending Map texture slots.
   • Detail Map – Select Detail mapping and Use UV set 2 for detail map to apply the second UV channel to the Detail texture slot.
   • Emittance Map – Select Use UV set 2 for emittance map to apply the second UV channel to the Emittance and Decal texture slots.

Independent tiling and UV sets

On the Second Diffuse Map, you can set independent values for the blend layer's texture inputs (tiling, rotation, and oscillation). Changes to these values don't affect the tiling, rotation, and oscillation values on the first Diffuse Map. In addition, these values aren't applied to the Blend Map. You can use the Blend Mask Tiling parameter under Shader Params to tile the Blend Map.

You can also set independent values for tiling, rotation, and oscillation for the Detail and Emittance map features.

Follow these steps to set independent values for the texture inputs:
1. In Lumberyard Editor, choose Tools, Material Editor.
2. In the left pane, navigate to and select the material to use.
3. In the right pane, do the following:
   • Under Texture Maps, modify the values for Tiling, Rotator, and Oscillator for your diffuse maps.
   • Under Shader Params, modify the Blend Mask Tiling parameter for your blend map.
FBX soft naming conventions

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use soft naming conventions when authoring assets in your content creation tools, such as Autodesk 3ds Max or Maya. Soft naming conventions are prefixes or suffixes that you add to either nodes in your scene or the .fbx file name. In Lumberyard, Asset Processor recognizes these soft naming conventions and then applies an action based on the specified soft naming convention.

Lumberyard provides soft naming conventions as a convenience for content creators to automate steps that are typically done manually in FBX Settings. Depending on the soft naming conventions that you specify, Asset Processor automatically adds those modifiers to the scene settings.

Contents
- Viewing soft naming conventions (p. 444)
- Soft naming convention parameters (p. 446)
- Examples (p. 446)
- Configuring soft naming conventions (p. 447)
- Moving FBX files between projects (p. 448)

Note
The Scene Processing gem is required to use FBX Settings. This gem is enabled by default.

The following table lists current soft naming conventions and the actions that are applied.

Default soft naming conventions

<table>
<thead>
<tr>
<th>Soft Naming Convention</th>

### Viewing soft naming conventions

You can use the System Entity Editor to view the current soft naming conventions for your project.

**To view the soft naming conventions**

1. In Project Configurator choose Advanced Editor Settings for your project.
2. Expand the Scene Processing Config section to find the soft naming conventions.

**Note**

If the Scene Processing Config section doesn't appear, choose Add Component and then choose Scene Processing Config.
Naming conventions

- Node name setting
  - Pattern: _lod1
  - Matcher: PostFix
  - Virtual Type: LODMesh1
  - Include child nodes

- Node name setting
  - Pattern: _lod2
  - Matcher: PostFix
  - Virtual Type: LODMesh2

- Node name setting
  - Pattern: _lod3
  - Matcher: PostFix
  - Virtual Type: LODMesh3
  - Include child nodes

- Node name setting
  - Pattern: _lod4
  - Matcher: PostFix
  - Virtual Type: LODMesh4
  - Include child nodes

- Node name setting
  - Pattern: _lod5
  - Matcher: PostFix
  - Virtual Type: LODMesh5
  - Include child nodes

- Node name setting
  - Pattern: _phys

  - Virtual Type: PhysicsMesh
  - Include child nodes

- Node name setting
  - Pattern: _ignore
  - Matcher: PostFix
  - Virtual Type: Ignore
  - Include child nodes

- File name setting
  - Pattern: _ignore
  - Matcher: PostFix
  - Virtual Type: Ignore
  - Include child nodes

Select required graph types
Soft naming convention parameters

You can use the System Entity Editor to match the files that use the specified pattern for the node name or file name. The soft naming conventions are matched based on the pattern of the node name or file name that you specify.

There are three approaches available for matching:

**Postfix**

Checks if the node or file name ends in the specified pattern. For file name, the extension isn't included.

**Prefix**

Checks if the node or file name starts with the specified pattern. This approach doesn't include any paths that are in front of the node or file name.

**Regex**

For complex pattern matching, you can use regular expressions to match the entire node (for example, `root.group_a.group_b.mesh`) or file path (for example, `example/file/object.fbx`). This approach is more complex but useful if you want more granular control. For example, you can use regular expression to have all files in an `/animation/` directory export only the animation files.

For **Node name settings**, you can specify the following:

**Virtual type**

Provides the list of virtual types that the nodes are converted to after their pattern matches. You can assign multiple virtual types to a single node.

**Include child node**

If enabled, the virtual type applies to the node and all of its child nodes. You can use this option to apply the change to a parent node and all of its children without adding a separate rule for each child node.

For **File name settings**, you can specify the following:

**Virtual type**

Provides the list of virtual types that the files are converted to after their pattern matches.

**Graph type**

Select one or more graph types that the virtual type is applied to.

**Inclusive**

If enabled, the virtual type applies to all graph node types that are selected. If disabled, the virtual type applies to all graph node types that are unselected.

**Examples**

Using these parameters, you can customize how Asset Processor processes .fbx files that you import.

**Example Node name setting**

You can pair a node name in a source asset file to a predefined Lumberyard virtual type.
1. For **Node name setting**, for **Pattern**, specify _lod1_.
2. For **Matcher**, specify **Postfix**.
3. For **Virtual type**, specify LODMESH1 and select the **Include child nodes** check box.
4. When Asset Processor processes the .fbx file, it checks for node names with the _lod1 suffix. If any nodes match, Asset Processor assigns them the LODMESH1 virtual type, and the change applies to all child nodes.

**Example File name setting**

You can pair a file name in a source asset file to a predefined Lumberyard virtual type.

1. For **Node name setting**, for **Pattern**, specify anim_.
2. For **Matcher**, specify **Prefix**.
3. For **Virtual type**, specify **Ignore**.
4. For **Graph type**, specify IAnimData and select the **Inclusive** check box.
5. When Asset Processor processes your files, it checks for file names with the anim_ prefix and that use the IAnimData graph type. If any file names match, Asset Processor assigns them the **Ignore** virtual type.

**Configuring soft naming conventions**

The preconfigured soft naming conventions might not apply to your workflow. You can change the existing soft naming conventions or create and delete them as needed.

**To change soft naming conventions**

1. In the System Entity Editor, for **Node name settings**, you can specify the following options:
   a. For **Pattern**, specify a value. The matcher uses this value to check against the file.
   b. For **Matcher**, select one of the following:
      - PreFix
      - PostFix
      - Regex
   c. For **Virtual type**, select one of the following:
      - Ignore
      - LODMesh1 – LODMesh5
      - PhysicsMesh
   d. For **Include child nodes**, specify whether the virtual type applies to the node and its children.
2. For **File name setting**, you can specify the following options:
   a. For **Pattern**, enter a value. The matcher uses this value to check against the file.
   b. For **Matcher**, select one of the following:
      - PreFix
      - PostFix
      - Regex
   c. For **Virtual type**, select one of the following:
      - Ignore
      - LODMesh1 – LODMesh5
- **PhysicsMesh**
  - **Graph type**: select the graph types that you want.
  - **Inclusive**: specify whether the virtual type applies to graph node types that you selected in the previous step. If disabled, the virtual type applies to graphs that are unselected.

3. To add a configuration, click the + icon.
4. For **Classes**, choose **File name setting** or **Node name setting** and then click **Save**.
5. To delete a configuration, click the x icon.
6. Click **Save**.

### Moving FBX files between projects

Soft naming conventions are project-specific. As a result, different projects can process the `.fbx` file differently.

**To process the FBX file the same way between projects**

1. In the **FBX Settings** tool, open the `.fbx` file to move.
2. Click **Update** at least once. This creates a manifest (.fbx.assetinfo) file.
3. When you move the `.fbx` file to another project, move the manifest file as well. This ensures that the `.fbx` file is processed the same way, regardless of the specified soft naming conventions.

### Process custom assets with Python Asset Builder

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

With Python Asset Builder, you can create Python scripts that process custom assets produced from content creation tools such as Maya and Houdini, or any content tool with a known file format.

To use Python Asset Builder you must enable the Python Asset Builder gem (p. 1192).

### Python Asset Builder terms

The input and output files for a Python Asset Builder are both assets of some type. This documentation uses the following terms to distinguish between the input and output of **Python Asset Builder**.

**Source asset file**

An input asset file, such as an asset produced by a content creation tool, that will be processed by **Asset Processor** to generate a **product asset file**, source dependencies, and build dependencies.

**Product asset file**

An output asset file produced by Python Asset Builder that can be consumed by a game launcher or Lumberyard Editor.

### Writing a Python Asset Builder

There are four steps to create a Python Asset Builder:
• **Create or modify a bootstrap script (p. 449)** - Add a new Python Asset Builder script to a bootstrap location.

• **Register a Python Asset Builder (p. 449)** - Add logic to the Python Asset Builder that registers an asset builder pattern and handlers for job creation and processing.

• **Create jobs with Python Asset Builder (p. 452)** - Define logic in the callback method for `CreateJobs` that responds with the job description to process source asset files.

• **Process job with Python Asset Builder (p. 456)** - Define logic for `ProcessJob` to generate product asset files and dependencies.

---

### Create or modify a bootstrap script

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To make your Python Asset Builder script available to the asset processing system, you must add a `bootstrap.py` file to the path or modify an existing `bootstrap.py` file. We recommend you use a location that is relative to where your Python Asset Builder scripts will be stored, such as one of the following:

- `lumberyard_version\dev\MyProject\Editor\Scripts\bootstrap.py`
- `lumberyard_version\dev\Gems\MyGem\Editor\Scripts\bootstrap.py`

To add your Python Asset Builder, import it in the `bootstrap.py` file.

```python
import asset_builder_my_asset_type
```

The above example assumes that the Python Asset Builder is named `asset_builder_my_asset_type.py`, and that it's in the same directory as the `bootstrap.py` file.

### Register a Python Asset Builder

A Python Asset Builder script must register a file pattern and unique builder ID for the asset builder. To describe the asset builder, use `azlmbr.asset.builder.AssetBuilderDesc`. To bind the script to the asset building process, use `azlmbr.asset.builder.PythonAssetBuilderRequestBus`. You can register the asset builder by a file extension pattern such as `*.myasset` or by a folder and file regular expression pattern such as `^[a-zA-Z]:\MyAssets[\S|\S]*\S*.*$).

When the Python Asset Builder is successfully registered, a handler for the builder ID is used to handle asset builder events to create jobs and process jobs. The script creates a `azlmbr.asset.builder.PythonBuilderNotificationBusHandler` in the module to add the callback handlers.

---

**Contents**

- **PythonAssetBuilderRequestBus (p. 450)**
Register

- AssetBuilderPattern (p. 450)
- AssetBuilderDesc (p. 450)
- PythonBuilderNotificationBusHandler (p. 451)
- Example: Register an asset builder (p. 451)

PythonAssetBuilderRequestBus

The PythonAssetBuilderRequestBus is a singleton EBus that serves methods to enable Python asset builders.

```python
azlmbr.asset.builder.PythonAssetBuilderRequestBus
```

# Registers an asset builder using a builder descriptor.
# input: azlmbr.asset.builder.AssetBuilderDesc
# output: Outcome_bool
'RegisterAssetBuilder'

# Fetches the current executable folder.
# input: N/A
# output: Outcome_string
'GetExecutableFolder'

AssetBuilderPattern

The AssetBuilderPattern is a structure that defines the type of pattern to use to watch for source asset files.

```python
class azlmbr.asset.builder.AssetBuilderPattern
```

- type (azlmbr.asset.builder.AssetBuilderPattern Type) How to use the pattern to watch source assets
- pattern (str) The file path pattern to use

AssetBuilderPattern Type

The pattern type can be either Wildcard or Regex. This informs the asset builder registration how to use the pattern field.

```python
# The pattern is a file wildcard pattern (glob).
azlmbr.asset.builder.AssetBuilderPattern_Wildcard

# The pattern is a regular expression pattern.
azlmbr.asset.builder.AssetBuilderPattern_Regex
```

AssetBuilderDesc

AssetBuilderDesc describes the asset builder for the Asset Processor so it can invoke callbacks for the create jobs event and the process job events for the patterns being that you are registering with the source asset watching system.
The `name` field is a human readable name that is used to trace how the product asset was processed.

The `version` field should be incremented if all the source assets for this builder should be reprocessed, for example, when the product asset contents are redefined.

The `busId` should be in the form of a `azlmbr.math.Uuid`, which can be created once via Python or other methods. You can use Visual Studio's GUID tool, or create one with Python 3:

Create a UUID with Python 3

```python
>>> import uuid
>>> uuid.uuid4()
UUID('639f403e-1b7e-4cfe-a250-90e6767247cb')
```

```python
azlmbr.asset.builder.AssetBuilderDesc
```

```python
class azlmbr.asset.builder.AssetBuilderDesc
- `busId (azlmbr.math.Uuid)`: The builder unique ID
- `name (str)`: The name of the Builder
- `patterns (list of AssetBuilderPattern)`: The collection of file patterns that the builder will use to determine if a file will be processed by that builder
- `version (number)`: Changing this version number will cause all your assets to be re-submitted to the builder for job creation and rebuilding
```

```python
PythonBuilderNotificationBusHandler
```

The notification bus handler is used by Python Asset Builder to call back to the Python script to handle asset building events such as `create jobs` and `process job` to process source asset files. The handler must be created in the global module scope so that the callbacks can stay active.

```python
azlmbr.asset.builder.PythonBuilderNotificationBusHandler
```

```
# Callback function type for creating jobs from job requests.
# input: tuple(azlmbr.asset.builder.CreateJobsRequest)
# output: azlmbr.asset.builder.CreateJobsResponse
'OnCreateJobsRequest'

# Callback function type for processing jobs from process job requests.
# input: azlmbr.asset.builder.ProcessJobRequest
# output: azlmbr.asset.builder.ProcessJobResponse
'OnProcessJobRequest'
```

Example: Register an asset builder

This example code shows how to register an asset builder. The `on_create_jobs` and `on_process_job` functions are stubbed out. See the subsequent topics for information on creating and processing jobs.

```python
import azlmbr.asset
import azlmbr.asset.builder
import azlmbr.bus
```
import azlmbr.math

busId = azlmbr.math.Uuid_CreateString('{CF5C74D1-9ED4-4851-85B1-9B15090DBEC7}', 0)

def on_create_jobs(args):
    # TODO: create jobs logic.
    return azlmbr.asset.builder.CreateJobsResponse()

def on_process_job(args):
    # TODO: process job logic.
    return azlmbr.asset.builder.ProcessJobResponse()

# register asset builder
def register_asset_builder():
    assetPattern = azlmbr.asset.builder.AssetBuilderPattern()
    assetPattern.pattern = '*.newasset'
    assetPattern.type = azlmbr.asset.builder.AssetBuilderPattern_Wildcard

    builderDescriptor = azlmbr.asset.builder.AssetBuilderDesc()
    builderDescriptor.name = "New Asset"
    builderDescriptor.patterns = [assetPattern]
    builderDescriptor.busId = busId
    builderDescriptor.version = 1

    if outcome.IsSuccess():
        # created the asset builder to hook into the notification bus
        h = azlmbr.asset.builder.PythonBuilderNotificationBusHandler()
        h.connect(busId)
        h.add_callback('OnCreateJobsRequest', on_create_jobs)
        h.add_callback('OnProcessJobRequest', on_process_job)
        return h

    # the module global asset builder handler
handler = register_asset_builder()

Create jobs with Python Asset Builder

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When you create a job with the Python Asset Builder, the callback for OnCreateJobsRequest will be called with a CreateJobsRequest in a tuple. The callback will return a CreateJobsResponse as the response using the data inside the request.

Contents
- CreateJobsRequest (p. 452)
- CreateJobsResponse (p. 453)
- Example: Create jobs (p. 456)

CreateJobsRequest

CreateJobsRequest provides data for operations related to the enabled platforms. This data is used to build the output JobDescriptor for a specific enabled platform. The CreateJobsRequest data contains input job data that is sent by Asset Processor to the builder for creating jobs.
Create Jobs

**azlmbr.asset.builder.CreateJobsRequest**

class azlmbr.asset.builder.AssetBuilderDesc
- **builderId** (azlmbr.math.Uuid) The builder id to identify which builder will process this
  job request
- **watchFolder** (str) Contains the sub-folder that the source file came from, out of all the
  folders being watched by the asset processor
- **sourceFile** (str) The source file path that is relative to the watch folder (watchFolder)
- **sourceFileUUID** (azlmbr.math.Uuid) The source file's UUID; will be used for its Asset ID
- **enabledPlatforms** (list of azlmbr.asset.builder.PlatformInfo) Information about each
  platform the builder is expected to build

**PlatformInfo**

This structure indicates the platform that has been enabled for the project.

**azlmbr.asset.builder.PlatformInfo**

class azlmbr.asset.builder.PlatformInfo
- **identifier** (str) The ID of the platform such as 'pc' or 'ios'
- **tags** (set of string) The tags such as "console" or "tools" on that platform

**CreateJobsResponse**

The response from the callback determines what work to process for the source asset file. In most cases,
the builder creates a job descriptor for each source asset and for each enabled platform.

**azlmbr.asset.builder.CreateJobsResponse**

class azlmbr.asset.builder.CreateJobsResponse
- **result** (azlmbr.asset.builder.CreateJobsResponse Return Code) The result code from the
  create jobs request
- **sourceFileDependencyList** (list of SourceFileDependency) This is required for source files
  that want to declare dependencies on other source files
- **createJobOutputs** (list of JobDescriptor) JobDescriptor is used by the builder to store
  job related information

**CreateJobsResultCode**

These are the possible result codes from CreateJobs request.

**azlmbr.asset.builder.CreateJobsResponse Return Code**

# Jobs failed to be created.
azlmbr.asset.builder.CreateJobsResponse_ResultFailed

# The builder is in the process of shutting down.
azlmbr.asset.builder.CreateJobsResponse_ResultShuttingDown

# Jobs were created successfully.
azlmbr.asset.builder.CreateJobsResponse_ResultSuccess
SourceFileDependency

This structure defines source asset file dependency information that the builder will send to Asset Processor.

The sourceFileDependencyPath field can be either be a relative path from the assets folder, or an absolute path.

The sourceFileDependencyUUID field is the source asset file UUID part of the asset ID, without the sub-id.

Important
The builder does not need to provide both the sourceFileDependencyUUID and the sourceFileDependencyPath info to Asset Processor. Either one will be sufficient.

azlmbr.asset.builder.SourceFileDependency
class azlmbr.asset.builder.SourceFileDependency
- sourceFileDependencyPath (str) Filepath on which the source file depends
- sourceFileDependencyUUID (azlmbr.math.Uuid) UUID of the file on which the source file depends
- sourceDependencyType (azlmbr.asset.builder.SourceFileDependency Type) Defaults to azlmbr.asset.builder.SourceFileDependency_Absolute

SourceFileDependency Type

azlmbr.asset.builder.SourceFileDependency Type

# Source file depends on other source file
azlmbr.asset.builder.SourceFileDependency_Absolute

# Allow wildcard matches using LIKE
azlmbr.asset.builder.SourceFileDependency_Wildcards

JobDescriptor

JobDescriptor is used by the builder to store job-related information.

The priority field is the value for the jobs within the job queue. A priority value less than 0 means the job's priority is not considered. A priority value of 0 or greater prioritizes the job by value. The higher the value, the higher priority.

Note
Priorities for critical and non-critical jobs are set separately.

The checkExclusiveLock field is a flag to determine whether Asset Processor needs to check the source asset file for exclusive lock before processing the job. Asset Processor will lock and unlock the source asset file to ensure it is not opened by another process. This prevents premature processing of some source asset files that are opened for writing, but have zero bytes for longer than the modification threshold. This will time out if the Asset Processor cannot get an exclusive lock.

The checkServer field determines whether Asset Processor needs to check the server for the outputs of this job before starting to process the job locally. If Asset Processor is running in server mode, then this is used to determine whether it needs to store the outputs of this job on the server.

If the failOnError field is set to True, then all reported errors, asserts, and exceptions cause the job to fail, even if the result code is ProcessJobResult_Success.
Create Jobs

The `setPlatformIdentifier` and `getPlatformIdentifier` methods set and retrieve the platform identifier such as `pc` or `android` for the job description. It is the identifier of the platform from the `PlatformInfo` struct.

```python
class azlmbr.asset.builder.JobDescriptor
- jobParameters (JobParameterMap) Any builder specific parameters to pass to the Process Job Request
- additionalFingerprintInfo (str) Any additional info that should be taken into account during fingerprinting for this job
- jobKey (str) Job specific key, e.g. TIFF Job
- priority (int) Priority value for the jobs within the job queue
- checkExclusiveLock (bool) Attempt to get an exclusive lock file for before we process the job
- checkServer (bool) Check the server for the outputs of this job before we start processing the job
- jobDependencyList (list of azlmbr.asset.builder.JobDependency) This is required for jobs that want to declare job dependency on other jobs
- failOnError (bool) Reported errors, asserts, and exceptions will automatically cause the job to fail
+ set_platform_identifier(platformIdentifier:str) -> None; Sets platform identifier
+ get_platform_identifier() -> platformIdentifier:str; Gets platform identifier
```

**JobParameterMap**

The `JobParameterMap` is a Dictionary of Numbers to Strings. This is a map data structure that holds parameters that are passed into a job for ProcessJob requests. These parameters can optionally be set during the create job function of the builder so that they are passed along to the ProcessJobFunction. The values (key and value) are arbitrary and it is up to the builder on how to use them.

**Example:**

```python
jobParameterMap = {1 : "MyValue", 2 : "Another Value"}
```

**JobDependency**

Job dependency information that the builder sends to the Asset Processor.

```python
class azlmbr.asset.builder.JobDependency
- sourceFile (azlmbr.asset.builder.SourceFileDependency) Source file dependency information that the builder will send to the asset processor
- jobKey (str) JobKey of the dependent job
- platformIdentifier (str) Platform Identifier of the dependent job
- type (azlmbr.asset.builder.JobDependency Type) Type of Job Dependency (order or fingerprint)
```

**JobDependency Type**

```python
azlmbr.asset.builder.JobDependency Type
```
Process job

# This implies that the dependent job should get processed by Asset Processor, if the fingerprint of job it depends on changes.
azlmbr.asset.builder.JobDependency_Fingerprint

# This implies that the dependent job should only run after the job it depends on is processed by Asset Processor.
azlmbr.asset.builder.JobDependency_Order

# This is similar to Order where the dependent job should only run after all the jobs it depends on are processed by the Asset Processor.
# The difference is that here only those dependent jobs matter that have never been processed by Asset Processor.
# Also important to note is the fingerprint of the dependent jobs do not alter the fingerprint of the job.
azlmbr.asset.builder.JobDependency_OrderOnce

Example: Create jobs

This is a simple example of how the asset builder might create jobs when Asset Processor detects a new or changed source asset file in the watch folders of the registered pattern.

```python
# Creates a single job to compile for each platform
def on_create_jobs(args):
    # get the request from the 'args'
    request = args[0]

    # Create job descriptor for each platform
    jobDescriptorList = []
    for platformInfo in request.enabledPlatforms:
        jobDesc = azlmbr.asset.builder.JobDescriptor()
        jobDesc.jobKey = 'My New Asset Job'
        jobDesc.priority = 1
        jobDesc.set_platform_identifier(platformInfo.identifier)
        jobDescriptorList.append(jobDesc)

    response = azlmbr.asset.builder.CreateJobsResponse()
    response.result = azlmbr.asset.builder.CreateJobsResponse_ResultSuccess
    response.createJobOutputs = jobDescriptorList
    return response
```

Process job with Python Asset Builder

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Asset Processor calls the registered callback when it has a job for the builder to begin processing. The callback processes the source asset file, performs all the work inside the temporary directory, creates at least one product asset file, registers the product asset files via a JobProduct entry inside a ProcessJobResponse instance, and returns a success value inside the ProcessJobResponse.

Contents
- ProcessJobRequest (p. 457)
- ProcessJobResponse (p. 457)
- ProcessJobResponse ResultCode (p. 458)
ProcessJobRequest

This is the input into the OnProcessJobRequest function to perform the steps that are needed to process a source asset file. This contains the input data that's needed to process the job for the source asset file.

The jobDescription field contains the job parameters that the OnCreateJobs step created for this job.

The tempDirPath field is the path to the temporary directory that the builder uses to write out intermediate and final product asset files output by this job. The output files are stored inside the temporary directory relative to where the final product asset file will be placed in the cache and pak files.

The sourceFileUUID field is both the unique ID of the source asset file, and the first part of the Asset ID that is used for all the product files output by this job. The only way to differentiate the product files is the subId used in the JobProduct structure.

azlmbr.asset.builder.ProcessJobRequest

class azlmbr.asset.builder.ProcessJobRequest
- sourceFile (str) Relative source file name
- watchFolder (str) Watch folder for this source file
- fullPath (str) Full source file name
- builderGuid (azlmbr.math.Uuid) Builder id
- jobDescription (azlmbr.asset.builder.JobDescriptor) Job descriptor for this job created in OnCreateJobs
- tempDirPath (str) Temp directory that the builder should use to create job outputs for this job request
- platformInfo (azlmbr.asset.builder.PlatformInfo) The information about the platform that this job was emitted for
- sourceFileDependencyList (list of azlmbr.asset.builder.SourceFileDependency) Source file dependency information
- sourceFileUUID (azlmbr.math.Uuid) The UUID of the source file
- jobId (number) Job id for this job, this is also the address for the JobCancelListener

ProcessJobResponse

This is the class that the OnProcessJobRequest callback returns to describe the job's results. The ProcessJobResponse contains job data that indicates the outputs from the job in the outputProducts field, the result code, and schedule sources to be reprocessed.

The outputProducts field indicates what product files need to be copied to the project cache folder. If this is empty, it indicates that the job failed.

The sourcesToReprocess field triggers a rebuild of source assets (via absolute paths) due to the work performed in this job. To reprocess these sources, the builder updates fingerprints in CreateJobs of those builders that process them, like changing source dependencies.
azlmbr.asset.builder.ProcessJobResponse

class azlmbr.asset.builder.ProcessJobResponse:
    - resultCode (azlmbr.asset.builder.ProcessJobResponse ResultCode) baz
    - outputProducts (list of azlmbr.asset.builder.JobProduct) List of job product files
    - requiresSubIdGeneration (bool) Used to determine if legacy RC products need sub ids generated for them
    - sourcesToReprocess (list of str) List of absolute source paths to trigger rebuilds

ProcessJobResponse ResultCode

The process job response result code has both a 'Success' and a 'Failure', but it also has some specific failure cases, such as detecting a crash or network issues.

# When everything was processed correctly the job should return ProcessJobResponse_Success
azlmbr.asset.builder.ProcessJobResponse_Success

# If the job did not create ALL of the expected outputs it should return ProcessJobResponse_Failed
azlmbr.asset.builder.ProcessJobResponse_Failed

# If a tool or internal API returned an exception it should return ProcessJobResponse_Crashed
azlmbr.asset.builder.ProcessJobResponse_Crashed

# If the job detected a cancellation during processing it should return ProcessJobResponse_Cancelled
azlmbr.asset.builder.ProcessJobResponse_Cancelled

# If the job could not reach a remote service or resource it should return ProcessJobResponse_NetworkIssue
azlmbr.asset.builder.ProcessJobResponse_NetworkIssue

JobProduct

A successful processing of a source asset returns one or more JobProduct entries in the ProcessJobResponse's outputProducts field.

The productSubID field is a stable and unique product identifier for each product file created by this process job for the source asset file. It can be any unsigned 32-bit integer that disambiguates different outputs from the same source. If builder source asset files produce only one product, the builder can use 0.

The productAssetType field maps to a C++ AZ::Data::AssetData type ID.

One way to determine the asset type ID from Python is to call the AssetCatalogRequestBus using the asset's display name:

```python
assetType = azlmbr.asset.AssetCatalogRequestBus(azlmbr.bus.Broadcast, 'GetAssetTypeByDisplayName', "Font")
print(f'Asset type {assetType}')
```
dependenciesHandled indicates to the **Asset Processor** that the builder has output all possible dependencies for this source asset file for this job product file. This can be true if there are no output product files. This should be set to True only if the builder outputs its dependencies or the output product doesn’t have dependencies. When set to False, **Asset Processor** emits a warning that dependencies have not been handled.

The **JobProduct** constructor takes in a product file name (relative to the source asset path), an asset type (Uuid), and a product sub-ID number.

```python
class azlmbr.asset.builder.JobProduct
    - productFileName (str) Relative or absolute product file path
    - productAssetType (azlmbr.math.Uuid) The asset type ID this product file loads into the asset catalog
    - productSubID (number) A stable product identifier
    - productDependencies (list of ProductDependency) Product assets this source asset depends on
    - pathDependencies (set of ProductPathDependency) Specifies dependencies by relative path to source assets
    - dependenciesHandled (bool) Indicates that the builder has output all possible dependencies
+ JobProduct(productFileName:str, productAssetType:azlmbr.math.Uuid, productSubID:number) A constructor to set a job product
```

**ProductDependency**

The product dependency information that the builder sends to **Asset Processor** to indicate that a product asset depends on another product asset during load.

```python
class azlmbr.asset.builder.ProductDependency
    - dependencyId (azlmbr.math.Uuid) Asset ID of this product asset dependency
```

**ProductPathDependency**

The **ProductPathDependency** represents the product's dependency information that the builder detected on another product file (relative to the source asset path). If the source asset ID can be determined, we recommend that you use the **productDependencies** instead to indicate the product's dependency information in terms of asset IDs. It's preferable to depend on product files whenever possible, to avoid introducing unintended dependencies.

The **dependencyType** field indicates if the path points to a source file or a product file.

```python
class azlmbr.asset.builder.ProductPathDependency
    - dependencyPath (str) Relative path to the asset dependency
    - dependencyType (azlmbr.asset.builder.ProductPathDependency Type) Indicates if the dependency path points to a source file or a product file
```
**ProductPathDependency Type**

ProductPathDependency Type indicates how to use the dependency path in the ProductPathDependency. A dependency on a source file is converted into dependencies on all product files produced from the source. It's preferred to depend on product files whenever possible, to avoid introducing unintended dependencies.

```python
# If the source asset depends on another product asset file the value should be SourceFile
azlmbr.asset.builder.ProductPathDependency_Type_SourceFile

# If the source asset depends on another source asset the value should be ProductFile
azlmbr.asset.builder.ProductPathDependency_Type_ProductFile
```

**Example: Process**

This is a simple example of how the asset builder might process a job when Asset Processor detects a new or changed source asset file in the watch folders of the registered pattern.

```python
# Using the incoming 'request' find the type of job via 'jobKey' to determine what to do
def on_process_job(args):
    try:
        # Get request information
        request = args[0]

        # Prepare output folder
        basePath, _ = os.path.split(request.sourceFile)
        outputPath = os.path.join(request.tempDirPath, basePath)
        os.makedirs(outputPath)

        # Write out a simple file
        productFileNameOnly = 'myfile.txt'
        filename = os.path.join(outputPath, productFileNameOnly)
        file = open(filename, "w+")
        file.write('some data')
        file.close()

        # Prepare output entry data
        productOutputs = []
        basePath, sceneFile = os.path.split(request.sourceFile)
        assetProductName = os.path.join(basePath, productFileNameOnly)
        outputFilename = os.path.join(request.tempDirPath, assetinfoFilename)

        # Create job product entry
        assetType = azlmbr.math.Uuid_CreateString('{F67CC648-EA51-464C-9F5E-4A9CE41A7F86}', 0)
        product = azlmbr.asset.builder.JobProduct(assetProductName, assetType, 0)
        product.dependenciesHandled = True
        productOutputs.append(product)

        # Fill out response object
        response = azlmbr.asset.builder.ProcessJobResponse()
        response.outputProducts = productOutputs
        response.resultCode = azlmbr.asset.builder.ProcessJobResponse_Success
        return response
    except:
        # An exception should record a proper failure
        response = azlmbr.asset.builder.ProcessJobResponse()
```

Version 1.28

460
response.resultCode = azlmbr.asset.builder.ProcessJobResponse_Crashed
return response
Working with component entities

The component entity system provides a modular and intuitive construction of game elements. The component entity system works at both the system level and the entity level. It employs reflection, serialization, messaging using the event bus (EBus), fully cascading prefabs (slices), and the ability to drag-and-drop and edit entities and their components in Lumberyard Editor.

Use the following Lumberyard Editor tools to improve the workflow for the component entity system.

- Entity Outliner (p. 462)
- Entity Inspector (p. 475)

**Note**
The component entity system replaces the (now legacy) Object and Entity System in the Amazon Lumberyard Legacy Reference.

See the following topics to add components to entities and customize their properties in Lumberyard Editor.

For information on programmatically creating your own custom components, see Programmer’s Guide to Entities and Components (p. 973).

**Topics**

- Entity Outliner (p. 462)
- Entity Inspector (p. 475)
- Working with Components (p. 479)
- Working with Slices (p. 510)
- Component Reference (p. 532)
- Converting Entities with the Legacy Converter (p. 963)
- Programmer’s Guide to Entities and Components (p. 973)
- Gameplay Bus (p. 1030)
- Reflecting Lumberyard Classes, Methods, and EBus Interfaces (p. 1032)

**Entity Outliner**

The **Entity Outliner** shows all the entities and slices in the level. You can view the parenting hierarchies, lock selections, show and hide entities in the viewport, and create search filters.
To open the Entity Outliner

1. In Lumberyard Editor, choose Tools, Entity Outliner.
2. In the Entity Outliner, you can create, select, search, and filter for entities.

You can select multiple entities by doing one of the following in the Entity Outliner:

- Use CTRL + Left Mouse Click to select multiple entities one at a time to be part of a multi-selection.
- Use Shift + Left Mouse Click to select a range of entities.

**Note**

- Entities in white are freestanding entities.
- Entities in blue are part of a slice. For more information, see the slice icons (p. 511).

**Working with Entities**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

**Topics**

- Creating an Entity (p. 463)
- Reordering Entities (p. 464)
- Hiding and Showing Entities (p. 465)
- Locking Entities (p. 465)
- Search and Filter for Entities (p. 466)

**Creating an Entity**

Entities are objects with which the player interacts.

To create an entity
Do one of the following:

- In the Lumberyard Editor viewport, right-click and choose Create entity. This creates an entity at the cursor location with a basic Transform (p. 878) component, which gives the entity a 3D location in the level.
- In the Entity Outliner (p. 462), right-click and choose Create entity. This creates an entity in the center of your viewport.
- Use the Asset Browser (p. 296) to create entities that already have the preferred configuration, depending on the particular asset.

For example, if you drag a .cgf mesh asset from the Asset Browser into the viewport, Lumberyard creates an entity, adds a Mesh (p. 684) component, and assigns the asset to the Mesh component. The same is possible for particles, slices, and Lua scripts.

To assign entities to a parent entity

1. In the viewport or the Entity Outliner, right-click and then choose Create entity. This creates an empty entity, which will be the parent entity.
2. Do one of the following:
   - In the Entity Outliner, select and drag the child entities on top of the new parent entity.
   - Select one or more entities that are to be the child entities. In the Entity Inspector, for the Transform component, beside the Parent Entity property, click the picker icon and then select the parent entity in the viewport.
   - Select one or more entities that are to be the child entities. From the Entity Outliner, drag the parent entity into the Entity Inspector and drop it beneath the Transform component into the Parent Entity property.

Reordering Entities

When you create entities or instantiate slices, they appear at the bottom of the list in the Entity Outliner.

To reorder entities in the Entity Outliner

1. To move an entity, right-click an entity and choose Move up or Move down.
2. You can also drag and drop one or more entities into the preferred order. Select and drag the entity until a white line appears in your preferred location.

3. To make an entity the child of another entity, select and drag the entity to its intended parent. A white box appears around the parent entity.

Hiding and Showing Entities

You can hide entities so that they don't appear in the viewport, so that the viewport shows only the entities that you want. If you hide a parent entity, all children entities are also hidden. You can also hide child entities within a parent entity.

To hide and show entities

1. In the Entity Outliner, click the eye icon next to the entity. The crossed-out eye icon indicates that the entity doesn't appear in the viewport.
2. To show the entity, click the icon again.

Locking Entities

You can lock entities so that they can't be selected in the viewport, so that you can select only the entities that you want to edit. If you lock a parent entity, all children entities are also locked. You can also lock child entities within a parent entity.
To lock entities

1. In the Entity Outliner, click the lock icon next to the entity. The icon appears white when the entity is locked.

2. To unlock the entity, click the lock icon again.

Search and Filter for Entities

For levels that have many entities, you can search and filter for the entities that you want. Enter text in the search filter box to find specific entities.

To search for an entity by name

1. In the Entity Outliner, enter the name for the entity.
2. To filter by component, click the filter icon.
3. Enter component names in the search field that appears or scroll and select the entities that you want. Any entity that has the specified component appears in the results.

Example

The entities that appear have either the Camera or the Trigger Area components attached.
4. To clear search results, click **Clear**.

**To search for an entity by ID**

- In the **Entity Outliner**, enter the complete ID for the entity. Partial matches and wildcard searches are not supported.

You can also sort entities so that they appear in the order that you want in the **Entity Outliner**.

**To sort entities**

1. In the **Entity Outliner**, click the sort icon.

2. Choose the following options:
   - **Sort: Manually** – Manually organize entities. See Reordering Entities (p. 464).
   - **Sort: A to Z** – Sort entities alphabetically, in ascending order.
   - **Sort: Z to A** – Sort entities, in descending order.
   - **Scroll to Selected** – When you select an entity in the viewport, the **Entity Outliner** scrolls to that entity. If you select multiple entities, the **Entity Outliner** scrolls to the last selected entity.
Working with Entities

- **Expand to Selected** – When you select an entity in the viewport, the **Entity Outliner** expands the hierarchy to show any child entities.

You can also select an entity in the **Entity Outliner** to find it in the viewport or in reverse. This feature helps you find the entities that you want, especially in large levels.

**To locate an entity or slice**

1. In the **Entity Outliner**, right-click an entity and choose **Find in viewport**. The viewport navigates to the corresponding entity.

2. In the **Entity Outliner**, right-click the slice or slice entity and choose **Find slice in Asset Browser**. The **Asset Browser** navigates to the corresponding slice.
3. In the viewport, right-click a slice or entity and choose **Find in Entity Outliner**. The **Entity Outliner** navigates to the corresponding item.

![Entity Outliner menu](image)

**Working with Layers**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/beta/3d-engine/) or visit the [AWS Game Tech blog](https://aws.amazon.com/beta/3d-engine/blog/) to learn more.

Use the Lumberyard layer system to organize level data into discrete files. The layer system segments level content so that members of a development team can work on different aspects of a level asynchronously.

Layers are standard Lumberyard entities with a special editor-only layer component. In your game, this component appears as an empty entity in your hierarchy. When you export your game, the behavior you designed is unchanged and all entities in your level are added to the exported data.

**Topics**

- Creating a Layer (p. 470)
- Modifying a Layer (p. 471)
- Adding Entities to a Layer (p. 473)
- Saving a Layer (p. 473)
- Recovering a Layer (p. 474)
- Layer-Specific Components (p. 474)
Creating a Layer

When you create a layer, you can add entities to that layer. This helps you organize the content in your game. For example, you might create a layer for all character entities and another layer for vegetation.

To create a layer

1. In Lumberyard Editor, choose Tools, Entity Outliner.
2. In the Entity Outliner, right-click and choose Create layer.
3. With the layer selected in the Entity Outliner, you can modify its properties in the Entity Inspector.

<table>
<thead>
<tr>
<th>Layer Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Layer name.</td>
</tr>
<tr>
<td></td>
<td><strong>Warning</strong> If you rename a layer, this creates a new layer the next time you save your level.</td>
</tr>
<tr>
<td>Status</td>
<td>You can set the following options:</td>
</tr>
</tbody>
</table>
## Working with Layers

### Layer Properties

<table>
<thead>
<tr>
<th>Layer Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Start active – Layer is active when the level starts.</td>
<td></td>
</tr>
<tr>
<td>• Start inactive – Layer is inactive when the level starts. Overrides the status property of the entities contained in the layer.</td>
<td></td>
</tr>
<tr>
<td>• Editor only – Layer is only active in editor mode. However, entities within that layer that are not marked Editor only will still appear in the game.</td>
<td></td>
</tr>
</tbody>
</table>

### Color

Specifies the display color of the layer. Use the color picker or manually type in the color value field. This is the line color used to show the layer container in the Entity Outliner.

Default: gray

### Save as binary

Saves the layer in binary format. Binary assets, which are not human readable, serialize faster and are smaller on disk.

---

**Modifying a Layer**

After you create a layer, you can modify it by adding entities, reorganizing its hierarchy, adding nested layers, renaming the layer, and so on.

**To show a layer's context menu**

1. In the Entity Outliner, right-click the layer.
2. You can do the following in the context menu.

   Actions highlighted in yellow affect the selected layer. The other options are standard context menu actions that don't affect the selected layer.
The following options in the context menu perform actions on the selected layer.

<table>
<thead>
<tr>
<th>Layer Context Menu</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create child entity</td>
<td>Adds an entity to the layer as a direct descendant.</td>
</tr>
<tr>
<td>Save layer</td>
<td>Saves the selected layer.</td>
</tr>
<tr>
<td>Assign to layer</td>
<td>Moves the selection and makes it a child of a new or chosen layer.</td>
</tr>
<tr>
<td>Duplicate</td>
<td>Makes a copy of the layer and its contents.</td>
</tr>
<tr>
<td>Delete</td>
<td>Removes the layer (and contents) from the scene.</td>
</tr>
<tr>
<td>Open pinned Inspector</td>
<td>Opens a copy of the Entity Inspector that is locked to the properties of the layer.</td>
</tr>
<tr>
<td>Rename</td>
<td>Renames the layer.</td>
</tr>
<tr>
<td>Move up and Move down</td>
<td>Moves the selected layer up or down one entry.</td>
</tr>
<tr>
<td>Find in viewport</td>
<td>Frames the viewport camera to see the contents of the layer.</td>
</tr>
</tbody>
</table>

**Layer Hierarchies**

You can nest layers within other layers. This is useful if you want to organize the entities in your level. This behavior is similar to creating hierarchies for parent and child entities.
Note
You can't make a layer a child of a non-layer entity and you can't save a layer in a slice.

You can nest layers to break up your level into smaller, more workable sections. If you are creating a large level, for example, you might have a single vegetation layer. If you have just one vegetation layer, then only one environment artist could edit this layer at a time. To allow multiple artists to work on the vegetation layer at once, you can nest other layers within the vegetation layer and assign each nested layer to different artists. This helps build a well-organized hierarchy to keep the game's structure efficient.

Adding Entities to a Layer

Layers can contain freestanding (non-slice) entities and slices.

To add an entity to a layer

- In the Entity Outliner, do one of the following:
  - Select and drag an entity to a layer or within the layer hierarchy.
  - Right-click an entity, pause on Assign to layer, and then select a layer.

Saving a Layer

The component entity system saves references to layers and their hierarchies in the level data. When you add or remove a layer from your level, you must save your level before making more changes. If you don't save your level, layers and their contents will not load correctly the next time you open the level.

Lumberyard layers are saved as .layer files in the level_name/layers directory. The layer's filename is saved as layer_name.layer. If a layer is nested within another layer, then the parent layer name is prepended to the layer filename.

When a layer contains unsaved changes, an asterisk (*) appears next to the layer name. After you save the level or the layer, the asterisk is removed.

Layer names at the same hierarchy level must be unique. Layers at the same hierarchy level with duplicate names display a warning (!) and can't be saved until you rename them.
To save your level and all layers
- In Lumberyard Editor, choose File, Save or press Ctrl+S.

To save specific layers only
1. Select the layer you want to save, or press CTRL and then select multiple layers.
2. In the Entity Outliner, right-click the selection and choose Save.

Recovering a Layer
If you delete a layer from a level in Lumberyard Editor, you can reimport it.

To reimport a deleted layer
1. Using a file browser, copy onto your desktop the layer file for the layer that you want to recover, such as level_name\layer\layer_name.layer.
2. In Lumberyard Editor, create a new layer in your level and enter the same name as the deleted layer.
3. Save the level and close Lumberyard Editor.
4. Copy the layer file from your desktop into Lumberyard's layer directory, such as level_name\layers.
5. Rename the copied layer file to match and replace the layer that you created in Lumberyard Editor.
6. Reopen the level. The newly created layer now references the recovered layer information.

Layer-Specific Components
A layer is simply an entity with special rules. As such, you can add layer-specific components to layers. By default, Lumberyard doesn't contain any layer-specific components, but you can create your own, such as special layer components for streaming or tags.

Any given component can appear in only one context menu. By default, Lumberyard has the Game, System, and Layer contexts for components.

You can test creating a layer-specific component by editing the Comment component.

To modify the Comment component
1. In a text editor, open the EditorCommentComponent.cpp file.
2. Change the AZ_CRC attribute to Layer and delete the CRC value.
3. Save the file.
4. In Lumberyard Editor, add the Comment component to a layer.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **Entity Inspector** manages all the components for each entity. Select an entity in the **Entity Outliner** or the viewport to see the attached components in the **Entity Inspector**.

**To open the Entity Inspector**

1. In Lumberyard Editor, choose **Tools, Entity Inspector**.
2. Select an entity in the viewport or the **Entity Outliner**.
3. In the **Entity Inspector**, you can see the following:
   - **Name** – Name of the entity. You can enter a different name for the entity.
   - **Entity Icon** – Customizable icon to help you recognize entities in the viewport.
   - **Status** – Active status of the entity. When the level starts, the entity can be active, inactive, or active but only in editor mode.
   - **Entity ID** – If this entity ID is called out in messages, errors, or asserts, you can find the entity by searching for it in the **Entity Outliner**.
   - Components attached to the entity appear below.

Use the **Entity Inspector** to do the following:

- Add components to entities (p. 479)
- Modify component properties (p. 481)
- Remove, copy, cut, and paste components (p. 480)
- Set the entity status (p. 476)
- Customize the entity icon (p. 477)
- Pin an entity's inspector (p. 478)
- Create your own help topic for your custom component (p. 482)
Note
For a list and descriptions of available components, see Component Reference (p. 532). You can also click the Help icon in the header of each component to open a help topic.

Setting an Entity Status

By default, an entity starts as active in a level. When you create a game, you can specify that an entity remain inactive until activated through some mechanism such as a script or player action. You can also set an entity as editor only if you want to disable an entity during gameplay mode or you want to create test entities or visual comments for users working in your game.

To set an entity’s status

1. In the Entity Outliner or the viewport, select an entity.
2. In the Entity Inspector, choose the Status drop-down menu, and select one of the following options:
   - Start active – Entity is active when the level starts.
   - Start inactive – Entity is inactive when the level starts.
   - Editor only – Entity is only active in editor mode.
3. When you set an entity as Start Inactive or Editor only, select the entity to view its status in the Entity Outliner and the viewport.

Example Start Inactive

Inactive entities have a strikethrough icon and inactive text appears in the viewport.
Customizing the Entity Icon

The default icon for an entity without any added components is the Transform ( ▶️ ) component's icon. When you add another component, the icon changes to the first component that you add to that entity.

You can also specify your own icon.

To customize an entity icon

1. In the Entity Inspector, click the icon image at the top.
2. Choose Set custom icon.
3. Select an icon from your game project directory.
Pinning an Entity's Inspector

You can pin an entity's inspector to keep it open and visible even when you select another entity. You can pin inspectors for multiple entities, and also pin multiple inspector instances of the same entity. This helps you compare the entities and their components to each other.

A pinned inspector has the following features:

- Always shows the pinned entity even when you select a different entity.
- Functions like the main Entity Inspector window.
- Closes when you open a different level or exit Lumberyard.
- If you convert a loose entity to a slice, the pinned inspector points to the new slice entity that corresponds to the previously loose entity.
- Persists when entering and exiting game mode.
- Updates all pinned inspectors for a particular entity when you modify that entity.

You can pin an inspector from the Entity Outliner or the Entity Inspector.

To pin an inspector

1. Select an entity.
2. Do one of the following:
   a. In the Entity Outliner, right-click the entity and then choose Open pinned Inspector.
   b. In the Entity Inspector, click the pin icon.
3. In Lumberyard Editor, you can view the pinned entity inspectors.

**Example**

[Image of pinned entity inspectors]

---

**Working with Components**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the component entity system tools to create entities and add components to them. Before you can work with components, you must create an entity (p. 463).

**Topics**

- Adding Components to an Entity (p. 479)
- Managing Components (p. 480)
- Editing Component Properties (p. 481)
- Disabling and Enabling Components on Entities (p. 482)
- Editing Components in the Viewport (p. 483)
- Using Manipulators (p. 490)
- Working with the Viewport Interaction Model (p. 494)

**Adding Components to an Entity**

After you create an entity, you can add components to it.
Managing Components

To add a component to an entity

1. In the Entity Inspector, click Add Component or right-click and choose Add Component.
2. Components are grouped by category, such as Animation, Camera, and Gameplay. To find a specific component quickly, enter the name into the search bar at the top of the component list.
   
   **Note**
   You can pause on the component name to see a description of that component.
3. Select the component.
4. Specify your settings for the component.
5. If you add a component that requires another component to function, the Entity Inspector displays the following message.

   For example, the Ragdoll component also requires the Skinned Mesh component. Click Add Required Component and select the required component.

   **Note**
   Components must have the required dependencies to appear in game mode. The Entity Inspector displays a warning message for the following scenarios:
   
   - Incompatibilities exist between components
   - A component is missing a required component
   - A component is a duplicate

   You must resolve the issue before you can use the component for the entity. Otherwise, the component is disabled.

Managing Components

You can also use the context menu in the Entity Inspector to remove, copy, and reorder components.

To manage components from the context menu

1. In the Entity Outliner or in the viewport, select the entity.
2. In the Entity Inspector (p. 475), right-click the component, or click the menu button in the header, and then select one of the following:
   
   - **Add component** – Add a component to the entity
   - **Delete component** – Remove a component from an entity
   - **Cut component** – Cut a component from one entity and paste it onto a different entity
   - **Copy component** – Copy a component and then paste it onto the same entity, which creates a duplicate component that you can customize
   - **Paste component** – Copy a component and then paste it onto a different entity
   - **Enable component** – Make a component available
   - **Disable component** – Make a component unavailable
• **Move component up** – Move a component up the list
• **Move component down** – Move a component down the list
• **Move component to top** – Move a component to the top of the list
• **Move component to bottom** – Move component to the bottom of the list

You can also click and drag individual components into a desired order. Organize the components for an entity in any order that makes sense to you. The custom order for your components is saved to the level. The component order has no significance to its function.

**Note**
- The Transform (p. 878) component is automatically added to an entity and can't be moved from the component list.
- Some actions are disabled, depending on the context. For example, you can't paste a component if you haven't copied one.

## Editing Component Properties

You can edit properties for your components such as changing the mesh asset file for the Mesh component.

**To edit component properties**

1. In the **Entity Outliner** or the viewport, select the entity.
2. In the **Entity Inspector**, select the component and edit its properties.
3. To undo a change that you made to a property, press Ctrl+Z. To redo the change, press Ctrl+Shift+Z.
4. To edit multiple entities at the same time, select the entities that you want and make your changes. The changes that you make to the first entity propagate to all selected entities.

**Note**
- If your entity is part of a slice instance, any properties that you modify from the source slice asset appear in orange in the **Entity Inspector**.
- To save a change to a slice, see Modifying a Slice and Saving Changes (p. 519)
- To revert an override, see Reverting and Forcing Overrides (p. 522)

For more information about slices, see Working with Slices (p. 510).

## Copying and Pasting Asset References

In the **Entity Inspector**, you can copy an asset reference from one component and paste it into another component. You can copy assets as scripts, mesh assets, particle effect libraries, cubemap assets, and so on.

**To copy and paste an asset reference**

1. In the **Entity Inspector**, select the component and right-click the asset reference field.
2. Choose **Copy asset reference**.
3. Select another component, right-click the asset reference field, and choose **Paste asset reference**.
Creating Custom Component Help Topics

If you have created your own components, you can point the component header's help icon to your own documentation.

To do this, add the `HelpPageURL` attribute to your component reflection.

For example:

```csharp
Attribute(AZ::Edit::Attributes::HelpPageURL, "https://docs.aws.amazon.com/lumberyard/latest/userguide/component-comment.html")
```

Disabling and Enabling Components on Entities

After you add components to entities, you can choose to disable and enable them as needed. This can help you see how different components interact with the entity. For example, if you create an entity and add the `Area Light`, `Environment Probe`, and `Point Light` components to it, you can see how the different light components interact with the entity.

You can disable the components that you don't want and reenable them later. Disabled components are read only and don't activate, generate warnings, or export with game data.

**To disable and enable components**

1. In the **Entity Outliner**, select the entity that you want.
2. In the **Entity Inspector**, under **Add Component**, right-click the component that is associated with the entity.
3. Choose **Disable component** to disable the component.
Disabled components are dimmed with stripes.

4. To reenable a disabled component, right-click the component and choose **Enable component**.

**Editing Components in the Viewport**

This feature is in **preview** release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

When you're working with components, you can lock a single component for editing. You can't edit any other components that are attached to the entity. This feature prevents you from accidentally editing other components that are attached to the entity. For example, if you have an entity with attached
Spline and Mesh components, you can lock the Spline component, make your changes to the spline, and stop editing.

This feature supports the following components:

- Box Shape (p. 818)
- OccluderArea (p. 701)
- Portal (p. 717)
- Polygon Prism Shape (p. 708)
- Spline (p. 866)
- Tube Shape (p. 894)
- VisArea (p. 918)

Topics

- Editing a Single Component in the Viewport (p. 484)
- Editing Multiple Components in the Viewport (p. 487)

If you want to add this feature to other components, you must make code changes to Lumberyard Editor. For more information, see the Programmer's Guide to Component Mode (p. 992).

Editing a Single Component in the Viewport

For components that support this feature, the component is locked when you edit its properties in the viewport.

To edit a single component in Component Mode

1. In Lumberyard Editor, create an entity. See Creating an Entity (p. 463).
2. In the Entity Inspector, choose Add Component and select the Spline component.

Example

An entity with the Spline component appears in the viewport.
3. In the viewport, double-click the spline or, in the Entity Inspector, click Edit.

**Example**

The manipulator appears in the viewport. The vertices turn red. When you select a vertex, the manipulator appears.
All other components attached to the entity are dimmed in the **Entity Inspector**, and you can't edit them.

4. Select a vertex and make changes such as adding, moving, or deleting vertices.
5. When you've finished, press **Esc** or, in the **Entity Inspector**, on the component, click **Done**.

The vertices become yellow again.

**Editing Multiple Components in the Viewport**

In some cases, Component Mode supports editing multiple components. This is useful when you want to lock a specific component type for editing. Component Mode supports this feature in the following cases:
• An entity has dependent components, such as the **Tube Shape** and **Spline** components
• You select multiple entities that all have the same component that supports Component Mode (such as a **Box Shape**)

**To edit multiple components in Component Mode**

1. In Lumberyard Editor, create an entity. See *Creating an Entity* (p. 463).
2. In the **Entity Inspector**, choose **Add Component** and then select components that have this feature. See *supported components* (p. 484).

1. In the **Entity Inspector**, choose **Edit**. You can't edit the **Transform** component, but the **Spline** and **Tube Shape** components are active.
2. Make your changes to the component.
3. To switch between components, do one of the following:
   • Select the entity and press **Tab**. The **Entity Inspector** highlights the selected component.
   • In the Lumberyard Editor toolbar menu, choose **Edit** and choose **Edit Next** or **Edit Previous**.

**Example**

The **Transform** component is dimmed, but you can edit the **Spline** and **Tube Shape** components.
In the following example, a radius for the Tube Shape is selected.
Note

The Lumberyard Editor Edit menu shows the available actions for the selected component. You can specify different shortcuts except for the Save, Undo, and Redo actions.

Example

For example, if you select a vertex point for a Tube Shape component, the Edit menu shows the available shortcuts.

Using Manipulators

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
With manipulators, you can edit certain component properties directly in the viewport instead of the component's property window. Manipulators help you visualize and achieve the results that you want for your components. For example, you can add, move, and delete vertices on a Spline (p. 866) component to create the exact curvature that you want for your level.

By default, some components support manipulators. When you author new components, you can also manually add manipulator support. For more information, see Editing Components in the Viewport (p. 483).

Topics
- General Case Manipulators (p. 491)
- Special Case Manipulators (p. 491)
- Advanced Use Case Manipulators (p. 491)
- Manipulator Appearance (p. 492)
- Creating New Manipulators (p. 492)
- EBus Request Bus Interface (p. 493)

General Case Manipulators

The following are general case manipulators.

**Linear Manipulator**
- Moves the position of an object along one axis.

**Planar Manipulator**
- Moves the position of an object along a plane, which is two axes, such as XY, YZ, or XZ.

**Surface Manipulator**
- Moves the position of the object over the terrain.

**Translation Manipulator**
- Aggregate manipulator that combines multiple linear and planar manipulators (depending on which axes are defined) and an optional surface manipulator.

**Selection Manipulator**
- Performs no movement but provides an interface to detect when part of a component has been clicked.

Special Case Manipulators

The following special case manipulators appear only on applicable components.

**Line Segment Selection Manipulator**
- Determines the location on a line segment over which the mouse is hovering to insert a new point.

**Spline Selection Manipulator**
- Determines the location on a spline over which the mouse is hovering to insert a new point.

Advanced Use Case Manipulators

You can provide a streamlined editing experience by creating a system that manages manipulators across components with similar requirements.
For example, you can edit the vertex positions for the following components in the viewport.

- OccluderArea (p. 701)
- Polygon Prism Shape (p. 708)
- Portal (p. 717)
- Spline (p. 866)
- VisArea (p. 918)

EditorVertexSelection is an example of a component that encapsulates manipulator behavior that can be shared by multiple components – in this case, all components that require vertex editing.

The following core classes are related to EditorVertexSelection.

- HoverSelection (Spline and LineSegment variants)
- VertexContainerInterface
- VariableVertices
- FixedVertices (for when selection and editing of vertices is allowed, but vertices cannot be added or removed)
- Many other manipulators such as Translation, LineSegmentSelection, and SplineSelection.

**Manipulator Appearance**

A manipulator's visual appearance does not determine its behavior. This means that any manipulator can have any view. This is abstracted through the ManipulatorView class. Lumberyard provides a number of concrete views, such as Line, Cylinder, Cone, Box, Quad, and Billboard.

You can choose which view to use with a particular manipulator. All manipulators delegate their rendering to a ManipulatorView. The view also updates the bounds of the manipulator to handle interaction and picking. ManipulatorView provides several utility functions to make creating views easier. You can ignore these and create custom implementations if preferred.

**Creating New Manipulators**

To create a manipulator, you must derive from BaseManipulator. By doing so, you can observe how existing manipulators are implemented and follow a similar approach.

The following are key functions to implement:

- OnMouseDown
- OnMouseUp
- OnMouseOver
- Draw
- Invalidate
- SetBoundsDirty

To call the mouse functions, in the derived manipulator constructor, Attach must be called; for example, AttachLeftMouseDownImpl();.

The new manipulator should provide callbacks in the overridden mouse functions so that classes can handle their own unique use cases.
**Note**
Adding new manipulators is often unnecessary. The existing set provides most of the behavior that is required. For example, you can use the manipulator `LinearManipulators` in a variety of scenarios. This is recommended for most users.

**EBus Request Bus Interface**

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information, see [Working with the Event Bus (EBus) system](p. 1851).

**Manipulator Manager Requests**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>

</table>
Working with the Viewport Interaction Model

This feature is experimental and is missing some core functionality.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The new Viewport Interaction Model replaces the old interaction model in the viewport. This feature combines free and local selection so that you can more easily select, move, and modify entities in the viewport. With the Viewport Interaction Model, you can create custom reference spaces to move your entities. With custom reference spaces, you can move your selected entities in relation to the reference that you specified. The Viewport Interaction Model also unifies entity and component manipulators so that you can interact with entities and components in the same way. Gizmos are deprecated.

The Viewport Interaction Model provides the following benefits:

- Improves the ability to select your preferred entity, especially for nested hierarchies or levels that have many entities.
- Prevents you from accidentally deselecting an entity. The entity that you select is locked for editing.
- Adds keyboard and mouse actions that you can apply to your selected entities. For example, you can freely switch between local, parent, and world space to make changes to your selected entities.
- Establishes an editing pattern that matches the Component Mode feature. For more information, see Editing Components in the Viewport (p. 483).

See the following concepts for the Viewport Interaction Model:

**Manipulator**

With manipulators, you can edit component properties directly in the viewport instead of the Entity Inspector.

For more information, see Using Manipulators (p. 490).

**Custom Reference Target**

When you select an entity, you can specify whether to move that entity in relation to another entity.

**Viewport Interaction Model Limitations**

This feature has the following limitations:

- The Viewport Interaction Model supports component entities only and doesn't support legacy entities, such as terrain and vegetation.
- When you enable the Viewport Interaction Model, this feature removes some toolbar options in the Lumberyard Editor Interface (p. 183), such as vertex snapping.
- You can't change or customize shortcuts for the Viewport Interaction Model.
Enabling Viewport Interaction Model

By default, the Viewport Interaction Model isn't enabled for the editor. You can enable it from the Global Preferences window.

To enable the Viewport Interaction Model

1. In Lumberyard Editor, choose Edit, Editor Settings, Global Preferences to open the Preferences window.
2. Select Enable New Viewport Interaction Model (EXPERIMENTAL).
3. Restart Lumberyard Editor.
4. Open a level and, in the Asset Browser, select and drag two assets into the viewport.
5. In the viewport, select an entity. A manipulator appears on the entity. The entity is locked for editing. If you click another entity in the viewport, the first entity remains selected.

Use the following shortcuts on a selected entity.

<table>
<thead>
<tr>
<th>Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Press Space or Esc.</td>
<td>Deselects the entity. You can also double-click elsewhere in the viewport to deselect the entity.</td>
</tr>
<tr>
<td>Press and hold Ctrl, then click and drag the manipulator in the viewport.</td>
<td>Selects the manipulator so that you can move it in the viewport. This enables you to adjust the manipulator independent from the entity.</td>
</tr>
<tr>
<td>Press and hold Ctrl and Alt and click a target entity.</td>
<td>Moves the manipulator to the target entity that you clicked. The target entity becomes a reference space for manipulating the selected entity.</td>
</tr>
</tbody>
</table>

See Using Custom Reference Spaces (p. 498).

Modifying the Transform

When you move the manipulator to another location in the viewport, you can modify the scale, rotation, or translation of the entity. This feature makes it easier for you to manage your entities.

To modify the transform

1. In the viewport, select an entity. The manipulator appears.
2. Click and drag the manipulator to transform the selected entity.
3. Press and hold Ctrl, and click and drag the manipulator to another location.
4. Use the manipulator again to adjust the scale, rotation, or translation of the entity.

**Example**

In the following example, the manipulator is moved away from the car, switches to rotate mode, and rotates the car.

The following are shortcuts to switch between the different manipulator modes.

<table>
<thead>
<tr>
<th>Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Press 1.</td>
<td>Switches to translation mode.</td>
</tr>
<tr>
<td>Press 2.</td>
<td>Switches to rotate mode.</td>
</tr>
<tr>
<td>Press 3.</td>
<td>Switches to scale mode.</td>
</tr>
<tr>
<td>Press and hold Ctrl, then scroll the middle mouse button.</td>
<td>Switches between translation and rotation modes.</td>
</tr>
<tr>
<td>Press and hold Ctrl, move the mouse to a target location, then press the middle mouse button.</td>
<td>Moves the manipulator to the location that you specified in the viewport.</td>
</tr>
</tbody>
</table>

**Reference Space Model**

You can use the Viewport Interaction Model to create reference spaces for your selected entities. This enables you to customize your selected entities in relation to a reference space.

When working with reference spaces, remember the following rules:

- New selections always default to their parent space. This will be the world coordinate space if the entity does not have a parent.
- Holding Shift aligns the manipulator to the world coordinate space.
• Holding Alt aligns the manipulator to an entity's local coordinate space.
• You can easily access custom spaces by moving the manipulator (press Ctrl and click and drag) or picking a target entity as a reference space (press Ctrl and Alt and click a target entity).

The Viewport Interaction Model simplifies the mental mode for you and doesn't require you to keep track manually of the last space (local or world) that you were using. You can specify a target and define that target as custom reference spaces. This new reference space model covers any arbitrary transformation.

Switching Between Local and World Space

You can use the manipulator to switch between local and world space without losing focus of your entity selection in the viewport.

To switch between local and world space

1. In the viewport, select a child entity that has a parent. Your selection always defaults to parent space.
2. Use the manipulator to modify the entity.
3. To switch to world space, press and hold Shift. To switch to local space, press and hold Alt. Use the manipulator to modify the entity.

Note

• If you selected an entity that doesn't have a parent, your selection defaults to world space.
• Parent space is the transform that the parent entity has in the hierarchy. If an entity doesn't have a parent, the entity uses world space instead.

Example

In the following example, the entity moves in world space because the car does not have a parent. When you select the child entity (the tire), the manipulator switches to the parent space of that entity (the car).
The following are shortcuts to work with the reference space mode.

<table>
<thead>
<tr>
<th>Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select an entity or group of entities and press and hold <strong>Shift</strong>.</td>
<td>Switches the manipulator to world space.</td>
</tr>
<tr>
<td>Select a group of entities and press and hold <strong>Alt</strong>.</td>
<td>Switches the manipulator to local space.</td>
</tr>
<tr>
<td>Select an entity or group of entities and press <strong>R</strong>.</td>
<td>Resets the transform to the parent space.</td>
</tr>
<tr>
<td>Select a manipulator and press <strong>Ctrl + R</strong>.</td>
<td>Resets the manipulator back to parent space. This shortcut applies only if the manipulator transform has been modified. <strong>Note</strong> Currently, this shortcut doesn’t affect the manipulator in scale mode.</td>
</tr>
<tr>
<td>Select an entity or group of entities, press and hold <strong>Ctrl</strong> and <strong>Alt</strong>, and press the middle mouse button on a target entity.</td>
<td>Copies the <strong>Transform</strong> settings for the entity that you selected and applies them to a target entity. The <strong>Transform</strong> settings depend on the manipulator mode (translation, rotation, scale) that you’re in. For example, if you select an entity and the manipulator mode is rotation, this shortcut applies the rotation values to a target entity. This ensures that both entities (your selection and the target) have the same rotation.</td>
</tr>
<tr>
<td>Select an entity and press <strong>P</strong>.</td>
<td>Toggles pivot mode. For more information, see Using Pivot Mode (p. 508).</td>
</tr>
</tbody>
</table>

### Using Custom Reference Spaces

You can adjust the manipulator independent of the entity to create a custom reference space. You can also pick another target entity as a reference space. When you specify a reference space, the entities that you select move in relation to that space.

**To create a custom reference space**

1. In the viewport, select an entity.
2. Select a manipulator mode, such as translation.
3. Press and hold **Ctrl** and **Alt** and click a target entity in the viewport. This matches the manipulator to the translation or orientation of the target entity.

**Example**

In the following example, the excavator entity becomes a reference space for the car. When the manipulator moves the car, the car moves in relation to the reference space.
4. Use the manipulator to modify the entity.

The following are shortcuts for working with custom reference spaces.

<table>
<thead>
<tr>
<th>Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Press and hold Ctrl and drag the manipulator in the viewport.</td>
<td>Moves the manipulator to another reference point.</td>
</tr>
<tr>
<td>Press and hold Ctrl and Alt and click another entity.</td>
<td>Moves the manipulator to a target entity to use as a reference point for the selected entity.</td>
</tr>
</tbody>
</table>

**Note**
The manipulator and the custom reference space are context-based and apply only when you select an entity. If you don't select an entity, there's no manipulator, and you can't create a reference space. The reference space doesn't persist across selections. However, if you move the reference space, you can undo that action.

**Using Group Selections and Reference Spaces**

In the viewport, you can select multiple entities. This is called a group selection. You can use the following shortcuts for group selection.

<table>
<thead>
<tr>
<th>Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Click and drag in the viewport to create a box around entities.</td>
<td>Selects multiple entities.</td>
</tr>
<tr>
<td>Press and hold Ctrl and click and drag in the viewport.</td>
<td>Deselect multiple entities.</td>
</tr>
<tr>
<td>Press and hold Ctrl and click a target entity.</td>
<td>Adds or removes an entity from the selection. If you already selected a group of entities, this</td>
</tr>
</tbody>
</table>
When you select a group of entities, the Viewport Interaction Model follows the same model as selecting a single entity. For a group selection, the manipulator acts like a temporary parent entity. This means that the feature works the same for a single entity or a group of entities. By default, a manipulator defaults to the common parent of the group selection. If you select entities that don’t share a common parent, world space is used.

**To use group selections and reference spaces**

1. In the viewport, select multiple entities.
2. Press and hold Ctrl and click and drag the rotation manipulator.
3. Press Shift to change from custom to world space.
4. Use the manipulator to modify the entities.

**Example**

In the following example, three entities are selected. Because there is no common parent of the group, the manipulator defaults to world space. The entities now move in relation to the parent (the manipulator).

5. Press and hold Ctrl and Alt and click a target entity. This selects a reference space.
6. Use the manipulator to modify the entities.

**Example**

In the following example, a group of entities move in relation to the reference space.
7. Press and hold **Ctrl**, and move the manipulator in the viewport. This creates a custom reference space.

**Example**

In the following example, you can select a group of entities and move the manipulator in the viewport to create a custom reference space.

8. Select child entities of the same parent entity and use the manipulator to change them. When you select a group of entities that share the same parent, the manipulator defaults its orientation to the parent.
Example

In the following example, two child entities (the tires) are selected. The manipulator rotates the child entities in relation to its parent (the car).

9. Press and hold Alt while modifying a group of selected entities. This enables you to control changes to the entities in local space. You can quickly iterate and modify your entities and view the changes in the viewport.

Example

In the following example, you can press and hold Alt during translation. This moves each entity in their own local space.
10. Select child entities from different parent entities and press and hold Alt. You can modify multiple entities at the same time, even if they have different parents.

**Example**

In the following example, child entities from different parents are selected. The manipulator modifies the child entities at the same time.

11. Press and release Alt to dynamically change the reference space.

**Example**

In the following example, the manipulator changes the scale for the selected entities, switching from world to local space.
Resetting the Transform

You can reset the transform for an entity, so that you return the entity to its previous location.

**To reset the transform**

- In the viewport, select an entity or group of entities and press **R**.

Note that the effect of the reset depends on the current manipulator mode. For example, if you are in the translation mode, the translation is reset for the selected entity or entities.

The reset operation can be modified using the **Shift**, **Alt**, or **Ctrl** keys to perform different kinds of resets. Each of the reset operations can also be found in the *Edit* menu. See the following table for a description of each option.

<table>
<thead>
<tr>
<th>Reset Type</th>
<th>Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reset Entity Transform</td>
<td><strong>R</strong></td>
<td>Resets the transform to parent space.</td>
</tr>
<tr>
<td>Reset World Transform</td>
<td><strong>Shift + R</strong></td>
<td>Resets the transform to world space. This shortcut ignores hierarchy depth.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong> This has no effect in the translation or scale mode.</td>
</tr>
<tr>
<td>Reset Local Transform</td>
<td><strong>Alt + R</strong></td>
<td>Resets the transform to local space.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong> This has no effect in the translation mode.</td>
</tr>
<tr>
<td>Reset Manipulator</td>
<td><strong>Ctrl + R</strong></td>
<td>Resets the manipulator back to default parent space.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong> This shortcut doesn't reset the manipulator scale.</td>
</tr>
</tbody>
</table>

**Example**

In the following example, you can reset the transform as the entity transforms are changing and return them to their original transform.
Matching the Transform

Instead of manually copying values from one entity's position to another, you can use the ditto feature to share an entity's transform data from one entity to another. This feature enables you to duplicate the same transform data for your entities. For example, to make your child entities face the same direction, you can select the entities and use the ditto feature to apply the change to the entities at once.

To match a transform using the ditto feature

1. In the viewport, select an entity.
2. Press and hold Ctrl and press the middle mouse button on a target entity. After the target is selected, the current selection transform matches that of the target.

Example

In the following example, the ditto feature shares an entity's orientation with another entity. Both entities have the same value.
The following is a shortcut to use the ditto feature.

<table>
<thead>
<tr>
<th>Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select an entity or group of entities, press and hold Ctrl, and press the middle mouse button on a target entity.</td>
<td>Applies the transform from a target entity to a selection.</td>
</tr>
</tbody>
</table>

### Ditto a Group Selection

You can use the ditto feature for a group of entities. This makes it easier for you to modify multiple entities at once.

**To match the transform for a group of entities**

1. In the viewport, select a group of entities.
2. Press and hold Ctrl and press the middle mouse button to match an entity's transform data to the group manipulator.

**Example**

In the following example, you can select entities (a group selection of tires) and use the ditto feature to match a target entity (the car).
See the following shortcut to use the ditto feature.

<table>
<thead>
<tr>
<th>Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select a group of entities, press and hold Ctrl, and press the middle mouse button on a target entity.</td>
<td>Matches the translation, rotation, or scale for the group of entities to that of the target entity.</td>
</tr>
</tbody>
</table>

**Ditto a Group Selection to Local Space**

You can ditto a group of entities to local space so that you can modify entities in local space in relation to another entity.

**To ditto a group selection to local space**

1. In the viewport, select a group of entities.
2. Press and hold Ctrl and Alt and press the middle mouse button to select a target entity. This sets the local space of each entity in the selected group to the target entity that you specified.

**Example**

In the following example, select a group of entities and use the ditto feature to set them to the local space of the target entity.
See the following shortcut to use the ditto feature for a group selection.

<table>
<thead>
<tr>
<th>Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select an entity or group of entities, press and hold <strong>Ctrl</strong> and <strong>Alt</strong>, and press the middle mouse button on a target entity.</td>
<td>Sets the local space of each selected entity to the target entity that you specified.</td>
</tr>
</tbody>
</table>

### Using Pivot Mode

You can use pivot mode to use the default pivot or the entity's center as the manipulator point of reference. This feature is useful if you want to modify multiple entities using a central point of reference.

**Note**
Currently, this is a global toggle and doesn't support mixed use cases, such as using the center of an entity to snap it to the pivot of another entity.

**To use pivot mode**

1. In the viewport, select an entity or group of entities.
2. Press **P** to switch between the pivot and the entity's center.

**Example**

In the following example, the selected entities pivot around the manipulator.
Using the Camera Space

A camera space manipulator is built into the rotation manipulator. You can rotate entities based on the editor’s camera view.

**To use the camera space**

1. In the viewport, select an entity.
2. Adjust the camera around the selected entity in the viewport. You can use the following camera shortcuts to adjust your view.

**Adjusting the Camera View**

<table>
<thead>
<tr>
<th>Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hold right mouse button and move the mouse.</td>
<td>Enables you to look freely in the level.</td>
</tr>
<tr>
<td>Hold Alt + left mouse button and move the mouse.</td>
<td>Orbits the camera around a fixed point.</td>
</tr>
<tr>
<td>Do one of the following while moving the mouse in the viewport:</td>
<td>Dollies the camera to zoom in or out.</td>
</tr>
<tr>
<td>• Hold Alt + right mouse button.</td>
<td></td>
</tr>
<tr>
<td>• Hold middle mouse button + right mouse button.</td>
<td></td>
</tr>
<tr>
<td>Hold middle mouse button and move the mouse.</td>
<td>Pans the camera.</td>
</tr>
<tr>
<td>Hold Alt + middle mouse button and move the mouse.</td>
<td>Pans the camera inverted.</td>
</tr>
</tbody>
</table>
Moving the Camera

<table>
<thead>
<tr>
<th>Shortcut</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Press W, A, S, and D.</td>
<td>Moves the camera forward, left, back, and right.</td>
</tr>
<tr>
<td>Press Q and E.</td>
<td>Moves the camera down and up.</td>
</tr>
<tr>
<td>Press and hold Shift and press W, A, S, and D.</td>
<td>Quickly moves the camera in the specified direction.</td>
</tr>
</tbody>
</table>

Example

In the following example, you can adjust the camera space so that your selected entity remains the center of focus in the viewport.

Working with Slices

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A slice is a collection of configured entities (p. 462) that is stored as a single unit in a reusable asset. You can use slices to conveniently group entities and other slices for reuse. Slices are similar to prefabs but are part of the new component entity system. Slices can contain component entities, whereas prefabs cannot. Unlike prefabs, slices can be nested into a fully cascading hierarchy. For example, a level, a house, a car, and an entire world are all slices that depend on (cascade) from a number of other slices.

You can generate a slice asset that contains any number of entities that you have placed and configured. These entities can have arbitrary relationships. For example, they can exist in a parent/child transform hierarchy, although this is not required.
A slice can contain instances of other slices. Modifications of a slice instance within another slice causes the changes to be stored in the instance as overrides (in the form of a data differential or delta). The modifications stored can be changes such as entity additions, entity removals, or component property changes.

When you build a level, you place certain items repeatedly, such as a prop, furniture, or a piece of landscaping. To create multiples of an item, you could copy and paste it throughout your level. Doing this would result in each item having its own independent properties. If you wanted to change one property, such as making all the motorbikes blue instead of red, you would have to modify each one. This is time consuming and inefficient.

With Lumberyard's slices, you can modify one instance of the item and then save that change to all the other instances of your item within the game project. Saving changes to the other instances is not an automatic process. This means that you can modify a slice instance and then not save the changes. This makes that instance unique. You can also detach a slice instance so that it does not inherit saved modifications. That detached slice instance becomes a regular entity with individual properties.

Slices contain entities, including their components and properties, and may also contain instances of other slices. This ability to nest slices without flattening the hierarchy is a feature unique to Lumberyard.

Slices are saved as `.slice` files within your game project directory.

**Example**

In the **Entity Outliner**, you can identify different entities by their icon and color.

![Entity Outliner](image-url)
### Icon Description

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CrateWallParent</td>
<td>Entities that are white are standalone. They are not part of a slice instance.</td>
</tr>
<tr>
<td>gsg_maze_floodlight</td>
<td>Entities that are blue are part of a slice instance.</td>
</tr>
<tr>
<td>Maze_PickupObjective GraphicNeutralPos</td>
<td>Entities with lines indicate a hierarchy with a parent and child. In this example, the parent and child entities are part of a slice instance.</td>
</tr>
<tr>
<td>gsg_maze_doorway</td>
<td>Entities that are orange have overrides, which means they have different component property values than the source slice.</td>
</tr>
<tr>
<td>DoorWay_Parent</td>

### Topics

- Anatomy of a Slice (p. 514)
- Creating a Slice (p. 516)
- Instantiating a Slice (p. 517)
- Creating Nested Slices (p. 517)
- Modifying a Slice and Saving Changes (p. 519)
- Detaching Entities and Slice Instances (p. 522)
- Reverting and Forcing Overrides (p. 522)
- Slice Reloading (p. 524)
- Working with Dynamic Slices (p. 524)
- Slice Favorites (p. 526)
- Converting Slices with the Slice Upgrade Pipeline (p. 529)

The sections in this chapter use the following terminology to describe working with slices.

### Source Slice

The source slice is the `.slice` asset that is saved in the game project directory when you create a slice.
Owning Slice

Entities in a slice instance originate from an owning slice. For example, a tire entity from an instance of `wheel.slice` is owned by `wheel.slice`. Slices automatically pass down changes to any slice instance entities that they own. For example, say that you update the material reference on a tire entity that is owned by a `wheel.slice` instance. When you push that change to the source `wheel.slice`, Lumberyard updates all other tire entities of `wheel.slice`.

Entities can have more than one owning slice. To continue the example, `motorcycle.slice` owns two instances of `wheel.slice`. The tire entity within the two `wheel.slice` instances, which is within `motorcycle.slice`, inherits from both the wheel slice and the motorcycle slice.

Slice Instance

A slice instance is a distinct instantiation of a source slice. The slice instance inherits entities and properties from its source slice (the `.slice` file) and is updated when the source slice changes.

You can modify one slice instance. To apply those modifications to all instances of the source slice, you can save the changes to the source slice asset.

When you work with one instance of a slice, those changes are exclusive to that slice until you push the changes to the source slice.

Slice Entity

Entities that are owned by a slice are called slice entities. A slice entity inherits from its source slice. The Entity Outliner distinguishes slice entities from non-slice entities by color. Slice entities are blue, and non-slice entities are white.

Saving Slice Overrides

Saving slice overrides means to commit entity modifications from an instance to a source slice. When you use the `Save slice overrides` command, Lumberyard prompts you to choose which modifications or overrides to save. For a nested slice, you can also choose which slice in the hierarchy receives the overrides.

After you save overrides, Lumberyard automatically updates all instances of that slice. If any of those slice instances have unsaved overrides or modifications, it does not accept updates to those overrides. You can revert a slice’s entities and properties to resync to the source slice.

For more information, see Modifying a Slice and Saving Changes (p. 519).

Note

Lumberyard does not save the `Translate` value in the `Transform` component to the slice. This value determines an entity’s position in the level and as such is excluded from affecting other slice instances.

Overriding

Changing any part of a slice, such as adding a component or modifying a property, results in an override or modification. This means that the slice instance is different from the source slice. Overrides to component properties are marked in a bold orange font in the Entity Inspector to distinguish it from properties that haven’t changed.

If you save those overrides, they are saved to all the slice instances. This means they are no longer overrides and the font returns to normal.Overrides that you don’t save to the slice are maintained for that instance even when other changes are received from the source slice.

You can also force an override for a property that you haven’t yet modified, as well as revert overrides to an entity, component, or property.

For more information, see Reverting and Forcing Overrides (p. 522).
Detaching

You can detach an entity within a slice. This removes it from that slice instance, and that entity no longer receives updates when changes are saved to the source slice.

You can also detach any slice instance. This means that it no longer receives any changes saved to the slice.

For more information, see Detaching Entities and Slice Instances (p. 522).

Nesting

When a slice instance is nested, that means that it is a child of another slice instance.

If you push a nested slice instance to its parent's source slice, then the nested slice instance inherits from both its original source slice and any source slices that own its parents.

A nested slice instance shares a transform hierarchy with its parent. For more information, see Transform Hierarchy.

Inheriting

Slice instances inherit data from all source slices in their hierarchy. When a slice instance inherits from multiple source slices, inheritance priority occurs from top to bottom in the outliner hierarchy.

A slice instance can lose its inheritance. If you modify a slice instance and then don't save those changes to the source slice, that slice instance loses its inheritance. To restore the inheritance, you must either reset the slice instance or save the changes.

Transform Hierarchy

A transform hierarchy defines movement, rotation, and scaling of entities in both the editor and at runtime. A child entity shares the transform data of its parent. This means that you can move, rotate, or scale a parent, and its children always follow. You can, however, move, rotate, and scale a child independent of its parent.

Slice Hierarchy

A slice hierarchy defines a slice instance's relationship to its source slices. An entity inside of a nested slice can potentially inherit from multiple source slices. When this happens, slice data at the top of the slice hierarchy overrides slice data at the bottom of that hierarchy.

Data Patch

Generically speaking, a data patch captures the difference between two serializable objects, such that when you take the first object and apply the patch, you get the second object as a result. With respect to slices, when you edit an instance of a slice in the Editor and create an override, a data patch is generated and saved to a slice file. A data patch stored in a slice preserves the information needed to modify the source slice to create a slice with overrides. This may be as simple as changing a value in a field, or something more complex such as adding or removing components or entire entities.

Anatomy of a Slice

The following diagram illustrates an example slice A, which contains references to two other slices B and C. Slice A has two instances each of B and C:
Each instance contains a data patch, which may be empty if no changes or overrides are present. If the instantiation of slice B in slice A has been modified in comparison with the source asset B, the data patch contains the differences. When slice A is instantiated again, it contains instances of slice B, but with the modifications applied. Any nonoverridden fields propagate through the hierarchy. If you change a property value in the slice B asset on disk, the instance of B contained in slice A will reflect that change — if the property for that instance has not already been overridden, as reflected in the instance's data patch.

In addition to references to other slices, slices can contain zero or more entities. These entities are original to this slice and are not acquired through referenced slice instances. A slice does not have to contain references to other slices. A slice that contains only original entities (as represented by the bottom box in the diagram) and no references to other slices is called a *leaf slice*.

Slice files in a Lumberyard project have the extension "*.slice". They are stored in an XML format.

**Anatomy of a Slice Data Patch**

When a slice contains a reference to another slice, and an override is made to this reference, the difference between the two is captured in a data patch. The overrides can be simple, such as a change to a value in a field, or more complex, such as the addition or removal of entire components or entities. The format of the serialized data in a slice file depends on the version of Lumberyard.

**Readable XML Data Patch Format (v1.23+)**

Component names, data types, and version information are readily identifiable in this data patch format. There is no need to launch Lumberyard Editor to see this information. The following example shows that:

- This data patch is for the EditorCommentComponent.
Creating a Slice

A slice can contain any number of entities that have their own transform hierarchy. The slice, however, must have a single transform root. This means that you can change the size and position of child entities without affecting the parent entity. But if you change the size or position of the parent entity, the child entities automatically adjust as well.

To create a slice

1. In the viewport or in the Entity Outliner, select one or more entities to include in the slice.
2. In the viewport or the Entity Outliner choose Create slice.
3. Save the slice file to the preferred location. We recommend that you save slices to your game project folder. Name your slices meaningfully and organize them into directories and subdirectories.
**Note**

- If you want Lumberyard Editor to add a number to your slices by default (for example, `NewSlice001`), you can set this option in the General Settings. For more information, see General Settings (p. 239).
- To save multiple entities in a slice, they must have a single transform root. If they don't, then a Cannot Create Slice dialog box appears, giving you the opportunity to fix this issue by creating a root entity. Select Yes to create a root entity while creating the slice.

You also create a slice from another slice. This creates a new slice and that slice will no longer inherit from its previous source slice.

For example, if you have a slice instance named `car.slice` and you want to use that slice instance to create a new slice, you can create a detached slice named `bus.slice`. You will then have two separate slices that no longer inherit from each other.

**To create a slice from an existing slice and remove inheritance**

1. In the Entity Outliner, select and right-click the slice instance that you want.
2. Choose Create detached slice.
3. Enter a file name for the slice and then save.

### Instantiating a Slice

Loading an instance of a slice in your level is called instantiating a slice.

**To instantiate a slice**

- Do one of the following:
  - In the viewport, right-click and choose Instantiate slice. In the Pick Slice dialog box, select a slice, and then click OK.
  - Drag a slice asset from the Asset Browser (p. 296) into the viewport. The slice is instantiated at the drop location.

### Creating Nested Slices

A nested slice contains instances of other slices. Nested slices can store their own overrides for component and entity properties. They can also contain their own entities.

For example, suppose that you have a slice called `wheel.slice`, composed of one wheel. You have another slice called `motorcycle_body.slice`, composed of an engine, seat, and frame. You create a new slice called `motorcycle.slice` and add two instances of the wheel slice and one instance of...
the motorcycle body slice, and then save the changes. The body and wheel slices are now nested in the motorcycle slice.

**To create a nested slice**

1. In the **Entity Outliner**, drag one or more slices onto another slice. The slices become child entities of the slice you dropped them on.
2. Right-click the parent entity and choose **Create slice**.
3. The **Create Slice** dialog box will appear giving you a choice of creating a fresh slice or a nested slice. Choose **Nested Slice**.

![Create Slice dialog box](image)

4. Enter a file name for the slice and then save.

When you create a slice hierarchy, you can select the root slice for that slice. This is useful if you have a large slice hierarchy and you want to quickly navigate between the slice instances.

**To move up or down the slice hierarchy**

1. In the **Entity Outliner**, right-click a child entity in the slice hierarchy and choose **Select slice root**.
2. In the dialog menu, view the slice hierarchy for the selected slice.
3. Choose a slice to select that slice in the **Entity Outliner**.

**Note**

- To select the top slice in the hierarchy, select a slice and press **Shift+R**.
- To select the next parent slice up, press **R**.

**Modifying a Slice and Saving Changes**

If you modify an entity that is part of a slice instance, you create an override for that change. An override means that the slice instance has different component properties than its source slice. You can verify that a slice has overrides with the following:

- In the **Entity Inspector**, the components and the properties that differ from the source slice appear orange. For more information, see **Entity Inspector** (p. 475).
- In the **Entity Outliner**, the entity appears orange and has a dot if a child slice has an override. For more information, see the **Entity Outliner table** (p. 511).

**Example**

In the **Entity Inspector**, for this slice instance, the **Mesh asset** property is different from its source slice, so the component and the property name appears orange.
In the **Entity Outliner**, the slice instances with overrides appear orange.

You can then choose to save that override to all other slice instances.

**To save a slice override**

1. In the viewport or the **Entity Outliner**, right-click the entity, choose **Save slice overrides**, and then select the slice. This saves the override to all other slice instances. The number of changes appears next to the slice.

   **Note**
   You can also right-click the component property in the **Entity Inspector** and choose **Save field override**.

**Example**

This shows a slice instance with eight total changes: one removal and seven updates.

2. To save multiple slice overrides, in the **Entity Outliner** or the viewport, select your entities, right-click and then choose **Save slice overrides, Save slice overrides (Advanced)**.
3. In Save Slice Overrides – Advanced dialog box, for Property, select the changes that you want and then select the target slices to which you want to save the overrides. You can also select or deselect the following check boxes.

- **Changed** – Overrides to existing entities.
- **Added** – Added entities.
- **Removed** – Deleted entities.

4. When finished, choose **Save Selected Overrides**.

**Note**

- To quickly save changes to a selected slice, select the slice and press **Alt+S**.
- Because slices can be nested, you can save modifications to one or more levels of the nested slice hierarchy. To save changes to the top slice root in the hierarchy, select the root slice and press **Ctrl+Alt+S**.
Detaching Entities and Slice Instances

You can detach entities within a slice or detach the entire slice instance.

- When you detach an entity, that entity no longer inherits any changes from its source slice. Use this feature so that the entity becomes a standalone entity.
- When you detach a slice instance, the entities in the slice instance hierarchy no longer inherit changes from the former source slice. Use this feature if you want this slice instance (and all its child slices) to become standalone entities.
- This option appears only when you are managing slice hierarchies for a slice instance.

To detach specific entities within a slice instance

1. In the Entity Outliner, select one or more entities within a slice instance.
2. Right-click the selection and choose Detach, Selection.

   A dialog box appears that tells you that the entity will be converted into a non-slice entity and that the action cannot be undone.
3. Choose Detach. The selected entities are now standalone.

You can also detach the entire slice instance so that all entities in the instance are standalone.

To detach a slice instance

1. In the Entity Outliner, select any part of a slice.
2. Right-click the selection and choose Detach, Instance.

   A dialog box appears that tells you that the detached instance will no longer inherit any changes from its slice and that all entities in the slice instance will be converted into non-slice entities.
3. Choose Detach. All entities are now standalone.

Reverting and Forcing Overrides

When you change any part of a slice instance, such as adding a component, removing a component, or modifying a component property, you create an override. Overrides to component properties are highlighted with bold orange text in the Entity Inspector. You can revert the override to remove the override in order to resume inheriting from the source slice.
To revert property overrides

1. In the Entity Inspector, right-click the property, component, or entity that you modified.
2. Choose Revert overrides and choose one of the following:
   - **Property** – Revert changes to the property that you selected.
   - **Component** – Revert all changes to the component that you selected.
   - **Entity** – Revert all changes to the entity that you selected, such as added or removed components or changed properties.

Note

- In the Entity Inspector, reverting overrides to a parent entity doesn’t revert overrides to its children. This only affects changes that you made directly to the parent entity.
- If you revert overrides to the parent entity in Entity Outliner, this change also reverts overrides to its children.

Forcing a Property Override

Unmodified properties inherit changes made to the source slice. If you don’t want a property to inherit changes from the source slice, you can create an override to the property.

To force a property override

1. In the Entity Inspector, right-click an unchanged component property.
2. Choose Force property override.
The property override appears orange to indicate that it no longer inherits modifications from the slice.

### Slice Reloading

Slices support runtime reloading. If a slice has changed for any reason—such as a data push operation, retrieval from source control, or manual edit—Lumberyard Editor reloads the slice asset. Lumberyard Editor also recalculates any slice instances that were affected by the change.

### Working with Dynamic Slices

Slices are a powerful tool for organizing entity data in your worlds. In the editor, you can choose to cascade slices and organize entity data in any desired granularity and still receive the benefits of data sharing and inheritance throughout the hierarchy. A level-based game, for example, implements each level as its own slice asset that contains instances of many other slices. These slices can potentially cascade many levels deep. You can choose to create slices from other slices and inherit only the elements that you want.

Standard slice assets (.slice files) rely on the editor and cannot be instantiated at run time. However, Lumberyard provides a mechanism for designating any .slice asset that you've built as a dynamic slice. When you designate a slice as a dynamic slice, the Asset Processor processes and optimizes the slice for you, producing a .dynamicslice file asset. A dynamic slice is simply the runtime version of its source slice, containing only runtime components. The editor-dependent components have been converted to their runtime counterparts. Furthermore, dynamic slices no longer maintain a data hierarchy because doing so would increase memory footprint and reduce instantiation performance.

In the level-based game example previously mentioned, you could designate your giant level slice as a dynamic slice. When your game loads the level, it does so by instantiating the resulting .dynamicslice file.

You can choose to generate dynamic slices at whatever granularity is appropriate for your game. Because slices are loaded entirely asynchronously, they are a good choice for streaming strategies. For example, a
driving game might represent each city block as a separate slice and choose to load the slices predictively based on player driving behavior.

To create a dynamic slice

1. In the Asset Browser, right-click a .slice asset and choose Set Dynamic Slice.

2. Asset Processor processes the source .slice file and generates a .dynamicslice file. In the Asset Browser, you can see the .dynamicslice file appears as its own asset.

To remove a dynamic slice

- In the Asset Browser, right-click the dynamic file and choose Unset Dynamic Slice.

Asset Processor deletes the .dynamicslice file from the asset cache.

Instantiating Dynamic Slices

You can use the Spawner (p. 859) component to instantiate dynamic slices.

To instantiate dynamic slices

1. In the Asset Browser, select and then drag the .dynamicslice asset to the Slice property for the Spawner component.
2. To instantiate the dynamic slice when the level starts, select Spawn On Activate.
3. To instantiate the dynamic slice at a different time, you can use scripting or C++. The following Lua snippet uses an EBus call to tell the Spawner component to instantiate its dynamic slice:
SpawnerComponentRequestBus.Event.Spawn(self.entityId)

For more information about working with slices, see Working with Slices (p. 510).

Additional Links

- Amazon Lumberyard Getting Started series - Spawning dynamic slices (video)
- Spawning and Shooting a Projectile with Legacy Physics and Dynamic Slices with Lumberyard Script Canvas (video)

Slice Favorites

You can flag a slice as a favorite to make it easier to access and instantiate into your scenes. To use the slice favorites feature, enable the Slice Favorites (p. 1203) gem.

Slice favorites are:

- Saved per user and per project.
- Instantiated from the viewport or Entity Outliner.
- Flagged as a favorite from the Asset Browser.
- Stored in a directory structure that you can organize and rename to suit your work flow.
- Shared by importing or exporting.

Opening the Slice Favorites Panel

Your slice favorites appear in the Slice Favorites panel, where you can reorganize and manage them.

To open the Slice Favorites panel, do one of the following

- In the Entity Outliner, right-click to open the context menu, and choose Slice favorites, Manage favorites.

- In Lumberyard Editor, choose Tools, Other, Slice Favorites.

The Slice Favorites panel appears in its default location, above the Entity Inspector.
Flagging a Slice as a Favorite

You can flag a slice as a favorite so that your slice appears in the **Slice Favorites** panel.

**To flag a slice as a favorite**

- In the **Asset Browser**, do one of the following:
  - Right-click a slice and choose **Add as slice favorite**.
  - Drag a slice to the **Slice Favorites** panel.

Removing a Slice Favorite

You can remove a slice favorite so that it no longer appears in the **Slice Favorites** panel.

**To remove a slice favorite, do one of the following**

- In the **Asset Browser**, right-click the slice and choose **Remove as slice favorite**.
- In the **Slice Favorites** panel, right-click the slice, choose **Remove selected**, and then confirm the removal in the dialog.

Managing Slice Favorites

You can perform a variety of actions to manage your slice favorites in the **Slice Favorites** panel.

**To manage slices in Slice Favorites, you can do the following**

**Drag and Drop**

- Select one or more slices or folders to drag them into other folders or to reorder them in the list.
Add a folder

Right-click the Slice Favorites panel and choose Add folder.

Rename a folder

Right-click a folder in the Slice Favorites panel and choose Rename.

Rename a slice

Right-click a slice in the Slice Favorites panel, and choose Rename.

Note
Renaming a slice changes its display name in the Slice Favorites panel, but doesn't change the slice file name.

Import favorites from an XML file

Right-click the Slice Favorites panel and choose Import slice favorites.
Export favorites to an XML file

Right-click the Slice Favorites panel and choose Export slice favorites, and then select or create an XML to export.

Instantiating a Slice Favorite

To instantiate a slice favorite, do one of the following:

- Right-click the viewport or Entity Outliner, choose Slice favorites, and then navigate to the slice you want to instantiate.

- Drag a slice from the Favorite Slices panel into the viewport or the Entity Outliner.

Converting Slices with the Slice Upgrade Pipeline

In v1.23, Amazon Lumberyard introduced a new file format for component slices. Specifically, the override data found in data patches is now stored in a readable XML format instead of a hexadecimal byte stream. This is useful when performing diff and merge operations on your slice files, and enables a more robust versioning system for your serialized components. Use the Slice Upgrade Pipeline to automatically convert slice files to the latest slice file format.
Note
For more information about this new data patch format, and an example, see Anatomy of a Slice Data Patch (p. 515).

When do I use the Slice Upgrade Pipeline?

Use the Slice Upgrade Pipeline in Lumberyard v1.23 or later when:

• Adding a slice that was saved using an older version of the slice file format.
• Installing a new version, such as v1.23, or a build of Lumberyard that makes changes to the slice file format.
• Asset Processor logs indicate that your project has slices that require an upgrade. If so, the log displays a warning similar to the following:

This slice file is out of date: C:\lumberyard_version\dev\MyGame\slices\myslice.slice
To enable automatic upgrades:
In the settings file SliceBuilderSettings.json, set EnableSliceConversion to true and restart Asset Processor

Note
Currently, this pipeline does not update your slices when changing your component serialization. If you want to do that, use the Resave All Slices command on the File menu in Lumberyard Editor.

It is important to upgrade your slice assets as soon as possible, because:

• You can read, edit, and merge data patches more efficiently in upgraded slice assets.
• Upgrading your slices lets you use the new TypeChange and NameChange class builders when versioning your components. For more information about the component versioning system, see Versioning your Component Serialization (p. 1043).
• Delaying the upgrade puts you at a heightened risk of losing data in the future when changing serialization of your components. For more information about this risk, see Avoiding Data Loss when Serializing Component Data (p. 1049).

Note
In Lumberyard v1.23 and later, any slices with data patches still using the old format are updated automatically when changes are pushed to them. This is regardless of the slice conversion setting.

How do I convert my slices using the Slice Upgrade Pipeline?

Enable the Slice Upgrade Pipeline and restart Asset Processor to convert your slice files to the new format.

Perform the following steps:

1. Ensure that all source slice files are writable.
   • If you're using Perforce, recursively check out all the slice files that you want to upgrade by running the following Perforce command: p4 edit ...\*.slice
     You must change any read-only slices not tracked by Perforce to read-write manually.
2. Enable deep slice resaving in the file `SliceBuilderSettings.json`. This file is in your root dev directory. Open the file and change the setting `EnableSliceConversion` to true. By default, this option is disabled.

3. Restart Asset Processor.
   a. Close Lumberyard Editor.
   b. In the Windows taskbar, right-click Asset Processor, and choose Quit or press Ctrl+Q.
   c. Restart the project or branch that you are working on. Asset Processor automatically starts.

4. On the Tools tab in Asset Processor, trigger a Full Scan of assets.

![Asset Processor](image)

**Note**
For more information about using Asset Processor, see Using Asset Processor (p. 248).

5. Open Asset Processor logs. Confirm that there are no warning messages about slice files that are out of date or failed to convert.

After you perform these steps, while the Slice Upgrade Pipeline remains enabled, and Asset Processor is running, any slices that you copy or pull into your project are automatically converted by Asset Processor to the new format. A restart and full scan is not needed in this case.

**Troubleshooting the Slice Upgrade Pipeline**

Look at Asset Processor logs for slice files that failed conversion or display warnings. The following sections describe problems you might encounter.

**Warnings in the Slice Builder Settings File**

The Slice Upgrade Pipeline requires the settings file `SliceBuilderSettings.json` to be present in the `lumberyard_version\dev` folder. The default content of this file is:

```json
{
   "EnableSliceConversion": false
}
```

If there are problems with this file, one of the following warnings may appear in the Asset Processor log:

- Failed to Load Slice Builder Settings File. Using Default Slice Builder Settings.
• Slice Builder Settings File Missing. Using Default Slice Builder Settings.
• Loading Slice Builder Settings Failed. Using Default Slice Builder Settings.

Make sure the settings file exists in the correct location, is not open in another application, and contains the json content shown above.

Slice Dependency
If a nested slice is missing dependencies, the upgrade process fails because the slice instantiation failed. Correct the dependency problem to continue the upgrade.

Failed to Upgrade Slice: SlicePath - Slice Instantiation Failed.

Read-Only Files
Slices marked as read-only fail to process with the following log output:

This slice file is out of date: SlicePath
To Enabled Automatic Upgrades:
Make sure the slice isn't marked Read-Only. If using Perforce, check out the slice file.

Renaming the source slice file
During the upgrade process, if the source slice file cannot be renamed for any reason, one of the following errors may appear in the Asset Processor log:

• Failed to Upgrade Slice: SlicePath - Could not rename existing file
• Failed to Upgrade Slice: SlicePath - Could not rename new slice temp file
• Failed to Upgrade Slice: SlicePath - Could not open replacement slice file for writing
• Failed to Upgrade Slice: SlicePath - Could not write replacement slice file

If any of these errors appear, make sure the slice file is not open in another application, and that the file can be written to the directory where the source slice is located.

Component Reference

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Entity Inspector to add the following components to your entities.

Note
Some components are only available through gems. For example, you must enable the Rain (p. 1194) gem for your project, so that the Rain (p. 768) component is available. For more information, see Add modular features and assets with Gems (p. 1064).

• Capsule Shape (p. 818)
• Compound Shape (p. 818)
• Cylinder Shape (p. 818)
• Polygon Prism Shape (p. 708)
• Sphere Shape (p. 818)
• Spline (p. 866)
• Tube Shape (p. 894)
• White Box component (p. 946)
• White Box Collider component (p. 960)

Terrain
• Legacy Terrain level component (p. 651)
• River (p. 796)
• Road (p. 808)

UI
• UI Canvas Asset Ref (p. 897)
• UI Canvas Proxy Ref (p. 898)
• UI Canvas on Mesh (p. 897)

VR
• VR Preview (p. 924)
Miscellaneous

- Transform (p. 878)

Actor

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Actor component to create characters for your game. After you import your character files from your DCC tool into Lumberyard, you can create an entity and add the Actor component to it. For example, you must use an Actor component to create a controllable character for your game.

For the Actor component to work properly, you must also add one of the following:

- Simple Motion (p. 826) component – Uses a single motion for your actor.
- AnimGraph (p. 545) component – Uses an animation graph to control your actor's behavior.

Topics

- Actor Component Properties (p. 536)
- Using Multiple Skin Attachments for an Actor (p. 537)
- Setting Up Actor Entities (p. 541)

Actor Component Properties

The Actor component has the following properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Actor asset</td>
<td>Specifies the actor file that you want to add to your entity.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LOD Materials</td>
<td>Specifies the material that is linked to your actor asset.</td>
</tr>
<tr>
<td>Attachment type</td>
<td>The Actor component has the following attachment types:</td>
</tr>
<tr>
<td></td>
<td>• Actor Attachment – Attaches the current actor to the target entity.</td>
</tr>
<tr>
<td></td>
<td>• Skin Attachment – Attaches a skin attachment to a target entity.</td>
</tr>
<tr>
<td>Draw skeleton</td>
<td>Determines whether character joints are visible.</td>
</tr>
<tr>
<td>Draw character</td>
<td>Determines whether character mesh is visible.</td>
</tr>
<tr>
<td>Skinning method</td>
<td>Specifies the skinning method to use for the actor. You can choose the following options:</td>
</tr>
<tr>
<td></td>
<td>• Dual quat skinning – Specify dual quaternion skinning to help smooth deformation effects and preserve the volume of the mesh. Dual quaternion skinning is a technique that uses dual quaternions to provide a more visually pleasing appearance for blended vertex positions in a skinned mesh. This technique effectively substitutes an interpolation of rotation for the linear interpolation. Dual quaternion skinning preserves volumes and resists twists better than linear skinning.</td>
</tr>
<tr>
<td></td>
<td>• Linear skinning – Specify linear skinning to make a mesh follow a character’s joint. When a character flexes a joint, the mesh vertices move with the bones of the character’s animation skeleton. For example, a vertex in a flexible area like an elbow or knee calculates where it will be if the vertex moves with each bone that affects it and then linearly interpolates between them.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> Linear skinning tends to collapse around joints with twists or large blend angles.</td>
</tr>
<tr>
<td></td>
<td>You can also enable linear skinning in Geppetto. For more information, see Enabling Linear Skinning with Geppetto in the Amazon Lumberyard Legacy Reference.</td>
</tr>
</tbody>
</table>

Using Multiple Skin Attachments for an Actor

You can use multiple skin attachments on an actor or character to add interchangeable parts such as a hat or belt. The meshes for these additional attachments can be a part of a single FBX file or separated into multiple FBX files. When deciding whether to use a single FBX file or multiple FBX files, consider the following:
Topics

• Using a Single FBX File (p. 538)
• Using Multiple FBX Files (p. 541)

Single FBX file with all skinned attachments (meshes) embedded

• Works well for an actor with a limited set of added or active attachments.
• Causes initial performance slowdown with Asset Processor, especially with high fidelity meshes. The end result performance, however, is the same as with multiple FBX files.
• Reduces number of FBX files to manage, but limits flexibility in modifying assets.

Multiple FBX files, each embedded with a skin attachment (mesh) that can be applied to an actor.

• Multiple source files to manage within a project.
• Provides flexibility for multiple content creators to manipulate meshes as needed.
• Asset Processor generates an .mtl (material) file for each FBX regardless of whether you intend to share materials.

Whether you use a single FBX file or multiple FBX files, you create an actor for each skinned mesh attachment. The single FBX file method requires some additional configuration in the FBX Settings tool.

For more information, see Customize FBX asset export with FBX Settings (p. 409).

To download the assets used in the following sections, see Amazon Lumberyard Downloads and choose the Lumberyard characters file.

Using a Single FBX File

When you use a single FBX file embedded with multiple meshes, you must create an actor for each attachment. For example, a cowboy character would be an actor, while his interchangeable hat and belt must each be added as additional actors.

To add multiple actors from a single FBX file in the FBX Settings tool

1. In Lumberyard Editor's Asset Browser, right-click the .fbx file that contains your meshes and choose Edit Settings.
2. On the Actors tab, click Add another actor.
   You should already have one actor for your character. The additional actors that you add are the attachments, such as articles of clothing.
3. For the Actor group, enter the actor name such as cowboy_hat and then click the mesh icon to select the mesh that you want as an attachment.
4. In the Select nodes dialog box, select the mesh, and then click Select.
Your **Actor** groups should look like the following.
Example
5. Click **Update** to save your settings and close the **FBX Settings** tool.

6. In the **Asset Browser**, navigate to the directory that contains your FBX file to view your actor files. You can see the primary actor and each attachment that you added.

**Example**

In the **Asset Browser**, a single FBX file contains the primary actor and the attachments.

![Asset Browser example](image)

**Using Multiple FBX Files**

When you use an FBX file for each skin attachment, Asset Processor automatically generates an **Actor** file for each FBX file. Modify the **FBX Settings** tool only if you want to change the default Asset Processor behavior.

**Example**

In the **Asset Browser**, multiple FBX files each contain a separate actor file.

![Additional Asset Browser example](image)

**Setting Up Actor Entities**

After you set up your skinned meshes as actors, you can create your actor entities. You then parent the attachments to the main entity and line the attachments up to the primary actor.
To create actor entities

1. From the **Asset Browser**, select and drag the main actor file and the attachment actor files into the viewport.

   Lumberyard automatically adds each file as its own actor component entity.

2. In the **Entity Outliner**, click and drag the attachment entities to the main entity; this parents the attachment actor entities to the main actor entity.

   **Note**
   The attachments entities may not line up with the main entity. You'll fix this in the next step.
Example

3. To align the children with its parent, select a child (attachment) entity and then in the Entity Inspector, specify the Translate values to 0. Repeat for any other child entities.
The attachments now line up with the main actor entities.

4. For each child entity, do the following:
   a. In the **Actor** component, for **Attachment type**, choose **Skin attachment**.
   b. For **Target entity**, click the picker icon and then select the primary actor to attach the skinned mesh (for example, the **cowboyactor**).
Your component entity setup is complete. When your primary actor animates, the additional skinned mesh attachments animate with the primary actor skeleton.

**AnimGraph**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the AnimGraph component to add an animation graph and motion set to your character. Add this component to the Actor (p. 536) component to control character behavior from an animation graph. For single motions, see the Simple Motion (p. 826) component.

**AnimGraph Component Properties**

The AnimGraph component has the following properties:

- **Anim graph**
  - Lets you select the animation graph that was created in the Animation Editor.

- **Motion set asset**
  - Lets you select the motion set that was created in the Animation Editor.

- **Active motion set**
  - Lets you select the motion set that was created in the Animation Editor.

- **Parameters**
  - Displays the parameters that were created with the Animation Graph.

**Anim Graph Net Sync**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The AnimGraph (p. 545) component, which adds an animation graph and motion set to a character, does not automatically synchronize its parameters across the network. Lumberyard's GridMate networking system (p. 1990) provides a server an authoritative way of replicating these parameters. This replication enables the movements of a character on a server to be mirrored on all of the clients that are connected to the server.

To implement the replication, use Lumberyard's Anim Graph Net Sync component, which is included with the EMotion FX Animation (p. 1124) gem. The Anim Graph Net Sync component requires the Network Binding (p. 700) component and can be added to any entity that has the AnimGraph component.

For more information, see Synchronizing Animations Across a Network (p. 2051).
Area Light

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Area Light component on an entity to light an area.

The Area Light component has the following settings:

Visible
- Shows the light.

On initially
- When created, the light is on by default.

General Settings

See the following general settings:

Color
- The color of the light.

Diffuse multiplier
- Sets the strength of the diffuse color.

Specular multiplier
- Sets the strength of the specular brightness.

Ambient
- Light acts as a multiplier for cubemap values.

Area Light Settings

See the following area light settings:

Area width
- Width of the area light in meters.

Area Height
- Height of the area light in meters.

Max Distance
- Maximum distance in meters that the area light extends.

FOV
- Field of View (FOV) in degrees.

Options

See the following options:
View distance multiplier

Adjusts the maximum view distance. For example, 1.0 uses the default and 1.1 is 10% farther than the default.

Minimum spec

Minimum specification value at which the light is enabled.

Cast shadow spec

The minimum specification at which shadows are cast.

Voxel GI mode

Mode for light interaction with voxel global illumination (GI). Choose None, Static, or Dynamic.

Use VisAreas

Light uses visible areas. If unselected, light ignores visible areas.

Indoor only

Light is only rendered indoors.

Affects this area only

Light affects only the immediate area.

Volumetric fog only

Light affects only volumetric fog.

Volumetric fog

Light affects volumetric fog and surrounding area.

Shadow Settings

See the following shadow settings:

Terrain Shadows

Includes the terrain in the shadow casters for this light.

Animation

See the following animation settings:

Style

Enter a number to specify a preset light animation curve to play as defined in the Light.cfx file. Valid values are 0 to 48. You can also use values 40 to 48 for testing and debugging.

Speed

Multiple of the base animation rate. For example, a value of 2.0 makes an animation play twice as fast.

Phase

Animation start offset from 0 to 1. A value of 0.1 is 10% into the animation. For example, you can use this setting, for to prevent lights in the same scene, with the same animation, from being animated in unison.
EBus Request Bus Interface

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

SetLightState

Turns the light on or off.

Parameters

On or Off

Return

None

Scriptable

Yes

TurnOnLight

Turns the light on.

Parameters

None

Return

None

Scriptable

Yes

TurnOffLight

Turns off the light.

Parameters

None

Return

None

Scriptable

Yes

ToggleLight

Toggles the light state from on to off, or off to on.
Area Light

Parameters

None

Return

None

Scriptable

Yes

EBus Notification Bus Interface

Use the following notification functions with the EBus interface to communicate with other components of your game.

For more information, see Working with the Event Bus (EBus) system (p. 1851).

LightTurnedOn

Sends a signal when the light is turned on.

Parameters

None

Return

None

Scriptable

Yes

LightTurnedOff

Sends a signal when the light is turned off.

Parameters

None

Return

None

Scriptable

Yes

The following is an example of script using the Request Bus Interface.

```lua
function example:OnActivate()
    LightComponentRequestBus.Event.TurnOnLight(self.entityId)
    LightComponentRequestBus.Event.TurnOffLight(self.entityId)
    LightComponentRequestBus.Event.ToggleLight(self.entityId)
end
```
Attachment

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/game/) or visit the [AWS Game Tech blog](https://aws.amazon.com/training/learning-journey/video-game-engineer/) to learn more.

The **Attachment** component lets an entity attach to a bone on the skeleton of another entity.

### Attachment Component Properties

![Attachment Component](image)

The **Attachment** component has the following properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target entity</td>
<td>Specifies the character entity that you want to attach.</td>
</tr>
<tr>
<td>Joint name</td>
<td>Specifies the joint that you want to attach to the entity.</td>
</tr>
<tr>
<td>Position offset</td>
<td>Specifies the x, y, and z local position offset from the target bone.</td>
</tr>
<tr>
<td>Rotation offset</td>
<td>Specifies the x, y, and z local rotation offset from the target bone.</td>
</tr>
<tr>
<td>Scale offset</td>
<td>Specifies the x, y, and z local scale offset from the target bone.</td>
</tr>
<tr>
<td>Attached initially</td>
<td>Specifies whether to attach to the target entity automatically.</td>
</tr>
<tr>
<td>Scaling</td>
<td>Specifies how the object scaling is determined. You can specify the following values:</td>
</tr>
<tr>
<td></td>
<td>• Use world scale – Attached object is scaled in world space.</td>
</tr>
<tr>
<td></td>
<td>• Use target entity scale – Attached object adopts scale of target entity.</td>
</tr>
<tr>
<td></td>
<td>• Use target bone scale – Attached object adopts scale of target entity/joint.</td>
</tr>
</tbody>
</table>

### EBus Request Bus Interface

Use the following request functions with the event bus (EBus) interface to communicate with other components of your game.

For more information, see Working with the Event Bus (EBus) system (p. 1851).
### Lumberyard User Guide

#### Audio Area Environment

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach</td>
<td>Changes the attachment target for an entity. The entity will detach from its previous target.</td>
<td>entityIdId – ID of the entity in which to attach. targetBoneName – Name of bone in which to attach the entity. If a bone is not found, then attach to target entity's transform origin. offsetTransform – Attachment's offset from target.</td>
<td>Yes</td>
</tr>
<tr>
<td>Detach</td>
<td>Detaches the target from the entity.</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>SetAttachmentOffset</td>
<td>Update entity's offset from target.</td>
<td>offsetTransform – Attachment's offset from target.</td>
<td>Yes</td>
</tr>
</tbody>
</table>

### EBus Notification Bus Interface

Use the following notification functions with the EBus interface to communicate with other components of your game.

For more information, see [Working with the Event Bus (EBus) system](#) (p. 1851).

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>OnAttached</td>
<td>Indicates that the entity has attached to the target.</td>
<td>entityIdId – ID of the target in which is being attached.</td>
<td>Yes</td>
</tr>
<tr>
<td>OnDetached</td>
<td>Indicates that the entity is detaching from its target.</td>
<td>entityIdId – ID of the target in which is being detached.</td>
<td>Yes</td>
</tr>
</tbody>
</table>

### Audio Area Environment

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Using the **Audio Area Environment** component, you can apply environment effects to sounds that an entity triggers. You must also add a shape component to use the audio area environment component.

**Audio Area Environment Properties**

The **Audio Area Environment** component has the following properties:
**Broad-phase Trigger Area**

Link this property to an entity that includes a trigger area and shape. This trigger area is used for broad-phase checks. The **Audio Area Environment** component tracks any entity that moves inside the trigger area.

Default: None

**Environment name**

The name of the Audio Translation Layer (ATL) (p. 3147) environment to apply to entities in the area.

Default: None

**Environment fade distance**

The distance around a shape where the environment amounts will fade based on an entity's distance from the shape. Only positive, non-zero values are valid.

Default: 1.0

---

**Using the Audio Area Environment Component**

Setting up the **Audio Area Environment** component requires two entities. The second entity is linked to the **Audio Area Environment** component in the first entity, acting as a broad-phase trigger area. When these entities are configured properly, any entity that passes near or through the inner shape of the first entity will have an environment amount applied to any triggered sounds.

**To set up the Audio Area Environment component**

1. In Lumberyard Editor, right-click the viewport in your level, and click **Create new component entity**.
2. Click **Tools**, **Entity Inspector**. Be sure that your new component entity is selected in the viewport.
3. In the **Entity Inspector**, click **Add Component**, **Shape**, and then select one of the shape options.
4. Click **Add Component**, **Audio**, **Audio Area Environment**.
5. Repeat steps 1 – 4 to add another entity with a **Shape** (any) component and a **Trigger Area** component (located under **Scripting**).
6. Place and size the two entities so that the following conditions are met:
   - The second entity's shape completely encompasses the first entity's shape.
   - The second entity's shape is larger than the first entity's shape by at least the value for the **Environment fade distance**. This allows the **Audio Area Environment** component to track an entity's distance from the inner shape when the entity enters the outer trigger area.
7. (Optional) In the **Entity Inspector**, for the **Trigger Area** component, use the **Tag Filters** to filter entities that you don't want the **Audio Area Environment** component to process.

---

**Audio Environment**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **Audio Environment** component provides access to features of the Audio Translation Layer (ATL) (p. 3147) environments. Environments are used to apply environmental effects such as reverb or echo.
Audio Environment Properties

The Audio Environment component has the following property:

Default Environment

Enter the name of the audio environment to use by default when setting amounts.

EBus Request Bus Interface

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

SetAmount

Sets the amount of environmental 'send' to apply to the default environment, if set.

Parameters

- amount – Float value of the amount to set

Return

- None

Scriptable

- Yes

SetEnvironmentAmount

Sets the amount of environmental 'send' to apply to the specified environment.

Parameters

- environmentName – Name of ATL Environment to set an amount on
- amount – Float value of the amount to set

Return

- None

Scriptable

- Yes

Audio Listener

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
With the **Audio Listener** component, you can place a virtual microphone in the environment. An audio listener acts as a sink for sound sources in the virtual world, and 3D audio rendering is processed with respect to the listener's world transform. You can specify the audio listener's position and rotation independently.

### Audio Listener Properties

The **Audio Listener** component has the following properties:

**Rotation Entity**

Link this property to an entity where the audio listener adopts the rotational part of the transform. The current entity is used if a value is not specified.

**Position Entity**

Link this property to an entity where the audio listener adopts the positional part of the transform. The current entity is used if a value is not specified.

**Fixed Offset**

Link this property to an entity where the audio listener adopts the offset part of the transform. The current entity is used if a value is not specified.

**Listener Enabled**

Controls the initial state of the listener.

### Using the Audio Listener Component

Only one audio listener is supported in a game. You can add the **Audio Listener** component to an entity that contains the game camera.

**To set up the Audio Listener component**

1. In Lumberyard Editor, right-click the viewport in your level, and click **Create new component entity**.
2. Click **Tools, Entity Inspector**. Be sure that your new component entity is selected in the viewport.
3. In the **Entity Inspector**, click **Add Component, Audio, Audio Listener**.

### EBus Request Bus Interface

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

**SetRotationEntity**

Specify the entity with the rotational part of the transform that the audio listener will adopt.

**Parameters**

- **entityId** – Entity to use for the rotational part of the transform

**Return**

None
Scriptable

Yes

SetPositionEntity

Specify the entity with the positional part of the transform that the audio listener will adopt.

Parameters

entityId – Entity to use for the positional part of the transform

Return

None

Scriptable

Yes

SetFullTransformEntity

Specify the entity with the full transform that the audio listener will adopt.

Parameters

entityId – Entity to use for the transform

Return

None

Scriptable

No

Audio Preload

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Using the Audio Preload component, you can load and unload ATL preloads, which contain references to soundbanks. You can specify the loading type as automatic or manual. The automatic loading type means that preloads load when the component activates and unload when it deactivates. The manual loading type means the component does not take any action until the user makes a request.

Audio Preload Properties

The Audio Preload component has the following properties:

Preload Name

Name of the default ATL Preload that this component loads or unloads. Modify this property to define a custom default ATL preload.

Default: Blank

Load Type

Set to Auto or Manual.
If set to **Auto**, preloads load when component activates and unload when component deactivates.
If set to **Manual**, preloads load and unload only when the user makes the request to the interface.
Default: Auto

**EBus Request Bus Interface**

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see *Working with the Event Bus (EBus) system (p. 1851).*

<table>
<thead>
<tr>
<th>Load</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Load</td>
</tr>
<tr>
<td><strong>Description</strong></td>
<td>Loads the default ATL preload (if it is set)</td>
</tr>
<tr>
<td><strong>Parameters</strong></td>
<td>None</td>
</tr>
<tr>
<td><strong>Return</strong></td>
<td>None</td>
</tr>
<tr>
<td><strong>Scriptable</strong></td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Load</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Unload</td>
</tr>
<tr>
<td><strong>Description</strong></td>
<td>Unloads the default ATL preload (if it is set)</td>
</tr>
<tr>
<td><strong>Parameters</strong></td>
<td>None</td>
</tr>
<tr>
<td><strong>Return</strong></td>
<td>None</td>
</tr>
<tr>
<td><strong>Scriptable</strong></td>
<td>Yes</td>
</tr>

</tbody>
</table>
Audio Proxy

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Audio Proxy component is a required dependency if you add multiple audio components to an entity. It acts as a proxy audio object wrapped in a component. For example, if you have an audio trigger component and an audio rtpc component on the same entity, they communicate to the same audio object using this audio proxy component.

Audio Rtpc

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Audio RTPC component provides basic Real-Time Parameter Control (RTPC) (p. 3147) functionality. An RTPC is a named variable that the audio system can interpret in many different ways. It allows game developers to set the value from the game at run time to produce real-time tweaking of sounds.

Audio RTPC Component Properties

The Audio RTPC component has the following property:

Default Rtpc

Enter the name of the audio RTPC to use by default. You can associate any RTPC name with the entity, typically one that is meant to affect a particular trigger.
EBus Request Bus Interface

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

SetValue

Sets the value of the default RTPC.

Parameters

value – Float value of the RTPC

Return

None

Scriptable

Yes

SetRtpcValue

Sets the value of the specified RTPC.

Parameters

rtpcName – Name of the RTPC to set
value – Float value to set

Return

None

Scriptable

Yes

Audio Switch

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Audio Switch component provides basic Audio Translation Layer (ATL) (p. 3147) switch functionality. With switches (and switch states), you can specify the state of an entity. The audio middleware interprets states, modifies the behavior of sounds, and plays the appropriate sounds.

Audio Switch Properties

The Audio Switch component has the following properties:

Default Switch

Enter the name of the audio switch to use by default. You can associate any audio switch with the entity.
Default State

Enter the name of the audio switch state to use by default. Use the Audio Controls Editor (p. 3142) to assign the state to the switch. When this component is activated, the default switch is set to the default state.

EBus Request Bus Interface

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

SetState

Sets the specified state of the default switch.

Parameters

- stateName – Name of the state to set

Return

- None

Scriptable

- Yes

SetSwitchState

Sets a specified switch to a specified state.

Parameters

- switchName – Name of the switch to set

- stateName – Name of the state to set

Return

- None

Scriptable

- Yes

Audio Trigger

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Audio Trigger component provides basic play and stop features so that you can set up Audio Translation Layer (ATL) (p. 3147) play and stop triggers that can be executed on demand. With an audio trigger, you can also enable the player to run or stop audio triggers by name on entities.
Audio Trigger Properties

The Audio Trigger component has the following properties.

Default 'play' Trigger

Enter the name of the audio trigger that this component runs when 'play' is called. You can change this property to specify a different default audio trigger.

Default 'stop' Trigger

Enter the name of the audio trigger that this component runs when 'stop' is called. You can specify any trigger here; you do not need to specify a 'stop' trigger in order to stop audio, but it is a best practice to pair the two triggers. If you leave this setting blank, the 'stop' trigger simply stops the audio trigger specified for 'play'.

Obstruction Type

Select an option for the raycasts used in calculation of obstruction and occlusion.

• Ignore
• SingleRay
• MultiRay

Play immediately

Select this option to run upon component activation the audio 'play' trigger.

EBus Request Bus Interface

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

Play

Runs the default 'play' trigger, if set.

Parameters

None

Return

None

Scriptable

Yes

Stop

Runs the default 'stop' trigger, if set. If no 'stop' trigger is set, ends the default 'play' trigger.

Parameters

None
Audio Trigger

ExecuteTrigger
Runs the specified audio trigger.

Parameters
triggerName – Name of the audio trigger to run.

Return
None

Scriptable
Yes

KillTrigger
Cancels the specified audio trigger.

Parameters
triggerName – Name of the audio trigger to cancel.

Return
None

Scriptable
Yes

KillTrigger
Cancels all audio triggers that are active on an entity.

Parameters
None

Return
None

Scriptable
Yes

SetMovesWithEntity
Specifies whether triggers should update position as the entity moves.

Parameters
shouldTrackEntity – Boolean indicating whether triggers should track the entity's position.
EBus Response Bus Interface

Use the following response functions with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

OnTriggerFinished

Informs all listeners about an audio trigger that has finished playing (the sound has ended).

Parameters

- triggerId – ID of trigger that was successfully executed.

Return

- None

Scriptable

- Yes

Behavior Tree

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Behavior Tree component to load and run a behavior tree for the attached entity.

Behavior Tree Component Properties

The Behavior Tree component has the following properties:

Behavior tree asset

- Select an XML file that contains a behavior tree definition.

Enabled initially

- When selected, the behavior tree is loaded and activated with the entity.

EBus Request Bus Interface

Use the following request functions with the event bus (EBus) interface, BehaviorTreeComponentRequestBus, to communicate with other components of your game.
For more information about using the EBus interface, see Working with the Event Bus (EBus) system (p. 1851).

StartBehaviorTree

Starts an inactive behavior tree associated with this entity.

Parameters

None

Return

None

Scriptable

Yes

StopBehaviorTree

Stops an active behavior tree associated with this entity.

Parameters

None

Return

None

Scriptable

Yes

GetVariableNameCrcs

Gets a list of all crc32s of the variable names.

Parameters

None

Return

AZStd::vector<AZ::Crc32>

Scriptable

Yes

GetVariableValue

Gets the value associated with a variable.

Parameters

AZ::Crc32 variableNameCrc

Return

bool
Scriptable

Yes

SetVariableValue

Sets the value associated with a variable.

Parameters

AZ::Crc32 variableNameCrc

bool newValue

Return

None

Scriptable

Yes

The following is an example of script using the Request Bus Interface.

```lua
local behaviortreescript =
{
    Properties =
    {
        Target = EntityId(),
    },
}

function behaviortreescript:OnActivate()
    BehaviorTreeComponentRequestBus.Event.StartBehaviorTree(self.entityId)
    BehaviorTreeComponentRequestBus.Event.SetVariableValue(self.entityId,
        Crc32("HasTarget"), self.Properties.Target:IsValid())
end

return behaviortreescript
```

Blast Family component

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

With the Blast Family component, you can enable destruction simulation using the NVIDIA Blast library, and set properties for the simulation. The Blast Family component is used with the Blast Family Mesh Data component. This topic describes the properties of the Blast Family component.

The Blast Family component is provided by the NVIDIA Blast gem (p. 1181).

For information on using the Blast Family component see Simulated destruction with NVIDIA Blast (p. 2833).
Blast Family component properties

Blast Asset

The blast asset that will be used for the destruction simulation.

Blast Material

A blast material from the blast material library. Blast materials define how much damage various forces cause to the bonds holding the fractured asset together, and how much damage is required to trigger destruction. For more information, see Specify destruction properties with Blast materials (p. 2851).

Physics Material

The physics material for the blast asset. Physics materials define physical properties such as friction.

Collision Layer

The collision layer for this Blast Family.

Collides With

The collision group containing the layers that this Blast Family collides with.

Simulated

When enabled, this Blast Family's collision will be part of the PhysX simulation.

In Scene Queries

When enabled, this Blast Family's colliders will be available for scene queries.

CCD Enabled

When enabled, this Blast Family will use continuous collision detection. CCD is useful for ensuring accurate collision detection for high-speed objects.

Tag

Set a tag for this Blast Family. Tags can be used to quickly identify components in script or code.
Blast Family Mesh Data component

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

With the Blast Family Mesh Data component, you can set the mesh and material assets for NVIDIA Blast entities. The Blast Family Mesh Data component is used with the Blast Family component. This topic describes the properties of the Blast Family Mesh Data component.

The Blast Family Mesh Data component is provided by the NVIDIA Blast gem (p. 1181).

For information on using the Blast Family Mesh Data component see Simulated destruction with NVIDIA Blast (p. 2833).

Blast Family Mesh Data component properties

Show mesh assets

When enabled, you can manually add mesh assets to this Blast Family Mesh Data component.

The Show mesh assets property exposes the Mesh assets list. Choose the + button to the right of Mesh assets to add a list entry. Choose the Folder button to select a mesh for the list entry.

Material

The material that supplies the visual appearance for the meshes in this Blast Family Mesh Data component.

Blast Slice

A blast slice for this Blast Family Mesh Data component. Blast slices are generated when blast assets are processed by the Python asset builder for NVIDIA Blast. A blast slice will automatically add the mesh assets and material to the Blast Family Mesh Data component.

Camera

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The **Camera** component allows an entity to be used as a camera. To use the **Camera** component, you must first add a Camera Framework gem to your project. For information, see [Camera Framework Gem](p. 1121).

**Camera Component Properties**

![Camera component properties](image)

The **Camera** component has the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field of view</td>
<td>Vertical field of view in degrees.</td>
<td>75.0 degrees</td>
</tr>
<tr>
<td>Near clip distance</td>
<td>Distance to the near clip plane of the view frustum in meters.</td>
<td>0.2 m</td>
</tr>
<tr>
<td>Far clip distance</td>
<td>None</td>
<td>1024.0 m</td>
</tr>
<tr>
<td>Frustum length</td>
<td>Frustum length percentage.</td>
<td>1.0 percent</td>
</tr>
<tr>
<td>Frustum color</td>
<td>Frustum color.</td>
<td>255,255,0</td>
</tr>
</tbody>
</table>
**Description**

**Distance clip distance**

near far plane of the view frustum in meters.

Default value: 1024

**Editor this camera**

selected camera as its view.

For more information, see *Changing the Camera View* (p. 209).

**Frustum length**

the frustum shape.

Default value: 1.0 percent
### Description

**Frustum color**

the frustum shape.

Default value: 255, 255, 0

### EBus Request Bus Interface

Use the following request functions with the event bus (EBus) interface, CameraRequestBus, to communicate with other components of your game.

For more information, see Working with the Event Bus (EBus) system (p. 1851).

<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetFov</td>
<td>Gets the current field of view.</td>
</tr>
<tr>
<td>SetFov</td>
<td>Sets the current field of view.</td>
</tr>
<tr>
<td>GetNearClipDistance</td>
<td>Gets the current near clip distance.</td>
</tr>
<tr>
<td>SetNearClipDistance</td>
<td>Sets the current near clip distance.</td>
</tr>
<tr>
<td>GetFarClipDistance</td>
<td>Gets the current far clip distance.</td>
</tr>
<tr>
<td>SetFarClipDistance</td>
<td>Sets the current far clip distance.</td>
</tr>
</tbody>
</table>

The following is an example of script using the **Request Bus Interface**.

```lua
local camerasample = {
    Properties = {
    },
}

function camerasample:OnActivate()
    CameraRequestBus.Event.SetFov(self.entityId, 85)
    local nearClip = CameraRequestBus.Event.GetNearClipDistance(self.entityId)
    CameraRequestBus.Event.SetFarClipDistance(self.entityId, nearClip + 1024)
end

return camerasample
```

### Creating Camera Entity from View

You can create a static camera view from a specific entity by right-clicking an entity in the viewport and choosing **Create camera entity from view**. This places a new entity with a camera component at the same point. You can adjust the view of the camera by modifying its transform component.
Camera Rig

Use the **Camera Rig** component to add and remove behaviors to drive your camera entity. To use the camera component, you must first add the Camera Framework Gem (p. 1121) to your project.

**Camera Rig Component Properties**

The **Camera Rig** component has the following properties:

**Target acquirers** (p. 570)

Array of behaviors that define how a camera selects a target. The rig tries each acquirer in the order listed until one successfully finds a target.

**Look-at behaviors** (p. 571)

Array of behaviors that modify the look-at target transform. The rig runs each in order to generate a final target transform.

**Transform behaviors** (p. 573)

Array of behaviors that modify the camera transform based on the look-at target transform. The rig runs each in order before setting the camera component's transform.

**Target Acquirers**

**Target Acquirers** identify valid targets and acquire their transforms for use in other rig behaviors.

**Acquire By Tag**

**AcquireByTag** has the following properties:

**Target tag**

Find a target by tag. If multiple entities are found, it uses the first to respond.

**Use Target Rotation**

If selected, uses the target's rotation when determining camera behavior.

**Use Target Position**

If selected, uses the target's position when determining camera behavior.
Acquire By Entity Id

AcquireByEntityId has the following properties:

Entity Target

Select a specific entity to use as the camera target

Use Target Rotation

If selected, uses the target's rotation when determining camera behavior.

Use Target Position

If selected, uses the target's position when determining camera behavior.

Look-at Behaviors

Look-at Behaviors changes the target transform to modify camera behavior.

OffsetPosition

Use OffsetPosition to change the position of the target's transform. Positions are often determined from the base of a model. But suppose, for example, that you want to determine its position 1.8 meters up from its base. You can use this property to achieve that positional offset.

Look-at Behaviors has the following properties:

Positional Offset

Vector displacement of the target transform's position.

Offset Is Relative

If selected, uses local coordinates. If deselected, uses world-basis vectors for the offset.
**Rotate Camera Target**

Use **Rotate Camera Target** to rotate the target separately from its source target. For example, you may want your character to look up and down without pitching.

**Rotate Camera Target** has the following properties:

- **Axis of Rotation**
  
  The target cardinal's axis around which the camera rotates. Select the X, Y, or Z axis.

- **Event Name**
  
  Name of event that provides the values for the rotation.

- **Invert Axis**
  
  If selected, inverts the axis of rotation.

- **Rotation Speed Scale**
  
  Multiplier for new input values to scale the speed of rotation.

**SlideAlongAxisBasedOnAngle**

Use **SlideAlongAxisBasedOnAngle** to modify the position of the look-at target based on an angle. For example, say that you set the target to slide along the forward and backward axis based on pitch. As the target pitched down, then the position would move ahead of the target. If the target is attached to the character, then every time the target looked down, it would be ahead of the character. Every time it looked up, it would be behind the character.

**SlideAlongAxisBasedOnAngle** has the following properties:
Axis to slide along

Select an axis along which the target slides:
- Forwards and Backwards
- Right and Left
- Up and Down

Angle Type

Select an angle type on which to base the slide:
- Pitch
- Yaw
- Roll

Vector Component to Ignore

Select a vector component to ignore: None, X, Y, or Z.

Max Positive Slide Distance

The maximum slide along the axis when the angle reaches 90 degrees.

Max Negative Slide Distance

The maximum slide along the axis when the angle reaches -90 degrees.

Transform Behaviors

Transform Behaviors are a critical component of how the camera responds to the target. For example, you can set the camera to face the target, follow from a distance, or follow the target at a specific angle.

FaceTarget

FaceTarget causes the camera to change the rotation of its transform to look at the target. To use this feature, simply add it. There are no additional properties to configure.

FollowTargetFromAngle

FollowTargetFromAngle causes the camera to follow the target from a specified angle. This feature works well for top-down, isometric, and side scrolling cameras.

Follow Target from Angle has the following properties:

Angle

Angle at which to follow the target.
Rotation Type

Rotation type of the angle for following the target: yaw, pitch, or roll.

Distance from Target

The distance in meters from which the camera follows the target.

FollowTargetFromDistance

FollowTargetFromDistance causes the camera to follow the target from a specified distance. You can also set named events to trigger the camera to zoom in on or out from a target.

FollowTargetFromDistance has the following properties:

Follow Distance

The distance in meters from which the camera follows the target.

Minimum Follow Distance

Minimum distance from which the camera follows the target.

Maximum Follow Distance

Maximum distance from which the camera follows the target.

Zoom In Event Name

Event name that reduces the current follow distance, in effect zooming in.

Zoom Out Event Name

Event name that increases the current follow distance, in effect zooming out.

Zoom Speed Scale

Scale amount for the incoming zoom value.

Player Index

The index of the player (device index) that this feature supports.

Offset Position

Offset Position sets the camera's position to the target's position with an offset.
**Offset Position** has the following properties:

**Offset**

The vector offset in meters from the target.

**Is Offset Relative**

If selected, local basis vectors are used. If deselected, world basis vectors are used.

**Rotate**

Use **Rotate** to rotate a camera about one of its axes (X, Y, or Z).

**Rotate** has the following properties:

**Angle**

Angle in degrees to rotate the camera.

**Axis**

Axis about which to rotate the camera.

**Cloth component**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **Cloth** component treats the vertices of any mesh that it references as cloth particles and applies physical properties, forces, and constraints to simulate the behavior of cloth. You can add this
component to any entity that has Mesh or Actor components. You can add multiple cloth components to an entity.

The Cloth component is provided by the NVIDIA Cloth gem (p. 1182).

For information on using the Cloth component see Simulate cloth with NVIDIA Cloth (p. 2857).

**Cloth component property groups**

- Base properties (p. 576)
- Motion constraints properties (p. 577)
- Backstop properties (p. 578)
- Damping properties (p. 578)
- Inertia properties (p. 579)
- Wind properties (p. 579)
- Collision properties (p. 580)
- Self Collision properties (p. 581)
- Fabric stiffness properties (p. 581)
- Fabric compression properties (p. 582)
- Fabric stretch properties (p. 583)
- Tether constraints properties (p. 583)
- Quality properties (p. 584)

**Base properties**
**Simulate in editor**

Enable to simulate cloth in editor.

**Mesh node**

The mesh node to simulate as cloth. The meshes available in the list have Cloth modifiers applied in FBX Settings.

**Mass**

Scale multiplier applied to the mass of all cloth particles. A value of 0.0 in this property makes all cloth particles static.

**Custom Gravity**

Enable to override global gravity and set a custom gravity value for this cloth.

**Gravity**

Set gravity for this cloth. The default, -9.81 on the Z axis, is standard gravity.

*Note*

The Gravity property is enabled by the Custom Gravity property.

**Gravity Scale**

Scale multiplier applied to the gravity of cloth particles.

**Stiffness frequency**

Stiffness exponent that adjusts the overall stiffness of the cloth simulation. This exponent is applied per second to these properties:

- Damping
- Damping - Linear drag
- Damping - Angular drag
- Wind - Air drag coefficient
- Wind - Air lift coefficient
- Self collision - Stiffness
- Fabric stiffness
- Fabric compression
- Fabric stretch
- Tether - Stretch

**Motion constraints properties**

<table>
<thead>
<tr>
<th>Motion constraints</th>
<th>Max Distance</th>
<th>Scale</th>
<th>Bias</th>
<th>Stiffness</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>10.0 m</td>
<td>1.0</td>
<td>0.0 m</td>
<td>1.0</td>
</tr>
</tbody>
</table>

**Max distance**

Maximum distance limit in meters for cloth particle movement.

**Scale**

Scale value applied to all motion constraints.
0.0: Motion constraints have no effect.
1.0: Motion constraints are fully applied.

Bias
Bias value in meters added to all motion constraints. Valid values range from -$\text{Infinity}$ to $\text{Infinity}$.

Stiffness
Stiffness for motion constraints.
0.0: Stiffness is not applied to motion constraints.
1.0: Stiffness is fully applied to motion constraints.

**Backstop properties**

<table>
<thead>
<tr>
<th>Backstop</th>
<th>0.1 m</th>
<th>0.0 m</th>
<th>0.0 m</th>
</tr>
</thead>
<tbody>
<tr>
<td>Radius</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Back offset</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Front offset</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note**
Backstop properties are only available when a Backstop vertex color stream is specified in the Cloth modifier for the selected Mesh node in FBX Settings.

Radius
The radius in meters of the backstop sphere.

Back offset
The offset in meters for backstop spheres behind the cloth.

Front offset
The offset in meters for backstop spheres in front of the cloth.

**Damping properties**

<table>
<thead>
<tr>
<th>Damping</th>
<th>X 0.2</th>
<th>Y 0.2</th>
<th>Z 0.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linear drag</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Angular drag</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Damping
Damping of cloth particle velocity.
0.0: Velocity is unaffected.
1.0: Velocity is zeroed.

Linear Drag
Portion of velocity applied to cloth particles.
0.0: Cloth particles are unaffected.
1.0: Damped global cloth particle velocity.

Angular Drag

Portion of angular velocity applied to turning cloth particles.

0.0: Cloth particles are unaffected.
1.0: Damped global cloth particle angular velocity.

Inertia properties

Linear

Portion of linear acceleration applied to cloth particles.

0.0: Cloth particles are unaffected.
1.0: Physically correct linear acceleration.

Angular

Portion of angular acceleration applied to turning cloth particles.

0.0: Cloth particles are unaffected.
1.0: Physically correct angular acceleration.

Centrifugal

Portion of angular velocity applied to turning cloth particles.

0.0: Cloth particles are unaffected.
1.0: Physically correct angular velocity.

Wind properties

Note

The component wind properties create wind that effects only the cloth referenced by the component. To create wind that can effect multiple components across multiple entities, see Create global or localized wind forces with PhysX (p. 2822).
Note
Wind is disabled when both the below Air drag and Air lift coefficients are 0.0.

Enable local wind velocity

Enable to set a wind Local velocity for this cloth. When disabled, the velocity from Physics::WindBus will be used.

Local velocity

Wind vector (direction and magnitude) in world coordinates. A greater magnitude applies a stronger wind force.

Note
The wind Local velocity property is enabled by the Enable local wind velocity property.

Air drag coefficient

Specifies how much drag air applies to the cloth particles.

Air lift coefficient

Specifies how much lift air applies to the cloth particles.

Air density

The density of air used for drag and lift calculations.

Collision properties

Friction

Controls the amount of friction between cloth particles and colliders.

0.0: Friction disabled.

Mass scale

Controls how quickly cloth particle mass is increased during collisions.

0.0: Mass scale disabled.

Continuous detection

Continuous collision detection improves collision by computing the time of impact between cloth particles and colliders.

Warning
The increase in quality can impact performance. We recommend that you use Continuous detection only when necessary.

Affects static cloth particles

Enable to allow colliders to move static cloth particles. Static cloth particles have a 0.0 inverse mass.
Self Collision properties

Distance

The minimum distance that the colliding cloth particles must maintain from each other in meters.

0.0: Self collision disabled.

Stiffness

Stiffness for the self collision constraints.

0.0: Self collision disabled.

Fabric stiffness properties

Horizontal

Stiffness value for horizontal stretch and compression constraints.

0.0: No horizontal stretch and compression constraints.

Horizontal multiplier

Scale value for horizontal stretch and compression constraints.

0.0: No horizontal stretch and compression constraints applied.

1.0: Fully apply horizontal stretch and compression constraints.

Vertical

Stiffness value for vertical stretch and compression constraints.

0.0: No vertical stretch and compression constraints.

Vertical multiplier

Scale value for vertical stretch and compression constraints.

0.0: No horizontal stretch and compression constraints applied.
1.0: Fully apply horizontal stretch and compression constraints.

**Bending**

Stiffness value for bending constraints. This value defines how easily a cloth folds on itself.

0.0: No bending constraints.

**Bending multiplier**

Scale value for bending constraints.

0.0: No bending constraints applied.

1.0: Fully apply bending constraints.

**Shearing**

Stiffness value for shearing constraints. This value defines how easily a cloth twists.

0.0: No shearing constraints.

**Shearing multiplier**

Scale value for shearing constraints.

0.0: No shearing constraints applied.

1.0: Fully apply shearing constraints.

---

**Fabric compression properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Horizontal limit</td>
<td>0.0</td>
</tr>
<tr>
<td>Vertical limit</td>
<td>0.0</td>
</tr>
<tr>
<td>Bending limit</td>
<td>0.0</td>
</tr>
<tr>
<td>Shearing limit</td>
<td>0.0</td>
</tr>
</tbody>
</table>

**Horizontal limit**

Compression limit for horizontal constraints. This property is affected by **Horizontal multiplier** in the **Fabric stiffness** property group.

0.0: Horizontal compression disabled.

**Vertical limit**

Compression limit for vertical constraints. This property is affected by **Vertical multiplier** in the **Fabric stiffness** property group.

0.0: Vertical compression disabled.

**Bending limit**

Compression limit for bending constraints. This property is affected by **Bending multiplier** in the **Fabric stiffness** property group.

0.0: Bending compression disabled.

**Shearing limit**

Compression limit for shearing constraints. This property is affected by **Shearing multiplier** in the **Fabric stiffness** property group.
0.0: Shearing compression disabled.

Fabric stretch properties

Note
For Fabric stretch properties, reduce Stiffness of Tether constraints or increase its Scale to allow cloth to stretch.

<table>
<thead>
<tr>
<th>Fabric stretch</th>
</tr>
</thead>
<tbody>
<tr>
<td>Horizontal limit</td>
</tr>
<tr>
<td>Vertical limit</td>
</tr>
<tr>
<td>Bending limit</td>
</tr>
<tr>
<td>Shearing limit</td>
</tr>
</tbody>
</table>

Horizontal limit
Stretch limit for horizontal constraints. This property is affected by Horizontal multiplier in the Fabric stiffness property group.

0.0: Horizontal stretch disabled.

Vertical limit
Stretch limit for vertical constraints. This property is affected by Vertical multiplier in the Fabric stiffness property group.

0.0: Vertical stretch disabled.

Bending limit
Stretch limit for bending constraints. This property is affected by Bending multiplier in the Fabric stiffness property group.

0.0: Bending stretch disabled.

Shearing limit
Stretch limit for shearing constraints. This property is affected by Shearing multiplier in the Fabric stiffness property group.

0.0: Shearing stretch disabled.

Tether constraints properties

<table>
<thead>
<tr>
<th>Tether constraints</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stiffness</td>
</tr>
<tr>
<td>Scale</td>
</tr>
</tbody>
</table>

Stiffness
Stiffness for tether constraints.

0.0: Tether constraints disabled.

1.0: Tether constraints behave like springs.
**Scale**

Scale factor for tether constraint **Stiffness**

**Quality properties**

- **Solver frequency**
  - Target solver iterations per second. The executed number of iterations per second may vary dependent on many performance factors. However, at least one iteration per frame is solved regardless of the value set.

- **Acceleration filter iterations**
  - Number of iterations to average the delta time factor used for gravity and external acceleration.

- **Remove static triangles**
  - Enable to remove triangles composed of static cloth particles. Enabling this property improves performance, however the removed static cloth particles will not be present for collision and self collision calculations.

**Comment**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **Comment** component allows you to add long-form text comments for component entities. When enabled, the **Comment** component displays a dialog box that expands based on the size of the comment that you enter. The following examples demonstrate how you can use the comment text box:

- Explain how the scripts or components on an entity interact with other scripts or components
- Describe how everything in a level ties together
- Send descriptions, instructions, or notes to team members
Comment Properties

The Comment component has the following property:

Comment text box

Stores the user comment for the component entity.

Default: None

Using the Comment Component

You can use this feature by adding the component to an entity in your level.

To use the Comment component

1. In Lumberyard Editor, right-click the viewport in your level, and click Create entity.
2. In the Entity Inspector, click Add Component.
3. Under Editor, click Comment.
4. In the Entity Inspector, under Comment, add comments for the component entity in the text box.

Decal

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Decal component to place a component on an entity.

Decal Component Properties

The Decal component has the following properties:

Visible

If selected, shows the decal.

Projection Type

Specifies the type of decal projection: Planar, On Terrain, or On Terrain and Static Objects.

Default value: Planar

Material

The decal's material file.

Sort Priority

Sort priority relative to other decals in the system.

Valid values: 0 – 255

Default value: 16
Decal

**Depth**
Projection depth for deferred decals.
Valid values: 0 – 10
Default value: 1

**Offset**
Allows offsetting the decal relative to the entity's position.
Default value: 0,0,0

**Opacity**
Degree of transparency for the decal (only available for deferred decals).

**Deferred**
Shows No for Planar and On Terrain Projection Type. Shows Yes for On Terrain and Static Objects.

**Max view distance**
The furthest distance at which this decal can be viewed.

**View distance multiplier**
Multiplier to the automatically computed fade-out camera distance.

**Minimum spec**
Minimum spec for the decal to be active.

**EBus Request Bus Interface**
Use the following request function with the EBus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

**SetVisibility**
Sets an explicit value (true/false) on the decal's visibility.

**Parameters**
- true or false

**Show**
Shows the decal.

**Parameters**
- None

**Hide**
Hides the decal.
Environment Probe

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Environment Probe component to achieve the right visual quality for a space. Environment probes help to determine proper reflections, ambient diffuse values, particle diffuse values, and shadow colors.

For information about how to blend environment probes to create a smooth transition, for example, from day to night, see Blending Environment Probes (p. 1252).

The Environment Probe component has the following settings:

Visible
  Shows the light.

On initially
  Specify if the light is on when created.

General Settings

See the following general settings:

Color
  The color of the light.

Diffuse multiplier
  Sets the strength of the diffuse color.

Specular multiplier
  Sets the strength of the specular brightness.

Environment Probe Settings

See the following environment probe settings:

Area dimensions
  The width, height, and depth in meters of the environment probe's effective area.
Sort priority

Priority number for probe rendering. Lower priority numbers (for example, 0 or 1) are rendered on top of the higher priority numbers (for example, 100).

Resolution

Cubemap resolution in pixels that is generated by this probe.

Box projected

Enables box projection. Does not require regeneration of the cubemap.

Box height

Height of the box projection.

Box length

Length of the box projection.

Box width

Width of the box projection.

Attenuation falloff

The value that the light begins to falloff. For example, a value or 1.0 means the light starts to fall off at 1.0 meter.

Options

See the following options:

View distance multiplier

Adjusts the maximum view distance. For example, 1.0 uses the default and 1.1 is 10% farther than the default.

Minimum spec

Minimum specification value at which the light is enabled.

Voxel GI mode

Mode for light interaction with voxel global illumination (GI).

Use VisArea

Light is affected by visible areas.

Indoor only

Light is only rendered indoors.

Affects this area only

Light affects only the immediate area.

Volumetric fog only

Light affects only volumetric fog.

Volumetric fog

Light affects volumetric fog and surrounding area.
**Animation**

See the following animation settings:

**Style**

Enter a number to specify a preset light animation curve to play as defined in the `Light.cfx` file. Valid values are 0 to 48. You can also use values 40 to 48 for testing and debugging.

**Speed**

Multiple of the base animation rate. For example, a value of 2.0 makes an animation play twice as fast.

**Phase**

Animation start offset from 0 to 1. A value of 0.1 is 10% into the animation. For example, you can use this setting to prevent lights in the same scene, with the same animation, from being animated in unison.

**Cubemap Generation**

See the following cubemap generation settings:

**Cubemap**

Click **Generate** to generate or regenerate a cubemap for this probe. The button is enabled only when **Use customized cubemap** is deselected.

Click **Reset** to reset a cubemap for this probe.

**View cubemap**

Displays a preview of the cubemap in the viewport. You can only select this option when a cubemap exists.

**Use customized cubemap**

If selected, you can specify a custom cubemap for **Cubemap asset**. If deselected, a cubemap is generated.

**Cubemap asset**

File path for the cubemap asset.

**Additional Resources**

For more information about the **Environment Probe** component, see the following:

- Intro to Environment Lighting
- Getting Started: Using Lighting Tutorial (video)

**EBus Request Bus Interface**

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).
All light components share common EBus functions. For more information, see Light Components EBus Request Bus Interface (p. 548).

FastNoise Gradient

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **FastNoise Gradient** component generates gradient signals with pseudorandom values. The values are mapped to the world positions in the game project. It uses the third-party, open source FastNoise library, which provides a collection of noise algorithms to generate different noises. You can interpret the values to produce a variety of game effects throughout the world. For example, you can use this component with the Vegetation Gem to randomly scatter vegetation throughout your world.

The generated gradient signals can be used with other components provided by the **Gradient Signal** gem.

The **FastNoise Gradient** component is provided by the section called “Fast Noise Gem” (p. 1127).

Properties

The **FastNoise Gradient** component has the following properties. The properties listed varies depending on the **Noise Type** property.

**Preview and Preview Settings**

A preview image of the gradient signal.

**Noise Type**

The type of pseudorandom algorithm used to generate noise.

- **Value**: First, this algorithm generates noise in a similar way as the **White Noise** noise type. Then, each value is interpolated with other surrounding values. The result looks like a zoomed-out version of the **White Noise** noise type.
- **Value Fractal**: First, this algorithm generates noise in a similar way as the **Value** noise type. Then, it creates fractals using those values.
- **Perlin**: The perlin noise algorithm generates noise in a more natural, ordered sequence. This noise type is well-suited for modeling natural phenomena such as clouds, water, and vegetation distributions.
• **Perlin Fractal**: First, this algorithm generates noise in a similar way as the **Perlin** noise type. Then, it creates fractals using those values.

• **Simplex**: This algorithm generates noise in a similar way as the Perlin noise type, but with less directional artifacts and improved computational complexity.

• **Simplex Fractal**: First, this algorithm generates noise in a similar way as the **Simplex** noise type. Then, it creates fractals using those values.

• **Cellular**: First, the cellular noise algorithm selects random feature points throughout the world and assigns each a value. Then, the gradient signals mapped to the world coordinates have the same value as its closest feature point. The result looks like clusters of different values.

• **White Noise**: This algorithm generates pseudo-random values using the world coordinates. The result produces extremely different values for adjacent world points.

• **Cubic**: First, this algorithm generates noise in a similar way as the **White Noise** noise type. Then each value is interpolated with other surrounding values using a cubic function. The result looks similar to the **Perlin** noise type, but with less directional artifacts and a higher occurrence of extreme values.

• **Cubic Fractal**: First, this algorithm generates noise in a similar way as the **Cubic** noise type. Then, it creates fractals using those values.

### Random Seed

The algorithm uses this value to generate a random number sequence. Different values generate different sequences. The slider goes from 1 to 100, but you can enter any value from 1 to 214748647.

### Frequency

*A value that scales the generated noise.* A smaller value zooms into the noise, making the noise appear larger and less frequent. A larger value zooms out of the noise, making the noise appear smaller and more frequent.

### Octaves

*Fractal noise types only.* The number of repetitions in the algorithm to generate Fractal noise. A higher value causes finer details in the noise. Values greater than 4 are almost unnoticeable.

### Lacunarity

*Fractal noise types only.* A multiplier that defines how much the frequency changes with each octave. A smaller value zooms into the noise, making the noise appear larger and less frequent. A larger value zooms out of the noise, making the noise appear smaller and more frequent.

### Gain

*Fractal noise types only.* A multiplier that blends between the lower octaves and the higher octaves. A smaller blends towards the lower octaves, a higher value blends towards the higher octaves.

### Distance Function

*Cellular noise types only.* The cellular noise algorithm uses the distance function to calculate which cell values to use for a given point in the world. It affects how the cellular shape is distorted.

### Return Type

*Cellular noise types only.* The cellular noise calculation returns this value and uses it to generate the gradient signal.

- **Distance2Div** the distance of the closest feature point divided by the distance of the second-closest feature point.
- **Distance** the distance to the nearest feature point at any given world position.
- **Distance2** the distance to the second-nearest feature point at any world position.
- **Distance2Add** the distance of the two closest feature points added together.
• **Distance2Mul** the distance of the two closest feature points multiplied together.
• **Distance2Sub** the distance of the two closest feature points subtracted together.
• **CellValue** the value of the nearest feature point at any given world position.

**Jitter**

*Cellular noise types only.* A value that scales the location of the feature points. For ideal results, use a value between 0.0 and 1.0, where 0.0 provides no jitter.

**Advanced Settings**

In addition, the **FastNoise Gradient** component has the following advanced properties:

**Interpolation**

*Value, Value Fractal, Perlin, and Perlin Fractal noise only.* The noise generation algorithm uses this type of interpolation when calculating noise values.
• **Linear** interpolation provides angular artifacts.
• **Hermite** interpolation provides smoothed, blurred noise.
• **Quintic** interpolation is similar to hermite, but provides more defined edges without calculating angular artifacts.

**Fractal Type**

*Fractal noise types only.* The noise generation algorithm uses this type of fractal when calculating the noise values.
• **FBM (Fractional Brownian Motion)** adds multiples of frequencies and amplitudes of the noise signal together.
• **Billow** is a variant of FBM where the absolute value of multiple frequencies and amplitudes are added together. This produces extreme gradient signal values.

• **Rigid Multi** is also a variant of FBM, where the inverse of the absolute value of multiple frequencies and values of the noise signal are subtracted from each other. This produces extreme elevations in the gradient signal values.

## Fog Volume

This feature is in *preview* release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the **Fog Volume** component to create fog effects in your game. For more information, see Volumetric Fog (p. 1825).

By default, the **Fog Volume** component renders in nonvolumetric mode. To enable volumetric rendering, you must specify the `e_VolumetricFog` console variable. For more information, see Console Variables for Volumetric Fog (p. 1827) and Using the Console Window (p. 210).

**Note**

The **Fog Volume** component must have a **Box Shape** (p. 818) component attached to the entity. The entity uses the **Box Shape** component to set the area of the fog.

You can also change global fog properties in the **Time of Day** editor. For more information, see Setting Global (Time of Day) Fog (p. 1823).
Contents

- Fog Volume Properties (p. 594)
  - Rendering General (p. 595)
  - Fall Off Settings (p. 595)
  - Ramp (Volumetric Fog Only) (p. 596)
  - Density Noise (Volumetric Fog Only) (p. 597)
  - Light Component Fog Properties (p. 597)
- Volumetric Fog Examples (p. 599)

Fog Volume Properties

The Fog Volume component has the following properties:

Volume type

Specify the volume shape, which can be an ellipsoid or cuboid. A Box Shape (p. 818) component attached to the entity defines the boundaries for both shapes.

Color

Color of the fog. Specify a color with the Color Picker.

Default: 255, 255, 255

HDR Dynamic (Nonvolumetric fog only)

Specify the brightness of the fog color.

Default: 0

Valid values: 0 – 20

Use global fog color

If true, the Color property is ignored, and the global fog color is used instead. In the Time of Day editor, you can specify the global fog color with the Color (bottom) parameter. For more information, see Setting Global (Time of Day) Fog (p. 1823).

Default: False

Soft edges

Specify a factor to soften the edges of the fog volume. When you view the fog volume, the fog gradually fades into the surrounding area.

Default: 1

Valid values: 0 to 1

Wind influence (Volumetric fog only)

Specify the influence that the global wind has on the fog volume.

Default: 1

Valid values: 0 to 20

Fog Density

Specify the density of the fog volume.
Density offset
Specify the offset of the density of the fog volume. Specify higher values to reduce fog density around the edges.
Default: 0
Valid values: -1000 to 1000

Near cutoff
Stops rendering the fog volume, depending on the camera distance from the object, in meters.
Default: 0
Valid values: 0 to 2

Rendering General
The Fog Volume component has the following rendering options:

Minimum spec
Minimum specifications for the fog volume to be active.
Default: Low

View distance multiplier
Adjusts the maximum view distance.
Default: 1
Valid values: 0 to ∞ (infinity)

Ignore vis. areas
Specify whether the Fog Volume component affects visible areas and clip volumes. If true, the fog volume does not affect visible areas and clip volumes.
Default: False

Affect this area only
Specify whether the Fog Volume component affects only the specified area. If false, the Fog Volume component can affect multiple visible areas and clip volumes.
Default: False

Fall Off Settings
The Fog Volume component has the following fall off settings:

Longitude
Direction of the fall off or where the fog starts to fade in the world space. Specify a value of 0 so that the fog starts to fade on the east side of the Fog Volume component.
Fog Volume

Default: 0
Valid values: 0 to 360

**Latitude**

Direction of the fall off or where the fog starts to fade in the world space. Specify a value of 90 so that the fog starts to fade on top of the Fog Volume component.

For more information, see Volumetric Fog Examples (p. 599).

Default: 90
Valid values: 0 to 360

**Shift**

Specify how much to move the fog density along the fall-off direction. Specify a positive value to move thicker fog layers along the fall off direction of the fog volume. Specify a negative value to move thicker layers along the opposite direction.

Default: 0
Valid values: −50 — 50

**Scale**

Scales the density distribution along the fall-off direction. Specify higher values to make the fog fall off more rapidly.

Default: 1
Valid values: −50 to 50

**Ramp (Volumetric Fog Only)**

The Fog Volume component has the following ramp options:

**Start**

Specify the start distance of the fog density ramp, in meters.

Default: 1
Valid values: 0 to 30000

**End**

Specify the end distance of the fog density ramp, in meters.

Default: 50
Valid values: 0 to 30000

**Influence**

Specify the influence of the fog density ramp.

Default: 0
Valid values: 0 to 1
Density Noise (Volumetric Fog Only)

The Fog Volume component has the following density noise options:

**Scale**

Specify the noise value for the fog volume density. This parameter defines the thickness of the individual patches of fog. Specify a low value to thin out the fog density and increase the space between patches of fog.

Default: 1

Valid values: 0 to 10

**Offset**

Offsets the noise value for the density. Specify a value to break the solid shape of the fog volume into patches.

Default: 1

Valid values: –2 to 2

**Time frequency**

Specify the time frequency of the noise for the density. Specify high frequencies to create fog that changes quickly. You can use this parameter to cause the individual fog patches to morph into different shapes over the course of their lifetime.

*Note*

As a best practice, specify a low value. High values can cause the fog to morph too quickly.

Default: 0

Valid values: 0 to 1

**Spatial frequency**

Specify the spatial frequency of the noise for the density. You can use this parameter to define the amount of patchy fog in the fog volume. You can increase the z-value to create a layered effect in the volume; this stacks fog patches on top of each other. Specify higher x- and y-values to create more individual fog patches within the volume.

Default: 10, 10, 10

Light Component Fog Properties

If you add light components to your entities, you can also specify following parameters for light components:

**Volumetric Fog**

Enables the light to affect volumetric fog.

**Volumetric Fog Only**

Enables the light to affect volumetric fog and not affect other objects, such as meshes.

Example

In the following example, the parameter **Volumetric Fog On** is enabled for the light component.
Example

In the following example, the parameter Volumetric Fog is disabled for the light component.

For more information about light components, see Rendering (p. 534).
Volumetric Fog Examples

Example

In the following example, the value for **Latitude** is 0. The fall off appears on the left side of the fog volume, along the x-axis.

![Fog Volume Example 1](image1.png)

Example

In the following example, the value for the **Latitude** is 90. The fall off appears on the top for the fog volume.

![Fog Volume Example 2](image2.png)
**Note**
For the **Fog Volume** component, the **Latitude** and **Longitude** parameters work in the world space. Local transform changes do not affect these parameters. The **Latitude** and **Longitude** parameters orient the fog volume on the xy-plane. You can specify different values to orient the fog volume in any direction.

**Geom Cache**

This feature is in **preview** release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

The **Geometry Cache** component renders mesh data and can play vertex-based animations from **Alembic** files. With this, you can simulate highly complex geometry effects that might otherwise be unachievable.
Geom Cache Parameters

Use the following parameters to customize your geometry cache.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cast Shadows</td>
<td>When selected, the geometry cache casts shadows.</td>
</tr>
<tr>
<td>Visible</td>
<td>When selected, the geometry cache is visible.</td>
</tr>
<tr>
<td>Use Vis Areas</td>
<td>When selected, the geometry cache can be obscured by vis areas and portals.</td>
</tr>
<tr>
<td>Play on Start</td>
<td>When selected, the geometry cache animation plays in the editor and plays when the component initializes.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Loop</td>
<td>When selected, the geometry cache animation loops indefinitely.</td>
</tr>
<tr>
<td>View Distance Multiplier</td>
<td>This value is multiplied by the Max View Distance parameter to get the true maximum viewing distance.</td>
</tr>
<tr>
<td>LOD Distance Ratio</td>
<td>This affects how LODs are chosen. A lower value means that less detailed LODs are used at shorter view distances.</td>
</tr>
<tr>
<td>Start Time</td>
<td>The time in seconds into the animation that the component start playing at. For example, use 0.0 to start at the beginning. Use 1.0 to start 1 second into the animation.</td>
</tr>
<tr>
<td>Min Spec</td>
<td>The minimum engine spec that this Geometry Cache renders at. To render at all specs, select Low.</td>
</tr>
<tr>
<td>Max View Distance</td>
<td>The maximum distance from which this geometry cache can be seen. This value is multiplied by the View Distance Multiplier to get the true maximum view distance.</td>
</tr>
<tr>
<td>Geometry Cache Asset</td>
<td>The geometry cache asset to render.</td>
</tr>
<tr>
<td>Stand-in</td>
<td>The entity to render (instead of the geometry cache) when the current camera is farther away than the Stand-in Distance. The given entity must have a mesh component attached.</td>
</tr>
<tr>
<td>Last Frame Stand-in</td>
<td>The entity to render (instead of the geometry cache) when the animation is on the last frame. The given entity must have a mesh component attached.</td>
</tr>
<tr>
<td>First Frame Stand-in</td>
<td>The entity to render (instead of the geometry cache) when the animation is on the first frame. The given entity must have a mesh component attached.</td>
</tr>
<tr>
<td>Stand-in Distance</td>
<td>Defines how far away the current camera must be from the geometry cache's center before the Stand-in takes its place.</td>
</tr>
<tr>
<td>Stream In Distance</td>
<td>Defines how close the camera has to be for the geometry cache to start streaming in animation data to prepare for animation.</td>
</tr>
<tr>
<td>Material Override</td>
<td>An override material to use instead of the one given by the geometry cache asset.</td>
</tr>
</tbody>
</table>
GeometryCacheComponentRequests Interface

This EBus is used to communicate to an entity with a **Geometry Cache** component. This is available at runtime and at edit time and can be accessed from C++, Lua and ScriptCanvas. Some functionality may be restricted to C++ exclusively.

For more information about using the event bus (EBus) interface, see [Working with the Event Bus (EBus) system](p. 1851).

**GeometryCacheComponentRequests**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Play</td>
<td>Begins playing the geometry cache's animation. If the animation is already playing, this does nothing. From here the animation can be paused with Pause or stopped with Stop.</td>
<td>None</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>Pause</td>
<td>Pauses the geometry cache's animation. From here the animation can be resumed by calling Play.</td>
<td>None</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>Stop</td>
<td>Stops the geometry cache's animation. The animation is brought back to the First Frame where the First Frame Stand-in can be used. From here the animation can be restarted with Play.</td>

### GeometryCacheComponentNotifications Interface

This EBus is used to react to events that take place in the **Geometry Cache** component.

For more information about using the event bus (EBus) interface, see *Working with the Event Bus (EBus) system* (p. 1851).

#### GeometryCacheComponentNotifications

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>OnPlaybackStart</td>
<td>Event that triggers when geometry cache playback starts.</td>
<td>None</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>OnPlaybackPause</td>
<td>Event that triggers when geometry cache playback pauses.</td>
<td>None</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>OnPlaybackStop</td>
<td>Event that triggers when geometry cache playback stops.</td>
<td>None</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>OnStandinChanged</td>
<td>Event that triggers when the geometry cache changes which stand-in is in use.</td>
<td>StandinType</td>
<td>None</td>
<td>Yes</td>
</tr>
</tbody>
</table>

This does trigger if a stand-in is turned off and the Geometry Cache becomes active instead.

The parameter includes which StandinType the Geometry Cache has changed to.

The following is a notification bus sample script.

```plaintext
function example:OnActivate()
```
The following is a more complete example script of how to use the geometry cache from Lua. See the inline comments for descriptions of what the script is performing at that point.

```lua
-- Load helpers for handling input events from Lua.
local inputMultiHandler = require('Scripts.Utils.Components.InputUtils')

local geomcachetest = 
{ Properties = 

|-- Specify an existing entity to swap with an existing stand-in
replacementStandin = {default = EntityId()} 
},

function geomcachetest:OnActivate() 

|-- Subscribe to geometry cache notifications on this entity
self.geometryCacheNotificationHandler = GeomCacheComponentNotificationBus.Connect(self, self.entityId); 

|-- Subscribe to some input events
|-- Here it is assumed that 4 events are hooked up to input
self.inputHandlers = inputMultiHandler.ConnectMultiHandlers{
    [InputEventNotificationId("PlayAnimation")] = {
        OnPressed = function(floatValue) self:PlayAnimation(floatValue) end,
    },
    [InputEventNotificationId("PauseAnimation")] = {
        OnPressed = function(floatValue) self:PauseAnimation(floatValue) end,
    },

High Quality Shadow

This feature is in preview release and is subject to change.

Version 1.28
614
You can use the **High Quality Shadow** component to give an entity its own shadow map that is a higher resolution than you could achieve with a global shadow map. This component applies to light from the sun and helps provide crisp, well-defined shadows. You can use this on main characters or prominent elements to improve their appearance.

This component can impact performance and memory, and should be used sparingly. As such, it can be useful to dynamically change the `Enabled` setting as performance needs change during the game. Use the `Set Enabled (p. 2670)` node to enable or disable the **High Quality Shadow** component in the Script Canvas editor. For example, if your main character has a high quality shadow, you can enable it during cutscenes and disable it during gameplay.

For more information, see **Shadow Nodes (p. 2669)**.

### High Quality Shadow Component Properties

The **High Quality Shadow** component has the following properties:

- **Enabled**
  
  Enable the shadow map.

- **Const Bias**

  Avoid the self shadow artifacts.

- **Slope Bias**

  Avoid the self shadow artifacts.

- **Jitter**

  Filter kernel size, which directly affects shadow softness.

- **Bounding Box Scale**

  Set the scale factor for the bounding box of the selected entity. This is useful if the engine bounding box is too small or too large.

- **Shadow Map Size**

  Set the size of the custom shadow map. The value automatically rounds to the next power of two.

### Infinite Ocean

You can use the **Infinite Ocean** component to add an ocean surface to your level. The ocean expands to the horizon, no matter where the camera moves in the environment.

- Ocean simulation is based on a fast Fourier transform (FFT) noise-based gradient, normal, and height maps, and mixes multiple frequencies and scale for ambient waves.
• Players can interact with ocean waves and generate wave propagation, such as shooting at the water.
• On higher-end machines, vertex displacement is used and supports additional water interaction, such as buoyancy and floating objects.

Note
To enable the Infinite Ocean component, you must enable the Water gem. For more information, see Add modular features and assets with Gems (p. 1064).

Example Infinite Ocean Component

Water rendering in real time is complex due to visual and physical contributing factors. For example, light behaves differently when it moves from air into water. Most sunlight reflects off the ocean, but a large amount also penetrates into the water, which absorbs light more strongly than air. The visible light consists of a rainbow with different wavelengths, which appears as different colors.

For example, blue light penetrates farther in the water, giving the ocean its blue and green colors. In contrast, the ocean absorbs red, orange, and yellow wavelengths, which removes these colors. When light hits a substance, the light does one of the following:

• The light hits molecules of a substance and then scatters and bounces off in different directions.
• The light passes through the substance.
• The substance absorbs the light, either completely or only some wavelengths. In Lumberyard this is called underwater fog.
In Lumberyard, various elements such as sunlight, reflections, and environment probes contribute to how the ocean surface renders. These elements approximate how light is scattered and absorbed in the ocean.

**Topics**
- Adding the Infinite Ocean Component (p. 617)
- Understanding Water Properties (p. 617)
- Infinite Ocean Component Properties (p. 618)
- Water Shader Material for the Infinite Ocean Component (p. 629)
- Best Practices Working with the Infinite Ocean Component (p. 630)
- Additional Workflow (p. 630)
- Console Variables for the Infinite Ocean Component (p. 632)
- Infinite Ocean Component with the Track View Editor (p. 634)
- Infinite Ocean Component Request Bus Interface (p. 635)
- Using the Infinite Ocean Component with Script Canvas (p. 641)

**Adding the Infinite Ocean Component**

**To create an infinite ocean in your level**

1. Create an entity (p. 463) in your level.
2. In the **Entity Inspector**, click **Add Component**, and then choose the **Infinite Ocean** component.

   For more information, see Working with Components (p. 479).

**Understanding Water Properties**

When working with water properties, the color and appearance come from two places:

- Reflections that occur on the surface.
- How light interacts with water molecules and suspended particles in the water. In Lumberyard this is called *underwater fog*.

The following images demonstrate how bright highlights come from the sky reflection, mostly at sharp angles or in bright reflection points. Notice how the underwater fog appears differently, as particles such as algae, dust, and plankton can change the appearance of the water.

**Example**

In the following example, the underwater fog appears greenish.
Example

In the following example, the underwater fog appears brown.

Avoid using only the reflection to achieve the appearance that you want. The water appearance is the sum of the reflection on the ocean surface and the underwater fog below the surface.

Infinite Ocean Component Properties

Use the following parameters for the Infinite Ocean component to change how the ocean appears.

Contents
- General (p. 619)
- Animation (p. 619)
- Fog (p. 620)
- Caustic (p. 622)
- Reflection (p. 623)
- Advanced (p. 624)
- Tessellation Examples (p. 624)
General

See the following general parameters.

Enable Ocean Bottom

Toggle the infinite plane below the ocean.

Default value: True

Water Material

Render the ocean with this assigned material. The material must be a water shader.

You can find the default material in the \lumberyard_version\dev\Engine\EngineAssets\Materials\Water\ocean_default.mtl directory.

Default value: ocean_default.mtl

Animation

Use the following animation parameters to control the movement of the waves and the scrolling of the water texture, with the wind speed and direction.

Waves Amount

Specify the frequency of ocean waves. Higher values create waves that appear smaller and closer together.

Default value: 0.75

Valid values: 0.20 to 5.0

Waves Size

Specify the height of ocean waves.

Tip

For Wave Size, higher values work better with lower values for Waves Amount.

Default value: 1.25

Valid values: 0 to 3.0

Waves Speed

Specify the speed of ocean wave movement.

Default value: 1.0

Valid values: 0 to 5.0

Wind Direction

Specify the direction of the ocean wind, in radians.

Default value: 1.0

Valid values: 0 to 6.28

Wind Speed

Specify the speed of the ocean wind.
Fog

Use the following fog parameters to control the density and color of the ocean (underwater fog). This simulates how light bounces off, is absorbed by, and scatters with the particulate matter in the water.

Color

Specify the color to render the underwater fog.

Default value: 5, 36, 32

Color Multiplier

Influence the intensity of the underwater fog color with this multiplier.

Default value: 0.15

Valid values: 0 to 1.0

Density

Specify the density of the underwater fog. Higher values make transparency fall more quickly.

Default value: 0.07

Valid values: 0 to 1.0

Near Fog Color

Reduce the underwater fog color to this color near shallow depths.

Tip

Keep the default value or specify a near-black color.

Default value: 1, 7, 5

Example Low Density

In the following example, the value for the Density parameter is low. This makes the water more transparent, so that you can see the legs of the pier and the sand.
Example High Density

In the following example, the value for the **Density** parameter is high. This makes the water appear cloudier and obscures details like the legs of the pier and sand.
Caustic

The following caustic parameters control how the refracted rays of light animate and project on objects below the ocean surface.

Enable Caustics

Apply the caustic effect of the ocean on geometry below the ocean surface.

Default value: True

Depth

Maximum depth below the ocean height at which caustic effects still appear, in meters.

Default value: 8

Valid values: 0 to 100.0

Intensity

Specify the intensity of the light in the ocean caustic effect. A value of 0 turns off caustic effects. Near-zero values show caustic effects strongly. For example, a value of 0 to 0.01 is a sudden change.

Default value: 1

Valid values: 0 to 10.0

Tiling

Specify the amount of ocean caustic effect that is tiled. Lower values spread out the effect and higher values tighten the detail.

Default value: 2
Valid values: 0.10 to 10.0

Distance Attenuation

Specify the attenuation distance (from the camera) that caustic effects of the ocean are applied.

Lower values apply caustic effects closer to the camera.

Larger values apply caustic effects farther from the camera.

Default value: 10.

Valid values: 0 to 100.0

Example Caustics

The following is an example of how light interacts with the water below the surface.

Reflection

The following reflection parameters are set for the resolution of the reflection texture map (this is based on screen size * resolution scale) and a set of flags that the reflection system uses when the camera is above the ocean.

Resolution Scale

Scale of the screen resolution that is used to render ocean reflections.

Default value: 0.50

Valid values: 0 to 1.0
Reflect Entities
Specify whether entities are included when reflections are rendered in the ocean.
Default value: True

Reflect Objects
Specify whether entities with the Mesh component attached are included when reflections are rendered in the ocean.
Default value: True

Reflect Terrain
Specify whether terrain detail materials are included when reflections are rendered in the ocean.
Default value: True

Reflect Particles
Specify whether particles are included when reflections are rendered in the ocean. For example, if your level has a flame particle effect on a torch, a value of false means that the torch flame does not reflect into the ocean.
Default value: True

Advanced
In most cases, you don't need to change the values for the advanced parameters. For example, you should set the Tessellation parameter once and not during runtime updates.

Tessellation
Specify the amount of ocean water surface geometry tessellation. For more information, see Tessellation Examples (p. 624).

Note
The Tessellation parameter affects the 3D mesh for the ocean triangles. Higher values create more polygons and a smoother ocean surface, at a higher performance cost.

Default value: 85
Valid values: 10 to 500

Godrays Enabled
Enable god rays (or sun beams) to appear below the ocean surface.
Default value: True

Underwater Distortion
Specify the amount of the scene that is distorted when it renders while the camera is underwater. For best practice, specify a value less than 1.0.

Default value: 1
Valid values: 0 to ∞

Tessellation Examples
The Infinite Ocean component has controls for setting the level of tessellation (number of vertices and polygons) for the generated mesh that defines the surface of the ocean.
Note
We recommend that you set and configure the **Tessellation** parameter once to achieve the desired look and feel for your level. Although you can change this value at run time, this forces Lumberyard to rebuild the mesh, which can cause an undesirable hitch in performance. If you must change the tessellation value during run time, we recommend that you do so under controlled conditions where you can hide the changes.

**Example Tessellation = 10, low setting**

At lower settings, there is a noticeable impact on the visual quality.
In the following example, the lower visual quality is more noticeable with higher values for **Waves Size** parameter. There are fewer vertices to displace in the simulation, so the waves are not well-defined.

Example Tessellation = 85, default setting

In most cases, the default settings for the **Tessellation** parameter are sufficient.
Specifying lower values for the **Waves Amount** parameter works better with higher values on the **Waves Size** parameter, but the higher tessellation smooths out the ocean surface.
Example Tessellation = 500, high setting

In the following example, higher values for the **Tessellation** parameter minimally impact the visual quality.

Specifying a high value for the **Waves Amount** parameter creates a choppier ocean surface, so it's helpful to increase the value for the **Tessellation** parameter.
Water Shader Material for the Infinite Ocean Component

The Infinite Ocean component is compatible only with a material that uses the water shader, such as the default ocean_default.mtl file. The water shader is a dedicated shader that Lumberyard uses only to render the ocean, and adds effects such as reflection, ripple, and foam.

Example Water Shader

The following is an example of how you can configure the water shader material in the Material Editor.
Note
When you set up water materials for the ocean, disable the Water Volume parameter. When you set up water material for other types of water volumes, such as lakes and rivers, enable the Water Volume parameter.

For more information, see Water Shader (p. 1715).

For lakes, rivers, and other bodies of water, use the WaterVolume Shader (p. 1719).

Best Practices Working with the Infinite Ocean Component

See the following best practices when working with the Infinite Ocean component.

• You can use the default parameters for the Infinite Ocean component and the ocean_default.mtl material to create a default ocean, but you can change the settings as needed.

  Note
  Changing the ocean_default.mtl material affects any level that has an ocean that uses the material.

• You can change the colors that contribute to how the ocean appears.
  • For the Infinite Ocean component, use the Color and Near Fog Color parameters. For more information, see Fog (p. 620).
  • For the water material (ocean_default.mtl), use the Diffuse Color and Specular Color parameters. For more information, see Water Shader Material for the Infinite Ocean Component (p. 629).

• Use both reflections and the underwater fog to achieve the water appearance that you want. For more information, see Reflection (p. 623) and Fog (p. 620).

• If your environment looks dull, you'll get dull reflections in the water. Create an interesting sky look and skyline gradient. If you are creating a night scene, use bright spots such as city lights.

• Use foam effects sparingly.

• Ocean reflection draw distance is tied to the terrain detail draw distance.

To customize the ocean appearance for a specific level, do the following:

1. Navigate to the lumberyard_version/dev/Engine/EngineAssets/Materials/Water/ocean_default.mtl directory and copy the ocean_default.mtl file to create another file.

2. Specify the new file for the Infinite Ocean component. See General (p. 619).

3. In the Material Editor, customize the material settings for your current level.

Tip
For best performance, we recommend the following:

• If your level doesn't require sun reflection, disable these parameters.

• If your level doesn't require foam, disable this parameter.

• If you don't need caustic rendering, set the Caustic Multiplier parameter to 0 to disable it.

Additional Workflow

See the following when working with the Infinite Ocean component.

Note
The e_VolumetricFog console variable is currently not compatible with the Infinite Ocean component and can cause rendering issues for underwater fog.
Slices

- You can create a slice that contains an entity with an Infinite Ocean component; however, not all slice features are supported at this time.
- You can dynamically spawn a slice that contains an Infinite Ocean component; however, asynchronous loading of the Infinite Ocean component is not supported at this time.
- Only one Infinite Ocean component can be active at a time. If you create a second Infinite Ocean component in your level or place a slice that contains another Infinite Ocean component, an error appears in the console.
- You can load more than one Infinite Ocean component in a scene, but you must manage which entity has the active component.

For example, in the Entity Inspector, use the Start Active parameter to toggle the active state of the entity to which the Infinite Ocean component is attached.

This allows you to have multiple Infinite Ocean components, each with a different look and feel, set their starting states (activate one and disable the others), and then toggle the active state during run time to control which ocean is rendered.

Parent and Child Entities

- You can use the entity's Transform (p. 878) component to control the surface height of the Infinite Ocean component.
- Specify the z-axis of the Transform component to set the Infinite Ocean component's height.
- The Infinite Ocean component respects the hierarchical transforms, so if the entity is a child nested within a hierarchy, the parent transform above it contributes to the height of the Infinite Ocean component.

Ocean Bottom

The ocean bottom feature toggles on an infinite plane that draws below the ocean. The plane draws black, and its main purpose is to fix the depth buffer behind the water in areas beyond the level geometry.

- If you are using the ocean bottom, the parent transform of the Infinite Ocean component sets the ocean’s height. If the height of the ocean is near or below 0 and you are using the ocean bottom, there can be some visual anomalies.
- Normally, the ocean bottom height is set to 0 (z-axis is 0). This setting is not controlled by the parent transform.
- Since the ocean level can be freely transformed, including negative heights below 0, the ocean bottom is configured to always draw at least 5 meters below the height of the ocean surface.

Note
Currently, you can change the ocean bottom only in the code.

To change the ocean bottom settings

1. Navigate to the lumberyard_version/dev/Engine/Shaders/HWScripts/CryFX directory.
2. For the WaterOceanBottom.cfg shader, specify a value for the MIN_WATER_DEPTH parameter.

If you want a better looking ocean bottom near the visible playable area, we recommend that you create a large bottom ocean geometry with a material assignment to match the look and feel of your level.
### Console Variables for the Infinite Ocean Component

You can specify the following console variables to enable advanced settings for the **Infinite Ocean** component. In general, you don’t need to change these settings. For more information, see Using the Console Window (p. 210).

<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| e_HwOcclusionCullingWater | Specify the ocean occlusion culling so that the ocean doesn't render if it’s not visible. We recommend that you keep the default value of 1.  
0 = Off  
1 = On |
| e_WaterOcean | Enable or disable the ocean.  
0 = Disables the ocean.  
1 = Enables the ocean as normal.  
2 = Enables the ocean and fog in one frame. This can cause a small increase in performance but provides a slightly different look. |
| e_WaterOceanFFT | Enable or disable using fast Fourier transforms with water. This console variable has interdependencies with other console variables and should only be used with `sys_spec_water`.  
0 = Off  
1 = On |
| e_WaterTessellationSwathWidth | Used only in older style oceans (non-FFT water). If the value is negative, the triangle mesh generates normally. If the value is positive, the value determines the length of triangle strips used in the mesh. |
| q_ShaderWater | Control the shader quality of the ocean. This value should only be changed with other console variables that are controlled by the `sys_spec_water` console variable.  
Valid values: 0 to 3 |
| r_WaterReflectionsMinVisiblePixelsUpdate | Percentage of water reflecting pixels that are required to update the reflection every frame.  
For example, if the value is set to 0.4, the water’s reflection updates every frame as long as the ocean covers 40% or more of the screen. At least 40% of pixels is needed to show the reflection in the ocean.  
If the ocean covers less than 40% of the screen, the reflection no longer updates every frame.
<table>
<thead>
<tr>
<th>Console Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>frame. The update rate is then controlled by <code>r_WaterReflectionsMinVisUpdateDistanceMul</code> and <code>r_WaterReflectionsMinUpdateFactorMul</code>.</td>
<td>0 to 1</td>
</tr>
<tr>
<td><code>r_WaterReflectionsMinVisUpdateDistanceMul</code></td>
<td>Use this multiplier with the <code>r_WaterUpdateDistance</code> console variable to determine the update rate of the water reflection. This distance is from the camera's position, the last time the reflection is rendered to the current camera position.</td>
</tr>
<tr>
<td><code>r_WaterReflectionsMinUpdateFactorMul</code></td>
<td>A multiplier on the distance the camera is from the water (this value is always 0.3 or less). This distance is based on the camera's position and is used to determine the update rate of the water reflection. This distance is not based on what is in the camera's view.</td>
</tr>
<tr>
<td><code>r_WaterTessellationHW</code></td>
<td>Enable or disable DX11-style tessellated water. This value should only be changed with other console variables that are controlled by the <code>sys_spec_water</code> console variable.</td>
</tr>
<tr>
<td><code>r_WaterUpdateDistance</code></td>
<td>Distance that the camera normally needs to move before the reflection is updated. You can change the distance with the <code>r_WaterReflectionsMinVisUpdateDistanceMul</code> console variable.</td>
</tr>
<tr>
<td><code>r_WaterUpdateFactor</code></td>
<td>Determine how long to wait between updating water reflections.</td>
</tr>
</tbody>
</table>
**sys_spec_water**

This is a special data-driven console variable that controls other console variables related to the **Infinite Ocean** component and water volumes.

You can find the console variables that are defined by this value in the `sys_spec_water.cfg` file, located in the `lumberyard_version/dev/Engine/Config/CVarGroups/` directory.

In general, you don't need to change this file, and many of the console variables that are set in this file for different system specs do not affect the **Infinite Ocean** component.

---

### Infinite Ocean Component with the Track View Editor

You can add the **Infinite Ocean** component to an entity sequence in the Track View. This lets you control the component's parameters to be keyframes and changed along the timeline of the sequence.
Note
Some Infinite Ocean component parameters are not available in the Track View. The Wind Speed and Wind Direction parameters are not supported at this time.

For more information, see Using the Track View Editor (p. 1584).

Infinite Ocean Component Request Bus Interface

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

Lua Scripting

In general, the Lua scripting API for the Infinite Ocean component maps directly to the component properties with the Get* and Set* functions. However, there are some exceptions where there is only a Get function, and you can't directly set a value, such as the ocean height.

Note
You can specify float numbers for most functions, but some require an enumeration and/or a boolean value.

Example

```lua
function example:OnActivate()
    OceanEnvironmentRequestBus.Broadcast.SetFogDensity(2)
end
```

OceanLevel

Returns the height of the ocean in the world z-axis.

Note
There is no function to set the ocean level, since this parameter is attached to the Transform component.

Parameters

None

Return

Type: Float

Scriptable

Yes

Example

```lua
```

WaterTessellationAmount

Sets the amount of geometry tessellation for rendering the ocean surface.
Parameters
Type: Int

Return
Type: Int

Scriptable
Yes

Example
OceanEnvironmentRequestBus.Broadcast.SetWaterTessellationAmount(int)
OceanEnvironmentRequestBus.Broadcast.GetWaterTessellationAmount()

AnimationWindDirection and AnimationWindSpeed
Sets the direction and speed of the ocean wind.

Parameters
Type: Float

Return
Type: Float

Scriptable
Yes

Example
OceanEnvironmentRequestBus.Broadcast.SetAnimationWindDirection(float)
OceanEnvironmentRequestBus.Broadcast.GetAnimationWindDirection()
OceanEnvironmentRequestBus.Broadcast.SetAnimationWindSpeed(float)
OceanEnvironmentRequestBus.Broadcast.GetAnimationWindSpeed()

AnimationWavesSpeed, AnimationWavesSize, and AnimationWavesAmount
Specifies the animation parameters of the ocean waves, such as speed, size, and amount.

Parameters
Type: Float

Return
Type: Float

Scriptable
Yes

Example
OceanEnvironmentRequestBus.Broadcast.SetAnimationWavesSpeed(float)
OceanEnvironmentRequestBus.Broadcast.GetAnimationWavesSpeed()
OceanEnvironmentRequestBus.Broadcast.SetAnimationWavesSize(float)
OceanEnvironmentRequestBus.Broadcast.GetAnimationWavesSize()
OceanEnvironmentRequestBus.Broadcast.SetAnimationWavesAmount(float)
**ReflectResolutionScale**

Specifies the scale of the screen resolution to use for rendering ocean reflections.

**Parameters**
- Type: Float

**Return**
- Type: Float

**Scriptable**
- Yes

**Example**

```csharp
OceanEnvironmentRequestBus.Broadcast.SetReflectResolutionScale(float)
OceanEnvironmentRequestBus.Broadcast.GetReflectResolutionScale()
```

**ReflectionAnisotropic**

Enables the anisotropic filter for rendered ocean reflections.

**Parameters**
- Type: Boolean

**Return**
- Type: Boolean

**Scriptable**
- Yes

**Example**

```csharp
OceanEnvironmentRequestBus.Broadcast.SetReflectionAnisotropic(boolean)
OceanEnvironmentRequestBus.Broadcast.GetReflectionAnisotropic()
```

**ReflectRenderFlag**

For each reflection flag, you can specify how the ocean renders reflections.

You can specify the following flags:

- `ReflectionFlags.TerrainDetailMaterials`
- `ReflectionFlags.StaticObjects`
- `ReflectionFlags.Particles`
- `ReflectionFlags.Entities`

**Parameters**
- Type: Enum flag and boolean
Return

Type: Boolean
Scriptable
Yes

Example

OceanEnvironmentRequestBus.Broadcast.SetReflectRenderFlag(ReflectionFlags.TerrainDetailMaterials, boolean)

UseOceanBottom

Toggles the infinite plane below the ocean.

Parameters

Type: Boolean

Return

Type: Boolean
Scriptable
Yes

Example

OceanEnvironmentRequestBus.Broadcast.SetUseOceanBottom(boolean)
OceanEnvironmentRequestBus.Broadcast.GetUseOceanBottom()

GodRaysEnabled

Enables god rays (sun beams) under the ocean.

Parameters

Type: Boolean

Return

Type: Boolean
Scriptable
Yes

Example

OceanEnvironmentRequestBus.Broadcast.SetGodRaysEnabled(boolean)

UnderwaterDistortion

Specifies the amount of the scene that is distorted when it renders while the camera is underwater.
Parameters
Type: Float
Return
Type: Float
Scriptable
Yes
Example
OceanEnvironmentRequestBus.Broadcast.SetUnderwaterDistortion(float)

FogColor, FogColorMultiplier, and NearFogColor

Specifies the color for the underwater fog of the ocean.

You can specify a color value, such as Color(1.0,2.0,3.0,1.0), and then pass it as an argument like the following: SetFogColor(Color(1.0,2.0,3.0,1.0))

The FogColorPremultiplied function is applied to the ocean's fog color. You can use the GetFogColorPremultiplied function to return the result of Fog Color * Fog Color Multiplier.

Note
Currently, you cannot directly specify values for the FogColorPremultiplied function.

For SetFogColorMultiplier and GetFogColorMultiplier functions:
Parameters
Type: Float
Return
Type: Float
Scriptable
Yes

For SetFogColor, GetFogColor, SetNearFogColor, and GetNearFogColor functions:
Parameters
Type: Color
Return
Type: Color
Scriptable
Yes

Example
OceanEnvironmentRequestBus.Broadcast.SetFogColor(Color)
OceanEnvironmentRequestBus.Broadcast.GetFogColor()
CausticsEnabled

Applies the caustics effect of the ocean on geometry below the ocean surface.

**Parameters**
- Type: Boolean

**Return**
- Type: Boolean

**Scriptable**
- Yes

**Example**

```csharp
OceanEnvironmentRequestBus.Broadcast.SetCausticsEnabled(boolean)
OceanEnvironmentRequestBus.Broadcast.GetCausticsEnabled()
```

CausticsDepth, CausticsIntensity, CausticsTiling, CausticsDistanceAttenuation

Specifies the caustics parameters for the Infinite Ocean component.

**Parameters**
- Type: Float

**Return**
- Type: Float

**Scriptable**
- Yes

**Example**

```csharp
OceanEnvironmentRequestBus.Broadcast.SetCausticsDepth(float)
OceanEnvironmentRequestBus.Broadcast.GetCausticsDepth()
OceanEnvironmentRequestBus.Broadcast.SetCausticsIntensity(float)
OceanEnvironmentRequestBus.Broadcast.GetCausticsIntensity()
OceanEnvironmentRequestBus.Broadcast.SetCausticsTiling(float)
OceanEnvironmentRequestBus.Broadcast.GetCausticsTiling()
OceanEnvironmentRequestBus.Broadcast.SetCausticsDistanceAttenuation(float)
OceanEnvironmentRequestBus.Broadcast.GetCausticsDistanceAttenuation()
```

OceanMaterialName

Renders the ocean with the assigned material.

You can find the default material in the `lumberyard_version/dev/Engine/EngineAssets/Materials/Water/ocean_default.mtl` directory.

**Parameters**
- The path to the ocean material file.
Infinite Ocean

Type: String
Return

Type: String

Scriptable
Yes

Example

OceanEnvironmentRequestBus.Broadcast.SetOceanMaterialName(string)
OceanEnvironmentRequestBus.Broadcast.GetOceanMaterialName()

Using the Infinite Ocean Component with Script Canvas

You can use the Infinite Ocean component with the Script Canvas editor to change the component parameters at run time, using a visual scripting workflow. In the following example, the Script Canvas script changes the size of the ocean waves over time.

To use the Infinite Ocean component with the Script Canvas editor

1. In Lumberyard Editor, create an entity (p. 463) and attach the Infinite Ocean component. Ensure that the component is positioned correctly in your level.
2. In the Entity Inspector, for Wave Size, enter 0. This creates a flat ocean, so you can see how the Script Canvas editor interacts with the component.
3. Click Add Component and then click the Script Canvas (p. 818) component.
4. In the Script Canvas component, click the icon to open the Script Canvas editor.
5. Select the entity with the Infinite Ocean component attached and drag it to the Script Canvas editor.
6. In the Script Canvas editor, save the file as oceanscript.scriptcanvas.
7. In the Node Palette, search for the On Entity Activated node and drag it to the canvas.
   • In the canvas, from the Ocean EntityRef node, drag Get to connect it to the Source pin of the Game Entity node.
8. In the Node Palette, search for the Timer node and drag it to the canvas.
   • In the canvas, from the Game Entity node, drag the Out pin to connect it to the Start pin of the Timer node.
9. In the Node Palette, search for the Sin node and drag it to the canvas. This node provides a value that goes up and down.
   a. In the canvas, from the Timer node, drag the Out pin to connect it to the In pin of the Sin node.
   b. Drag the Seconds pin to connect it to the Angle pin of the Sin node.
   Note
   The Sin node returns values that are –/+. Negative numbers cause errors with the Wave Size parameter. Use the Add node to ensure that only positive values are returned.
10. In the Node Palette, search for the Add node and drag it to the canvas.
    a. In the canvas, from the Sin node, drag the Out pin to connect it to the In pin of the Add node.
    b. Drag the Angle pin and to connect it to the Value A pin of the Add node.
    c. For the Add node, enter 1.0 for Value B. This shifts the sine wave from (-1.0 to 1.0) to (0.00 to 2.00).
11. In the Node Palette, search for the SetAnimationWavesSize node and drag it to the canvas.
a. In the canvas, from the Add node, drag the Out pin to connect it to the In pin of the SetAnimationWavesSize node.
b. Drag the Result pin to connect it to the Number:0 pin of the SetAnimationWavesSize node.

Your script should look like the following:

![Image of script canvas]

12. Save your script.
13. In the Entity Inspector, select the entity with the Script Canvas component attached. Click the browse (...) button and navigate to the oceanscript.scriptcanvas file. Select oceanscript.scriptcanvas and then click OK.
14. To start the game, press Ctrl+G. You can see the size of the ocean waves increase and decrease over time.

**Input**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Input component to bind raw input to events in your game. The Input component references an .inputbindings file, which binds a set of inputs (such as from a mouse, keyboard, game controller, and so on) to an event.

For example, you can add the Input component to an entity and specify in the .inputbindings file that when you press the keyboard spacebar, the entity rotates.

**Note**

To work with inputs, you must enable the Input Management Framework (p. 1150) and the Starting Point Input (p. 1206) gems. For more information, see Add modular features and assets with Gems (p. 1064).

**Topics**

- Input Properties (p. 642)
- Working with the Input Component (p. 643)
- Input Component EBus Interface (p. 648)

**Input Properties**

![Image of Input properties]
The **Input** component has the following properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Input to event bindings</strong></td>
<td>References an <code>.inputbindings</code> file that defines the bindings of raw input to events.</td>
</tr>
<tr>
<td><strong>Input contexts</strong></td>
<td>A string to specify valid context(s) for the <code>.inputbindings</code> file.</td>
</tr>
</tbody>
</table>

An empty string "" is the default context. This context is active whenever it's explicitly pushed to the top of the input context stack, or when the input context stack is empty.

You can use this parameter to specify what context asset binding is available for the component. This is useful if you want the component to switch between different input events.

For an example of working with contexts, see Input Request Bus (p. 650).

**Note**

Input event bus (EBus) messages aren't generated while the **Console** window is open.

---

**Working with the Input Component**

You can create an `.inputbindings` file for an **Input** component and specify the input values and events.

**Topics**

- Creating an Input to Event Binding Asset (p. 643)
- Creating Input Event Groups (p. 644)
- Creating Event Generators (p. 644)
- Mapping Input Events to Gameplay Actions (p. 645)
- Testing Your Input Events (p. 647)

---

**Creating an Input to Event Binding Asset**

Follow these steps to create an `.inputbindings` file.

**To create an input to event binding asset**

1. Create (p. 463) an entity.
2. In the **Perspective** viewport, select the entity.
3. In the **Entity Inspector**, click **Add Component**, and add the **Input** component.
4. In the **Entity Inspector** (p. 475), under **Input**, click the Input Bindings Editor icon to open the **Asset Editor**.
5. In the **Asset Editor**, choose **File, New, Input Bindings**.

6. Enter a name for the `.inputbindings` file and click **Save**.

### Creating Input Event Groups

After you create your `.inputbindings` file, you can add input event groups for different actions.

**To add an input event group**

1. In the **Asset Editor**, for your `.inputbindings` file, click the + icon.

2. For **Event Name**, enter a name for your event, such as **Action**.

### Creating Event Generators

After you create your input event group, you can add event generators to the group. An event generator is a handler that generates the named event. For example, a pressed key, a held mouse button, or a series of actions on a game controller results in the named event.

**To add an event generator to your input event group**

1. In the **Asset Editor**, for your input event group, next to **Event Generators**, click the + icon.

2. In the **Class to create** window, select **Input**, and click **OK**.

3. Specify your changes for the event generator. Each event generator has a set of properties that you can customize.

### Event Generator Properties

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input Device Type</td>
<td>The type of device that generates the input. Select from a list of available devices such as keyboard, mouse, and gamepad.</td>
</tr>
<tr>
<td>Input Name</td>
<td>A list of input options that depend on the selected input device type. For example, if you select <strong>keyboard</strong> for the <strong>Input Device Type</strong>, a list of possible keystrokes appear in this list, such as <code>keyboard_key_edit_space</code>.</td>
</tr>
<tr>
<td>Event value multiplier</td>
<td>A multiplier by which to scale the input value.</td>
</tr>
<tr>
<td>Dead zone</td>
<td>Specifies the threshold in which an event is generated.</td>
</tr>
</tbody>
</table>
### Name | Description
--- | ---
 | Values below this number are inactive and events are not generated.
 | Values above this number are active and events are generated.
 | For example, you can specify `gamepad` for the **Input Device Type** and `gamepad_thumbstick_r` for the **Input Name**.
 | If you specify a **Dead zone** value of 0.50, the thumbstick must move more than 50% to the right before the event is generated.

**Example**

The following `.inputbindings` file specifies a keyboard for the device type and the spacebar for the input name.

4. Save your `.inputbindings` file.
5. In the **Entity Inspector**, in the **Input** component, for **Input to event binding**, click the browse (…) icon and select your `.inputbindings` file.

**Mapping Input Events to Gameplay Actions**

After you create an `.inputbindings` file and specify your input events, you can use a Script Canvas graph or Lua script to map the input events to gameplay actions. You can create your graph in a visual scripting environment with the **Script Canvas** editor or write your own scripts with the Lua Editor (Lua IDE).

**Using a Script Canvas Graph for Input**

You can create a Script Canvas graph that maps to your input events. For more information, see Creating Gameplay with Script Canvas (p. 2420).

**To use a Script Canvas graph for input**

1. In the **Perspective** viewport, select the entity.
2. In the **Entity Inspector**, click **Add Component** and add the **Script Canvas** component.
3. In the **Script Canvas** component, for **Script Canvas Asset**, specify a Script Canvas graph like the following.
Example Script Canvas Graph

In the following graph, the Input Handler node maps the Event Name Action to the .inputbindings file.

Using a Lua Script for Input

You can also create a Lua script that maps to your input events. For more information about Lua, see Writing Lua Scripts (p. 2683).

To add a Lua script for input

1. In the Perspective viewport, select the entity.
2. In the Entity Inspector, click Add Component, and add the Lua Script (p. 683) component.
3. In the Lua Script component, specify a Lua script file like the following.
Example Lua Script

The following Lua script maps the Event Name Action to the .inputbindings file.

```lua
local tutorial_input = {
  Properties = {
  },
}

function tutorial_input:OnActivate()
  self.Inputs = {
    self.Inputs.OnPressed = function(_, value)
      TransformBus.Event.SetLocalScaleZ(self.entityId, 2.0)
    end
    self.Inputs.OnHeld = function (_, value)
      TransformBus.Event.RotateAroundLocalZ(self.entityId, 0.01)
    end
    self.Inputs.OnReleased = function (_, value)
      TransformBus.Event.SetLocalScaleZ(self.entityId, 1.0)
    end
    self.InputNotificationBus = InputEventNotificationBus.Connect( inputNotificationId("Action"))
  end

  function tutorial_input:OnDeactivate()
    self.InputNotificationBus:Disconnect()
  end

  return tutorial_input
```

Testing Your Input Events

After you specify the Script Canvas graph or Lua script, you can test your input events.

To test your input events

1. In the Perspective viewport, select your entity.
2. In the Entity Inspector, click Add Component, and add the Mesh (p. 684) component.
3. For Mesh asset, specify a mesh asset file. This gives your entity a shape. For example, you can specify the lumberyard_version\dev\SamplesProject\Objects\Primitives\cube_001.cgf file.
4. Press Ctrl+G to enter game mode.
5. Press the keyboard spacebar so that your entity rotates on the local z-axis.
Example

6. To exit gameplay mode, press Esc

Input Component EBus Interface

Input subcomponents are objects that have the same lifetime as components and must override Activate and Deactivate.

```cpp
// InputSubComponent
void Activate(const AZ::InputEventNotificationId& channelId) override;
void Deactivate(const AZ::InputEventNotificationId& channelId) override;
```

You can use the GameplayNotificationBus to work with the InputSubComponent. For more information, see GameplayNotifications (p. 1031).
You can find example Lua scripts and code in the `lumberyard_version\dev\Gems\StartingPointInput\Assets\Scripts\Input` directory.

**Input Event Notification Bus**

Use the following notification functions with the event notification bus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>OnPressed</td>
<td>Event sent when an input surpasses the threshold.</td>
<td>Float</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>OnHeld</td>
<td>Event sent when an input continues to surpass the threshold.</td>
<td>Float</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>OnReleased</td>
<td>Event sent when an input no longer surpasses the threshold.</td>
<td>Float</td>
<td>None</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Example**

```lua
local held = 
{
    Properties = 
    {
        IncomingInputEventName = "",
        OutgoingGameplayEventName = "",
    },
}

function held:OnActivate()
    local inputBusId = InputEventNotificationId(self.Properties.IncomingInputEventName)
    self.inputBus = InputEventNotificationBus.Connect(self, inputBusId)
end

function held:OnHeld(floatValue)
end

function held:OnReleased(floatValue)
    GameplayNotificationBus.Event.OnEventEnd(GameplayNotificationId(self.entityId, self.Properties.OutgoingGameplayEventName), floatValue)
end

function held:OnDeactivate()
    self.inputBus:Disconnect()
end

return held
```
**Input Request Bus**

Use the following functions with the input request bus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>PushContext</td>
<td>Pushes a new context onto the stack, which becomes the active context.</td>
<td>String</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>PopContext</td>
<td>Removes the top context from the input context stack.</td>
<td>None</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>PopAllContexts</td>
<td>Clears the context stack, and the active context becomes the empty string: &quot;&quot;</td>
<td>None</td>
<td>Empty string</td>
<td>Yes</td>
</tr>
<tr>
<td>GetCurrentContext</td>
<td>Returns the context at the top of the stack. If the stack is empty, returns: &quot;&quot;</td>
<td>None</td>
<td>String</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Example Input Contexts**

You can use the **Input contexts** parameter to specify what context asset binding is available. For example, you can switch contexts so that when a character is under water, the input events are different than when the character is on the ground.

For example, for the **Input** component, you can specify **Input contexts**, such as an empty string, "under water", and "run". When you add a **Lua** component to the entity, you can specify the different **Input contexts**, "under water", and "run" in your Lua script.

This means that when your Lua script runs, the Lua script tells the **Input** component which context to use.

```lua
local foo = {
  Properties = {
    Context = {
      default = "", description = "A context to push onto the input stack. Like console, or UI, or turret, under water, etc."},
    }
}{}

function foo:OnActivate()
  -- by default the context is blank ""
  InputRequestBus.Broadcast.PushContext(self.Properties.Context) -- context stack is now 1)user defined property
```
Legacy Terrain level component

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Legacy Terrain level component enables the legacy terrain system. This component works as a switch. When the Legacy Terrain level component is added to a level, terrain is displayed and can be edited. When the Legacy Terrain level component is removed from the level, terrain is not displayed and cannot be edited. Adding or removing the Legacy Terrain level component is a non-destructive operation. Existing terrain heightmap and texture data remains intact when the Legacy Terrain level component is removed from the level.

Note
The Legacy Terrain component is a level component and is added to the level through the Level Inspector.

To enable the Legacy Terrain system in a level

1. In the Lumberyard Editor, open the Level Inspector by choosing its tab, or by choosing Level Inspector from Tools in the main menu bar.
2. In the **Level Inspector**, choose **Add Component**. In the components list, choose **Legacy Terrain**.

The terrain is displayed in the **Perspective** view.

**Note**
The **Legacy Terrain** level component has no properties because it is a switch that enables the legacy terrain system.

### Resize legacy terrain

Terrain size is defined by a *heightmap*, which is a gray scale texture that contains elevation information, and a *meters per texel* property. The meters per texel property sets the relationship between texels in the heightmap and the terrain size in world space. A **1024 x 1024** heightmap with 1 meter per texel creates a terrain that's 1.024 square kilometers in size. Each texel in the heightmap defines one square meter of the terrain.

#### To resize terrain

1. In the Lumberyard Editor main menu bar, open the **Terrain Editor** by choosing **Terrain Editor** from **Tools** in the main menu bar.
2. In the main menu bar for the **Terrain Editor**, choose **Resize Terrain** from the **Modify** menu.
3. Choose from the lists to set the **Heightmap Resolution** and **Meters Per Texel** properties for the legacy terrain.

### Generate a legacy terrain texture

Terrain textures for the legacy terrain system are generated within Lumberyard Editor.
To generate a legacy terrain texture

1. In the Lumberyard Editor, main menu bar, choose the Game menu.
2. In the Game menu, choose the Terrain group, and then Generate Terrain Texture.
3. Select one of the Texture Dimensions options in the Generate Terrain Texture window and choose OK.

Use PhysX or legacy physics with legacy terrain

If your project uses legacy physics components, interactions between the terrain and physics entities will work without additional steps.

If your project uses the PhysX system, you must add a PhysX Terrain level component to enable PhysX entities to interact with the terrain. The PhysX Terrain level component is added in the Level Inspector with the Legacy Terrain level component.
To enable PhysX with the Legacy Terrain system in a level

1. In the Lumberyard Editor, open the Level Inspector by choosing its tab, or by choosing Level Inspector from Tools in the main menu bar.
2. Choose Add Component in the Level Inspector and select PhysX Terrain from the components list.

Important
For historical reasons, the PhysX Terrain component can be added to the level via the Entity Inspector but this is not recommended. This functionality has been maintained for compatibility. The PhysX Terrain component should not be instantiated more than once in a level. In the future and for new projects, use the Level Inspector to add the PhysX Terrain level component to the level.

Lens Flare

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The **Lens Flare** component allows the placement of a lens flare on an entity.

## Lens Flare Component Properties

The **Lens Flare** component has the following properties:

**Visible**
- If selected, shows the lens flare.

**Library**
- Select a lens flare library that has been authored by the **Lens Flare** editor.

**Lens flare**
- Select a lens flare from the available flares in the lens flare library.

**Flare Settings**

**Minimum spec**
- The minimum spec at which this lens flare is enabled.
  - Default: Low

**FOV**
- The field of view (FOV) in degrees around the lens flare. Use **360** degrees to make the lens flare visible from all angles.
  - Default: 360

**Size**
- The size of the lens flare.

**Attach to sun**
- If selected, attaches the lens flare to the sun (as opposed to attaching to the entity).

**Ignore vis areas**
- If selected, lens flare ignores vis areas.

**Indoor only**
- If selected, lens flare is rendered indoors only.

**On initially**
- If selected, the lens flare is on when the scene starts.

**View distance multiplier**
- Adjust the maximum view distance. For example, **1.0** would use the default and **1.1** would be 10% further than the default.

**Color Settings**

**Tint**
- Color of the lens flare.
Lens Flare

Tint [alpha]

Alpha value that sets the flare's transparency.

Brightness

Brightness of the lens flare.

Animation

Sync with light

If selected, uses the animation settings of the provided light. Select the light entity in the **Light** setting.

Light

This setting appears when the **Sync with light** setting is selected. Use the picker (hand icon) to select the light component you want to sync animation settings with.

Style

Light animation curve ID (style) as it corresponds to values in `Light.cfx`.

Speed

Multiple of the base animation rate.

Phase

Animation start offset from 0 to 1. 0.1 would be 10% into the animation.

**EBus Request Bus Interface**

Use the following request function with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

- `SetLensFlareState` (on or off) – Turns the lens flare on or off.
- `TurnOnLensFlare` – Turns the lens flare on.
- `TurnOffLensFlare` – Turns the lens flare off.
- `ToggleLensFlare` – Toggles the lens flare state (on to off, or off to on).

**EBus Notification Bus Interface**

Use the following notification functions with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

- `LensFlareTurnedOn` – Sends a signal when the lens flare is turned on.
- `LensFlareTurnedOff` – Sends a signal when the lens flare is turned off.

The following is an example of script using the **Request Bus Interface**.
function example:OnActivate()
    LensFlareComponentRequestBus.Event.SetLensFlareState(self.entityId, LensFlareComponentState.Off)
    LensFlareComponentRequestBus.Event.TurnOnLensFlare(self.entityId)
    LensFlareComponentRequestBus.Event.TurnOffLensFlare(self.entityId)
    LensFlareComponentRequestBus.Event.ToggleLensFlare(self.entityId)
end

### Lightning

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the **Lightning** component to create a single lightning bolt effect. In Lumberyard Editor, you can add the **Lightning** component to entities and trigger them later from Lua or Script Canvas. For best results, use the **Lightning** component as part of a dynamic slice along with a spawning system. After the **Lightning** component finishes its effect, the entity is automatically destroyed. This makes it easier for you to spawn entities with a **Lightning** component, without needing manually to manage the lifetime of each entity.

**Note**

To enable the **Lightning** component, you must enable the Lightning gem. For more information, see Lightning Arc Gem (p. 1152).

The **Lightning** component does not produce visual effects on its own. The component schedules timings with a specified set of entities. You can use the following components to create the lightning bolt effect:

- **Particle** (p. 702) component emitter to create the lightning bolt.
- A **Light** component for the dynamic lighting and shadowing. You can use any of the light components, but the **Point Light** (p. 706) component is recommended.
- **Sky Highlight** (p. 847) component for the bright flash in the sky.
- **Audio Trigger** (p. 559) and **Audio Proxy** (p. 557) components for the rumbling of thunder.
- The **Lightning** component to manage the lifetimes and intensities of the other entities to create a flash of lightning.

**Example**

The **Lightning** component randomly spawns in a small area.
Contents

- Lightning Component Properties (p. 659)
  - Lightning Bolt (p. 659)
  - SkyHighlight (p. 659)
  - Light (p. 659)

  - SetSpeedOfSoundScale (p. 664)
  - GetSpeedOfSoundScale (p. 664)
  - SetLightRadiusVariation (p. 664)
  - GetLightRadiusVariation (p. 665)
  - SetLightIntensityVariation (p. 665)
• GetLightIntensityVariation (p. 665)
• SetParticleSizeVariation (p. 665)
• GetParticleSizeVariation (p. 666)
• SetLightningDuration (p. 666)
• GetLightningDuration (p. 666)
• Request Bus Example Script (p. 667)

Lightning Component Properties

The Lightning component has the following properties:

Start on Activate

Specifies whether lightning effects start when the Light component activates.

Relative to Player

Specifies whether the lightning effects are relative to the current active camera.

Duration

Amount of time in seconds that the lightning strike lasts.

The particle effect lasts for the specified duration; the lighting effects can flash multiple times depending on how quickly the light intensity disappears.

Lightning Bolt

The Lightning component has the following lightning bolt options:

Particle Entity

(Optional) An entity with a Particle (p. 702) component that creates a lightning bolt effect. This particle can be emitted multiple times depending on the duration of the effect.

Size Variation

Specifies how much of the particle entity's global size parameter is randomly modified. For more information, see SetParticleSizeVariation (p. 665).

SkyHighlight

The Lightning component has following sky highlight options:

Sky Highlight Entity

(Optional) An entity with a Sky Highlight component that creates a flash of light in the sky. The properties of the Sky Highlight component are respected.

Light

The Lightning component has following light options:

Light Entity

(Optional) An entity with a Light component that creates dynamic lightning. The properties of the Light component are the same, but its intensity and radius are modified.
(Point Light (p. 706) is recommended)

**Radius Variation**

Specifies how much the light's radius is randomly modified. For more information, see `SetLightRadiusVariation` (p. 664).

**Intensity Variation**

Specifies how much the light's intensity is randomly modified. For more information, see `SetLightIntensityVariation` (p. 665).

**Audio**

The **Lightning** component has following audio options:

**Audio Entity**

An entity with the **Audio Trigger** (p. 559) and **Audio Proxy** (p. 557) components attached. These components are required if you want to enable audio. You can also add an optional **Audio Rtpc** (p. 557) component. The audio components plays the audio, depending on the distance away from the listener.

**Speed of Sound Scale**

Specifies how long it takes for audio to arrive at the listener, in seconds. For more information, see `SetSpeedOfSoundScale` (p. 664).

**EBus Request Bus Interface**

Use the following request functions with the EBus interface to communicate with other components of your game. You can use this EBus to communicate to an entity with a **Lightning** component attached. The EBus is available at game run time and editing and can be accessed from C++, Lua, and the **Script Canvas** editor.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

**StartEffect**

Enables the lightning effect.

**Parameters**

None

**Return**

None

**Scriptable**

Yes

**SetStartOnActivate**

Specify if the lightning effect starts when the **Lightning** component activates.

**Note**

This function is useful only during edit time.
Parameters
   Type: Boolean
Return
   None
Scriptable
   Yes

GetStartOnActivate
Returns true if the lightning effect starts when the Lightning component activates.
Parameters
   None
Return
   Type: Boolean
Scriptable
   Yes

SetRelativeToPlayer
Specify if the start of the lightning effect is relative to the player camera.
Parameters
   Type: Boolean
Return
   None
Scriptable
   Yes

GetRelativeToPlayer
Returns true if the start of the lightning effect is relative to the player camera.
Parameters
   Type: Boolean
Return
   None
Scriptable
   Yes

SetLightningParticleEntity
Sets the entity that contains the Particle (p. 702) component that is used for the lightning particle. The entity is destroyed when the effect finishes.
Lumberyard User Guide

Lightning

Parameters
Type: AZ::EntityId

Return
None

Scriptable
Yes

GetLightningParticleEntity
Retuns the entity that contains the Particle (p. 702) component.

Parameters
None

Return
Type: AZ::EntityId

Scriptable
Yes

SetLightEntity
Sets the entity that contains the Light component, which is used for lightning effects.
The entity is destroyed when the effect finishes.

Parameters
Type: AZ::EntityId

Return
None

Scriptable
Yes

GetLightEntity
Returns the entity that contains the Light component.

Parameters
None

Return
Type: AZ::EntityId

Scriptable
Yes

SetSkyHighlightEntity
Sets the entity that has the Sky Highlight component for this effect.
The entity is destroyed when the effect finishes.

**Parameters**

None

**Return**

Type: AZ::EntityId

**Scriptable**

Yes

**GetSkyHighlightEntity**

Returns the entity that has the **Sky Highlight** component.

**Parameters**

None

**Return**

Type: AZ::EntityId

**Scriptable**

Yes

**SetAudioEntity**

Sets the entity that has the audio component for this effect.

To enable audio, the entity must have the **Audio Trigger (p. 559)** and **Audio Proxy (p. 557)** components and an optional **Audio Rtpc (p. 557)** component. If an audio component is missing, the lightning effect may not work as expected.

The entity is destroyed when the effect finishes.

**Parameters**

Type: AZ::EntityId

**Return**

None

**Scriptable**

Yes

**GetAudioEntity**

Returns the entity that has the audio component.

**Parameters**

None

**Return**

Type: AZ::EntityId
Scriptable

Yes

SetSpeedOfSoundScale

Sets the speed of sound scale for this effect. You can use this parameter if want the audio to take more or less time to reach the player and you don't want to move your lightning effect.

Note
Sound travels at 340.29 meters per second. A value of 0.5 makes sound from this effect take half as much time to reach the player.

Parameters

Type: Float

Return

None

Scriptable

Yes

GetSpeedOfSoundScale

Returns the speed of sound scale for this effect.

Parameters

None

Return

Type: Float

Scriptable

Yes

SetLightRadiusVariation

Sets the amount of random variation to apply to the light's radius.

This variation is a percentage of the light's radius. A value of 0.2 means that between ~20% and 20% of the light's radius value is added back to the light's radius.

For example, the light radius is 5.0, and variation is 0.2; this means that the range of the light radius is: 5.0 +/− (5.0 * 0.2) or 5.0 +/− 20% of 5.0.

Parameters

Type: Float

Return

None

Scriptable

Yes
**GetLightRadiusVariation**

Returns the amount of random variation to apply to the light's radius.

**Parameters**

None

**Return**

Type: Float

**Scriptable**

Yes

**SetLightIntensityVariation**

Sets the amount of random variation to apply the Light component's diffuse and specular multipliers.

The Light component calculates the light intensity based on the duration of the lightning effect. This value is a percentage of that light intensity value. A value of 0.2 means that between −20% and 20% of the light intensity value is added back to the light's diffuse and specular multipliers.

For example, the light intensity is 10.0, and variation is 0.3; this means that the range of the light radius is: 10.0 +/− (10.0 * 0.3) or 10.0 +/− 30% of 10.0.

**Parameters**

Type: Float

**Return**

None

**Scriptable**

Yes

**GetLightIntensityVariation**

Returns the amount of random variation to apply the light's diffuse and specular multipliers.

**Parameters**

None

**Return**

Type: Float

**Scriptable**

Yes

**SetParticleSizeVariation**

Sets the amount of random variation to apply to the particle's size.

This variation is a percentage of the Particle (p. 702) component's Global size scale parameter. A value of 0.2 means that between −20% and 20% of the particle's global size value is added back to the size of the emitted particles.
For example, the particle size is $1.0$, and variation is $0.5$; the range of the light radius is: $1.0 +/-(1.0 * 0.5)$ or $1.0 +/-$ $50\%$ of $1.0$.

**Parameters**

- Type: Float

**Return**

- None

**Scriptable**

- Yes

---

**GetParticleSizeVariation**

Returns the amount of random variation to apply to the particle's size.

**Parameters**

- None

**Return**

- Type: Float

**Scriptable**

- Yes

---

**SetLightningDuration**

Sets how long the lightning strike lasts, in seconds. This value determines how long the lightning particle effect lasts. During this time, the sky highlight and light can continue to flash.

**Parameters**

- Type: Double

**Return**

- None

**Scriptable**

- Yes

---

**GetLightningDuration**

Returns how long the lightning strike lasts, in seconds.

**Parameters**

- None

**Return**

- Type: Double

**Scriptable**

- Yes
Request Bus Example Script

```lua
function example:OnActivate()
    LightningComponentRequestBus.Event.StartEffect(self.entityId)
end
```

Lighting Arc

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Lightning Arc component to create short arcs (also called sparks) between an emitter and a series of target entities. When an arc is emitted, the arc jumps between the center of the entity to which the Lightning Arc component is attached and the center of the target entity.

To enable the Lightning Arc component, you must enable the Lightning Arc gem. For more information, see Lightning Arc Gem (p. 1152).

Example

The Lightning Arc component is attached to the entity in the center, and the arc randomly jumps between three targets. This example uses the default lightning material in the Lightning Arc gem and the Tesla_core arc preset. For more information, see Customizing a Lightning Arc Preset (p. 1156).
Lightning Arc Component Properties

The Lightning Arc component has the following properties:

**Enabled**

Specifies whether the Lightning Arc component emits arcs.

**Targets**

The collection of targets to which the Lightning Arc component emits arcs.

**Material**

The lightning arc material. This parameter does not require a specific type of material, but it's recommended that you use the Illum shader (p. 1697) and a texture with opacity.

You can find the default files in the following directory: Gems\LightningArc\Assets\materials\effects

Default value: None

**Arc Preset Name**

The name of the arc preset in use; the arc preset is specified in the lightningarceffects.xml file. If you change any of the arc parameters in this file, this field changes to <Custom>.

You can find the available arc preset names in the following directory: Gems\LightningArc\Assets\libs\lightningarc\lightningarceffects.xml

**Refresh Presets**

If you make changes to the lightningarceffects.xml file, click Refresh Presets to get the most recent arc preset names.

**Arc Parameters**

The Lightning Arc component has the following lightning options:

**Contents**

- Lightning (p. 668)
- Branch (p. 669)
- Strike (p. 669)
- Beam (p. 669)

**Lightning**

**Deviation**

Amount of deviation applied to the arcs. Specify lower values to make the arc appear more smooth.

**Fuzziness**

Amount of noise applied to the arcs.
Velocity

Specify how fast an arc drifts upward after it is emitted.

Branch

The **Lightning Arc** component has following branch options:

Max Level

Maximum number of branches that can spawn from an arc. For more information, see `SetBranchMaxLevel (p. 679)`.

Probability

Specifies how likely that a child branch spawns from an arc. For more information, see `SetBranchProbability (p. 678)`.

Strike

The **Lightning Arc** component has following strike options:

Time Min

Minimum amount of time that an arc is kept alive.

Time Max

Maximum amount of time that an arc is kept alive.

Fade Out

Specifies how long it takes for an arc to fade out.

Segment Count

Number of segments in an arc. Specify more segments to make the arcs appear more winding.

Point Count

Number of points for each segment. Specify more points to increase the noise effect that is defined by the **Fuzziness** parameter.

Max Strike Count

Specify how many arcs can be alive at one time from this **Lightning Arc** component.

Beam

The **Lightning Arc** component has following beam options:

Size

The width of the arcs that the **Lightning Arc** component creates. The branches that spawn off the arc beam will have half this size.

Tex Tiling

Texture tiling based on the world size of the arc beam. For more information, see `SetBeamTexTiling (p. 680)`.

Tex Shift

Specify how fast to move through textures in the arc's animation. For more information, see `SetBeamTexShift (p. 681)`.
**Tex Frames**

Specify how many frames are in the arc's animation.

**Tex FPS**

Specify how many frames per second are in the arc's animation.

### Timing

The **Lightning Arc** component has following timing options:

**Delay**

Time between emitted arcs, in seconds.

**Delay Variation**

Variation in time between emitted arcs. For more information, see [SetDelayVariation](#).

### EBus Request Bus Interface

Use the following request functions with the EBus interface to communicate with other components of your game. You can use this EBus to communicate to an entity with a **Lightning Arc** component attached. The EBus is available at game run time and editing and can be accessed from C++, Lua, and the **Script Canvas** editor.

For more information about using the event bus (EBus) interface, see [Working with the Event Bus (EBus) system](#).

**Contents**

- *Enable* (p. 671)
- *Disable* (p. 671)
- *Toggle* (p. 672)
- *IsEnabled* (p. 672)
- *SetTargets* (p. 672)
- *GetTargets* (p. 672)
- *SetDelay* (p. 673)
- *GetDelay* (p. 673)
- *SetDelayVariation* (p. 673)
- *GetDelayVariation* (p. 674)
- *SetStrikeTimeMin* (p. 674)
- *GetStrikeTimeMin* (p. 674)
- *SetStrikeTimeMax* (p. 674)
- *GetStrikeTimeMax* (p. 675)
- *SetStrikeFadeOut* (p. 675)
- *GetStrikeFadeOut* (p. 675)
- *SetStrikeSegmentCount* (p. 675)
- *GetStrikeSegmentCount* (p. 676)
- *SetStrikePointCount* (p. 676)
- *GetStrikePointCount* (p. 676)
• **SetLightningDeviation** (p. 677)
• **GetLightningDeviation** (p. 677)
• **SetLightningFuzziness** (p. 677)
• **GetLightningFuzziness** (p. 677)
• **SetLightningVelocity** (p. 678)
• **GetLightningVelocity** (p. 678)
• **SetBranchProbability** (p. 678)
• **GetBranchProbability** (p. 679)
• **SetBranchMaxLevel** (p. 679)
• **GetBranchMaxLevel** (p. 679)
• **SetMaxStrikeCount** (p. 679)
• **GetMaxStrikeCount** (p. 680)
• **SetBeamSize** (p. 680)
• **GetBeamSize** (p. 680)
• **SetBeamTexTiling** (p. 680)
• **GetBeamTexTiling** (p. 681)
• **SetBeamTexShift** (p. 681)
• **GetBeamTexShift** (p. 681)
• **SetBeamTexFrames** (p. 682)
• **GetBeamTexFrames** (p. 682)
• **SetBeamTexFPS** (p. 682)
• **GetBeamTexFPS** (p. 682)
• **Request Bus Example Script** (p. 683)

### Enable

Enables the component to emit lightning arcs.

**Parameters**

None

**Return**

None

**Scriptable**

Yes

### Disable

Disables lightning arc emission.

**Parameters**

None

**Return**

None
**Scriptable**

Yes

**Toggle**

Toggles lightning arc emission.

**Parameters**

None

**Return**

None

**Scriptable**

Yes

**IsEnabled**

Returns whether the **Lightning Arc** component emits lightning arcs.

**Parameters**

None

**Return**

Type: Boolean

**Scriptable**

Yes

**SetTargets**

Sets the target entities to which the **Lightning Arc** component emits arcs.

**Parameters**

AZStd::vector<AZ::EntityId>

Type: Vector of entity IDs.

**Return**

None

**Scriptable**

Yes

**GetTargets**

Returns the target entities to which the **Lightning Arc** component emits arcs.

**Parameters**

None
Return

`AZStd::vector<AZ::EntityId>`

Type: Vector of entity IDs.

Scriptable

Yes

SetDelay

Sets the time between emitted arcs, in seconds.

Parameters

Type: Double

Return

None

Scriptable

Yes

GetDelay

Returns the time between emitted arcs, in seconds.

Parameters

None

Return

Type: Double

Scriptable

Yes

SetDelayVariation

Sets the variation in time between emitted arcs.

Delay variation is a random range applied to the `Delay` parameter to calculate the time that the next arc emits.

The random variation is in the following range: `[delay variation * 0.5, delay variation]`.

For example, if the delay is `2.0` and the delay variation is `1.0`, the range of time between arc emissions is `[2.5 and 3.0]`.

Parameters

Type: Double

Return

None
Scriptable
Yes

**GetDelayVariation**

Returns the variation in time between emitted arcs.

**Parameters**
None

**Return**
Type: Double

Scriptable
Yes

**SetStrikeTimeMin**

Sets the minimum amount of time that an arc is kept alive.

**Parameters**
Type: Float

**Return**
None

Scriptable
Yes

**GetStrikeTimeMin**

Returns the minimum amount of time that an arc is kept alive.

**Parameters**
None

**Return**
Type: Float

Scriptable
Yes

**SetStrikeTimeMax**

Sets the maximum amount of time that an arc is kept alive.

**Parameters**
Type: Float

**Return**
None
Scriptable
Yes

GetStrikeTimeMax
Returns the maximum amount of time that an arc is kept alive.

Parameters
None

Return
Type: Float

Scriptable
Yes

SetStrikeFadeOut
Sets how long it takes for an arc to fade out.

Note
Lumberyard completes this fade out internally by scaling the size to 0 rather than adjusting the transparency.

Parameters
Type: Float

Return
None

Scriptable
Yes

GetStrikeFadeOut
Returns how long it takes for an arc to fade out.

Parameters
None

Return
Type: Float

Scriptable
Yes

SetStrikeSegmentCount
Sets the number of segments in an arc.

Specify more segments to make the arcs appear more winding. A Lightning arc component must have a minimum of 1 segment. If you specify 0, a warning appears and 1 is used instead.
Parameters
  Type: AZ::u32

Return
  None

Scriptable
  Yes

GetStrikeSegmentCount
Returns the number of segments in an arc.

Parameters
  None

Return
  Type: AZ::u32

Scriptable
  Yes

SetStrikePointCount
Sets the number of points for each segment.

Note
Specify more points to increase the noise effect that is defined by the Fuzziness parameter. A Lightning arc component must have a minimum of 1 point. If you specify 0, a warning appears and 1 is used instead.

Parameters
  Type: AZ::u32

Return
  None

Scriptable
  Yes

GetStrikePointCount
Returns the number of points for each segment in an arc.

Parameters
  None

Return
  Type: AZ::u32

Scriptable
  Yes
SetLightningDeviation

Sets the amount of deviation applied to the arcs.

**Note**
Specify lower values to make the arc appear more smooth.

**Parameters**
Type: Float

**Return**
None

**Scriptable**
Yes

GetLightningDeviation

Returns the amount of deviation applied to the arcs.

**Parameters**
None

**Return**
Type: Float

**Scriptable**
Yes

SetLightningFuzziness

Sets the amount of noise applied to the arcs.

**Parameters**
Type: Float

**Return**
None

**Scriptable**
Yes

GetLightningFuzziness

Returns the amount of noise applied to the arcs.

**Parameters**
None

**Return**
Type: Float
Scriptable

Yes

SetLightningVelocity
Sets how fast an arc drifts upwards after it emits.

Parameters
Type: Float

Return
None

Scriptable

Yes

GetLightningVelocity
Returns how fast an arc drifts upwards after it emits.

Parameters
None

Return
Type: Float

Scriptable

Yes

SetBranchProbability
Sets how likely a branch spawns off of an arc.

A branch (or child arc) is an arc that is half the size and intensity of the parent arc. A branch has the same emission point and target as its parent.

- A value of 0 means that branches do not spawn.
- A value of 0.5 means there is a 50% chance of spawning a branch.
- A value of 2.0 means there is a 100% chance of spawning two branches.

For more information about setting the maximum number of branches, see SetBranchMaxLevel (p. 679).

Parameters
Type: Float

Return
None

Scriptable

Yes
**GetBranchProbability**

Returns how likely a branch spawns off the parent arc.

**Parameters**

None

**Return**

Type: Float

**Scriptable**

Yes

**SetBranchMaxLevel**

Sets the maximum number of branches that can spawn off the parent arc.

- A value of 0 means branches do not spawn, regardless of branch probability.
- A value of 3 means that between 0 and 3 branches can spawn, depending on the branch probability.

**Parameters**

Type: AZ::u32

**Return**

None

**Scriptable**

Yes

**GetBranchMaxLevel**

Returns the maximum number of branches allowed to spawn off the parent arc.

**Parameters**

None

**Return**

Type: AZ::u32

**Scriptable**

Yes

**SetMaxStrikeCount**

Sets how many arcs can be alive at one time from this Lightning Arc component; this includes parent and branch arcs.

**Parameters**

Type: AZ::u32
Return

None
Scriptable
Yes

GetMaxStrikeCount

Returns the maximum number of arcs that can be alive at one time from this *Lightning Arc* component.

Parameters

None
Return

Type: AZ::u32
Scriptable
Yes

SetBeamSize

Sets the width of the generated arcs. Branch arcs be half this size.

Parameters

Type: Float
Return

None
Scriptable
Yes

GetBeamSize

Returns the width of the generated arcs.

Parameters

None
Return

Float
Scriptable
Yes

SetBeamTexTiling

Sets the texture tiling based on the world size of the arc beam.

- A value of 2.0 means that the texture wraps around twice for each meter.
- A value of 0.25 means that the texture wraps around four times for each meter.
Note
Only the U coordinate of the texture map is affected by this parameter.

Parameters
Type: Float

Return
None

Scriptable
Yes

GetBeamTexTiling
Returns the texture tiling parameter for the arc beam.

Parameters
None

Return
Type: Float

Scriptable
Yes

SetBeamTexShift
Sets how fast to move through textures in the arc's animation.

Note
The U value of the texture coordinate moves at this specified rate. The V value is automatically calculated to select the correct frame.

Parameters
Type: Float

Return
None

Scriptable
Yes

GetBeamTexShift
Returns how fast to move through textures in the arc's animation.

Parameters
None

Return
Type: Float
SetBeamTexFrames
Sets how many frames are in an arc's animation.

Parameters
Type: Float

Return
None

GetBeamTexFrames
Returns the number of frames in an arc's animation.

Parameters
None

Return
Type: Float

SetBeamTexFPS
Sets how many frames per second are in an arc's animation.

Parameters
Type: Float

Return
None

GetBeamTexFPS
Returns how many frames per second are in an arc's animation.

Parameters
None

Return
Type: Float
Scriptable

Yes

Request Bus Example Script

```lua
function example:OnActivate()

-- Send some events to a LightningArcComponent attached to the same entity as this script
  LightningArcComponentRequestBus.Event.Toggle(self.entityId)
  LightningArcComponentRequestBus.Event.SetDelayVariation(self.entityId, 0.4)
end
```

EBus Notification Bus Interface

Use the following notification functions with the Lightning Arc component notification EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

OnSpark

Notifies an event that triggers when the specified component fires a spark.

Parameters

None

Return

None

Scriptable

Yes

Notification Bus Example Script

```lua
function example:OnActivate()

  -- Listen for lightning arc notifications on the same entity to which this script is attached
  self.lightningArcHandler = LightningArcComponentNotificationBus.Connect(self, self.entityId)
end

function example:OnSpark()

  Debug.Log("On Spark Triggered")
end

function example:OnDeactivate()

  self.lightningArcHandler:Disconnect()
end
```

Lua Script

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
You can use the **Lua Script** component to add arbitrary Lua logic to an entity in the form of a Lua script. For information on the **Lua Script** component and writing Lua scripts, see **Writing Lua Scripts (p. 2683)**.

## Mesh

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

You can add the **Mesh** component to an entity to provide visual geometry on an entity. The **Mesh** component has key controls and options for Lumberyard's basic rendering features. The supported geometry type is meshes (`.cgf`).

### Mesh Component Properties

![Mesh component properties](image)

The **Mesh** component has the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visible</td>
<td>Entity is visible.</td>
</tr>
<tr>
<td>Mesh asset</td>
<td>Specifies the asset file for the mesh entity.</td>
</tr>
<tr>
<td>Material override</td>
<td>Specifies an override material.</td>
</tr>
<tr>
<td>Opacity</td>
<td>The entity's degree of transparency.</td>
</tr>
<tr>
<td>Max view distance</td>
<td>Maximum distance from which this entity can be viewed.</td>
</tr>
<tr>
<td>View distance multiplier</td>
<td>Adjusts the maximum view distance. If set to 1.0, then the default maximum view distance is used. For example, 1.1 extends the default by 10%.</td>
</tr>
<tr>
<td>LOD distance ratio</td>
<td>Sets the level of detail (LOD) ratio over distance.</td>
</tr>
<tr>
<td>Cast shadows</td>
<td>Casts shadow maps.</td>
</tr>
<tr>
<td>Use VisAreas</td>
<td>Allows vis areas to control the component's visibility.</td>
</tr>
</tbody>
</table>
Advanced

The **Mesh** component has different advanced properties that depend on whether your mesh is static or dynamic.

- A mesh is dynamic when the **Static** property is not set on the **Transform** component. This is the default setting when you create an entity. Dynamic meshes do not affect nav meshes.
- A mesh is static when the **Static** property is set on the **Transform** component. You can use static objects for more optimal paths during rendering and processing. We recommend that you create static meshes whenever possible. A static mesh can move or deform only when the **Receive Wind** or **Deformable Mesh** properties are set.

For more information, see [Transform Component Properties (p. 879)](#).

### Advanced Properties for Dynamic Meshes

If your mesh is dynamic, the **Mesh** component has the following advanced properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Receive wind</td>
<td>Affected by wind.</td>
</tr>
<tr>
<td>Accept decals</td>
<td>Receives decals.</td>
</tr>
<tr>
<td>Deformable mesh</td>
<td>Allows static mesh assets to deform that have specific dynamic data. For example, you can have a mesh deform asset that is stationary.</td>
</tr>
</tbody>
</table>

### Advanced Properties for Static Meshes

If the mesh is static, the **Mesh** component has the following advanced properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rain occluder</td>
<td>Blocks or stops dynamic raindrops.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Affect dynamic water</td>
<td>Generates ripples in dynamic water.</td>
</tr>
<tr>
<td>Receive wind</td>
<td>Affected by wind.</td>
</tr>
<tr>
<td>Accept decals</td>
<td>Receives decals.</td>
</tr>
<tr>
<td>Affect navmesh</td>
<td>Affects navmesh generation.</td>
</tr>
<tr>
<td>Visibility occluder</td>
<td>Blocks visibility of other objects.</td>
</tr>
<tr>
<td>Deformable mesh</td>
<td>Allows static mesh assets to deform that have specific dynamic data. For example, you can have a mesh deform asset that is stationary.</td>
</tr>
<tr>
<td>Affects GI</td>
<td>Affects global illumination results.</td>
</tr>
</tbody>
</table>

**Note**

If you select the Receive wind or Deformable mesh settings, the entity's Transform component remains Static, but the mesh is considered dynamic.

**Navigation**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Navigation component provides path-finding and path-following functionality for AI movement, typically on a navigation mesh.

**Topics**
- Navigation Component Properties (p. 687)
Navigation Component Properties

The Navigation component has the following properties:

Agent Type

Specifies this AI's entity type for navigation purposes. Defining the agent type determines which navigation area (p. 693) the entity follows in a scenario where there are different navigation meshes for larger vehicles and smaller humanoid bots. These agent types are defined in the lumberyard_version\dev\your_project_name\Scripts\AI\Navigation.xml file.

To define an agent type on your navigation area, see the Navigation Area (p. 693) component.

Agent Speed

Sets the speed of the agent while navigating when using the Transform or Physics movement methods.

Default value: 1

Agent Radius

Sets the entity radius for navigation purposes. Independent of physics or other collision concerns, the pathfinder uses this value to move around an area with obstacles while cutting corners.

Default value: 4

Arrival Distance Threshold

Sets the minimum distance from an end point when an entity's movement stops and is considered complete.

Default value: 0.25

Repath Threshold

Sets the minimum distance from the previously known location before an entity's new path is calculated.

Default value: 1

Movement Method

Sets the movement method to use when following a path. This can be Transform, Physics, or Custom.
Default value: Transform

- **Transform** – Move the entity that this component is on using the Transform bus. This method ignores all physics so the object may go through walls and terrain.

- **Physics** – Move the entity using physics if the entity has a PhysX Rigid Body, PhysX Character Controller, Rigid Body Physics or Character Physics component. If the entity does not have one of these valid physics components it will not move.

- **Custom** – Provide path updates and let the game logic move the entity however they want. This method is useful when you want to move an animated entity that uses root motion. By listening to the `OnTraversalPathUpdate` notification, you can move your entity toward the next point along a path. Once the entity gets within the arrival distance threshold another `OnTraversalPathUpdate` notification with the next path position will be provided and so on until the end of the path is reached.

**Allow Vertical Navigation**

Set to true if you want to allow the navigation agent to include the vertical velocity when navigating a path, or false if you just want the velocity to be constrained to the X and Y plane (2D). Vertical navigation can be used for flying entities or entities that move with the Transform method but must move vertically. Enabling this property can also help prevent "stair stepping" for entities moving down ramps or steep terrain.

Default value: `false`

**NavigationComponentRequestBus EBus Interface**

Use the following request functions with the `NavigationComponentRequestBus` event bus (EBus) interface to communicate with other components of your game.

For more information about using the EBus interface, see *Working with the Event Bus (EBus) system* (p. 1851).

**FindPath**

Finds a requested path configuration.

**Parameters**

- `request` – Allows the issuer of the request to override one, all, or none of the pathfinding configuration defaults for this entity.

**Return**

A unique identifier for this pathfinding request.

**Scriptable**

- No

**FindPathToEntity**

Creates a pathfinding request to navigate toward the specified entity.

**Parameters**

- `EntityId` – ID of the entity toward which you want to navigate.

**Return**

A unique identifier for the pathfinding request.
**Scriptable**

Yes

**FindPathToPosition**

Creates a pathfinding request to navigate towards the specified world position. Note that while this may seem like the obvious simple choice for pathing, it is often more useful to use FindPathToEntity with a dummy entity because then the pathing will automatically update if you move the dummy entity to a new location before pathing is complete.

**Parameters**

- **Destination** – World position you want to navigate to.

**Return**

- A unique identifier for the pathfinding request.

**Scriptable**

Yes

**Stop**

Stops all pathfinding operations for the provided requestId. Use the ID to ensure that the request you want to cancel is the request that is currently processing. If the specified requestId is different from the ID of the current request, then the Stop command is ignored.

**Parameters**

- **requestId** – ID of the request to cancel.

**Return**

- None

**Scriptable**

Yes

**GetAgentSpeed**

Returns the current AI Agent's speed.

**Parameters**

- None

**Return**

- Returns the current agent's speed as a float.

**Scriptable**

Yes

**SetAgentSpeed**

Updates the AI Agent's speed.
Parameters

agentSpeed – Specifies the new agent speed as a float.

Return

None

Scriptable

Yes

GetAgentMovementMethod

Returns the current AI Agent's movement method.

Parameters

None

Return

Returns the current agent's movement method.

Scriptable

Yes

SetAgentMovementMethod

Updates the AI Agent's movement method.

Parameters

movementMethod – Specifies the new agent movement method (Transform, Physics or Custom).

Return

None

Scriptable

Yes

NavigationComponentNotificationBus EBus Interface

Use the following notification functions with the NavigationComponentNotificationBus event bus (EBus) interface to communicate with other components of your game.

For more information about using the EBus interface, see Working with the Event Bus (EBus) system (p. 1851).

OnSearchingForPath

Indicates that the pathfinding request has been submitted to the navigation system.

Parameters

requestId – ID of the request for which the path is being searched.

Return

None
Scriptable
  Yes

**OnPathFound**
Indicates that a path has been found for the indicated request.

**Parameters**

  - requestID – ID of the request for which the path has been found.
  - currentPath – The path calculated by the pathfinder.

**Return**
Returns a boolean value indicating whether this path is to be traversed.

Scriptable
  No

**OnTraversalStarted**
Indicates that traversal for the indicated request has started.

**Parameters**

  - requestId – ID of the request for which traversal has started.

**Return**
None

Scriptable
  Yes

**OnTraversalInProgress**
Indicates that traversal for the indicated request is in progress.

**Parameters**

  - requestId – ID of the request for which traversal is in progress.
  - distanceRemaining – Remaining distance in this path.

**Return**
None

Scriptable
  Yes

**OnTraversalPathUpdate**
Indicates that the path for the traversal has updated. If the `nextPathPosition` and `inflectionPosition` are equal, they represent the end of the path.
Parameters

requestId – ID of the request for which traversal is in progress.

nextPathPosition – Furthest point on the path we can move to without colliding with anything.

inflectionPosition – Next point on the path beyond nextPathPosition that deviates from a straight-line path.

Return

None

Scriptable

Yes

OnTraversalComplete

Indicates that traversal for the indicated request completed successfully.

Parameters

requestId – ID of the request for which traversal has completed.

Return

None

Scriptable

Yes

OnTraversalCancelled

Indicates that traversal for the indicated request was canceled before successful completion. A path request may be canceled if no path could be found or if the request was stopped by the game.

Parameters

requestId – ID of the request for which traversal was canceled.

Return

None

Scriptable

Yes

Navigation Pathing Cvars

ai_DrawPathFollower

Enables PathFollower debug drawing, displaying agent paths and safe follow target.

0 – Off
1 – On
Navigation Area

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Navigation Area component defines the features of a navigable area or volume for use by the AI System. You use this component with the Polygon Prism Shape (p. 708) component, which defines the volume of the navigation area.

**Note**
When you add a Navigation Area component, you must also add the Polygon Prism Shape component.

For instructions on how to adjust the Polygon Prism Shape component, see Polygon Prism Shape (p. 708).

When you create a Navigation Area, all areas that are traversable by the specified AI Agent Type (p. 696) show as blue when you render the navigation mesh (p. 695). Any areas that are not traversable render as blank areas, such as deep pits and steep slopes. Exclusion areas and areas around static objects also render as blank areas. Even if your navigation area is divided into separate pieces by static objects, terrain features, and exclusion areas, each traversable area renders blue.
You can use a **Navigation Seed (p. 699)** component to fine-tune AI accessibility.

### To add a Navigation Area

1. In the Viewport, near where you want to create your navigation area, right-click and choose **Create entity**.
2. With your new entity selected in the **Entity Outliner**, add (p. 479) the **Navigation Area** component to it.

![Navigation Area component](image)

3. In the **Navigation Area** component, next to **Agent Types**, click +.

   Next to [0], select **MediumSizedCharacters**. This property defines the **types of agents (p. 696)** that can navigate in this area.

4. Add the **Polygon Prism** component. Adjust the size and shape (p. 710) of the **Polygon Prism**. Ensure that your terrain and objects intersect with the volume of the polygon prism. Adjust the **height (p. 711)** if necessary.

   If your polygon prism hovers above your terrain and does not fully intersect with it, the navigation system does not produce the appropriate traversable areas. The following examples show a navigation area that is too high above the terrain (1), and a navigation area appropriately situated on the terrain (2). If your navigation area is too high, use the **move (p. 201)** tool to lower the Z (up and down) position of the entity.

![Navigation examples](image)

### To view the generated Navigation Area mesh

1. In Lumberyard Editor, choose **Game, AI, Show Navigation Areas**.
2. In Lumberyard Editor, choose **Game, AI, View Agent Type**, and then enable the agent type that you want to display.
3. In Lumberyard Editor, choose **Game, AI, Continuous Update** to show changes in the navigation mesh as you modify the terrain or area.
Navigation Area

A navigation mesh shows traversable areas in blue.

**Topics**
- Navigation Area Component Properties (p. 696)
- Navigating Around Static Objects (p. 696)
- Creating Navigation Mesh Exclusion Areas (p. 697)
- Navigation Physics Integration (p. 698)
- NavigationAreaRequestBus EBus Interface (p. 698)

**Navigation Area Component Properties**

The **Navigation Area** component has the following properties:

**Agent Types**

Specifies the types of AI that can traverse this navigation area. These agent types are defined in `lumberyard_version\dev\your_project_name\Scripts\AI\Navigation.xml`. To specify multiple agent types for this area, click the + icon.

You use this property to restrict which agents can navigate within that area. For example, you can allow characters to navigate within a narrow corridor but restrict vehicles.

To define an agent type on your AI, see the **Navigation** (p. 686) component.

**Exclusion**

When selected, creates a subtractive navigation area. This creates a cutout within an existing navigation mesh. For more information, see **Creating Navigation Mesh Exclusion Areas** (p. 697).

**Navigating Around Static Objects**

When Lumberyard creates the navigation mesh, it can automatically exclude areas that should not be traversable, such as a large boulder or tree trunk. To ensure that these areas are correctly detected by the navigation system, you must specify its **Transform** component as static.

**To mark an entity as static**

1. In the **Entity Outliner**, select the entity. This can be a tree, boulder, building, or any object that you don't want the AI to walk through.
2. In the **Transform (p. 878)** component, select the **Static** property.

The following example shows a navigation mesh around a boulder when the **Static** property is not selected.

![Image 1](image1.png)

The following example shows the same navigation mesh, but with the **Static** property selected on the boulder.

![Image 2](image2.png)

### Creating Navigation Mesh Exclusion Areas

You can use the **Navigation Area** component to manually create areas to exclude from the navigation mesh. This means that the AI agents cannot traverse these areas. To do this, you create a navigation area and select the **Exclusion** property, as shown in the following image.

![Image 3](image3.png)

The following example shows a navigation mesh (1) and the same navigation mesh with an exclusion area (2).
To create an exclusion area

1. If you have not already, you must first create a navigation area (p. 695) that is not an exclusion area.
2. Create an entity, and add to it the **Navigation Area** and **Polygon Prism Shape** components.
3. In the **Navigation Area** component, select the **Exclusion** property.
4. In the **Viewport**, place the exclusion area within the navigation mesh.
5. Shape the polygon to the preferred shape for the exclusion area.

**Navigation Physics Integration**

The navigation system builds the navigation mesh based on all the static physics colliders provided by the physics system, including terrain. By default, both the CryPhysics and PhysX systems (AZ::Physics) are supported. This can be changed with the *ai_NavPhysicsMode* cvar:

**ai_NavPhysicsMode**

Navigation physics integration mode which determines where collider and terrain data used in navigation mesh calculations comes from.

Default: 1

- 0 – CryPhysics only
- 1 – CryPhysics and AZ::Physics
- 2 – AZ::Physics only

**Physics integration details**

When AZ::Physics integration mode is enabled, the navigation mesh voxelizer issues a WorldRequestBus::Overlap static query to gather colliders within a bounding box. Shape geometry is returned from the new AZ::Shape::GetGeometry() method. PhysX colliders for terrain, shapes, and meshes will provide triangle data in an operation that acquires a PhysX scene read lock while retrieving geometry data.

**NavigationAreaRequestBus EBus Interface**

Use the following request function with the NavigationAreaRequestBus EBus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851)
**RefreshArea**

You can use the `PolygonPrismShapeComponentRequestBus` (p. 716) to modify the polygon prism area by adding, removing, and updating its vertex positions. Use `RefreshArea` to update the navigation area after making changes to the area.

**Parameters**

None

**Return**

`AZ::ConstPolygonPrismPtr`

**Scriptable**

No

**Note**

The Navigation Area component depends on the Polygon Prism component, which also uses `VertexContainer` functions. For more information, see Vertex Containers (p. 904).

---

**Navigation Seed**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

The **Navigation Seed** component marks chunks of the **Navigation Area** (p. 693) that are accessible to AI agents. Game developers can use this component as a visual aid to determine where AI agents can go.

The **Navigation Area** (p. 693) component can generate a complex-looking mesh with disconnected islands. If this happens, it can be difficult to determine the precise places that your AI can reach. In this case, use the **Navigation Seed** component to render a color-coded map. The blue chunks are accessible to AI and the red chunks are inaccessible.
For example, static objects (p. 696), exclusion areas (p. 697), or terrain features can divide a navigation area (p. 693) into multiple chunks. The Navigation Seed component marks in blue where AI can reach if they are already in that chunk (for example, if they spawned there). You might have multiple navigation areas in one location, such as for different agent types (p. 687). In this case, use the Navigation Seed component to calculate accessibility for all agent types (p. 696) or a specific agent type in the chunk where you placed the navigation seed.

**To use the Navigation Seed component**

1. Create a navigation area (p. 693).
2. Divide the navigation area into multiple chunks using static objects (p. 696), exclusion areas (p. 697), or terrain.
3. Add (p. 479) the Navigation Seed component to the navigation area entity or to a separate entity.
4. If you want to specify an agent type (p. 687), select it in the Navigation Seed component.
5. Move (p. 201) the seed around.

   If you turned on visualization (p. 695), all AI-accessible areas render blue in the chunk where you placed the navigation seed. Inaccessible areas render red.

**To calculate accessibility for agent types**

- In the Navigation Seed component, do one of the following:
  
  a. To calculate accessibility for all agent types, leave the Agent Type field blank.
  b. To calculate accessibility for a specific agent type, select a type in the Agent Type drop-down list.

By default, the navigation seed visualization system is not enabled. You must use the console to enable some flags.

**To enable Navigation Seed visualization**

- Enable the following console variables. To do this, set the value to 1.
  
  ai_MNMDebugAccessibility (In Lumberyard Editor, you can also choose Game, AI, Visualize Navigation Accessibility.)
  
  ai_DebugDraw
  
  ai_DebugDrawNavigation

For more information, see Using the Console Window (p. 210).

**Note**

The Navigation Seed component exists only in Lumberyard Editor.

---

**Network Binding**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Network Binding component marks an entity as able to be replicated across the network. It interfaces with the NetBindable interface in order to call the functions specified there.
OccluderArea

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the OccluderArea component to create a custom-shaped occlusion plane with four vertices. This is useful if you don't want Lumberyard to render everything that is behind the OccluderArea component. This can result in better performance in areas where automatic occlusion doesn't work well. For example, if you have many objects behind a wall, you can add an occluder area behind the wall so that those objects don't appear.

Note
You can't modify the OccluderArea (p. 701), Portal (p. 717), and VisArea (p. 918) components at runtime.

Topics
• OccluderArea Component Properties (p. 701)
• Occluder Area Component Example (p. 702)

OccluderArea Component Properties

The OccluderArea component has the following properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DisplayFilled</td>
<td>Displays the occluder area as a filled volume in the Lumberyard Editor viewport.</td>
</tr>
<tr>
<td>CullDistRatio</td>
<td>A multiplier on the range where the culling effect stops.</td>
</tr>
<tr>
<td>UseInIndoors</td>
<td>The occluder area works inside visible areas.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DoubleSide</td>
<td>Specifies whether the occluder area works from both sides.</td>
</tr>
<tr>
<td>Vertices</td>
<td>The vertices that define the shape of the occluder area. Occluder areas always have four vertices.</td>
</tr>
<tr>
<td>Edit</td>
<td>Choose Edit, and the component is locked for editing. For more information, see Editing Components in the Viewport (p. 483).</td>
</tr>
</tbody>
</table>

**Occluder Area Component Example**

The following example shows two boxes. One box is hidden behind the occluder area, but you can see its shadow. The other box is outside the occluder area and appears normally on screen.

**Particle**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the **Particle** component to place a single particle emitter on an entity. An entity can have multiple **Particle** components.
Particle Component Properties

The Particle component has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visible</td>
<td>If set, renders the emitter.</td>
</tr>
<tr>
<td>Enable</td>
<td>If set, activates the particle effect.</td>
</tr>
<tr>
<td>Particle effect library</td>
<td>Specifies the particle effect library.</td>
</tr>
<tr>
<td></td>
<td>The Particle component uses the effects from an XML file.</td>
</tr>
<tr>
<td>Emitters</td>
<td>Select an emitter from the list after specifying a particle effect library.</td>
</tr>
</tbody>
</table>

Version 1.28
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

</tbody>
</table>
| Strength Curve Time     | Controls all **Strength Over Emitter Life** curves. The curves will use this **Strength Curve Time** parameter instead of the actual emitter lifetime.  
Negative values are ignored.  
Valid values: \(-1 \text{ to } 1\) |
| Ignore rotation         | If set, ignores the entity's rotation.                                      |
| Not attached            | If set, ignores the entity's position. The emitter does not follow its entity. |
| Register by bounding box| If set, uses the bounding box instead of the entity's position to appear in the visible area. |
| Use LOD                 | If cleared, ignores the emitter's level of detail (LOD).                    |
| Target Entity           | Uses the specified target entity for emitters with the **Target Attraction** parameter or similar features enabled.  
For more information, see **Movement Attribute** (p. 1529). |
| View distance multiplier| Adjusts the maximum view distance. If the value is 1, the default is used. If the value is 1.1, the view distance would be 10% further than the default.  
Set the value to 100 for infinite visibility.  
Valid values: 0 to 100 |
| Use VisAreas            | Allow visible areas to control this component's visibility.                |
| Enable audio            | If set, enables audio.                                                     |
| Audio RTPC              | Select the audio **Real-Time Parameter Control (RTPC)** (p. 3147) that the particle effect instance drives. |

### EBus Request Bus Interface

Use the following request function with the EBus (event bus) interface to communicate with other components of your game.

For more information, see **Working with the Event Bus (EBus) system** (p. 1851).

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hide</td>
<td>Hides the emitter.</td>
<td>None</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>Show</td>
<td>Shows the emitter.</td>
<td>None</td>
<td>None</td>
<td>Yes</td>
</tr>
</tbody>
</table>
**Point Light**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the **Point Light** component on an entity to create a point of light.

The **Point Light** component has the following settings:

**Visible**

- Shows the light.

**On initially**

- Specify if the light is on when created.

**General Settings**

See the following general settings:

**Color**

- The color of the light.
  - Default value: 0xFFFFFFFF

**Diffuse multiplier**

- Sets the strength of the diffuse color.
  - Default value: 1

**Specular multiplier**

- Sets the strength of the specular brightness.
  - Default value: 1

---

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>SetVisibility</td>
<td>Sets an explicit value for emitter visibility.</td>
<td>Boolean</td>
<td>None</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Example**

The following script uses the EBus interface.

```plaintext
function example:OnActivate()
    ParticleComponentRequestBus.Event.Show(self.entityId)
    ParticleComponentRequestBus.Event.Hide(self.entityId)
    ParticleComponentRequestBus.Event.SetVisibility(self.entityId, false)
end
```
Ambient

Light acts as a multiplier for cubemap values.

Point Light Settings

See the following point light settings:

Max Distance

Maximum distance, in a radius, from which this light is visible.

Default value: 2

Attenuation bulb size

Radius in meters before light falloff begins.

Default value: 0

Options

See the following options:

View distance multiplier

Adjusts the maximum view distance. For example, 1.0 uses the default and 1.1 is 10% farther than the default.

Default value: 1

Minimum spec

The minimum specification value at which this light is enabled.

Default value: Low

Cast shadow spec

The minimum specification at which shadows are cast.

Default value: Never

Voxel GI mode

Mode for light interaction with voxel global illumination (GI). Choose None, Static, or Dynamic.

Use VisAreas

Light is affected by visible areas. If unselected, light ignores visible areas.

Indoor only

Light is only rendered indoors.

Affects this area only

Light affects only the immediate area.

Volumetric fog only

Light affects only volumetric fog.
Volumetric fog

Light affects volumetric fog and surrounding area.

Shadow Settings

See the following shadow settings:

Terrain Shadows

Includes the terrain in the shadow casters for this light.

Animation

See the following animation settings:

Style

Enter a number to specify a preset light animation curve to play as defined in the Light.cfx file. Valid values are 0 to 48. You can also use values 40 to 48 for testing and debugging.

Default value: 0

Speed

Multiple of the base animation rate. For example, a value of 2.0 makes an animation play twice as fast.

Default value: 1

Phase

Animation start offset from 0 to 1. A value of 0.1 is 10% into the animation. For example, you can use this setting to prevent lights in the same scene, with the same animation, from being animated in unison.

Default value: 0

EBus Request Bus Interface

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

All light components share common EBus functions. For more information, see Light Components EBus Request Bus Interface (p. 548).

Polygon Prism Shape

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
You can use the **Polygon Prism Shape** component to define a volume. A right polygonal prism is a 3D prism made from two translated polygons connected by rectangles. The **Polygon Prism Shape** component is defined by one polygon and a height property. All vertices lie on the local plane, where $z = 0$. The polygon is defined in the xy-plane of the entity. All vertices are in the local space of the entity. You can use the **Polygon Prism Shape** component with the **Trigger Area** (p. 890) component to create a volume for the trigger area bounds.

**Note**
The **Polygon Prism Shape** component supports only simple polygons. It can't have self-intersecting sides. Parallelogram sides aren't supported.

**Contents**
- Polygon Prism Shape Component Properties (p. 709)
- Working with Polygon Prism Components (p. 710)
- EBus Request Bus Interface (p. 716)
  - Example Polygon Prism Component EBus Request (p. 717)

### Polygon Prism Shape Component Properties

The **Polygon Prism Shape** component has the following properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visible</td>
<td>The component always appears in the viewport, even if the entity isn't selected.</td>
</tr>
<tr>
<td>Game View</td>
<td>Renders the shape in game mode in Lumberyard Editor. To enter game mode, press Ctrl + G.</td>
</tr>
<tr>
<td>Shape Color</td>
<td>Specifies the color to render the shape.</td>
</tr>
<tr>
<td>Height</td>
<td>The height of the polygon prism shape, in meters.</td>
</tr>
<tr>
<td>Edit</td>
<td>Choose <strong>Edit</strong>, and the component is locked for editing. For more information, see Editing Components in the Viewport (p. 483).</td>
</tr>
</tbody>
</table>

By default, when you add the **Polygon Prism Shape** component to an entity, the component has four vertices.
Working with Polygon Prism Components

Each vertex has one planar and two linear manipulators. Combined, these are called the translation manipulator. You can use the translation manipulator to move the vertices. The translation manipulator limits moving a vertex only to the xy-plane. No surface manipulator is present as all vertices must exist on the same plane. You can't change the z-position of the polygon in the local space.

To change the vertex positions

- Do one of the following:
  - In the Polygon Prism Shape component property window, change the vertex values.
  - Select a vertex. In the translation manipulator, click and drag the green or red arrow to a position.
Note
The manipulators follow the grid snap setting that you can configure in the Lumberyard Editor toolbar.

You can use the blue arrow in the center of the volume to change the height.

To change the height of the polygon prism
- Drag the blue arrow to change the height of the polygon prism.
Note

If the entity is scaled, the manipulators continue to behave correctly, but the scaling must be uniform so that the x, y, and z scale values match.

To select multiple vertices

- Press *Shift* and select the vertices. Selected vertices appear yellow.

Note

Currently, you can’t click and draw a box around the vertices to select them. You can also snap a vertex to another position on the terrain.
To snap a vertex to another position

1. Select a vertex.
2. Hold **Shift+Ctrl** and click another position on the terrain. The vertex snaps to that position.

You can also add vertices to the polygon prism.

To add a vertex to the polygon prism

1. Pause on a line and hold **Ctrl**. A preview appears where you can add a vertex.
2. Click to add the vertex to the polygon prism.
You can also delete vertices from the polygon prism.

To delete a vertex from a polygon prism

1. Hold Alt and pause on a vertex. The vertex appears gray.
2. Click the vertex to remove it from the polygon prism. You can also select a vertex and press **Delete**.
**EBus Request Bus Interface**

Use the following request functions with the `PolygonPrismShapeComponentRequestBus` EBus interface to communicate with other components of your game. The **Polygon Prism Shape** component also uses `VertexContainer` functions. For more information, see [Vertex Containers](p. 904).

For more information about using the event bus (EBus) interface, see [Working with the Event Bus (EBus) system](p. 1851).

<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetPolygonPrism</td>
<td>Returns a constant pointer to the underlying polygon prism shape data.</td>
<td>None</td>
<td><code>AZ::ConstPolygonPrismPtr</code></td>
<td>Yes</td>
</tr>
<tr>
<td>SetHeight</td>
<td>Sets the height of the polygon prism shape.</td>
<td>Height</td>
<td>None</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Default value: 1.0

Min: 0.0

Max: N/A
Example Polygon Prism Component EBus Request

The following script uses the request bus interface.

```lua
-- PolygonPrism Interface
local polygonPrism = PolygonPrismShapeComponentRequestBus.Event.GetPolygonPrism(self.entityId);

polygonPrism.height
polygonPrism.vertexContainer:Size()
polygonPrism.vertexContainer[1]

PolygonPrismShapeComponentRequestBus.Event.SetHeight(self.entityId, 5.0);

-- VertexContainer interface
local firstVertex = spline.vertexContainer[1];
local lastVertex = spline.vertexContainer[spline.vertexContainer:Size()];

-- Attention: You can use the bus interface directly, but here (at the moment at least) indexing will start from 0, not 1 as is the norm in Lua. Instead, you should use the functions directly on the VertexContainer, listed below
PolygonPrismShapeComponentRequestBus.Event.AddVertex(self.entityId, Vector2(10, 10));
PolygonPrismShapeComponentRequestBus.Event.UpdateVertex(self.entityId, 0, firstVertex + Vector2(5, 5));
PolygonPrismShapeComponentRequestBus.Event.InsertVertex(self.entityId, spline.vertexContainer:Size() - 1, lastVertex);
PolygonPrismShapeComponentRequestBus.Event.ClearVertices(self.entityId);
PolygonPrismShapeComponentRequestBus.Event.RemoveVertex(self.entityId, spline.vertexContainer:Size() - 1);

-- Prefer these functions - indexing will start from 1
polygonPrism.vertexContainer:AddVertex(lastVertex + Vector2(5, 5));
polygonPrism.vertexContainer:UpdateVertex(1, firstVertex + Vector2(10, 10));
polygonPrism.vertexContainer:InsertVertex(polygonPrism.vertexContainer:Size(), lastVertex + Vector2(2, 2));
polygonPrism.vertexContainer:Clear();
polygonPrism.vertexContainer:RemoveVertex(polygonPrism.vertexContainer:Size());
```

Portal

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Portal component to create efficient indoor areas with the VisArea (p. 918) component. You can use portals to specify areas where you can look out of a visible area and see beyond it, such as windows or doors between visible areas.

To use the Portal component, its volume must overlap at least two or more visible areas.

Note
You can't modify the OccluderArea (p. 701), Portal (p. 717), and VisArea (p. 918) components at runtime.

Topics
Portal Component Properties

The Portal component has the following properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Height</td>
<td>The height of the portal.</td>
</tr>
<tr>
<td>DisplayFilled</td>
<td>Displays the portal as a filled volume in the Lumberyard Editor viewport.</td>
</tr>
<tr>
<td>AffectedBySun</td>
<td>Specifies whether the sun affects objects in the portal.</td>
</tr>
<tr>
<td>ViewDistRatio</td>
<td>A multiplier on how far the portal is rendered.</td>
</tr>
<tr>
<td>SkyOnly</td>
<td>Renders only the skybox outside the portal.</td>
</tr>
<tr>
<td>OceanIsVisible</td>
<td>Renders the ocean outside the portal.</td>
</tr>
<tr>
<td>UseDeepness</td>
<td>The portal is treated as an object with a volume instead of a plane.</td>
</tr>
<tr>
<td></td>
<td>If false, the portal acts as if it does not have a volume and is</td>
</tr>
<tr>
<td></td>
<td>treated like a plane between the four floor points.</td>
</tr>
<tr>
<td>DoubleSide</td>
<td>Cameras can look through the portal from both sides. If false, the portal</td>
</tr>
<tr>

<td>Specify whether to blend light between connected visible areas.</td>
</tr>
</tbody>
</table>
### Portal Component Examples

#### Example 1

In the following examples, two boxes are inside several visible areas. The visible areas are connected by the portals, which are green. The portal lets you see between the visible areas. The shadows of the boxes inside the visible areas appear because the **AffectedBySun** option is enabled.

![Portal Example 1](image)

#### Example 2

The following example shows how the portal lets you see between two visible areas. Although the boxes are in separate visible areas, the portal creates a window between them so that you can see both boxes.

![Portal Example 2](image)
Example 3

In the following example, you see the portal at an angle. You can't see the box in the other visible area because there is no portal in that line of sight.
Example 4

In the following example, you can see a box through a different portal, but because the DoubleSide option is disabled, the portal is one-sided.
Example 5

In the following example, if you go through the portal and look back, you can see the other visible areas, but you can't see the boxes in those areas. You can't see through portals that aren't connected to the visible area that you're in.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the **Projector Light** component on an entity to project a light.

The **Projector Light** component has the following settings:

**Visible**

Show the light.

**On initially**

Specify if the light is on when created.

**General Settings**

See the following general settings:

**Color**

The color of the light.
Default value: 0xFFFFFFFF

**Diffuse multiplier**

Sets the strength of the diffuse color.

Default value: 1

**Specular multiplier**

Sets the strength of the specular brightness.

Default value: 1

**Ambient**

If selected, light acts as a multiplier for cubemap values.

---

**Project Light Settings**

See the following point light settings:

**Max Distance**

Maximum distance that the projector light extends, in meters.

Default value: 5

**Attenuation bulb size**

Radius before light begins to fade, in meters.

Default value: 0

**FOV**

Projector light's field of view (FOV), in degrees.

Default value: 90

**Near plane**

Distance of the near plane to the projector light, in meters. Objects behind this plane are not affected by the projector light.

**Texture**

Projector light's texture file. Without a texture, light does not shine.

**Material**

Projector light's material file.

---

**Options**

See the following options:

**View distance multiplier**

Adjusts the maximum view distance. For example, 1.0 uses the default and 1.1 is 10% farther than the default.
Default value: 1

**Minimum spec**

The minimum specification value at which this light is enabled.

Default value: Low

**Cast shadow spec**

The minimum specification at which shadows are cast.

Default value: Never

**Voxel GI mode**

Mode for light interaction with voxel global illumination (GI). Choose None, Static, or Dynamic.

**Use VisAreas**

Light is affected by visible areas. If unselected, light ignores visible areas.

**Indoor only**

Light is only rendered indoors.

**Affects this area only**

Light affects only the immediate area.

**Volumetric fog only**

Light affects only volumetric fog.

**Volumetric fog**

Light affects volumetric fog and surrounding area.

### Shadow Settings

See the following shadow settings:

**Terrain Shadows**

Includes the terrain in the shadow casters for this light.

### Animation

See the following animation settings:

**Style**

Enter a number to specify a preset light animation curve to play as defined in the `Light.cfx` file. Valid values are 0 to 48. You can also use values 40 to 48 for testing and debugging.

Default value: 0

**Speed**

Multiple of the base animation rate. For example, a value of 2.0 causes an animation to play twice as fast.
Default value: 1

**Phase**

Animation start offset from 0 to 1. A value of 0.1 is 10% into the animation.

For example, you can use this setting to prevent lights in the same scene, with the same animation, from being animated in unison.

Default value: 0

**Additional Resources**

- For more information about the **Projector Light** component, see the following:
  - Intro to Environment Lighting
  - Getting Started: Using Lighting Tutorial (video)

**EBus Request Bus Interface**

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

All light components share common EBus functions. For more information, see Light Components EBus Request Bus Interface (p. 548).

**PhysX Ball Joint component**

With the **PhysX Ball Joint** component, you can create a dynamic ball joint that constrains an entity to the joint with freedom to rotate around the y- and z-axes of the joint.
**PhysX Ball Joint component properties**

![PhysX Ball Joint component properties](image)

- **Local Position**
  - Specify the position of the joint relative to the entity transform.

- **Local Rotation**
  - Specify the rotation of the joint relative to the entity transform.

- **Lead Entity**
  - Specify the parent entity that will drive the joint.

- **Breakable**
  - When enabled, the joint will break if sufficient force is applied. Enabling **Breakable** exposes the **Maximum Force** and **Maximum Torque** properties.

**Note**

- **PhysX Rigid Body** components that have their **Compute Mass** property enabled might have very large mass values. If the entity containing the joint component or the leader entity have their **Compute Mass** property enabled, the **Maximum Force** and **Maximum Torque** properties might require very high values to resist breaking.
**Maximum Force**

When **Breakable** is enabled, specify the maximum force the joint can sustain before breaking. Valid values range from 0.01 to Infinity.

**Maximum Torque**

When **Breakable** is enabled, specify the maximum torque the joint can sustain before breaking. Valid values range from 0.01 to Infinity.

**Display Setup in Viewport**

When enabled, a cone that represents the orientation and limits of the ball joint and a line that represents the connection between the joint and its leader are displayed. The shape of the cone is defined by the **Y axis angular limit** and the **Z axis angular limit**.

**Select Lead on Snap**

When enabled, snapping the joint to an entity in component mode will set the entity as the **Lead Entity**. The entity containing the joint component is excluded from this operation.

**Lead-Follower Collide**

When enabled, the lead entity and follower entity (the entity containing the joint component) will collide.

**Limit**

When enabled, the lead entity's movement around the joint axes is constrained by angular limits. Enabling **Limit** exposes the **Soft Limit**, the **Y axis angular limit**, and the **Z axis angular limit** properties.

**Soft Limit**

When enabled, the lead entity's movement around the joint axes is allowed to pass the specified limit. With **Soft Limit** enabled, when the lead entity rotates past the limit, the lead entity's movement is treated as a spring and will slow, then spring back to the limit area. Enabling **Soft Limit** exposes the **Damping** and **Stiffness** properties.

**Damping**

When **Soft Limit** is enabled, the spring's drive relative to the velocity of the follower when outside the rotation limit. Valid values range from 0.001 to 1000000.0.

**Stiffness**

When **Soft Limit** is enabled, the spring's drive relative to the position of the follower when outside the rotation limit. Valid values range from 0.001 to 1000000.0.

**Y axis angular limit**

The rotation limit around the joint's y-axis when **Limit** is enabled. Valid values range from 0.1 to 180.0.

**Z axis angular limit**

The rotation limit around the joint's z-axis when **Limit** is enabled. Valid values range from 0.1 to 180.0.

**Edit**

When clicked, component edit mode is enabled. In component edit mode, all components are locked except for the **PhysX Ball Joint** component. The properties of the **PhysX Ball Joint** component can be edited in **Perspective**. Press **Tab** to cycle through the component edit modes. Click **Done** to exit component mode.
PhysX Character Controller

You can use the PhysX Character Controller component to implement basic character interactions with the physical world. For example, you can prevent characters from walking through walls or passing through terrain. You can also control interactions with slopes and steps and manage interactions with other characters.

The following diagram shows some of the features of the PhysX Character Controller component. Because it is usually more convenient to work with a character's foot position, the entity position coincides with the base of the controller. For details about the contact offset, see Contact Offset (p. 733).

The PhysX Character Controller component requires the PhysX Characters (p. 1188) gem, which you can enable (p. 1064) in the Project Configurator.

Topics

- Using the PhysX Character Controller Component (p. 730)
- PhysX Character Controller Properties (p. 730)
- Differences Between PhysX and Legacy Character Physics Components (p. 734)
Using the PhysX Character Controller Component

To use the **PhysX Character Controller** component, add it to an entity (p. 479) that represents a character.

You can control the character's movement by using Script Canvas, the C++ API, or animation systems that use the C++ API.

**PhysX Character Controller Properties**

You can configure the properties for the **PhysX Character Controller** component in the **Entity Inspector (p. 475)**.

The **PhysX Character Controller** has the following component properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Collision Layer</td>
<td>Collision layer assigned to the controller. The default is <strong>Default</strong>.</td>
</tr>
<tr>
<td>Collides With</td>
<td>Collision layers that this character controller collides with. Possible</td>
</tr>
<tr>
<td></td>
<td>values are those that you define in the collision groups section of the</td>
</tr>
<tr>
<td></td>
<td>PhysX configuration.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>

<td>You can specify the following values:</td>
</tr>
<tr>
<td></td>
<td>• All</td>
</tr>
<tr>
<td></td>
<td>• None</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>The collision filters determine whether dynamic objects collide with the controller. A separate set of filters control what objects can impede the character from moving. The movement filters are currently hard-coded so that static objects obstruct character movement.</td>
</tr>
<tr>
<td>Material Library</td>
<td>PhysX material (p. 2797) assigned to this character controller.</td>
</tr>
<tr>
<td></td>
<td>• Click the browse icon (...) to open the Pick Physics Material dialog box.</td>
</tr>
<tr>
<td></td>
<td>• Click the Open in Asset Editor icon to open the material in the Asset Editor.</td>
</tr>
<tr>
<td></td>
<td>• Click the X icon to clear the asset.</td>
</tr>
<tr>
<td>Material Slot</td>
<td>Specifies a material from the material library. To select a material from the library, click the drop-down list. The default is the first value configured.</td>
</tr>
<tr>
<td></td>
<td>If the material library is empty, this option does not appear and the default material values (0.5 and average for all parameters) are used.</td>
</tr>
<tr>
<td>Maximum Slope Angle (p. 732)</td>
<td>Angle in degrees of the largest slope that the character controller can climb.</td>
</tr>
<tr>
<td>Step Height (p. 732)</td>
<td>Height of steps in meters that the character controller can traverse.</td>
</tr>
<tr>
<td>Minimum Movement Distance</td>
<td>Distance in meters below which the controller doesn't attempt to move. Used to avoid jittering.</td>
</tr>
<tr>
<td>Collider Tag</td>
<td>A tag string used to identify the collider associated with the character controller.</td>
</tr>
<tr>
<td>Slope Behavior</td>
<td>Behavior of the controller on surfaces above the maximum slope.</td>
</tr>
<tr>
<td></td>
<td>You can specify the following values:</td>
</tr>
<tr>
<td></td>
<td>• Prevent Climbing</td>
</tr>
<tr>
<td></td>
<td>• Force Sliding</td>
</tr>
<tr>
<td></td>
<td>The default is Prevent Climbing.</td>
</tr>
<tr>
<td>Contact Offset (p. 733)</td>
<td>Additional distance in meters beyond the controller that is monitored for potential contact. Used for smoother contact resolution.</td>
</tr>
<tr>
<td>Scale</td>
<td>Scales the size of the collider created in PhysX relative to the dimensions specified for the controller. A value slightly smaller than 1 is recommended.</td>
</tr>
<tr>
<td></td>
<td>The default is 0.8.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **Shape (p. 734)**| Shape of the character controller. You can specify the following values:  
• Box  
• Capsule  
The default is **Capsule**. |
| **Height (Capsule Only)** | Height of the capsule in meters. |
| **Radius (Capsule Only)** | Radius of the capsule in meters. |
| **Dimensions (Box Only)** | The x, y, and z dimensions of the box in meters. |

**Maximum Slope Angle**

The maximum slope angle is the largest slope that the character controller can climb. The character cannot move in directions that exceed this slope. If the character is standing on a slope above the maximum slope angle, its behavior depends on the slope behavior setting. The range of values allowed in the **Entity Inspector** is from 0 to 89 degrees.

**Step Height**

The maximum slope angle determines the step height that the controller can climb.

**Example**

Capsule controllers might be able to climb steps slightly higher than the step height because the curved bottom can slide upwards on steps. Refer to the following image:
The contact offset is the distance padding between the collider shape and the contact surface. The contact offset allows the simulation to provide smoother collision behavior.

**Note**

The contact offset is included in the calculation for the foot position.

**Example**

In the editor debug draw for the PhysX Character Controller component, the effect of the contact offset is represented by the wireframe that surrounds the solid shape of the collider, as in the following image.
Shape

You can use character controller collider with the following shapes:

- Capsule
- Box

Use the **Shape** property in the **Entity Inspector** to choose the desired shape. When you do so, the relevant dimensions are displayed for editing. The dimension settings are identical to the capsule and box options for the **PhysX Collider (p. 735)** component.

Differences Between PhysX and Legacy Character Physics Components

Character controllers are usually **kinematic** or **dynamic**. Dynamic character controllers are controlled through their velocity or by applying forces. Kinematic character controllers are controlled directly by position. Each controller type has advantages and disadvantages.
For more information, see Character Controllers in the NVIDIA documentation.

In Lumberyard, the PhysX Character Controller component is kinematic. The legacy Character Physics component is dynamic.

Because the PhysX Character Controller component is kinematic and not affected by outside forces, it is not affected by gravity out of the box. This separation allows you to use Script Canvas or C++ to implement custom behavior for gravity. Kinematic controllers behave as if they have infinite mass when dynamic objects collide with them. Your custom gameplay logic determines how the controller responds to collisions such as the recoil from heavy impacts.

**PhysX Collider**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Performance demands in games and real-time applications require physics simulations to be solved in fractions of a second. The PhysX Collider component allows you to specify primitive shapes or PhysX mesh assets to calculate collisions between entities, ensuring fast physics simulation. A simple entity such as a crate might have a single PhysX Collider component, while more complex entities, such as vehicles, might require multiple PhysX Collider components.

**Note**

The PhysX Collider component attached to an entity by itself creates a static (non-moving) entity, such as a wall or a mountain. To create a dynamic (moving) entity, you also need to add a PhysX Rigid Body component. The PhysX Rigid Body Physics component requires either a primitive collider or convex mesh collider. Triangle mesh physics assets work only with static entities.

The PhysX Collider component requires the PhysX gem enabled in your project.

For more information, see PhysX system.

**Topics**

- PhysX Collider properties
- Static PhysX entities
- Primitive colliders
- Physics asset colliders
- Collider component mode
- Colliders as triggers
PhysX Collider properties

Collision Layer
The collision layer that's assigned to the collider. For more information, see Collision Layers (p. 2785).

Collides With
The collision group containing the layers that this collider collides with. For more information, see Collision Groups (p. 2787).

Trigger
Set this collider as a trigger. A trigger performs a quick overlap test and does not apply forces or return contact point information. Use this to speed-up PhysX computations where a simple overlap between colliders is sufficient.

**Note**
Triangle meshes are not supported as triggers.
Trigger Area components cannot be used with PhysX Collider.

### Simulated
When enabled, this shape collider will be part of the physics simulation.

### In Scene Queries
When enabled, this shape collider can be queried for raycasts, shapecasts and overlap.

### Offset
Local offset position of the collider, relative to the entity.

### Rotation
Local rotation of the collider about the Offset of the PhysX collider component.

### Physics Material - Library
Set the physics material library for this collider.

### Physics Material - Mesh Surfaces
Choose a material from the physics material library for this collider. A collider can have multiple materials assigned. For more information, see Physics materials (p. 2797).

### Tag
Set a tag for this collider. Tags can be used to quickly identify components in script or code.

### Rest offset
PhysX bodies come to rest separated by the sum of their rest offset values. The Rest offset value must be less than the Contact offset value. Valid values range from \(-\infty\) to 50.

### Contact offset
PhysX bodies generate contacts when they are within the sum of their contact offset values. The Contact offset value must be greater than the Rest offset value. Valid values range from 0 to 50.

### Shape
Shape of the collider. A collider can be a primitive shape or a physics asset.

To use a primitive shape, choose Box, Sphere, or Capsule. For more information, see Primitive colliders (p. 739).

To use a physics asset, choose Physics Asset. For more information, see Physics asset colliders (p. 739).

### PhysX Mesh (Physics Asset shape)
Assign a physics asset to the collider. For more information, see FBX Settings PhysX export (p. 439).

### Radius (Sphere shape)
Radius multiplier of the sphere collider. The size of the sphere primitive is the Radius multiplied by the largest value in the Scale property in the Transform (p. 878) component.
Dimensions (Box shape)

Width, depth, and height of the box collider.

Height (Capsule shape)

Height of the capsule primitive shape. The height property of the capsule must be at least twice the radius property. For example, if the radius of the capsule is 5.0, the minimum height is 10.0.

Radius (Capsule shape)

Radius of the capsule primitive shape. The radius property of the capsule must be no greater than half the height property. For example, if the height of the capsule is 10.0, the maximum radius is 5.0.

Asset Scale

Scale the collider shape independent of the entity.

Physics Materials from Mesh

When the Physics Asset shape is selected, and Physics Materials from Mesh is enabled, the physics material for this collider is automatically set based on the surface type in the mesh's material. If the surface type in the mesh's material doesn't exist in the Physics Material - Library, the Physics Material - Mesh Surface is set to default. The collider Mesh Surfaces properties cannot be edited while this option is enabled.

Draw Collider

Render the collider in the viewport. Enabled by default.

Edit

Enable collider component mode to edit properties of the collider in the viewport using manipulators.

Static PhysX entities

A PhysX entity that is static can interact with other entities, but doesn't move.

To create a static PhysX entity

1. Create an entity. For more information, see Creating an Entity (p. 463).
2. In the Entity Inspector, choose Add Component and then select Mesh (p. 684) component.
3. In the Mesh component, choose a mesh asset for the Mesh asset property.
4. In the Entity Inspector, choose Add Component and then select PhysX Collider component.
5. In the **PhysX Collider** component, set the **Shape** to **Box**, and edit the **Dimensions** property so the box encloses the mesh asset.

6. Press **Control+G** to enter play mode. Because your entity does not have a **PhysX Rigid Body** component, it is static and does not move.

**Tip**
On the **Transform (p. 878)** component, enable the **Static** property. This enables optimizations for static entities.

### Primitive colliders

When you add the **PhysX Collider** component to an entity, you can specify the following basic collider shapes.

- **Sphere**
- **Box**
- **Capsule**

These primitive shapes don't have an underlying mesh. Because they are defined by dimensions rather than a mesh, they are high-performance colliders and should be used when possible.

### Physics asset colliders

Physics asset colliders are meshes that are created in a modeling application, or are convex meshes that are automatically generated by the FBX exporter. Because physics asset colliders are more complex than shapes, they are less efficient. Physics asset colliders should be used in cases where collision detection that more closely resembles the complex shape of the visible mesh is required. To generate PhysX collider mesh assets for your project, see **FBX Settings PhysX export (p. 439)**.
To define a mesh collider that has varying properties:

- Use a third-party content creation tool to define a mesh collider and use the FBX exporter to convert the mesh collider for your project. Mesh colliders created this way can only be added to static entities.
- Alternatively, attach multiple PhysX Collider components to the entity, and specify different PhysX collider shapes and properties for each component.

To create a mesh collider

1. Create an entity. For more information, see Creating an Entity (p. 463).
2. In the Entity Inspector, choose Add Component and then select Mesh (p. 684).
3. In the Mesh component, choose a mesh asset for the Mesh asset property.
4. In the Entity Inspector, choose Add Component and then select PhysX Collider.
   
   **Note**
   
   If the asset specified for the Mesh component contains a PhysX collider mesh asset, the PhysX Collider automatically sets its Shape property to Physics Asset, and its PhysX Mesh property to the PhysX collider mesh asset. If the asset specified for the Mesh component contains more than one PhysX collider mesh asset, the first PhysX collider mesh asset found is assigned to the PhysX Mesh property.

5. In the PhysX Collider properties, ensure that the Shape property has Physics Asset selected.
6. For PhysX Mesh, ensure that the desired PhysX collider mesh asset is selected. Click the ... button to the right of PhysX Mesh to change the mesh asset.

**Note**

To generate PhysX collider mesh assets for your project, see FBX Settings PhysX export (p. 439).

**Example**

Instead of a primitive shape, the entity has a PhysX collider mesh asset specified for the PhysX Collider component.
Note
To make an entity dynamic, in the Entity Inspector, choose Add Component and then select PhysX Rigid Body Physics component. Only primitive shapes and convex meshes can be used for dynamic colliders. If you assign a triangle mesh, the collider won't work. For dynamic objects, be sure to disable the Static property of the Transform component of your entity.

Collider component mode

In collider component mode, you edit colliders with manipulators in the viewport. To enter collider component mode, choose the Edit button at the bottom of the PhysX Collider component properties in the Entity Inspector.

Sub component modes

There are three editing modes available in collider component mode.

- **Resize** mode, which is unique to each collider type, scales the collider.

  The manipulator displayed in the viewport in resize mode is dependent on the collider shape. For primitive colliders, the resize manipulator handles are represented as black squares. For Physics Asset colliders, the resize manipulator is represented as a familiar scale manipulator.

- **Offset** mode translates the collider relative to its entity transform.

- **Rotation** mode rotates the collider about the component's Offset.
Resize (Sphere Shape)

*Sphere* resize mode has one linear manipulator that controls the *Radius* property.

Resize (Box Shape)

*Box* resize mode has six linear manipulators, one on each side of the box. The manipulators control the width, depth, and height *Dimensions* property.
**Resize (Capsule Shape)**

Capsule resize mode has two linear manipulators. The manipulator at the top of the capsule controls the **Height** property. The manipulator on the side controls the **Radius** property.

**Resize (Physics Asset Shape)**

Physics Asset resize mode has a three axis scale manipulator.

**Offset**

Offset mode has a three axis translate manipulator.
Rotation

Rotation mode has a three axis rotate manipulator.

Collider component mode hotkeys

These navigation hotkeys are available in collider component mode.

• 1 – Resize mode.
• 2 – Offset mode.
• 3 – Rotation mode.
• Control + Mouse Wheel Up – Next mode.
• Control + Mouse Wheel Down – Previous mode.
• R – Reset current mode. This is effectively an undo operation. You can step through the Resize, Offset, and Rotation modes and press R to reset changes to the current mode.
• Escape – Exit component mode.

Colliders as triggers

Triggers allow colliders to perform efficient overlap tests. Colliders marked as triggers won't have forces applied when they intersect with another collider. This is useful for detecting when something enters a certain area or when two objects overlap. Use Lua or Script Canvas to detect overlap.

Note
Because triggers don't perform contact resolution, the contact points between a trigger and another collider aren't available.
Triangle meshes are not supported as triggers.
Trigger Area components cannot be used with PhysX Collider.

PhysX Fixed Joint component

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

With the PhysX Fixed Joint component, you can create a dynamic fixed joint that constrains an entity to the joint with no degree of freedom in any axis.

PhysX Fixed Joint component properties
Local Position

Specify the position of the joint relative to the entity transform.

Local Rotation

Specify the rotation of the joint relative to the entity transform.

Lead Entity

Specify the parent entity that will drive the joint.

Breakable

When enabled, the joint will break if sufficient force is applied. Enabling Breakable exposes the Maximum Force and Maximum Torque properties.

Note

PhysX Rigid Body components that have their Compute Mass property enabled might have very large mass values. If the entity containing the joint component or the leader entity have their Compute Mass property enabled, the Maximum Force and Maximum Torque properties might require very high values to resist breaking.

Maximum Force

When Breakable is enabled, specify the maximum force the joint can sustain before breaking. Valid values range from 0.01 to Infinity.

Maximum Torque

When Breakable is enabled, specify the maximum torque the joint can sustain before breaking. Valid values range from 0.01 to Infinity.

Display Setup in Viewport

When enabled, a line that represents the connection between the joint and its leader are displayed.

Select Lead on Snap

When enabled, snapping the joint to an entity in component mode will set the entity as the Lead Entity. The entity containing the joint component is excluded from this operation.

Lead-Follower Collide

When enabled, the lead entity and follower entity (the entity containing the joint component) will collide.

Edit

When clicked, component edit mode is enabled. In component edit mode, all components are locked except for the PhysX Ball Joint component. The properties of the PhysX Ball Joint component can be edited in Perspective. Press Tab to cycle through the component edit modes. Click Done to exit component mode.

PhysX Force Region

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the PhysX Force Region component to specify a region that applies physical force to entities. For each physics simulation frame, the component applies force to entities that are in the
region's bounds. You can use this component to simulate effects such as simulating gravity, slowing down, or deflecting an entity to another direction.

To create a force region, you must do the following:

- Enable the PhysX (p. 1188) gem for your game project
- Add a PhysX Collider (p. 735) component to the same entity
- For the PhysX Collider component, you must select the Trigger property for the force region to work

The PhysX Collider component's shape, size, and orientation represent the region that applies force to incoming entities.

**Note**

- For the Shape property, if you select PhysicsAsset, you must select a PxMesh asset file. If the asset isn't a convex mesh (for example, it's a triangle mesh), the collider won't work as a trigger for collisions.

<tr>
<td>Debug Forces</td>
<td>A debug arrow draws in gameplay mode. The debug arrow indicates the direction of the net force for each entity inside the force region.</td>
</tr>
<tr>
<td>Forces</td>
<td>Specifies the force types that act in the force region. You can add multiple force types for the same component.</td>
</tr>
</tbody>
</table>

**Force Types**

You can add multiple force types to the component. When an entity enters the force region, the entity moves according to the net value of the forces that you specify.

**Contents**
- Linear Damping (p. 749)
- Local Space (p. 749)
- Point (p. 750)
- Simple Drag (p. 750)
- Spline Follow (p. 750)
- World Space (p. 751)

**Linear Damping**

Applies a force in the opposite direction to an entity's velocity. For example, you can create a force that simulates a swamp or mud.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Damping</td>
<td>The amount of damping to apply. You can't specify negative values. Specify higher values to apply more damping. Specify 0 for no damping.</td>
</tr>
</tbody>
</table>

**Local Space**

Applies a force in local space, relative to the force region's orientation. For example, you can create a force that simulates a hair dryer or a vacuum cleaner.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Direction</td>
<td>The direction of the force in the local space of the force region.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>You can specify a value from -1000000 to 1000000, but Lumberyard Editor normalizes the value to a range of -1 and 1.</td>
</tr>
</tbody>
</table>

**Magnitude**

The amount of force to apply. Specify a negative value to apply the force in the opposite direction.

**Point**

Applies a force relative to the center of force region. The magnitude determines if the force is inward or outward. For example, you can create a force that simulates an explosion or a black hole.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Magnitude</strong></td>
<td>The amount of force to apply. Specify a positive value for an outward force and a negative value for an inward force.</td>
</tr>
</tbody>
</table>

**Simple Drag**

Applies a force that simulates air resistance. **Simple Drag** always applies force in the opposite direction of colliding entities. Larger and faster entities experience more drag. Entities are approximated as spheres.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Region Density** | The density of the volume. Specify higher values to increase the drag force.  
**Note** | You can specify only positive values. |

**Spline Follow**

Applies a force to make entities follow a spline. The force uses a proportional-derivative (PD) controller that simulates a spring moving along a spline. For example, you can create a force that simulates a water slide.

**Note**

- For the force region entity, if you change the **Scale** property of the **Transform** component, the scaling must be uniform so that the x, y, and z scale values match. If scaling isn’t uniform, the spline doesn’t correctly reflect the path of the force.
- The end of the spline must be outside the force region so that entities can exit after following the spline.
### Property

<td>Specify a negative value to apply the force in the opposite direction.</td>
</tr>
<tr>
<td><strong>Lookahead</strong></td>
<td>The distance, in meters, that entities look ahead in their path to reach a node on the spline.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>The Lookahead value determines how far ahead entities look for the next node to steer towards. At each physics simulation frame, the entity in the spline changes its direction to realign itself to the identified node.</td>
</tr>
<tr>
<td></td>
<td>If spline nodes are close together, you can specify a smaller Lookahead value so that entities can detect the next node.</td>
</tr>
<tr>
<td></td>
<td>If nodes are far apart, you can specify a higher Lookahead value so that entities can detect the next node.</td>
</tr>
</tbody>
</table>

### World Space

Applies a force in world space. World space force doesn't take into account an entity's orientation. For example, you can create a force that simulates gravity.

**Note**

You can define the direction for world space so that it always applies force in the direction that you want, regardless of the colliding entity.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Direction</strong></td>
<td>The direction of the force in world space.</td>
</tr>
<tr>
<td><strong>Magnitude</strong></td>
<td>The amount of force to apply. Specify a negative value to apply the force in the opposite direction.</td>
</tr>
</tbody>
</table>

**Note**

When you select a force type, remember the following:
• For **Simple Drag**, you can't define the direction of force. **Simple Drag** always works in the opposite direction of the entity's movement. In contrast, you can define a direction of force using **World Space**, which always acts in the direction that you specify, regardless of the direction of the moving entity.

• To determine how much force to apply, **Linear Damping** takes into account the colliding entity's velocity and mass but not its shape. In contrast, **Simple Drag** takes into account the colliding entity's velocity, cross-section area, and the **Region Density** of the force region.

### Creating a Force Region

You can create a force region so that force applies to another entity that enters the region.

**To create a PhysX Force Region component**

1. In Lumberyard Editor, create an entity. For more information, see Creating an Entity (p. 463).
2. Enter a name for the entity, such as **ForceRegion**.
3. In the **Entity Inspector**, choose **Add Component** and select a **PhysX Force Region** component.
4. Choose **Add Required Component** and select the **PhysX Collider** component.
5. For the **PhysX Collider** component, do the following.
   a. Select the **Trigger** property.
   b. For **Shape**, select a shape such as **Box**.
6. For the **PhysX Force Region** component, do the following.
   a. Select the **Visible** and **Debug Forces** properties.
   b. For **Forces**, click the + icon and for **Force Type**, select a force such as **Local Space**.
   c. For **Magnitude**, enter a value such as **20**.

   Blue arrows appear on the entity that indicate the direction of the force.

7. To collide an entity with the force region, create a dynamic entity named **Sphere** and attach the **PhysX Collider** and **PhysX Rigid Body Physics** components. These components enable the entity to interact with other PhysX entities.
8. (Optional) Add a **Mesh** component and, for **Mesh asset**, select a mesh asset, such as a **primitive_sphere.cgf**.
9. Select and drag the **Sphere** entity so that it's above the force region.
10. After you create your dynamic entity, press **Ctrl+G** to enter gameplay mode.

**Example**

The sphere falls and collides with the force region. The force region applies force and pushes the sphere in the opposite direction.
11. To leave gameplay mode, press Esc.

**Note**
To display PhysX debug visualizations, see Debugging PhysX (p. 2826).
For more information about using PhysX components, see *PhysX system* (p. 2772).
PhysX Hinge Joint component

With the PhysX Hinge Joint component, you can create a dynamic hinge joint that constrains an entity to the joint with freedom to rotate around the x-axis of the joint.

PhysX Hinge Joint component properties

Local Position

Specify the position of the joint relative to the entity transform.

Local Rotation

Specify the rotation of the joint relative to the entity transform.

Lead Entity

Specify the parent entity that will drive the joint.
Breakable

When enabled, the joint will break if sufficient force is applied. Enabling Breakable exposes the Maximum Force and Maximum Torque properties.

Note
PhysX Rigid Body components that have their Compute Mass property enabled might have very large mass values. If the entity containing the joint component or the leader entity have their Compute Mass property enabled, the Maximum Force and Maximum Torque properties might require very high values to resist breaking.

Maximum Force

When Breakable is enabled, specify the maximum force the joint can sustain before breaking. Valid values range from 0.01 to Infinity.

Maximum Torque

When Breakable is enabled, specify the maximum torque the joint can sustain before breaking. Valid values range from 0.01 to Infinity.

Display Setup in Viewport

When enabled, three planes are displayed showing the orientation and limits of the joint. Red and green planes show the Positive angular limit and Negative angular limit. The white plane shows the 0 degree rotation of the joint. The shared edge of the three planes is the x-axis of the hinge joint. A line displays the connection between the joint and the Lead Entity.

Select Lead on Snap

When enabled, snapping the joint to an entity in component mode will set the entity as the Lead Entity. The entity containing the joint component is excluded from this operation.

Lead-Follower Collide

When enabled, the lead entity and follower entity (the entity containing the joint component) will collide.

Limit

When enabled, the lead entity's movement around the joint axis is constrained by angular limits. Enabling Limit exposes the Soft Limit, the Positive angular limit, and the Negative angular limit properties.

Soft Limit

When enabled, the lead entity's movement around the joint axis is allowed to pass the specified limit. With Soft Limit enabled, when the lead entity rotates past the limit, the lead entity's movement is treated as a spring and will slow then spring back to the limit area. Enabling Soft Limit exposes the Damping and Stiffness properties.

Damping

When Soft Limit is enabled, the spring's drive relative to the velocity of the follower when outside the rotation limit. Valid values range from 0.001 to 1000000.0.

Stiffness

When Soft Limit is enabled, the spring's drive relative to the position of the follower when outside the rotation limit. Valid values range from 0.001 to 1000000.0.

Positive angular limit

When Limit is enabled, the positive rotation limit around the joint's axis. Valid values range from 0.1 to 360.0.

Negative angular limit

When Limit is enabled, the negative rotation limit around the joint's axis. Valid values range from 0.1 to 360.0.
**Edit**

When clicked, component edit mode is enabled. In component edit mode, all components are locked except for the **PhysX Ball Joint** component. The properties of the **PhysX Ball Joint** component can be edited in **Perspective**. Press **Tab** to cycle through the component edit modes. Click **Done** to exit component mode.

---

**PhysX Ragdoll**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the AWS Game Tech blog to learn more.

You can use the **PhysX Ragdoll** component to create a physical representation of a character in the animation system and to simulate certain behaviors, such as hit reactions and character death. The physical representation consists of a hierarchy of rigid bodies with simple shapes that are connected by joints. You can adjust the ragdoll settings as needed for physical plausibility and performance.

The **PhysX Ragdoll** component requires the **PhysX Characters** (p. 1188) gem.

For more information about the PhysX system, see **Simulating physics behavior with the PhysX system** (p. 2772).

---

**Using the PhysX Ragdoll Component**

You use the PhysX system and the **Animation Editor** to create a ragdoll.

**To use the PhysX Ragdoll component**

1. In Lumberyard Editor, add the **PhysX Ragdoll** component to an entity that represents a character. For more information, see **Adding Components to an Entity** (p. 479).
2. Choose **Tools**, **Animation Editor**.
3. Use the **Animation Editor** to create and control the physical representation of the ragdoll. For more information, see **Creating and Simulating a PhysX Ragdoll** (p. 1458).

---

**PhysX Ragdoll Component Properties**

</table>
PhysX Rigid Body

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The PhysX Rigid Body component defines the entity as a rigid object that is solid and can move and collide with other PhysX entities. For example, you can add the PhysX Rigid Body component to the entity to create a projectile.

You can specify two main modes for a PhysX Rigid Body component.

Dynamic

Dynamic rigid bodies will be fully simulated by Lumberyard and respond to collision events with other rigid bodies. Lumberyard will apply forces to two dynamic objects that collide, which results in a realistic physics simulation. The simulation will also apply a gravity force to rigid bodies in dynamic mode. You can disable this feature for each rigid body on the component. Dynamic rigid bodies should be used for semi-realistic solid objects that are effected by gravity and other forces.

Dynamic is the default.

Kinematic

Kinematic rigid bodies are not fully simulated. Kinematic rigid bodies are moved by script and not effected by forces or gravity. Movement is created with the SetKinematicTarget method that you specify in the script.

Use this feature for objects such as moving platforms, doors, or anything that doesn't need to be fully simulated by physics.

Note

You should always add the PhysX Rigid Body component to the top level of an entity hierarchy. If you add the component to a child entity, this can cause conflicts with the entity's world transform and result in undefined behavior.

The PhysX Rigid Body components requires the PhysX (p. 1188) gem.

For more information, see PhysX system (p. 2772).

Topics

- PhysX Rigid Body component properties (p. 760)
- Creating a Dynamic PhysX Entity (p. 762)
PhysX Rigid Body component properties

The **PhysX Rigid Body** component has the following properties.

**Initial linear velocity**

Specifies the starting linear velocity of the rigid body when spawned. This creates movement in the direction of the linear velocity.

**Initial angular velocity**

Specifies the starting angular velocity of the rigid body when spawned. This creates rotation in the direction of the angular velocity.

**Linear damping**

Specifies the rate of decay over time for linear velocity even if no forces are acting on the rigid body. A non-zero eventually stops the rigid body if no linear force is applied.
Value must be non-negative between 0 and \textit{infinity}.

**Angular damping**

Specifies the rate of decay over time for angular velocity even if no forces are acting on the rigid body. A non-zero eventually stops the rigid body if no torque force is applied.

Value must be non-negative between 0 and \textit{infinity}.

**Sleep threshold**

Specifies the kinetic energy per unit mass below which the rigid body can go to sleep.

Value must be non-negative between 0 and \textit{infinity}.

**Start asleep**

When enabled, the rigid body component is asleep when the entity is spawned, and will wake when a sufficient force is applied.

**Interpolate motion**

When enabled, the resulting motion from the simulation is smoothed.

Enable this property for objects that require smooth motion such as vehicles.

**Gravity enabled**

When enabled, the rigid body is effected by gravity. This only applies to dynamic rigid bodies.

**Kinematic**

When enabled, the rigid body is kinematic. The rigid body is not be effected by gravity or other forces and is moved by script.

When disabled, the rigid body is dynamic. The rigid body responds to gravity and other forces and its motion is simulated by PhysX.

**CCD enabled**

When enabled, the rigid body is will have continuous collision detection (CCD). This property is useful for high speed objects to ensure accurate collision detection. Enabling continuous collision detection reveals two additional properties, \textit{Min advance coefficient} and \textit{CCD Friction}.

**Note**

To set this property, you must also set the \textit{Continuous Collision Detection} in the \textit{PhysX Configuration} window. See World Configuration (p. 2775).

**Min advance coefficient**

Lower values reduce clipping but can affect motion smoothness.

The value must be a decimal between 0.01 and 0.99.

**CCD friction**

When enabled, friction is applied when CCD collisions are resolved.

**Compute mass**

When enabled, mass is computed for the rigid body.

**Mass**

When \textit{Compute Mass} is disabled, a \textit{Mass} value can be specified for the PhysX rigid body. Valid \textit{Mass} values range for 0 to \textit{infinity}. 
**Compute COM**

When enabled, the center of mass is computed for the rigid body.

**COM offset**

When **Compute COM** is disabled, the center of mass can be specified as an offset.

**Compute inertia**

When enabled, inertia is computed based on the mass and shape of the rigid body.

**Inertia diagonal**

When **Compute inertia** is disabled, an **Inertia diagonal** can be specified as the diagonal elements of the inertia tensor.

**Maximum angular velocity**

Angular velocity is clamped to the specified value. Valid values range from 0 to *infinity*.

**Include non-simulated shapes in Mass**

When enabled, non-simulated shapes will be included in the mass, center of mass, and inertia calculations.

**Debug draw COM**

When enabled, the center of mass is displayed for this PhysX rigid body.

---

**Creating a Dynamic PhysX Entity**

A PhysX entity that is dynamic can move and collide with other entities.

**To create a dynamic PhysX entity**

1. Create an entity. For more information, see Creating an Entity (p. 463).
2. In the **Entity Inspector**, choose **Add Component** and then select a **Mesh** (p. 684) component.
3. For **Mesh asset**, select the mesh asset so that your entity is visible, such as a box .cgf.
4. Add the **PhysX Collider** component to the entity.
5. Add the **PhysX Rigid Body** component to the entity.
6. Create another entity for your PhysX terrain. For more information, see the **PhysX Terrain** (p. 767) component.
7. Press **Ctrl+G** to enter gameplay mode.

**Example**

The entity has a **PhysX Collider** component and a **PhysX Rigid Body** component attached. Because the object is dynamic, it falls and then collides with the **PhysX Terrain** component.
Note

- For the Transform (p. 878) component, clear the Static property. This ensures that the mesh moves with the physics simulation.

PhysX Shape Collider

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The PhysX Shape Collider component creates NVIDIA PhysX simulation collider geometry based on the shape definition supplied by a Shape component. The PhysX Shape Collider supports the following Shape components:

- Box (p. 820)
• Capsule (p. 821)
• Polygon Prism (p. 708)
• Sphere (p. 824)

Note

The PhysX Shape Collider component attached to an entity with a supported Shape component creates a static (non-moving) entity. To create a dynamic (moving) entity, you also must add a PhysX Rigid Body (p. 759) component.

Although the PhysX Shape Collider is similar to the PhysX Collider (p. 735) component, you might want to use the PhysX Shape Collider instead in these scenarios:

• The shape information defined by the Shape component is used elsewhere in code or script. For example, the shape defines another volume, such as an audio volume or fog volume, and you want to keep the collider geometry and volume synchronized.
• You want to use a Shape component such as Polygon Prism Shape (p. 708) that is not provided by PhysX Collider.
• You have existing Shape components and don't want to migrate them to use PhysX Collider components.

The PhysX Shape Collider component has some limitations compared to the PhysX Collider component:

• Only one Shape component can be used per entity, and so only one PhysX Shape Collider component is supported per entity. Any number of PhysX Collider components can also be used on the same entity, however.
• The position and rotation of the PhysX Shape Collider component can't be offset relative to the entity position.

To use the PhysX Shape Collider component you must enable PhysX (p. 1188) gem in your project.

For more information, see PhysX system (p. 2772).

Topics

• PhysX Shape Collider properties (p. 765)
• Complex polygon prism shapes (p. 766)
• Colliders as triggers (p. 745)
PhysX Shape Collider properties

**Collision Layer**

The collision layer that's assigned to this shape collider. For more information, see Collision Layers (p. 2785).

**Collides With**

The collision group containing the layers that this shape collider collides with. For more information, see Collision Groups (p. 2787).

**Trigger**

When enabled, this shape collider functions as a trigger. A trigger performs a quick overlap test and does not apply forces or return contact point information. Use this to speed up PhysX computations where a simple overlap between colliders is sufficient.

**Note**

Trigger Area components are legacy components and cannot be used with PhysX Shape Collider.

**Simulated**

When enabled, this shape collider will be part of the physics simulation.

**In Scene Queries**

When enabled, this shape collider can be queried for raycasts, shapecasts and overlap.

**Physics Material - Library**

Set the physics material library for this shape collider.

**Physics Material - Mesh Surfaces**

Choose a material from the physics material library for this shape collider.
Tag

Set a tag for this shape collider. Tags can be used to quickly identify components in script or code.

Rest offset

PhysX bodies come to rest separated by the sum of their rest offset values. The Rest offset value must be less than the Contact offset value. Valid values rage from $-\infty$ to 50.

Contact offset

PhysX bodies generate contacts when they are within the sum of their contact offset values. The Contact offset value must be greater than the Rest offset value. Valid values rage from 0 to 50.

Draw collider

Render this shape collider in the viewport. Enabled by default.

Complex polygon prism shapes

The Polygon Prism Shape (p. 708) is automatically subdivided into convex portions, which means that polygon prisms can be used with dynamic rigid bodies or as triggers in PhysX. The subdivision is automatically updated if the vertices of the polygon prism are modified.

If the vertices are modified so that the polygon prism is no longer a simple polygon, for example, if the polygon prism is self-intersecting, it isn't possible to subdivide the polygon prism into convex pieces. An error will display in the Editor Console, as shown in the following example.
**Colliders as triggers**

Triggers allow colliders to perform efficient overlap tests. Colliders marked as triggers won't have forces applied when they intersect with another collider. This is useful for detecting when something enters a certain area or when two objects overlap. Use Lua or Script Canvas to detect overlap.

**Note**

Because triggers don't perform contact resolution, the contact points between a trigger and another collider aren't available. Trigger Area components are legacy components and cannot be used with PhysX Shape Collider.

**PhysX Terrain**

**Important**

The PhysX Terrain component and associated documentation are legacy features retained for compatibility. For new projects, use the **Legacy Terrain** level component, and the **PhysX Terrain** level component. For more information, see [Legacy Terrain level component (p. 651)](#).

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the [AWS Game Tech blog](https://aws.amazon.com/gaming/) to learn more.

The **PhysX Terrain** component exports and saves the terrain as an asset that loads at runtime. The **PhysX Terrain** component is required for games in which physics interacts with the terrain. For example, you can create a terrain collider so that your entities can interact with it, such as a barrel that falls to the ground and then rolls to a stop.

For more information about using PhysX components, see [PhysX system (p. 2772)](#).

</tbody>
</table>
Creating a PhysX Terrain Collider

As a best practice, create a top-level entity in your level and add the PhysX Terrain component. You only need one entity with the PhysX Terrain attached for your level.

To create a PhysX Terrain Collider

1. In Lumberyard Editor, create an entity. For more information, see Creating an Entity (p. 463).
2. Enter a name for the entity, such as terrain.
3. In the Entity Inspector, choose Add Component and then select a PhysX Terrain component. The terrain collider appears in the viewport.

   **Note**
   The Transform component for the entity is ignored and doesn't affect the position of the terrain.

4. To have an entity interact with the terrain collider, you can create a dynamic entity so that the two entities interact. For more information, see Creating a Dynamic PhysX Entity (p. 762).
5. After you create your dynamic entity, press Ctrl+G to enter gameplay mode. The dynamic entity falls and then collides with the terrain collider.
6. Press Esc to leave gameplay mode.

   **Note**
   In some cases, performance can be impacted when a large body intersects the terrain. To overcome this issue, you can clear the Persistent Contact Manifold option in the World Configuration (p. 2775). If you clear this option, keep the size of the colliders that intersect the terrain small.

Rain

This feature is in preview release and is subject to change.
You can use the **Rain** component to create rain effects, puddles, and ripples on the terrain. You can add multiple **Rain** components to your entities in a level, but the level uses only one of the **Rain** components. The last **Rain** component to activate takes priority and Lumberyard renders that component.

To enable the **Rain** component, you must enable the Rain gem. For more information, see [Rain Gem](p. 1194).

**Note**
If your level has a [Snow](p. 853) and **Rain** component, the component that activates last takes priority; you cannot enable both **Snow** and **Rain** components at the same time.

**Contents**
- Turning Rain On or Off (p. 769)
- Editing Rain Effects (p. 770)
- Rain Component Properties (p. 770)
- EBus Request Bus Interface (p. 772)
  - Request Bus Example Script (p. 776)

**Turning Rain On or Off**

You can toggle rain on or off in Lumberyard Editor by enabling or disabling **AI/Physics**, or by running or stopping the game.

**To toggle rain effects on or off in Lumberyard Editor**
- Do one of the following:
On the bottom right of the viewport, click **AI/Physics**.

Choose **Game, Enable Physics/AI**.

Press **Ctrl+P**.

Press **Ctrl+G** to enter gameplay mode. Press **Esc** to stop the game.

## Editing Rain Effects

You can edit rain effects only when the **AI/Physics** toggle is disabled.

**To edit rain effects**

1. Disable **AI/Physics**.
2. Make changes to the **Rain** component properties.
3. Enable **AI/Physics**. After you reenable **AI/Physics**, your changes appear in the viewport.

### Rain Component Properties

The **Rain** component has the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Enabled</strong></td>
<td>Specifies whether rain effects are enabled.</td>
</tr>
<tr>
<td></td>
<td>Default value: <strong>True</strong></td>
</tr>
<tr>
<td><strong>Use VisArea</strong></td>
<td>Specifies whether rain appears when the player is inside of a visible area.</td>
</tr>
<tr>
<td></td>
<td>For more information, see the <strong>VisArea</strong> component.</td>
</tr>
</tbody>
</table>
## Property Description

### Disable Occlusion
Specifies whether objects will ignore rainfall effects. You can enable the Rain occluder parameter in the Mesh component for your objects; rain effects do not affect these objects.

For more information, see Mesh Component: Advanced Options (p. 685).

Default value: `false`

### Radius
Radius of the area where puddles are created. Rain continues to affect the screen even outside the specified radius.

Default value: 10000

Valid values: 0 to 10000

### Amount
Amount of rain and other effects that the Rain component creates.

Default value: 1

Valid values: 0 to 100

### Diffuse Darkening
Amount of darkening that is applied to surfaces that the rain affects.

Default value: 0.5

Valid values: 0 to 1

The Rain component has the following raindrop options.

### Amount
Quantity of raindrops.

Default: 0.5

Valid values: 0 to 100

### Speed
Speed of the falling raindrops.

Default: 1.0

Valid values: 0 to 100

### Lighting
Brightness of the raindrops.

Default: 1.0

Valid values: 0 to 100

The Rain component has the following puddle options.
### Property Description

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amount</td>
<td>Amount of depth and brightness of rain puddles.</td>
</tr>
<tr>
<td></td>
<td>Default: 1.5</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 to 10</td>
</tr>
<tr>
<td>Mask Amount</td>
<td>Strength of the puddle mask. A value of 1 creates puddles of rain between patches of land.</td>
</tr>
<tr>
<td></td>
<td>Default: 1</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 to 1</td>
</tr>
<tr>
<td>Ripple Amount</td>
<td>Strength and frequency of the ripples in the rain puddles.</td>
</tr>
<tr>
<td></td>
<td>Default: 2</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 to 100</td>
</tr>
<tr>
<td>Splashes Amount</td>
<td>Strength and frequency of the splashes that the raindrops create.</td>
</tr>
<tr>
<td></td>
<td>Default: 1.3</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 to 1000</td>
</tr>
</tbody>
</table>

### EBus Request Bus Interface

Use the following request functions with the EBus interface to communicate with other components of your game. You can use this EBus to communicate to an entity with a Rain component attached. The EBus is available at game run time and editing and can be accessed from C++, Lua, and the Script Canvas editor.

When set, the individual setters on this bus update the rain simulation immediately. This can cause performance implications if you want to change multiple parameters. To avoid this, you can set multiple parameters at once with GetRainOptions (p. 775) and SetRainOptions (p. 775).

For more information, see Working with the Event Bus (EBus) system (p. 1851).

<table>
<thead>
<tr>

**Request Bus Example Script**

```lua
function example:OnActivate()
    RainComponentRequestBus.Event.SetAmount(self.entityId, 5.0)
    RainComponentRequestBus.Event.Toggle(self.entityId)
end
```

**Random Timed Spawner**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Random Timed Spawner component to spawn a specified dynamic slice. The component spawns the slice at a specified interval (and random interval variation) to a random position inside of a specified volume.

The Random Timed Spawner component requires that the following components are also attached to the entity:

- **Spawner (p. 859)** component – Manages the spawning of the slice.
- **Box Shape (p. 818)** or **Cylinder Shape (p. 818)** component – Defines the volume of possible positions where the entities can spawn.

With these components, you can control the random distribution that determines the random points inside the volume.

Currently, you can specify how entities spawn in random positions with the following random distribution types:

- Normal distribution
- Uniform Real distribution
The **Random Timed Spawner** component is part of the LmbrCentral gem. For more information, see Add modular features and assets with Gems (p. 1064).

**Example**

The following **Random Timed Spawner** component has the distribution type, Uniform Real.

---

**Contents**

- Random Timed Spawner Properties (p. 777)
  - Timing (p. 778)
- EBus Request Bus Interface (p. 778)
  - Enable (p. 778)
  - Disable (p. 779)
  - Toggle (p. 779)
  - IsEnabled (p. 779)
  - SetRandomDistribution (p. 779)
  - GetRandomDistribution (p. 780)
  - SetSpawnDelay (p. 780)
  - GetSpawnDelay (p. 780)
  - SetSpawnDelayVariation (p. 780)
  - GetSpawnDelayVariation (p. 781)
  - Notification Bus Example Script (p. 781)

**Random Timed Spawner Properties**

**Enabled**

Enables slices to spawn with the specified parameters.
Default value: True

**Random Distribution**

Specify the random distribution type when the Random Timed Spawner component creates random spawn positions.

Default value: Uniform Real

Valid values: Normal, Uniform Real

**Timing**

**Spawn Delay**

Time between spawns, in seconds.

If the Enabled parameter is true, a value of 2.0 means that every two seconds after the Random Timed Spawner component is activated, a spawn is triggered.

Default value: 5.0

Valid values: $\infty$ to $\infty$

**Spawn Delay Variation**

Amount of random variation to apply to the spawn delay.

For example, a value of 1.0 and a Spawn Delay value of 2.0 means that the range of possible spawn times is (2.0 +/- 1.0) or between 1.0 and 3.0 seconds.

Default value: 0

Valid values: $\infty$ to $\infty$

**EBus Request Bus Interface**

You can use this EBus to communicate to an entity with a Random Timed Spawner component attached. The EBus is available at game run time and editing and can be accessed from C++, Lua, and the Script Canvas editor.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

**Enable**

Starts random spawning.

**Parameters**

None

**Return**

None

**Scriptable**

Yes
**Disable**

Stops random spawning.

**Parameters**

None

**Return**

None

**Scriptable**

Yes

**Toggle**

Toggles random spawning.

**Parameters**

None

**Return**

None

**Scriptable**

Yes

**IsEnabled**

Returns whether the **Random Timed Spawner** component is spawning entities.

**Parameters**

None

**Return**

Type: Boolean

**Scriptable**

Yes

**SetRandomDistribution**

Sets the type of random distribution that determines where the **Random Timed Spawner** component places the entities that spawn.

**Parameters**

Type: AZ::RandomDistributionType

**Return**

None
Scriptable
Yes

GetRandomDistribution
Returns the type of random distribution for the Random Timed Spawner component.

**Note**
In Lua, this value is returned as a number:
0 – Normal distribution
1 – Uniform Real distribution

Parameters
None

Return
Type: AZ::RandomDistributionType

Scriptable
Yes

SetSpawnDelay
Sets the time between entity spawns, in seconds.

Parameters
Type: Double

Return
None

Scriptable
Yes

GetSpawnDelay
Returns the time between entity spawns, in seconds.

Parameters
None

Return
Type: Double

Scriptable
Yes

SetSpawnDelayVariation
Sets the random variation in spawn delay, in seconds.
The **Random Timed Spawner** component uses the specified value to calculate a random value that is added to the **Spawn Delay** parameter.

For example, a **SpawnDelayVariation** value of 1.0 and a **Spawn Delay** value of 2.0 means that the range of possible spawn times is \((2.0 \pm 1.0)\) or between 1.0 and 3.0 seconds.

For more information, see [Timing](p. 778).

**Parameters**

Type: Double

**Return**

None

**Scriptable**

Yes

**GetSpawnDelayVariation**

Returns the random variation in spawn delay, in seconds.

**Parameters**

None

**Return**

Type: Double

**Scriptable**

Yes

**Notification Bus Example Script**

```lua
function example:OnActivate()
    RandomTimedSpawnerComponentRequestBus.Event.SetSpawnDelay(self.entityId, 0.5)
    RandomTimedSpawnerComponentRequestBus.Event.SetSpawnDelayVariation(self.entityId, 0.03)
end
```

**Render to Texture**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](or visit the [AWS Game Tech blog](to learn more).

You can use the **Render to Texture** component to render the scene from a specific camera to a texture. You can use this feature to create rear-view mirrors, security camera screens, and draw 3D models in the viewport.
To enable this component, you must enable the Render to Texture (p. 1197) gem. To enable gems, see Enabling Gems (p. 1064).

Topics

- Adding the Render to Texture Component in a Scene (p. 782)
- Adding a Render Target to a UI Element (p. 783)
- Render to Texture Properties (p. 784)
- EBus Request Bus Interface (p. 794)
- EBus Notification Bus Interface (p. 795)
- Known Limitations (p. 795)

Adding the Render to Texture Component in a Scene

Example

Entity (1) has a Camera (p. 566) component and a Render to Texture component. This entity faces a game object, entity (2). In entity (1), the Render to Texture component specifies a render target. A material file references that render target as its diffuse texture. The material is then added to entity (3), so that the render target appears in the viewport.

To use the Render to Texture component

1. In Lumberyard Editor, create an entity in the viewport. For more information, see Creating an Entity (p. 463).
2. In the Entity Inspector, click Add Component.
3. Select the Camera component, choose Be this camera, and then move the camera entity using the viewport camera controls to look at an object in your level.
4. In the **Entity Inspector**, click **Add Component**.
5. Select the **Render to Texture** component.
6. For **Texture name**, enter a name that starts with the $ character, such as $rendertarget.
   **Note**
   The $ character tells Lumberyard that the texture will not be loaded from disk. If you don't specify the $ character, Lumberyard will try to locate the texture file from disk, which can impact performance.
7. To open the **Material Editor**, choose **Tools, Material Editor** or press M.
8. Click the **Add New Item** icon to create a material, enter a name such as **RenderToTexture**, and then click **Save**.
9. In the **Texture Maps** section, for **Diffuse**, enter the **Texture name** that you specified, such as $rendertarget.
10. In the **Asset Browser**, navigate to **primitive_plane.cgf**, and then select and drag the file into the viewport.
11. Assign the material to the primitive plane entity. In the **Mesh** component, for the **Material override** property, specify the material file that you created, such as **RenderToTexture.mtl**.
   The primitive plane entity now shows the texture from the **Render to Texture** component.

**Adding a Render Target to a UI Element**

You can also specify the render target in an **Image** component for a UI element. For example, you can add the render target to appear in a button or object that a user can select in a UI menu.

For more information, see Visual Components (p. 2936).

**Example**

A camera entity (1) faces the **Render to Texture** entity (2), which has a **Render to Texture** component attached. The **Texture name** is $rendertarget.

![Image of camera and render target](image)

**To add a render target to a UI Image component**

1. Complete steps 1 to 6 in the previous procedure. See Adding the Render to Texture Component in a Scene (p. 782).
2. In Lumberyard Editor, choose **Tools, UI Editor**.
3. In the **UI Editor**, create or open a UI canvas.
4. Right-click the canvas and choose **New, Element from Slice Library, Image.**
5. In the **Image** component, for **SpriteType**, click the drop-down menu, and then select **Render target.**
6. For **Render target name**, enter the same texture name in the **Render to Texture** component, such as `$rendertarget`.

The **UI Image** component displays the render target in the **UI Editor**.

---

### Render to Texture Properties

![Render to Texture Properties](Image)

- **Camera**: 
  - **Texture name**: `$rendertarget`
  - **Max FPS**: 30.0
  - **Width**: 512
  - **Height**: 512
  - **Apply Gamma**: unchecked
  - **Alpha Mode**: **Opaque**
- **Scene Settings**
  - **Enable Ocean**: checked
  - **Enable Terrain**: checked
  - **Enable Vegetation**: checked
  - **Enable Shadows**: checked
  - **GSM LODs**: -1
  - **GSM range**: -1.0
  - **GSM range step**: -1.0
- **Post Effects**
  - **Antialiasing Mode**: **FXAA**
- **Debug**
  - **Display Debug Image**: unchecked
  - **Update in editor**: checked
The **Render to Texture** component has the following properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Camera** | Entity with a Camera component attached to use as the view. If you specify an entity without a Camera component, only the position and orientation will be used from that entity. If you don't specify an entity, this property defaults to the entity to which the Render To Texture component
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Texture name</td>
<td>the texture to which to render. Follow the Lumberyard convention of using a $ as the first character in the texture name. This is how Lumberyard denotes render targets.</td>
</tr>
<tr>
<td>Maximum FPS</td>
<td>per second at which this view updates.</td>
</tr>
<tr>
<td>Width</td>
<td>of the render texture, in pixels.</td>
</tr>
</tbody>
</table>
Render to Texture

Name

Description

Height

Height of the render texture, in pixels.
**Apply Gamma**

**Description**

Apply Gamma application to the texture. If you want to use this texture with a material inside the main view, leave this property disabled, because gamma will be applied to the entire scene during post-processing.

**Note**

As a best practice, if you are using render targets in the UI, clear the **Apply Gamma**
property and don't select the Render Target sRGB property in the UI Image (p. 2936) component. However, if the texture appears too dark, you can set either property.
**Description**

**Alpha Mode**

Specify the following values:

- **Opaque**
  
  Disables alpha output in the render target.

- **Depth Based**
  
  Uses the scene depth for the alpha channel in the render target.

**Enable Ocean**

Enables drawing the ocean in the render target.

**Enable Terrain**

Enables terrain in the render target.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vegetation</td>
<td>Enables vegetation in the render target.</td>
</tr>
<tr>
<td>Shadows</td>
<td>Enables shadows in the render target.</td>
</tr>
<tr>
<td>GSM LODs</td>
<td>Global shadow map levels of detail (LOD) to use for the render to texture scene. A value of -1 will use the current settings for the e_GsmLodsNum console variable.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>GSM range</td>
<td>Global shadow map range to use for the render to texture scene. A value of -1 will use the current settings for the e_GsmRange console variable.</td>
</tr>
</tbody>
</table>
### Description

**GSM Global Shadow Map**

<table>
<thead>
<tr>
<th>range step</th>
<th>use for</th>
<th>render to texture scene.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A value of -1 will use the current settings for the e_GsmRangeStep console variable.

### Antialiasing Mode

Specify the following values:

- **FXAA**
  - Enables fast approximate antialiasing (FXAA) when rendering the scene to the render target.
- **None**
  - Disables antialiasing.
### Render to Texture

**Description**

**Displays Debug Image**

Images in Lumberyard Editor only.

**Updates in editor**

Render target outside of game mode while in Lumberyard Editor.

---

### EBus Request Bus Interface

You can use the event bus (EBus) interface to communicate with other components in your game.

For more information, see [Working with the Event Bus (EBus) system](#) (p. 1851).

<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
<th>Parameter</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetTextureResourceId</td>
<td>Gets the resource ID of the render target. A value of -1 is an invalid render target.</td>
<td>None</td>
<td>integer</td>
<td>Yes</td>
</tr>
</tbody>
</table>
| SetAlphaMode          | Sets the alpha mode for the render target.                                  | 0 = Disabled  
1 = Opaque  
2 = Depth based | None      |         | Yes        |
| SetCamera             | Sets the entity with a **Camera** component to use for rendering.           | EntityID  | None    | Yes        |
| SetEnabled            | Enables or disables rendering to texture.                                  | 0 = Disable  
1 = Enable   | None    |         | Yes        |
### Request Name | Description | Parameter | Return | Scriptable
--- | --- | --- | --- | ---
SetMaxFPS | Sets the maximum rate at which this render target updates, in frames per second. | FPS | None | Yes
SetWriteGamma | Enables or disables gamma application. | 0 = Disable | None | Yes
1 = Enable

### EBus Notification Bus Interface
You can use the event bus (EBus) interface to communicate with other components in your game.

For more information, see Working with the Event Bus (EBus) system (p. 1851).

### Known Limitations
The **Render to Texture** component supports DirectX 11 for Windows.

**Prevent Graphical Artifacts When Render to Texture is Active with the Following CVARs**

Forces the object LOD to update at the beginning of the frame instead of the end of the previous frame. If you don’t set this console variable, you may see LOD flickering.

For more information about setting console variables, see Using the Console Window (p. 210).

- `e_LodForceUpdate=1`

Disables precaching of the streaming system due to common large jumps in the camera position when the render to texture feature is active.

- `e_AutoPrecacheCameraJumpDist=0`
Enables subpixel morphological antialiasing (SMAA) instead of temporal antialiasing (TAA).

\[ r_{\text{AntialiasingMode}}=2 \]

Disables volumetric fog.

\[ e_{\text{volumetricFog}}=0 \]

Disables multi-GPU mode.

\[ r_{\text{MultiGPU}}=0 \]

Disables sparse voxel octree global illumination (SVOGI gem).

\[ e_{\text{GI}}=0 \]

You might see flickering, black or blurry textures if the streaming system thrashes while the `Render to Texture` component is active. This can occur in a scene that uses a large amount of texture memory.

To fix this, increase the value for `r_TexturesStreamPoolSize`, or set the `Max FPS` property to 0 so that the component updates each frame. This might help the streaming system balance texture priorities.

**Tip**

To verify if the graphics artifacts are a result of streaming thrashing, set `r_TexturesStreamingDebug` to 2. This console variable shows the textures that are streamed in and the memory usage.

### Unsupported Features in the Render Target

The following features are not supported for the `Render to Texture` component because they don't work with multiple cameras.

- TAA and SMAA
- Lens flares
- Sun shafts
- Volumetric fog
- CBuffer (constant buffer) occlusion (vis areas are supported)
- Motion blur
- Merged mesh vegetation
- Shadows cache

**River**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
Use the River component to carve riverbeds into the terrain and fill them with moving water. The River component uses 2D materials to create the illusion of flowing water. Optimally, you should use this component to create flat rivers along level terrain. To create rivers that run downhill, you can create a series of rivers separated by occasional waterfalls.

The River component requires the Spline (p. 866) component to shape its path along the x, y, and z axes. After you place a river, you can edit the points in the river's spline.

To use the River component, you must enable (p. 1064) the Roads and Rivers gem. For more information, see Enabling Gems (p. 1064).

Topics
- River Properties (p. 798)
- Working with the River Component (p. 800)
- River Request Bus Interface (p. 805)
See the following River component properties.

</table>

**Working with the River Component**

See the following procedures to create a river and modify its appearance.
Creating a River

To create a realistic river, use the River component's Carve River Bed tool to prepare the surrounding terrain. This tool carves out a riverbed and creates riverbanks on the edges of the river that are higher than the river's water level.

You can also paint the river bottom with a different texture than the surrounding area. This is useful if the water has translucent properties. For more information on painting the terrain, see Painting Terrain Texture Layers (p. 1234).

To create a river

1. Create an entity. (p. 463)
2. Add (p. 479) the River component.
3. Add the Spline (p. 866) component.

   The Spline component defines the path and shape of the river. For information about how to add, remove, and edit individual points, see the Spline (p. 866) component.

4. Under Terrain Editing, specify values for the following parameters:
   - **Border width** – Sets the width of the slope on the river's sides.
   - **Embankment height** – Defines the height of the hills on the river edges. If the river is at ground level, this parameter makes the river appear to flow in the riverbed.
   - **Depth of the river bed** – Defines the depth of riverbed.
   - **Riverbed width offset** – Defines the width of the riverbed in relation to the river's width. For example, a value of 0 makes the riverbed the same width as the river; –1 makes the riverbed one meter narrower than the river; 1 makes the riverbed one meter wider than the river.

5. Click Carve River Bed.

Example

A river on the ground before a riverbed has been carved out.
A river with a **Border width** of 5.0, **Embankment** of 1.0, **Depth** of 2.0, and **River bed offset** of -1.

You can also lower the river below the ground level and carve the riverbed. This achieves a different type of terrain deformation.

A river with a **Border width** of 10.0, **Embankment** of 3.0, **Depth** of 2.0, and **River bed offset** of -1.

This river is positioned below ground level.
Modifying the River Width

You can use the **Global width** parameter to adjust the river's width. This parameter modifies all the points on the river.

For more refined control over the river's width, you can adjust the individual points with the **Per-Vertex Width Modifiers** parameter.

![Per-Vertex Width Modifiers](image)

**To adjust the width of individual points**

- In the **River** component, specify a negative or positive number for the element that you want to modify.

  Negative numbers subtract from the **Global Width** parameter, while positive numbers add to it. A value of 0 means that point is at global width.

**Example**

The global width of this river is 2, and the width at the selected point is set to 5. That means the total width at the selected point is 7.
Erasing River Vegetation

You can erase vegetation around the river's borders.

To erase vegetation

1. In the River component, for Vegetation Editing, set the Erase width. This defines the amount of vegetation to erase at the river's edges.
2. Set the Erase variance. This parameter randomizes the removal of vegetation so that the edge looks more natural.

Setting River Material Properties

The road material must use the WaterVolume Shader (p. 1719).

To set the river material

1. Press M or navigate to Tools, Material Editor
2. Select the defaultRiver or other appropriate river material.
For information about the WaterVolume Shader properties, see WaterVolume Shader (p. 1719).

**River Request Bus Interface**

The River component uses two event bus (EBus) interfaces, the RiverRequestBus and the RoadsAndRiversGeometryRequestsBus, which is shared with the Road component.

For information about the RoadsAndRiversGeometryRequestsBus, see RoadsAndRiversGeometryRequestsBus Interface (p. 817).

Use the following request functions with the RoadsAndRiversGeometryRequestsBus to communicate with other components of your game.

For more information, see Working with the Event Bus (EBus) system (p. 1851).

**Road**

This feature is in *preview* release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Road component to create paths in Lumberyard Editor. You can create roads that follow the curvature of existing terrain by applying a texture over the terrain texture. You can also use the Align heightmap feature with the Road component to shape the terrain to the height and curvature of the road you placed.

To enable the Road component, you must enable the Roads and Rivers gem. For more information, see Add modular features and assets with Gems (p. 1064).

The Road requires the Spline (p. 866) component to shape its path along the X, Y, and Z axes. After you place a road, you can edit the points in the road's spline.

**Note**

You can rebuild roads at runtime by modifying the spline. However, this method can be slow. We recommended that you avoid modifying the spline continuously at runtime.

**Topics**

- Road Properties (p. 809)
- Creating a Road (p. 810)
- Modifying Road Width (p. 811)
- Setting Road Material Properties (p. 812)
- Using Roads to Modify Terrain (p. 813)
Road Properties

See the following Road properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<tr>
<td>Ignore terrain holes</td>
<td>If enabled, the road texture is rendered over terrain holes.</td>
</tr>
<tr>
<td>Border width</td>
<td>Width of the border extending from the sides of the road. Use with the Align heightmap (p. 813) feature.</td>
</tr>
<tr>
<td>Erase width</td>
<td>Distance from the road edges in which the vegetation should be removed. Specifying a value of 0 removes only vegetation that is on the road. Specify positive values to remove vegetation in a wider border from the road’s edge. Specify negative values to leave some vegetation within the borders of the road. For more information, see Erasing Vegetation (p. 815).</td>
</tr>
<tr>
<td>Erase variance</td>
<td>Randomizes the removal of vegetation so that the road edges appear more natural.</td>
</tr>
</tbody>
</table>

**Creating a Road**

**To create a road**

1. Create an entity. (p. 463)
2. Add (p. 479) the Road component.
3. Add the Spline (p. 866) component.
The **Spline** component defines the path and shape of the road. For information about how to add, remove, and edit individual points, see [Spline](p. 866).

The road is created with the default material **defaultRoad**. The **Spline** component defaults to the **Linear Spline Type** and contains four vertices (0, 1, 2, 3). For a road that curves smoothly, specify the [Bezier](p. 871) **Spline Type**.

### Modifying Road Width

You can modify the road's width by adjusting the road's **Global width** property. Adjusting this property modifies all the points on the road.

For more granular control over the road's width, you can adjust individual points with the **Per-Vertex Width Modifiers** property.

**To adjust the width of individual points**

- In the **Road** component properties, enter a negative or positive number for the property that you want to modify.

  Negative numbers subtract from the **Global width** property, while positive numbers add to it. A value of 0 means that point is at global width.

  **Example**

  The global width of this road is 2, and the width at the selected point is set to 5. The total width at the selected point is 7.
Setting Road Material Properties

Roads are Decals (p. 585) placed along a spline. This makes the material setup of a road similar to that of decals.

The road material must use the Illum Shader (p. 1697) and should also enable the Decal and Vertex Colors parameters in the Shader Generation Params.

To open the Material Editor

1. In Lumberyard Editor, choose Tools, Material Editor or press M.
2. Select the road material and expand the Shader Generation Params, and select the following parameters:

   **Vertex Colors**

   Activates a blend fadeout at each end of the road. This is a 100% to 0% fadeout over the length of the final step. The textures and alpha channel have no influence on the fadeout.

   **Decal**

   Enables alpha blending on the sides of the road, which comes from the diffuse texture's alpha channel.
**Example**

In the left image, **Vertex Colors** is enabled. In the right image, the parameter is disabled.

**Using Roads to Modify Terrain**

You can use roads to modify the shape of the terrain.
To modify the terrain with roads

1. Create a road. (p. 810)
2. Manipulate the individual vertices to shape the road. For more information, see Spline (p. 866).
3. In the Road component's properties, under Terrain Editing, set the Border width. This parameter defines the width of the slope at the edges of the road.
4. Click Align heightmap.

Example

The following image shows a road that has been created and shaped, but not yet aligned.

Example

The following image shows the road and terrain after alignment with a Border width of 5.

Example

The following image shows the road and terrain after alignment with a Border width of 20.
Erasing Vegetation

You can erase vegetation around the road's borders.

**To erase vegetation**

1. In the Road component's properties, under *Vegetation Editing*, specify the *Erase width*. This parameter defines the amount of vegetation to erase at the road's edges.

2. Specify the *Erase variance*. This parameter randomizes the removal of vegetation, so that the edge looks more natural.

**Example**

The following image shows the road with no vegetation erased.

**Example**

The following image shows the road with *Erase width* set to 0.
Example

The following image shows the road with **Erase width** set to 1 and **Erase variance** set to 5.

RoadRequestBus Interface

Use the following request functions with the RoadRequestBus EBus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Return</th>

Script Canvas

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the **Script Canvas** component to add a script to an entity.

**Script Canvas Component Properties**

The **Script Canvas** component has the following properties:

**Script Canvas Asset**

Specify the script file that you want to add to the component.

**Shapes: Cylinder, Capsule, Disk, Box, Sphere, Compound**

Add shape components to entities that have other components that require shapes.

For example, add shape components to your entities to create volumes for the following:

- Create a trigger volume using the *Trigger Area (p. 890)* component. Entities that enter the volume trigger an action.
- Create a collision volume using the *PhysX Collider (p. 735)* component. Entities that collide with the collision volume respond to the impact, such as slowing down or bouncing back.
- Define reverb or echo effects using the *Audio Environment (p. 552)* component.
- Create an audio area using the *Audio Trigger (p. 559)* component so that a specific sound plays in that area of the level.

**Note**

You can add only one shape component to an entity. If you need more than one shape on an entity, create child entities.

Each shape component provides a generic *ShapeService* that exposes functionality common to all shapes. Each shape also provides a more specific service, such as *BoxShapeService* or *SphereShapeService*.

The **Shape** component includes the following shapes and properties:

**Topics**

- Scaling Shapes (p. 819)
- Box Shape Component Properties (p. 820)
- Capsule Shape Component Properties (p. 821)
• Compound Shape Component Properties (p. 822)
• Cylinder Shape Component Properties (p. 822)
• Disk Shape Component Properties (p. 823)
• Sphere Shape Component Properties (p. 824)
• Request EBus Interface (p. 824)

Scaling Shapes

As a best practice, when you scale a shape, adjust the shape component's properties, such as its Dimensions, Height, and Radius.

Tip
Modify the shape component's properties instead using the Scale tool (p. 201), which changes the entity's Transform (p. 878) component.

Example

See the following examples for the different scaling:

1. In nonuniform scaling, adjusting an entity's transform scale leads to different values for X, Y, and Z.
2. In uniform scaling, X, Y, and Z have the same value.
3. In uniform normalized scaling, all of the scale values are 1.

If an entity has been scaled nonuniformly, rendering and intersection tests use the largest component of the scale vector. Although this can work, the best practice is to keep a uniform and, ideally, normalized (1, 1, 1) transform scale, as shown in the third example.
Box Shape Component Properties

The **Box Shape** component has the following properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visible</td>
<td>The component always appears in the viewport, even if the entity isn't selected.</td>
</tr>
<tr>
<td>Game View</td>
<td>Renders the box shape in game mode in Lumberyard Editor.</td>
</tr>
<tr>
<td></td>
<td>To enter game mode, press <strong>Ctrl+G</strong></td>
</tr>
<tr>
<td>Shape Color</td>
<td>Specifies the color to render the shape.</td>
</tr>
<tr>
<td>Dimensions</td>
<td>Defines dimensions of the shape along all three axes in local space.</td>
</tr>
<tr>
<td></td>
<td>If the Transform (p. 878) component applies a scale, these dimensions are multiplied by the same value.</td>
</tr>
<tr>
<td>Edit</td>
<td>Choose <strong>Edit</strong>, and the component is locked for editing. For more information, see Editing Components in the Viewport (p. 483).</td>
</tr>
</tbody>
</table>

The **Box Shape** component also has its own Component Mode with several linear manipulators for each axis.
Capsule Shape Component Properties

The Capsule Shape component has the following properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visible</td>
<td>The component always appears in the viewport, even if the entity isn't selected.</td>
</tr>
<tr>
<td>Game View</td>
<td>Renders the shape in game mode.</td>
</tr>
<tr>
<td></td>
<td>To enter game mode, press Ctrl + G.</td>
</tr>
<tr>
<td>Shape Color</td>
<td>Specifies the color to render the shape.</td>
</tr>
<tr>
<td>Height</td>
<td>The end-to-end height of the capsule, including the cylinder and both caps.</td>
</tr>
</tbody>
</table>
Shapes: Cylinder, Capsule, Disk, Box, Sphere, Compound

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Radius</td>
<td>The radius of the capsule. If the Transform (p. 878) component applies a scale, these dimensions are multiplied by the same value.</td>
</tr>
</tbody>
</table>

### Compound Shape Component Properties

With the **Compound Shape** component, you can combine shapes to create a complex object to generate a physics collider, trigger shape, or any other application of shapes. The individual shapes might or might not be children of the entity with the **Compound Shape** component.

**Note**

- To move the shapes together with the compound shape, set them as child entities.
- To move the shapes independent of the entity with the compound shape, don’t set them as child entities.
- For EBus (event bus) requests, compound shapes service the full shape component bus. However, each individual shape that you add increases the cost of requests such as `IsPointInside`.

See the following **Compound Shape** properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Child Shape Entities</td>
<td>Specifies the entities and their shapes that make up the compound shape. These entities might or might not be children of the entity with the compound shape.</td>
</tr>
</tbody>

### Cylinder Shape Component Properties

The **Cylinder Shape** component has the following properties.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visible</td>
<td>The component always appears in the viewport, even if the entity isn’t selected.</td>
</tr>
<tr>
<td>Game View</td>
<td>Renders the shape in game mode in Lumberyard Editor.</td>
</tr>
<tr>
<td></td>
<td>To enter game mode, press Ctrl + G.</td>
</tr>
<tr>
<td>Shape Color</td>
<td>Specifies the color to render the shape.</td>
</tr>
<tr>
<td>Height</td>
<td>The height of the cylinder. If the Transform (p. 878) component applies a scale, these dimensions are multiplied by the same value.</td>
</tr>
<tr>
<td>Radius</td>
<td>The radius of the cylinder. If the Transform (p. 878) component applies a scale, these dimensions are multiplied by the same value.</td>
</tr>
</tbody>
</table>

**Disk Shape Component Properties**

![Disk Shape Component Properties](image)

See the following Disk Shape properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visible</td>
<td>The component always appears in the viewport, even if the entity isn’t selected.</td>
</tr>
<tr>
<td>Game View</td>
<td>Renders the shape in game mode in Lumberyard Editor.</td>
</tr>
<tr>
<td></td>
<td>To enter game mode, press Ctrl + G.</td>
</tr>
<tr>
<td>Shape Color</td>
<td>Specifies the color to render the shape.</td>
</tr>
<tr>
<td>Radius</td>
<td>The radius of the disk.</td>
</tr>
<tr>
<td></td>
<td>If the Transform (p. 878) component applies a scale, these dimensions are multiplied by the same value.</td>
</tr>
</tbody>
</table>
Sphere Shape Component Properties

See the following Sphere Shape properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visible</td>
<td>The component always appears in the viewport, even if the entity isn't selected.</td>
</tr>
<tr>
<td>Game View</td>
<td>Renders the shape in game mode in Lumberyard Editor.</td>
</tr>
<tr>
<td></td>
<td>To enter game mode, press Ctrl + G.</td>
</tr>
<tr>
<td>Shape Color</td>
<td>Specifies the color to render the shape.</td>
</tr>
<tr>
<td>Radius</td>
<td>The radius of the sphere. If the Transform component applies a scale, these dimensions are multiplied by the same value.</td>
</tr>
</tbody>
</table>

Request EBus Interface

All shape components provide access to two separate request buses. The first bus is the ShapeComponentRequestsBus (p. 824) that returns general information about the shape component. The second bus is the ShapeNameComponentRequestsBus (p. 825) that returns property configurations for the specified shape.

Use the following request functions with the event bus interface to communicate with other components in your game.

For more information, see Working with the Event Bus (EBus) system (p. 1851).

ShapeComponentRequestsBus

The following table describes the ShapeComponentRequestsBus.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Parameter</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>DistanceFromPoint</td>
<td>Returns the minimum distance between a specified point and the shape.</td>
<td>point - Vector3 point to calculate distance from.</td>
<td>Distance from point to shape. Type: Float</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Shapes: Cylinder, Capsule, Disk, Box, Sphere, Compound

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Parameter</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DistanceSquaredFromPoint</strong></td>
<td>Returns the minimum squared distance between a specified point and the shape.</td>
<td>point – Vector3 point to calculate square distance from.</td>
<td>Square distance from point to shape. Type: Float</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>GetEncompassingAabb</strong></td>
<td>Returns an AABB that encompasses the entire shape.</td>
<td>None</td>
<td>AZ::Aabb that encompasses the shape.</td>
<td>No</td>
</tr>
<tr>
<td><strong>GetShapeType</strong></td>
<td>Returns the specified shape type for the component.</td>
<td>None</td>
<td>AZ::Crc32(shape)</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td>For example: AZ::Crc32(&quot;Box&quot;)</td>
<td></td>
<td></td>
<td>AZ::Crc32(&quot;Sphere&quot;)</td>
</tr>
<tr>
<td><strong>IsPointInside</strong></td>
<td>Checks whether a specified point is inside or outside a shape.</td>
<td>point – Vector3 point to check.</td>
<td>Indicates whether the point is inside or outside the shape. Type: Boolean</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**ComponentRequestsBus**

Each shape component has its own specific event bus for accessing that particular shape. The buses have similar functions and only differ for the requested shape type.

**BoxShapeComponentRequestsBus**

<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
<th>Parameter</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>GetBoxConfiguration</strong></td>
<td>Returns the configuration of the BoxShape.</td>
<td>None</td>
<td>BoxShapeConfiguration object that contains the configuration for the box shape.</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**CapsuleShapeComponentRequestsBus**

<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
<th>Parameter</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>GetCapsuleConfiguration</strong></td>
<td>Returns the configuration</td>
<td>None</td>
<td>CapsuleShapeConfiguration object that contains the configuration</td>
<td>Yes</td>
</tr>
<tr>
<td>Request Name</td>
<td>Description</td>
<td>Parameter</td>
<td>Return</td>
<td>Scriptable</td>
</tr>
<tr>
<td>----------------------</td>
<td>---------------------------</td>
<td>-----------</td>
<td>-------------------------------------------------------------</td>
<td>------------</td>
</tr>
<tr>
<td></td>
<td>of the CapsuleShape.</td>
<td></td>
<td>configuration for the capsule shape.</td>
<td></td>
</tr>
</tbody>
</table>

**CompoundShapeComponentRequestsBus**

<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
<th>Parameter</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetCompoundShapeConfiguration</td>
<td>Returns the configuration of the CompoundShape.</td>
<td>None</td>
<td>CompoundShapeConfiguration object that contains the configuration for the compound shape.</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**CylinderShapeComponentRequestsBus**

<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
<th>Parameter</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetCylinderConfiguration</td>
<td>Returns the configuration of the CylinderShape.</td>
<td>None</td>
<td>CylinderShapeConfiguration object that contains configuration for the cylinder shape.</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**SphereShapeComponentRequestsBus**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Parameter</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetSphereConfiguration</td>
<td>Returns the configuration of the SphereShape.</td>
<td>None</td>
<td>SphereShapeConfiguration object that contains the configuration for the sphere shape.</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**ShapeComponentNotificationsBus**

All shapes share a single notification bus named ShapeComponentNotificationsBus.

<table>
<thead>
<tr>
<th>Notification Name</th>
<th>Description</th>
<th>Parameter</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>OnShapeChanged</td>
<td>Notifies listeners that the shape component has been updated.</td>
<td>ShapeChangeReasons – Indicates whether the shape was updated from a transform change or a shape parameter change.</td>
<td>Void</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Simple Motion**

This feature is in preview release and is subject to change.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Simple Motion component to play a motion without an animation graph. Add this component to the Actor (p. 536) component to use a single motion for your actor. For complex motions, see the AnimGraph (p. 545) component.

For creating cinematics with the Simple Motion component, see Creating Character Animations with the Simple Motion Component (p. 1622).

**Simple Motion Component Properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Preview in Editor</td>
<td>Plays the motion in Lumberyard Editor.</td>
</tr>
<tr>
<td>Motion</td>
<td>Specifies the motion that you want the actor to play.</td>
</tr>
<tr>
<td>Loop motion</td>
<td>Runs the animation continuously.</td>
</tr>
<tr>
<td>Retarget motion</td>
<td>Allows motion that was created with an actor that was configured with specific bone lengths to be played on another actor with different bone lengths. When applied, the motion does not affect bone lengths. The skeleton must follow the same hierarchy and the bone names must be identical to work properly.</td>
</tr>
<tr>
<td>Reverse motion</td>
<td>Runs the animation in reverse.</td>
</tr>
<tr>
<td>Mirror motion</td>
<td>Mirrors the animation of the character's body parts. For example, if the actor kicks with the right leg while the left leg is planted, the mirror effect causes the left leg to kick while the right leg is planted.</td>
</tr>
<tr>
<td>Play speed</td>
<td>Specifies the rate at which the motion is played.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Blend in time</td>
<td>Specifies the blend in time for the motion, in seconds. You can set this parameter for a motion that you want to start and that is blending from a previous motion.</td>
</tr>
<tr>
<td>Blend out time</td>
<td>Specifies the blend out time for the motion, in seconds. You can set this parameter for a motion that is currently playing and that will blend into the next motion.</td>
</tr>
</tbody>
</table>

**Simple State**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **Simple State** component provides a simple state machine. Each state is represented by a name and zero or more entities. The entities are activated upon entering the state and deactivated upon exiting it. A simple state component may be in NullState, which means no state is active.
Simple State Component Properties

The Simple State component has the following properties:

**Initial state**

The active state when the simple state component is first activated.

**Reset on activate**

If selected, simple state returns to the configured initial state when activated, and not the state held before deactivating.

**States**

The list of states on this simple state component.

**State ([0], [1], [2], etc)**

Includes a name for the state and a set of entities that are activated when the state is entered and deactivated when the state is exited.

**Name**

The name of this state. Indicates the state to which to transition on the SetState API.

**Entities**

List of the entities referenced by this state.

**EBus Request Bus Interface**

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

**SetState**

Sets the active state to the named state.

**Parameters**

- **stateName**

**EBus Notification Bus Interface**

Use the following notification functions with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

**OnStateChanged**

Notifies that the state has changed from state **oldName** to state **newName**.

**Parameters**

- **oldName**
The following is an example of script using the **Request Bus Interface**.

```lua
local simplestateexample = {
    Properties = {
        TransitionInterval = 1.0,
        States = {"Houses", "Nope", "Lamps", "Tree", "HouseAndTree", "NoState"},
    }
}

function simplestateexample:OnActivate()
    self.TransitionCountDown = self.Properties.TransitionInterval
    self.StateIdx = 0
    self.tickBusHandler = TickBus.Connect(self)
    self.stateChangedHandler = SimpleStateComponentNotificationBus.Connect(self, self.entityId)
    Debug.Log("SimpleStateComponent activated for entity: " .. tostring(self.entityId.id))
end

function simplestateexample:OnDeactivate()
    self.tickBusHandler:Disconnect()
    self.stateChangedHandler:Disconnect()
end

function simplestateexample:OnTick(deltaTime, timePoint)
    self.TransitionCountDown = self.TransitionCountDown - deltaTime
    if (self.TransitionCountDown < 0.0) then
        self.StateIdx = (self.StateIdx + 1) % table.getn(self.Properties.States)
        self.TransitionCountDown = self.Properties.TransitionInterval
    end
end

function simplestateexample:OnStateChanged(oldState, newState)
    Debug.Log("Old State: " .. (oldState or "NullState") .. " => New State: " .. (newState or "NullState"))
end

return simplestateexample
```

**Sky Cloud**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **Sky Cloud** component creates realistic and detailed cloud effects in your game levels. To use the **Sky Cloud** component, you must enable the **Sky Clouds** gem in your project. For more information, see Add modular features and assets with Gems.
For information about cloud shading settings, placing distance clouds, and adding cloud shadows, see *Adding Clouds* (p. 1293).

**Note**
The *Sky Cloud* component replaces *legacy clouds*.

**Example Sky Cloud Component**

Lumberyard features two variations of cloud rendering:

**Common clouds**

This sprite-based rendering path uses simple shading to optimize performance. Close up, these clouds appear in 3D but once the clouds are a certain configurable distance from the viewer, an imposter (p. 3283) is substituted.

**Volumetric clouds**

This implementation uses advanced shading to create realistic voxelized (p. 3286) 3D clouds but is slower to render.

With the *Sky Cloud* component, you can do the following:

- Randomly generate common and volumetric clouds in controlled areas.
- Control where clouds generate by using entities with *Box Shape* (p. 818) components.
- Define the area in which clouds can move with a loop box.
- Programmatically manage *Sky Cloud* component properties with the Script Canvas editor, Lua scripting, and the Track Editor.
- Create and use slices that include cloud components.

The following procedure demonstrates how to create a common or volumetric cloud with the *Sky Cloud* component. After you create a cloud, you can customize its appearance and movement using the procedures in this chapter.
Creating a Cloud with the Sky Cloud Component

To create a cloud

1. Create an entity. (p. 463)
2. In the Entity Outliner, select the new entity and in the Entity Inspector, click Add Component and then click the Sky Cloud component.

3. Click Add Required Component to add the Box Shape (p. 818) component.

4. In the Entity Inspector, at the bottom of the Sky Cloud component properties, click Generate. This generates a common cloud that uses sprite-based shading in the viewport.
5. To turn the common cloud into a volumetric cloud, select the Volumetric Rendering (p. 835) property.
Sky Cloud Component Properties

The Sky Cloud component properties are grouped into the following categories. See the individual sections for detailed descriptions for the available parameters.

Cloud material

Sets the material for common cloud rendering (p. 1653). The default material is `baseclouds.mtl`. To select a different material, click (...) and choose a material based on the common cloud shader.

Volumetric Rendering (p. 835)

Enables volumetric cloud rendering (p. 1714) and specifies the cloud's material and density.

Movement (p. 835)

Defines how the clouds move over time.

Display (p. 835)

Controls which visual aids are displayed when viewing the cloud in Lumberyard Editor.
Generation (p. 836)
Defines parameters for cloud generation when you click Generate.

Volumetric Rendering Parameters
When you enable Volumetric Rendering, you create a realistic-looking volumetric cloud that is voxelized (p. 3286) and uses the Volume Object shader (p. 1714).

When Volumetric Rendering is not enabled, you create a sprite-based common cloud, which uses the Common Cloud shader (p. 1653).

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>If selected, this cloud is drawn with volumetric rendering. If not selected, the common cloud shader is used.</td>
</tr>
<tr>
<td>Volume material</td>
<td>Volume Object (p. 1714) based material used for rendering volumetric clouds. Volumetric rendering must be enabled for this parameter. The default material is volumeClouds.mtl.</td>
</tr>
<tr>
<td>Density</td>
<td>Defines the volumetric cloud's density. Volumetric rendering must be enabled for this parameter.</td>
</tr>
</tbody>
</table>

Movement Parameters
The Movement parameters define how the cloud moves within its loop box (p. 836).

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoMove</td>
<td>If selected, the cloud moves on its own.</td>
</tr>
<tr>
<td>Velocity</td>
<td>Velocity in meters per second and cloud movement in the X, Y, and Z axes.</td>
</tr>
<tr>
<td>FadeDistance</td>
<td>Distance in meters from the loop box edge. Defines where the cloud begins to fade out before wrapping around to the other side.</td>
</tr>
</tbody>
</table>

Display Parameters
Enable Display parameters to help visualize the cloud while editing.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display Spheres</td>
<td>Displays a sphere for each particle. Enable this parameter to visualize the overall volume of the cloud.</td>
</tr>
<tr>
<td>Display Volumes</td>
<td>Displays the box for each volume that is part of the cloud. Enable this parameter to see the general shape of the cloud. For more information, see Setting Up Cloud Generation Areas (p. 843).</td>
</tr>
</tbody>
</table>
### Generation Parameters

The *Generation* parameters define variables to create clouds through procedural generation.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Display Bounds</strong></td>
<td>Displays the bounds of the entire cloud including all particles. Enable this parameter to help you place clouds.</td>
</tr>
</tbody>
</table>

### Creating a Loop Box

When you add a *Sky Cloud* component to an entity, you also add a *Box Shape* component to function as a loop box. The loop box specifies the bounds in which the cloud can move. When the cloud reaches one side of the loop box, the cloud automatically repositions to the other end so that its movement loops.

**To set up the loop box**

1. In the *Entity Outliner*, select the entity with the *Sky Cloud* component.
2. In the *Entity Inspector*, modify the *Box Shape (p. 832)* component. Set the *Dimensions* values to your preferred loop box size.
For example, \( X = 500.00 \) m, \( Y = 500.00 \) m, \( Z = 200.00 \) m.

3. To see the cloud's movement within the loop box, select AutoMove in the Sky Cloud component properties.
Setting Fade Distance

The **Fade Distance** determines where the cloud begins to fade out as it reaches the edge of the loop box. This prevents the cloud from popping in and out at the edges of the box.

With smaller values, the cloud fades out close to the edge of the loop box. With larger values, the cloud begins to fade closer to the middle of the loop box.

**Example**

The following images show two clouds.

Cloud (1) is near the edge of the loop box but appears solid because of a small fade value. Cloud (2) is equally near the edge but appears faded because of a larger fade value.
To set the fade distance

1. In the **Entity Outliner**, select the entity with the **Sky Cloud** component.
2. In the **Entity Inspector**, in the **Sky Cloud** component properties, adjust the **FadeDistance** slider or enter a value in the **FadeDistance** box.

   **Note**
   This value, measured in meters, should not exceed half of the length of the loop box in the direction that the cloud is moving.

### Changing the Cloud Display

The **Sky Cloud** component's **Display** parameters change how the cloud is displayed in the viewport. You can use these parameters to visualize aspects of the cloud.
When **Display Spheres** is selected, the viewport displays a sphere for each cloud particle.

**To display the cloud as spheres**

1. In the **Entity Outliner**, select the entity with the **Sky Cloud** component.
2. In the **Entity Inspector**, in the **Sky Cloud** component properties, select **Display Spheres**.
Example

When **Display Volumes** is selected, the viewport displays the boxes that make up each part of the cloud volume. For more information, see Setting Up Cloud Generation Areas (p. 843).

To display the cloud as volumes

1. In the **Entity Outliner**, select the entity with the **Sky Cloud** component.
2. In the **Entity Inspector**, in the **Sky Cloud** component properties, select **Display Volumes**.
Example

When **Display Bounds** is selected, the viewport displays a box that includes all areas of the cloud.

To display the cloud's bounds

1. In the **Entity Outliner**, select the entity with the **Sky Cloud** component.
2. In the **Entity Inspector**, in the **Sky Cloud** component properties, select **Display Bounds**.
Example

Setting Up Cloud Generation Areas

You can set up cloud generation areas to customize the shape of your cloud. To define these areas, add **Box Shape** components to child entities under the main parent entity.
To define cloud generation areas

1. Create an entity (p. 463) with a descriptive name, such as **CloudGenerator**.
   
   This will be the parent entity for your cloud generation areas.

2. Add the **Sky Cloud** and **Box Shape** components to the entity.

3. In the **Entity Inspector**, for the **Sky Cloud** component, clear the **Fill by Loopbox** check box.
   
   Clearing this option makes the clouds render inside the child entities rather than in the current entity’s box shape.
4. Create another entity with a descriptive name, such as CloudVolume1, and then add the Box Shape component.

5. Modify the dimensions and position of the Box Shape component to accommodate a cloud that you want to create.

6. Repeat the previous two steps, adding new entities until you achieve the configuration that you want for your clouds.
7. To parent all of the entities to the CloudGenerator entity, select all of the entities and drag it to the parent entity.

8. Select the parent entity and in the Entity Inspector, for the Sky Cloud component, click Generate.
Sky Highlight

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Sky Highlight component creates large bursts of light in the sky. You can use this component with the Lightning (p. 657) component to simulate the sky lighting up when a bolt of lightning flashes.

To enable the Sky Highlight component, you must enable the Lightning Arc gem. For more information, see Lightning Arc Gem (p. 1152).

Note
You can add multiple Sky Highlight components to your entities in a level, but the level uses only one of the Sky Highlight components. The last Sky Highlight component to activate takes priority and Lumberyard renders that component.

Example
The following is a sky highlight effect in the distance.
Contents

- Sky Highlight Component Properties (p. 848)
- EBus Request Bus Interface (p. 849)
  - Enable (p. 849)
  - Disable (p. 849)
  - Toggle (p. 850)
  - IsEnabled (p. 850)
  - SetColor (p. 850)
  - GetColor (p. 851)
  - SetColorMultiplier (p. 851)
  - GetColorMultiplier (p. 851)
  - SetVerticalOffset (p. 851)
  - GetVerticalOffset (p. 852)
  - SetSize (p. 852)
  - GetSize (p. 852)
  - Notification Bus Example Script (p. 852)

Sky Highlight Component Properties

Enabled

Sky highlight effect is rendered when the entity activates.

Default value: True
Color

Color of the sky highlight effect. The default color is a pale blue.

Default value: 204, 204, 255

Color Multiplier

Multiplier to apply to the color. You can use this parameter to adjust the color intensity at run time.

Default value: 1

Valid values: 0 to 100

Vertical Offset

Offsets the height of the sky highlight render position. Specify a value to render the sky highlight above or below the entity's transform.

Default value: 0

Valid values: 0 to 100

Size

Size of the sky highlight effect.

Default value: 10

Valid values: 0 to 100

EBus Request Bus Interface

You can use this EBus to communicate to an entity with a Sky Highlight component attached. The EBus is available at game run time and editing and can be accessed from C++, Lua, and the Script Canvas editor.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

Enable

Enables the sky highlight effect.

Parameters

None

Return

None

Scriptable

Yes

Disable

Disables the sky highlight effect.
Parameters

None

Return

None

Scriptable

Yes

Toggle

Toggles whether the sky highlight effect is enabled.

Parameters

None

Return

None

Scriptable

Yes

IsEnabled

Returns whether the sky highlight effect is enabled.

Parameters

None

Return

Type: Boolean

Scriptable

Yes

SetColor

Sets the color of the sky highlight.

The Color Multiplier parameter uses this value to calculate the final sky highlight color.

Parameters

None

Return

None

Scriptable

Yes
**GetColor**

Returns the color of the sky highlight.

**Note**
This value is not affected by the **Color Multiplier** parameter.

**Parameters**
None

**Return**
None

**Scriptable**
Yes

**SetColorMultiplier**

Sets the color multiplier of the sky highlight.

The **Color** parameter uses this value to calculate the final sky highlight color.

**Parameters**
None

**Return**
None

**Scriptable**
Yes

**GetColorMultiplier**

Returns the color multiplier of the sky highlight.

**Parameters**
None

**Return**
None

**Scriptable**
Yes

**SetVerticalOffset**

Sets how far to offset the sky highlight effect from the entity's transform, on the global z-axis.

**Parameters**
Type: Float
**GetVerticalOffset**

Returns the vertical offset of the sky highlight.

**Parameters**

None

**Return**

Type: Float

**SetSize**

Sets the size of the sky highlight.

**Parameters**

Type: Float

**Return**

None

**GetSize**

Returns the size of the sky highlight.

**Parameters**

None

**Return**

Type: Float

**Notification Bus Example Script**

```function example:OnActivate()```
Snow

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Snow component to create snowfall effects and create patches of snow and ice on the terrain. You can add multiple Snow components to your entities in a level, but the level uses only one Snow component. The last Snow component to activate takes priority and Lumberyard renders that component.

To enable the Snow component, you must enable the Snow gem. For more information, see Snow Gem (p. 1203).

Note
If your level has a Snow and Rain (p. 768) component, the component that activates last takes priority; you cannot enable both Snow and Rain components at the same time.

Contents

• Turning Snow On or Off (p. 854)
• Editing Snow Effects (p. 854)
• Snow Component Properties (p. 854)

Version 1.28
853
• EBus Request Bus Interface (p. 856)
  • Example Snow Component Request Bus (p. 858)

Turning Snow On or Off

You can toggle snow on or off in Lumberyard Editor by enabling or disabling AI/Physics, or by running or stopping the game.

To toggle snow effects on or off in Lumberyard Editor

• Do one of the following:
  • On the bottom right of the viewport, click AI/Physics.
  • Choose Game, Enable Physics/AI.
  • Press Ctrl+P.
  • Press Ctrl+G to enter gameplay mode. Press Esc to stop the game.

Editing Snow Effects

You can edit snow effects only when the AI/Physics toggle is disabled.

To edit snow effects

1. Disable AI/Physics.
2. Make changes to the Snow component properties.
3. Enable AI/Physics. After you reenable AI/Physics, your changes appear in the viewport.

Snow Component Properties

The Snow component has the following properties:
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>Specifies whether snow effects are enabled.</td>
</tr>
<tr>
<td></td>
<td>Default value: <code>True</code></td>
</tr>
<tr>
<td>Radius</td>
<td>Radius of snow on the surface.</td>
</tr>
<tr>
<td></td>
<td>Default: 50</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 to 1600</td>
</tr>
<tr>
<td>Snow Amount</td>
<td>Amount of snow on the surface.</td>
</tr>
<tr>
<td></td>
<td>Default: 10</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 to 100</td>
</tr>
<tr>
<td>Frost Amount</td>
<td>Amount of frost on the surface.</td>
</tr>
<tr>
<td></td>
<td>Default: 1</td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 to 100</td>

</table>
### Property | Description
---|---
Turbulence | Turbulence that is applied to the snowflakes.
  - Default: 0.1
  - Valid values: 0 to 100
Turbulence Frequency | Turbulence frequency that is applied to the snowflakes.
  - Default: 0.1
  - Valid values: 0 to 100

### EBus Request Bus Interface

Use the following request functions with the EBus interface to communicate with other components of your game. You can use this EBus to communicate to an entity with a **Snow** component attached. The EBus is available at game time and editing, and can be accessed from C++, Lua, and the **Script Canvas** editor.

When set, the individual setters on this bus update the snow simulation immediately; this can cause some performance implications if you want to change multiple parameters. To avoid this, you can set multiple parameters at once with **GetSnowOptions** (p. 858) and **SetSnowOptions** (p. 858).

For more information, see Working with the Event Bus (EBus) system (p. 1851).

**Example Snow Component Request Bus**

```csharp
function example:OnActivate()
    SnowComponentRequestBus.Event.SetFrostAmount(self.entityId, 10)
```
Use the Spawner component to spawn a design-time or runtime dynamic slice (*.dynamicslice) at an entity's location with an optional offset.

Spawner Component Properties

The Spawner component has the following properties:

**Dynamic slice**

The slice to spawn.

**Spawn on activate**

If selected, the component spawns the selected slice, upon activation.

Default value: False

**Destroy on deactivate**

If selected, the component destroys any slices that it spawned, upon deactivation.
Default value: False

**EBus Request Bus Interface**

Use the following request functions with the **Spawner** component EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see *Working with the Event Bus (EBus) system* (p. 1851).

A **SliceInstantiationTicket** is the ID for the slice that spawns. You can use this ID with the **Spawner** component to interact with the entities that came from the spawned slice. For example, you can use the **DestroySpawnedSlice** (p. 862) function to destroy all entities from that spawned slice.

**Spawn**

Spawns the selected slice at the entity's location.

**Parameters**

- None

**Return**

- The ID of the spawning slice.

  Type: **SliceInstantiationTicket**

**Scriptable**

- Yes

**SpawnRelative**

Spawns the selected slice at the entity's location with the specified relative offset.

**Parameters**

- **offset** – The coordinates to offset the slice when it spawns.

  Type: Transform

**Return**

- The ID of the spawning slice.

  Type: **SliceInstantiationTicket**

**Scriptable**

- Yes

**SpawnAbsolute**

Spawns the provided slice at the specified world transform.

**Parameters**

- **world** – The world coordinates.
Type: Transform

Return
The ID of the spawning slice.
Type: SliceInstantiationTicket

Scriptable
Yes

SpawnSlice
Spawns the selected slice at the entity's location.

Parameters
slice – The dynamic slice asset.

Return
The ID of the spawning slice.
Type: SliceInstantiationTicket

Scriptable
No

SpawnSliceRelative
Spawns the selected slice at the entity's location with the specified relative offset.

Parameters
slice – The dynamic slice asset.
offset – The coordinates to offset the slice when it spawns.

Type: Transform

Return
The ID of the spawning slice.
Type: SliceInstantiationTicket

Scriptable
No

SpawnSliceAbsolute
Spawns the selected slice at the specified world transform.

Parameters
slice – The dynamic slice asset.
world – The world coordinates.
Spawner

Type: Transform

Return

The ID of the spawning slice.

Type: SliceInstantiationTicket

Scriptable

No

DestroySpawnedSlice

Destroys all entities from the slice that spawned. If the slice is not finished spawning, the slice is canceled. The Spawner component can destroy only slices that it spawned.

Parameters

ticket – The ID of the spawned slice.

Type: SliceInstantiationTicket

Return

None

Scriptable

Yes

DestroyAllSpawnedSlices

Destroys all entities that the Spawner component spawned. Slices that are not finished spawning are canceled.

Parameters

None

Return

None

Scriptable

Yes

GetCurrentlySpawnedSlices

Returns the IDs for spawned slices that are not yet destroyed. A slice is considered destroyed when all its entities are destroyed. The function also includes slices that have not yet finished spawning. This function returns only slices spawned by this Spawner component.

Parameters

None

Return

Type: Vector of SliceInstantiationTickets.
Scriptable

Yes

HasAnyCurrentlySpawnedSlices

Returns whether this Spawner component has spawned any slices, including any slices that are not yet destroyed. A slice is considered destroyed when all its entities are destroyed. Returns `true` if any slices have not yet finished spawning.

Parameters

None

Return

Type: Boolean

Scriptable

Yes

GetCurrentEntitiesFromSpawnedSlice

Returns the IDs of current entities from a slice that spawned. Note that spawning is not instant; if a slice is still spawning, then the entities are not returned. If an entity has been destroyed since it was spawned, its ID is not returned. This function can query only slices spawned by this Spawner component.

Parameters

ticket – The ID of the spawned slice.

Type: SliceInstantiationTicket

Return

Type: Vector of entity IDs.

Scriptable

Yes

GetAllCurrentlySpawnedEntities

Returns the IDs of all existing entities spawned by this Spawner component. Spawning is not instant; if a slice is still spawning, then entities are not returned. If an entity has been destroyed since it was spawned, its ID is not returned.

Parameters

None

Return

Type: Vector of entity IDs.

Scriptable

Yes
EBus Notification Bus Interface

Use the following EBus notification functions with the Spawner component to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

OnSpawned

Notifies that a slice finished spawning.

Parameters

spawnedEntities – Entities that the Spawner component spawned.

Type: Vector of entity IDs.

Return

None

Scriptable

Yes

OnSpawnBegin

Notifies that the slice is beginning to spawn its entities.

Parameters

ticket – The ID of the spawned slice.

Type: SliceInstantiationTicket

Return

None

Scriptable

Yes

OnSpawnEnd

Notifies that the slice finished spawning its entities.

Parameters

ticket – The ID of the spawned slice.

Type: SliceInstantiationTicket

Return

None

Scriptable

Yes
OnEntitySpawned
Notifies that an entity spawned.

Parameters

  ticket – The ID of the spawned slice.
  Type: SliceInstantiationTicket

  spawnedEntity – The entity ID.

Return

  None

Scriptable

  Yes

OnEntitiesSpawned
Notifies that the entities spawned from a slice and sends a list of the entity IDs.

Parameters

  ticket – The ID of the spawned slice.
  Type: SliceInstantiationTicket

  spawnedEntities – The IDs of the entities.
  Type: A vector of entity IDs.

Return

  None

Scriptable

  No

OnSpawnedSliceDestroyed
Notifies when a slice that spawned is destroyed. This occurs when all entities from a spawn are destroyed or when the slice fails to spawn.

Parameters

  ticket – The ID of the spawned slice.
  Type: SliceInstantiationTicket

Return

  None

Scriptable

  Yes
This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can create lines and curves in Lumberyard Editor by using the Spline component,

A spline is a curve that connects two or more specific points. This is useful if you want to animate entities along a spline, such as a road or river.

Topics
• Spline Properties (p. 866)
• Working with Spline Components (p. 867)
• EBus Request Bus Interface (p. 873)

Spline Properties

The Spline component has the following properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visible</td>
<td>The component always appears in the viewport, even if the entity isn't selected.</td>
</tr>
</tbody>
</table>
| Spline Type | Interpolation type to use between vertices. The component supports the following spline types:  
  • Linear
  • Bézier
  • Catmull-Rom |
| Closed      | Specifies whether a spline is a closed or open loop. |
| Granularity | This property is available only for Bézier and Catmull-Rom spline types.  
  The number of steps for each segment that are in the spline. A step is one of the many short lines that are arranged to approximate the |
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>shape of the curve. A segment is the part of the spline between two vertices.</td>
</tr>
<tr>
<td><strong>Knot Parameterization</strong></td>
<td>This property is available only for the Catmull-Rom spline type.</td>
</tr>
<tr>
<td></td>
<td>Adjusts the curvature and smoothness of the spline. Specify a value to support parameterization.</td>
</tr>
<tr>
<td></td>
<td>A value of 0 creates a standard Catmull-Rom spline. A value of 1 creates a chordal Catmull-Rom spline.</td>
</tr>
<tr>
<td></td>
<td>For more information, see Knot Parameterization examples (p. 872).</td>
</tr>
<tr>
<td><strong>Edit</strong></td>
<td>Choose Edit and the component is locked for editing. For more information, see Editing Components in the Viewport (p. 483).</td>
</tr>
</tbody>
</table>

By default, a Spline component has four vertices that are spaced evenly in a line. The vertex positions are stored in the local space of the entity.

![Spline component with vertices and manipulators](image)

**Working with Spline Components**

You can move the vertices in the local space of the entity along each axis. Each vertex has a planar, linear, and surface manipulator. Combined, these are called the translation manipulator. You can use the translation manipulator to move the vertices.

**To change the vertex positions for a spline**

1. Do one of the following:
   - In the viewport, double-click the spline.
   - In the Entity Inspector, choose Edit. For more information, see Editing Components in the Viewport (p. 483).
2. Do one of the following:
Spline

- Select a vertex on the component and drag either the blue, green, or red arrow (linear manipulator) or the hollow blue, green, or red square (planar manipulator) to a position.
- Select a vertex on the component and drag the yellow point (surface manipulator) to move the vertex.

**Note**
The manipulators follow the grid snap setting that you can specify in Lumberyard Editor toolbar. For more information, see Using the Top Toolbar (p. 200).

You can also select multiple vertices.

**To select multiple vertices on a spline**
- Hold Ctrl and select the vertices. Selected vertices appear yellow.
Currently, you can't click and draw a box around the vertices to select them.

**Note**
Currently, you can't click and draw a box around the vertices to select them.

You can also snap a vertex to another position on the terrain.

**To snap a vertex to another position**
1. Select a vertex.
2. Hold Shift+Ctrl and click another position on the terrain. The vertex snaps to that position.

You can also add vertices to the spline.

**To add a vertex to a spline**
1. Pause over a line and hold Ctrl. A preview appears where you can add the vertex.
2. Click to add the vertex to the spline.
You can also delete vertices from the spline.

**To delete a vertex from the spline**

1. Hold Alt and pause on a vertex. The vertex appears gray.

2. Click the vertex to delete it. You can also select a vertex and press Delete.

**Note**

Linear and Bézier splines must have a minimum of two vertices. Catmull-Rom splines must have a minimum of four vertices.
If you change the spline type, the component is updated to represent the new interpolation method.

**Example Bézier**
Note
The first and last vertices of a Catmull-Rom spline are only control points. They don't form part of the curve. A well-formed Catmull-Rom spline must have a minimum of four vertices. The spline doesn't render if there are fewer than four vertices.

The following examples show how Catmull-Rom splines change when you adjust the Knot Parameterization property.

Example Knot Parameterization = 0
Example Knot Parameterization =1

Example Linear and Bézier Splines

The following examples are linear and Bézier splines with the same vertices but with open and closed loops.

EBus Request Bus Interface

Use the following request functions with the SplineComponentRequestBus EBus interface to communicate with other components of your game. The Spline component also uses VertexContainer functions. For more information, see Vertex Containers (p. 904).

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).
<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetSpline</td>
<td>Returns a constant pointer to the underlying spline type. You can use this function to query the spline against raycasts and positions. You can also request information, such as the length of the spline, its position, normal, and tangent at various points along the spline.</td>
<td>None</td>
<td>AZ::ConstSplinePtr</td>
<td>Yes</td>
</tr>
<tr>
<td>ChangeSplineType</td>
<td>Changes the spline type. The AZ::u64 value refers to the RTTI hash of the underlying spline type. For example, AZ::LinearSpline::RTTI_Type().GetHash().</td>
<td>AZ::u64</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>SetClosed</td>
<td>Specifies whether the spline forms a closed or open loop.</td>
<td>Boolean</td>
<td>None</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Example**

The following script uses the request bus interface.

```lua
local spline = SplineComponentRequestBus.Event.GetSpline(self.entityId);

-- GetNearestAddressPosition
local posSplineQueryResult = spline:GetNearestAddressPosition(Vector3(0, 0, 0));

posSplineQueryResult.splineAddress
posSplineQueryResult.splineAddress.segmentIndex
posSplineQueryResult.splineAddress.segmentFraction
posSplineQueryResult.distanceSq

-- GetNearestAddressRay
local raySplineQueryResult = spline:GetNearestAddressRay(Vector3(10, -1, 0), Vector3(0, -1, 0));

raySplineQueryResult.splineAddress.segmentIndex
raySplineQueryResult.splineAddress.segmentFraction
raySplineQueryResult.distanceSq
raySplineQueryResult.rayDistance

local splineAddressFromDistance = spline:GetAddressByDistance(3.0);
```
local splineAddressFromFraction = spline:GetAddressByFraction(0.75);

-- Test SplineAddress Constructor (1 param)
local splineAddress_1 = SplineAddress(2);

-- Test SplineAddress Constructor (2 params)
local splineAddress_2 = SplineAddress(1, 0);

spline:GetPosition(splineAddress_1)
spline:GetNormal(splineAddress_1)
spline:GetTangent(splineAddress_1)
spline:GetLength(splineAddress_1)
spline:GetSplineLength()
spline:GetSegmentLength(1)
spline:GetSegmentCount()
spline:GetSegmentGranularity()

local aabb = spline:GetAabb(Transform:CreateIdentity());

local closed = spline:IsClosed();
local firstVertex = spline.vertexContainer[1];
local lastVertex = spline.vertexContainer[spline.vertexContainer:Size()];

-- Attention: You can use the bus interface directly, but here (at the moment at least) indexing will start from 0, not 1 as is the norm in Lua. Instead, you should use the functions directly on the VertexContainer, listed below
SplineComponentRequestBus.Event.AddVertex(self.entityId, lastVertex + Vector3(1, 2, 3));
SplineComponentRequestBus.Event.UpdateVertex(self.entityId, 0, firstVertex + Vector3(1, 2, 3));
SplineComponentRequestBus.Event.InsertVertex(self.entityId, spline.vertexContainer:Size() - 1, lastVertex + Vector3(1, 2, 3));
SplineComponentRequestBus.Event.ClearVertices(self.entityId);
SplineComponentRequestBus.Event.RemoveVertex(self.entityId, spline.vertexContainer:Size() - 1);

-- Prefer these functions - indexing will start from 1
spline.vertexContainer:AddVertex(lastVertex + Vector3(1, 2, 3));
lastVertex + Vector3(1, 2, 3));
spline.vertexContainer:UpdateVertex(1, firstVertex + Vector3(1, 2, 3));
spline.vertexContainer:InsertVertex(spline.vertexContainer:Size(), lastVertex + Vector3(1, 2, 3));
spline.vertexContainer:ClearVertices();
spline.vertexContainer:RemoveVertex(spline.vertexContainer:Size());

Tag

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Tag component to apply one or more labels, or tags, to an entity such as burning or player. You can use these tags to find or filter entities with particular traits. For example, you can set a weapon to inflict double damage to entities tagged as burning.

EBuses – Request Bus Interface: TagGlobalRequestBus

Use the following request function with the TagGlobalRequestBus EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).
RequestTaggedEntities

Handlers respond if they have the tag (listening on the tag's channel). Use AZ::EBusAggregateResults to handle more than the first responder.

Parameters
None

Return
const AZ::EntityId

Scriptable
Yes

EBuses – Request Bus Interface: TagRequestBus

Use the following request functions with the TagRequestBus EBus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

HasTag

Returns true if the entity has the tag.

Parameters
const Tag&

Return
bool

Scriptable
Yes

AddTag

Adds the tag to the entity if it didn't already have it.

Parameters
const Tag&

Return
None

Scriptable
Yes

AddTags

Add a list of tags to the entity if it didn't already have them.
**Tag**

**Parameters**

const Tags&

**Return**

None

**Scriptable**

No

**RemoveTag**

Removes a tag from the entity if it had it.

**Parameters**

const Tag&

**Return**

None

**Scriptable**

Yes

**RemoveTags**

Removes a list of tags from the entity if it had them.

**Parameters**

const Tags&

**Return**

None

**Scriptable**

No

**GetTags**

Gets the list of tags on the entity.

**Parameters**

None

**Return**

const Tags&

**Scriptable**

No

The following is an example of script using the **Request Bus Interface**.

```cpp
local enemies = TagGlobalRequestBus.Event.RequestTaggedEntities(Crc32("Enemy"));
```
local burning = TagComponentRequestBus.Event.HasTag(self.entityId, Crc32("Burning"));

**EBus – Notification Bus Interface:**
**TagComponentNotificationsBus**

Use the following request functions with the **TagComponentNotificationsBus** notification bus interface to communicate with other components of your game.

For more information about using the event bus (EBus) interface, see *Working with the Event Bus (EBus) system* (p. 1851).

**OnTagAdded**
Notifies listeners about tags being added.

**Parameters**
- const Tag& – Indicates the tag was added

**Return**
None

**Scriptable**
Yes

**OnTagRemoved**
Notifies listeners about tags being removed.

**Parameters**
- const Tag& – Indicates the tag was removed

**Return**
None

**Scriptable**
Yes

**Transform**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The **Transform** component controls the translation, rotation, and scale information of an entity in the 3D world. When you create an entity in Lumberyard Editor, the **Transform** component is automatically added. The translation is the coordinate location (x, y, and z axes) of the entity. The rotation is the degree in which the entity is rotated around its center. The scale is the dimension of the entity in comparison to its original size.

*World space* refers to the entity’s absolute translation, rotation, and scale in the level. If a child is attached to a parent entity, *local space* refers to the entity’s translation, rotation, and scale relative to its parent entity.
Transform Component Properties

The **Transform** component has the following properties:

**Parent entity**

The entity assigned as the parent. If a parent entity is specified, the **Transform** component follows the parent entity.

**Values**

The **Transform** component has the following values:

**Translate**

The local position (relative to the parent) in meters.

**Rotate**

The local rotation (relative to the parent) in degrees.

**Scale**

The local scale.

**Parent activation**

Configures transform behavior when the parent entity activates.

**Static**

Entities that can't be moved at run time. Some systems in Lumberyard treat static entities differently than movable entities (for example, the renderer can optimize static entities, making them less resource intensive to draw).

**Network Sync**

The **Transform** component has following network sync options:

**Sync to replicas**

Transform component syncs in a networked game. If you enable this option, you must also add the **Network Binding** (p. 700) component. Otherwise, the entity is not replicated and the interpolation options don't apply.

**Position Interpolation**

The smoothing of position between network updates and interruptions. This is useful if your objects change location and you notice visual jitter or sudden changes in orientation due to network conditions.

**Rotation Interpolation**

The smoothing of rotation between network updates and interruptions. This is useful if your objects rotate and you notice visual jitter or sudden changes in orientation due to network conditions.

**Note**

Scale interpolation is not supported in the **Transform** component.

**EBus Request Bus Interface**

**TransformBus** is the request bus for the **Transform** component. An entity's transform is the translation, rotation, and scale information.
For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

Use the following request functions with the EBus interface to communicate with other components of your game.

**GetLocalTM**

Returns the entity's local transform. Doesn't include the parent entity's transform.

**Parameters**

None

**Return**

Entity's local transform.

**SetLocalTM**

Sets the entity's local transform, relative to its parent entity, and notifies all listeners.

**Parameters**

Entity's local transform.

**Return**

None

**GetWorldTM**

Returns the entity's world transform, including the parent entity's transform.

**Parameters**

None

**Return**

Entity's world transform.

**SetWorldTM**

Sets the world transform and notifies all listeners.

**Parameters**

Entity's world transform.

**Return**

None

**GetLocalAndWorld**

Retrieves the entity's local and world transforms.

**Parameters**

Transform [out] – Local transform, relative to parent entity.
Transform [out] – World transform.

**Return**

None

**SetWorldTranslation**

Sets the entity's world space translation.

**Parameters**

New world space location, in x, y, and z coordinates.

Type: Vector3

**Return**

None

**SetLocalTranslation**

Sets the entity's local space translation, which is relative to its parent entity.

**Parameters**

New local space location, in x, y, and z coordinates.

Type: Vector3

**Return**

None

**GetWorldTranslation**

Gets the entity's world space translation.

**Parameters**

None

**Return**

Entity's world space, in x, y, and z coordinates.

Type: Vector3

**GetLocalTranslation**

Gets the entity's local space translation, which is relative to its parent entity.

**Parameters**

None

**Return**

Entity's local space, in x, y, and z coordinates.

Type: Vector3
**MoveEntity**
Moves the entity within world space.

**Parameters**
- Offset in world space, in x, y, and z coordinates.
  - Type: Vector3

**Return**
None

**SetWorldX**
Sets the entity's translation x-axis coordinate in world space.

**Parameters**
- X-axis coordinate in world space.
  - Type: Float

**Return**
None

**SetWorldY**
Sets the entity's translation y-axis coordinate in world space.

**Parameters**
- Y-axis coordinate in world space.
  - Type: Float

**Return**
None

**SetWorldZ**
Sets the entity's translation z-axis coordinate in world space.

**Parameters**
- Z-axis coordinate in world space.
  - Type: Float

**Return**
None

**GetWorldX**
Gets the entity's translation x-axis coordinate in world space.

**Parameters**
None
Return

- X-axis coordinate in world space.
  Type: Float

GetWorldY

Gets the entity's translation y-axis coordinate in world space.

Parameters
- None

Return

- Y-axis coordinate in world space.
  Type: Float

GetWorldZ

Sets the entity's translation z-axis coordinate in world space.

Parameters
- None

Return

- Z-axis coordinate in world space.
  Type: Float

SetLocalX

Sets the entity's translation x-axis coordinate in local space.

Parameters
- X-axis coordinate in local space.
  Type: Float

Return

- None

SetLocalY

Sets the entity's translation y-axis coordinate in local space.

Parameters
- Y-axis coordinate in local space.
  Type: Float

Return

- None
SetLocalZ
Sets the entity's translation z-axis coordinate in local space.

Parameters
Z-axis coordinate in local space.
Type: Float

Return
None

GetLocalX
Gets the entity's translation x-axis coordinate in local space.

Parameters
None

Return
X-axis coordinate in local space.
Type: Float

GetLocalY
Gets the entity's y-axis coordinate in local space.

Parameters
None

Return
Y-axis coordinate in local space.
Type: Float

GetLocalZ
Gets the entity's z-axis coordinate in local space.

Parameters
None

Return
Z-axis coordinate in local space.
Type: Float

GetWorldRotation
Gets the angles in radians for each principle axis around which the world transform is rotated in the following order: z-axis, y-axis, x-axis.
Parameters

None

Return

The Euler angles in radians, which indicate the degree of rotation around each principle axis.

Type: Vector3

GetWorldRotationQuaternion

Gets the quaternion that represents the world rotation.

Parameters

None

Return

The quaternion that represents the world rotation.

Type: Quaternion

SetLocalRotation

Sets the local rotation around each principle axes in the following order: z-axis, y-axis, x-axis.

Parameters

The Vector3 denoting radian angles of the rotations around each principle axis.

Type: Vector3

Return

None

SetLocalRotationQuaternion

Sets the local rotation matrix using a quaternion.

Parameters

The local rotation matrix.

Type: Quaternion

Return

None

RotateAroundLocalX

Rotates around the local x-axis for a radian angle.

Parameters

The radian angle to rotate around the local x-axis.

Type: Float
**GetLocalRotation**

Gets angles in radian for each principle axis around which the local transform is rotated in the following order: z-axis, y-axis, x-axis.

**Parameters**

None

**Return**

Indicates how much in radian is rotated around each principle axis.

Type: Vector3

**GetLocalRotationQuaternion**

Gets the quaternion representing the local rotation.

**Parameters**

None

**Return**

The quaternion that represents the local rotation.

Type: Quaternion
SetLocalScale
Sets local scale of the transform.

Parameters
Local scale of the transform, in x, y, and z coordinates.
Type: Vector3

Return
None

SetLocalScaleX
Sets local scale of the transform on the x-axis.

Parameters
X-axis coordinate for the local scale.
Type: Float

Return
None

SetLocalScaleY
Sets local scale of the transform on the y-axis.

Parameters
Y-axis coordinate for the local scale.
Type: Float

Return
None

SetLocalScaleZ
Sets local scale of the transform on the z-axis.

Parameters
Z-axis coordinate for the local scale.
Type: Float

Return
None

GetLocalScale
Gets the scale value on each axis in local space.

Parameters
None
**Return**

Scale value for each axis in local space.

Type: Vector3

**GetWorldScale**

Gets the scale value on each axis in world space. Note that the transform is skewed when it is rotated and has a parent transform scale in which the returned world scale from this function is inaccurate.

**Parameters**

None

**Return**

Scale values for each axis in world space.

Type: Vector3

**GetParentId**

Returns the parent entity's ID. If the entity does not have a parent, the entity ID is invalid.

**Parameters**

None

**Return**

EntityID of the parent

Type: Int

**SetParent**

Sets the entity's parent entity and notifies all listeners. The entity's local transform is moved into the parent entity's space to preserve the entity's world transform.

**Parameters**

EntityId – Parent entity ID

Type: Int

**Return**

None

**SetParentRelative**

Sets the entity's parent entity, moves the transform relative to the parent entity, and notifies all listeners. This function uses the world transform as a local transform and moves the transform relative to the parent entity.

**Parameters**

EntityId – Parent entity ID

Type: Int
Return
None

GetChildren
Returns the entity IDs of the entity's immediate children.

Parameters
None

Return
Vector of EntityIds

GetAllDescendants
Returns the entity IDs of all descendants of the entity. The descendants are the entity's children, the children's children, and so on. The entity IDs are ordered breadth first.

Parameters
None

Return
Vector of EntityIds

GetEntityAndAllDescendants
Returns the entity ID of the entity and all its descendants. The descendants are the entity's children, the children's children, and so on. The entity IDs are ordered breadth first, and this entity's ID is the first in the list.

Parameters
None

Return
Vector of EntityIds

IsStaticTransform
Returns whether the transform is static. A static transform doesn't move and doesn't respond to requests to move it.

Parameters
None

Return
Boolean

EBus Notification Bus Interface

TransformNotificationBus is the notification bus for the Transform component. Use the following notification functions with the EBus interface to communicate with other components of your game.
For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

**OnTransformChanged**
Signals that the local or world transform of the entity changed.

**Parameters**
- Transform – The new local transform of the entity
- Transform – The new world transform of the entity

**OnParentChanged**
Signals that the parent of the entity changed.

**Parameters**
- EntityId – The entity ID of the previous parent. The entity ID is invalid if there was no previous parent.
- EntityId – The entity ID of the new parent. The entity ID is invalid if there is no new parent.

**OnChildAdded**
Signals that a child was added to the entity.

**Parameters**
- EntityId – The entity ID of the added child

**OnChildRemoved**
Signals that a child was removed from the entity.

**Parameters**
- EntityId – The entity ID of the removed child

**Trigger Area**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Trigger Area component provides generic triggering services by using Shape (p. 818) components as its bounds.

**To add a trigger component**

1. Create a new entity, or add the Trigger Area component to an existing entity.
2. In the Entity Inspector, click Add Component, then select Trigger Area.

   Entity Inspector displays a message, "This component is missing a required component service and has been disabled."
3. Click **Add Required Component**, then click one of the shape components that appears.

   The shape component you select defines the boundaries for the trigger.

4. If you want to change the boundaries of your shape component, simply remove the existing shape component, and then add a different shape component.

   **Note**
   - The **Trigger Area** component does not work with the PhysX system.

### Trigger Area Component Properties

The **Trigger Area** component has the following properties:

**Network Bindable**

Network bindable components are synchronized over the network.

**Bind To Network**

   When selected, synchronizes component across the network.

**Activation**

**Trigger once**

   If selected, the trigger deactivates after the first trigger event.

**Activated by**

   Select whether trigger is activated by **All entities**, which allows any entity to trigger the area, or by **Specific Entities**, which allows you to select specific entities.

**Tag filters**

**RequiredTags**

   A list of tags that are required for an entity to trigger this area.

**ExcludedTags**

   A list of tags that exclude an entity from triggering this area.

### EBus Request Bus Interface

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see [Working with the Event Bus (EBus) system](p. 1851).

**AddRequiredTag**

   Adds a required tag to the activation filtering criteria of this component. Results in a reevaluation of the trigger. Entities inside that no longer satisfy tag criteria are ejected.

**Parameters**

   ```cpp
   const Tag&
   ```
requiredTag – Tag to be added
Return
None
Scriptable
Yes

RemoveRequiredTag
Removes a required tag from the activation filtering criteria of this component. Results in a reevaluation of the trigger. Entities inside that no longer satisfy tag criteria are ejected.

Parameters
const Tag&
    requiredTag – Tag to be removed
Return
None
Scriptable
Yes

AddExcludedTag
Adds an excluded tag to the activation filtering criteria of this component. Results in a reevaluation of the trigger. Entities inside that no longer satisfy tag criteria are ejected.

Parameters
const Tag&
    excludedTag – Tag to be added
Return
None
Scriptable
Yes

RemoveExcludedTag
Removes an excluded tag from the activation filtering criteria of this component. Results in a reevaluation of the trigger. Entities inside that no longer satisfy tag criteria are ejected.

Parameters
const Tag& excludedTag – Tag to be removed
Return
None
Scriptable
Yes
EBus Notification Bus Interface

Use the following request functions with the EBus interface to communicate with other components of your game.

For more information about using the Event Bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

The Trigger component sends notifications to:

- Entities listening on the TriggerAreaNotificationBus for the entity with the trigger on it.
- Entities listening on the TriggerAreaEntityNotificationBus for the entity that enters or exits the trigger.

TriggerAreaNotificationBus

This bus allows the game to listen for events associated with a particular trigger. Notifies of all the entities that enter and exit this trigger.

OnTriggerAreaEntered

Notifies listeners when enteringEntityId enters this trigger.

Parameters

  enteringEntityId – ID of entity that has entered this trigger

Return

  None

Scriptable

  Yes

OnTriggerAreaExited

Notifies listeners when enteringEntityId exits this trigger.

Parameters

  enteringEntityId – ID of entity that has exited this trigger

Return

  None

Scriptable

  Yes

TriggerAreaEntityNotificationBus

This bus allows the game to listen for trigger-related events associated with a particular entity. Notifies every time the player enters or exits any trigger.

OnEntityEnteredTriggerArea

Sent when the entity enters triggerId.

Parameters

  triggerId – ID of entity that the trigger is on
Return

None

Scriptable

Yes

**OnEntityExitedTriggerArea**

Sent when the entity exits triggerID.

**Parameters**

- `triggerId` - *ID of entity that the trigger is on*

**Return**

None

Scriptable

Yes

The following is an example of script using the EBus interface.

```lua
local triggerexample = {
    Properties = {
    }
}

function triggerexample:OnActivate()
    self.triggerHandler = TriggerAreaEntityNotificationBus.Connect(self, self.entityId)
end

function triggerexample:OnDeactivate()
    self.triggerHandler:Disconnect()
end

function triggerexample:OnEntityEnteredTriggerArea(entityId)
    Debug.Log("------- TRIGGERED.")
end

return triggerexample
```

**Tube Shape**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Create tube-like volumes along a spline by using the **Tube Shape** component. To create a tube shape, add the **Spline** component to an entity to define its shape. In the **Tube Shape** component, define a radius to control its volume. You can specify a different tube radius at each vertex in the spline.
Note
The Tube Shape component requires the Spline (p. 866) component.

Topics
- Tube Shape Properties (p. 895)
- EBus Request Bus Interface (p. 896)

Example Tube Shape Component

Tube Shape Properties

![Tube Shape Properties](image)

Version 1.28
895
The **Tube Shape** component has the following properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visible</td>
<td>The component always appears in the viewport, even if the entity isn't selected.</td>
</tr>
<tr>
<td>Game View</td>
<td>Renders the shape in game mode.</td>
</tr>
<tr>
<td></td>
<td>To enter game mode, press <strong>Ctrl + G</strong>.</td>
</tr>
<tr>
<td>Shape Color</td>
<td>Specifies the color to render the shape.</td>
</tr>
<tr>
<td>Radius</td>
<td>The radius of the tube.</td>
</tr>
<tr>
<td>Variable Radius</td>
<td>Defines the variable radius at each point along the spline. This value is added to the radius to calculate the final radius of the tube.</td>
</tr>
<tr>
<td>Edit</td>
<td>Choose <strong>Edit</strong>, and the component is locked for editing. For more information, see <strong>Editing Components in the Viewport</strong> (p. 483).</td>
</tr>
</tbody>
</table>

**EBus Request Bus Interface**

You can use the event bus (EBus) interface to communicate with other components in your game. For more information, see **Working with the Event Bus (EBus) system** (p. 1851).

<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
<th>Parameter</th>
<th>Return</th>
<th>Scriptable</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetRadius</td>
<td>Returns the radius of the tube.</td>
<td>Void</td>
<td>Float</td>
<td>Yes</td>
</tr>
<tr>
<td>GetTotalRadius</td>
<td>Returns the total interpolated radius of the tube. This is the sum of the radius and the variable radius.</td>
<td>SplineAddress</td>
<td>Float</td>
<td>Yes</td>
</tr>
<tr>
<td>GetVariableRadius</td>
<td>Returns the variable radius along the spline.</td>
<td>Int</td>
<td>Float</td>
<td>Yes</td>
</tr>
<tr>
<td>SetRadius</td>
<td>Sets the radius of the tube.</td>
<td>Float</td>
<td>Void</td>
<td>Yes</td>
</tr>
<tr>
<td>SetVariableRadius</td>
<td>Sets the variable radius of the tube at a spline point.</td>
<td>Int, Float</td>
<td>Void</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Example**

The following script uses the request bus interface.

```lua
function Script:OnActivate()
    TubeShapeComponentRequestsBus.Event.SetRadius(self.entityId, 5.0);
end
```
UI Canvas Asset Ref

With the **UI Canvas Asset Ref** component, you can associate a UI canvas with a component entity in a level.

When you set up a UI canvas asset ref component, you can:

- Select whether to automatically load the UI canvas when the level loads
- Use Script Canvas that is associated with the UI canvas to reference it using the **UI Canvas Asset Ref** Script Canvas nodes.

Use this component in conjunction with the **UI Canvas on Mesh** (p. 897) component if you want to place a UI canvas on a 3D mesh that a player can interact with.

For more information about how to use the **UI Canvas Asset Ref** component, see Placing UI Canvases in the 3D World (p. 2897).

**UI Canvas Asset Ref Component Properties**

The **UI Canvas Asset Ref** component has the following properties:

- **Canvas pathname**
  
  The relative pathname of the UI canvas asset file.

- **Load automatically**
  
  If selected, the canvas is automatically loaded when this component entity is loaded, typically when the level is loaded.

UI Canvas on Mesh

With the **UI Canvas on Mesh** component, you can place a UI canvas on a component entity in the 3D world that a player can interact with via ray casts. Use this component in conjunction with the **UI Canvas Asset Ref** (p. 897) component.

For more information about how to use the **UI Canvas Asset Ref** component, see Placing UI Canvases in the 3D World (p. 2897).

**UI Canvas on Mesh Component Properties**

The UI Canvas on Mesh component has the following properties:

- **Render target override**
  
  For simple cases, you can leave this property blank. The UI canvas specifies a render target, and that render target can be used as a texture name for the material on the 3D mesh.
You can use the **Render target override** property when you want to load two unique instances of the same UI canvas that the user can set to different states. This example case is demonstrated in the **UiIn3DWorld** level in the **Samples Project**.

**Unique Instances of Canvas**

These two entities each load a unique instance of the same canvas. The sphere above casts a shadow on the left entity because it is using the Illum shader.

**UI Canvas Proxy Ref**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

With the UI Canvas Proxy Ref component, you can associate a component entity in a level with another component entity that is managing a UI canvas. Use this component in conjunction with the **UI Canvas on Mesh** (p. 897) component if you want to place a UI canvas on a 3D mesh that a player can interact with in several places in the 3D world.
Use of this component is often a special case, as it supports displaying the same UI canvas on multiple entities in the 3D world. The UI Canvas Proxy Ref component allows the component entity that it is on to act as if it had a UI Canvas Asset Ref (p. 897) component but without having to load another copy of the UI canvas. This means that, as the user interacts with one UI canvas on a 3D object, the other 3D object shows the same changes.

To see an example of using the UI Canvas Proxy Ref component, open the UiIn3DWorld level in the Samples Project.

The following picture shows three entities that share the same loaded canvas. The curved plane entity has a UI Canvas Asset Ref component and the egg and the sphere both have UI Canvas Proxy Ref components:

---

UI Canvas Proxy Ref Component Properties

The UI Canvas Proxy Ref component has the following properties:
Canvas Asset Ref entity

Click the picker (hand icon) to select the component entity that you want to mirror. The picked component must have the UI Canvas Asset Ref component on it.

Vegetation Layer Spawner

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Vegetation Layer Spawner component to define areas and rules for procedurally placing dynamic vegetation or other static meshes in your Lumberyard level.

To use the Vegetation Layer Spawner component, you must enable the Vegetation gem.

With the Vegetation Layer Spawner component, you can do the following:

- Create vegetation within a user-defined area at runtime
- Configure layer settings to determine the depth or relative ordering in which to apply vegetation layers
- (Optional) Add modifier and filter components to add variation to placed vegetation
- (Optional) Use selector components to determine which vegetation assets to place at a given location
- Control the preview settings for attached components
- Inherit behavior from a parent Vegetation Layer Blenders component

Add the following required components when using the Vegetation Layer Spawner component:

- A Shape or Vegetation Reference Shape component to define the vegetation's spawn area
- The Vegetation Asset List component to list mesh assets, material assets, and other settings for the vegetation

The following optional components change the Vegetation Layer Spawner component's behavior:

- Vegetation Filter components use various conditions to determine whether to create vegetation
- Vegetation Modifier components change the appearance of generated vegetation
- Vegetation Selector components determine which asset descriptors are selected for creation

For information on how to use the Vegetation Layer Spawner, see Dynamic vegetation (p. 1314).

Vegetation Layer Spawner Properties

The Vegetation Layer Spawner component has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Override Preview Settings</td>
<td>Controls whether user-specified settings or default settings are used to display the preview. Select this option to expose additional related properties.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Pin Preview to Shape</td>
<td>Specified shape entity determines the preview position and size. Remove the target entity to expose Preview Position and Preview Size.</td>
</tr>
<tr>
<td>Preview Position</td>
<td>Specifies an offset for the world space location at the center of the box. This box is used for sampling values that the preview window displays.</td>
</tr>
<tr>
<td>Preview Size</td>
<td>Specifies a scale for the world space dimensions of the box that is used for sampling values that the preview window displays.</td>
</tr>
<tr>
<td>Constrain to Shape</td>
<td>When enabled, forces preview widgets to display only content that is in the component's shape instead of the filling the entire image.</td>
</tr>
<tr>
<td>Layer Priority</td>
<td>Defines a high-level priority or depth for vegetation to be sorted and processed relative to other layers.</td>
</tr>
<tr>
<td></td>
<td>All foreground layers are processed and can plant vegetation before all background layers.</td>
</tr>
<tr>
<td>Sub Priority</td>
<td>Defines a priority that is used to sort and apply vegetation areas in the same layer.</td>
</tr>
<tr>
<td></td>
<td>Vegetation layers with higher priorities are applied before those with lower priorities.</td>
</tr>
<tr>
<td>Inherit Behavior</td>
<td>Enables certain vegetation layer components to use the filters and modifiers that are attached to a parent entity in a vegetation layer blender hierarchy.</td>
</tr>
<tr>
<td>Allow Empty Meshes</td>
<td>Enables unspecified or invalid meshes to plant and claim space. Spawners typically plant only visible vegetation instances, which claim space and prevent other vegetation from being planted. By default, unspecified or invalid meshes are skipped.</td>
</tr>
<tr>
<td>Filter Stage</td>
<td>Defines when vegetation filters are processed. Individual vegetation filters can override this setting. For more information, see the text following this table.</td>
</tr>
</tbody>
</table>

For the Filter Stage property, the **PreProcess** option results in faster processing than the **PostProcess** option, which ensures accuracy.

- **PreProcess** – Processes vegetation filters before modifiers. This means that fewer instances are processed for modifiers, which generally process faster. However, modifiers that affect slope, altitude, and so on might affect the criteria that would have filtered out the instance. Running the filters first means that the modified data isn't checked by the filter.
• **PostProcess** – Processes vegetation modifiers before filters. This means that modifiers process every potential instance before filters remove them. Because of the added calculations, this method is slower but ensures correct filtering out of vegetation whose filter criteria has been modified.

**Example**

A Vegetation Altitude Filter is set to filter out vegetation below 32 meters. A Vegetation Position Modifier is set to shift vegetation left by 5 meters. The initial Vegetation Layer Spawner is placed in a box sitting at 32 meters. With the **PreProcess** option (A), the filter is applied first, and then the modifier shifts vegetation left into the canyon. With the **PostProcess** option (B), the modifier shifts vegetation left into the canyon first. The filter is then applied, which removes the vegetation below 32 meters.

![Example Image](image)

**Ebus Request Bus Interface**

The Vegetation Layer Spawner component uses Vegetation::SpawnerRequestBus and Vegetation::AreaInfoBus interfaces.

For more information about using the event bus (EBus) interface, see Working with the Event Bus (EBus) system (p. 1851).

Use the following request functions with the EBus interface to communicate with other components of your game.

Use the following EBus requests with the Vegetation::SpawnerRequestBus interface.

<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Return</th>
<th>Scriptable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetAreaPriority</td>
<td>Get the priority (in the layer) of the vegetation area. Higher numbers have higher priority.</td>
<td>None</td>
<td>Float</td>
<td>Yes</td>
</tr>
<tr>
<td>SetAreaPriority</td>
<td>Set the priority (in the layer) of the vegetation area.</td>
<td>Float</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>GetAreaLayer</td>
<td>Get the layer of the vegetation area.</td>
<td>None</td>
<td>Float</td>
<td>Yes</td>
</tr>
<tr>
<td>Request Name</td>
<td>Description</td>
<td>Parameters</td>
<td>Return</td>
<td>Scriptable?</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>SetAreaLayer</td>
<td>Set the layer of the vegetation area.</td>
<td>AreaLayer</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>GetAreaProductCount</td>
<td>Get the number of currently spawned instances in the vegetation area.</td>
<td>AZ::u32</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>GetInheritBehavior</td>
<td>Get the Inherit Behavior setting, which controls whether shapes, modifiers, and filters of a parent entity affect this area.</td>
<td>Bool</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>SetInheritBehavior</td>
<td>Set the Inherit Behavior setting.</td>
<td>None</td>
<td>Bool</td>
<td>Yes</td>
</tr>
<tr>
<td>GetAllowEmptyMeshes</td>
<td>Get the Allow Empty Meshes setting, which controls whether empty meshes in the Vegetation Asset List are spawned as empty spaces.</td>
<td>Bool</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>SetAllowEmptyMeshes</td>
<td>Set the Allow Empty Meshes setting.</td>
<td>None</td>
<td>Bool</td>
<td>Yes</td>
</tr>
<tr>
<td>GetFilterStage</td>
<td>Get the filter stage. PreProcess means that vegetation filters are applied before vegetation modifiers. PostProcess means that they’re applied afterwards.</td>
<td>FilterStage</td>
<td>None</td>
<td>Yes</td>
</tr>
<tr>
<td>SetFilterStage</td>
<td>Set the filter stage.</td>
<td>None</td>
<td>FilterStage</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Use the following EBus requests with the Vegetation: :AreaInfoBus interface.
<table>
<thead>
<tr>
<th>Request Name</th>
<th>Description</th>
<th>Parameters</th>
<th>Return</th>
<th>Scriptable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetPriority</td>
<td>Get the combined layer and area priority value as a single combined global priority.</td>
<td>None</td>
<td>Float</td>
<td>Yes</td>
</tr>
<tr>
<td>GetEncompassingAabb</td>
<td>Get the axis-aligned bounding box for the entire vegetation area.</td>
<td>None</td>
<td>AZ::Aabb</td>
<td>Yes</td>
</tr>
<tr>
<td>GetProductCount</td>
<td>Get the number of currently spawned instances in the vegetation area. Same as GetAreaProductCount.</td>
<td>None</td>
<td>AZ::u32</td>
<td>Yes</td>
</tr>
<tr>
<td>GetChangeIndex</td>
<td>Get an incrementing number that represents the number of times that the spawner area has been refreshed since creation.</td>
<td>None</td>
<td>AZ::u32</td>
<td>Yes</td>
</tr>
</tbody>
</table>

### Vertex Containers

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

VertexContainer is a concrete type and an interface that is used by several Lumberyard component buses. It is implemented directly by the Polygon Prism Shape (p. 708) component and the Spline (p. 866) component and used indirectly by the Navigation Area (p. 693) component.

### Vertex Container Interface

A vertex container provides the ability to access, modify, add, and remove vertices. A vertex container has several interfaces that build upon one another.

These include the following interfaces:

**Contents**
- FixedVertices Interface (p. 905)
- VariableVertices Interface (p. 905)
- VertexContainerInterface (p. 905)
FixedVertices Interface

The simplest interface is FixedVertices. FixedVertices supports GetVertex and UpdateVertex functions for vertices in a container and a Size function that returns the number of vertices in the container.

Because the number of vertices is fixed, vertices cannot be added or removed. You can implement this interface with an array or AZStd::fixed_vector.

VariableVertices Interface

The VariableVertices interface supports all the functionality of FixedVertices, but also provides AddVertex, InsertVertex, and RemoveVertex functions. VariableVertices also provides a utility function called Empty that checks whether a container has any elements or is empty.

To implement the VariableVertices interface, you can use either an AZStd::vector or a VertexContainer.

VertexContainerInterface

The VertexContainerInterface provides an interface to all functionality provided by the previous two interfaces and the VertexContainer type. For convenience, the VertexContainerInterface also provides SetVertices and ClearVertices functions that can update all vertices or remove all vertices in one operation. The SetVertices function takes a vertices parameter that contains a list of all vertices to be stored.

**Note**

A VertexContainer owns the vertices to which it has access; they are not stored elsewhere (a VertexContainer is not a view).

As mentioned, the VertexContainerInterface is implemented by the Spline component and Polygon Prism component EBuses. The Navigation Area component also uses the interface through its dependence on the Polygon Prism Shape component. Each of these components uses the VertexContainer type internally to manage its vertices.

For more information about the interfaces in the VertexContainerInterface, see the code and code comments in the lumberyard_version\dev\Code\Framework\AzCore\AzCore\Math\VertexContainerInterface.h file.

For more information about the VertexContainer type, see the code and code comments in the lumberyard_version\dev\Code\Framework\AzCore\AzCore\Math\VertexContainer.h file.

**Note**

The VertexContainer can store Vector2 or Vector3 types. The vector type is determined at compile time when the type is created. This is useful for certain components that do not allow points to be modified on the Z (vertical) axis and treat points just in two dimensions. The Polygon Prism component uses the Vector2 type.

EBus Request Bus Interface Example

The following is an example of a Lua script that uses the RequestBus interface.

```lua
local firstVertex = <type_with_vertex_container>.vertexContainer[1];
local lastVertex = <type_with_vertex_container>.vertexContainer[spline.vertexContainer:size()];

...RequestBus.Event.AddVertex(self.entityId, lastVertex + Vector3(1, 2, 3));
...RequestBus.Event.UpdateVertex(self.entityId, 0, firstVertex + Vector3(1, 2, 3));
...RequestBus.Event.InsertVertex(self.entityId, spline.vertexContainer:size() - 1, lastVertex + Vector3(1, 2, 3));
...RequestBus.Event.ClearVertices(self.entityId);
...RequestBus.Event.RemoveVertex(self.entityId, spline.vertexContainer:size() - 1);
```
Video Playback

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Video Playback component to play a video on an entity in your Lumberyard level. For example, you can use a flat or plane entity to simulate a movie screen. You add the video playback component to the entity and specify a video file to display.

You can also play a video on a level loading screen. For more information, see Defining Game and Level Load Screens (p. 2910).

You can use Script Canvas or Lua scripting to trigger the video to play, pause, or stop, depending on player actions.

Prerequisites

To use the Video Playback component, you must do the following:

- Install either FFmpeg or LibAV.
- Enable the Video Playback gem for your game project. See Enabling Gems (p. 1064).
- Rebuild your game project.

**Important**

Two additional steps are required to use FFmpeg in the current Lumberyard release.

1. In the file, \dev\Gems\VideoPlayback\Code\Source\decoder.h, at line 32, insert the following preprocessor directive.

   ```
   #pragma warning(disable : 4996)
   ```

   This preprocessor directive will disable compilation warnings associated with FFmpeg, which would otherwise be treated as errors.

2. Once your project is compiled, you will need to manually copy the .dll files from \3rdParty\FFmpeg\3.2\bin\ to the build output folder \dev\Bin64\vc141_or_vc142

You can also set your video to play in visual stereo (not audio stereo). To test this feature, you must use a virtual reality head mounted display (HMD).

**Note**

Audio isn't currently supported with the Video Playback component, but you can trigger audio playback separately if you want to play audio with your video.

Topics
Setting Up Video Playback

To set up video playback in Lumberyard, you must install either FFmpeg or LibAV.

- If both are installed, Lumberyard uses FFmpeg.
- To use LibAV, remove FFmpeg and see Installing LibAV (p. 907).

**Note**
Certain third-party software might require a license. Consult the terms of service before installing the software.

Installing FFmpeg

To install FFmpeg for Lumberyard, follow these steps.

**To install FFmpeg**

1. Locate a Windows build from the download page on FFmpeg.
2. Download a developer build (sometimes referred to as a "shared" build) that contains bin, include, and lib directories. Unzip the files.
3. Navigate to lumberyard_version/3rdParty and create a directory named FFmpeg.
4. In FFmpeg, create a directory named 3.2.
   **Note**
   You must name the directory 3.2, regardless of the FFmpeg version that you're using.
5. Copy the bin, include, and lib folders to the lumberyard_version/3rdParty/FFmpeg/3.2 directory.
6. Run Lumberyard Setup Assistant and, on the Install optional SDKs page, verify that Lumberyard detects FFmpeg.

Installing LibAV

To install LibAV for Lumberyard, follow these steps.

**To install LibAV**

2. Select the release-lgpl build and download the latest x86_64 version of LibAV. As of this writing, version 11.7.7 is the latest build.
3. Navigate to lumberyard_version/3rdParty and create a directory named libav.
4. In the libav directory, create a directory named 11.7.

   **Note**
   You must name the directory 11.7, regardless of the LibAV version that you’re using.

5. Extract the .7z file to the 11.7 directory.

   **Note**
   To open and extract .7z files, you must use a 7z application, such as 7-Zip.

In the 11.7 directory, you should have the following:

- A directory named usr
- config.log
- md5sum

6. Run Lumberyard Setup Assistant and, on the **Install optional SDKs** page, verify that Lumberyard detects LibAV.

---

### Using the Video Playback Component

After you complete the **Prerequisites (p. 906)**, you can use the **Video Playback** component.

Video playback supports the following container formats:

- .mp4
- .mkv (recommended)
- .webm (recommended)

Video playback supports the following codecs:

- .h264
- .h265
- VP8 (recommended)
- VP9 (recommended)

The basic setup for the **Video Playback** component includes the following:

- Add a **Camera** component
- Add a **Mesh** and **Video Playback** component
- Configure your material

**To use the Video Playback component**

1. If you don’t yet have a camera in your scene, place a **Camera (p. 566)** component where your video playback is to be placed.
You can use the camera to view your video playback. Ensure that the camera is facing the direction where you place your video playback component.

2. Create an entity. For more information, see Creating an Entity (p. 463).

3. Use the Entity Inspector (p. 475) to add a Mesh (p. 684) component to your entity.

4. For the Mesh component, select a Mesh asset. This is the asset that your video renders on. A cube or plane is a good test mesh.

![Mesh component settings](image)

5. Add the Video Playback component to the same entity.

6. In the Video Playback component, for Video, select the video to display.

7. For Texture name, enter dollar sign ($) and a name for your texture. You can enter any name, but it must begin with a $ character to indicate that it's a render target. For example, $videotest is a valid name, but videotest isn't.

![Video Playback component settings](image)

8. For Frame queue ahead count, set the number of frames to buffer.

   We recommend that you use a value from 1 to 3.

   Queueing too many frames to buffer (for example, a value of 100 frames) can use too much memory and cause performance issues.

9. Open the Material Editor (p. 1636).

10. To create a material, click the Add New Item icon. Enter a descriptive name, such as myvideomaterial.
11. Under **Texture Maps**, on the **Diffuse** line, enter the name of your video component’s **Texture name** field. You must include the $ character.
12. Close the **Material Editor** and return to the **Entity Inspector (p. 475)**. In the **Mesh** component, for the **Material override** property, select the material that you created.

![Material Editor Screenshot](image)

You can trigger the video to play at the start of your game using Lua scripting.

**Setting Up Stereo Video Playback**

Before setting up stereo video playback, ensure that you have completed the setup instructions in **Setting Up Video Playback (p. 907)**.

Stereo video playback means that the video presents a slightly different image for each eye, creating a 3D feel. Stereo in this case refers to visual stereo only; audio is not supported in the video playback component. While audio is not supported and must be synced externally, it is possible to play back spatialized audio. To do so, you must use the full, commercial version of Wwise and a 3D spatializer plugin such as Oculus Spatializer or RealSpace 3D.

To set up stereo video playback, your source video file must be laid out for stereo. Lumberyard supports videos in a top-bottom or bottom-top layout. You must have a VR headset to verify that the video is playing in stereo.

To set up stereo video playback, follow the instructions in **Using the Video Playback Component (p. 908)**. The only differences in the setup are the following:

- You must use a source video file with 3D or stereo information
- Set the **Stereo Layout** property initially to **Auto-Detect**. If it fails to auto-detect, manually set it to **Top-Bottom** or **Bottom-Top**.

All supported video files should have their stereo layout written into their metadata. This, however, is not a requirement and may not have been inserted by your encoder. If you would like to inject stereo metadata into your video, see [https://support.google.com/jump/answer/7044297?hl=en](https://support.google.com/jump/answer/7044297?hl=en).

![Video Playback Screenshot](image)

When you enter game mode (using **Ctrl G**), you should see the left eye of your video play. If you do not see this, try changing your **Stereo layout** setting.

To verify that your video is playing in stereo, you must enter VR mode. You can enter VR mode by clicking **VR Preview** at the bottom right corner of the viewport. Then press **Ctrl G** to enter game mode.
If your **VR Preview** button isn’t enabled, or you can’t get into VR preview mode, ensure that your VR headset is working outside of Lumberyard and then restart the Lumberyard editor.

Playing stereo video is resource intensive. Because the video is often close in proximity to the player, it becomes easy to detect inconsistencies and artifacts in the video. To prevent that, use higher resolution videos whenever possible. To conserve resources, do not play more than one or two high resolution stereo videos at a time.

**Lua Bindings for Video Playback**

You can use Lua bindings to interact programmatically with video playback components that you’ve placed in your scene. Lua provides a way to establish complex logic for playing, pausing, and stopping videos.

**Global Functions**

The following functions provide programming interfaces for the video playback systems.

**VideoPlaybackRequestBusSender**

**Parameters**

- **EntityID**

**Return**

Returns the `VideoPlaybackRequestBusSender` object that is connected to the specified entity. For more information, see `VideoPlaybackRequestBusSender Object (p. 912)`.

**VideoPlaybackNotificationBusHandler**

Exposes callbacks to your Lua script that are triggered by events during video playback.

For more information, see `VideoPlaybackNotificationBusHandler Object (p. 913)`.

**Parameters**

- **Table** – The Lua table to which you want to expose the callback functions. Pass `self` to expose the callbacks to the current Lua script.

- **EntityId** –

**Return**

Returns the `VideoPlaybackRequestBusSender` object that is connected to the specified entity. For more information, see `VideoPlaybackRequestBusSender Object (p. 912)`.

**VideoPlaybackRequestBusSender Object**

The `VideoPlaybackRequestBusSender` object contains functions with which you can send requests to the video playback component.

**Bool IsPlaying()**

Returns `true` if the video is playing. If the video is paused or stopped, returns `false`.

**Void Play()**

Plays the video. If no video is selected or the video is already playing, this has no effect.

**Void Pause()**

Pauses the video. If the video is already paused, this has no effect.
Void Stop()

Stops the video and remains on the last frame. When the video plays again, it begins at the first frame of the video. If the video is already stopped, this has no effect. If the video is playing or paused, the video stops.

Void EnableLooping(Bool)

Sets whether this video automatically restarts from the beginning once the end of the video is reached. Pass true to enable looping or false to disable looping. Looping is disabled by default.

Void SetPlaybackSpeed(Float)

Sets how fast the video plays. For example, 1.0 is normal speed, 0.5 is half speed, 2.0 is double speed, and so on.

Caution is advised when setting the video speed. Setting a speed that is too high can result in choppy playback.

VideoPlaybackNotificationBusHandler Object

The VideoPlaybackNotificationBusHandler object exposes callback functions to your Lua script that are triggered by events that happen during video playback.

Void OnPlaybackStarted()

Called when video playback begins.

Void OnPlaybackPaused()

Called when video playback pauses. Not called when video stops.

Void OnPlaybackStopped()

Called when video playback is stopped by the user. If the video reaches the end and is not set to loop, this function is not called.

Void OnPlaybackFinished()

Called when all frames in the video are played. This is not called if the user manually stops video playback. If looping is enabled, this function is called every time the video loops.

Video Playback Bink

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Video Playback Bink component to play a video on an entity in your Lumberyard level. For example, you can use a flat or plane entity to simulate a movie screen. You add the video playback component to the entity and specify a Bink video file to display.

You can also play a video on a level loading screen. For more information, see Defining Game and Level Load Screens (p. 2910).

You can use Script Canvas or Lua scripting to trigger the video to play, pause, or stop, depending on player actions.

Prerequisites

To use the Video Playback Bink component, you must do the following:
- Obtain a Bink license. Contact RAD Game Tools for information on how to license Bink.
- Install the **Video Playback Bink** gem and the Bink libraries into the gem.

**Note**
A Bink license is needed to gain access to this gem. Installation instructions are provided with the gem.

- Enable the **Video Playback Bink** gem for your game project. See Enabling Gems (p. 1064).
- Rebuild your game project.

**Topics**
- Using the Video Playback Bink Component (p. 914)
- Lua Bindings for Video Playback Bink (p. 917)

**Using the Video Playback Bink Component**

After you complete the Prerequisites (p. 913), you can use the **Video Playback Bink** component.

Video playback supports the `.bk2` format and the Bink codec.

The basic setup for the **Video Playback Bink** component includes the following:

- Add a **Camera** component
- Add a **Mesh** and **Video Playback Bink** component
- Configure your material

**To use the Video Playback Bink component**

1. If you don't yet have a camera in your scene, place a **Camera** (p. 566) component where your video playback is to be placed.
   
   You can use the camera to view your video playback. Ensure that the camera is facing the direction where you place your video playback component.

2. Create an entity. For more information, see Creating an Entity (p. 463).

3. Use the **Entity Inspector** (p. 475) to add a **Mesh** (p. 684) component to your entity.

4. For the **Mesh** component, select a **Mesh asset**. This is the asset that your video renders on. A cube or plane is a good test mesh.

5. Add the **Video Playback Bink** component to the same entity.
6. In the **Video Playback Bink** component, for **Video**, select the video to display.

7. For **Texture name**, enter dollar sign ($) and a name for your texture. You can enter any name, but it must begin with a $ character to indicate that it’s a render target. For example, $videotest is a valid name, but videotest isn’t.

![Video Playback Bink](image)

8. For **Frame queue ahead count**, set the number of frames to buffer.

   We recommend that you use a value from 1 to 3.

   Queueing too many frames to buffer (for example, a value of 100 frames) can use too much memory and cause performance issues.

9. Open the **Material Editor (p. 1636)**.

10. To create a material, click the **Add New Item** icon. Enter a descriptive name, such as **myvideomaterial**.

![Material Editor](image)

11. Under **Texture Maps**, on the **Diffuse** line, enter the name of your video component’s **Texture name** field. You must include the $ character.
12. Close the **Material Editor** and return to the **Entity Inspector** (p. 475). In the **Mesh** component, for the **Material override** property, select the material that you created.

You can trigger the video to play at the start of your game using Lua scripting.
Lua Bindings for Video Playback Bink

You can use Lua bindings to interact programmatically with video playback components that you've placed in your scene. Lua provides a way to establish complex logic for playing, pausing, and stopping videos.

Global Functions

The following functions provide programming interfaces for the video playback systems.

**VideoPlaybackRequestBusSender**

**Parameters**

- **EntityID**

**Return**

Returns the VideoPlaybackRequestBusSender object that is connected to the specified entity. For more information, see VideoPlaybackRequestBusSender Object (p. 917).

**VideoPlaybackNotificationBusHandler**

Exposes callbacks to your Lua script that are triggered by events during video playback.

For more information, see VideoPlaybackNotificationBusHandler Object (p. 918).

**Parameters**

- **Table** – The Lua table to which you want to expose the callback functions. Pass self to expose the callbacks to the current Lua script.

  **EntityId** –

**Return**

Returns the VideoPlaybackRequestBusSender object that is connected to the specified entity. For more information, see VideoPlaybackRequestBusSender Object (p. 917).

**VideoPlaybackRequestBusSender Object**

The VideoPlaybackRequestBusSender object contains functions with which you can send requests to the video playback component.

**Bool IsPlaying()**

Returns true if the video is playing. If the video is paused or stopped, returns false.

**Void Play()**

Plays the video. If no video is selected or the video is already playing, this has no effect.

**Void Pause()**

Pauses the video. If the video is already paused, this has no effect.

**Void Stop()**

Stops the video and remains on the last frame. When the video plays again, it begins at the first frame of the video. If the video is already stopped, this has no effect. If the video is playing or paused, the video stops.
Void EnableLooping(Bool)

Sets whether this video automatically restarts from the beginning once the end of the video is reached. Pass true to enable looping or false to disable looping. Looping is disabled by default.

Void SetPlaybackSpeed(Float)

Sets how fast the video plays. For example, 1.0 is normal speed, 0.5 is half speed, 2.0 is double speed, and so on.

Caution is advised when setting the video speed. Setting a speed that is too high can result in choppy playback.

VideoPlaybackNotificationBusHandler Object

The VideoPlaybackNotificationBusHandler object exposes callback functions to your Lua script that are triggered by events that happen during video playback.

Void OnPlaybackStarted()

Called when video playback begins.

Void OnPlaybackPaused()

Called when video playback pauses. Not called when video stops.

Void OnPlaybackStopped()

Called when video playback is stopped by the user. If the video reaches the end and is not set to loop, this function is not called.

Void OnPlaybackFinished()

Called when all frames in the video are played. This is not called if the user manually stops video playback. If looping is enabled, this function is called every time the video loops.

VisArea

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A vis area (visible area) is a shape object that helps you manage visibility and culling in a scene. When a camera is in a visible area, the camera can see only other objects that are also in the visible area. You can use the VisArea component to define indoor areas and manage overdraw. Objects are inside a visible area only if their center is inside the area.

You can also add a Portal (p. 717) component to an entity to create windows between visible areas. This helps you create beautiful areas that render efficiently.

Visible areas are only dynamic during editing. If you modify the VisArea component or move the entity that the VisArea component is attached to at runtime, the area that the VisArea component defines isn't affected. Also, the VisArea component doesn't work if it's spawned as part of a dynamic slice.
For more information, see Working with the Event Bus (EBus) system (p. 1851).

**Note**
You can't modify the OccluderArea (p. 701), Portal (p. 717), and VisArea (p. 918) components at runtime.

**Topics**
- VisArea Component Properties (p. 919)
- Vis Area Component Examples (p. 919)

### VisArea Component Properties

The VisArea component has the following properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Height</td>
<td>The height of the visible area.</td>
</tr>
<tr>
<td>DisplayFilled</td>
<td>Displays the visible area as a filled volume in the Lumberyard Editor viewport.</td>
</tr>
<tr>
<td>AffectedBySun</td>
<td>Objects in the visible area are affected by the sun.</td>
</tr>
<tr>
<td>ViewDistRatio</td>
<td>A multiplier on the view distance of the visible area during editing.</td>
</tr>
<tr>
<td>OceanIsVisible</td>
<td>Renders the ocean outside the visible area.</td>
</tr>
<tr>
<td>Edit</td>
<td>Choose Edit, and the component is locked for editing. For more information, see Editing Components in the Viewport (p. 483).</td>
</tr>
</tbody>
</table>

### Vis Area Component Examples

**Example 1**

The following example shows two boxes. One box is inside the visible area, and one is outside. From outside the visible area, the inside box isn't visible. The DisplayFilled option is enabled so that the visible area appears orange.

You can see the shadow of the box inside the visible area because the AffectedBySun option is enabled.
Example 2

In the same example, the `DisplayFilled` option is disabled in the visible area.
Example 3

In the following example, you can see the box inside the visible area, but you can't see the box outside the visible area.

You can see the ocean inside the visible area because the **OceansVisible** option is enabled.
Example: Non-Planar Legacy Vertices

If you're familiar with the legacy visible areas, you might be used to seeing the legacy visualization. In the legacy system, if you raise one vertex of the visible area higher than the other vertices, the legacy visualization displays the visible area incorrectly.

The following example is the legacy visualization for a visible area. One vertex appears higher than the others.
Example: Planar Vertices with VisArea Component

The following is an example of the VisArea component with the same vertices.
The second example is correct because the visible area is the volume on the xy-plane with a z-position and a height. This makes it faster to determine whether an object is inside the VisArea component.

The position on the z-axis is the position of the lowest point. The height is the specified height plus the difference in height between the highest and lowest point. This remains true even after transformations. If you rotate a visible area on the x- or y-axis, you might see volumes that don't make sense. All points after a transformation are projected onto the xy-plane.

When legacy visible areas are converted, Lumberyard corrects this behavior for you. All points are made planar, and any difference in height between points applies to the visible area's height.

**VR Preview**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The **VR Preview** component, when added to an entity or spawned from a slice, creates a user-editable navigation mesh (p. 686). The navigation mesh is used to define valid areas that users can teleport to. The **VR Preview** component sets up necessary dependencies for exploring or navigating a scene in virtual reality. This component contains no editable properties.

**To use the VR Preview component**

1. Create a new entity (p. 463).
2. Open the **Entity Inspector** (p. 475). Add the **VR Preview** component to the entity by clicking **Add Component, VR, VR Preview**.
   
   A navigation mesh of 50x50x50 size is generated around the entity.
3. Save the entity to a slice (p. 519).
   
   Now you can drag the saved slice to another part of the level, and the navigation mesh will be generated around the entity.

The navigation mesh that is generated is a separate entity from the original entity. Lumberyard names the new nav mesh entity by appending `_NavMesh` to the original entity name.

If you delete the original entity, the nav mesh entity continues to exist. However, if you delete the nav mesh entity, it won't be generated again.

**Water Volume**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the **Water Volume** component to add small and medium bodies of water to your level. Use the following properties to adjust the water volume's physical attributes, aesthetic, and complex interactions.

To use the **Water Volume** component, you must enable the Water gem for your game project and then rebuild the project. For more information, see **Enabling Gems** (p. 1064).

**Topics**

- **Water Volume Component Properties** (p. 925)
- **EBus Request Bus Interface** (p. 929)
- **Setting up Volume to Spill** (p. 943)
- **Setting up Wave Simulation** (p. 945)

**Water Volume Component Properties**

The **Water Volume** component has the following properties:

**Material**

- Specifies the water material to use. The material must have the **Water** shader added.
Minimum Spec

Sets the minimum engine specification for the volume to render.

Default: Low

Surface U Scale

Specifies how much to tile the water surface texture on the u-axis.

Default: 1.0

Range: 0.0 to # (infinity)

Surface V Scale

Specifies how much to tile the water surface texture on the v-axis.

Default: 1.0

Range: 0.0 to #

View Distance Multiplier

Adjusts the maximum view distance. The default value is 1.0. To specify a maximum view distance that is 10% further than the default, use 1.1.

Default: 1.0

Range: 0.0 to #

Fog

Density

Sets the density of the water fog.

Default: 0.5

Range: 0.0 to #

Color

Sets the color of the water fog.

Default: Deep blue (RGB 0.005, 0.01, 0.02)

Color Multiplier

Multiplies this value by the Color parameter to produce the final fog color.

Default: 1.0

Range: 0.0 to #

Color Affected by Sun

Determines whether the sky color affects the water's fog color. This property is useful for outdoor water volumes.

Default: True

Shadowing

Specifies how much shadows affect the water's fog color.

Default: 0.5
Cap at Volume Depth

Determined whether fog is rendered when the player is under the volume.

Default: False

Caustics

Enabled

Enables water caustics.

Default: True

Intensity

Affects the brightness and visibility of caustics.

Default: 1.0

Range: 0.0 to #

Tiling

Affects the number of caustics that are rendered.

Default: 1.0

Range: 0.0 to #

Height

Determines how far above the surface caustics are rendered.

Default: 0.5

Range: 0.0 to #

Advanced

Spillable Volume

Specifies the volume quantity that can spill into a container below.

Default: 0.0

Range: 0.0 to #

Volume Accuracy

Specifies the accuracy of the surface level of the spilled volume.

Default: 0.001

Range: 0.0 to #

Extrude Border

Specifies the border amount to add to the spilled volume.

Default: 0.0

Range: 0.0 to #
**Convex Border**

Determines whether the convex hull of the container should be considered.

Default: false

**Object Size Limit**

Sets the minimum volume that an object must have to affect the water surface.

Default: 0.001

Range: 0.0 to #

**Wave Simulation**

**Surface Cell Size**

Specifies the size of wave simulation cells.

Default: 0.0

Range: 0.0 to #

**Speed**

Specifies how fast each wave moves.

Default: 100.0

Range: 0.0 to #

**Dampening**

Specifies how much dampening force to apply during simulation.

Default: 0.2

Range: 0.0 to #

**Timestep**

Specifies the frequency of wave simulation ticks.

Default: 0.02

Range: 0.0 to #

**Sleep Threshold**

Sets the lowest velocity for a cell to rest.

Default: 0.01

Range: 0.0 to #

**Depth Cell Size**

Specifies the size of the depth cell.

Default: 8.0

Range: 0.0 to #

**Height Limit**

Sets the highest and lowest heights that the surface can be deformed.
Water Volume

Default: 7.0
Range: 0.0 to #

**Force**

Specifies the strength of the wave force.

Default: 10.0
Range: 0.0 to #

**Simulation Area Growth**

Adds space if the water simulation causes expansion.

Default: 0.0f
Range: 0.0 to #

**EBus Request Bus Interface**

Use the following request functions with the EBus interface to communicate with other components of your game. You can use this EBus to communicate to an entity with a **Water Volume** component attached. The EBus is available at game time and editing and can be accessed from C++, Lua, and the [Script Canvas](#) editor.

For more information about using the event bus (EBus) interface, see [Working with the Event Bus (EBus) system](#) (p. 1851).

**SetSurfaceUScale**

Sets how much to tile the surface texture horizontally (u-axis of the UV map). The surface texture is often defined as a bump or normal map.

**Parameters**

Type: Float

**Return**

None

**Scriptable**

Yes

**GetSurfaceUScale**

Returns how much to tile the surface texture horizontally (u-axis of the UV map).

**Parameters**

None

**Return**

Type: Float

**Scriptable**

Yes
**SetSurfaceVScale**

Sets how much to tile the surface texture vertically (v-axis of the UV map). The surface texture is often defined as a bump or normal map.

**Parameters**
- Type: Float

**Return**
- None

**Scriptable**
- Yes

**GetSurfaceVScale**

Returns how much to tile the surface texture vertically.

**Parameters**
- None

**Return**
- Type: Float

**Scriptable**
- Yes

**SetFogDensity**

Sets the density of the underwater fog in the volume. A lower value produces clearer water, and a higher value produces murkier water.

**Parameters**
- Type: Float

**Return**
- None

**Scriptable**
- Yes

**GetFogDensity**

Returns the fog density in the water volume.

**Parameters**
- None

**Return**
- Type: Float
Scriptable
Yes

SetFogColor
Sets the color of the underwater fog in the volume. The FogColorMultiplier parameter modifies the fog color before rendering.

Parameters
AZ::Color
Return
None
Scriptable
Yes

GetFogColor
Returns the color of the underwater fog in the volume. The FogColorMultiplier parameter does not affect the returned value.

Parameters
None
Return
AZ::Color
Scriptable
Yes

SetFogColorMultiplier
Sets the value to multiply with the FogColor parameter before rendering. A higher value produces brighter underwater fog.

Parameters
Type: Float
Return
None
Scriptable
Yes

GetFogColorMultiplier
Returns the value to multiply with the FogColor parameter before rendering.

Parameters
None
Return
Type: float
Scriptable
Yes

SetFogColorAffectedBySun
Sets whether the sun affects the underwater fog in the volume. If true, the SunColor value affects the fog color. You can set the SunColor in the Time of Day Editor. For outdoor water volumes, use true. For indoor water volumes, use false.

Parameters
Type: Boolean
Return
None
Scriptable
Yes

GetFogColorAffectedBySun
Returns whether the sun affects the underwater fog in the volume.

Parameters
None
Return
Type: Boolean
Scriptable
Yes

SetFogShadowing
Sets the strength of the shadows that fall on the water volume. If 0.0, shadows have no effect on the water volume. If 1.0, a dark shadow falls on the water volume. You must set r_FogShadowsWater to 1 for the parameter to have any effect.

Parameters
Type: Float
Return
None
Scriptable
Yes
Valid values
0.0 to 1.0
GetFogShadowing

Returns the strength of the shadows that fall on the water volume. Valid values are 0.0 to 1.0. However, this property returns the value for the FogShadowing parameter, regardless of the valid range.

Parameters

None

Return

Type: Float

Scriptable

Yes

SetCapFogAtVolumeDepth

Sets whether the underwater fog effect caps at the volume depth. If false, underwater fog renders despite the distance of the camera below the water volume.

Parameters

Type: Boolean

Return

None

Scriptable

Yes

GetCapFogAtVolumeDepth

Returns whether the underwater fog effect caps at the volume depth.

Parameters

None

Return

Type: Boolean

Scriptable

Yes

SetCausticsEnabled

Sets whether the water volume produces caustics. You must set r_WaterVolumeCaustics to 1 for the water caustic settings to have any effect. To display caustics, set the water volume to a world height of 1 or higher.

Parameters

Type: Boolean

Return

None
Scriptable
Yes

GetCausticsEnabled
Returns whether the water volume produces caustics.

Parameters
None

Return
Type: Boolean

Scriptable
Yes

SetCausticIntensity
Sets the intensity of the caustics for the water volume. This property scales the normal map when rendering to the caustic map to produce a stronger caustic effect.

Parameters
Type: Float

Return
None

Scriptable
Yes

GetCausticIntensity
Returns the intensity of the caustics for the water volume.

Parameters
None

Return
Type: Float

Scriptable
Yes

SetCausticTiling
Sets a multiplier to use for tiling the water volume's caustics. This value is multiplied with the tiling that's applied to the surface normals. You can then scale the caustic tiling separately from the material.

Parameters
Type: Float
Return

None

Scriptable

Yes

**GetCausticTiling**

Returns the value that is multiplied to the surface's normal tiling during caustic generation.

**Parameters**

None

**Return**

Type: Float

Scriptable

Yes

**SetCausticHeight**

Sets the allowable height to cast caustics above the water's surface. If 0.0, caustics render only beneath the water's surface. If you use a value greater than 0, caustics can cast on nearby surfaces that are not in the water volume.

**Parameters**

Type: Float

**Return**

None

Scriptable

Yes

**GetCausticHeight**

Returns the allowable height to cast caustics above the water's surface.

**Parameters**

None

**Return**

Type: Float

Scriptable

Yes

**SetSpillableVolume**

Sets how much volume can spill. Volumes can spill into a container but cannot spill onto terrain. A higher value allows more of the container volume to fill with water. If greater than 0, the water volume raycasts...
onto nearby geometry and attempts to spill into it. The geometry must have a concave mesh on a mesh component.

Parameters
Type: Float

Return
None

Scriptable
Yes

GetSpillableVolume
Returns how much volume can spill.

Parameters
None

Return
Type: Float

Scriptable
Yes

SetVolumeAccuracy
Sets the accuracy of the water level for the spilled water volume. The water level for spilled volume is iteratively calculated until the value is within the distance to the water level expected by the water volume. A higher value requires more iterations to calculate the water level. If 0.0, the water level iterations will reach a hard-coded limit of 100 iterations.

Parameters
Type: Float

Return
None

Scriptable
Yes

GetVolumeAccuracy
Returns the accuracy of the water level for the spilled water volume.

Parameters
None

Return
Type: Float
SetExtrudeBorder

Sets how much to increase the border of the water volume when spilled. If 0, wave simulation may cause the open edges of a water volume's surface to be visible. This is useful for wave simulation.

Parameters
   Type: Float

Return
   None

Scriptable
   Yes

GetExtrudeBorder

Returns how much to increase the border of the water volume when spilled.

Parameters
   None

Return
   Type: Float

Scriptable
   Yes

SetConvexBorder

Sets whether the water volume should look for a convex border when spilling. This is useful if the volume spills into a container that has multiple contours. Because water volumes don't support multiple contours, this property uses logic to break the volume into multiple volumes that can fit the contoured container.

Parameters
   Type: Boolean

Return
   None

Scriptable
   Yes

GetConvexBorder

Sets whether the water volume should look for a convex border when spilling.
Parameters

None

Return

Type: Boolean

Scriptable

Yes

SetObjectSizeLimit

Sets the minimum volume that is required for an object to experience volume displacement. Objects that have a volume that is smaller than this value will not deform the surface.

Parameters

Type: Float

Return

None

Scriptable

Yes

GetObjectSizeLimit

Returns the minimum volume that is required for an object to experience volume displacement.

Parameters

None

Return

Type: Float

Scriptable

Yes

SetWaveSurfaceCellSize

Sets the size of each wave simulation cell. The number of wave simulation cells is determined by the size of the volume and the individual size of the cells. This affects the water surface mesh.

- A large water volume with a small cell size produces a high number of cells and a large, complicated surface mesh. This type of mesh can make it difficult to evaluate wave simulation, unless you tune other parameters.
- A small water volume with a large cell size produces a low number of cells and a small, simple surface mesh.

Use the p_draw_helpers a_g console variable to see the tessellated surface mesh. You may need to move the editor's viewport camera closer to the volume for the mesh to render.

Parameters

Type: Float
Return
None
Scriptable
Yes

GetWaveSurfaceCellSize
Returns the size of each wave simulation cell.

Parameters
None
Return
Type: Float
Scriptable
Yes

SetWaveSpeed
Sets how fast the waves move.

Parameters
Type: Float
Return
None
Scriptable
Yes

GetWaveSpeed
Returns how fast the waves move.

Parameters
None
Return
Type: Float
Scriptable
Yes

SetWaveDampening
Sets how much to dampen the wave simulation. A higher value produces waves that lose velocity more quickly.
GetWaveDampening

Returns how much to dampen the wave simulation.

Parameters

None

Return

Type: Float

Scriptable

Yes

SetWaveTimestep

Sets how often the wave simulation ticks. A lower value produces frequent simulation ticks, which resolves a simulation quickly.

Parameters

Type: Float

Return

None

Scriptable

Yes

GetWaveTimestep

Returns how often the wave simulation ticks.

Parameters

None

Return

Type: Float

Scriptable

Yes
SetWaveSleepThreshold

Sets the minimum velocity that is required for a cell to sleep. A cell is at rest and no longer applies force to its neighbors when the velocity reaches this threshold.

Parameters

  Type: Float

Return

  None

Scriptable

  Yes

GetWaveSleepThreshold

Returns the minimum velocity that is required for a cell to sleep.

Parameters

  None

Return

  Type: Float

Scriptable

  Yes

SetWaveDepthCellSize

Sets the size of each depth cell in a wave simulation. The number of wave simulation cells is determined by the size of the volume and the individual size of the cells. A smaller cell size produces more depth cells and an intensive wave simulation.

Parameters

  Type: Float

Return

  None

Scriptable

  Yes

GetWaveDepthCellSize

Returns the size of each depth cell in a wave simulation.

Parameters

  None

Return

  Type: Float
SetWaveHeightLimit

Sets the height and depth limit for generated waves. A height limit of 3 means the cell deforms up three units and down three units.

Parameters

Type: Float

Return

None

Scriptable

Yes

GetWaveHeightLimit

Returns the height and depth limit for generated waves.

Parameters

None

Return

Type: Float

Scriptable

Yes

SetWaveForce

Sets the amount of force that wave simulation cells apply to each other. A low wave force produces high resistance between cells. A high wave force produces less resistance and transmits more energy between cells. More transmitted energy results in larger, more pronounced waves.

Parameters

Type: Float

Return

None

Scriptable

Yes

GetWaveForce

Returns the amount of force that wave simulation cells apply to one another.

Parameters

None
Return
Type: Float
Scriptable
Yes

SetWaveSimulationAreaGrowth
Sets the size boundary to add to a simulation area. This determines where the water volume simulation can move and grow outside the initial defined area. Increase the variable to add the size boundary to the simulation area. The p_draw_helpers_a_gj console variable draws the wave simulation area as a checkerboard height field.

Parameters
None
Return
None
Scriptable
Yes

GetWaveSimulationAreaGrowth
Returns the size boundary to add to a simulation area.

Parameters
None
Return
None
Scriptable
Yes

Example Water Volume Component Request Bus

```lua
function example:OnActivate
    local waveForce = WaterVolumeComponentRequestBus.Event.GetWaveForce(self.entityId)
    WaterVolumeComponentRequestBus.Event.SetWaveForce(self.entityId, waveForce * 10)
end
```

Setting up Volume to Spill

You can set water volumes to spill into container volumes. If the Spillable Volume parameter is a value above 0, the volume raycasts down and searches for a suitable container to spill into. This includes any mesh component with a concavity. A higher value for the Spillable Volume parameter produces a higher water level in the target container.

The spilled water volume behaves similarly to the source water volume and can simulate waves. The spilled volume is calculated iteratively, and the Volume Accuracy parameter determines the accuracy of
the water level. Spilled water volumes are calculated once and should not incur a per-frame performance penalty due to volume calculation.

The following image shows water volume above a pool that does not allow spilling.

The following image shows the water volume spilling 100 units into the pool.

The following image shows the water volume spilling 1000 units into the pool.
Setting up Wave Simulation

You can use wave simulation to create the appearance of the water surface reacting to physical forces. This feature does not simulate ocean waves. Because wave simulation is an expensive task, consider the performance impact before you enable this feature.

To enable wave simulation on a water volume, set the **Surface Cell Size** parameter to a value above 0. For smaller water volumes, you can use a value of 2 or 3. A smaller cell size produces more cells and a longer evaluation time for the simulation.

Even without wave simulation the **Water** shader deforms the surface mesh to make the water appear in motion.

**Example**

The following is an example **Water Volume** component.
White Box component

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The White Box component is a tool you can use to sketch 3D proxy meshes in Lumberyard Editor. Add the White Box component to an entity, select a primitive shape to use as a basis for your proxy mesh, then enter edit mode to access the tools to quickly rough out a mesh for your entity.

Because White Box is implemented as a component, you can create well-defined entities that accurately represent the size, shape, and function of the final production entity in Lumberyard Editor before investing the time and effort into building finished models for your entity. Meshes created with White Box can be saved to disk as white box mesh assets (.wbm) and reused in other White Box components. White box meshes can also be exported to .obj files and used as a template in a third-party 3D modeling application to build final production assets.

Topics
- White Box properties (p. 947)
- White Box edit mode (p. 948)
White Box properties

![White Box properties](image)

**Default Shape**

The default primitive shape of the white box mesh. From the list you can select a primitive shape, or choose to load a saved white box mesh (.wbm) asset. The default primitive size is one meter in world space.

**White Box default shapes:**

- Cube
- Tetrahedron
- Icosahedron
- Cylinder
- Sphere
- Custom Mesh Asset

**Note**

When Custom Mesh Asset is selected, a Mesh Asset file field appears in the component interface below Default Shape that you can use to select a saved white box mesh (.wbm) asset.

**Save as asset**

Save the proxy mesh to a white box mesh (.wbm) asset. You can load the saved (.wbm) asset in other White Box components. The .wbm file functions like an instance, and any changes made to the mesh propagate to all White Box components that use the .wbm file.
Tint

Set a tint color for the white box mesh. Choose the swatch to open a color picker, or enter comma separated red, blue, and green 8-bit values into the field to set a tint color for the **White Box** component.

Use Texture

Enable **Use Texture** to display a checkerboard texture on the white box mesh. Each square is a half meter in size, and the texture is projected on the local X, Y, and Z axes of the mesh. This maintains an easy reference for the size of the proxy mesh, regardless of how the entity is oriented in the level.

Visible

Enable **Visible** to make the white box mesh visible at runtime. When you use White Box to create custom invisible collision meshes, disable the **Visible** property to hide the mesh at runtime.

Edit

Choose this button to enter edit mode and modify the white box mesh. For information on editing the white box mesh, see **White Box edit mode** (p. 948). Choose this same button (labeled **Done**) to exit edit mode.

Export

Export the mesh to a .obj file. The .obj file can be loaded into a 3D modeling application and used as a template for creating the production mesh asset for the entity.

**White Box edit mode**

In edit mode, you can quickly sketch meshes for your entities in Lumberyard Editor by selecting and dragging the face, edge, and vertex components of the white box mesh. To begin, add a **White Box**
component to an entity, choose a default primitive shape in the White Box component interface, and choose Edit to enter edit mode.

**Move**

**Move polygon**

1. Hover over a polygon.
2. Hold the left mouse button.
3. Drag the polygon along its normal.

**Move edge**

1. Hover over an edge.
2. Hold the left mouse button.
3. Drag the edge.
Move vertex

1. Hover over a vertex. The vertex will highlight.
2. Hold the left mouse button.
3. Drag the vertex along the edge guides.
Scale

Scale polygon

1. Select (left click) a polygon.
2. Hover over one of the polygon's vertices.
3. Hold the left mouse button.
4. Drag the vertex toward or away from the center of the selected polygon.

Scale edge

1. Select (left click) an edge.
2. Hover over one of the edge's vertices.
3. Hold the left mouse button.
4. Drag the vertex along the length of the selected edge.
Non-uniform scale edge

1. Select (left click) an edge.
2. Hover over one of the edge's vertices.
3. Hold Alt and drag the vertex along the length of the selected edge.
Extrude

**Extrude polygon**

1. Hover over a polygon.
2. Hold **Ctrl** and left mouse button.
3. Drag the polygon along its normal.
Extrude edge

1. Hover over an edge.
2. Hold Ctrl and left mouse button.
3. Drag the edge.
Extrude scale

1. Select (left click) a polygon.
2. Hover over one of the polygon's vertices.
3. Hold Ctrl and left mouse button.
4. Drag the vertex toward or away from the center of the selected polygon to scale.
5. Hover over the selected polygon.
6. Hold the left mouse button.
7. Drag the polygon along its normal.
**Flip edge**

1. Hold **Ctrl + Shift** to show hidden edges.
2. Right click on a hidden edge to flip its orientation.
Hide/Show edge

Hide an edge

1. Select (left click) an edge.
2. Press H.
Show edge

1. Hold Ctrl and Shift to show edges.
2. Select (left click) an edge to unhide it.
Hide/Show vertex

Hide a vertex

1. Select (left click) a vertex.
2. Press H.
Show vertex

1. Hold Ctrl and Shift to show hidden vertices.
2. Select (left click) a vertex to unhide it.

White Box Collider component

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can enable collision on white box meshes in Lumberyard by adding the White Box Collider component to an entity that has a White Box component mesh. The White Box Collider component supports collision layers and physics materials. It can be used with static and kinematic white box meshes. The White Box Collider component uses the white box mesh as the collision surface. Unlike the PhysX Collider component, there is no need to specify a collision shape or provide a PhysX mesh asset.
In the animation above, the **White Box Collider** component is applied to a static **White Box** component. The **White Box** component can be edited and the changes tested for collision immediately.
In the animation above, the door was created with White Box and animated with a script. Note when
the White Box component is edited, the White Box Collider component automatically recognizes the
changes to the mesh. You can then test the changes immediately.

**White Box Collider properties**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
Collision Layer
The collision layer that's assigned to the collider. For more information, see Collision Layers (p. 2785).

Collides With
The collision group containing the layers that this collider collides with. For more information, see Collision Groups (p. 2787).

Physics Material - Library
Set the physics material library for this collider.

Physics Material - Mesh Surfaces
Choose a material from the physics material library for this collider. The material is applied to the entire white box entity.

Tag
Set a tag for this collider. Tags can be used to quickly identify components in script or code.

Body Type
Select Static for non-moving entities. Select Kinematic for animated entities.

Note
The White Box collider must be set to Static to interact with the PhysX Character Controller.

Converting Entities with the Legacy Converter

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Legacy Converter converts your legacy entities (CryEntities) to the new component entity system. Legacy features will eventually be removed from Lumberyard Editor. When you use the Legacy Converter, it tries to convert all legacy entities in your level. You cannot select which entities to convert or skip. Once an entity is converted, it cannot be converted back to a legacy entity.

Topics
- Converting Your Legacy Entities (p. 963)
- List of Legacy Entity Conversions (p. 964)

Converting Your Legacy Entities
If your level has legacy entities, Lumberyard Editor detects them and prompts you to convert them.

To convert your legacy entities
1. Do any of the following to open the Legacy Converter:
   - If the CryEntity Removal gem is enabled, and you load a level that contains legacy entities, the Legacy Converter opens by default.
List of Legacy Entity Conversions

The Legacy Converter converts each legacy entity to its corresponding component entity. For a list of legacy entities, see the Entity Reference in the Amazon Lumberyard Legacy Reference.

Converted entities keep the same position in the viewport. For more information, see Using the Viewport (p. 207).
Note
Some legacy entities cannot be converted at this time.

See the following tables for the converted component entity.

Contents
- Area Box Entity (p. 965)
- Area Sphere Entity (p. 965)
- Brush, Geom, and Simple Entities (p. 965)
- Camera Entity (p. 966)
- Camera Target Entity (p. 966)
- Comment Entity (p. 966)
- Environment Probe Entity (p. 967)
- Decal Entity (p. 968)
- Designer Objects (p. 969)
- Groups and Layers (p. 970)
- Light Entity (p. 971)
- Light Entity with Lens Flare (p. 972)
- Particle Effect Entity (p. 972)
- Proximity Trigger Entity (p. 973)
- Tag Point Entity (p. 973)

Area Box Entity
An area box entity is converted to a component entity that is attached with a Box Shape (p. 818) component.

<table>
<thead>
<tr>
<th>Settings in Area Box Entity</th>
<th>Converted Settings in Box Shape Component</th>
</tr>
</thead>
<tbody>

<td>Field of View</td>
</tr>
<tr>
<td>NearZ</td>
<td>Near Clip Distance</td>
</tr>
<tr>
<td>FarZ</td>
<td>Far Clip Distance</td>
</tr>
</tbody>
</table>

**Camera Target Entity**

The camera target entity is converted to an empty component entity.

**Comment Entity**

A Comment entity is converted to a component entity that is attached with a [Camera (p. 566)](#) component.

- Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Comment component allows you to add long-form text comments for component entities. When enabled, the Comment component displays a dialog box that expands based on the size of the comment that you enter. The following examples demonstrate how you can use the comment text box:

- Explain how the scripts or components on an entity interact with other scripts or components
- Describe how everything in a level ties together
- Send descriptions, instructions, or notes to team members
Comment Properties

The Comment component has the following property:

- Comment text box: Stores the user comment for the component entity.

Default: None

Using the Comment Component

You can use this feature by adding the component to an entity in your level.

To use the Comment component:

1. In Lumberyard Editor, right-click the viewport in your level, and click Create entity.
2. In the Entity Inspector, click Add Component.
3. Under Editor, click Comment.
4. In the Entity Inspector, under Comment, add comments for the component entity in the text box.

<table>
<thead>
<tr>
<th>Settings in Comment Entity</th>
<th>Converted Settings in Comment Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text</td>
<td>Comment</td>
</tr>
</tbody>
</table>

Environment Probe Entity

The environment probe entity is converted to a component entity that is attached with an Environment Probe (p. 587) component.

<table>
<thead>
<tr>
<th>Settings in Environment Probe Entity</th>
<th>Converted Settings in Environment Probe Component</th>
</tr>
</thead>
<tbody>

</tbody>
</table>
Designer Objects

The Legacy Converter converts designer objects to a component entity that is attached with the following components:

- **Mesh** (p. 684)
- **Static Physics** component.
- **Mesh Collider**

The Legacy Converter converts the original shape of designer objects into .cgf files and then saves them to your game project directory.

<table>
<thead>
<tr>
<th>Settings in Designer Object</th>
<th>Converted Settings in Mesh Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>Geometry</td>
<td>Mesh asset (.cgf file)</td>
</tr>
</tbody>
</table>

**Example**

1. You have a legacy designer object named *Designer1* shaped as a sphere.

2. With the Legacy Converter, you convert the object into a entity with the **Mesh**, **Static Physics**, and **Mesh Collider** components attached.

3. The Legacy Converter creates a .cgf file and saves it to the `lumberyard_version\dev\game-project\Objects\DesignerConversion\level-name` directory.
4. In the **Mesh** component, the **Mesh asset** property specifies this `Designer1.cgf` file. The entity has the same shape as the original designer object.

**Note**
You cannot edit a designer object after it is converted into a component entity. You can use the legacy **Designer Tool** to create your object and convert it again. For more information, see Using the Designer Tool in the Amazon Lumberyard Legacy Reference.

### Groups and Layers

Groups and layers are converted to empty component entities with the same names.

Legacy entities that are nested under legacy groups or layers appear nested under the newly created component entities, which keep the same hierarchy.

If a legacy entity belongs to a layer and a group, the converted component entity appears under the converted group component entity. It also appears as a child of the converted layer component entity.

**Example**

1. You have the following legacy entities in your level:
   - LegacyEntityA belongs to LegacyLayerA, so the hierarchy appears as: LegacyLayerA [LegacyEntityA]
2. You use the Legacy Converter to convert your entities.
3. The converted entities have the following hierarchy:

   ```
   ```
**Light Entity**

A light entity with the **Planar Light** setting specified is converted to a component entity that is attached with a **Area Light (p. 546)** component.

A light entity with the **Projector** setting specified to **Texture** is converted to a component entity attached with a **Projector Light (p. 723)** component.

A light entity with neither the **Planar Light** or **Projector** setting specified to **Texture** is converted to a component entity attached with a **Point Light (p. 706)** component

## List of Legacy Entity Conversions

### Settings in Light Entity | Converted Settings in Area Light, Projector Light, and Point Light Components
---
Entity Properties: Shadows: ShadowUpdateRatio | Shadow Settings: Shadow update ratio

### Settings in Light Entity | Converted Settings in Projector Light Component
---
AttenuationBulbSize | Projector Light Settings: Attenuation bulb size
Projector: ProjectNearPlane | Projector Light Settings: Near plane
Projector: ProjectorFov | Projector Light Settings: FOV
Projector: Texture | Projector Light Settings: Texture
Radius | Projector Light Settings: Max distance

### Settings in Light Entity | Converted Settings in Area Light Component
---
Radius | Area Light Settings: Max distance
Shape: SourceDiameter | Area Light Settings: Area height
Shape: SourceWidth | Area Light Settings: Area width

### Settings in Light Entity | Converted Settings in Point Light Component
---
AttenuationBulbSize | Point Light Settings: Attenuation bulb size
Radius | Point Light Settings: Max distance

### Light Entity with Lens Flare
A light entity with a lens flare is converted to a component entity that is attached with a Lens Flare component and a light component.

The lens flare asset that is specified for a light entity is converted to the Lens Flare component settings: Library and Lens flare.

### Particle Effect Entity
The particle effect entity is converted to a component entity that is attached with a Particle component.

**Programmer's Guide to Entities and Components**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

This guide provides engine and game programmers with examples and best practices for creating and reflecting custom Lumberyard components in C++.

For information on using the component entity system in Lumberyard Editor, see Working with component entities (p. 462).

For C++ API reference documentation on the component entity system, see the Amazon Lumberyard C++ API Reference.

Lumberyard uses a lightweight entity/component model called the component entity system for both game objects and systems. Lumberyard entities are simply an ID and a container of components. They have no functionality associated with them. Lumberyard's component model is granular: It expects each...
Creating a Component

A component in Lumberyard is a simple class that inherits from Lumberyard's `AZ::Component`. A component's behavior is determined by its reflected data and the actions it takes when it is activated. This section shows you how to create Lumberyard components programmatically. For information about

adding and customizing the components available in Lumberyard Editor, see Working with component entities (p. 462).

**Component Example**

An example component class skeleton follows:

```cpp
#include <AzCore/Component/Component.h>

class MyComponent
    : public AZ::Component
{
 public:
    AZ_COMPONENT(MyComponent, "{0C09F774-DECA-40C4-8B54-3A93033EC381}", AZ::Component);

    // AZ::Component interface implementation.
    void Init() override            {}
    void Activate() override      {}
    void Deactivate() override      {}

    // Required Reflect function.
    static void Reflect(AZ::ReflectContext* context);

    // Optional functions for defining provided and dependent services.
    static void GetProvidedServices(AZ::ComponentDescriptor::DependencyArrayType& provided);
    static void GetDependentServices(AZ::ComponentDescriptor::DependencyArrayType& dependent);
    static void GetRequiredServices(AZ::ComponentDescriptor::DependencyArrayType& required);
    static void GetIncompatibleServices(AZ::ComponentDescriptor::DependencyArrayType& incompatible);
};
```

**Component Members**

The required and optional members that a component comprises are as follows:

AZ::Component

Every component must include AZ::Component somewhere in its inheritance ancestry. Noneditor components generally inherit directly from AZ::Component, as in the following example:

```cpp
class MyComponent
    : public AZ::Component
{
}
```

You can also create your own component class hierarchies.

AZ_COMPONENT Macro

Every component must specify the AZ_COMPONENT macro in its class definition. The macro takes two arguments:

1. The component type name.
2. A unique UUID. You may use any UUID generator to produce the value. Visual Studio provides this functionality through Tools, Create GUID. Use the Registry Format setting, and then copy and paste the value that is generated.

A sample AZ_COMPONENT macro follows:

```cpp
AZ_COMPONENT(MyComponent, "{0C09F774-DECA-40C4-8B54-3A93033EC381}", AZ::Component);
```
AZ::Component Functions

To define a component's behavior, you generally override three AZ::Component functions: Init, Activate, and Deactivate:

```cpp
void Init() override {}  // Optional
void Activate() override {}  // Required
void Deactivate() override {}  // Required
```

These functions are as described as follows:

**Init()**

(Optional) Called only once for a given entity. It requires minimal construction or setup work, since the component may not be activated anytime soon. An important best practice is to minimize your component's CPU and memory overhead while the component is inactive.

**Activate()**

(Required) Called when the owning entity is being activated. The system calls your component's Activate() function only if all dependent or required services are present. Your Activate function is always called after any components that it depends on. In addition, the component makeup of an entity never changes while the entity is active. Consequently, it is safe to cache pointers or references to other components on the entity when performance is critical.

**Deactivate()**

(Required) Called when the owning entity is being deactivated. The order of deactivation is the reverse of activation, so your component is deactivated before the components it depends on. As a best practice, make sure your component returns to a minimal footprint when it is deactivated. In general, deactivation should be symmetric to activation.

*Note*

Destruction does not necessarily follow deactivation. An entity can be deactivated and then activated again without being destroyed, so ensure that your components support this efficiently. However, when you do destroy your entity, Lumberyard ensures that your Deactivate() function is called first. Components must be authored with this in mind.

**Reflect()**

(Required) All components are AZ reflected classes. Because all components must be serializable and editable, they must contain a Reflect() function, as in the following example:

```cpp
// Required Reflect function.
static void Reflect(AZ::ReflectContext* context);
```

For more information, see Reflecting a Component for Serialization and Editing (p. 977).

Logical Services

(Optional) Components can define any combination of logical services that they provide, depend on, require, or are incompatible with. To define these logical services, use the following functions:

```cpp
// Optional functions for defining provided and dependent services.
static void GetProvidedServices(AZ::ComponentDescriptor::DependencyArrayType& provided);
static void GetDependentServices(AZ::ComponentDescriptor::DependencyArrayType& dependent);
static void GetRequiredServices(AZ::ComponentDescriptor::DependencyArrayType& required);
static void GetIncompatibleServices(AZ::ComponentDescriptor::DependencyArrayType& incompatible);
```
Registering Your Component

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You register a component during application startup. You implement the registration in the AZ::Module class of the module in which the component is written.

The following example module creates descriptors for the components that are declared within the module.

```cpp
//MyModule.cpp
MyModule::MyModule()
{
    // Create descriptors for components declared within this module.
    m_descriptors.insert(m_descriptors.end(), {
        MyComponent::CreateDescriptor(),
    });
}
```

For more information, see the The Module Class (p. 1093) section of the Using AZ Modules to Initialize Gems (p. 1090).

Reflecting a Component for Serialization and Editing

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Components use AZ reflection to describe the data they serialize and how content creators interact with them.

The following example reflects a component for serialization and editing:

```cpp
class MyComponent
    : public AZ::Component
{
    // ... AZ_COMPONENT, Activate(), Deactivate(), etc, ...
    static void Reflect(AZ::ReflectContext* context);

    enum class SomeEnum
    {
        EnumValue1,
        EnumValue2,
    }
    float m_someFloatField;
    AZStd::string m_someStringField;
    SomeEnum m_someEnumField;
    AZStd::vector<SomeClassThatSomeoneHasReflected> m_things;
    int m_runtimeStateNoSerialize;
}

void MyComponent::Reflect(AZ::ReflectContext* context)
```

Version 1.28
977
AZ::SerializeContext* serialize = azrtti_cast<AZ::SerializeContext*>(context);
if (serialize)
{
    // Reflect the class fields that you want to serialize.
    // In this example, m_runtimeStateNoSerialize is not reflected for serialization.
    // Base classes with serialized data should be listed as additional template
    // arguments to the Class< T, ... >() function.
    serialize->Class<MyComponent, AZ::Component>()
        ->Version(1)
        ->Field("SomeFloat", &MyComponent::m_someFloatField)
        ->Field("SomeString", &MyComponent::m_someStringField)
        ->Field("Things", &MyComponent::m_things)
        ->Field("SomeEnum", &MyComponent::m_someEnumField);  
    AZ::EditContext* edit = serialize->GetEditContext();
    if (edit)
    {
        edit->Class<MyComponent>("My Component", "The World's Most Clever Component")
            ->ClassElement(AZ::Edit::ClassElements::EditorData, "")
            ->Attribute(AZ::Edit::Attributes::AppearsInAddComponentMenu, AZ_CRC("Game"))
            ->DataElement(AZ::Edit::UIHandlers::Default, &MyComponent::m_someFloatField, "Some Float", "This is a float that means X.")
            ->DataElement(AZ::Edit::UIHandlers::Default, &MyComponent::m_someStringField, "Some String", "This is a string that means Y.")
            ->DataElement(AZ::Edit::UIHandlers::ComboBox, &MyComponent::m_someEnumField, "Choose an Enum", "Pick an option among a set of enum values.")
                ->EnumAttribute(MyComponent::SomeEnum::EnumValue1, "Value 1")
                ->EnumAttribute(MyComponent::SomeEnum::EnumValue2, "Value 2")
            ->DataElement(AZ::Edit::UIHandlers::Default, &MyComponent::m_things, "Bunch of Things", "A list of things for doing Z.");
    }
}

The preceding example adds five data members to MyComponent. The first four data members will be serialized. The last data member will not be serialized because it contains only the runtime state. This is typical; components commonly contain some members that are serialized and others that are not.

It is common for fields to be reflected for serialization, but not for editing, when using advanced reflection features such as change callbacks (p. 981). In these cases, components may conduct complex internal calculations based on user property changes. The result of these calculations must be serialized but not exposed for editing. In such a case, you reflect the field to SerializeContext but do not add an entry in EditContext. An example follows:

serialize->Class<MyComponent>()
    ->Version(1)
    ...
    ->Field("SomeFloat", &MyComponent::m_someFloatField)
    ->Field("MoreData", &MyComponent::m_moreData)
    ...
...
AZ::EditContext* edit = serialize->GetEditContext();
if (edit)
{
    edit->Class<MyComponent>("My Component", "The World's Most Clever Component")
        ->ClassElement(AZ::Edit::ClassElements::EditorData, "")
}
Reflecting a Component for Serialization and Editing

```cpp
->Attribute(AZ::Edit::Attributes::AppearsInAddComponentMenu, AZ_CRC("Game"))
->DataElement(AZ::Edit::UIHandlers::Default, &MyComponent::m_someFloatField, "Some Float", "This is a float that means X.")
->Attribute(AZ::Edit::Attributes::ChangeNotify, &MyComponent::CalculateMoreData)
// m_moreData is not reflected for editing directly.
```

Lumberyard has reflection contexts for different purposes, including the following:

- **Serialization Context** (p. 1033) – Contains reflection data for serialization and construction of objects.
- **Edit Context** (p. 1052) – Contains reflection data for visual editing of objects, as in Lumberyard Editor.
- **Behavior Context** (p. 1053) – Contains reflection for runtime manipulation of objects from Lua, Script Canvas (p. 2420), or other external sources.
- **NetworkContext** – Contains reflection for networking purposes, including marshaling, quantization, and extrapolation.

**Note**
This topic covers only SerializeContext and EditContext.

All of Lumberyard's reflection API operations are designed to be simple, human readable, and human writable, with no forced dependency on code generation.

A component's `Reflect()` function is invoked automatically for all relevant contexts.

The following code dynamically casts the anonymous context provided to a serialize context, which is how components discern the type of context that `Reflect()` is being called for.

```cpp
AZ::SerializeContext* serialize = azrtti_cast<AZ::SerializeContext*>(context);
```

**Serialization**

Reflecting a class for serialization involves a builder pattern style markup in C++, as follows:

```cpp
serialize->Class<TestAsset>()
->Version(1)
->Field("SomeFloat", &MyComponent::m_someFloatField)
->Field("SomeString", &MyComponent::m_someStringField)
->Field("Things", &MyComponent::m_things)
->Field("SomeEnum", &MyComponent::m_someEnumField)
```

The example specifies that `m_someFloatField`, `m_someStringField`, `m_things`, and `m_someEnumField` should all be serialized with the component. Field names must be unique and are not user facing.

**Tip**
We recommend that you keep field names simple for future proofing. If your component undergoes significant changes and you want to write a data converter to maintain backward data compatibility, you must reference the field names directly.

The preceding example reflects two primitive types—a float, and a string—as well as a container (vector) of some structure. AZ reflection, serialization, and editing natively support a wide variety of types:

- Primitive types, including integers (signed and unsigned, all sizes), floats, and strings
- Enums
Lumberyard User Guide Lumberyard User Guide
Reﬂecting a Component for Serialization and Editing

• AZStd containers (ﬂat and associative), including AZStd::vector, AZStd::list, AZStd::map,
AZStd::unordered_map, AZStd::set, AZStd::unordered_set, AZStd:pair, AZStd::bitset,
AZStd::array, ﬁxed C-style arrays, and others.
• Pointers, including AZStd::smart_ptr, AZStd::intrusive_ptr, and raw native pointers.
• Any class or structure that has also been reﬂected.

Note

The example omits the reﬂection code for SomeClassThatSomeoneHasReflected. However,
you need only reﬂect the class. After that, you can freely reﬂect members or containers of that
class in other classes.
For C++ API reference documentation on the serialize context, see the SerializeContext Class Reference in
the Amazon Lumberyard C++ API Reference.

Editing
When you run Lumberyard tools such as Lumberyard Editor, an EditContext and a
SerializeContext are provided. You can use the robust facilities in these contexts to expose your
ﬁelds to content creators.
The following code demonstrates basic edit context reﬂection:
AZ::EditContext* edit = serialize->GetEditContext();
if (edit)
{
edit->Class<TestAsset>("My Component", "The World's Most Clever Component")
->ClassElement(AZ::Edit::ClassElements::EditorData, "")
->Attribute(AZ::Edit::Attributes::AppearsInAddComponentMenu, AZ_CRC("Game"))
->DataElement(AZ::Edit::UIHandlers::Default, &MyComponent::m_someFloatField, "Some
Float", "This is a float that means X.")
->DataElement(AZ::Edit::UIHandlers::Default, &MyComponent::m_someStringField, "Some
String", "This is a string that means Y.")
->DataElement(AZ::Edit::UIHandlers::ComboBox, &MyComponent::m_someEnumField,
"Choose an Enum", "Pick an option among a set of enum values.")
->EnumAttribute(MyComponent::SomeEnum::EnumValue1, "Value 1")
->EnumAttribute(MyComponent::SomeEnum::EnumValue2, "Value 2")
->DataElement(AZ::Edit::UIHandlers::Default, &MyComponent::m_things, "Bunch of
Things", "A list of things for doing Z.")
;
}

Although this example demonstrates the simplest usage, many features and options are available when
you reﬂect structures (including components) to the edit context. For the ﬁelds to be exposed directly to
content creators, the example provides a friendly name and a description (tooltip) as the third and fourth
parameters of DataElement. For three ﬁelds, the ﬁrst parameter of DataElement is the default UI
handler AZ::Edit::UIHandlers::Default. The property system's architecture supports the ability
to add any number of UI handlers, each valid for one or more ﬁeld types. A given type can have multiple
available handlers, with one handler designated as the default. For example, ﬂoats by default use the
SpinBox handler, but a Slider handler is also available.
An example of binding a ﬂoat to a slider follows:
->DataElement(AZ::Edit::UIHandlers::Slider, &MyComponent::m_someFloatField, "Some Float",
"This is a float that means X.")
->Attribute(AZ::Edit::Attributes::Min, 0.f)
->Attribute(AZ::Edit::Attributes::Max, 10.f)
->Attribute(AZ::Edit::Attributes::Step, 0.1f)

Version 1.28
980


Reflecting a Component for Serialization and Editing

The `AZ::Edit::UIHandlers::Slider` UI handler expects `AZ::Edit::Attributes::Min` and `AZ::Edit::Attributes::Max` attributes. Optionally, you can provide a value for `AZ::Edit::Attributes::Step`. The example provides incremental increases of 0.1. If you do not provide a value for `AZ::Edit::Attributes::Step`, a default stepping of 1.0 is used.

**Note**

The property system supports external UI handlers, so you can implement your own UI handlers in your own modules. You can customize the behavior of the field, the Qt control that it uses, and the attributes that it observes.

For C++ API reference documentation on the edit context, see the `EditContext Class Reference` in the Amazon Lumberyard C++ API Reference.

**Attributes**

The example also demonstrates the use of attributes. Attributes are a generic construct on the edit context that allows the binding of literals, or functions that return values, to a named attribute. UI handlers can retrieve this data and use it to drive their functionality.

Attribute values can be bound to the following:

- **Literal values**
  
  ```
  Attribute(AZ::Edit::Attributes::Min, 0.0f)
  ```

- **Static or global variables**
  
  ```
  Attribute(AZ::Edit::Attributes::Min, &g_globalMin)
  ```

- **Member variables**
  
  ```
  Attribute(AZ::Edit::Attributes::Min, &MyComponent::m_min)
  ```

- **Static or global functions**
  
  ```
  Attribute(AZ::Edit::Attributes::ChangeNotify, &SomeGlobalFunction)
  ```

- **Member functions**
  
  ```
  Attribute(AZ::Edit::Attributes::ChangeNotify, &MyComponent::SomeMemberFunction)
  ```

**Change Notification Callbacks**

Another commonly used feature of the edit context is its ability to bind a change notification callback:

```c++
->DataElement(AZ::Edit::UIHandlers::Default, &MyComponent::m_someStringField, "Some String", "This is a string that means Y."
->Attribute(AZ::Edit::Attributes::ChangeNotify, &MyComponent::OnStringFieldChanged)
```

The example binds a member function to be invoked when this property is changed, which allows the component to conduct other logic. The `AZ::Edit::Attributes::ChangeNotify` attribute also looks for an optional returned value that tells the property system if it needs to refresh aspects of its state. For example, if your change callback modifies other internal data that affects the property system, you can request a value refresh. If your callback modifies data that requires attributes be reevaluated (and any bound functions be reinvoked), you can request a refresh of attributes and values. Finally, if your callback conducts work that requires a full refresh (this is not typical), you can refresh the entire state.

The following example causes the property grid to refresh values when `m_someStringField` is modified through the property grid.

```c++
AZ::Edit::PropertyRefreshLevels::ValuesOnly signals the property grid to update the GUI with changes to the underlying data.
```
Reflecting a Component for Serialization and Editing

->DataElement(AZ::Edit::UIHandlers::Default, &MyComponent::m_someStringField, "Some String", "This is a string that means Y.")
->Attribute(AZ::Edit::Attributes::ChangeNotify, &MyComponent::OnStringFieldChanged)

AZ::u32 MyComponent::OnStringFieldChanged()
{
    m_someFloatField = 10.0f;

    // We've internally changed displayed data, so tell the property grid to refresh values (cheap).
    return AZ::Edit::PropertyRefreshLevels::ValuesOnly;
}

AZ::Edit::PropertyRefreshLevels::ValuesOnly is one of the following refresh modes that you can use (%dev\Code\Framework\AzCore\AzCore\Serialization\EditContextConstants.inl):

- **AttributesAndValues** – Reevaluates attributes of the properties displayed in the UI and refreshes their values. Because attributes can be bound to data members, member functions, global functions, or static variables, it's sometimes necessary to ask the property grid to reevaluate them. Doing so might include reinvoking bound functions.
- **EntireTree** – Refreshes the entire tree that is displayed in the UI.
- **None** – Specifies that the properties that are displayed in the UI should not be refreshed.
- **ValuesOnly** – Refreshes only the values of the properties that are displayed in the UI. The property grid updates the GUI to reflect changes to underlying data that might have occurred in the change callback.

The following more complex example binds a list of strings as options for a combo box. The list of strings is attached to a string field Property A. Suppose you want to modify the options available in the combo box for Property A with the values from another Property B. In that case you can bind the combo box AZ::Edit::Attributes::StringList attribute to a member function that computes and returns the list of options. In the AZ::Edit::Attributes::ChangeNotify attribute for Property B, you tell the system to reevaluate attributes, which in turn reinvokes the function that computes the list of options.

... bool m_enableAdvancedOptions;
AZStd::string m_useOption;
...

->DataElement(AZ::Edit::UIHandlers::Default, &MyComponent::m_enableAdvancedOptions, "Enable Advanced Options", "If set, advanced options will be shown.")
->Attribute(AZ::Edit::Attributes::ChangeNotify, AZ::Edit::PropertyRefreshLevels::AttributesAndValues)
->DataElement(AZ::Edit::Edit::UIHandlers::ComboBox, &MyComponent::m_useOption, "Options", "Available options.")
->Attribute(AZ::Edit::Attributes::StringList, &MyComponent::GetEnabledOptions)
...

AZStd::vector<AZStd::string> MyComponent::GetEnabledOptions()
{
    AZStd::vector<AZStd::string> options;
    options.reserve(16);
    options.push_back("Basic option");
    options.push_back("Another basic option");
Defining and Using Component Services

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Components can optionally specify a list of services that they provide, are incompatible with, depend on, or require. When you create a component, you can use this service specification to define relationships between various components. The component entity system uses this list for the conditional addition and removal of components at both edit time and at run time. The service specification also defines the order in which components are activated when an entity is activated. Specifically, components that provide services that another component depends on are activated first.

The following example shows a service specification.

```cpp
static void GetProvidedServices(AZ::ComponentDescriptor::DependencyArrayType& provided)
{
    provided.push_back(AZ_CRC("ProvidedService"));
    provided.push_back(AZ_CRC("AnotherProvidedService"));
}
static void GetRequiredServices(AZ::ComponentDescriptor::DependencyArrayType& required)
{
    required.push_back(AZ_CRC("RequiredService"));
    required.push_back(AZ_CRC("AnotherRequiredService"));
}
static void GetIncompatibleServices(AZ::ComponentDescriptor::DependencyArrayType& incompatible)
{
    incompatible.push_back(AZ_CRC("IncompatibleService"));
}
static void GetDependentServices(AZ::ComponentDescriptor::DependencyArrayType& dependent)
{
    dependent.push_back(AZ_CRC("DependentOnService"));
}
```

**ProvidedService** – Specifies the service that the component provides. For example, a TransformComponent could provide a TransformService that in turn provides locational information.

**RequiredService** – Specifies a service that the component requires. The components that provide the required services are guaranteed to be present and active before this component is activated. For example, an audio component might need to know where it is located and therefore require a TransformService. Because of this requirement, the audio component can be added only to entities that have the component that provides the TransformService.

**DependentService** – Specifies a service on which the component depends but does not require. The component entity system guarantees that the components that provide dependent services are activated
before the component itself is activated. For example, an audio component could depend on the physics component. If the entity has physics, the audio component can query the physics component for physical material information. However, the audio component does not require that physics be present.

**IncompatibleService** – Specifies a service that cannot work with the component. Consider these examples:

- An entity can have only one type of collider. Therefore, the `PrimitiveColliderService` specifies that the `MeshColliderService` is incompatible with it and vice versa.
- The same effect can be achieved if two collider components already provide the `ColliderService` themselves and therefore specify the `ColliderService` as incompatible. Marking a component as incompatible with `ColliderService` ensures that no other component that has the same service is added to the entity.
- The `IncompatibleService` specification is frequently used to specify that multiples of the same component cannot exist on an entity.

## Editor Components

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Some components in Lumberyard have separate editor and runtime versions. The editor version is active in the editor. The runtime version is used for running the level in game or in the editor by pressing `Ctrl+G` or clicking `AI/Physics` below the viewport. Lumberyard uses editor components to maintain a clean separation between tools-specific code and data on one hand, and leaner runtime component data on the other. In general, runtime game components do not require editor counterparts. Components rarely need to be fully active at edit time. The light and mesh components are exceptions because they must behave the same at edit time as at run time.

*EditContext* reflection is fully supported in runtime components. Edit time is the only time when editor components are active. At run time, when Lumberyard processes a level or dynamic slice, it uses the runtime equivalents of editor components. Using the *EditContext* from a runtime component is usually sufficient to provide a rich editing experience.

**Important**

Editor components are not required. An editor component is necessary only if one of the following is true:

- Your component must be fully active at edit time. Edit time refers to standard editing mode; runtime components are used for the `AI/Physics` mode and gameplay (`Ctrl+G`).
- You must add special tools functionality to your component that requires that you compile only into your editor binaries.
- Your component provides functionality only in the editor and does not export a runtime component (for example, if your component manages selection logic).

## Sample Editor Component

The following code shows a sample editor component.

```c
/* Include the following headers: 
* EditorComponentBase.h - the editor component base class. Derive from 
* this class to create a component to use in the editor that is the 
* counterpart of the version of the component that is used during runtime. 
*/
```
Editor Component and Runtime Component Differences

The code for editor components is similar to the code for runtime components. The following sections list the key differences. It is safe to assume that editor component code is the same as it is for runtime component code other than the differences listed. For more information, see Creating a Component (p. 974).

Base Classes

All editor components include the AzToolsFramework::Components::EditorComponentBase class somewhere in their inheritance ancestry. If a component must display edit-time visualization, it must be a handler on the AzFramework::EntityDebugDisplayEventBus::Handler bus, as in the following example.

```cpp
#include <AzToolsFramework/ToolsComponents/EditorComponentBase.h>
#include <AzToolsFramework/ToolsComponents/EditorVisibilityBus.h>
#include <AzFramework/Entity/EntityDebugDisplayBus.h>
#include <MyComponent.h>

class MyEditorComponent
    : public AzToolsFramework::Components::EditorComponentBase
    , private AzFramework::EntityDebugDisplayEventBus::Handler
{
    public:
        AZ_EDITOR_COMPONENT(MyEditorComponent, "{5034A7F3-63DB-4298-83AA-915AB23EFEA0}");
        // Perform reflection for this component. The context parameter is the reflection context.
        static void Reflect(AZ::ReflectContext* context);

        // AZ::Component interface implementation.
        void Init() override;
        void Activate() override;
        void Deactivate() override;

        // AzFramework::EntityDebugDisplayEventBus implementation.
        void DisplayEntityViewport(const AzFramework::ViewportInfo& viewportInfo,
                                   AzFramework::DebugDisplayRequests& debugDisplay) override;

        // Optional functions for defining provided and dependent services.
        static void GetProvidedServices(AZ::ComponentDescriptor::DependencyArrayType& provided);
        static void GetDependentServices(AZ::ComponentDescriptor::DependencyArrayType& dependent);
        static void GetRequiredServices(AZ::ComponentDescriptor::DependencyArrayType& required);
        static void GetIncompatibleServices(AZ::ComponentDescriptor::DependencyArrayType& incompatible);

        // Facilitate the translation of an editor component into a runtime component.
        void BuildGameEntity(AZ::Entity* gameEntity) override;
};
```
### Macro

Every editor component must specify the `AZ_EDITOR_COMPONENT` macro within its class definition. The macro takes two arguments:

1. The component type name.
2. A unique UUID. You may use any UUID generator to produce the value. Visual Studio provides this functionality through `Tools, Create GUID`. Use the `Registry Format` setting, and then copy and paste the value that is generated.

A sample `AZ_EDITOR_COMPONENT` macro follows.

```cpp
AZ_EDITOR_COMPONENT(MyEditorComponent, "{5034A7F3-63DB-4298-83AA-915AB23EFEA0}");
```

**Note**

Some Lumberyard editor components specify `AzToolsFramework::Components::EditorComponentBase` as the base class but use the `AZ_COMPONENT` instead of the `AZ_EDITOR_COMPONENT` macro, as in the following example.

```cpp
AZ_COMPONENT(EditorMannequinComponent, "{C5E08FE6-E1FC-4080-A053-2C65A667FE82}", AzToolsFramework::Components::EditorComponentBase);
```

### The DisplayEntityViewport Method

To draw debug visuals in the viewport for a specific entity, implement the `DisplayEntityViewport` method of the `AzFramework::EntityDebugDisplayEventBus` interface. Use this location for custom primitive edit-time visualization code.

```cpp
#include <AzFramework/Entity/EntityDebugDisplayBus.h>
...
void DisplayEntityViewport(const AzFramework::ViewportInfo& viewportInfo, AzFramework::DebugDisplayRequests& debugDisplay) override;
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>viewportInfo</td>
<td>Determines information such as camera position.</td>
</tr>
<tr>
<td>debugDisplay</td>
<td>Contains the interface for debug draw or display commands.</td>
</tr>
</tbody>
</table>

### The BuildGameEntity Method

The `BuildGameEntity` method from `EditorComponentBase.h` facilitates the translation of an editor component into a runtime component. Override this method as follows.

```cpp
#include <AzToolsFramework/ToolsComponents/EditorComponentBase.h>
...
void BuildGameEntity(AZ::Entity* gameEntity) override;
```

A typical implementation of the `BuildGameEntity` method performs the following actions:
Creating System Components

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

System components are similar to other components in Lumberyard's component entity framework. However, instead of creating game entity behavior, they control the behavior of the engine itself. System components are first-class elements of the game engine and are included at a deep level early in the initialization process. For more information, see System Components (p. 1098) in the AZ Modules (p. 1090) section.

Like any Lumberyard component (p. 974), a system component can provide services and can depend on or require other system component services. Lumberyard provides precise control over the order of engine initialization and system dependencies.

When you author system components, follow the best practices for component authoring. For example, your system components should use the following:

- Working with the Event Bus (EBus) system (p. 1851) to expose their interfaces.
- Reflection (p. 977) to serialize and edit settings in the Advanced Settings dialog of the Project Configurator (p. 1104).
- The same AZ::Component Functions (p. 976) for activation and deactivation.

Important
Just like game components, system components often provide request and notification buses. However, because system components are global systems, they should not specify IDs for their buses like game components. Game developers should be able to call your system's EBuses without having to deal with or know about the system entity that contains all system components.

Topics
- Creating a System Component in a Gem (p. 987)
- Making a Component a System Component (p. 989)

Creating a System Component in a Gem

Lumberyard enables the creation of custom system components through gems and AZ modules. Gems are a specialization of AZ modules. For more information, see Gems and AZ Modules (p. 1100). Most Lumberyard games organize their game code in one or more gems. These gems can contain system components that integrate with the game engine as well as components for use on game entities.

When you create a system component as part of a gem, note the following requirements:

- Your gem's GetRequiredSystemComponents() function must return the system component.
Creating System Components

- Your `GemNameBus.h` file goes under the `lumberyard_version\dev\Gems\GemName\Code\Include\GemName` directory.
- Your component source files go under the `lumberyard_version\dev\Gems\GemName\Code\Source` directory.

Example: HttpRequestorSystemComponent

The HttpRequestor gem (p. 1144) makes asynchronous HTTP/HTTPS requests and returns data through a callback function that you provide. The HttpRequestor gem uses the EBus for communication and provides all requests asynchronously. The HttpRequestorSystemComponent is part of the HttpRequestor gem. You can find the source code files for the gem under the `lumberyard_version\dev\Gems\HttpRequestor\Code` directory.

The HttpRequestor EBus

The following code shows the EBus implementation for HttpRequestor (`HttpRequestorBus.h`).

```cpp
#include <AzCore/EBus/EBus.h>
#include "HttpTypes.h"

namespace HttpRequestor
{
    class HttpRequestorRequests : public AZ::EBusTraits
    {
        public:
            static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Single;
            static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::Single;

        // Public functions
            virtual void AddRequest(const AZStd::string& URI, Aws::Http::HttpMethod method, const Callback& callback) = 0;
            virtual void AddRequestWithHeaders(const AZStd::string& URI, Aws::Http::HttpMethod method, const Headers & headers, const Callback& callback) = 0;
            virtual void AddRequestWithHeadersAndBody(const AZStd::string& URI, Aws::Http::HttpMethod method, const Headers & headers, const AZStd::string& body, const Callback& callback) = 0;
            virtual void AddTextRequest(const AZStd::string& URI, Aws::Http::HttpMethod method, const TextCallback& callback) = 0;
            virtual void AddTextRequestWithHeaders(const AZStd::string& URI, Aws::Http::HttpMethod method, const Headers & headers, const TextCallback& callback) = 0;
            virtual void AddTextRequestWithHeadersAndBody(const AZStd::string& URI, Aws::Http::HttpMethod method, const Headers & headers, const AZStd::string& body, const TextCallback& callback) = 0;
        }
    using HttpRequestorRequestBus = AZ::EBus<HttpRequestorRequests>;
} // namespace HttpRequestor
```

The HttpRequestorSystemComponent Class

The following code shows the HttpRequestorSystemComponent class (`HttpRequestorSystemComponent.h`).

```cpp
#include <AzCore/Component/Component.h>
#include <HttpRequestor/HttpRequestorBus.h>
#include "HttpRequestManager.h"
```

Version 1.28
988
namespace HttpRequestor

class HttpRequestorSystemComponent : public AZ::Component,
  protected HttpRequestorRequestBus::Handler
{
  public:
    AZ_COMPONENT(HttpRequestorSystemComponent, "{CF29468F-1F67-497F-B4FF-C0F123584864}");

    static void Reflect(AZ::ReflectContext* context);
    static void GetProvidedServices(AZ::ComponentDescriptor::DependencyArrayType& provided);
    static void GetIncompatibleServices(AZ::ComponentDescriptor::DependencyArrayType& incompatible);
    static void GetRequiredServices(AZ::ComponentDescriptor::DependencyArrayType& required);
    static void GetDependentServices(AZ::ComponentDescriptor::DependencyArrayType& dependent);

    protected:

    //////////////////////////////////////////////////////////////////////////
    // HttpRequestorRequestBus interface implementation
    //////////////////////////////////////////////////////////////////////////
    void AddRequest(const AZStd::string& URI, Aws::Http::HttpMethod method, const Callback& callback) override;
    void AddRequestWithHeaders(const AZStd::string& URI, Aws::Http::HttpMethod method, const Headers & headers, const Callback& callback) override;
    void AddRequestWithHeadersAndBody(const AZStd::string& URI, Aws::Http::HttpMethod method, const Headers & headers, const AZStd::string& body, const Callback& callback) override;
    void AddTextRequest(const AZStd::string& URI, Aws::Http::HttpMethod method, const TextCallback& callback) override;
    void AddTextRequestWithHeaders(const AZStd::string& URI, Aws::Http::HttpMethod method, const Headers & headers, const TextCallback& callback) override;
    void AddTextRequestWithHeadersAndBody(const AZStd::string& URI, Aws::Http::HttpMethod method, const Headers & headers, const AZStd::string& body, const TextCallback& callback) override;

    //////////////////////////////////////////////////////////////////////////
    // AZ::Component interface implementation
    //////////////////////////////////////////////////////////////////////////
    void Init() override;
    void Activate() override;
    void Deactivate() override;

    //////////////////////////////////////////////////////////////////////////
    private:
    ManagerPtr m_httpManager;
};

Making a Component a System Component

After you create the code for your component, add it to your project’s system entity to make it a system component.

**To define a component as a system component**

1. Use the `GetRequiredSystemComponents()` function to add your component to the system entity for your project during application startup.
The following example is from HttpRequestorModule.cpp.

```cpp
#include "HttpRequestor_precompiled.h"
#include "HttpRequestorSystemComponent.h"
#include <AzCore/Module/Module.h>

namespace HttpRequestor
{
    class HttpRequestorModule
    : public AZ::Module
    {
        public:
            AZ_RTTI(HttpRequestorModule, "{FD411E40-AF83-4F6B-A5A3-F59AB71150BF}",
                     AZ::Module);

            HttpRequestorModule()
            : AZ::Module()
            {
                // Push results of [MyComponent]:CreateDescriptor() into m_descriptors here.
                m_descriptors.insert(m_descriptors.end(), {
                    HttpRequestorSystemComponent::CreateDescriptor(),
                });
            }

            /**
             * Add required SystemComponents to the SystemEntity.
             */
            AZ::ComponentTypeList GetRequiredSystemComponents() const override
            {
                return AZ::ComponentTypeList{
                    azrtti_typeid<HttpRequestorSystemComponent>(),
                };
            }
    }
}
```

2. (Optional) Expose the system component to the System Entity Editor (p. 50). This enables game developers to configure the component’s properties on a per-project basis. To do so, reflect the system component to the EditContext and set the AppearsInAddComponentMenu field to System.

The following example is from HttpRequestorSystemComponent.cpp.

```cpp
#include "HttpRequestor_precompiled.h"
#include <AzCore/Serialization/SerializeContext.h>
#include <AzCore/Serialization/EditContext.h>
#include "HttpRequestorSystemComponent.h"

namespace HttpRequestor
{
    void HttpRequestorSystemComponent::Reflect(AZ::ReflectContext* context)
    {
        if (AZ::SerializeContext* serialize = azrtti_cast<AZ::SerializeContext*>(context))
        {
            serialize->Class<HttpRequestorSystemComponent>();
        }
    }
```
The "HttpRequestor" and "Will make HTTP Rest calls" string parameters specify the UI name and tooltip information for the component in the Add Component list. The Category field specifies the group in which the component appears. In this case, no category is specified, so the group is Miscellaneous by default.

The following image shows the result in the System Entity Editor.
For detailed steps on using the System Entity Editor to add a system component to a project, see Configuring System Entities (p. 1104).

**Programmer's Guide to Component Mode**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
If you're a programmer, you can edit your components to add support for Component Mode. This can help designers on your team work more easily with components. You can use this feature to do the following:

- Use manipulators to edit a component directly in the viewport
- Create editing modes and tools without needing to create custom standalone editors
- Create your own shortcuts

For more information, see Editing Components in the Viewport (p. 483).

**Topics**

- Step 1: Choose a Component (p. 993)
- Step 2: Add a ComponentModeDelegate (p. 994)
- Step 3: Write a New Component Mode (p. 1000)
- Step 4: Add Shortcuts for Component Mode (p. 1009)
- Step 5: Handle Selection in the Viewport (p. 1011)
- Step 6: Building Component Mode (p. 1013)
- Tips for Working with Component Mode (p. 1014)

**Note**
Before you start, you should be familiar with the component entity framework and have written a component. For more information, see the Programmer's Guide to Entities and Components (p. 973).

**Step 1: Choose a Component**

Select a component to add a Component Mode to. Components such as shape, light, and physics are good examples because their data exists in the 3D world and you can view the changes directly in the viewport. Other components such as Audio and Script Canvas are less useful because they have properties that you can't edit in the viewport.

This walkthrough uses the Point Light (p. 706) component because it's visually easy to model. At the end of the walkthrough, you can edit the Point Light component in the viewport instead of manually entering values in the Entity Inspector.

**Note**
Component Mode is an edit-time only feature. For more information, see Editor Components (p. 984).

Before

By default, you can't edit the Point Light component in the viewport. You can edit its properties only in the Entity Inspector.
After you add a Component Mode to a component, you can click and drag the manipulator to adjust the Point Light component's area of effect.

For a list of available components, see Component Reference (p. 532).

Step 2: Add a ComponentModeDelegate

To add this feature to the Point Light component, you must update the component so that it can detect the intent to begin editing a component and manage the creation of a Component Mode. To do so, add a new type called a ComponentModeDelegate to your existing component.

To add a ComponentModeDelegate

1. Navigate to the EditorPointLightComponent.h file and open the file in a text editor.
2. Add the ComponentModeDelegate.
Example EditorPointLightComponent.h

Before

```
#pragma once

#include "EditorLightComponent.h"

namespace LmbrCentral
{
    /*
    * In-editor Point Light component.
    * Handles previewing and activating lights in the editor.
    */
    class EditorPointLightComponent
    : public EditorLightComponent
    {
        public:
            AZ_COMPONENT(EditorPointLightComponent, "{00818135-138D-42AD-8657-FF3FD38D9E7A}", AzToolsFramework::Components::EditorComponentBase);

            static void Reflect(AZ::ReflectContext* context);

            void Init() override;

        protected:
            const char* GetLightTypeText() const override
            {
                return "Point Light";
            }
    } // class EditorPointLightComponent
} // namespace LmbrCentral
```

After

```
See the following code changes.

```
#pragma once

#include "EditorLightComponent.h"

// BEGIN ADD
#include <AzToolsFramework/ComponentMode/ComponentModeDelegate.h>
// END ADD

namespace LmbrCentral
{
    /*
    * In-editor Point Light component.
    * Handles previewing and activating lights in the editor.
    */
    class EditorPointLightComponent
    : public EditorLightComponent
    {
        public:
            AZ_COMPONENT(EditorPointLightComponent, "{00818135-138D-42AD-8657-FF3FD38D9E7A}", AzToolsFramework::Components::EditorComponentBase);

            static void Reflect(AZ::ReflectContext* context);

            void Init() override;
    } // class EditorPointLightComponent
} // namespace LmbrCentral
```
In this example, there's an #include for ComponentModeDelegate.h, which is where you add the file as a member. The using declaration reduces the length of the m_componentDelegate definition. The updated file also provides Activate and Deactivate member functions for the component.

3. Save the file.

Now that you've updated the EditorPointLightComponent.h file, you must make changes to the EditorPointLightComponent.cpp implementation file.

To update the EditorPointLightComponent.cpp

1. In a text editor, open the EditorPointLightComponent.cpp file.
2. Add an #include for the unwritten Component Mode and comment out the change. This becomes the EditorPointLightComponentMode.h file.

   // #include "EditorPointLightComponentMode.h"

3. Serialize the m_componentModeDelegate member to expose it to the EditContext.

   ->Field("ComponentMode", &EditorPointLightComponent::m_componentModeDelegate)

4. Enter the following changes so that the ComponentModeDelegate appears in the Entity Inspector. This change adds the Edit button to the Point Light component.

   ->DataElement(AZ::Edit::UIHandlers::Default, &EditorPointLightComponent::m_componentModeDelegate, "Component Mode", "Point Light Component Mode")
   ->Attribute(AZ::Edit::Attributes::Visibility, AZ::Edit::PropertyVisibility::ShowChildrenOnly)

   **Tip**

   The Attribute ensures that the Edit button appears inline without being nested inside the ComponentModeDelegate class/struct.

5. Inside the Activate call, add the following code.
m_componentModeDelegate.ConnectWithSingleComponentMode(
    EditorPointLightComponent, /*EditorPointLightComponentMode*/(
        AZ::EntityComponentIdPair(GetEntityId(), GetId()), nullptr);

a. The helper function ConnectWithSingleComponentMode handles the most common case of adding a Component Mode. This call wraps a more complex API where multiple Component Modes can be activated at the same time.

For example, see the EditorTubeShapeComponent.h file.

b. Specify the component type and Component Mode itself.

   Note
   The template parameters generalize connecting and instantiating Component Modes. For more information, see the CreateComponentModeBuilder.h and its AddComponentModes function.

c. Specify the EntityId that the component is attached to and the ComponentId.

   Note
   It’s possible (although not often used) to address an EBus not only by the EntityId but by the EntityId and ComponentId pair. A ComponentId isn’t guaranteed to be unique on its own, but when it’s combined with an EntityId, you can target a specific component attached to an entity. This is useful when you have multiple components of the same type attached to a single entity.

d. The final argument is a nullptr, which is an EditorComponentSelectionRequestBus::Handler. To use this handler, the EditorComponent must implement the EditorComponentSelectionRequestsBus. If the EBus was implemented, you can pass ‘this’ here, but as you haven’t implemented it yet, enter nullptr for now.

   These changes enable you to double-click in the viewport to select a component. You implement the EditorComponentSelectionRequestBus in Step 5: Handle Selection in the Viewport (p. 1011).

   For examples, see the EditorBaseShapeComponent.h and EditorSplineComponent.h files.

6. Enter the following code to disconnect the ComponentModeDelegate when the EditorComponent is deactivated.

m_componentModeDelegate.Disconnect();

This change ensures that the ComponentModeDelegate disconnects from the various EBuses that are connected to in the Activate function.

Example EditorPointLightComponent.cpp

Your code should look like the following.

Before

```cpp
#include "LmbrCentral_precompiled.h"
#include "EditorPointLightComponent.h"
#include <AzCore/Serialization/SerializeContext.h>
#include <AzCore/Serialization/EditContext.h>
#include <AzCore/RTTI/BehaviorContext.h>
```
namespace LmbrCentral
{
    void EditorPointLightComponent::Reflect(AZ::ReflectContext* context)
    {
        if (auto serializeContext = azrtti_cast<AZ::SerializeContext*>(context))
        {
            serializeContext->Class<EditorPointLightComponent, EditorLightComponent>()
                ->Version(1);
        }

        if (AZ::EditContext* editContext = serializeContext->GetEditContext())
        {
            editContext->Class<EditorPointLightComponent>(
                "Point Light", "The Point Light component allows an entity to create a point of light")
                ->ClassElement(AZ::Edit::ClassElements::EditorData,"
                    ->Attribute(AZ::Edit::Attributes::Category, "Rendering")
                    ->Attribute(AZ::Edit::Attributes::Icon, "Editor/Icons/Components/PointLight.png")
                    ->Attribute(AZ::Edit::Attributes::ViewportIcon, "Editor/Icons/Components/Viewport/PointLight.png")
                    ->Attribute(AZ::Edit::Attributes::AppearsInAddComponentMenu,
                        AZ_CRC("Game", 0x232b318c))
                    ->Attribute(AZ::Edit::Attributes::AutoExpand, true)
                    ->Attribute(AZ::Edit::Attributes::Visibility,
                        AZ::Edit::PropertyVisibility::ShowChildrenOnly)
                    ->Attribute(AZ::Edit::Attributes::HelpPageURL, "https://docs.aws.amazon.com/lumberyard/latest/" userguide/component-point-light.html")
                ;
        }
    }

    if (auto behaviorContext = azrtti_cast<AZ::BehaviorContext*>(context))
    {
        behaviorContext->Class<EditorPointLightComponent>()
            ->RequestBus("EditorPointLightComponentBus");
    }

    void EditorPointLightComponent::Init()
    {
        SetLightType(EditorLightConfiguration::LightType::Point);
        EditorLightComponent::Init();
    }
} // namespace LmbrCentral

After

#include "LmbrCentral_precompiled.h"

}
// END ADD
Step 3: Write a New Component Mode

Now that you've updated the header and implementation file, this procedure shows you how to write a new Component Mode. To do so, you create a EditorPointLightComponentMode.h file, which is the interface for Component Mode.

To write a new Component Mode

1. Navigate to the \lumberyard_version\dev\Gems\LmbrCentral\Code\Source\Rendering directory.
2. In a text editor, create a file and name it EditorPointLightComponentMode.h.
3. Enter the following code. This includes the EditorBaseComponentMode.h file so that you can inherit from the EditorBaseComponentMode.

   ```cpp
   #include <AzToolsFramework/ComponentMode/EditorBaseComponentMode.h>
   ```

4. Ensure that all Component Modes must inherit from EditorBaseComponentMode.

   ```cpp
   : public AzToolsFramework::ComponentModeFramework::EditorBaseComponentMode
   ```

5. For the EditorBaseComponentMode, enter the following code to override the Refresh function.

   ```cpp
   // EditorBaseComponentMode
   void Refresh() override;
   ```

   The Refresh function is called after any undo or redo action to ensure that a Component Mode is updated to reflect the current state of the component. For example, the manipulator positions must be updated after you undo or redo an action.

   **Note**
   The EditorBaseComponentMode interface is designed to be as light as possible. Opt-in only the parts that you need.

6. Declare the manipulator to modify a specific property on the component. The example uses the LinearManipulator, so that you can adjust a point along a given axis.

   ```cpp
   AZStd::shared_ptr<AzToolsFramework::LinearManipulator>
   m_pointMaxDistanceManipulator; ///< Manipulator for point max distance property.
   ```

   **Note**
   • You must use an AZStd::shared_ptr to manage the lifetime of the LinearManipulator property, which the ManipulatorManager requires.
   • In this procedure, you use only the LinearManipulator property, but there are other properties available. The PlanarManipulator allows two degrees of freedom to edit a value, and the AngularManipulator can rotate a value. You can also use aggregate manipulators such as the TranslationManipulators and RotationManipulators. You can also create and extend your own manipulators by inheriting from BaseManipulator. However, this is an advanced topic and isn't encouraged because you can achieve most functionality by customizing behavior in the existing manipulator callbacks.

7. Save your file.

   **Example EditorPointLightComponentMode.h**

   Your code should look like the following. Note the light interface.
#pragma once

#include <AzToolsFramework/ComponentMode/EditorBaseComponentMode.h>

namespace AzToolsFramework
{
    class LinearManipulator;
}

namespace LmbrCentral
{
    class EditorPointLightComponentMode
    : public AzToolsFramework::ComponentModeFramework::EditorBaseComponentMode
    {
        public:
            EditorPointLightComponentMode(
                const AZ::EntityComponentIdPair& entityComponentIdPair, AZ::Uuid componentType);
            ~EditorPointLightComponentMode();

            // EditorBaseComponentMode
            void Refresh() override;

        private:
            AZStd::shared_ptr<AzToolsFramework::LinearManipulator> m_pointMaxDistanceManipulator; /// Manipulator for point max distance property.
        };
    } // namespace LmbrCentral

Implement Component Mode

Now that you've written the interface portion of a Component Mode, create a EditorPointLightComponentMode.cpp file. This file implements a Component Mode for the Point Light component.

In this procedure, you make the following changes to the file:

1. Construction (p. 1003)
2. Manipulator Setup (p. 1003)
3. Manipulator Callbacks (p. 1006)

Example EditorPointLightComponentMode.cpp

After you complete this procedure, your EditorPointLightComponentMode.cpp file looks like the following.

#include "LmbrCentral_precompiled.h"
#include "EditorPointLightComponentMode.h"

#include <AzCore/Component/TransformBus.h>
#include <AzToolsFramework/Manipulators/LinearManipulator.h>
#include <AzToolsFramework/Manipulators/ManipulatorManager.h>

#include <LmbrCentral/Rendering/EditorLightComponentBus.h>

namespace LmbrCentral
{
    EditorPointLightComponentMode::EditorPointLightComponentMode(
        const AZ::EntityComponentIdPair& entityComponentIdPair, AZ::Uuid componentType)
: EditorBaseComponentMode(entityComponentIdPair, componentType)
{
    AZ::Transform worldFromLocal = AZ::Transform::CreateIdentity();
    AZ::TransformBus::EventResult(
        worldFromLocal, GetEntityId(), &AZ::TransformInterface::GetWorldTM);

    m_pointMaxDistanceManipulator = AzToolsFramework::LinearManipulator::MakeShared(worldFromLocal);
    m_pointMaxDistanceManipulator->AddEntityId(GetEntityId());
    m_pointMaxDistanceManipulator->SetAxis(AZ::Vector3::CreateAxisX());
    Refresh();

    const AZ::Color manipulatorColor(0.3f, 0.3f, 0.3f, 1.0f);
    const float manipulatorSize = 0.05f;

    AzToolsFramework::ManipulatorViews views;
    views.emplace_back(AzToolsFramework::CreateManipulatorViewQuadBillboard(manipulatorColor, manipulatorSize));
    m_pointMaxDistanceManipulator->SetViews(AZStd::move(views));

    struct SharedState
    {
        float m_startingPointMaxDistance = 0.0f;
    };

    auto sharedState = AZStd::make_shared<SharedState>();
    m_pointMaxDistanceManipulator->InstallLeftMouseDownCallback(
        [this, sharedState] (const AzToolsFramework::LinearManipulator::Action& action) mutable
            {
                float currentMaxDistance = 0.0f;
                EditorLightComponentRequestBus::EventResult(
                    currentMaxDistance, GetEntityId(), &EditorLightComponentRequests::GetPointMaxDistance);
                sharedState->m_startingPointMaxDistance = currentMaxDistance;
            });

    m_pointMaxDistanceManipulator->InstallMouseMoveCallback(
        [this, sharedState](const AzToolsFramework::LinearManipulator::Action& action)
            {
                const AZ::VectorFloat axisDisplacement = action.LocalPositionOffset().Dot(action.m_fixed.m_axis);
                EditorLightComponentRequestBus::Event(
                    GetEntityId(), &EditorLightComponentRequests::SetPointMaxDistance,
                    (sharedState->m_startingPointMaxDistance + axisDisplacement).GetMax(AZ::VectorFloat(0.1f)));

                const AZ::Vector3 localPosition = action.LocalPosition().GetMax(AZ::Vector3(0.1f, 0.0f, 0.0f));
                m_pointMaxDistanceManipulator->SetLocalTransform(AZ::Transform::CreateTranslation(localPosition));
                m_pointMaxDistanceManipulator->SetBoundsDirty();
                // ensure property grid values are refreshed
                AzToolsFramework::ToolsApplicationNotificationBus::Broadcast(
                    &AzToolsFramework::ToolsApplicationNotificationBus::Events::InvalidatePropertyDisplay,
                    AzToolsFramework::Refresh_Values);
            });

    m_pointMaxDistanceManipulator->Register(AzToolsFramework::g_mainManipulatorManagerId);
```cpp
EditorPointLightComponentMode::~EditorPointLightComponentMode()
{
    m_pointMaxDistanceManipulator->Unregister();
}

void EditorPointLightComponentMode::Refresh()
{
    float currentMaxDistance = 0.0f;
    EditorLightComponentRequestBus::EventResult(
        currentMaxDistance, GetEntityId(),
        &EditorLightComponentRequests::GetPointMaxDistance);
    m_pointMaxDistanceManipulator->SetLocalTransform(
        AZ::Transform::CreateTranslation(AZ::Vector3::CreateAxisX() *
        currentMaxDistance));
} // namespace LmbrCentral
```

**Note**

Most of the code in the file is related to the manipulator. Manipulators are low-level but provide a large degree of control.

**Construction**

The Component Mode constructor contains the majority of the logic.

**To construct a Component Mode**

1. Navigate to the `lumberyard_version\dev\Gems\LmbrCentral\Code\Source\Rendering` directory.
2. In a text editor, create a file and name it `EditorPointLightComponentMode.cpp`.
3. Call the `EditorBaseComponentMode` constructor and specify the `Entity` and `ComponentId`, along with the `componentType`.

```cpp
EditorPointLightComponentMode::EditorPointLightComponentMode(
    const AZ::EntityComponentIdPair& entityComponentIdPair, AZ::Uuid componentType)
    : EditorBaseComponentMode(entityComponentIdPair, componentType) // IMPORTANT
```

**Manipulator Setup**

Next, set up the manipulator for the component.

**To set up the manipulator**

1. In the `EditorPointLightComponentMode.cpp` file, identify the `LinearManipulator` in the code.
2. Request the world transform of the entity that the component is attached to and pass that value to the constructor of the manipulator. You must set the space that the manipulator is going to operate in. With components, this value is usually the entity transform. If you want the manipulator to operate in world space, you can pass the identity transform here.

```cpp
AZ::Transform worldFromLocal = AZ::Transform::CreateIdentity();
AZ::TransformBus::EventResult(
    worldFromLocal, GetEntityId(), &AZ::TransformInterface::GetWorldTM);
```
Note

The naming `worldFromLocal` is chosen to indicate how this transform is modifying a position. For example, if you have a position in the local space of the entity, this transform takes it from local to world space. The naming style helps debug the multiplication order of transforms and vectors. Lumberyard uses column major ordering, which is a matrix multiplication that occurs right to left.

For example, if you have the vector, `localPosition` and the transform `worldFromLocal`, multiplying `worldFromLocal * localPosition` has the correct output because the local identifiers are next to each other. This transforms the `localPosition` to its position in world space.

3. (Optional) Add the `EntityId` to the manipulator. This is helpful to track manipulator undo and redo operations on entities.

During each mouse move, the added `EntityIds` are marked as `dirty`. When a manipulator action ends, Lumberyard compares the entity and component serialized state before and after the event. If the entity changed, Lumberyard records an undo step. If not, Lumberyard throws away the potential undo action. It's important to note that this tracks the change the manipulator caused on the serialized entity state. If you have other custom operations that you want to undo, create a new `UndoCommand` that derives from `URSequencePoint`.

```cpp
m_pointMaxDistanceManipulator->AddEntityId(GetEntityId());
```

4. For the `SetAxis` function, specify a vector in the local space of the entity. This defines the vector that the `LinearManipulator` moves along in local space. The following example uses the x-axis, but you can specify another vector.

```cpp
m_pointMaxDistanceManipulator->SetAxis(AZ::Vector3::CreateAxisX());
```

5. To set the position of the manipulator, query the `EditorLightComponent`. You don't have a direct reference (pointer) to the component or entity. All communication is made using EBuses.

```cpp
// From void EditorPointLightComponentMode::Refresh()
float currentMaxDistance = 0.0f;
EditorLightComponentRequestBus::EventResult(
    currentMaxDistance, GetEntityId(),
    &EditorLightComponentRequests::GetPointMaxDistance);
```

Note

Using EBuses and EntityIds offers the following advantages:

- You don't need to couple a Component Mode to a specific component. For example, `Box Shape` and `PhysX Collider` components need similar editing capabilities, such as the ability to resize the dimensions of an oriented bounding box in the viewport. The `EditorBoxShapeComponent.h` and `EditorPhysXColliderComponent.h` files include the `BoxManipulatorRequestBus`. This provides an interface to get the shape or collider transform and get or set its dimensions. This way, you can apply the `BoxComponentMode` for both files.

- You can avoid difficulties with entities being destroyed and recreated with each undo and redo action. If an entity changes while recording an undo action, the act of undoing the action destroys the current entity and recreates it by returning the entity to its previous saved state. If a Component Mode has a direct reference to the `EditorComponent` and not just an `EntityId`, managing the lifetimes would be more complex. This means that the `EditorComponent` that you want to edit must expose the get and set actions.
that you need on its request bus. Otherwise, a Component Mode can't read or write the actions.

6. The call to `SetLocalTransform` sets the transform of the manipulator. By default, this value is the same local space of the entity. To calculate this value, query the current `PointMaxDistance` and offset the manipulator handle by that distance along the x-axis.

In the following example, the `ManipulatorView` doesn't have an orientation. You can specify `CreateTranslation` on the `Transform` class.

```cpp
// From void EditorPointLightComponentMode::Refresh()
m_pointMaxDistanceManipulator->SetLocalTransform(AZ::Transform::CreateTranslation(AZ::Vector3::CreateAxisX() * currentMaxDistance));
```

7. Configure the `ManipulatorView`.

The behavior of a manipulator is decoupled from how it appears in the viewport. This means that a `LinearManipulator` can look like a line, cone, cube, or screen-aligned quad. `LinearManipulator` supports multiple views, which is useful with the classic `TranslationManipulator`. You can draw a line and cone (an arrow) to represent the `LinearManipulator` that corresponds to each axis.

8. Create an `AZStd::vector` of views and a `QuadBillboardView` that specifies the color and dimensions of the shape.

9. Add the new views to the manipulator itself with `SetViews`.

**Example**

```cpp
const AZ::Color manipulatorColor(0.3f, 0.3f, 0.3f, 1.0f);
const float manipulatorSize = 0.05f;
AZToolsFramework::ManipulatorViews views;
views.emplace_back(AZToolsFramework::CreateManipulatorViewQuadBillboard(manipulatorColor, manipulatorSize));
m_pointMaxDistanceManipulator->SetViews(AZStd::move(views));
```

10. Save the file.

**Example**

Your code should look like the following so far.

```cpp
// EditorPointLightComponentMode::EditorPointLightComponentMode()
AZ::Transform worldFromLocal = AZ::Transform::CreateIdentity();
AZ::TransformBus::EventResult(
    worldFromLocal, GetEntityId(), &AZ::TransformInterface::GetWorldTM);

m_pointMaxDistanceManipulator =
    AZToolsFramework::LinearManipulator::MakeShared(worldFromLocal);
m_pointMaxDistanceManipulator->AddEntityId(GetEntityId());
m_pointMaxDistanceManipulator->SetAxis(AZ::Vector3::CreateAxisX());

// Refresh(); inlined/expanded
float currentMaxDistance = 0.0f;
EditorLightComponentRequestBus::EventResult(
    currentMaxDistance, GetEntityId(), &EditorLightComponentRequests::GetPointMaxDistance);

m_pointMaxDistanceManipulator->SetLocalTransform(AZ::Transform::CreateTranslation(AZ::Vector3::CreateAxisX() * currentMaxDistance));
const AZ::Color manipulatorColor(0.3f, 0.3f, 0.3f, 1.0f);
```
const float manipulatorSize = 0.05f;

AzToolsFramework::ManipulatorViews views;
views.emplace_back(AzToolsFramework::CreateManipulatorViewQuadBillboard(manipulatorColor,
manipulatorSize));

m_pointMaxDistanceManipulator->SetViews(AZStd::move(views));

### Manipulator Callbacks

Next, set up how the manipulator should respond when you interact with it in the viewport.

### To set up manipulator callbacks

1. In the EditorPointLightComponentMode.cpp file, enter the following code to create a piece of shared state that each callback can use.

```cpp
struct SharedState
{
    float m_startingPointMaxDistance = 0.0f;
};

auto sharedState = AZStd::make_shared<SharedState>();
```

**Note**

You can add a member to the EditorPointLightComponentMode and refer to that in each lambda expression. However, because only the lambda expressions care about this state, keep its scope as constrained as possible.

2. Use AZStd::shared_ptr to ensure that the lambda expressions capture the pointer by value. This guarantees that the lambda expressions own the shared state and effectively close over it. This is similar to a closure in JavaScript.

```cpp
m_pointMaxDistanceManipulator->InstallLeftMouseDownCallback(
    [this, sharedState] (const AzToolsFramework::LinearManipulator::Action& /*action*/) mutable
    {
        float currentMaxDistance = 0.0f;
        EditorLightComponentRequestBus::EventResult(
            currentMaxDistance, GetEntityId(),
            &EditorLightComponentRequests::GetPointMaxDistance);

        sharedState->m_startingPointMaxDistance = currentMaxDistance;
    });
```

3. Reference the data contained in EditorPointLightComponentMode so that it can capture the this pointer.

```cpp
m_pointMaxDistanceManipulator->InstallMouseMoveCallback(
    [this, sharedState] (const AzToolsFramework::LinearManipulator::Action& action)
    {
        const AZ::VectorFloat axisDisplacement =
            action.LocalPositionOffset().Dot(action.m_fixed.m_axis);

        EditorLightComponentRequestBus::Event(
            GetEntityId(), &EditorLightComponentRequests::SetPointMaxDistance,
            (sharedState->m_startingPointMaxDistance +
            axisDisplacement).GetMax(AZ::VectorFloat(0.1f)));

        const AZ::Vector3 localPosition = action.LocalPosition().GetMax(AZ::Vector3(0.1f, 0.0f, 0.0f));
```
Lumberyard User Guide
Programmer's Guide to Component Mode

m_pointMaxDistanceManipulator->SetLocalTransform(AZ::Transform::CreateTranslation(localPosition));

m_pointMaxDistanceManipulator->SetBoundsDirty();

// ensure property grid values are refreshed
AzToolsFramework::ToolsApplicationNotificationBus::Broadcast(
    &AzToolsFramework::ToolsApplicationNotificationBus::Events::InvalidatePropertyDisplay,
    AzToolsFramework::Refresh_Values);
});

The callback that you get from the LinearManipulator passes a struct called Action. This struct contains information about the current state of the manipulator.

4. To determine how far you move along the axis, add a .Dot between the LocalPositionOffset and the fixed axis of the manipulator. This gives you a projection of the LocalPositionOffset onto the axis and the distance moved.

```cpp
const AZ::VectorFloat axisDisplacement = action.LocalPositionOffset().Dot(action.m_fixed.m_axis);
```

The manipulator action has three parts. You can specify these properties to control how they should modify your component.

- **Fixed** – Contains data associated with the manipulator, which is set at creation. Often, this is the axis or plane of movement.
- **Start** – State of the manipulator at MouseDown.
- **Current** – Current state of the manipulator during a MouseMove.

5. After you calculate the axisDisplacement, specify that value to set the current PointMaxDistance, which updates the state of the component. You must update the LocalTransform of the manipulator. If you don't, the visual representation of the manipulator doesn't change. To do this, read the LocalPosition of the action and set the LocalTransform of the manipulator.

```cpp
const AZ::Vector3 localPosition = action.LocalPosition().GetMax(AZ::Vector3(0.1f, 0.0f, 0.0f));
m_pointMaxDistanceManipulator->SetLocalTransform(AZ::Transform::CreateTranslation(localPosition));
```

6. After you update the LocalTransform of the manipulator, you must mark its bounds as dirty so that they can be recalculated for intersection tests.

```cpp
m_pointMaxDistanceManipulator->SetBoundsDirty();
```

7. Enter the following code to notify the editor that you modified a property that needs to be refreshed in the Entity Inspector. If you don't make this update, the component's properties in the Entity Inspector don't match with how the component appears in the viewport.

```cpp
AzToolsFramework::ToolsApplicationNotificationBus::Broadcast(
    &AzToolsFramework::ToolsApplicationNotificationBus::Events::InvalidatePropertyDisplay,
    AzToolsFramework::Refresh_Values);
```

8. Register the manipulator with the main ManipulatorManager. This ensures that this manipulator is associated with the main viewport.

```cpp
m_pointMaxDistanceManipulator->Register(AzToolsFramework::g_mainManipulatorManagerId);
```
9. You must unregister the manipulator from the ManipulatorManager when it gets destroyed. To do this, add this function to your Component Mode destructor.

```cpp
EditorPointLightComponentMode::~EditorPointLightComponentMode()
{
    m_pointMaxDistanceManipulator->Unregister();
}
```

**Example**

In the following code, override `InstallLeftMouseDownCallback` and `InstallMouseMoveCallback` callbacks to achieve the preferred behavior. This code lists the callback logic.

```cpp
struct SharedState
{
    float m_startingPointMaxDistance = 0.0f;
};
auto sharedState = AZStd::make_shared<SharedState>();

m_pointMaxDistanceManipulator->InstallLeftMouseDownCallback(
    [this, sharedState](const AzToolsFramework::LinearManipulator::Action& /*action*/)
    mutable
    {
        float currentMaxDistance = 0.0f;
        EditorLightComponentRequestBus::EventResult(
            currentMaxDistance, GetEntityId(),
            &EditorLightComponentRequests::GetPointMaxDistance);
        sharedState->m_startingPointMaxDistance = currentMaxDistance;
    });

m_pointMaxDistanceManipulator->InstallMouseMoveCallback(
    [this, sharedState](const AzToolsFramework::LinearManipulator::Action& action)
    {
        const AZ::VectorFloat axisDisplacement = action.LocalPositionOffset().Dot(action.m_fixed.m_axis);
        EditorLightComponentRequestBus::Event(
            GetEntityId(), &EditorLightComponentRequests::SetPointMaxDistance,
            (sharedState->m_startingPointMaxDistance +
                axisDisplacement).GetMax(AZ::VectorFloat(0.1f)));

        const AZ::Vector3 localPosition = action.LocalPosition().GetMax(AZ::Vector3(AZ::VectorFloat(0.1f)));
        m_pointMaxDistanceManipulator->SetLocalTransform(AZ::Transform::CreateTranslation(localPosition));
        m_pointMaxDistanceManipulator->SetBoundsDirty();
        // ensure property grid values are refreshed
        AzToolsFramework::ToolsApplicationNotificationBus::Broadcast(
            &AzToolsFramework::ToolsApplicationNotificationBus::Events::InvalidatePropertyDisplay,
            AzToolsFramework::Refresh_Values);
    });
```

10. To see a Component Mode in action, switch back to the `EditorPointLightComponent.h` and remove the comment lines that you added to your code. See `EditorPointLightComponent.cpp` (p. 995).

```cpp
#include "EditorPointLightComponentMode"
```
Step 4: Add Shortcuts for Component Mode

In the following procedure, create shortcuts that are specific to the component that you're editing. For example, if you're editing a Spline component and want to add shortcuts for working with vertices, you can create a shortcut such as Ctrl+D to duplicate a point or Delete to remove it. When adding shortcuts, note the following changes in your code:

- EditorBaseComponentMode provides an additional function to override in its interface called PopulateActionsImpl.

```cpp
AZStd::vector<AzToolsFramework::ActionOverride> PopulateActionsImpl() override;
```

- The PopulateActionsImpl function returns a vector of available actions that you can perform in Component Mode. By default, you always get the following shortcuts, which you can't change:
  - Ctrl+S – Save
  - Ctrl+Z – Undo
  - Ctrl+Shift+Z – Redo
  - Esc – Leave Component Mode

To create shortcuts for Component Mode

1. In the EditorPointLightComponentMode.cpp file, create an ActionOverride struct and use the Set chain methods to improve readability. The most important piece of this change is a unique identifier. The format is a reverse URL: com.company.action.component.type.

```cpp
static const AZ::Crc32 s_resetPointLight = AZ_CRC("com.amazon.action.pointlight.reset") ;
```

2. Specify what shortcut to use and then enter a name and description so that the shortcut appears in the Edit menu.

```cpp
.SetKeySequence(QKeySequence(Qt::Key_R))
.SetTitle("Reset")
.SetTip("Reset all Point Light State")
.SetEntityComponentIdPair(AZ::EntityComponentIdPair(GetEntityId(), GetComponentId()));
```

Note
You must provide the entity and component ID that this action corresponds to and finally the event or callback itself to perform.

3. To ensure that you can undo this action, create an undo batch and mark the entity as dirty.

```cpp
// Ensure that we record undo command for reset
AzToolsFramework::ScopedUndoBatch undoBatch("Reset Point Light");
AzToolsFramework::ScopedUndoBatch::MarkEntityDirty(entityId);
```
4. The current and next states of the entity are compared, and if they don't match, the undo action is recorded. Follow the `undoBatch` function with a series of calls to reset the state of the component and then refresh and update the position of any manipulators so that they accurately reflect the state of the component.

```cpp
/// Other set functions to return state to default...
// refresh manipulators
Refresh();

// ensure property grid values are refreshed
AzToolsFramework::ToolsApplicationNotificationBus::Broadcast(
    &AzToolsFramework::ToolsApplicationNotificationBus::Events::InvalidatePropertyDisplay,
    AzToolsFramework::Refresh_Values);
```

5. Save your file.

**Example EditorPointLightComponentMode.cpp**

You can add additional actions such as a shortcut to reset all properties on the component like the following.

```cpp
static const AZ::Crc32 s_resetPointLight = AZ_CRC("com.amazon.action.pointlight.reset") ;
AZStd::vector<AzToolsFramework::ActionOverride>
EditorPointLightComponentMode::PopulateActionsImpl()
{
    return AZStd::vector<AzToolsFramework::ActionOverride>
    {
        AzToolsFramework::ActionOverride()
        .SetUri(s_resetPointLight)
        .SetKeySequence(QKeySequence(Qt::Key_R))
        .SetTitle("Reset")
        .SetTip("Reset all Point Light State")
        .SetEntityComponentIdPair(AZ::EntityComponentIdPair(GetEntityId(), GetComponentId()))
        .SetCallback([this]() {
            const AZ::EntityId entityId = GetEntityId();

            // ensure we record undo command for reset
            AzToolsFramework::ScopedUndoBatch undoBatch("Reset Point Light");
            AzToolsFramework::ScopedUndoBatch::MarkEntityDirty(entityId);

            EditorLightComponentRequestBus::Event(
                entityId, &EditorLightComponentRequests::SetPointMaxDistance, 1.0f);

            /// other set functions to return state to default...

            // refresh manipulators
            Refresh();

            // ensure property grid values are refreshed
            AzToolsFramework::ToolsApplicationNotificationBus::Broadcast(
                &AzToolsFramework::ToolsApplicationNotificationBus::Events::InvalidatePropertyDisplay,
                AzToolsFramework::Refresh_Values);
        });
    }
};
```
Step 5: Handle Selection in the Viewport

In the following procedure, make changes to your code so that you can enter Component Mode by double-clicking the component in the viewport.

In Component Mode, you can modify the dimensions of the **Point Light** component directly in the viewport.

**To handle selection in the viewport**

1. In a text editor, open the `EditorPointLightComponent.h` file.
2. For the last parameter, add the `EditorComponentSelectionRequestsBus::Handler`.

```cpp
class EditorPointLightComponent
    : public EditorLightComponent,
     private AzToolsFramework::EditorComponentSelectionRequestsBus::Handler
```

3. To implement the `EditorComponentSelectionRequests`, you must override the following four functions:
   1. `GetEditorSelectionBoundsViewport` – Returns an AABB encompassing the visible extents of your component
   2. `EditorSelectionIntersectRayViewport` – Where you implement selection for the component
   3. `SupportsEditorRayIntersect` – Override this function and return true if you implemented `EditorSelectionIntersectRayViewport`
   4. `GetBoundingBoxDisplayType` – Used for debugging to ensure that the AABB is the correct fit.
      This example sets the function to `NoBoundingBox`

```cpp
// EditorComponentSelectionRequests
AZ::Aabb GetEditorSelectionBoundsViewport(const AzFramework::ViewportInfo& viewportInfo) override;
bool EditorSelectionIntersectRayViewport(const AzFramework::ViewportInfo& viewportInfo, const AZ::Vector3& src, const AZ::Vector3& dir, AZ::VectorFloat& distance) override;
bool SupportsEditorRayIntersect() override;
AZ::u32 GetBoundingBoxDisplayType() override;
```

4. Save the file.
5. In a text editor, open the `EditorPointLightComponent.cpp` file.
6. Connect and disconnect from the `EditorComponentSelectionRequestsBus` in the `Activate` and `Deactivate` functions of the component.

```cpp
void EditorPointLightComponent::Activate()
{
    ...
    AzToolsFramework::EditorComponentSelectionRequestsBus::Handler::BusConnect(GetEntityId());
    ...
}

void EditorPointLightComponent::Deactivate()
{
    ...
    AzToolsFramework::EditorComponentSelectionRequestsBus::Handler::BusDisconnect();
    ...
```
7. Add the following changes to your code:

- Add an implementation of `SupportsEditorRayIntersect` to return `true`. By default, this function returns `false`.
- Add an implementation of `GetBoundingBoxDisplayType` to return:
  
  ```cpp
  AzToolsFramework::EditorComponentSelectionRequests::BoundingBoxDisplay::NoBoundingBox
  ```

```cpp
bool EditorPointLightComponent::SupportsEditorRayIntersect()
{
    return true;
}

AZ::u32 EditorPointLightComponent::GetBoundingBoxDisplayType()
{
    return AzToolsFramework::EditorComponentSelectionRequests::BoundingBoxDisplay::NoBoundingBox;
}
```

**Note**

It's possible to instead return the:

```cpp
AzToolsFramework::EditorComponentSelectionRequests::BoundingBoxDisplay::BoundingBox
```

for debugging, but you shouldn't leave it enabled.

The next two functions show how to implement the picking and selection support.

8. Add the implementation for the `GetEditorSelectionBoundsViewport` function.

9. Create an AABB centered around the component covering its extents. In this case, get the position in world space of the entity and create an AABB with the radius of the point light. Because the point light is represented as a sphere, use the `GetPointMaxDistance` function.

**Example**

Your code should look like the following.

```cpp
AZ::Aabb EditorPointLightComponent::GetEditorSelectionBoundsViewport(
    const AzFramework::ViewportInfo& viewportInfo)
{
    AZ::Vector3 worldTranslation = AZ::Vector3::CreateZero();
    AZ::TransformBus::EventResult(
        worldTranslation, GetEntityId(), &AZ::TransformInterface::GetWorldTranslation);
    return AZ::Aabb::CreateCenterRadius(worldTranslation, GetPointMaxDistance());
}
```

In the next step, make changes to the `EditorSelectionIntersectRayViewport` function.

**Example**

```cpp
// top of file
<AzToolsFramework/Picking/Manipulators/ManipulatorBounds.h>

...

bool EditorPointLightComponent::EditorSelectionIntersectRayViewport(
    const AzFramework::ViewportInfo& viewportInfo,
    const AZ::Vector3& src, const AZ::Vector3& dir, AZ::VectorFloat& distance)
{
```
AZ::Transform worldFromLocal = AZ::Transform::CreateIdentity();
AZ::TransformBus::EventResult(worldFromLocal, GetEntityId(), &AZ::TransformInterface::GetWorldTM);

const float minorRadius = 0.1f;
const float majorRadius = GetPointMaxDistance();

const AZ::Vector3 axes[] = {
    AZ::Vector3::CreateAxisX(), AZ::Vector3::CreateAxisY(),
    AZ::Vector3::CreateAxisZ()
};

enum { AxisCount = 3 };
float distances[AxisCount] = { FLT_MAX, FLT_MAX, FLT_MAX };
bool intersection = false;
for (size_t axisIndex = 0; axisIndex < AxisCount; ++axisIndex)
{
    intersection = intersection
        || AzToolsFramework::Picking::IntersectHollowCylinder(
            src, dir, worldFromLocal.GetTranslation(), axes[axisIndex],
            minorRadius, majorRadius, distances[axisIndex]);
}

return intersection;

10. Get the position of the entity in world space and approximate a torus or flat hollow cylinder to
represent the rings of the Point Light component. The minor radius corresponds to the tube part of
the torus, which is its thickness.

11. You want a radius that is a reasonable size so that you can easily select it in the viewport. The major
radius is the distance from the center of the torus to the middle of the tube. Because you have a
ring for each axis, check that each one is using the IntersectHollowCylinder function, which
basically approximates a torus.

12. Test a ring for each axis and store the intersection distances to find the closest intersection.

    { 
        intersection = intersection
            || AzToolsFramework::Picking::IntersectHollowCylinder(
                src, dir, worldFromLocal.GetTranslation(), axes[axisIndex],
                minorRadius, majorRadius, distances[axisIndex]);
    }

    distance = AZ::GetMin(AZ::GetMin(distances[0], distances[1]), distances[2]);

13. Save the file.

Step 6: Building Component Mode

In the following procedure, you must build the editor so that you can view your changes in Lumberyard
Editor.

To build Component Mode

1. Navigate to the lumberyard_version\dev\Gems\LmbrCentral\Code directory.
2. In a text editor, open the `lmbrcentral_editor.waf_files.waf` file.
3. Navigate to the "Source/Rendering": section and add the files that you created for a Component Mode.

**Example**

```
"Source/Rendering/EditorPointLightComponent.h",
"Source/Rendering/EditorPointLightComponent.cpp",
"Source/Rendering/EditorPointLightComponentMode.h",
"Source/Rendering/EditorPointLightComponentMode.cpp",
```

4. Save the file.
5. Navigate to the `lumberyard_version/`dev directory.
6. In a command-line window, enter the following commands to build the editor.

```
lmbr_waf configure

lmbr_waf build_win_x64_vs2017_profile -p all
```

7. After your build succeeds, open Lumberyard Editor and choose or create a level.
8. In the viewport, create an entity, attach the **Point Light** component, and do one of the following:

   - Double-click the entity
   - In the **Entity Inspector**, choose **Edit**

9. Make changes to your component in the viewport. You can select the manipulator on the **Point Light** component to adjust the radius of the light area.
10. When you've finished, choose **Done**.

**Tips for Working with Component Mode**

See the following tips for adding a Component Mode to your component.

**Additional Input Handling**

If you want to handle mouse events in a specific way (for example, outside of using manipulators), you can override `HandleMouseInteraction`, which is part of the `EditorBaseComponentMode` class that is defined in the `ComponentModeRequestBus`.

---

**Version 1.28**

1014
This `HandleMouseInteraction` function is called whenever a mouse event happens. The `MouseInteractionEvent`, which is passed as an argument to the function, contains information such as the mouse pick ray, position in screen space, and buttons and modifier keys that are pressed.

```cpp
// EditorBaseComponentMode
void Refresh() override;
bool HandleMouseInteraction(
    const AzToolsFramework::ViewportInteraction::MouseInteractionEvent& mouseInteraction)
override;
```

**Additional Drawing**

If you want to add additional debug drawing while in Component Mode, you can implement the `AzFramework::EntityDebugDisplayEventBus` and then override `DisplayEntityViewport`. Remember to connect the `EntityDebugDisplayEventBus` in the Component Mode constructor and disconnect in the destructor.

This can be useful for additional drawing for an entity and its components.

**Note**

The `EntityDebugDisplayEventBus` is only addressed by `EntityId`. You might encounter issues when working with multiple components of the same type on a given entity.

See the following example for the `.h` file.

```cpp
// EditorPointLightComponentMode.h
// AzFramework::EntityDebugDisplayEventBus
void DisplayEntityViewport(
    const AzFramework::ViewportInfo& viewportInfo,
    AzFramework::DebugDisplayRequests& debugDisplay) override;
```

See the following example for the implementation `.cpp` file.

```cpp
// EditorPointLightComponentMode.cpp
EditorPointLightComponentMode::EditorPointLightComponentMode(
    const AZ::EntityComponentIdPair& entityComponentIdPair, AZ::Uuid componentType)
: EditorBaseComponentMode(entityComponentIdPair, componentType)
{
    ... 
    AzFramework::EntityDebugDisplayEventBus::Handler::BusConnect(GetEntityId());
}

EditorPointLightComponentMode::~EditorPointLightComponentMode()
{
    AzFramework::EntityDebugDisplayEventBus::Handler::BusDisconnect();
    ...
}

void EditorPointLightComponentMode::DisplayEntityViewport(
    const AzFramework::ViewportInfo& /*viewportInfo*/,
    AzFramework::DebugDisplayRequests& debugDisplay)
{
    ... 
}
```

**Components and EBuses**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
EBuses are not required for components, nor are they directly bound to components in any way. But because they form the backbone of communication among all Lumberyard components, EBuses offer many benefits. We highly recommend that you learn how to use them in your game, systems, and components. For more information, see Working with the Event Bus (EBus) system (p. 1851).

Most components provide two EBuses to facilitate communication: a request bus and a notification bus. Both these EBuses use the EBusAddressPolicy::ById address policy and the ID of the entity for identification.

**Request Bus**

A component's request bus allows other components or external systems to make requests of the component. Usually the runtime version of the component implements the request bus. However, the editor component can service the bus in special cases.

The following sections examine the individual parts of an example request bus.

**Transform Request Event Group**

The following example defines a group of events that the TransformComponent handles.

```cpp
class TransformComponentRequests
 : public AZ::ComponentBus // EBus traits for component buses: identification is based on an entity ID.
{
    public:

    // EBusTraits overrides - Only a single handler is allowed for a given entity ID.
    // Only one component on a entity can implement the events.
    static const EBusHandlerPolicy HandlerPolicy = EBusHandlerPolicy::Single;

    // Returns the local transform (parent transform excluded).
    virtual const Transform& GetLocalTM() = 0;

    // Sets the local transform and notifies all interested parties.
    virtual void SetLocalTM(const Transform& /*tm*/) {}

    // Returns the world transform (including parent transform).
    virtual const Transform& GetWorldTM() = 0;

    // Sets the world transform and notifies all interested parties.
    virtual void SetWorldTM(const Transform& /*tm*/) {}

    // Returns both local and world transforms.
    virtual void GetLocalAndWorld(Transform& /*localTM*/, Transform& /*worldTM*/) {}

    ...;
};
```

**Base Class and Trait Specification**

The base class for most AZ::Component request buses is AZ::ComponentBus. This class is a convenience to help set up EBus traits typical of component EBuses. You could also set up EBus traits by inheriting the default AZ::EBusTraits. Then you could optionally override any or all of the following traits. For more information, see EBus Configuration Options (p. 1854).

- Address policy
- Bus ID type
- Connection policy
- Handler policy
- Lock type
- Priority sorting

These two approaches are shown in the following examples.

```cpp
// Example using AZ::ComponentBus.
class TransformComponentRequests : public AZ::ComponentBus {
(...)
```

```cpp
// Example using AZ::EBusTraits
class TransformComponentRequests : public AZ::EBusTraits {
{
(...)
  // EBusTraits overrides.
  static const EBusAddressPolicy AddressPolicy = EBusAddressPolicy::ById; // OR YOUR CHosen POLICY
  static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Multiple; // OR YOUR CHosen POLICY
  using BusIdType = EntityId;
(...)
```

**EBus Request Bus Events**

EBus event definitions are the main part of the bus specification. This interface defines what your component does. In the following example, the TransformComponent allows the retrieval and modification of the local and world transforms. It also creates interfaces for setting parent–child relationships.

```cpp
...
// Returns the local transform (parent transform excluded).
virtual const Transform& GetLocalTM() = 0;

// Sets the local transform and notifies all interested parties.
virtual void SetLocalTM(const Transform& /*tm*/) {}

// Returns the world transform (including parent transform).
virtual const Transform& GetWorldTM() = 0;

// Sets the world transform and notifies all interested parties.
virtual void SetWorldTM(const Transform& /*tm*/) {}

// Returns both local and world transforms.
virtual void GetLocalAndWorld(Transform& /*localTM*/, Transform& /*worldTM*/) {};
...
```

**EBus Request Bus Definition**

After the event group has been declared, the EBus must be defined. Although you can use `AZ::EBus<TransformComponentRequests>` to define an EBus, we recommend that you use a typedef instead, as in the following example. This improves readability at bus call sites.

```cpp
typedef AZ::EBus<TransformComponentRequests> TransformComponentRequestBus;
```
Another best practice is to use descriptive names in EBuses and avoid overloaded functions. Explicit and descriptive function names prevent future API name collisions as classes inherit (potentially many of) your EBus interfaces. Avoiding overloaded functions improves the experience of using your EBuses from scripting environments. In Lua and in visual scripting, the extra expressiveness improves readability and clarity.

### Notification Bus

A component uses its notification bus to inform other components and the rest of the engine about relevant changes. To do this, it sends notifications in the form of EBus events to any class that monitors the bus. To monitor the bus, classes implement the notification bus handler interface (in the case of TransformComponent, this is `AZ::TransformNotificationBus::Handler`.)

**Note**

A request bus sends messages to a component; a notification bus sends messages from a component.

### Transform Notification Event Group

The following example defines a group of notification events that the TransformComponent sends.

```cpp
class TransformNotifications : public AZ::ComponentBus
{
public:
...
    // Called when the local transform of the entity has changed. Local transform update always implies world transform change too.
    virtual void OnTransformChanged(const Transform& /*local*/, const Transform& /*world*/) {}
};
```

The notification bus can also change its EBusTrait specification if required.

### Components as EBus Handlers

After you have created the EBus event groups and defined the EBuses, your component can implement the EBus interface by deriving the EBus handler. The following example is from the TransformComponent.

```cpp
class TransformComponent : public AZ::Component,
    private AZ::TransformComponentRequestBus::Handler
{
    ...

    // TransformBus.

    /// Returns true if the tm was set to the local transform.
    const AZ::Transform& GetLocalTM() override { return m_localTM; }

    /// Sets the local transform and notifies all interested parties.
    void SetLocalTM(const AZ::Transform& tm) override;

    /// Returns true if the transform was set to the world transform.
    const AZ::Transform& GetWorldTM() override { return m_worldTM; }
```
Tick Bus and Components

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The tick bus is the primary mechanism by which components subscribe to events that occur per simulation frame. Instead of connecting components to the tick bus, strive to make your components entirely driven by events. If your component requires tick-based functionality, it can implement the tick bus interface’s `OnTick` method and connect to the tick bus for the required period of time. To avoid poor scalability of polling-based update structures, components should limit the time that they are connected to the tick bus.

Traditionally, a component might use the `OnTick` method to check the state continuously but actively do processing for only a fraction of the connected time. Instead, the component should connect to the tick bus only when the state changes and disconnect after processing is complete. This approach is closer to that of event-based programming, in which polling is conducted only for short periods of time or not at all.

As an example, imagine a component that monitors the state of an entity after the entity enters a trigger. The component should avoid subscribing to the tick bus until the entity has entered the trigger. It should then disconnect from the tick bus as soon as the entity has left the trigger.

In the following example, the `NavigationComponent` implements the `OnTick` method.

```cpp
class NavigationComponent
    : public AZ::Component
    , public NavigationComponentRequestBus::Handler
    , public AZ::TickBus::Handler
{
    ... 
    // TickBus
    virtual void OnTick(float deltaTime, AZ::ScriptTimePoint time);
    ... 
}
```

To connect and disconnect from the tick bus, the component uses code like the following.

```cpp
AZ::TickBus::Handler::BusConnect();

AZ::TickBus::Handler::BusDisconnect();
```
Customizing Tick Order

By default, a handler receives events based on the order in which the components are initialized. To control the order that your component receives OnTick events, you can override the GetTickOrder() function to return a custom integer value. The integer value determines the order in which your component is ticked relative to other components on the tick bus. Lower values are ticked before higher values. Any value is permitted. For convenience, the AZ::ComponentTickBus enum (TickBus.h) provides some preset values. These values are shown in the following table.

### Tick Order Preset Values

<table>
<thead>
<tr>
<th>Name (C++)</th>
<th>Name (Lua/Script Canvas)</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TICK_FIRST</td>
<td>TickOrder.First</td>
<td>0</td>
<td>First position in the tick handler order.</td>
</tr>
<tr>
<td>TICK_PLACEMENT</td>
<td>TickOrder.Placement</td>
<td>50</td>
<td>Suggested tick handler position for components that need to be early in the tick order.</td>
</tr>
<tr>
<td>TICK_INPUT</td>
<td>TickOrder.Input</td>
<td>75</td>
<td>Suggested tick handler position for input components.</td>
</tr>
<tr>
<td>TICK_GAME</td>
<td>TickOrder.Game</td>
<td>80</td>
<td>Suggested tick handler position for game-related components.</td>
</tr>
<tr>
<td>TICK_ANIMATION</td>
<td>TickOrder.Animation</td>
<td>100</td>
<td>Suggested tick handler position for animation components.</td>
</tr>
<tr>
<td>TICK_PHYSICS</td>
<td>TickOrder.Physics</td>
<td>200</td>
<td>Suggested tick handler position for physics components.</td>
</tr>
<tr>
<td>TICK_ATTACHMENT</td>
<td>TickOrder.Attachment</td>
<td>500</td>
<td>Suggested tick handler position for attachment components.</td>
</tr>
<tr>
<td>TICK_PRE_RENDER</td>
<td>TickOrder.PreRender</td>
<td>750</td>
<td>Suggested tick handler position to update render-related data.</td>
</tr>
<tr>
<td>TICK_DEFAULT</td>
<td>TickOrder.Default</td>
<td>1000</td>
<td>Default tick handler position when the handler is constructed.</td>
</tr>
<tr>
<td>TICK_UI</td>
<td>TickOrder.UI</td>
<td>2000</td>
<td>Suggested tick handler position for UI components.</td>
</tr>
<tr>
<td>TICK_LAST</td>
<td>TickOrder.Last</td>
<td>10000</td>
<td>Last position in the tick handler order.</td>
</tr>
</tbody>
</table>

The following code examples show how to override the GetTickOrder() function in Lua and in C++.

```lua
-- Lua example
defunction MyLuaUIComponent:GetTickOrder()
    return TickOrder.UI
end
```

```cpp
// C++ example
int MyCppUIComponent::GetTickOrder()
{
    return TICK_UI;
}
```
Note
As of Lumberyard version 1.11, use of the `TickEvents::m_tickOrder` variable is deprecated. If you change the value of `m_tickOrder` instead of overriding `GetTickOrder()`, you will receive a warning. However, your component will still tick in the appropriate order.

Event-Based Programming and Event-Based Polling: Best Practices
It is important to know when to use the tick bus and when to use event-driven programming patterns instead.

Event-Based Polling
It is often convenient to tick a component every frame and monitor the state of other entities. For example, a `LookAt` camera component is commonly implemented to tick each frame, retrieve the transform of the target entity, and update its own transform accordingly.

Event-Based Programming
In Lumberyard, a more event-driven approach is to use the `TransformBus` to monitor the target entity for transform changes in a purely event-driven fashion. If the target entity doesn’t move, no work is done and no polling is required. When the target entity moves, the `LookAt` component adjusts its own entity's transform accordingly.

Use Notifications to Make Your Components Easy to Use
When authoring a component, try to anticipate the requirements of components that might depend on yours. Use a notification bus to expose the appropriate notifications for your component. This approach enables others to write code that consumes the services of your components in a faster and more scalable way.

For more best practices, see Components and EBuses: Best Practices (p. 1026).

Exposing Custom Components to Track View for Animation

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To include custom components in cinematic cut scenes and movies rendered to disk, you must expose animatable component properties to Lumberyard's Track View and `Entity Inspector`. To expose a custom component and its properties, you must perform three steps:

1. Create getter and setter methods for the animated property on one of the component’s request event buses.
2. Implement the getter and setter request handlers in your component.
3. Reflect your component to the edit context and the behavior context. Edit context reflection exposes your component in `Entity Inspector`, and behavior context reflection exposes it in the Track View.

Exposing a Custom Component: Example
The following example assumes that a custom component called `ImaginaryTargetComponent` has been created. The component has a `Vector3` property called `ImaginaryPosition` that you want...
to animate in Track View. A request bus called ImaginaryTargetComponentBus has also been created for the component. This example assumes that you are familiar with programming event buses and component handlers for them. For more information, see Working with the Event Bus (EBus) system (p. 1851) and Creating a Component (p. 974).

To expose a custom component to Track View

1. Create getter and setter methods

   Each property must provide a method to set its value and get its current value. To implement this, create setter and getter methods on one of the component's request buses. Then reflect those methods to the behavior context as part of the class reflection for the component.

   The following example creates setter and getter requests on the ImaginaryTargetComponentRequestBus.

   ```c++
   /*! *
   * ImaginaryTargetComponentRequests EBus Interface
   * Messages serviced by ImaginaryTargetComponents.
   */
   class ImaginaryTargetComponentRequests : public AZ::ComponentBus
   {
   public:

   // EBusTraits overrides - Application is a singleton.
   // Only one component on an entity can implement the events.
   static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Single;

   virtual AZ::Vector3 GetImaginaryTargetPosition() = 0;
   virtual void SetImaginaryTargetPosition(const AZ::Vector3& newPosition) = 0;
   
   using ImaginaryTargetComponentRequestBus = AZ::EBus<ImaginaryTargetComponentRequests>;
   }
   ```

2. Implement handlers in your component

   Implement handlers in your component for the setter and getter requests that you declared in the first step, as in the following example.

   ```c++
   class ImaginaryTargetComponent : public AzToolsFramework::Components::EditorComponentBase,
   public LmbrCentral::ImaginaryTargetComponentRequestBus::Handler
   {
   public:

   A2_EDITOR_COMPONENT(ImaginaryTargetComponent, "{4491D282-C120-4B2E-BC63-AC86296956A2}");

   ImaginaryTargetComponent() : m_imaginaryPosition(.0f) {};

   // ImaginaryTargetComponentRequestBus::Handler implementation.

   // Presumably these would be used for something useful; this example just
   // stores and returns the value.
   AZ::Vector3 GetImaginaryTargetPosition() override { return m_imaginaryPosition; }
   void SetImaginaryTargetPosition(const AZ::Vector3& newPosition) override
   { m_imaginaryPosition = newPosition; }

   protected:

   // Required Reflect function.
   static void Reflect(AZ::ReflectContext* context);
   ```
3. **Reflect your component**

Using the edit context and behavior contexts, reflect the component's class, request event bus, and setter and getter methods. Track View uses the setter and getter methods that you reflect in this step to set and get values for your animated property. You must also reflect a VirtualProperty declaration that tells Track View that your component is capable of being animated.

```cpp
/*static*/ void ImaginaryTargetComponent::Reflect(AZ::ReflectContext* context)
{
    AZ::SerializeContext* serializeContext =
        azrtti_cast<AZ::SerializeContext*>(context);

    if (serializeContext)
    {
        serializeContext->Class<ImaginaryTargetComponent,
            AzToolsFramework::Components::EditorComponentBase>()
            ->Version(0)
            ->Field("ImaginaryPosition",
                &ImaginaryTargetComponent::m_imaginaryPosition);

        AZ::EditContext* editContext = serializeContext->GetEditContext();
        if (editContext)
        {
            editContext->Class<ImaginaryTargetComponent>("ImaginaryTarget", "A Code Sample enabling Track View Animation")
                ->ClassElement(AZ::Edit::ClassElements::EditorData,"
                    ->Attribute(AZ::Edit::Attributes::Category, "Game")
                    ->Attribute(AZ::Edit::Attributes::AppearsInAddComponentMenu,
                        AZ_CRC("Game", 0x232b318c))
                ->DataElement(0, &ImaginaryTargetComponent::m_imaginaryPosition,
                    "Imaginary Target Pos", "Imaginary Target Position")
            ;
        }
    }

    AZ::BehaviorContext* behaviorContext = azrtti_cast<AZ::BehaviorContext*>(context);
    if (behaviorContext)
    {
        // Reflect the setter and getter methods and create a virtual property that
        // refers to them.
        behaviorContext->EBus<ImaginaryTargetComponentRequestBus>("ImaginaryTargetRequestBus")
            ->Event("GetImaginaryTargetPosition",
                &ImaginaryTargetComponentRequestBus::Events::GetImaginaryTargetPosition)
            ->Event("SetImaginaryTargetPosition",
                &ImaginaryTargetComponentRequestBus::Events::SetImaginaryTargetPosition)
                ->VirtualProperty("ImaginaryPosition", "GetImaginaryTargetPosition",
                    "SetImaginaryTargetPosition");

        // Attach the "ImaginaryTargetRequestBus" EBus that you reflected to the
        // behavior context of the ImaginaryTargetComponent class.
        behaviorContext->Class<ImaginaryTargetComponent>()
            ->RequestBus("ImaginaryTargetRequestBus");
    }
}
```
4. (Optional) Place Unit Attributes on Getters

The Track View user interface depends on the data type that the getter and setter use. The foregoing example uses a type of AZ::Vector3, so Track View creates a compound x, y, z track from the property. By contrast, if the getter and setters use a bool, Track View creates a Boolean track. For the majority of animatable properties, the type is sufficient. However, in some cases you might have to set units for a reflected property. For example, if your property's AZ::Vector3 represents a color, you must add an attribute to the reflection of the getter event. The attribute instructs Track View to use a color picker for that property. If you have a property called ImaginaryTargetColor that calls a getter event called GetImaginaryTargetColor, use reflection code like the following:

```cpp
->Event("GetImaginaryTargetColor",
    &ImaginaryTargetComponentRequestBus::Events::GetImaginaryTargetColor)
->Attribute("Units", AZ::Edit::Attributes:: PropertyUnits8BitColor)
```

Track View then uses a color track for the property, as the following image shows.

Other units can be found in the file dev\Code\Framework\AZCore\AZCore\Serialization \EditContextConstants.inl. As of Lumberyard release 1.8, these units are the following.

```cpp
const static AZ::Crc32 PropertyUnitsRadian = AZ_CRC("Radians");
const static AZ::Crc32 PropertyUnits8BitColor = AZ_CRC("8BitColor");
```

If you have an angular parameter in radians that you want to Track View to convert to degrees in its user interface, use AZ::Crc32 PropertyUnitsRadian.

Viewing the Result

Now you can view how the example component and property appear in the Entity Inspector and the Track View.
In the following Entity Inspector image, EditContext reflection has exposed the ImaginaryTarget component and its Imaginary Target Pos property.

In the following Track View image, BehaviorContext reflection has exposed the ImaginaryTarget component and the ImaginaryPosition track from the corresponding virtual property.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Follow these best practices for creating and using components and EBuses.

**EBus Names**

The following EBus naming conventions remove ambiguity and provide consistency.

- Use the name format `MyComponentRequestBus` for the bus that others use to invoke functions on `MyComponent`, as in the following example.

  ```cpp
class CheeseburgerComponentRequests : public AZ::ComponentBus
  {
    bool ICanHasCheeseburger() const = 0;
  };
  using CheeseburgerComponentRequestBus = AZ::EBus<CheeseburgerComponentRequests>;
```

- Use the name format `MyComponentNotificationBus` for events that are broadcast from `MyComponent`, as in the following example.

  ```cpp
class CheeseburgerComponentNotifications : public AZ::ComponentBus
```
Provide Default Implementations of Methods

Notification buses typically provide default implementations of the methods within the interface. Many other components can monitor your component's events, but not all of them are interested in every event that your component sends. If you provide default implementations for all your methods, other components that subscribe to your events can implement only those events that are relevant to them.

EBus Event Naming

Good EBus event names are verbose. Classes can monitor multiple buses, so descriptive event names makes it clear which bus the function corresponds to. This practice also prevents potential name collisions among event interfaces from different buses.

The following example is a clearly named `PhysicsComponentNotificationBus` event.

```cpp
virtual void OnPhysicsEnabled() = 0;
```

The following example is an ambiguously named `PhysicsComponentNotificationBus` event.

```cpp
virtual void OnEnabled() = 0;
```

Avoid Using Type Definitions for Serialized Data

An instructive example from Lumberyard shows the importance of using classes instead of type definitions for serialized data. Formerly, `EntityId` used the type definition `uint32_t`. When the decision was made to change this to 64-bit, upgrade functions had to be written for every class that contained an `EntityId`. If `EntityId` had been a class, a single upgrade function could have been written for the class, and no further work would have been required. Obviously, this principle does not apply to primitive types like `bool`, `float`, `int`, and `string`. However, if you have a specific type that is serialized and might change in the future, implement it as a reflected class. This provides a single context where you can easily make the conversion for the class or type.

EBus Results

Always initialize a variable before calling an EBus event that overwrites the variable. Even if you are sure that a particular class or component is listening on the bus, it's worth handling the exceptional case. This is especially true in distributed environments in which entities can come and go as part of area-of-interest or other dynamic patterns.

The following example initializes a result variable before calling an EBus event that produces a result.

```cpp
AZ::Transform targetEntityTransform = AZ::Transform::Identity(); // initialize result variable...
EBUS_EVENT_ID_RESULT(targetEntityTransform, targetEntityId, AZ::TransformBus, GetWorldTM); // ...in case of no response
```

EBus Timing

Following are some best practices for the timing of EBus actions.
• In the Activate() (p. 976) function, make sure that connecting to buses is the last step.
• In the Deactivate() (p. 976) function, make sure that disconnecting from buses is the first step.
• In a multithreaded environment, it's possible to receive bus events from the moment that you connect to the bus until the moment you disconnect. For this reason, make sure of the following:
  • Your component is fully activated before it starts reacting to events.
  • Your component stops receiving events before it starts deactivation.

This practice prevents your component from being in a half-activated state when it starts reacting to events, or in a half-deactivated while still receiving events.

• When you send events on a notification-style bus, the last step in a function should ensure that the data is fully populated.

The following is an example to avoid.

```cpp
EBUS_EVENT_ID(GetEntityId(), OnTransformChanged, newTransform);
m_transform = newTransform;
```

If a component is monitoring the OnTransformChanged event and sets your transform in response to the event, the component's action will be undone by the `m_transform = newTransform;` assignment.

### Making Functions Public or Protected

Consider the following when deciding to make functions public or private.

• Make your bus functions **public** if they constitute the public interface for your class. While it's discouraged, Lumberyard does not prevent users from getting direct pointers to components and calling functions directly. To avoid this, make sure that your useful functions are public. For example, `MyComponent` should probably implement functions from `MyComponentRequestBus` publicly.

• Make your bus functions **protected** if they contain the private workings of your class. For example, your component's reaction to the `TransformNotificationBus::OnTransformChanged` event would likely be a private implementation detail.

### Additional Resources

For more information on components and EBuses, consult the following resources.

• For examples of EBus usage, see Usage and Examples (p. 1853).
• For in-depth information about EBuses, including conceptual diagrams, see Event Buses in Depth (p. 1857).
• For questions and answers regarding best practices for components and EBuses, see Components and EBuses: Questions and Answers (p. 1028).
• For C++ API reference documentation on the core EBus code, see the EBus API Reference in the Amazon Lumberyard C++ API Reference.

### Components and EBuses: Questions and Answers

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The following are some questions and answers for using components and EBuses in Amazon Lumberyard.

**Q. Is it possible to mix Lumberyard’s legacy object entity system with its newer component entity system? If so, what is the best practice?**

**A.** If you enable legacy systems, the two systems can work side by side. However, no formal mechanisms exist to have them work together in the way most games would expect.

**Q. Are there combinations of components that should be avoided?**

**A.** In principle, no. However, every component has a small resource cost associated with it. When possible, avoid creating long chains of components if the desired objective be accomplished through simpler means.

**Q. When should I make an editor component?**

**A.** When editor–only functionality is required, or when the data in the editor must be different than the data in the runtime. For more information, see Editor Components (p. 984).

**Q. What is the best practice for a component to communicate with another component on the same entity? What if the component is on a different entity?**

**A.** Using EBuses for both events and event monitoring. For more information, see Working with the Event Bus (EBus) system (p. 1851).

**Q. What is the best way to find component entities at runtime?**

**A.** The method depends on the use case. Here are some possible approaches:

- Follow a convention in which you use the Tag (p. 875) component to apply tags to specific types of entities. Then use the tags to find the entities that you want. Note that searching through all the entities in a large world can be resource intensive.
- Create a custom component that listens on a new EBus for an event. At an appropriate time, emit that event so that all entities can react to it appropriately.
- If a hard connection is possible, use a component that contains an entity reference. Then look up the entity directly by ID at runtime.

**Q. What is the best way to group component entities?**

**A.** Because the Entity Outliner (p. 462) in Lumberyard Editor shows entities in parent–child hierarchy, group entities under a parent whenever possible. This provides contextual organization.

**Q. What are best practices for organizing and working with a large number of component entities in Lumberyard Editor?**

**A.** Where appropriate, use slices (p. 510) for repeated content. To make it easy to collapse or hide large groups of entities in the Entity Outliner, create a hierarchy of entities.

**Q. How should I decide whether to place code in a component constructor, in an OnInit, or in an OnActivate method?**

**A.** Use the following criteria:

- **Constructor:** Use for base initialization. A constructor is called only once, when the class is created.
- **OnInit:** Called only once, after all components have been created. Like a constructor, an OnInit method should contain only initialization code that is only required once. However, OnInit methods might be more appropriate in some cases for late binding or late initialization.
- **OnActivate:** Use this function for any task that needs to be set up or initialized every time the entity is activated. Entity activation occur multiple times depending on editor or game logic and the actions taken. Commonly, this includes tasks like connecting to EBuses so that the entity can be notified when events occur. Corresponding disconnects occur in DeActivate.
Q. What are best practices for adding or removing components at runtime?

A. Adding or removing components at runtime requires that the entity to which the component belongs be deactivated and then reactivated. This process is not resource intensive, but you must ensure that state is properly maintained by saving it before deactivation and restoring it after activation.

Q. What are best practices for creating entities and adding components at runtime using C++?

A. Only some Lumberyard components support runtime creation. Custom components must be specifically built to support runtime creation. For a discussion of the differences between editor and runtime components, see Editor Components (p. 984).

Gameplay Bus

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The gameplay bus alerts gameplay systems that an event has occurred. You can use the bus to send contextual messages between the visual scripting, scripting, and code parts of your game in a generic and extensible way.

The gameplay bus passes an `AZStd::any`, a class that uses type erasure to hold any C++ reflected type or any Lua primitive except for tables (string, number, Boolean, etc.). It includes mechanisms for type safety to ensure that it returns the same type that it is passed. In Lua, the type can be inspected if it has been exposed to the behavior context through the `typeid()` function, which uses the `AZ_RTTI` system.

Example

```lua
function MyComponent:OnEventBegin(param)
    if typeid(param) == typeid(Uuid) then
        -- param is a Uuid
    elseif typeid(param) == typeid(Vector3) then
        -- param is a Vector3
    end
end
```

**GameplayNotificationId**

The `GameplayNotificationId` is the type used as the ID for the gameplay bus. Its syntax is as follows.

```lua
GameplayNotificationId(const AZ::EntityId& entityChannel, AZ::Crc32 actionNameCrc, const AZ::Uuid& payloadType)
```

This function takes the `entityChannel`, `actionNameCrc`, and `payloadType` parameters and creates a unique ID that you can use to communicate with the bus.
entityChannel

When you write your events, choose the ID of an entity channel that makes sense in the context of your game. Components are automatically aware of the following two entity IDs, which you can use for channels. These IDs do not require an entity reference.

1. The component's own entity ID. To obtain it, call GetEntityId().
2. The default AZ::EntityId().

To communicate directly to a specific entity, use GetEntityId(). To communicate indirectly to a generic audience, use AZ::EntityId().

actionNameCrc

You can pass the actionNameCrc parameter as a string or as the AZ::Crc32 of that string when you construct the ID. This parameter should be the name of the event that gives context to the event data.

payloadType

Use the payloadType parameter to specify the type that is sent or received. This parameter is required starting in Lumberyard version 1.12.

GameplayNotifications

The GameplayNotifications class contains the gameplay bus type traits. It establishes the GameplayNotificationId as the bus ID. It defines the following events.

```c
void OnEventBegin(const AZStd::any& value)
void OnEventUpdate(const AZStd::any& value)
void OnEventEnd(const AZStd::any& value)
```

Script Examples

The Lua script examples in this section illustrate the use of GameplayNotificationBus to control what happens when an entity enters and then exits lava.

1. The following example implements the OnActivate function when the entity enters lava.

```lua
local InLavaBehavior = {
  Properties = {
  },
}

function InLavaBehavior:OnActivate()
  local gameplayId = GameplayNotificationId(self.entityId, "InLava")
  self.gameplayBus = GameplayNotificationBus.CreateHandler(self, inputBusId)
end
```

2. The following example implements the OnEventBegin function to start an animation associated with the event.

```lua
local InLavaBehavior = {
  Properties = {
  },
}

function InLavaBehavior:OnEventBegin()
  local gameplayId = GameplayNotificationId(self.entityId, "InLava")
  self.gameplayBus = GameplayNotificationBus.CreateHandler(self, inputBusId)
end
```
function InLavaBehavior:OnEventBegin(floatValue)
    local animInfo = AnimatedLayer("LavaHotFootDance", 0, true, 1.0, 0.0);
    SimpleAnimationComponentRequestBus.Event.StartAnimation(self.entityId, animInfo)

    -- tell the HUD to transition the screen effect to "In Lava"
    local gameplayId = GameplayNotificationId(EntityId(), "TransitionScreenEffect")
    GameplayNotificationBus.Event.OnEventBegin(gameplayId, "In Lava")
end

3. The following example implements the OnEventUpdating function to update a health component regarding the status of the entity.

function InLavaBehavior:OnEventUpdating(floatValue)
    -- alert the health component (this gameplay component is an example only) that we are taking damage, it can handle any death transitions
    HealthComponentBus.Event.TakeDamage(self.entityId, floatValue)
end

4. The following example implements the OnEventEnd function to end the animation and return status to normal.

function InLavaBehavior:OnEventEnd(floatValue)
    local animInfo = AnimatedLayer("Idle", 0, true, 1.0, 0.0);
    SimpleAnimationComponentRequestBus.Event.StartAnimation(self.entityId, animInfo)

    -- tell the HUD to transition the screen effect to "Normal"
    local gameplayId = GameplayNotificationId(EntityId(), "TransitionScreenEffect")
    GameplayNotificationBus.Event.OnEventBegin(gameplayId, "Normal")
end

5. The following example implements the OnDeactivate function to disconnect from the gameplay bus.

function InLavaBehavior:OnDeactivate()
    self.gameplayBus:Disconnect()
end

return InLavaBehavior

Reflecting Lumberyard Classes, Methods, and EBus Interfaces

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use Lumberyard's reflection system to expose runtime code for C++-based objects, for Lumberyard Editor, and for scripting.

Lumberyard provides the following reflection contexts for these purposes:

- **Serialization Context (p. 1033)** – Provides persistence for C++ based objects through reflection for serialization.
Serialization Context

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the serialization context (`\dev\Code\Framework\AzCore\AzCore\Serialization\SerializeContext.*`) to provide persistence for C++ objects or any Lumberyard type. To implement this, make an `AzTypeInfo` declaration or use `AZ_RTTI` (runtime type information), as in the following example:

```cpp
class SerializedObject
{
public:
    AZ_RTTI(SerializedObject, "");
    static void Reflect(AZ::ReflectContext* context)
    {
        SerializeContext* serializeContext = azrtti_cast<SerializeContext*>(reflection);
        if (serializeContext)
        {
            serializeContext->Class<SerializedObject>()
            ;
        }
    }
};
```

You can also reflect native types and POD structs for serialization by creating an `AZ_TYPE_INFO` specialization, as in the following code example:

```cpp
AZ_TYPE_INFO_SPECIALIZE(AZStd::chrono::system_clock::time_point, "{5C48FD59-7267-405D-9C06-1EA31379FE82}");
AZ_TYPE_INFO_SPECIALIZE(float, "{EA2C3E90-AFBE-44d4-A90D-FAAF79BAF93D}");
```

Fields

To associate a text string with the address to a field of a serialized object, use the `Field` function, as in the following example. You can use the builder pattern to serialize multiple fields.

```cpp
serializedContext->Class<SerializedObject>()
    ->Field("myIntField", &SerializedObject::myIntField)
    ->Field("myFloatField", &SerializedObject::myFloatField)
    ;
```

Serializers

Serializers are a useful way to provide custom data formats. If you want to do custom processing on an object before writing or reading it, you can override Lumberyard's default serializer.
To override the default serializer, implement the `AZ::SerializeContext::IDataSerializer` interface. Use the interface to override how data is handled as it is streamed into its persistent format. You can also use the interface to determine the actions that occur when the reflected object is serialized (read or written).

The `AZ::Uuid` class (\dev\Code\Framework\AzCore\AzCore\Math\MathReflection.cpp) provides a good example of a custom serializer. To save a UUID value, the code writes it directly into the stream. This part of the code is straightforward.

```
/// Store the class data into a binary buffer
size_t Uuid::Save(const void* classPtr, IO::GenericStream& stream, bool)
{
    const Uuid* uuidPtr = reinterpret_cast<const Uuid*>(classPtr);
    return static_cast<size_t>(stream.Write(16, reinterpret_cast<const void*>(uuidPtr->data)));
}
```

Loading a UUID is also straightforward, but the code does some error checking to ensure that the data is loaded as expected:

```
/// Load the class data from a stream.
bool Uuid::Load(void* classPtr, IO::GenericStream& stream, unsigned int /*version*/, bool)
{
    if (stream.GetLength() < 16)
    {
        return false;
    }
    Uuid* uuidPtr = reinterpret_cast<Uuid*>(classPtr);
    if (stream.Read(16, reinterpret_cast<void*>(&uuidPtr->data)) == 16)
    {
        return true;
    }
    return false;
}
```

The custom serializer has functions that convert the data between binary and text formats. By converting the data into text format, you can store it in `.xml` or `.json` files.

The following `DataToText` function reads the binary value for the UUID from the incoming stream. The function converts the binary value into an `AZStd::string` and then writes it to the outgoing stream.

```
size_t Uuid::DataToText(IO::GenericStream& in, IO::GenericStream& out, bool)
{
    if (in.GetLength() < 16)
    {
        return 0;
    }
    Uuid value;
    void* dataPtr = reinterpret_cast<void*>(&value.data);
in.Read(16, dataPtr);
    char str[128];
    value.ToString(str, 128);
    AZStd::string outText = str;
    return static_cast<size_t>(out.Write(outText.size(), outText.data()));
}
```

The following `TextToData` function converts the text input string into binary UUID format and then writes the binary data out to the stream.

```
/// Convert text data to binary to support the loading of legacy formats.
```
Serialization Context

// Respect the text version if the text->binary format has changed!
size_t Uuid::TextToData(const char* text, unsigned int, IO::GenericStream& stream, bool)
{
    Uuid uuid = Uuid::CreateString(text);
    stream.Seek(0, IO::GenericStream::ST_SEEK_BEGIN);
    return static_cast<size_t>(stream.Write(16, uuid.data));
}

Data Containers

To create custom serialization for templates and types that are not directly reflected through the 
SerializeContext::Reflect function, you can use data containers.

To create a data container, implement the AZ::SerializeContext::IDataContainer interface. You 
can use this interface to provide serialization for a class or template of classes and let the user choose 
the elements to be serialized. This is possible because IDataContainer allows the user to override an 
EnumElements function. The EnumElements function determines which elements of the serialized class 
are enumerated and are therefore capable of being serialized.

Templates

Data containers provide the best way to add support for templates to the serialization context. The 
following templates have a metaclass that implements the IDataContainer interface and serializes the 
templates.

AZStd::vector<T>
AZStd::basic_string<T>
AZStd::unique_ptr<T>

Nontemplate Types

You can use the IDataContainer interface to serialize nontemplate types like AZStd::any. This is 
because the type of element that is serialized is dependent on the type that is stored in the AZStd::any 
object.

Stable Elements

Elements are considered stable if their pointers do not change when other elements are added to or 
removed from a container. Lumberyard's implementation of stable elements corresponds to the C++ 
+17 rules for iterator invalidation as documented in section 26 of the ISO/IEC 14882:2017(E) standard. 
The elements in types like AZStd::vector are not stable because they are stored in a contiguous 
sequence. When an element that is not at the end of the vector is removed, all elements after it in 
memory must shift to the left to keep the sequence contiguous. Stable elements can be removed from 
a container without affecting other elements in the container. You can use the IsStableElements 
function to determine the status of a container's elements. If a container's elements are not stable, you 
must enumerate them in order for them to be serialized.

The following code example shows how to set up serialization for a container that stores a dynamic 
sequence of homogenous elements.

template<class T, bool IsStableIterators>
class AZStdBasicContainer
    : public SerializeContext::IDataContainer
{
    public:
        typedef typename T::value_type ValueType;
        typedef typename AZStd::remove_pointer<typename T::value_type>::type ValueClass;
        //... Functions implementing the IDataContainer interface
A `SerializeContext::ClassElement` is a struct that uniquely identifies a serialized element of a class. It includes fields like the following:

- **TypeId** – an ID for looking up data in `ClassData` within the `SerializeContext`.
- **Name, NameCrc** – The name and CRC with which the element is serialized.
- **Element-specific serialization attributes**

To look up the name of the `SerializeContext::ClassElement` that the data container supports, override the `GetElement` function, as in the following example.

```cpp
// Returns the class element by looking up the CRC value of the element.
// Returns null if the element with the specified name can't be found.
const SerializeContext::ClassElement* GetElement(u32 elementNameCrc) const override
{
    if (elementNameCrc == m_classElement.m_nameCrc)
    {
        return &m_classElement;
    }
    return nullptr;
}

// The following GetElement method uses the supplied DataElement object to lookup the
// ClassElement with the supplied parameter. Returns true if it finds a ClassElement.
bool GetElement(SerializeContext::ClassElement& classElement, const
SerializeContext::DataElement& dataElement) const override
{
    if (dataElement.m_nameCrc == m_classElement.m_nameCrc)
    {
        classElement = m_classElement;
        return true;
    }
    return false;
}
```

The following example shows how to override the `EnumElement` method to specify the elements that are enumerated. Enumerating them enables them to be saved.

```cpp
/// Enumerate elements in the array.
/// The ElementCB callback enumerates the children of the elements in the array.
/// By invoking the callback on an element, the enumeration continues down the path for
/// that element.
void EnumElements(void* instance, const ElementCB& cb) override
{
    T* arrayPtr = reinterpret_cast<T*>(instance);
    typename T::iterator it = arrayPtr->begin();
    typename T::iterator end = arrayPtr->end();
    for (; it != end; ++it)
    {
        ValueType* valuePtr = &*it;
        if (!cb(valuePtr, m_classElement.m_typeId, m_classElement.m_genericClassInfo ?
        m_classElement.m_genericClassInfo->GetClassData() : nullptr, &m_classElement))
        {
            break;
        }
    }
}
```

To make a template editable in Lumberyard Editor and the reflected property editor, override the constraint functions in the following code:
// The following code defines the characteristics of the container that is serialized. // The editing facilities use this information to determine how to edit the elements within the container.

/// Return the number of elements in the container.
size_t  Size(void* instance) const override
{
    const T* arrayPtr = reinterpret_cast<const T*>(instance);
    return arrayPtr->size();
}
/// Return the capacity of the container. Return 0 for objects without fixed capacity.
size_t  Capacity(void* instance) const override
{
    (void)instance;
    return 0;
}
/// Return true if the element pointers do not change when the element is added to or removed from the container. If false, you MUST enumerate all elements.
bool  IsStableElements() const override
    { return IsStableIterators; }
/// Return true if the container has a fixed size; otherwise false.
bool  IsFixedSize() const override
    { return false; }
/// Return true if the container has a fixed capacity; otherwise false.
bool  IsFixedCapacity() const override
    { return false; }
/// Return true if the container is a smart pointer.
bool  IsSmartPointer() const override
    { return false; }
/// Return true if the elements can be retrieved by index.
bool  CanAccessElementsByIndex() const override
    { return false; }

Notes

• When IsFixedSize and IsFixedCapacity are false, the plus (+) and minus (–) buttons in the property editor can be used to add and remove elements from the data container.
• When IsSmartPointer is false, the data container does not create an instance of theSmartPointer type when an element is added to the container.
• When CanAccessElementsByIndex is false, the serialization system checks whether to allocate memory for new elements. CanAccessElementsByIndex is true for fixed-size containers like AZStd::array, AZStd::pair, and AZStd::tuple because those containers already have memory storage allocated for their elements.

To load an element into the template class instance, override the ReserveElement, StoreElement and RemoveElements functions, as in the following example.

/// Use the reserve element function.
/// The reserve element function allows creation of the element on the data container instance.
/// The following code serializes an element and returns an address to the reserved element.
void*  ReserveElement(void* instance, const SerializeContext::ClassElement* classElement) override
{
    (void)classElement;
    T* arrayPtr = reinterpret_cast<T*>(instance);
    arrayPtr->push_back();
    return &arrayPtr->back();
}
/// Use the GetElementByIndex function to get an element’s address by its index.
// Call this function before the element is loaded.
void* GetElementByIndex(void* instance, const SerializeContext::ClassElement* classElement, size_t index) override
{
    (void)instance;
    (void)classElement;
    (void)index;
    return nullptr;
}

/// Use the store element function.
void StoreElement(void* instance, void* element) override
{
    (void)instance;
    (void)element;
    // Do nothing; you have already pushed the element.
    // However, you can assert and check if the element belongs to the container.
}

/// Remove the element from the container.
/// This also deletes the memory associated with the element.
bool RemoveElement(void* instance, const void* element, SerializeContext* deletePointerDataContext) override
{
    T* arrayPtr = reinterpret_cast<T*>(instance);
    for (typename T::iterator it = arrayPtr->begin(); it != arrayPtr->end(); ++it)
    {
        void* arrayElement = &(*it);
        if (arrayElement == element)
        {
            if (deletePointerDataContext)
            {
                DeletePointerData(deletePointerDataContext, &m_classElement, arrayElement);
            }
            arrayPtr->erase(it);
            return true;
        }
    }
    return false;
}

/// Remove elements (remove an array of elements) whether the container is stable or not.
/// Stability can be tested by IsStableElement.
size_t RemoveElements(void* instance, const void** elements, size_t numElements, SerializeContext* deletePointerDataContext) override
{
    if (numElements == 0)
    {
        return 0;
    }
    size_t numRemoved = 0;
    // Handle the case when the container does not have stable elements.
    if (!IsStableElements)
    {
        // If the elements are in order, you can remove all of them from the container.
        // Otherwise, they must be sorted again locally (not done in this example).
        // Or, ask the user to pass the elements in order and remove the first N possible
        // in order.
        for (size_t i = 1; i < numElements; ++i)
        {
            if (elements[i - 1] >= elements[i])
            {
                AZ_TracePrintf("Serialization", "RemoveElements for AZStd::vector will
                perform optimally when the elements (addresses) are sorted in accending order!");
                numElements = i;
            }
        }
        // Traverse the vector in reverse order, and then addresses of elements that should
        not change.
    }
Using the DataContainer to Serialize a Template Class

After you have defined a data container, you can use it to serialize a specific type. For example, to set up serialization for the templated `AZStd::vector<T>`, you must serialize `SerializeGenericTypeInfo<T>` for `AZStd::vector`. To create the class data structure, you use the following `Create<ContainerType>` function:

```cpp
SerializeContext::ClassData::Create<ContainerType>("AZStd::vector", GetSpecializedTypeId(), Internal::NullFactory::GetInstance(), nullptr, &m_containerStorage);
```

The `Create<ContainerType>` function parameters are explained in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;AZStd::vector&quot;</td>
<td>Specifies the user friendly name of the class in a JSON or XML stream.</td>
</tr>
<tr>
<td>GetSpecializedTypeId</td>
<td>Creates an ID that enables serialization of different types. For example, an <code>AZStd::vector</code> of integers can be serialized as a type that is different from an <code>AZStd::vector</code> of floats. The unique ID is made by aggregating the template type <code>AZStd::vector</code> with the contained type <code>T</code>.</td>
</tr>
<tr>
<td>Internal::NullFactory</td>
<td>Used to prevent heap memory from being used to create an <code>AZStd::vector</code>. To load an <code>AZStd::vector</code> element of a pointer type, change this to <code>Serialize::InstanceFactory&lt;AZStd::vector&lt;T,A&gt;&gt;</code>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>nullptr</td>
<td>This is the Serializer parameter. Because the serialization occurs through a data container, this parameter is nullptr.</td>
</tr>
<tr>
<td>&amp;m_containerStorage</td>
<td>The m_containerStorage structure is an AZStdBasicContainer that ClassData uses to serialize the AZStd::vector element array.</td>
</tr>
</tbody>
</table>

The following code example uses the Create<ContainerType> function to set up serialization for the templated AZStd::vector<T>.

```cpp
/// Generic serialization example for AZStd::vector.
template<class T, class A>
struct SerializeGenericTypeInfo< AZStd::vector<T, A> >
{
    typedef typename AZStd::vector<T, A> ContainerType;
    class GenericClassInfoVector
    :
        public GenericClassInfo
    {
        public:
            AZ_TYPE_INFO(GenericClassInfoVector, "{2BADE35A-6F1B-4698-B2BC-3373D010020C}");
            GenericClassInfoVector()
        { // The following code creates the ClassData structure that specifies how an element is serialized.
            m_classData =
                SerializeContext::ClassData::CreateContainerType("AZStd::vector", GetSpecializedTypeId(), Internal::NullFactory::GetInstance(), nullptr, &m_containerStorage);
            SerializeContext::ClassData* GetClassData() override
            { return &m_classData; }
            size_t GetNumTemplatedArguments() override
            { return 1; }
            const Uuid& GetTemplatedTypeId(size_t element) override
            { (void)element;
                return SerializeGenericTypeInfo<T>::GetClassTypeId(); }
            const Uuid& GetSpecializedTypeId() const override
            { return azrtti_typeid<ContainerType>(); }
            const Uuid& GetGenericTypeId() const override
            { return TYPEINFO_Uuid(); }
            void Reflect(SerializeContext* serializeContext)
            { if (serializeContext)
                { serializeContext->RegisterGenericClassInfo(GetSpecializedTypeId(), this, &AnyTypeInfoConcept<ContainerType>::CreateAny);
                    if (GenericClassInfo* containerGenericClassInfo =
                        m_containerStorage.m_classElement.m_genericClassInfo)
                    { containerGenericClassInfo->Reflect(serializeContext); }
                }
            }
            static GenericClassInfoVector* Instance()   
```

Version 1.28
1040
Serialization Context

```cpp
static GenericClassInfoVector s_instance;
return &s_instance;
}
Internal::AZStdBasicContainer<ContainerType, false> m_containerStorage;
SerializeContext::ClassData m_classData;
};
static GenericClassInfo* GetGenericInfo()
{
return GenericClassInfoVector::Instance();
}
static const Uuid& GetClassTypeId()
{
return GenericClassInfoVector::Instance()->m_classData.m_typeId;
}
```

Events

To process data before or after you read or write serialized data, you can write serialization event handlers. For example, by handling serialization events, you can perform runtime initializations specific to the data that is serialized.

To create a serialization event handler, implement the `AZ::SerializeContext::IEventHandler` interface as in the following example.

The example uses an event handler to update a map container within the `SceneData` class after a `SceneData` instance has been serialized.

```cpp
class SceneDataEventHandler : public AZ::SerializeContext::IEventHandler
{
public:
    /// Rebuild the endpoint map.
    void OnWriteEnd(void* classPtr) override
    {
        auto* sceneData = reinterpret_cast<SceneData*>(classPtr);
        BuildEndpointMap(*sceneData);
    }
};
```

Data Overlays

You can use the serialization context to provide data from an external source during serialization. These external sources of data are called *data overlays*.

To create a data overlay, you implement an EBus (p. 1851) through which the data is serialized. The following example is the code that implements unit testing for the data overlay feature (\dev\Code\Framework\AzCore\Tests\Serialization.cpp):

```cpp
struct DataOverlayTestStruct
{
```
The DataOverlayTestStruct holds data fields to be reflected for serialization:

```
serializeContext.Class<DataOverlayTestStruct>()
  ->Field("int", &DataOverlayTestStruct::m_int)
  ->Field("intVector", &DataOverlayTestStruct::m_intVector)
  ->Field("pointer", &DataOverlayTestStruct::m_ptr);
```

Next, implement the data overlay provider. The provider represents the data source that is overlaid into the serialized data.

The following code shows an example of a data overlay provider:

```
class DataOverlayProviderExample
 : public DataOverlayProviderBus::Handler
{
public:
  static DataOverlayProviderId GetProviderId() { return AZ_CRC("DataOverlayProviderExample", 0x60dafdbd); }  
  static u32 GetIntToken() { return AZ_CRC("int_data", 0xd74868f3); }  
  static u32 GetVectorToken() { return AZ_CRC("vector_data", 0x0aca20c0); }  
  static u32 GetPointerToken() { return AZ_CRC("pointer_data", 0xa46a746e); }
  DataOverlayProviderExample()
  {
    m_ptrData.m_int = 5;
    m_ptrData.m_intVector.push_back(1);
    m_ptrData.m_ptr = nullptr;
    m_data.m_int = 3;
    m_data.m_intVector.push_back(10);
    m_data.m_intVector.push_back(20);
    m_data.m_intVector.push_back(30);
    m_data.m_ptr = &m_ptrData;
  }
  void FillOverlayData(DataOverlayTarget* dest, const DataOverlayToken& dataToken) override
  {
    if (*reinterpret_cast<const u32*>(dataToken.m_dataUri.data()) == GetIntToken())
      { dest->SetData(m_data.m_int); }
    else if (*reinterpret_cast<const u32*>(dataToken.m_dataUri.data()) == GetVectorToken())
      { dest->SetData(m_data.m_intVector); }
    else if (*reinterpret_cast<const u32*>(dataToken.m_dataUri.data()) == GetPointerToken())
      { dest->SetData(*m_data.m_ptr); }
    }
  DataOverlayTestStruct m_data;
  DataOverlayTestStruct m_ptrData;
};
```
**Serialization Context**

DataOverlayProviderExample uses the Crc32 ID for the reflected DataOverlayTestStruct source data fields. Then the example implements the DataOverlayProviderBus::Handler FillOverlayData function. The FillOverlayData function is where the actual data overlay occurs. The DataOverlayToken holds the ID of the field that is serialized. If the ID matches one of the fields that you want to overlay, you can use DataOverlayTarget to set the data.

### Versioning your Component Serialization

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

As requirements, code, and data representation change, you may need to modify your implementation of data reflection. However, changes to serialized data can result in incompatibilities. To manage compatibility, you can assign a version number increment to your serialized data structures. With this approach, you can perform validation during serialization to ensure that the data being read matches the format that the reflection system specifies. We recommend that you increase the version number of serialized data anytime there is a change to the reflected fields.

The following code shows how to specify a version number for the serialization context.

```cpp
serializeContext->Class<SerializedStruct>()
    ->Version(1)
```

Successful conversion of serialized data to a newer version requires careful planning. Use the information in the following sections to help with your planning.

- Version Converters (p. 1043)
- Upgrade Class Builders (p. 1045)
- Deprecation (p. 1049)

**Important**

If you upgraded to Lumberyard v1.23 or later from a previous version of Lumberyard, and you have not converted your slice files to the new slice file format, you must upgrade these files using the Slice Upgrade Pipeline before you can use the NameChange and TypeChange class builders. For more information about this upgrade tool and how to use it, see Converting Slices with the Slice Upgrade Pipeline (p. 529).

**Important**

If you are using Lumberyard v1.22 or earlier, be sure to read important information about Avoiding Data Loss when Serializing Component Data (p. 1049).

### Version Converters

A version change can create incompatibilities that require data to be converted from one format to another. To resolve this, you can implement a version converter that reformats data "on the spot" to maintain data compatibility. For example, you might require a version converter if you change a data type or a container (for example, an AZStd::vector becomes an AZStd::unordered_map).

Use the `Version` function mentioned in the previous section to specify a version converter, as in the following example.

```cpp
serializeContext->Class<EditorEntitySortComponent, EditorComponentBase>()
    ->Version(2, &SerializationConverter)
```
Version converters operate directly on the serialized data.

To facilitate the creation of version converters, Lumberyard provides helper functions and examples such as the following:

- To locate a specific element to manipulate, you can use the `AZ::Utils::FindDescendantElements` helper function.
- To access serialized data and manipulate it, you can use the public functions in the `DataElementNode` class (`\dev\Code\Framework\AzCore\AzCore\Serialization\SerializeContext.h`).
- For version converter examples, see the AZ core serialization unit test in the `\dev\Code\Framework\AzCore\Tests\Serialization.cpp` file.

A version conversion operation that replaces a container might follow this common pattern:

1. Compare the version number of the data being serialized with the current version. If the versions do not match, perform the steps that follow.
2. Locate the element to convert by its `Crc32` key.
3. Create a container to store the updated elements.
4. Populate the new container with the existing data.
5. Delete the old element from the root data.
6. Use the same `Crc32` key to add the new container as a new element in the root data.

After this operation is completed, the data exists in the new format. When the data is serialized again, it is stored in the latest format.

The following code shows an example of data conversion:

```cpp
if (rootElement.GetVersion() <= 1)
{
    // This line of code:
    //  using Events = AZStd::vector<EBusEventEntry>;
    //  is changed to this:
    //  using EventMap = AZStd::unordered_map<AZ::Crc32, EBusEventEntry>;
    auto ebusEventEntryElements = AZ::Utils::FindDescendantElements(serializeContext, rootElement, AZStd::vector<AZ::Crc32> {AZ_CRC("m_events", 0x191405b4), AZ_CRC("element", 0x41405e39)});
    EBusEventHandler::EventMap eventMap;
    for (AZ::SerializeContext::DataElementNode* ebusEventEntryElement : ebusEventEntryElements)
    {
        EBusEventEntry eventEntry;
        if (!ebusEventEntryElement->GetDataHierarchy(serializeContext, eventEntry))
        {
            return false;
        }
        AZ::Crc32 key = AZ::Crc32(eventEntry.m_eventName.c_str());
        AZ_Assert(eventMap.find(key) == eventMap.end(), "Duplicated event found while converting EBusEventHandler from version 1 to 2.");
        eventMap[key] = eventEntry;
    }
    // Remove the previous Events element.
    rootElement.RemoveElementByName(AZ_CRC("m_events", 0x191405b4));
    // Replace it with the new EventMap element.
    if (rootElement.AddElementWithData(serializeContext, "m_eventMap", eventMap) == -1)
    {
        return false;
    }
    return true;
}
```
Note
If you need to emit a warning or error when a conversion fails (for example, for asset builds), use the `AZ_Warning` or `AZ_Error` macro. For related source code, see `lumberyard_version\dev\Code\Framework\AzCore\AzCore\Debug\Trace.h`.

Upgrade Class Builders

Slice data patches present a unique challenge to versioning your component data structures. Data patches cannot be upgraded by version converters because they do not contain all the information about a component class. Changing the serialization of a component without upgrading data patches that contain partial component data can lead to crashes, corrupted slice data, or invalid slice files that cannot be loaded or manipulated and must be rebuilt from scratch.

In most cases, the solution is to use NameChange and TypeChange class builders alongside your version converters. This causes the serializer to update the data patch and apply basic type changes and field name changes. These builders can be chained together to upgrade across multiple version changes, and can also be written to skip versions entirely.

Class Builder Syntax

Name-change class builders require an input and output version, followed by the input serialized name and a new output name.

```
NameChange(InputVersion, OutputVersion, "OldFieldName", "NewFieldName")
```

Type-change class builders require input and output data types as template arguments, followed by the relevant field name, the input and output version, and a conversion function.

```
TypeChange<InputType, OutputType>("FieldName", InputVersion, OutputVersion, Function<OutputType(InputType)>)
```

NameChange Class Builder Examples

In the following example, we use a NameChange class builder to change a serialized name of a field from "MyData", used in version 4 of the component serialization, to "Data" in version 5.

```cpp
serializeContext->Class<ExampleClass>()
  ->Version(5)
  ->Field("Data", &ExampleClass::m_data)
  ->NameChange(4, 5, "MyData", "Data");
```

You can also change the serialized name of a struct or class member when reflecting a class to the serialize context. In the following example, we use a NameChange class builder to change the name from "MyStructData" in version 4, to "StructData" in version 5.

```cpp
class ExampleClass
{
```
Serialization Context

DataStruct m_data;
};

serializeContext->Class<ExampleClass>()
 ->Version(5)
 ->Field("StructData", &ExampleClass::m_data)
 ->NameChange(4, 5, "MyStructData", "StructData");

TypeChange Class Builder Examples

In the following example, class member m_data has changed from an int in version 4 to a float in version 5. We add a TypeChange class builder to the serialization context so that any data patches containing the serialized field name "MyData" will be applied using the new data type.

// Serialization Context for Version 4:
class ExampleClass
{
    ...
    int m_data;
    reflect(...)
    {
        serializeContext->Class<ExampleClass>()
        ->Version(4)
        ->Field("MyData", &ExampleClass::m_data);
    }
};

// Serialization Context for Version 5:
class ExampleClass
{
    ...
    float m_data;
    reflect(...)
    {
        serializeContext->Class<ExampleClass>()
        ->Version(5)
        ->Field("MyData", &ExampleClass::m_data)
        ->TypeChange<int, float>("MyData", 4, 5, [](int in)->float { return (float)in; });
    }
};

You can also handle nesting value changes. In the following example, the field m_data has become nested inside of the new MyData struct in version 5. We use a TypeChange class builder to instruct the serializer to convert the simple int data type to the more complex MyData type.

// Serialization Context for Version 4:
class ExampleClass
{
    ...
    int m_data;
    reflect(...)
    {
        serializeContext->Class<ExampleClass>()
        ->Version(4)
        ->Field("MyData", &ExampleClass::m_data);
    }
};
Advanced Class Builder Examples

The following examples demonstrate more complex usage of class builders.

**Example : Multiple Upgrades in One Version**

Type changes take priority over name changes. You can apply both in the same version upgrade, but the type change is applied first. Therefore, always specify the old field name in the `TypeChange` when changing both a type and a name at the same time.

In the following example, a `TypeChange` changes the type from `float` to `int`. It is immediately followed by a `NameChange` that changes the serialized name from "FloatData" to "IntData".

```cpp
// Serialization Context for Version 4:
class ExampleClass
{
    ... ...
    float m_data;
    static void Reflect(...)
    {
        serializeContext->Class<ExampleClass>()
            ->Version(4)
            ->Field("FloatData", &ExampleClass::m_data);
    }
};

// Serialization Context for Version 5:
class ExampleClass
{
    ... ...
    int m_data;
    static void Reflect(...)
    {
        serializeContext->Class<ExampleClass>()
            ->Version(5)
            ->Field("IntData", &ExampleClass::m_data)
            ->TypeChange<float, int>("FloatData", 4, 5, [](float in)->int { return (int)in; })
            ->NameChange(4, 5, "FloatData", "IntData");
    }
};
```
Example: Version Skipping

A `TypeChange` can skip multiple versions. Skipping versions should be used only when intermediate type changes contain conversions that could lose data.

In the following example, using `ExampleClass`, the member variable `m_data` changes from a `float` in version 1 to an `int` in version 2. Then in version 3, `m_data` changes back to a `float`. Multiple `TypeChange` class builders are used to avoid losing the floating point precision when upgrading older overrides to version 3, while still providing the ability to fix data patches written using version 2 of `ExampleClass`.

```cpp
// Version 1 of ExampleClass:
class ExampleClass
{
    ...  
    float m_data;
    static void Reflect(...)
    {
        serializeContext->Class<ExampleClass>()
            ->Version(1)
            ->Field("Data", &ExampleClass::m_data);
    }
};

// Version 2 of ExampleClass:
class ExampleClass
{
    ...
    int m_data;
    static void Reflect(...)
    {
        serializeContext->Class<ExampleClass>()
            ->Version(2)
            ->Field("Data", &ExampleClass::m_data)
            ->TypeChange<float, int>("Data", 1, 2, [](float in)->int { return (int)in; });
    };

// Version 3 of ExampleClass:
class ExampleClass
{
    ...
    float m_data;
    static void Reflect(...)
    {
        serializeContext->Class<ExampleClass>()
            ->Version(3)
            ->Field("Data", &ExampleClass::m_data)
            ->TypeChange<float, int>("Data", 1, 2, [](float in)->int { return (int)in; })
            ->TypeChange<int, float>("Data", 2, 3, [](int in)->float { return (float)in; })
            ->TypeChange<float, float>("Data", 1, 3, [](float in)->float { return in; });
    }
};
```

**Note**

We strongly recommend that you do not use this version skipping technique with the `NameChange` builder. Doing so will cause problems for any `TypeChange` builders used on the same field in between the skipped versions as they try to match the serialized field name.
Deprecation

The serialization context also supports deprecation of a previously reflected class name. To deprecate a class, use the `ClassDeprecate` method. After a class is deprecated, any instances of the class are silently discarded during load.

The following example shows the use of the `ClassDeprecate` method.

```c++
serializeContext->ClassDeprecate("DeprecatedClass", "{893CA46E-6D1A-4D27-94F7-09E26DE5AE4B}");
```

Avoiding Data Loss when Serializing Component Data

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

There are ways that you can avoid data loss when serializing component data. This topic describes how to deal with slice data patch issues when using version converters, and provides some best practices for avoiding data loss.

Avoiding Data Loss and Maintaining Stability in Lumberyard v1.22 and Earlier

This section provides specific information and best practices for avoiding data loss in versions of Lumberyard up through and including v1.22. First, it describes what you need to keep in mind when using version converters, and how to help avoid subsequent data loss in your slice data patches. Then, it provides a two-step process for avoiding data loss and maintaining stability.

**Note**
In Lumberyard v1.23, the issues described in the following topics were addressed with the introduction of the new slice file format and the NameChange and TypeChange class builders.
For more information about these class builders and how to upgrade your slice file format, see Versioning your Component Serialization (p. 1043).

**Topics**
- The Data Patching Issue  (p. 1049)
- How to Avoid Data Loss  (p. 1051)

The Data Patching Issue

During development, components undergo significant changes. Member variables are added, removed, renamed, and changed. Consequentially, serialization of the component also changes. When any change affects serialization, a version converter function can modify older data so that it can continue working with the new object state.

**Note**
Version converter functions work only when an entire class is supplied.

However, there are some scenarios where an entire class is not available. For example, consider data patches in slice files, which represent the difference between two serializable objects. These patches can be as small as a single serialized value or include entire classes. In the cases where they don't have a full class worth of information, the information in a data patch cannot be run through a version converter function. This means that when serialization of a component changes, any data patches stored in nested slices that apply to those components are no longer valid and cannot be recovered.
The following is an example of a version change that could lead to data loss. This example starts with a basic component that has just enough information to be reflected. It uses an integer with a value between 1 and 100 to represent the current blend state.

```cpp
// Blend Component (V1)
class BlendComponent : public Component
{
public:

AZ_TYPE_INFO(BlendComponent, "{ED986571-2B3D-4E22-A2D8-F74A29A730DE}");
static void Reflect(ReflectContext* context)
{
    if (auto serializeContext = azrtti_cast<SerializeContext*>(context))
    {
        serializeContext->Class<BlendComponent>()
            ->Version(1)
            ->Field("BlendState", &BlendComponent::m_blendState);
    }
}

private:

// A value from 1 to 100 representing the blend state
int m_blendState;
};
```

At some point during development, it's decided that additional resolution is required for the blend component. So the integer is changed to a floating point value with a valid range between 0.0f and 1.0f to represent the current blend state. There are a lot of assets that were saved with the original integer value, so a version converter is added which performs this upgrade automatically.

```cpp
// Blend Component (V2)
class BlendComponent : public Component
{
public:

AZ_TYPE_INFO(BlendComponent, "{ED986571-2B3D-4E22-A2D8-F74A29A730DE}");
static void Reflect(ReflectContext* context)
{
    if (auto serializeContext = azrtti_cast<SerializeContext*>(context))
    {
        serializeContext->Class<BlendComponent>()
            ->Version(2, BlendComponent::VersionUpgrader)
            // /// SERIALIZATION OF THE FIELD HASN'T CHANGED ////
            ->Field("BlendState", &BlendComponent::m_blendState);
    }
}

///// ONLY WORKS WITH A CLASS ELEMENT REPRESENTING THE ENTIRE BLEND COMPONENT TYPE /////

bool VersionUpgrader(SerializeContext& context, DataElementNode& classElement)
{
    if(version < 2)
    {
        int oldBlendValue;
        int oldBlendIndex = classElement.FindElement(AZ_CRC("BlendState"));
        if(oldBlendIndex != -1)
        {
            if(classElement.GetSubElement(oldBlendIndex).GetData(oldBlendValue))
            {
                float newBlendValue = float(oldBlendValue) / 100.0f;
                classElement.RemoveElement(oldBlendIndex);
                classElement.AddElementWithData(context, "BlendState", newBlendValue);
            }
        }
    }
    return true;
}
```
This automatic conversion works great when loading all slices and levels containing entities with old BlendComponents in them. The earlier versions are automatically modified to properly take advantage of the new floating point format. However, this conversion function is not effective when data patches are involved. Since data patches do not contain a representation of the entire BlendComponent class, the version converter cannot be used to modify the lone value stored in the data patch. In fact, there is no way for the serializer to know that the integral value being supplied is out of date. Behavior at this point is undefined and could result in a crash or, in some cases, data loss and data corruption.

The following example shows the sequence of events that can cause the data loss or corruption.

**An example sequence of events**

1. BlendComponent Version 1 is created.
2. A content creator makes "Slice A," which includes an entity with BlendComponent Version 1 on it.
3. A content creator instantiates Slice A and changes the Blend Value field in the Blend Component.
4. The creator now selects Slice A, and possibly other entities, and creates a new nested slice, "Slice B."
5. Slice B now contains a data patch, which points to the Blend Value field in Slice A and contains an integer.
6. The BlendComponent is updated to Version 2. Blend Value is now stored as a float.
7. A content creator instantiates Slice B. This results in undefined behavior.

**How to Avoid Data Loss**

We recommend the following three-step process to help avoid data loss and stability issues in Lumberyard v1.22 and earlier:

1. Do not change existing serialization fields. If a change is required, add a new field. This prevents earlier data patches from potentially causing crashes and lets you continue loading old assets. When implementing a version converter, do not remove the old field. Just read the old field and add a new one.
2. In your component's Init function, perform the conversion again on the old data. If the result differs from the data in the new field, it must have come from a data patch, and you can replace it.
3. Propagate all changes made to the value in the new field over to the old field. This prevents the Init function from overwriting any future changes made to the new field's value when loading.

**Note**

If it is not possible to keep the two values in sync in step 3, then the only way to prevent further issues after following steps 1 and 2 is to load and resave all slices which contain the versioned component, and then remove the Init function and the old field.

The following example demonstrates these steps for preventing data loss by revising the earlier example of version 2 of the BlendComponent.
// Blend Component (V2)
class BlendComponent : public Component
{
public:
    AZ_TYPE_INFO(BlendComponent, "{ED986571-2B3D-4E22-A2D8-F74A29A730DE}");
    static void Reflect(ReflectContext* context)
    {
        if (auto serializeContext = azrtti_cast<SerializeContext*>(context))
        {
            serializeContext->Class<BlendComponent>()
                ->Version(2, BlendComponent::VersionUpgrader)
                ->Field("BlendState", &BlendComponent::m_blendState)
                // REFLECT THE NEW FIELD AND THE OLD FIELD /////
                ->Field("NewBlendState", &BlendComponent::m_floatBlendState);
        }
    }

    void Init() override
    {
        // MIGRATE DATA PATCHES TO NEW DATA HERE /////
        float newBlendState = float(m_blendState) / 100.0f;
        if (newBlendState != m_floatBlendState)
        {
            m_floatBlendState = newBlendState;
        }
    }

    bool VersionUpgrader(SerializeContext & context, DataElementNode & classElement)
    {
        if (version < 2)
        {
            int oldBlendValue;
            int oldBlendIndex = classElement.FindElement(AZ_CRC("BlendState"));
            if (oldBlendIndex != -1)
            {
                if (classElement.GetSubElement(oldBlendIndex).GetData(oldBlendValue))
                {
                    float newBlendValue = float(oldBlendValue) / 100.0f;
                    // NO LONGER REMOVE THE OLD DATA ///</
                    classElement.AddElementWithData(context, "NewBlendState",
                        newBlendValue);
                }
            }
        }
    }

    private:
    // A value from 1 to 100 representing the blend state
    // ADD A NEW FIELD RATHER THAN REPLACING THE OLD ONE /////
    int m_blendState;
    float m_floatBlendState;
};

Edit Context

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.
Download O3DE or visit the AWS Game Tech blog to learn more.

The Lumberyard edit context is a utility context that relies on the Serialization Context (p. 1033). You can use the edit context to expose parameters of serialized data for editing in Lumberyard Editor.
Lumberyard User Guide Lumberyard User Guide
Behavior Context

However, the edit context is an abstract container for edit data. As such, it is not directly tied to any
speciﬁc editor. Any editor can query the data in the edit context and implement its own visualization and
editing controls.
The following code shows an EditContext deﬁnition:
AZ::EditContext* editContext = serializeContext->GetEditContext();
if (editContext)
{
editContext->Class<MyEditStruct>("MyEditStruct", "My edit struct class used for ...")
;
}

An EditContext consists of ClassElements and DataElements.
• ClassElements – Specify attributes of the class that was reﬂected through the
SerializeContext::Class. You can use this to group common elements.
• DataElements – Specify the display, behavior, and visualization of the ﬁelds that were serialized
through SerializeContext::Field.

Attributes
You can use the EditContext to add arbitrary attributes to class and data elements.
Attributes are template based. As such, they can be of any type, including functions, as in the following
example.
editContext->Class<EditorLightComponent>(
"Light", "Attach lighting to an entity.")
->ClassElement(AZ::Edit::ClassElements::EditorData, "")
->Attribute(AZ::Edit::Attributes::AutoExpand, true)
->Attribute(AZ::Edit::Attributes::NameLabelOverride,
&EditorLightComponent::GetLightTypeText)
->DataElement(AZ::Edit::UIHandlers::Default, &EditorLightComponent::m_configuration,
"Settings", "Light configuration")
->Attribute(AZ::Edit::Attributes::Visibility,
AZ_CRC("PropertyVisibility_ShowChildrenOnly", 0xef428f20))
->ClassElement(AZ::Edit::ClassElements::Group, "Cubemap generation")
->Attribute(AZ::Edit::Attributes::Visibility, &EditorLightComponent::IsProbe)
->Attribute(AZ::Edit::Attributes::AutoExpand, true)

For convenience, Lumberyard stores a library of frequently used and implemented attributes in the ﬁle
dev\Code\Framework\AzCore\AzCore\Serialization\EditContextConstants.inl.

Behavior Context
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.
Download O3DE or visit the AWS Game Tech blog to learn more.
You can use the behavior context to reﬂect runtime code to make it accessible to scripting languages like
Lua or scripting environments like Lumberyard's Script Canvas. The behavior context provides bindings
that invoke runtime C++ code.
You can use the behavior context to bind the following C++ constructs for scripting:
Version 1.28
1053


• Classes (p. 1054)
• Methods (p. 1056)
• Properties (p. 1057)
• Constants (p. 1057)
• Enums (p. 1057)

In addition to the bindings for C++ constructs, the behavior context provides bindings for Lumberyard's EBus (p. 1851).

• EBus (p. 1058)
• Event Handlers (p. 1058)
• Events (p. 1059)

**Classes**

Classes that are bound to the behavior context become objects that can be instantiated in a script environment. To reflect a class, you must provide the type that is reflected as a template argument to the class function. The base classes should also be specified, as in the following example:

```cpp
if (BehaviorContext* behaviorContext = azrtti_cast<BehaviorContext*>(reflection))
{
    behaviorContext->Class<MyClass, TheBaseClass>();
}
```

**Attributes**

You can use the built-in attributes described in this section to decorate a class.

**Category**

Used by the editor to categorize the object in a list.

Type: string

You can use the forward slash (/) separator to nest categories, as in the following example:

```cpp
Attribute(AZ::Script::Attributes::Category, "Gameplay/Triggers")
```

**ExcludeFrom**

A flag that optionally hides this object from specific types of exposure. This flag is primarily used for internal objects that are not intended to be accessible by script.

Type: AZ::Script::Attributes::ExcludeFlags

Possible values: List, Documentation, Preview, All

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>List</td>
<td>Hides the object from editor lists.</td>
</tr>
<tr>
<td>Documentation</td>
<td>Makes the object unavailable for self-documentation.</td>
</tr>
<tr>
<td>Preview</td>
<td>Excludes this object from appearing in preview builds but can be enabled manually.</td>
</tr>
</tbody>
</table>
### Behavior Context

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>All</td>
<td>Hides the object from all possible uses.</td>
</tr>
</tbody>
</table>

#### Storage

Specifies the owner of the memory storage for the reflected object.

**Type:** AZ::Script::Attributes::StorageType

**Possible values:** ScriptOwn, RuntimeOwn, Value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScriptOwn</td>
<td>Specifies that the memory is owned and maintained by the script system (for example, Lua). This is the default value.</td>
</tr>
<tr>
<td>RuntimeOwn</td>
<td>Specifies that the memory is managed by a native code implementation in C++.</td>
</tr>
<tr>
<td>Value</td>
<td>Specifies that the object is stored by value in the script system's virtual machine (VM).</td>
</tr>
</tbody>
</table>

#### ConstructibleFromNil

Specifies whether the class is constructed by default when nil is provided.

**Type:** bool

**Possible values:** true, false

#### ClassNameOverride

Provides a custom name for script reflection that is different from the behavior context name.

**Type:** string

#### Ignore

Specifies whether the element is used script reflection.

**Type:** bool

**Possible values:** true, false

#### Deprecated

Marks a reflected class, method, EBus, or property as deprecated.

**Type:** bool

**Possible values:** true, false

#### ToolTip

Used by the editor to display additional information in a tool tip.

**Type:** string

### Class Reflection Examples

Classes reflected for scripting become objects that can be instanced in Lua, as in the following example:
local myObj = MyClass()

Classes can also specify custom constructors for scripting purposes. For example, the following constructor enables a custom constructor that specifies an integer:

behaviorContext->Class<MyClass>("MyClass")
    ->Constructor<int>()
;

This constructor enables the class to be instantiated in Lua in the following way:

-- Constructor in Lua
local myClass = MyClass(10)

Methods

You can reflect methods either as free functions or as part of classes, as in the following examples:

// This method is reflected as a free function:
behaviorContext->Method("AZTestAssert", &AZTestAssert);

// This method is reflected as a part of a class:
behaviorContext->Class<MyMath>("MyMath")
    ->Method("Cos", &cosf);

As in the previous example, class methods that are reflected for scripting are accessible through the reflected class:

-- Method from a class
local math = MyMath()
local result = math:Cos(3.14)

-- Free method
AZTestAssert(ScriptClass ~= nil)

Methods can specify parameters and default values for those parameters, as in the following example:

int globalMethod(int a)
{
    return a + 3;
}
behaviorContext->Method("globalMethod", &globalMethod, BehaviorMakeDefaultValues(555))

When you bind a method to the behavior context, you can provide an array of strings that contain the method's name and describe its arguments. This is useful when you want to provide friendly names or facilitate documentation.

The following example shows a method whose arguments contain descriptive strings.

// Given this method:
bool BoundsCheckMethodWithDefaultValue(float value, float epsilon, float minBounds, float maxBounds)
{
    (void)epsilon;
    return value >= minBounds && value < maxBounds;
// Bind the given method to the behavior context with friendly argument names.
Method("MemberWithDefaultValues", &BehaviorTestClass::BoundsCheckMethodWithDefaultValue,
  { {{"value", "Value which will be checked to be within the two bounds arguments"},
    {"delta", "The epsilon value"},
    BehaviorMakeDefaultValue(0.1f)},
    {{"minBound", "The minimum bounds value"},
    BehaviorMakeDefaultValue(0.0f)},
    {{"maxBound", "The maximum bounds value"},
    BehaviorMakeDefaultValue(1.0f)}}
  );

This approach is especially useful in Lumberyard's Script Canvas so that users can understand the meaning of the arguments that they are expected to provide.

**Properties**

You can reflect properties as parts of classes or as global properties. You can reflect properties as write only, read only or read/write. To do this, provide either a getter, a setter, or both for the property.

The following table shows helper macros that you can use to simplify the specification of a property's getter or setter or both.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Helper</th>
<th>Macro Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Setter</td>
<td>BehaviorValueSetter-&gt;Property(&quot;boolean&quot;, nullptr, BehaviorValueSetter(&amp;TestBehaviorContextProperties::m_booleanProp))</td>
<td></td>
</tr>
<tr>
<td>Getter</td>
<td>BehaviorValueGetter-&gt;Property(&quot;boolean&quot;, BehaviorValueGetter(&amp;TestBehaviorContextProperties::m_booleanProp), nullptr)</td>
<td></td>
</tr>
<tr>
<td>Both</td>
<td>BehaviorValueProperty-&gt;Property(&quot;isStatic&quot;, BehaviorValueProperty(&amp;AZ::TransformConfig::m_isStatic))</td>
<td></td>
</tr>
</tbody>
</table>

**Constants**

You can reflect constants into the behavior context. Constants are by definition read-only. The following examples reflect two constants into the behavior context:

```cpp
behaviorContext->Constant("SystemEntityId", BehaviorConstant(SystemEntityId));
behaviorContext->Constant("PI", BehaviorConstant(3.14f));
```

** Enums**

Enums are reflected globally into the behavior context. For this reason, it is important to give them unique names.

The following example reflects the enum `GE_VALUE1` and two of its possible values globally into the behavior context.

```cpp
behaviorContext->Enum<(int)GE_VALUE1>("GE_VALUE1");
behaviorContext->Enum<(int)GlobalClassEnum::Value1>("Value1");
```
EBus

The ability to bind an EBus to the behavior context enables scripting to become driven and modular. The two main use cases for reflecting EBuses to the behavior context are event handlers and events.

Because EBuses are highly configurable, the features that become available depend on how the EBuses was created. For more information, see the Working with the Event Bus (EBus) system (p. 1851).

Event Handlers

By reflecting event handlers, you can enable events to be implemented directly in script.

To implement an event handler

1. Given the following EBus, reflect an event handler:

   ```cpp
class TestBusMessages
   : public AZ::EBusTraits
   {
   public:
    virtual void SetSum1(int) = 0;
    virtual int GetSum1(int) = 0;
   };
   using TestBus = AZ::EBus<TestBusMessages>;
   ```

2. Implement the event handler bindings, as in the following example:

   ```cpp
class TestBusHandler
   : public TestBus::Handler
   , public AZ::BehaviorEBusHandler
   
   { public:
    AZ_EBUS_BEHAVIOR_BINDER(TestBusHandler, "{CD26E702-6F40-4FF9-816D-4DCB652D97DF}",
    AZ::SystemAllocator,
    SetSum1,
    GetSum1);
   void SetSum1(int d1) override
   {
    Call(FN_SetSum1, d1);
   }
   int GetSum1(int d1) override
   {
    int result = 0;
    CallResult(result, FN_GetSum1, d1);
    return result;
   }
   };
```

This handler is what binds a C++ EBus interface to a script language such as Lua.

3. Tell the behavior context reflection that the event handler is available, as in the following example.

   ```cpp
   behaviorContext.EBus<TestBus>("TestBus")-
   Handler<TestBusHandler>()->
   Event("SetSum1", &TestBus::Events::SetSum1)->
   Event("GetSum1", &TestBus::Events::GetSum1)->
   ;
   ```

4. Optionally provide the implementation for the EBus handler, as in the following example.
Lumberyard User Guide

Behavior Context

MyBusHandlerMetaTable1 = {
    SetSum1 = function(self, _1)
        -- custom handler code can go here!
        TestAssert(_1 == 1)
        end,
    GetSum1 = function(self, _1)
        -- custom handler code can go here!
        return _1
        end,
}

handler = TestBus.Connect(MyBusHandlerMetaTable1)

Events

Events provide a mechanism to broadcast or send an event directly to any object that is connected to the
EBus through an ID.

By reflecting events to an EBus, you can broadcast or send the events in scripting, as the following
examples show.

behaviorContext.EBus<TestBus>("TestBus") ->
    Handler<TestBusHandler>() ->
        Event("SetSum1", &TestBus::Events::SetSum1) ->
        Event("GetSum1", &TestBus::Events::GetSum1) ->
    ;

    -- Lua:
    local result = TestBus.Broadcast.GetSum1(1)

For information on addressing EBuses, see Working with the Event Bus (EBus) system (p. 1851).

For more information about the behavior context, see Behavior Context in Depth (p. 1059).

Behavior Context in Depth

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In Lumberyard 1.8, the behavior context replaces script context. The behavior context works with serialize context, edit context, and network context to provide rich C++ reflection. The behavior context focuses on the runtime aspects of C++ code and allows you to manipulate C++ code and objects while they are being created. All script bindings, including Lua, use this reflection. Reflection is also used for modification of objects while in running state (such as animating object properties) and reading of current properties for component state transitions. You can have multiple behavior contexts that are specialized for different purposes, and you can unreflect the behavior contexts in order to implement reloading. At a high level, the behavior context uses only a few primitives on which to build: properties, methods, classes, EBuses and attributes.

For C++ API reference documentation on the behavior context, see the BehaviorContext Class Reference in the Amazon Lumberyard C++ API Reference.

Reflection API

This section describes how methods, properties, classes, and other primitives are used in the Lumberyard reflection API.
Method

Methods reflect a C++ function. You can have global or class methods. Each method must have a unique name for its scope (global or class). You can also provide default values; this allows you to call reflected methods with fewer arguments. Default values are used right to left. You can also provide a debug description for your method. It's highly recommended that you do so. The debug description information is provided to users for context when they use the reflection, as is done with ClassView in the Lua editor. The system automatically generates a description that includes result and argument types. However, adding intent and additional details to your descriptions greatly improves the usability of your reflection. This is especially important when a method has many attributes.

Property

Properties access data and can be global properties or class properties. Each property must have a unique name for its scope. As is customary, a property has getter and setter methods. If you don’t provide a setter method for a property, the property is read only. If you don’t provide a getter method, the property is write only.

Lumberyard does support global functions, member functions, and Lambda functions as property getters and setters.

Lumberyard provides macros that you can use to wrap a class value. You can use BehaviorValueProperty(&value) to implement getter and setter methods, or you can implement them individually by using BehaviorValueGetter and BehaviorValueSetter. These macros implement Lambda functions for those values. When the state of your object is modified, you might have to perform operations other than simply setting the value. For this reason, it is a best practice to always implement your getters and setters. You can always change your implementation later.

Constant

Constants are implemented as read-only properties and can be global or restricted to a class. A behavior context macro called BehaviorConstant implements the Lambda getter for you.

Enum

Because class enums often require casting, Lumberyard currently treats all enums values as int. Enums are implemented as read-only int properties.

Class

Reflects a C++ class or struct. You can provide an optional name. If you do not provide a name, the class name from AzTypeInfo is used. That name must be unique for the scope. Because the system uses AzRTTI to build the class hierarchy, you can use RTTI if you want to reflect base class functionality.

- **Allocator** - You can provide a custom allocator/deallocator for your class. This allows you to override any existing allocation schema. If you do not provide a custom allocator, aznew/delete is used (AZ_CLASS_ALLOCATOR).
- **Constructor** - Allows you to enumerate the class constructors that you want to reflect. You must pass all constructor arguments as template augments.
- **Wrapping/WrappingMember** - Allows code to inform the system that it is a wrapper of another class. This is useful when you reflect smart pointers and string wrappers.
- **_userdata** - Allows you to provide a pointer to user data. The pointer is accessible from all callbacks (like a custom allocator) that you implement for the class.
- **Method** - Reflects a C++ class function. The first argument is the class pointer. This is the same usage as global methods.
- **Property** - Reflects class data. The first argument is the class pointer. This is the same usage as global properties.
- **Enum** - Enums are int read-only properties.
• **Constant** - Constants are read-only properties.

**Nested Classes**

To bind a nested class to the behavior context, you must do it from within a function on the nested class. C++ rules about nested class member access from outside scopes make this requirement necessary.

The following counterexample shows a poorly formed nested class. The code does not work.

```cpp
//Bad nested class
class Outer
{
    public:
        AZ_TYPE_INFO(Outer, "...");
        static void Reflect(AZ::ReflectContext* context);
        class Inner
        {
            public:
                AZ_TYPE_INFO(Inner, "...");
                int m_member = 0;
        }
};
void Outer::Reflect(AZ::ReflectContext* context)
{
    if (AZ::BehaviorContext* behavior = azrtti_cast<AZ::BehaviorContext*>(context))
    {
        behavior->Class<Inner>("OuterInner")
        ->Property("member", BehaviorValueProperty(&Inner::m_member))
    }
}
```

The following code shows a well formed nested class.

```cpp
//Good nested class
class Outer
{
    public:
        AZ_TYPE_INFO(Outer, "...");
        static void Reflect(AZ::ReflectContext* context);
        class Inner
        {
            public:
                AZ_TYPE_INFO(Inner, "...");
                static void Reflect(AZ::ReflectContext* context);
                int m_member = 0;
        }
};
void Outer::Reflect(AZ::ReflectContext* context)
{
    Inner::Reflect(context);
}
void Outer::Inner::Reflect(AZ::ReflectContext* context)
{
    if (AZ::BehaviorContext* behavior = azrtti_cast<AZ::BehaviorContext*>(context))
    {
```
EBus

EBus reflects Lumberyard event bus messages. Depending on your EBus configuration, Broadcast, Event (with ID) and Queuing are reflected. Queuing is a generic function to be executed when the bus messages are consumed.

- **Event** - Reflects an EBus event. Depending on your EBus configuration, Lumberyard automatically reflects Broadcast, Event, QueueBroadcast, and QueueEvent.
- **Handler** - Reflects a class that you must implement to forward messages from the EBus to behavior context methods. You must create a class that can monitor the specified EBus and forward messages to the behavior context. This is a requirement because the behavior context cannot guarantee that there is a handler for each message. If a message expects a result, you must provide a default result in case the message is not handled by the behavior context user. Keep in mind that the system creates as many of these handlers as the behavior context requires. Handlers can also execute in different threads. As a result, you should avoid static storage for values that change. The best way to understand this is to examine the example that follows.

Example

The following code example shows the use of the Lumberyard reflection API.

```cpp
// Global Property
behaviorContext.Property("globalProperty", &GlobalPropertyGetter, &GlobalPropertySetter); // Property with getter and setter function
behaviorContext.Property("globalProperty", []() { return g_globalValue; }, [](int value) { g_globalValue = value; }); // Property with Lambda functions.
behaviorContext.Property("globalReadOnlyProperty", &GlobalPropertyGetter, nullptr); // Read only property with a getter function.
behaviorContext.Property("globalReadOnlyProperty", []() { return g_globalValue; }, nullptr); // Read only property with a Lambda function.
behaviorContext.Property("globalReadOnlyProperty", BehaviorValueGetter(&g_globalValue), nullptr); // Read only property with a value and a helper macro.
// Write only is the same as ReadOnly, but with the setter enabled and the getter set to nullptr. These properties are rare.

// Global Methods
behaviorContext.Method("GlobalMethod", &GlobalMethod);

// Global Constants and Enums (implemented using properties). The functions are provided for clarity.
behaviorContext.Constant("PI", []() { return 3.14f; });
behaviorContext.Constant("PI", BehaviorConstant(3.14f));
behaviorContext.Enum<EnumIntValue>("EnumIntValue");

// Class - When you declare a class, if you want to reflect base class functionality, just use RTTI.
behaviorContext.Class<MyClass>() // The name of the class comes from AzTypeInfo. In this case the name is "MyClass".
    ->Constructor<int>() // Optional additional constructors. You can have as many as needed.
```
Constant("epsilon",BehaviorConstant(0.001f)) // Class constant. All features from the global versions apply.
Enum<MyClass::ENUM_VALUE>("ENUM_VALUE") // Class enum. All features from the global versions apply.
Method("Method",&MyClass::Method) // Class method. All features from the global versions apply.
Property("data", &MyClass::GetData(), &MyClass::SetData) // Class features. All features from the global versions apply.

// EBus
class MyEBusBehaviorHandler : public MyEBus::Handler, public AZ::BehaviorEBusHandler
{
public:
AZ_EBUS_BEHAVIOR_BINDER(MyEBusBehaviorHandler ,"{19F5C8C8-4260-46B1-B624-997CD3F10CBD}", AZ::SystemAllocator, // Name, TypeId and default allocator.
  OnEvent);// List of event names to handle and support for BehaviorContext.

void OnEvent(int a) override // This is an event listener like other EBus listeners.
{
  Call(FN_OnEvent,a); // Forward the event to a behavior listener if there is one.
  FN_***EventName*** events are declared by the AZ_EBUS_BEHAVIOR_BINDER macro.
}
};

behaviorClass.EBus<MyEBus>("MyEBus") // EBuses are not required to have TypeInfo, so you must always provide a name.
->Handler<MyEBusBehaviorHandler >() // Allow systems that use behavior context to create handlers for this EBus every time
  // they must listen for events. If you reflect a bus without a handler, behavior context users can only send events.
->Event("OnEvent", &MyEBus::Events::OnEvent) // Allow behavior context system to send an "OnEvent" event. The code automatically generates // Broadcast, Event, QueueBroadcast, QueueEvent, and QueueFunctions if the EBus configuration // supports them. You don’t have to provide events; you can only provide a handler if // you don’t have behavior context systems to send events.
;

// Properties, methods, classes and ebuses can have attributes. An attribute is a combination of a Crc32 ID and a value. The value // can be a constant, a variable address, a global function, a class member function, or a class member variable address.
behaviorClass.Method("GlobalMethod", &GlobalMethod)
  ->Attribute("ValueAttr",10) // Value attribute.
  ->Attribute("MethodAttr", &SomeOtherGlobalMethod)
;
// You add the same attributes to a property...
behaviorClass.Property("GlobalProperty", BehaviorValueProperty(&g_globalValue)
  ->Attribute("MyAttr",20)
;
// or to a class or class method or property.
behaviorClass.Class<MyClass>()
  ->Attribute("ClassAttr",100)
  ->Attribute("ClassAttr1", &MyClass::SomeMethod)
  ->Method("Method", &MyClass::Method)
  ->Attribute("MethodAttr",100)
  ->Property("data", BehaviorValueProperty(&MyClass::m_data))
    ->Attribute("PropertyAttr",500)
;
Add modular features and assets with Gems

Gems are packages that contain code and assets to augment your game projects. With the Programming with Gems (p. 1073), you can choose the features and assets that you need for your game project without including unnecessary components. For a list of all gems included in Lumberyard, see Gems Available in Lumberyard (p. 1113).

Lumberyard features two types of Gems:

- **Code & Assets** – Contains assets as well as code that performs certain functions upon the assets.
- **Assets Only** – Contains only assets and no code.

All Lumberyard gems are located in the following directory:

```
lumberyard_version\dev\Gems
```

The gems that you enable are automatically detected and built through the integrated Using the Waf Build System (p. 63).

**Note**

To enable **Code & Assets** Gems, you must select the Create, Modify and Build projects option in Lumberyard Setup Assistant. This option is not required for **Assets Only** gems. For more information, see Running Lumberyard Setup Assistant (p. 16).

You can enable Gems with the Project Configurator (p. 44) or the command line (Lmbr.exe (p. 56)).

**Topics**

- Enabling Gems (p. 1064)
- Creating a Gem (p. 1066)
- Programming with Gems (p. 1073)
- Gems Available in Lumberyard (p. 1113)

---

**Enabling Gems**

You can enable gems using the Project Configurator or from a command line. To enable a gem from a command line, see Gems Commands (p. 58).

**To enable gems with the Project Configurator**

1. Open the Lumberyard Project Configurator, located at `lumberyard-version\dev\Bin64\BuildPlatform\ProjectConfigurator.exe`. For example, when using Visual Studio
2017 as your build platform, the Project Configurator is located at `lumberyard-version\dev\Bin64\vc141\ProjectConfigurator.exe`.

2. In the Project Configurator, select your active game project and choose **Set as default**.

3. Click **Enable Gems**.

4. Select the gems that you want to enable.

5. Click **Save**.

6. If you enabled gems labeled **CODE & ASSETS**, you must build your game project to make the gems available in Lumberyard Editor. If you enabled only gems labeled **ASSETS ONLY**, you do not need to build your game project before opening it in Lumberyard Editor.

For more information, see **Building Lumberyard projects (p. 61)**.
Creating a Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can create your own gems by packaging your assets into the Lumberyard gem format. This makes your package distributable, shareable between projects, and easy for game developers to enable or disable as needed.

Creating your gem involves placing code, assets, and several other special files into the correct directory structure. This chapter describes the creating a gem procedure in detail.

To structure your assets as a gem, see the following.

Topics

• Creating a New Empty Gem (p. 1066)
• Packaging Your Assets (p. 1071)
• Testing Your Gem (p. 1072)
• Compressing Your Gem (p. 1072)

Creating a New Empty Gem

You can create a new, empty gem using either the Project Configurator (p. 1066) or the command line (p. 1069). When you create a new gem, Lumberyard automatically creates a directory structure for your gem in the `\dev\Gems\` directory. It also adds the special gem files and directories needed to function as a gem.

Topics

• Creating a Gem with the Project Configurator (p. 1066)
• Creating a Gem from the Command Line (p. 1069)

Creating a Gem with the Project Configurator

Use Project Configurator to create a new, empty gem.

1. Open the Lumberyard Project Configurator, located at `lumberyard-version\dev\Bin64\BuildPlatform\ProjectConfigurator.exe`. For example, when using Visual Studio...
2017 as your build platform, the Project Configurator is located at `lumberyard-version\dev\Bin64vc141\ProjectConfigurator.exe`.

2. Select the project and click **Enable Gems**.
3. Click **Create a new Gem** on the gems page for the game project that you selected.

4. In the **Create a new gem** dialog box:
   a. For **Name**, enter a name for the gem (for example, *MyNewGem*). The name must start with a letter, and only alphanumeric characters and underscore are allowed for the rest of the name. Other special characters or spaces are not allowed in the name.
   b. (Optional) For **Summary**, enter a description for the gem.

      This field also supports hyperlinks using a simple html anchor tag. When entering this directly into the **Summary** field in the Project Configurator, use the following syntax:

      ```html
      <a href="http://www.amazon.com">Amazon</a>
      ```

      If you are editing the Summary parameter in the gem.json file, use the following syntax:

      ```json
      "Summary": "<a href="http://www.amazon.com">Amazon</a>",
      ```
   c. For **Type**, select **Code & Assets** or **Assets Only**.
      - **Code & Assets** – Contains assets as well as code that performs certain functions upon the assets.
      - **Assets Only** – Contains only assets and no code.
   d. Choose **Create Gem**.
5. Close the Project Configurator.

The following directories and files are created in `\dev\Gems\gem_name\` for ‘Assets Only’ and ‘Code & Assets’ gems:

- **Assets** – Directory of assets for your gem, such as materials, models, textures, and audio files. The AZ::IO system automatically includes this directory so that you can reference assets provided by your gem. For example, if you have a material file, `\Assets\materials\MyMaterial.mtl`, you can reference it in your code with the path `materials\MyMaterial.mtl`.

  **Note**
  If this directory is not present, you can manually add it. If you don't have any assets in your gem, you can remove this folder.

- **Gem.json** – Metadata for this gem. Do not modify the **Uuid** or **Name** fields. You can specify the following gem metadata fields:
  
  - **Version** – `n.n.n` (numerical values only).
    
    Gem revision is not supported, so you should not plan to increment the revision after shipping the gem.
  
  - **DisplayName** – Friendly display name. Can contain spaces.
  
  - **Tags** – Searchable tags that are displayed in Project Configurator under the gem’s summary. Enter this as a comma-separated list of strings.
  
  - **IconPath** – Path to the gem’s display icon.
  
  - **Summary** – Detailed description of the gem. This parameter supports hyperlinks. To specify a hyperlink, use the following syntax:

    ```json
    "Summary": "<a href="http://www.amazon.com">Amazon</a>",
    ```

  - **Dependencies** – You can specify a dependency on another gem or on an engine version. Edit the `_comment` metadata.

    ```json
    "Dependencies": [
      {
        "Uuid": "540fa970c994668b5d02c66a39c6625",
        "VersionConstraints": [">1"
        ],
        "_comment": "zzzTestVer001"
      }
    ]
    ```
Creating a New Empty Gem

- preview.png – Preview image displayed in the Project Configurator gem's list.

For 'Code & Assets' gems, the following files and directories are also created (in addition to the files listed above):

- Code\gem_name\waf_files – Waf files json for your gem that specifies which files are built, how files should be combined into uber files, and how files are filtered in the Visual Studio Project.
- Code\gem_name\_test.waf_files – Additional files to include when building with the test specification.
- Code\wscript – Waf wscript Python file that defines libraries and other build settings used by your gem.
- Code\Include\gem_name\gem_name\Bus.h – Globally visible header that can be included by any project that uses your gem, or by other gems that depend on it. External code can call into your gem's module and receive events from your module through public event buses. Event buses allow simple and safe function calls between different modules of code.
- Code\Source\gem_name\Module.cpp – Implementation of the gem_name Module. Starting in Lumberyard 1.5, new gems are built around AZ modules. The default module registers one system component, the gem_name\SystemComponent.
- Code\Source\gem_name\SystemComponent.h – Header for the gem_name\SystemComponent implementation. This component is registered by the gem_name\Module and is a handler for the gem_name\Bus.
- Code\Source\gem_name\SystemComponent.cpp – gem_name\SystemComponent implementation. Inside this component are the typical Activate, Deactivate, Init, and Reflect methods.
- Code\Source\StdAfx.cpp – Code\Source\StdAfx.h
- Code\Tests\gem_name\Test.cpp

6. Build your game project:

- If your gem is a Code & Assets gem, you must build your project (p. 61).
- If your gem is an Assets Only gem, you do not need to build your project.

Creating a Gem from the Command Line

You can also use the command line to create a gem. You can do this in either the command line or the Project Configurator (p. 1066).

If you add a Code & Assets gem, you must build your project (p. 61) after adding the gem. Asset Only gems do not require a rebuild.

To create a gem with the command line

1. Open a command-line prompt and navigate to the lumberyard_version\dev\Bin64\vc141 directory.
2. Enter one of the following commands:

   - Create a Code & Asset gem if your gem contains assets as well as code that performs certain functions upon the assets.
   - lmbr gems create MyNewGem

   - Create an Assets Only gem if your gem contains only assets and no code.
Creating a New Empty Gem

```
lmbr gems create MyNewGem -asset-only
```

3. Close the command line.

The following directories and files are created in `\dev\gems\gem_name\` for 'Assets Only' and 'Code & Assets' gems:

- **Assets** – Directory of assets for your gem, such as materials, models, textures, and audio files. The AZ::IO system automatically includes this directory so that you can reference assets provided by your gem. For example, if you have a material file, `\Assets\materials\MyMaterial.mtl`, you can reference it in your code with the path `materials\MyMaterial.mtl`.

  **Note**
  If this directory isn't present, you can manually add it. If you don't have any assets in your gem, you can remove this folder.

- **Gem.json** – Metadata for this gem. Don't modify the Uuid or Name fields. You can specify the following gem metadata fields:
  - **Version** – n.n.n (numerical values only).
    Gem revision isn't supported, so you shouldn't plan to increment the revision after shipping the gem.
  - **DisplayName** – Friendly display name. Can contain spaces.
  - **Tags** – Searchable tags that are displayed in Project Configurator under the gem's summary. Enter this as a comma-separated list of strings.
  - **IconPath** – Path to the gem's display icon.
  - **Summary** – Detailed description of the gem. This parameter supports hyperlinks. To specify a hyperlink, use the following syntax:
    ```
    "Summary": "<a href="http:\/\/www.amazon.com\">Amazon</a>",
    ```
  - **Dependencies** – You can specify a dependency on another gem or on an engine version. Edit the `_comment` metadata.
    ```
    "Dependencies": [
      {
        "Uuid": "540faf970c994668b5d02c66a39c6625",
        "VersionConstraints": [
          ">1"
        ],
        "_comment": "zzzTestVer001"
      }
    ],
    ```
  - **preview.png** – Preview image displayed in the Project Configurator gem's list.

For 'Code & Assets' gems, the following files and directories are also created (in addition to the files listed above):

- **Code\gem_name.waf_files** – Waf files json for your gem that specifies which files are built, how files should be combined into uber files, and how files are filtered in the Visual Studio Project.
- **Code\gem_name_test.waf_files** – Additional files to include when building with the test specification.
- **Code\wscript** – Waf wscript Python file that defines libraries and other build settings used by your gem.
Packaging Your Assets

Before you can include your assets in your new gem, you must place them within your Lumberyard's game project root directory. This way, they will be imported by Lumberyard Asset Pipeline and converted into assets that Lumberyard can use. After you move and import your assets, you must test them in Lumberyard to ensure that they still work as intended. You then move the verified assets into the gem directory structure that was created when you created a new gem.

Tip
To avoid conflicts with similarly named assets, we recommend that you use a namespace workflow or acronyms when you create directories that contain assets in gems. For example, you can add a directory between Assets and Textures so that the directory doesn't conflict with other gems that might have identically named textures. Your structure might look like the following:

\lumberyard_version\dev\Gems\gem_name\Assets\example_name\Textures\CommonTextureName.tif

To package your assets

1. Prepare your asset directory.
   a. Create a directory directly beneath your game project's root directory. For example, the Samples Project's game project root directory is \dev\SamplesProject.
   b. Place into the new directory your assets and any related files and subdirectories containing files that your assets use, such as textures. Ensure that you maintain the original directory structure within the asset directory to avoid breaking relative file paths in your assets.
   c. If preferred, you can create additional subdirectories for organization purposes. Be sure to amend any file references that may be broken by the new structure.

2. Import the assets into Lumberyard. To do this, launch Lumberyard. The Asset Processor automatically detects the new assets and imports them.

3. Verify and test the assets.
   a. In Lumberyard, open a level and find your asset directory in the Asset Browser. If the Asset Browser is not open, click Tools, Asset Browser to open it.
b. Drag your assets into the level and verify that they look and function as intended. If necessary, make changes to the assets, such as assigning textures or changing materials.

c. Save any changes that you made to your assets and close Lumberyard.

4. Move the contents of your asset's root directory that you created in Step 1. Be sure to include the metadata files generated by the Asset Processor. Place the contents into the new gem's Assets directory. This is located at `\dev\Gems\gem_name\Assets`.

   **Note**
   The Gem's Assets directory maps to the root of your project folder. For example, if your asset is in `\dev\project_name\my_asset\`, then it maps to the gem at `\dev\Gems\my_gem\Assets\my_asset\`.

### Testing Your Gem

After you move your assets into the gem's directory structure, you can enable your new gem in your game project and test it in Lumberyard.

**To enable and test your new gem**

1. Open the Project Configurator by doing one of the following:
   - Open Lumberyard Setup Assistant and on the **Summary** page, click **Configure project**.
   - Open the Lumberyard Project Configurator directly from `lumberyard-version\dev\Bin64\BuildPlatform\ProjectConfigurator.exe`. For example, when using Visual Studio 2017 as your build platform, the Project Configurator is located at `lumberyard-version\dev\Bin64\vc141\ProjectConfigurator.exe`.

2. Enable (p. 1064) your new gem.

3. Close the **Project Configurator**.

4. Launch Lumberyard and open a level.

5. Use the **Asset Browser** to place the gem's assets into your scene. Verify that your assets look as intended. If they don't, verify that you have set up the directories correctly.

### Compressing Your Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can compress your gem to make it distributable to other Lumberyard game developers. To do this, you zip the contents of the gem directory using your preferred zip tool, and change the `.zip` filename extension to `.crate`. The compressed `.crate` file must be under 4GB in size. By renaming the `.zip` to `.crate`, game developers who use your gem can unpack and install it by drag and dropping it into Lumberyard.

**To compress your gem into a crate file**

1. Using a file browser, open your gem's directory. For example, `lumberyard_version\dev\Gems\my_gem`.

2. Select the contents of this directory and use your preferred zip tool to zip them.

   **Note**
   Don't include your gem's top level directory as part of the zip file. Select the files and directories inside the `my_gem` directory to zip.
3. After the .zip file is created, remove the .zip extension and rename it to .crate.

Your gem crate is ready for distribution.

Programming with Gems

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The modular gems system is a management infrastructure for sharing code and art assets between Lumberyard game projects. The modular gems system consists of gem packages that you can access and manage with the Project Configurator (p. 43) or \lmbx.exe (p. 56). You can use gems to add functionality such as code, art, scripts, supporting files, and references to other gems to your game project.

Topics
- Gem Structure (p. 1073)
- Adding C++ Code to a Lumberyard Game with Gems (p. 1086)
- Using AZ Modules to Initialize Gems (p. 1090)

Gem Structure

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Each gem package can contain the following:
• Assets
  • A `gem.json` file
  • An icon file
  • Code

To locate Lumberyard Gems

• Navigate to the `lumberyard_version\dev\Gems` directory. For more information, see Gems Available in Lumberyard (p. 1113).

Topics

• Gem Assets (p. 1074)
• Gem Icon File (p. 1074)
• Gem JSON File (p. 1074)
• Gem Code (p. 1077)
• Gem List File – `gems.json` (p. 1079)
• Accessing Gems in Code (p. 1079)
• Gem Configuration Examples (p. 1080)

Gem Assets

Each gem has an `Assets` directory that contains models, textures, scripts, and animations. Asset files are accessed the same way as they are in a game project. Lumberyard uses this root directory to find the asset file path. For example, when Lumberyard looks for the `textures\rain\rainfall_ddn.tif` file, it looks in the `<GemName>\Assets\textures\rain\rainfall_ddn.tif` directory.

Gem Icon File

The gem icon is a `.jpg`, `.png`, or `.gif` file. The following example is the icon for the Lightning Arc Gem (p. 1152).

![Lightning Arc Gem Icon](image)

Gem JSON File

Example

This example file contains metadata for the gem and the following properties.

```json
{
  "GemFormatVersion": 4, // Required
  "Uuid": "e5f049ad7f534847a89c27339cf6a6", // Required
  "Name": "ExampleGem", // Required
  "DisplayName": "Environment Gem", // Optional, defaults to the [Name] field
  "Summary": "Gem description.", // Optional, defaults to ""
}```
"Tags": [  "Weather",  "Weather Effects",  "Sky" ],
"EditorTargets": ["RainEditorPlugin"],
"LumberyardVersion": ["==1.11.0.0"],
"Version": "1.0.0",
"IconPath": "path\preview.png",
"Modules": [
  {
    "Type": "ModuleType",
    "Name": "ModuleName",
    "Extends": "GameModule"
  }
],

"Dependencies": [
  {
    "Uuid": "d378b5a7b47747d0a7aa741945df58f3",
    "VersionConstraints": ["~>1.0"],
    
  }
]

GemFormatVersion

Version number that identifies how a gem is built (folder structure and semantics) and determines compatibility with specific versions of Lumberyard. The version number is set automatically when you create a gem in the Project Configurator.

- Lumberyard 1.11 and later – Gems have a default value of 4 for the GemFormatVersion field.
- Lumberyard 1.5 to 1.10 – Gems have a default value of 3 for the GemFormatVersion field. The gems that are included with Lumberyard are AZ modules.
- Lumberyard 1.4 and earlier – Gems have a default value of 2 for the GemFormatVersion field.

Uuid

Unique ID that identifies the gem.

Name

Name of the gem.

DisplayName

Friendly name of the gem that appears in the Project Configurator.

Summary

Short description of the gem.

Tags

List of tags that describe the gem.

EditorTargets

List of additional Waf targets to build. This is useful for targets defined in the wscript such as adding editor plugins that accompany gems.

LumberyardVersion

Version of Lumberyard to specify. The value can be one of the following:
- An array of strings (for example, ["~>1.2.345.6789", "~>1.1.1", ">= 1.0"]).
• A single string that describes the constraint (for example, "==1.2.3").

For more examples of acceptable version specifiers, see the list under Dependencies (p. 1076).

**Version**

API version of the gem. The version should follow the Semantic Versioning specification.

**IconPath**

Path from the gem directory to the display icon. The icon can be a .jpg, .png, or .gif file. The recommended icon size is 160 x 90 px.

**Modules**

Code product that the gem produces. Each module entry can have the following fields:

• **Type** – Type of module that is defined. See Module Types (p. 1077).

• **Name** – Name of the module. You use this name when you refer to the module, and in the module's output file name.

• **Extends** – Module to use as a base. The value can be only "GameModule" and you can use this field only for the following module types:
  • EditorModule
  • Builder

If the module does not have a name, specify "GameModule".

By default, this module takes the following fields from the extended module's build settings. If you specify any of the following values, they override the parent module.

• file_list
• platforms
• configurations
• defines
• includes
• features
• lib
• libpath
• use
• uselib

**Dependencies**

UUIDs and versions of other gems to which the gem depends. Acceptable version specifiers have an operator and a version number. Consider these examples:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Minimum</th>
<th>Maximum</th>
</tr>
</thead>
<tbody>
<tr>
<td>== 1.2.3</td>
<td>Minimum: 1.2.3</td>
<td>Maximum: 1.2.3</td>
</tr>
<tr>
<td>&gt;= 1.2.3</td>
<td>Minimum: 1.2.3</td>
<td>Maximum: None</td>
</tr>
<tr>
<td>&lt;= 1.2.3</td>
<td>Minimum: None</td>
<td>Maximum: 1.2.3</td>
</tr>
<tr>
<td>&gt; 2.0.0</td>
<td>Minimum: 2.0.0 (exclusive)</td>
<td>Maximum: None</td>
</tr>
<tr>
<td>&lt; 2.0.0</td>
<td>Minimum: None</td>
<td>Maximum: 2.0.0 (exclusive)</td>
</tr>
<tr>
<td>~&gt; 1.2.3</td>
<td>Minimum: 1.2.3</td>
<td>Maximum: 1.3.0 (exclusive)</td>
</tr>
<tr>
<td>-&gt; 1.2</td>
<td>Minimum: 1.2.0</td>
<td>Maximum: 2.0.0 (exclusive)</td>
</tr>
</tbody>
</table>
The following fields apply to GemFormatVersion 3 and earlier:

**EditorModule**

Defines whether the gem produces a module that is loaded by Lumberyard Editor.

**LinkType**

Defines how other gems and game projects should link to this gem:
- **Static** – Does not produce a .dll file and does not link.
- **Dynamic** – Produces a .dll file and links all dependent projects against the .dll file using an import library.
- **NoCode** – Does not produce a .dll or .lib file. The gem contains assets but not code. You can add a gem with the NoCode value to a game project without rebuilding.

**Module Types**

Following are module types and how to define them. For examples of gems with module types defined, see Gem Configuration Examples (p. 1080).

**GameModule**

The most basic type of module. If you used gems before, your gems produce this type of module by default. These modules are loaded by Lumberyard Setup Assistant and Lumberyard Editor.

*Note*

If a gem has more than one GameModule type, you can omit the Name field for one GameModule type. This allows a gem's product .dll file to keep the same name when you upgrade to GemFormatVersion 4.

**EditorModule**

Loaded by Lumberyard Editor. If an EditorModule extends a GameModule, the EditorModule is loaded instead of the GameModule in Lumberyard Editor. This is useful when an EditorModule contains the same components as a GameModule, along with their editor components.

**StaticLib**

Module type that is useful when your gem requires helper code that is linked to all dependents of your gem, or when your gem provides only statically usable code. All modules in all gems that require this gem have this StaticLib linked against it.

**Builder**

Used by Asset Processor for building assets. For more information, see Creating a Custom Asset Builder (p. 318).

**Gem Code**

You can find a gem's code in the `<GemName>\Code` directory. The directory contains the following:

**wscript**

Waf build script that is generated by the template. The script contains all build configuration options, including target name, included paths, required libs, defines, and so on. In most cases, this script does not need to be changed.
For more information, see Wscript and Modules (p. 1078).

**gemname.waf_files**

JSON list of all files that are included in the game project. The root object contains properties for each uber file, and a special `NoUberFile` object. Each child object contains a named array of files, where the name is the filter that is used in generated projects. The gem template provides a default `.waf_files` list. All new files for your game project should be added to this file.

**gemname_tests.waf_files**

JSON list of all test files for a gem, in the same format as `gemname.waf_files`.

**Include/GemName**

Directory contains headers that define the gem's public API.

Other gems can include this directory. It should not contain implementations nor anything other than virtual function definitions. The gem template provides a default `GemNameBus.h` that contains a `GemNameRequestBus` interface, which defines public functionality.

For more information, see Working with the Event Bus (EBus) system (p. 1851).

**Source**

Directory that contains the following generated files:

- `StdAfx.h` – Includes frequently required files.
- `StdAfx.cpp` – Includes the `StdAfx.h` file.
- `GemNameSystemComponent.h` – Contains the definition of a system component that handles calls to `GemNameRequestBus`.
- `GemNameSystemComponent.cpp` – Contains the implementation of the `GemNameSystemComponent` class.
- `GemNameModule.cpp` – Contains the `AZ::Module` class definition, which is used to register components and do additional component reflection.

**Note**

This class can be made to extend `CryHooksModule` (in `IGem.h`) instead to have `gEnv` attached automatically.

**Tests**

Directory that contains unit tests for your gem. Add all files in this directory to the `gemname_tests.waf_files`.

- `GemNameTest.cpp` – Contains an example for writing gtests for your gem, which are unit test files for your gem.

**Wscript and Modules**

The gem's `wscript` must call `bld.DefineGem(...)` in order for the gem to build properly. The `DefineGem` function expects keyword arguments, mapping from a module's name to a data type dictionary of the build settings for the module. If the module does not have a name, its build settings may be placed directly in the call to `DefineGem()`.

For each module, the following default settings are applied:

- **target**: `gem_name_module_name`

  If the module does not have a name, the default value is `gem_name`.

- **file_list**: `gem_name_module_name.waf_files`

  If the module does not have a name, the default value is `gem_name.waf_files`
• **test file_list**: `gem_name_module_name_tests.waf_files`  
  If this file exists, it is automatically added to the `file_list` when building tests.

• **vs_filter**: "Gems"

• **output_file_name**: `Gem.gem_name.module_name.gem_uuid.gem_version`  
  If the module does not have a name, the default value is `Gem.gem_name.gem_uuid.gem_version`.

• **platforms**: all  
  For Builder and EditorModule module types, the default value is: ['win', 'darwin'].

  For more information, see *Module Types* (p. 1077).

  **Note**  
  Overriding this value is not recommended.

• **configurations**: all  
  For Builder and EditorModule module types, the default value is: ['debug_all', 'profile_all'].

  **Note**  
  Overriding this value is not recommended.

• **includes**: ['Include', 'Source']  
  This also contains the include path of all dependencies.

• **pch**: 'StdAfx.cpp'  
  **use**: All modules that require linking from all dependencies.

For more information about waf and wscript files, see *Using the Waf Build System* (p. 63).

### Gem List File – gems.json

You can find the `gems.json` list file at the root of each project directory. For example, for the Samples Project, the `gems.json` file is located in the `lumberyard_version\dev\SamplesProject` directory. This example file lists all gems used in the game project.

**Example**

```json
{
    "GemListFormatVersion": 2,  // Required
    "Gems": [  
        {
            "Path": "Gems/Rain",  // Required
            "Uuid": "e5f049ad7f534847a89c27b7339c6f6a6",  // Required
            "Version": "0.1.0",  // Required
            "_comment": "Rain"  // Optional, useful comment
        }
    ]
}
```

### Accessing Gems in Code

You can access gems through code, as in the following example:

```cpp
#include <GemName/GemNameBus.h>

EBUS_EVENT(GemName::GemNameRequestBus, MyFunction, withArgs);
```
Gem Configuration Examples

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The following are example configurations for gems and their wscript files.

Contents

- Gem with a GameModule (p. 1080)
- Gem with a GameModule and Name (p. 1080)
- Gem with a StaticLib and Name (p. 1081)
- Gem with an EditorModule and Name (p. 1081)
- Gem with an EditorModule that Extends a GameModule (p. 1082)
- Gem with a StaticLib and Standalone Module (p. 1083)
- Gem with a Header Only Library with Unit Testing (p. 1084)
- Gem with a StaticLib Only and Unit Testing (p. 1085)

Gem with a GameModule

The following example gem adds one module type as GameModule.

```json
{  
  "GemFormatVersion": 4,
  "Uuid": "e5f049ad7f534847a89c27b7339cf6a6", // Required
  "Name": "MyGem", // Required
  "Version": "1.0.0", // Required
  "Modules": [  // Optional
    
    {  
      "Type": "GameModule"  // Required
    }
  ]
}
```

The following is the wscript file for the gem.

```python
def build(bld):
    bld.DefineGem(
        # The following are the default settings, and do not need to be specified (unless changes are preferred)
        # target    = ['MyGem'],
        # file_list = ['mygem.waf_files'],
        # vs_filter = ['Gems'],
    )
```

Gem with a GameModule and Name

The following example gem has one module type as GameModule and specifies a name for that module.

```json
{  
  "GemFormatVersion": 4, // Required
  "Uuid": "e5f049ad7f534847a89c27b7339cf6a6", // Required
  "Name": "MyGem", // Required
```

Version 1.28
1080
The following is the `wscript` file for the gem.

```python
def build(bld):
    bld.DefineGem(
        Components = dict(
            # The following are the default settings, and do not need to be specified
            # target    = ['MyGem.Components'],
            # file_list = ['mygem_components.waf_files'],
            # vs_filter = ['Gems'],
            ),
        )
```

**Gem with a StaticLib and Name**

The following example gem has one module type as `StaticLib` and specifies a name for that module.

```python
{
    "GemFormatVersion": 4,                       // Required
    "Uuid": "e5f049ad7f534847a89c27b7339cf6a6", // Required
    "Name": "MyGem",                            // Required
    "Version": "1.0.0",                         // Required
    "Modules": [                                // Optional
        {
            "Type": "StaticLib",                // Required
            "Name": "HelperCode"                // Required
        }
    ]
}
```

The following is the `wscript` file for the gem.

```python
def build(bld):
    bld.DefineGem(
        HelperCode = dict(
            # The following are the default settings, and do not need to be specified
            # target    = ['MyGem.HelperCode'],
            # file_list = ['mygem_helpercode.waf_files'],
            # vs_filter = ['Gems'],
            ),
        )
```

**Gem with an EditorModule and Name**

The following example gem has one module type as `EditorModule` and specifies a name for the module.

```python
{
```
"GemFormatVersion": 4,                      // Required
"Uuid": "e5f049ad7f534f47a89c27b7339cf6a6", // Required
"Name": "MyGem",                            // Required
"Version": "1.0.0",
"Modules": []                                // Optional
{
    "Type": "EditorModule",               // Required
    "Name": "Editor",                  // Required
}

} 

The following is the wscript file for the gem.

def build(bld):
    bld.DefineGem(
        Editor = dict(
            # The following are the default settings, and do not need to be specified
            # unless changes are preferred
            # target    = ['MyGem.Editor'],
            # file_list = ['mygem_editor.waf_files'],
            # vs_filter = ['Gems'],
            # platforms = ['win', 'darwin'],
            # configurations = ['debug', 'debug_test', 'profile', 'profile_test'],
        ),
    )

Gem with an EditorModule that Extends a GameModule

The following example gem has two module types, GameModule and EditorModule, specifies a name for both, and then extends the EditorModule.

{
    "GemFormatVersion": 4,                      // Required
    "Uuid": "e5f049ad7f534f47a89c27b7339cf6a6", // Required
    "Name": "MyGem",                            // Required
    "Version": "1.0.0",
    "Modules": []                                // Optional
    {
        "Type": "GameModule",               // Required
        "Name": "Components"                // Optional
    },
    {
        "Type": "EditorModule",            // Required
        "Name": "Editor",                  // Required
        "Extends": "Components"            // Optional
    }
}

The following is the wscript file for the gem.

def build(bld):
    bld.DefineGem(
        Components = dict(
            # The following are the default settings, and do not need to be specified
            # unless changes are preferred
            # target    = ['MyGem.Components'],
            # file_list = ['mygem_components.waf_files'],
        ),
    )
Gem Structure

# vs_filter = ['Gems'],
defines   = ['MY_GEM'],
use        = ['AzCore'],
),
Editor = dict(
# The following are the default settings, and do not need to be specified
# (unless changes are preferred)
# target    = ['MyGem.Editor'],
# file_list = ['mygem_components.waf_files', 'mygem_editor.waf_files'],
# vs_filter = ['Gems'],
# platforms = ['win', 'darwin'],
# configurations = ['debug', 'debug_test', 'profile', 'profile_test'],
# defines   = ['MY_GEM'], # this is inherited from Components
# this is inherited from Components
use        = ['AzToolsFramework'], # This overrides the Components module's
    'use', so only 'AzToolsFramework' is 'use'd
   ),
}

Gem with a StaticLib and Standalone Module

The following example gem has a StaticLib module, a Standalone module, and specifies a name for both.

{
    "GemFormatVersion": 4,
    "Uuid": "089562a2cbbd41749b359f85fa04f1c9",
    "Name": "CrashReporting",
    "DisplayName": "CrashReporting",
    "Version": "0.1.0",
    "Summary": "Enable external crash reporting for a game project",
    "Tags": ["Untagged"],
    "IconPath": "preview.png",
    "Modules": [
        {
            "Type": "StaticLib",
            "Name": "StaticLibrary"
        },
        {
            "Type": "Standalone",
            "Name": "Uploader"
        }
    ]
}

The following is the wscript file for the gem.

```python
def build(bld):
    bld.DefineGem(
        StaticLibrary = dict(
            platforms   = ['win'],
            includes    = ['.', 'Include'],
            file_list   = ['crashreporting_static.waf_files'],
            win_file_list = ['crashreporting_static_win.waf_files'],
            use         = ['CrashHandler']
        )
    )

    uploader_file_list = ['game_crash_uploader.waf_files']
    platform = bld.env['PLATFORM']
    if platform == 'project_generator':
```

Version 1.28

1083
uploader_file_list.append('game_crash_uploader_win.waf_files')
uploader_file_list.append('game_crash_uploader_unimplemented.waf_files')
elif platform in ['win_x64_vs2017', 'win_x64_vs2019']:
    uploader_file_list.append('game_crash_uploader_win.waf_files')
else:
    uploader_file_list.append('game_crash_uploader_unimplemented.waf_files')

bld.CryQtApplication(
    # Settings
    target          = 'CrashReporting.Uploader',
    output_file_name = 'GameCrashUploader',
    file_list       = uploader_file_list,
    vs_filter       = 'Gems',
    includes        = ['Include'],
    platforms       = ['win'],
    configurations  = ['all'],
    use             = ['CrashUploaderSupport', 'AzCore'],
    disable_pch     = True,
    win_lib         = ['rpcrt4', 'version', 'powrprof', 'winhttp', 'user32', 'advapi32'])

Gem with a Header Only Library with Unit Testing

The following example gem has a Standalone module with unit testing.

```json
{
    "GemFormatVersion": 4,                      // Required
    "Uuid": "e5f049ad7f534847a89c27b7339cf6a6", // Required
    "Name": "MyGem",                            // Required
    "Version": "1.0.0",                         // Required
    "Modules": [],                              // Optional
    
    
    "Type": "Standalone",               // Required
    "Name": "Lib"                       // Optional
}
```

The following is the wscript file for the gem.

```python
def build(bld):
    bld.CryEngineModule(
        # The following are the default settings, and do not need to be specified
        # (unless changes are preferred)
        # target          = ['MyGem.Lib'],
        # file_list       = ['mygem_lib.waf_files'],
        # vs_filter       = ['Gems'],
        test_all_file_list = ['mygem_lib_tests.waf_files'],
        platforms       = ['win', 'darwin'],
        configurations  = ['debug_test', 'profile_test'],
    )
```

Note
The gem must exist in the gems.json for your project but should be removed from the game.xml and editor.xml files.

1. In Project Configurator, create the gem and make the changes to the gem.json and wscript files.
2. Do one of the following:
Gem with a StaticLib Only and Unit Testing

The following example gem has a StaticLib module, and a Standalone module for unit testing.

```json
{
    "GemFormatVersion": 4, // Required
    "Uuid": "e5f049ad7f534847a89c27b7339cf6a6", // Required
    "Name": "MyGem", // Required
    "Version": "0.1.0",
    "Modules": [
        {
            "Name": "StaticLibrary",
            "Type": "StaticLib"
        },
        {
            "Name": "UnitTestModule",
            "Type": "Standalone",
            "Extends": "StaticLibrary"
        }
    ]
}
```

The following is the wscript file for the gem.

```python
def build(bld):
    bld.DefineGem(
        StaticLibrary = dict(
            # The following are the default settings, and do not need to be specified
            # (unless changes are preferred)
            # target    = ['MyGem.Lib'],
            # file_list = ['mygem_lib.waf_files'],
            # vs_filter = ['Gems'],
        )
    )

    bld.CryEngineModule(
        # The following are the default settings, and do not need to be specified (unless changes are preferred)
        # vs_filter = ['Gems'],
        target          = 'TestGem.UnitTestModule',
        output_file_name = 'TestGemUnitTests',
        file_list = ['mygem_tests.waf_files'],
        platforms   = ['win', 'darwin'],
        configurations = ['debug_test', 'profile_test']
    )
```

**Note**

The gem must exist in the gems.json for your project but should be removed from the game.xml and editor.xml files.

1. In Project Configurator, create the gem and make the changes to the gem.json and wscript files.
2. Do one of the following:
   a. In a command line window, navigate to the \lmbr.exe file and enter the following command.

   \lmbr \projects \populate-appdescriptors

   b. In a text editor, delete the entries for the gem from the game.xml and gem.xml files.

**Adding C++ Code to a Lumberyard Game with Gems**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

To add C++ code or assets to your Lumberyard game, use a gem (p. 1064). This document shows you how to create a gem and the various techniques that you can use to add code to it.

**Creating and Configuring Gems**

Creating a gem is straightforward. To create or enable a gem for your game project, follow the steps in the Add modular features and assets with Gems (p. 1064). The gem that you create or enable is located in the \dev\Gems\<gem name> directory. The gem’s directory structure is similar to the following example. Your gem might not have all the directories listed.

```
\3rdParty
\Assets
\Code
 \Include
 \Source
 \Tests
\External
```

- 3rdParty – Contains third-party definition files that are specific to the gem.
- Assets – Contains assets to include in the game project that are specific to the gem.
- Code\Include – An additional header include path to add to a game project that uses the gem.
- Code\Source – Contains the source code for the gem.
- Code\Tests – Contains unit testing source code for projects that are built in a test configuration.
- External – Contains external libraries on which the gem depends that are specific to the gem.

**Code Directory Contents**

The \dev\Gems\<gem name>\Code subdirectory has the following items that Lumberyard creates by default:

<table>
<thead>
<tr>
<th>Item</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>An empty EBus (p. 1851) include file that is named after the gem.</td>
<td>\Include&lt;gem name&gt;&lt;gem name&gt;Bus.h</td>
</tr>
<tr>
<td>The AZ module for the gem</td>
<td>\Source&lt;gem name&gt;Module.cpp</td>
</tr>
</tbody>
</table>
Lumberyard User Guide
Adding C++ Code to a Lumberyard Game with Gems

<table>
<thead>
<tr>
<th>Item</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>The default systems component files</td>
<td>\Source&lt;gem name&gt;SystemComponent.h</td>
</tr>
<tr>
<td></td>
<td>\Source&lt;gem name&gt;SystemComponent.cpp</td>
</tr>
<tr>
<td>Standard precompiled header files</td>
<td>\Source\StdAfx.h</td>
</tr>
<tr>
<td></td>
<td>\Source\StdAfx.cpp</td>
</tr>
<tr>
<td>Skeleton unit test source file</td>
<td>\Tests&lt;gem name&gt;Test.cpp</td>
</tr>
</tbody>
</table>

Lumberyard also creates certain Waf (p. 63)–related files in the \dev\Gems\gem name\Code subdirectory. These files specify the source code content and how the gem is defined and built.

<table>
<thead>
<tr>
<th>Item</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manifest file for the Waf build of the gem</td>
<td>&lt;gem name&gt;.waf_files</td>
</tr>
<tr>
<td>Manifest file that lists additional files to for test configuration builds (for example, Tests/&lt;gem name&gt;Test.cpp)</td>
<td>&lt;gem name&gt;_tests.waf_files</td>
</tr>
<tr>
<td>Waf build script file that defines the gem</td>
<td>wscript</td>
</tr>
</tbody>
</table>

The manifest file that manages the source code uses the Lumberyard Waf waf_files schema to define the source files, their Microsoft Visual Studio filter, and uber (p. 139) file grouping. The default <gem name>.waf_files that the Project Configurator generates looks like the following:

```json
{
    "none": {
        "Source": [
            "\Source/StdAfx.cpp",
            "\Source/StdAfx.h"
        ]
    },
    "auto": {
        "Include": ["\Include/<gem name>/<gem name>Bus.h"
        ],
        "Source": [
            "\Source/<gem name>Module.cpp",
            "\Source/<gem name>SystemComponent.cpp",
            "\Source/<gem name>SystemComponent.h"
        ]
    }
}
```

The .waf_files file contains the following three levels of indentation:

- The first level contains the uber file mapping for uber file–enabled builds.
- none specifies files to be excluded from the uber file. Precompiled headers must be listed here.
- auto specifies files that are automatically combined into modules that are optimized for compile time by Waf.
- You can also specify a fixed uber file name (for example, my_gem_uber_0.cpp) at this level to specially group a set of files. All of the files in the grouping are combined into
my_gem_uber_0.cpp. This technique is useful to restrict which files are combined, like operating system-specific code.

- The second level represents the Visual Studio filters that determine how the files are organized in the Visual Studio solution that Waf generates.
- A special value called Root represents the root node of the project explorer in Microsoft Visual Studio (that is, the file is not placed in any subdirectory).
- The third level contains paths to the source files relative to the location of the waf_files file itself.

### Updating Gem Code

To update code in your gem, add a third-party library, new source code files, system components, or dependencies on other gems or Lumberyard modules.

#### Adding an External Third-Party Library to a Gem

A gem can use any Lumberyard third-party library, including its own private third-party library. To register a private third-party library for a gem, create a third-party configuration file in the \3rdParty directory of the gem. For more information, see Adding Third-Party Libraries (p. 105).

When you set the configuration file to an external third-party library, the library can be added as a gem dependency through the Waf dependency mechanism. For information about third-party library configuration files, see Creating Third-Party Library Configuration Files for Waf (p. 108).

Waf uses two conventions to add dependencies to third-party libraries: uselib and use. The convention uselib is a wscript keyword that configures a module to link to a library's include path, library path, and library. If a gem uses uselib to consume its gem-specific library, then that library is available to the gem only for compiling and linking.

The convention use is similar to the uselib keyword, except that the library's dependencies are recursively propagated to the module that adds the dependency. If a gem uses use to consume its gem-specific library, then the library can be used recursively. This means that if the gem is enabled, the gem-specific third-party library is also available to the game project or dependent gems.

#### Adding New Source C++ Files to Gems

To add source code (for example, C++ or Qt) to a gem, use the Lumberyard Using the Waf Build System (p. 63). Place internal source files (that is, files not meant to be exposed outside of the gem) under the \Code\Source directory. Place header files that can be included in projects or other gems in the \Code\Include\<gem name>\ directory. Place additional unit tests in the \Code\Tests directory.

To add code files to a gem

1. Add the files to the target location. For consistency, we recommend that you place the source files somewhere in the \Code directory.
2. Add the source files to the Waf manifest waf_files file. Following the format described earlier, add the source file paths to either the <gem name>.waf_files file and/or the <gem name>_test.waf_files file.
3. From a command prompt window, run lmbr_waf configure to configure Waf and regenerate the Microsoft Visual Studio solution.

#### Adding System Components

New gems come with a default system component called <gem name>SystemComponent. You can modify this system component according to your requirements. To communicate with the system component, you can define as many EBuses as required. If you want to add additional components,
you must add the component descriptor to the AZ module for the gem (`\Code\Source\<gem
name>Module.cpp`). For more information, see System Components (p. 1098) and Creating System Components (p. 987).

### Adding Dependencies to a Gem

In addition to adding dependencies to gem-specific third-party libraries, your gem can specify dependencies on Lumberyard Engine modules, other gems, or third-party libraries for Lumberyard.

#### Adding a Dependency on a Lumberyard Module

Any gem can be configured to depend on any of the following Lumberyard framework modules:

- AzCore
- AzFramework
- AzGameFramework
- AzQtComponents
- AzToolsFramework
- GridMate
- GridMateForTools

To declare a dependency on one of these Lumberyard modules, use the Waf `use` mechanism. The following example `wscript` file specifies a dependency on AzFramework.

```python
def build(bld):
    bld.DefineGem(
        # Add custom build options here
        includes = [bld.Path('Code/CryEngine/CryAction'),
                    use = ['AzFramework'],
    )
```

#### Adding a Dependency on Another Gem

You can configure gem A to depend on gem B by modifying gem A's `gem.json` and `wscript` files. The following example shows how the Twitch gem, included with Lumberyard, declares a dependency on the HttpRequestor gem (p. 1144). This `gems.json` file is located in the `lumberyard_installation\dev\Gems\Twitch` directory.

```json
{
    "GemFormatVersion": 3,
    "Uuid": "b63e64141fab40b791211ba257632e84",
    "Name": "Twitch",
    "DisplayName": "Twitch",
    "Version": "1.0.0",
    "LinkType": "Dynamic",
    "Summary": "Provides access to the Twitch Commerce SDK, social functions, login, chat, and other APIs.",
    "Tags": ["Twitch","Commerce","SDK","Social" ],
    "IconPath": "preview.png",
    "Dependencies": [
        {
            "Uuid": "28479e255bde466e91fc34ee808d9c7",
            "VersionConstraints": [ "->1.0" ],
            "_comment": "HttpRequestor"
        }
    ]
}
```
The Twitch gem specifies the HttpRequestor gem in the Dependencies section. The Dependencies section also has a VersionConstraints section that you can use to specify versioning requirements.

The Twitch gem's wscript file uses the use keyword to declare a dependency on HttpRequestor:

```python
def build(bld):
    import lumberyard_sdks
    file_list = []
    if lumberyard_sdks.does_platform_support_aws_native_sdk(bld):
        file_list.append('twitch.waf_files')
    else:
        file_list.append('lmbraws_unsupported.waf_files')

    bld.DefineGem(
        use = ['HttpRequestor', 'LmbrAWS'],
        uselib = [ 'TWITCHFSDK', 'AWS_CPP_SDK_CORE' ],
        includes = [],
        file_list = file_list,
        win_file_list = ['twitch_win.waf_files']
    )
```

Adding a Dependency on a Third-Party Library for Lumberyard

You can define a gem that uses a third-party library for Lumberyard that another module is also using. To do so, use the Waf uselib mechanism to add the dependency to the gem, as in the following example wscript file.

```python
def build(bld):
    bld.DefineGem(
        # Add custom build options here
        includes = [ bld.Path('Code/CryEngine/CryAction') ],
        use = [ 'AzFramework' ],
        uselib = [ 'AWS_CPP_SDK' ]
    )
```

For more information, see Adding Third-Party Libraries (p. 105) and Creating Third-Party Library Configuration Files for Waf (p. 108).

Note
Because the recursive nature of use can lead to linker errors, especially duplicate symbol errors, uselib is a better choice.

Using AZ Modules to Initialize Gems

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

AZ modules are code libraries designed to plug into Lumberyard games and tools. An AZ module is a collection of C++ code built as a static or dynamic library (.lib or .dll file) that implements specific initialization functions. When a Lumberyard application starts, it loads each module and calls these initialization functions. These initialization functions allow the module to connect to core technologies such as reflection, serialization, event buses (p. 1851), and the Working with component entities (p. 462).
Lumberyard uses the AZ module interface to extract the contents of your gem into the global environment. Each application has a single entity associated with it that is referred to as the system entity (p. 1104). AZ modules can add components to this entity before it is activated. Components that are added to the system entity are called system components. System components are often singleton/manager-type objects that aggregate or provide resources to game components or other systems. Like other entities, a system entity must have its dependencies present. You can assume that any systems that you depend on are booted and available when your system component is activated.

Modules are not a new concept in Lumberyard. In fact, the Lumberyard game engine is a collection of older style modules. These legacy modules have served the game engine well, but they have a number of shortcomings which are addressed by AZ modules, as presented in the next section.

Lumberyard currently supports both legacy modules and AZ modules but going forward will use AZ modules. Beginning in Lumberyard 1.5, a gem can contain AZ module code. Creating a new gem is the easiest way to get up a new AZ module up and running.

**Note**
AZ is the namespace of the AZCore C++ library upon which AZ modules are built. The letters AZ refer to Amazon; the term is a preview name that has nothing to do with Amazon Availability Zones and may be subject to change.

### Comparing AZ Modules to Legacy Modules

AZ modules have significant advantages over legacy modules, as the following table shows:

<table>
<thead>
<tr>
<th>Topic</th>
<th>Legacy Modules</th>
<th>AZ Modules</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compatibility</td>
<td>Modules can be converted to AZ modules with no loss of functionality.</td>
<td>Anything that can be done in a legacy module can also be done in an AZ module. Most AZ module code could live within a legacy module, but legacy modules are not likely to be compatible with future AZ module–based Lumberyard tools.</td>
</tr>
<tr>
<td>Ease of adding services</td>
<td>Adding services usually requires editing files in CryCommon. A file for the singleton's class interface must exist in the CryCommon directory, and a variable to hold the singleton in gEnv must exist.</td>
<td>Modules create components and attach them to the system entity. No editing of game engine files is required.</td>
</tr>
<tr>
<td>(singleton classes) to modules</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Ease of use for low-level</td>
<td>Modules load late, which prevents them from contributing low-level features to an application. All critical features must be in a single module that loads before others.</td>
<td>Modules load early in the application's startup sequence and are initialized in discrete stages. This allows <em>any</em> module to provide a low-level feature at an early stage that other modules can take advantage of later.</td>
</tr>
<tr>
<td>application features</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Exposure of properties</td>
<td>Modules have no uniform way to let users control settings for their service. Some services read settings from .xml files in the</td>
<td>AZ modules expose the properties of system components to the Lumberyard reflection system. The reflection system makes information about</td>
</tr>
<tr>
<td>Game engine dependency</td>
<td>Modules must run in the game engine and are difficult to extend for use in tools that do not have game code.</td>
<td>Modules are not specific to the game engine and can be used outside it.</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------</td>
</tr>
<tr>
<td>Initialization functions</td>
<td>Function parameters are specific to CryEngine.</td>
<td>Function parameters are specific to the AZ framework; for more information, see the following section.</td>
</tr>
<tr>
<td>Order of initialization</td>
<td>Singleton code often depends on services offered by other singletons, so modules must be initialized in a very particular order. However, the order is not obvious. If someone is unfamiliar with the code in the modules, their loading order is difficult to ascertain.</td>
<td>Each module explicitly states its dependencies on system components. After all system components are examined, they are sorted according to these dependencies and initialized in the appropriate order. Each module is a first-class citizen.</td>
</tr>
</tbody>
</table>

### A Self-Aware Method of Initialization

Legacy modules are loaded in a particular order. Because **CrySystem** is loaded and initialized before the game module, it must provide all low-level systems such as logging and file I/O that a subsequent module might depend on. The game module itself cannot provide such low-level systems because it's initialized too late.

**AZ modules**, on the other hand, are all loaded as early as possible, and then initialized in stages. Because each module explicitly states its dependencies on system components, all system components can be examined beforehand, sorted according to dependencies, and initialized in the appropriate order (p. 1098). This makes it possible for low-level functionality (like a custom logging system) to be implemented from a game module. For more information about the initialization order of components, see **The AZ Bootstrapping Process** (p. 1112).

### Relationship with the AZ Framework

**AZ modules** are designed to work with the AZ framework, which is a collection of Lumberyard technologies such as reflection, serialization, **event buses** (p. 1851), and the **Working with component entities** (p. 462). The AZ framework supports game development but can also be used outside it. For example, Lumberyard tools like the Lumberyard Setup Assistant, **Using Asset Processor** (p. 248) and the component entity system use the AZ framework and AZ modules, but contain no game code. When the Resource Compiler builds slices, it loads AZ modules to extract reflection information about components within them.

AZ modules are code libraries that are built to use the AZ framework. When an AZ framework application loads an AZ module, the AZ module knows how to perform tasks such as gathering reflection information about the data types defined within that library.

### Smarter Singletons

AZ modules build their services (which are singleton classes) by using the same component entity system that Lumberyard uses to build in-game entities. A module simply places a system component on the system entity. This solves many of the problems associated with singletons in legacy modules.
The GUI in Lumberyard Editor uses the reflection system to expose the properties of entities (gameplay components) to designers. In the same way, Lumberyard uses the reflection system to expose the properties of system components so that you can customize your settings for a particular game. Because system components are really no different from gameplay components, you can use the Project Configurator to edit the properties of system components (p. 1104) just as you edit the properties of in-game components.

**Current Lumberyard AZ Modules**

The gems (p. 1100) provided with Lumberyard are all built as AZ modules. In addition, there are two AZ modules that are not built as Gems.

- **LmbrCentral**
  
  LmbrCentral contains components that wrap functionality from legacy modules. For example, the MeshComponent utilizes IRenderNode under the hood. LmbrCentral is used by game applications.

- **LmbrCentralEditor**
  
  Components can have editor-specific implementations that integrate with technology not available in the game runtime environment. Therefore, a separate module, LmbrCentralEditor, is used by Lumberyard Editor. This module contains all the code from LmbrCentral, plus code that is only for use in tools. The LmbrCentralEditor module is not for use in standalone game applications.

**Parts of an AZ Module, Explained**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

An AZ module has three key components: a class that inherits from AZ::Module, one or more public facing event buses, and a system component class.

This page describes module initialization, the use of system components as singletons, how EBus calls communicate with this singleton, and how to call the module externally after you have created it.

**The Module Class**

Each AZ module must contain a class that inherits from AZ::Module. When the module is loaded by an application, an instance of the class is created very early in the application's lifetime and its virtual functions are called at the appropriate times as the application goes through its bootstrapping process (p. 1112). This class reflects (p. 977) the components declared in the module and adds critical components to the system entity (p. 1104).

*Note*

At its core, every Lumberyard application has a single system entity. When a Lumberyard application starts, it creates the system entity. This entity's components, known as system components, power major systems within Lumberyard. The system entity always has the ID AZ::SystemEntityId (0).

The following skeleton code shows the basic structure of an AZ::Module class.

```cpp
namespace AZ {

/**
 * AZ::Module enables static and dynamic modules (aka LIBs and DLLs) to
 * connect with the running \ref AZ::ComponentApplication.
 */

```
* Each module should contain a class which inherits from AZ::Module.
* This class must perform tasks such as reflecting the classes within
  * the module and adding critical components to the system entity.

```cpp
class Module
{
public:
  Module();
  virtual ~Module();

  // Override to require specific components on the system entity.
  virtual ComponentTypeList GetRequiredSystemComponents() const;
};
```

The AZ::Module class exposes all points of integration with the AZ framework as virtual functions. These points of integration have been created as virtual functions on a class so that, whether initialization code is in a static or dynamic library, it's written the same way as much as possible. The very first actual initialization calls do need to be different for static and dynamic libraries. Lumberyard provides a macro to define this uninteresting glue code and let you write the interesting initialization code within your AZ::Module class.

We recommend that your AZ::Module class contain as little implementation code as possible. When the AZ::Module class is created, the application is just starting up and many systems are unavailable. If the AZ::Module class spawns a singleton or manager class, there is no guarantee that the systems on which this singleton relies will be ready for use. Instead, you should build your singletons as Lumberyard system components (p. 1098), which can control their initialization order.

Beginning in Lumberyard 1.5, gems are built using AZ modules. The following example "HelloWorld" AZ module was made by creating a new gem (p. 1064). The CryHooksModule class in this example is a helper wrapper around AZ::Module and provides your entire module access to gEnv.

```cpp
// dev/Gems/HelloWorld/Code/Source/HelloWorldModule.cpp
#include "StdAfx.h"
#include <platform_impl.h>
#include "HelloWorldSystemComponent.h"
#include <IGem.h>

namespace HelloWorld
{
  class HelloWorldModule : public CryHooksModule
  {
    public:
      AZ_RTTI(HelloWorldModule, "{39C21561-D456-413F-8C83-4214F6DBCA5}",
        CryHooksModule);
  
      HelloWorldModule()
      : CryHooksModule()
      {
        // Create descriptors for components declared within this module.
        m_descriptors.insert(m_descriptors.end(), {
          HelloWorldSystemComponent::CreateDescriptor(),
        });
      }

      // Add required system components to the system entity.
      AZ::ComponentTypeList GetRequiredSystemComponents() const override
      {
        return AZ::ComponentTypeList{
          azrtti_typeid<HelloWorldSystemComponent>(),
        };
      }
  }

  // dev/Gems/HelloWorld/Code/Source/HelloWorldSystemComponent.h
  // dev/Gems/HelloWorld/Code/Source/HelloWorldSystemComponent.cpp
```

Version 1.28
1094
The EBus

External code can call into your module, and receive events from your module, through the module's public event buses (p. 1851) (EBus). The EBus allows simple and safe function calls between different modules of code.

A new gem comes with one EBus by default, as shown in the following example.

```plaintext
// dev/Gems/HelloWorld/Code/Include/HelloWorld/HelloWorldBus.h
#pragma once
#include <AzCore/EBus/EBus.h>
namespace HelloWorld
{
    class HelloWorldRequests : public AZ::EBusTraits
    {
    public:
    #define EBUS_TRAITS_OVERRIDE_HEADER
        // EBusTraits overrides
        // These settings are for a "singleton" pattern.
        // A single handler can connect to the EBus.
        static const AZ::EBusHandlerPolicy HandlerPolicy = AZ::EBusHandlerPolicy::Single;
        // A single address exists on the EBus.
        static const AZ::EBusAddressPolicy AddressPolicy = AZ::EBusAddressPolicy::Single;
    #undef EBUS_TRAITS_OVERRIDE_HEADER

    // Put your public methods here
    virtual void SayHello(const char* name) = 0;
    
    using HelloWorldRequestBus = AZ::EBus<HelloWorldRequests>;
} // namespace HelloWorld
```

Calls to this EBus are handled by the system component, as described in the following section.

The System Component Class

Any major systems in your module that require a singleton should be built as system components. New gems come with a system component by default. The system component class is created during application startup and attached to the system entity (see GetRequiredSystemComponents() in HelloWorldModule.cpp).

In the current example, the system component class handles calls to the public EBus declared in HelloWorldBus.h. The following code shows the HelloWorldSystemComponent class.

```plaintext
// dev/Gems/HelloWorld/Code/Source/HelloWorldSystemComponent.h
#pragma once
#include <AzCore/Component/Component.h>
#include <HelloWorld/HelloWorldBus.h>
namespace HelloWorld
```
class HelloWorldSystemComponent : public AZ::Component, protected HelloWorldRequestBus::Handler
{
  public:
  // Every component definition must contain the AZ_COMPONENT macro,
  // specifying the type name and a unique UUID.
  AZ_COMPONENT(HelloWorldSystemComponent, "{72DFB0EE-7422-4CEB-9A40-426F26530A92}");

  static void Reflect(AZ::ReflectContext* context);
  static void GetProvidedServices(AZ::ComponentDescriptor::DependencyArrayType& provided);
  static void GetIncompatibleServices(AZ::ComponentDescriptor::DependencyArrayType& incompatible);
  static void GetRequiredServices(AZ::ComponentDescriptor::DependencyArrayType& required);
  static void GetDependentServices(AZ::ComponentDescriptor::DependencyArrayType& dependent);

  protected:
  // AZ::Component interface implementation
  void Init() override;
  void Activate() override;
  void Deactivate() override;

  // HelloWorldRequestBus interface implementation
  void SayHello(const char* name) override;

};

namespace HelloWorld
{

  void HelloWorldSystemComponent::Reflect(AZ::ReflectContext* context)
  {
    // Reflect properties that game developers may want to customize.
    if (AZ::SerializeContext* serialize = azrtti_cast<AZ::SerializeContext*>(context))
    {
      serialize->Class<HelloWorldSystemComponent, AZ::Component>()
        ->Version(0)
        ->SerializerForEmptyClass();

      if (AZ::EditContext* ec = serialize->GetEditContext())
      {
        ec->Class<HelloWorldSystemComponent>("HelloWorld", "Says hello")
          ->ClassElement(AZ::Edit::ClassElements::EditorData, "")
          ->Attribute(AZ::Edit::Attributes::AppearsInAddComponentMenu,
                      AZ_CRC("System"))
            ->Attribute(AZ::Edit::Attributes::AutoExpand, true);

      }
    }
  }

}
void HelloWorldSystemComponent::GetProvidedServices(AZ::ComponentDescriptor::DependencyArrayType& provided)
{
    provided.push_back(AZ_CRC("HelloWorldService"));
}

void HelloWorldSystemComponent::GetIncompatibleServices(AZ::ComponentDescriptor::DependencyArrayType& incompatible)
{
    // Enforce singleton behavior by forbidding further components
    // which provide this same service from being added to an entity.
    incompatible.push_back(AZ_CRC("HelloWorldService"));
}

void HelloWorldSystemComponent::GetRequiredServices(AZ::ComponentDescriptor::DependencyArrayType& required)
{
    // This component does not depend upon any other services.
    (void)required;
}

void HelloWorldSystemComponent::GetDependentServices(AZ::ComponentDescriptor::DependencyArrayType& dependent)
{
    // This component does not depend upon any other services.
    (void)dependent;
}

void HelloWorldSystemComponent::Init()
{
}

void HelloWorldSystemComponent::Activate()
{
    // Activate() is where the component "turns on".
    // Begin handling calls to HelloWorldRequestBus
    HelloWorldRequestBus::Handler::BusConnect();
}

void HelloWorldSystemComponent::Deactivate()
{
    // Deactivate() is where the component "turns off".
    // Stop handling calls to HelloWorldRequestBus
    HelloWorldRequestBus::Handler::BusDisconnect();
}

void HelloWorldSystemComponent::SayHello(const char* name)
{
    AZ_Printf("HelloWorld", "Hello %s, you certainly look smashing tonight.", name);
}

For more information about system components, see System Components (p. 1098).

**Calling the Module from External Code**

To call your module, invoke your public function through EBus. This example uses the SayHello function.

```cpp
#include <HelloWorld/HelloWorldBus.h>
```
void InSomeFunctionSomewhere()
{
    // ...
    // Invoke the call through EBus.
    EBUS_EVENT(HelloWorld::HelloWorldRequestBus, SayHello, "Bruce");
    // ...
}

System Components

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A traditional game engine contains many singleton classes, each in charge of a major system. In Lumberyard, these singletons are built using the same component entity system (p. 462) that powers gameplay entities. When an application starts, a system entity is created. Components added to this entity are known as system components. The system entity always has the ID AZ::SystemEntityId(0).

When you build singletons as Lumberyard system components, you are using a powerful suite of complementary technologies that facilitate problem resolution through established patterns. This topic describes system components in detail.

Smart Initialization Order

As a game engine grows in size, it tends to develop many singleton classes. A singleton class often requires communication with other singletons to function. This means that the order in which singletons are initialized is very important. Lumberyard solves this by building singletons as components.

A component can declare the services that it provides and the services on which it depends. When components are activated, they are sorted according to these declared dependencies, ensuring proper initialization order.

The following example shows two components that Lumberyard has ordered for initialization.

class AssetDatabaseComponent : public Component
{
    ...
    static void GetProvidedServices(ComponentDescriptor::DependencyArrayType& provided)
    {
        provided.push_back(AZ_CRC("AssetDatabaseService"));
    }
    ...
};
class AssetCatalogComponent : public AZ::Component
{
    ...
    static void GetRequiredServices(AZ::ComponentDescriptor::DependencyArrayType& required)
    {
        required.push_back(AZ_CRC("AssetDatabaseService"));
    }
    ...
};

The example shows the following:
- AssetDatabaseComponent is activated before AssetCatalogComponent.
- In the AssetDatabaseComponent class, the GetProvidedServices function reveals that the class provides a service called AssetDatabaseService.
- In the AssetCatalogComponent class, the GetRequiredServices function reveals that AssetCatalogComponent depends on AssetDatabaseService. Lumberyard understands this dependency and orders the initialization accordingly.

For more information about the initialization order of components, see The AZ Bootstrapping Process (p. 1112).

Easily Configurable Components

Often, a singleton has settings that are configurable for each game. It can be difficult for a low-level singleton to access configuration data if the system used to process this data hasn't started. Therefore, low-level singletons often rely on simple data sources such as command line parsers or .ini files.

A system component can expose its configuration through AZ reflection (p. 977). The Advanced Settings dialog box in the Project Configurator (p. 1104) uses this feature to enable the configuration of system components on a per-game basis. The Project Configurator saves an application descriptor file (p. 1111) that contains the settings for each system component, and this file is used to bootstrap the application and configure each component before it is activated. This is the same technology that the Entity Inspector (p. 475) uses to configure gameplay entities in Lumberyard Editor.

For more information, see Configuring System Entities (p. 1104).

Writing System Components

To designate a component as a system component, rather than a gameplay component, you must set the AppearsInAddComponentMenu field to System when you reflect to the EditContext.

The following example code designates the MemoryComponent as a system component.

```cpp
void MemoryComponent::Reflect(ReflectContext* context)
{
    if (SerializeContext* serializeContext = azrtti_cast<SerializeContext*>(context))
    {
        ... 
        if (EditContext* editContext = serializeContext->GetEditContext())
        {
            editContext->Class<MemoryComponent>("Memory System", "Manages memory allocators")
                ->ClassElement(AZ::Edit::ClassElements::EditorData,"")
                ->Attribute(AZ::Edit::Attributes::AppearsInAddComponentMenu,
                AZ_CRC("System"))
                ... 
        }
    }
}
```

For more information on writing system components, see Creating System Components (p. 987).

Required System Components

Often, a module requires the existence of a system component. This requirement can be established through the module's GetRequiredSystemComponents() function. Any component type declared here is guaranteed to exist when the application starts.

In the following example, the Oculus gem requires the OculusDevice component.
AZ::ComponentTypeList OculusGem::GetRequiredSystemComponents() const override
{
    return AZ::ComponentTypeList{
        azrtti_typeid<OculusDevice>(),
    };
}

If a system component is optional, you can add it from Advanced Settings in the Project Configurator (p. 1104).

Gems and AZ Modules

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The gems system was developed to make it easy to share code between projects. Gems are reusable packages of module code and assets which can be easily added to or removed from a Lumberyard game. Gems also promote writing code in a way that is more modular than that found in legacy libraries. For example, each gem has its own include folder for its public interface code files. Gems also come with package management metadata such as semantic versioning and the ability to state dependencies on other gems.

Structure of a Gem

A gem's directory contents are organized as follows:

GemDirectory/
    Assets/ (assets usable to projects)
    Code/
        Include/ (public interface code files)
        Source/ (private implementation code files)
        Tests/ (code files for tests)
    wscript (waf build info)
    gem.json (gem metadata)

Waf Integration

Each game project must explicitly list the gems that it uses. When Using the Waf Build System (p. 63) runs, it builds only those gems which are actively in use. Waf also makes a gem's include/ directory accessible to any gems or projects that explicitly depend upon the gem.

Gems Built as AZ Modules

All gems that ship with Lumberyard are built as AZ modules. When you build a gem as an AZ module, the gem uses the initialization functions expected by the AZ framework. An AZ module gem has public interfaces that are event buses (p. 1851) and is better integrated with the new component entity system (p. 462).

When you use the Project Configurator to enable or disable a gem, Lumberyard updates the application descriptor file (p. 1111) accordingly to ensure it references all AZ modules. If you edit the dev \<project_asset_directory>\gems.json list of gems by hand, you can use the following command to bring the application descriptor file up to date:
About Gem Versioning

The GemFormatVersion value is versioning for how a gem is built. Gem version numbers like 0.1.0 refer to the gem's API version.

Gems from Lumberyard 1.4 and earlier (legacy gems) all have a GemFormatVersion value of 2. Starting in Lumberyard 1.5, all the gems included with Lumberyard are AZ modules and have a GemFormatVersion value of 3. This tells Lumberyard that the gem is an AZ module and that it should be loaded accordingly.

A gem may also have an API version number like 0.1.0. This is independent of the GemFormatVersion. The API version alerts your users to API changes. If the API version number changes, then users of the gem may need to make changes to their code. For example, the Rain gem will stay at version 0.1.0 until its API changes. If you were using the Rain gem from Lumberyard 1.4, you can still use the Rain gem from Lumberyard 1.5 without changing any of your data or code.

For more information about gems, see Add modular features and assets with Gems (p. 1064).

Creating an AZ Module That Is Not a Gem

AZ modules are in preview release and subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Beginning with Lumberyard 1.5, gems are AZ modules, so the preferred way to build an AZ module is to simply create a new gem. However, if your project requires an AZ module that must not be built as a gem, follow the steps provided here.

A. Start with a Gem

Because gems have all the required code for an AZ module, it's easier to create a gem first and then modify it not to be a gem. As an added convenience, the new gem names the code for you in an intuitive way. For an explanation of the code that you get in a new gem, see Parts of an AZ Module, Explained (p. 1093).

To create and modify a gem

1. First, create a gem by performing the following steps:
   a. Open the Lumberyard Project Configurator, located at \lumberyard-version\dev\Bin64\BuildPlatform\ProjectConfigurator.exe. For example, when using Visual Studio 2017 as your build platform, the Project Configurator is located at \lumberyard-version\dev\Bin64\vc141\ProjectConfigurator.exe.
   b. Select your project (the default is SamplesProject).
   c. Click Enable Gems.
   d. Click Create a New Gem.
   e. Enter the name for your new module. (The example on this page uses the name “HelloWorld”.)
   f. Click Ok.
2. Move and rename the code directory from the new gem to your desired location. For example, move the directory...
dev/Gems/HelloWorld/Code

to

dev/Code/<optional subfolder>/HelloWorld

3. To remove the remaining noncode pieces of the gem, delete the directory dev/Gems/HelloWorld.

B. Modify the AZ Module Declaration

AZ modules that are not gems must not have UUIDs in their names, so you must modify the gem's .cpp file accordingly.

To modify the .cpp file

1. Remove the code that looks like the following:

   // DO NOT MODIFY THIS LINE UNLESS YOU RENAME THE GEM
   // The first parameter should be GemName_GemIdLower
   // The second should be the fully qualified name of the class above
   AZ_DECLARE_MODULE_CLASS(HelloWorld_010c14ae7f0f4eb1939405d439a9481a,
                           HelloWorld::HelloWorldModule)

2. Replace the AZ_DECLARE_MODULE_CLASS declaration with one that follows this syntax:

   AZ_DECLARE_MODULE_CLASS(HelloWorld, HelloWorld::HelloWorldModule)

   The first argument (HelloWorld) is a unique identifier to be included in your project.json file, and should match the target field of your wscript. You will do these steps later. The second argument is the same fully qualified name of the class already defined in your .cpp file.

C. Remove CryEngine References (Optional)

If your module does not access code from CryEngine (for example, it does not access gEnv), perform these additional steps.

To remove CryEngine references

1. Make the following changes to your .cpp file (in this example, HelloWorldModule.cpp).

   a. Remove #include <platform_impl.h>
   b. Remove #include <IGem.h>
   c. Add #include <AzCore/Module/Module.h>
   d. Change HelloWorldModule to inherit directly from AZ::Module instead of from CryHooksModule.

2. Remove the following include statement from the StdAfx.h file:

   #include <platform.h> // Many CryCommon files require that this be included first.

D. Modify the Wscript and Waf Spec Files

Next, you must modify the default wscript file to remove gem-specific commands, add your module directory to the wscript file, and add your module to the appropriate waf spec files (p. 74).
To modify the wscript and waf spec files

1. Modify the wscript contents to resemble the following:

```python
def build(bld):
    bld.CryEngineModule(
        target          = 'HelloWorld',
        vs_filter       = 'Game', # visual studio filter path
        file_list       = 'HelloWorld.waf_files',
        platforms       = ["all"],
        configurations  = ["all"],
        pch             = ["source/StdAfx.h"],
        use             = ["AzFramework"],
        includes        = ["include", 'source'],
    )
```

2. Modify the wscript in a parent directory so that waf recurses your module's directory, as in the following example.

```python
# ...
SUBFOLDERS = [
    # ...,
    'HelloWorld',
]
# ...
```

3. To enable waf to build your module, add the module to the appropriate waf spec files in your Lumberyard directory (`dev\WAF\specs\*.json`), as in the following example:

```json
{
    // ...
    "modules": {
        // ...
        "HelloWorld"
    }
    // ...
}
```

E. Configure Your Project to Load the New Module

When your project launches, it loads the modules listed in the `dev/<project_assets>/Config/Game.xml` file (the `Editor.xml` file is used when Lumberyard Editor is launched). These files are automatically generated and should not be edited by hand.

To configure your project to load your AZ module

1. To ensure your non-gem module is included in these automatically generated lists, add the following lines to your `project.json` file (path location `dev/<project_asset_folder>/project.json`):

```json
{
    // ...
    "flavors": {
        "Game": {
            "modules": [
                "LmbrCentral",
                "HelloWorld"
            ]
        }
    }
    // ...
}
```
Using AZ Modules to Initialize Gems

Note
The flavors section may be missing from your project. If it is not present, Lumberyard assumes that the LmbrCentral module is used for Game, and that the LmbrCentralEditor module is used for Editor.

2. From the dev directory, run the following command from a command prompt.

```
Bin64\lmbr.exe projects populate-appdescriptors
```

This command modifies the Game.xml and Editor.xml files to list the HelloWorld module.

F. Add the Module's Public Interfaces to Your Project's Include Paths

Finally, to make your AZ module's public interfaces available to the rest of your project, you must inform them project of your module's include directory.

To make your AZ modules public interfaces available to your project

- In your project's wscript file, edit the includes line to point to your project's include directory, as in the following example.

```
... includes = [..., bld.Path('Code/Engine/HelloWorld/include')], ...
```

Configuring System Entities

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A single system entity lives at the heart of every Lumberyard application. The system entity's components, known as system components (p. 1098), power major systems within Lumberyard. You can use the Project Configurator's System Entity Editor to choose and configure the system components for your project. Editing the system entity for your project is like editing an entity in the Entity Inspector (p. 475).

To configure system entities

1. Compile a profile build of your project so that the Project Configurator can load your project's compiled code.
2. Open the Lumberyard Project Configurator, located at lumberyard-version\dev\Bin64\BuildPlatform\ProjectConfigurator.exe. For example, when using Visual Studio
2017 as your build platform, the Project Configurator is located at `lumberyard-version\dev\Bin64vc141\ProjectConfigurator.exe`.

3. In the Project Configurator, select your project.
4. Click **Advanced Settings**.

The first time that you use the System Entity Editor, it performs the following tasks:

1. Loads the configuration for your system entity.
2. Identifies system components that are missing.
3. Adds the missing system components to the configuration.
4. Displays the list in the **Added required components** dialog box. The following image shows an example.
Note
Some system components are optional, and some are required. Both the Lumberyard engine and the gems that your project uses can require certain components.

5. In the Added required components dialog box, click OK.
6. The Project option shows the project that you selected. Use the drop-down menu to select a different project to edit.

7. For the Configuration option, choose Game if you want to make changes to the system entity for the Game (launcher), or Editor to modify the system entity for the Editor.
8. To add a component to the system entity, click **Add Component**.
9. To see more information about a component before you add it, pause your pointer over the name.
10. To add the component to the system entity, select the component, and then click **Save**. The component appears in the list of components for the system entity.

11. To delete, disable, or change a component’s position, right-click the component and choose the corresponding action.
12. To configure system memory options, choose the **Memory Settings** tab.
13. Click **Save** to save your changes to disk. The changes that you make on the **System Entity** and **Memory Settings** tabs are saved to a Game.xml or Editor.xml application descriptor file.

**Application Descriptor Files**

When you edit a system entity's configuration with the Project Configurator **Advanced Settings** dialog box, you are actually editing an application descriptor file.

Application descriptor files list all modules that a project uses. Each project requires a Game.xml and an Editor.xml application descriptor file in its asset directory:

```
lumberyard_version\dev\project_asset_directory\Config\Game.xml
lumberyard_version\dev\project_asset_directory\Config\Editor.xml
```

In the Project Configurator **Advanced Settings** dialog box, these files correspond to the **Game** and **Editor** options in the **Configuration** menu.

The following example shows the beginning of a Game.xml file. Both the Game.xml file and the Editor.xml file have the same structure.

```xml
<ObjectStream version="1">
    <Class name="ComponentApplication::Descriptor"
      type="{70277A3E-2AF5-4309-9BBF-6161AFBDE792}"
        >
      <Class name="bool" field="useExistingAllocator" value="false" type="{A0CA880C-AFE4-43CB-926C-59AC48496112}"/>
```
The list of system components in the application descriptor file corresponds to the list of components on the System Entity tab in the Project Configurator, Advanced Settings, System Entity Editor dialog box. Each component can have its own settings. The application descriptor file also contains properties that determine how to allocate memory. These correspond to the settings on the Memory Settings tab in the System Entity Editor dialog box.

The AZ Bootstrapping Process

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

An AZ framework application initializes modules based on the dynamic libraries listed in the application descriptor file (p. 1111), and the static libraries referenced from the CreateStaticModules() function.

When an AzFramework::Application starts, the following order of events takes place:

1. The executable starts.
2. The AzFramework::Application class is initialized. It takes a path to an application descriptor file and a pointer to a function that will create the AZ::Modules from static libraries.
3. The application bootstraps itself just enough to read the application descriptor file.
4. The application descriptor file is read to get memory allocator settings and the list of dynamic libraries to load. Lumberyard is not yet able to read the system entity from the file.
5. Lumberyard shuts down the bootstrapped systems, configures them according to the settings it just loaded, and starts these systems back up.
6. Each dynamic library is loaded.
7. Each dynamic library's `InitializeDynamicModule()` function is run, which attaches the DLL to the global `AZ::Environment`.
8. Each static library's `AZ::Module` instance is created using the function pointer passed in during step 2.
9. Each dynamic library's `AZ::Module` instance is created by its `CreateModuleClass()` function.
10. Each AZ module's `RegisterComponentDescriptors()` function is called. Now the application knows how to serialize any components defined within a library.
11. The application descriptor file is read again to extract the system entity along with its components and their settings.
12. Each AZ module's `GetRequiredSystemComponents()` function is called. If any components are missing from the system entity, they are added.
13. The system entity is activated, and all of its system components are activated in the proper order.

At this point, initialization has been completed and the game is running.

## Gems Available in Lumberyard

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard ships with the following Gems that are ready to be enabled:

**Topics**
- Asset Memory Analyzer Gem (p. 1115)
- Camera Framework Gem (p. 1121)
- ChatPlay Gem (p. 1121)
- Cloud Canvas Cloud Gems (p. 1122)
- Cloud Canvas Gem (p. 1122)
- CryEntity Removal Gem (p. 1123)
- EMotion FX Animation Gem (p. 1124)
- Fast Noise Gem (p. 1127)
- GameEffect Gem (p. 1129)
- GameLift Gem (p. 1130)
- GameState Gem (p. 1135)
- GameState Samples Gem (p. 1138)
- Gestures Gem (p. 1141)
- Graphics Scripting (p. 1143)
- HMD Framework Gem (p. 1143)
- HttpRequestor Gem (p. 1144)
• Image Processing (p. 1147)
• In-App Purchases Gem (p. 1147)
• Input Management Framework Gem (p. 1150)
• Landscape Canvas Gem (p. 1151)
• Lightning Arc Gem (p. 1152)
• Legacy Terrain Gem (p. 1159)
• LmbrCentral Gem (p. 1163)
• LyShine (p. 1163)
• Maestro Gem (p. 1163)
• Metastream Gem (p. 1164)
• Microphone Gem (p. 1171)
• Multiplayer Gem (p. 1171)
• Multiplayer Analytics Gem (p. 1179)
• NullVR Gem (p. 1180)
• NVIDIA Blast gem (p. 1181)
• NVIDIA Cloth gem (p. 1182)
• Physically Based Shaders (PBS) Gem (p. 1183)
• PhysX (p. 1188)
• PhysX Characters (p. 1188)
• PhysX Debug (p. 1188)
• Physics Entities Gem (p. 1189)
• Primitive Assets Gem (p. 1190)
• Process Life Management Gem (p. 1191)
• Python Asset Builder gem (p. 1192)
• RAD Telemetry Gem (p. 1192)
• Rain Gem (p. 1194)
• Render to Texture (p. 1197)
• SaveData Gem (p. 1198)
• Scene Processing Gem (p. 1201)
• Script Canvas Gem (p. 1201)
• Scripted Entity Tweener Gem (p. 1202)
• Sky Clouds Gem (p. 1202)
• Slice Favorites (p. 1203)
• Snow Gem (p. 1203)
• Starting Point Input Gem (p. 1206)
• Twitch v5 Gem (p. 1207)
• Twitch API Gem (p. 1207)
• Twitch Chat API Gem (p. 1208)
• UiBasics Gem (p. 1209)
• User Login Default Gem (p. 1209)
• Video Playback Gem (p. 1209)
• Video Playback Bink Gem (p. 1209)
• Virtual Gamepad Gem (p. 1210)
• Virtual Reality Gems (p. 1215)
• Visibility (p. 1215)
Asset Memory Analyzer Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Resource management is critical, particularly on platforms such as mobile devices and consoles where heap (system memory) and VRAM (video memory) are limited. In any given project, the model, texture, animation, and audio resource files that make up the project’s assets use the bulk of the memory allocated to run the project. **Asset Memory Analyzer** shows how memory is allocated to assets as your project runs. It is an indispensable tool to balance memory usage and get the best performance for your project.

The **Asset Memory Analyzer** is an Amazon Lumberyard Gem that displays a table of heap and VRAM memory allocations per asset through the **ImGUI** (Immediate Mode Graphical User Interface) overlay. In addition to live display of memory allocations for assets loaded in the project, the **Asset Memory Analyzer** can export allocation data to JSON and CSV files.

- Enable the **Asset Memory Analyzer** (p. 1115)
- View Live Asset Memory Analysis with **ImGUI** (p. 1116)
- Export an Asset Memory Analysis Snapshot to a File (p. 1117)
- View a JSON Asset Memory Analysis Snapshot in a Browser (p. 1118)
- Instrumenting Code for Asset Memory Analysis (p. 1119)

**Enable the Asset Memory Analyzer**

To use the **Asset Memory Analyzer**, enable asset scope tracking, configure and compile a profile build of your project, and enable asset memory analysis.

1. Use Project Configurator to add the **Asset Memory Analyzer** Gem and ImGUI Gem to your project.
2. Uncomment the line `enable_memory_tracking` and set its value to `True` in the `user_settings.options` file located in `\dev\WAF\` to enable asset scope tracking.

```plaintext
... ;use_crcfix = True
enable_memory_tracking = True
;generate_sig_debug_output = False
...
```

3. Configure your project.

   `lmbr_waf configure`

4. Create a **profile** build of your project.

   `lmbr_waf build_win_x64_vs2019_profile -p all --progress`

5. Set the CVAR `assetmem_enabled=1` via the Editor Console to enable asset memory analysis. To make the setting persistent, add `assetmem_enabled=1` to an appropriate config file such as `/dev/system_windows_pc.cfg`.

Version 1.28
1115
View Live Asset Memory Analysis with ImGUI

To view live asset memory allocation, enable the ImGUI overlay during gameplay and choose Asset Memory Analyzer in the ImGUI window.

1. In the Lumberyard Editor, press Ctrl+G or press the Play button to run your project.
2. Press the Home key to open the ImGUI overlay window.
3. Choose Asset Memory Analyzer from the top of the ImGUI overlay window.

Each recorded asset is displayed along with the number of allocations and total size in kilobytes for both heap and VRAM. Use the selections at the top of the ImGUI overlay window to sort the table by heap size, heap count, VRAM size, VRAM count or by asset label alphabetically.

**Note**

The asset label is the full path for each asset from the root of the project folder.

Click the arrow to the left of an asset to expand it and view individual allocations and references belonging to the asset.
Export an Asset Memory Analysis Snapshot to a File

Snapshots of asset memory allocation can be exported to JSON or CSV files through three methods:

- Click Asset Memory Analyzer in the ImGui overlay window and choose Export JSON or Export CSV.
- Use the console commands assetmem_export_json or assetmem_export_csv in the Editor Console to generate the file.
- Call ExportJSONFile or ExportCSVFile on the AssetMemoryAnalyzerRequestBus in C++, with nullptr as the parameter, to generate the file in the default location.

EBUS_EVENT(AssetMemoryAnalyzerRequestBus, ExportJSONFile, nullptr);
The snapshot file is created in the project log directory located at `dev/Cache/ProjectName/pc/user/log` and named `assetmem-2020-01-30-11-45-25.json` or `.csv`.

**Note**
Due to the limitations of the CSV format, only a top-level overview of assets will be written to CSV, *without* the hierarchical drill-down available in the JSON file or the ImGui overlay window.

**View a JSON Asset Memory Analysis Snapshot in a Browser**

JSON snapshots can be viewed in a browser with a web viewer provided with Lumberyard. The web viewer is located at `\dev\Gems\AssetMemoryAnalyzer\www\AssetMemoryViewer\index.html`. Open the `index.html` file and drag-and-drop the JSON file onto the page, or click on the target area to browse to it. This displays the contents of the file in an expandable table.

**Note**
Chromium based browsers are most reliable.

The table can be sorted by any column. The columns give a breakdown by multiple categories:

- **Heap** allocations and VRAM allocations
- **Local** summary not including any sub-assets and **Total** summary including all sub-assets
- **Number** of allocations and **Kilobytes** allocated

Expanding assets will display individual allocations belonging to the asset and sub-assets that were loaded through references.

The fields at the top of the table can be used to filter the assets by their label on a number of conditions, including regular expressions.
Instrumenting Code for Asset Memory Analysis

Initial Loading of an Asset

The Asset Memory Analyzer traps allocations (heap and VRAM) that occur during a slice of code execution or scope when an asset is active for recording. When a system begins loading a new asset, it should use the AZ_ASSET_NAMED_SCOPE macro to demarcate the C++ scope in which that asset may be actively making allocations. For example:

```cpp
#include <AzCore/Debug/AssetMemoryDriller.h>

Foo* LoadMyFooAsset(const char* name)
{
    AZ_ASSET_NAMED_SCOPE("Foo: %s", name);
    Foo* result = aznew Foo(name);  // The call to aznew will be recorded as associated with the asset "Foo: <name>"
    return result;  // Once we exit this function, the asset will no longer be in scope, and subsequent allocations will not be recorded
}
```

Subsequent Processing of an Asset

When the asset is being updated, otherwise processed, or is being handed off to a different thread, it should use the AZ_ASSET_ATTACH_TO_SCOPE macro with a pointer that was allocated and tracked by the initial asset. This will associate any further allocations with the same asset until the scope of the declaration closes.

```cpp
#include <AzCore/Debug/AssetMemoryDriller.h>

void UpdateAllFoos(const AZStd::vector<Foo*>& allFoos)
{
    for (Foo* foo : allFoos)
    {
        AZ_ASSET_ATTACH_TO_SCOPE(foo);  // Subsequent allocations in this scope will associate with any asset that was in scope when foo was allocated
        UpdateFoo(foo);
    }
}

void UpdateFoo(Foo* foo)
{
    aznew Bar;  // This automatically gets recorded with the owning asset for foo
    AZStd::thread doThreadedWork([foo]()
    {
        // Work being done on a different thread means we need to reattach to the owning asset
        AZ_ASSET_ATTACH_TO_SCOPE(foo);
        aznew Bar;  // This will now be recorded under the owning asset for foo
    });
    doThreadedWork.join();
}
```

You can attempt to attach to any pointer that was created while that asset was in scope, or even any portion of memory that was allocated to it.

For instance, the following code is valid:
```cpp
#include <AzCore/Debug/AssetMemoryDriller.h>

struct Baz
{
    int a;
    char* b;
    double c;
};

Baz* CreateBaz(const char* name)
{
    AZ_ASSET_NAMED_SCOPE(name);
    Baz* baz = aznew Baz;  // bar is associated with the named asset
    return baz;
}

void TestScopes()
{
    Baz* baz = CreateBaz("My test baz");
    
    {  
        AZ_ASSET_ATTACH_TO_SCOPE(&baz->c);  // This works, even though "c" didn't have its
        own allocation
        baz->b = aznew char[32];  // This allocation will be recorded under the asset "My
        test baz"
    }
}
```

An original pointer to an object that was allocated within a scope is not required in order to attach to it. This makes it possible to attach across systems to objects that have been defined with multiple inheritance.

### EBus Processing of and Asset

EBus handlers can automatically attempt to attach to a scope for each handler receiving an event. This works when the handler was allocated as part of an asset.

If the handler was created while an asset was in scope, you can modify an EBus as follows:

```cpp
#include <AzCore/Debug/AssetMemoryDriller.h>

class MyEvents : public AZ::EBusTraits
{
    // Process individual events by first attempting to attach to the asset that owns the handler
    template<typename Bus>
    using EventProcessingPolicy = Debug::AssetTrackingEventProcessingPolicy<Bus>;

    // Regular Ebus definitions
    virtual void MyFunction() = 0;
};
```

Some Lumberyard EBuses use this feature, such as the **TickBus**. If you find others that should use it, please add them! You should not default to using this `EventProcessingPolicy` if it is not applicable.

Instrumentation does create some overhead which can negatively affect your project's performance.

Creating a new named scope requires:
• function calls
• an environment lookup
• locking a mutex
• two hashtable lookups
• thread-local modifications

Attaching to an existing scope requires:

• function calls
• an environment lookup
• locking a mutex
• a lookup in a large red-black tree
• thread-local modifications

Most often this is a relatively small cost, but it is significant enough that you should not use the
AZ.Asset.Attach.To.Scope macro or use the AssetTrackingEventProcessingPolicy on your
EBus gratuitously, especially if it is unlikely to attach to anything.

When asset tracking is disabled, i.e. if the AZ.Analyze.Asset.Memory macro remains undefined, there
is zero cost to instrumentation of scopes. This is default in performance builds.

Note
EBuses that use the AssetTrackingEventProcessingPolicy will still have the indirection
of a function call for each handler on the bus in debug builds only. Non-debug builds inline this
function call away.

Camera Framework Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.
Download O3DE or visit the AWS Game Tech blog to learn more.

The Camera and Camera Framework Gems are a base upon which you can build more complex camera
systems. This gem contains the Camera (p. 566) and the Camera Rig (p. 570), which work together to
define a basic camera and its control rig. You can customize the camera rig component through three
different behaviors:

• Target acquiring behavior
• Target transform modifying behaviors
• Final camera transform modifying behaviors

ChatPlay Gem

The ChatPlay Gem is deprecated and will be removed in a future version of Lumberyard. It has been
replaced by the Twitch Chat API Gem.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.
Download O3DE or visit the AWS Game Tech blog to learn more.
The Twitch ChatPlay Gem provides a flexible framework to create customized game interactions between broadcasters and spectators on Twitch, the world’s leading social video platform and community for gamers. Twitch ChatPlay includes support for chat commands, polls, and surveys that can be triggered by Twitch viewers through the Twitch chat channel.

For example, you can create a chat command #cheer that triggers celebration animations in your game.

- Intro to ChatPlay

**Cloud Canvas Cloud Gems**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

A Cloud Canvas cloud gem includes everything required for you to include AWS cloud-connected functionality in your project. A cloud gem is a package of specific cloud-connected functionality, assets and AWS resource definitions.

**Cloud Gems Included with Lumberyard**

Lumberyard includes the following cloud gems. You can enable them in a project by using the Lumberyard Project Configurator (p. 43) tool. For more information, visit the following links.

- **Dynamic Content** (p. 2155) – Allows Lumberyard .pak files that contain new and updated game assets to be uploaded to the cloud for subsequent automatic download to the game client.
- **Player Account** (p. 2188) – Provides a standalone player authentication and management solution that uses Amazon Cognito.
- **Web Communicator** (p. 2204) – Send AWS cloud service events to your game's connected editors or clients. Your editors or game clients can use this information to update themselves without having to poll AWS for updates.

AWS services accessed through Cloud Canvas may be subject to separate charges and additional terms. For more information, see Pricing (p. 2115).

**Cloud Canvas Gem**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Cloud Canvas Gem enables you to use Cloud Canvas visual scripting to AWS services. With Cloud Canvas you can build connected game features that use Amazon DynamoDB (DynamoDB), Amazon Lambda, Amazon Simple Storage Service (Amazon S3), Amazon Cognito, Amazon Simple Notification Service (Amazon SNS), and Amazon Simple Queue Service (Amazon SQS). You can also create cloud-hosted features such as daily gifts, in-game messages, leaderboards, notifications, server-side combat resolution, and asynchronous multiplayer gameplay (e.g. card games, word games, ghost racers, etc.). Cloud Canvas eliminates the need for you to acquire, configure, or operate host servers yourself, and reduces or eliminates the need to write server code for your connected gameplay features.
AWS services accessed via Cloud Canvas may be subject to separate charges and additional terms. For more information, see Implementing Connected Features with Cloud Canvas (p. 2106).

**CryEntity Removal Gem**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the CryEntity Removal gem to disable all legacy features from Lumberyard Editor. Legacy features appear as legacy in Lumberyard Editor and will eventually be removed. This includes the following features:

- **Database View** (p. 1264) (Legacy)
- **Object Selector** (Legacy)
- **Layer Editor** (Legacy)
- **Rollup Bar** (Legacy)
- **Asset Browser** (Legacy)

When the gem is enabled, Lumberyard Editor displays only the features and tools that use the new component entity system. For more information, see Working with component entities (p. 462).

By default, the gem is disabled. For more information about enabling gems, see Add modular features and assets with Gems (p. 1064).

**Note**

- When you enable the gem and open Lumberyard Editor, you are prompted to convert your legacy entities (CryEntities) to the new component entity system. Once an entity is converted, it cannot be converted back to a legacy entity. For more information about converting your entities, see Converting Entities with the Legacy Converter (p. 963).
- If you want to enable the legacy features again, return to the Project Configurator and disable the CryEntity Removal gem. When you reload Lumberyard Editor, the legacy features reappear.
- If you create a project with Lumberyard 1.12 or newer, the CryEntity Removal gem is enabled by default. If you want to use legacy features, disable the gem.
EMotion FX Animation Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

With the EMotion FX Animation gem, you can use the EMotion FX Animation Editor character animation system. The node-based system provides an intuitive approach to controlling character behavior from animation graphs. You can visually build hierarchal state machines and blend trees and use parameter controls for interactive testing. Character motion is controlled through motion extraction.

The character animation system includes tools for building the following:

- Transition conditions
- Blend spaces
- Sync tracking
- Motion events
- Mirroring animation
- Controllers

The Animation Editor is compatible with .fbx files and converts these files to the .actor and .motion formats.

For more information, see Create and animate characters (p. 1340).

Enable this gem for your project in the Project Configurator. For more information, see Creating a Game Project in Lumberyard (p. 45).
Lumberyard version 1.25 introduces deferred initialization for unique data in anim graphs. Rather than preallocating unique data for the whole anim graph upfront, allocation is deferred until the objects are used for the first time. For example, when transitioning into a given state, the unique data of the transition target is allocated and initialized right before the transition starts blending. This decreases instantiation time and makes spawning new characters that run an anim graph faster. The bigger the anim graph, the greater the speed improvement.

**Changes and using unique data in custom nodes**

- Unique data are no longer pre-allocated for the whole anim graph.
- Unique data are now allocated when they are needed and requested via `AnimGraphInstance::FindOrCreateUniqueData()`.
- Data shared across characters using the same anim graphs should be members of the anim graph node; for example, the name of the joint a look at node operates on.
- Instanced data belongs inside the node's unique data class. For example, the actual joint index based on the joint name stored in the node, as anim graphs can be shared across characters that have different skeletons.
• **UniqueData::Update()** is the place where the shared data is read and prepared to be used in an optimal way on the character instance. For example, this is where we would find the joint index for the given character instance, based on the shared joint name.

• **Update()** is called if the unique data is invalidated and requested for use with **AnimGraphInstance::FindOrCreateUniqueData()**.

• When a new joint name is selected in the UI, the unique datas for all currently present anim graph instances are invalidated and **Update()** is called to update all the joint indices.

• Newly created unique datas are invalidated by default and are updated automatically before their first usage.

### Accessing unique datas from within a custom node

There are two ways to access unique datas:

- **AnimGraphInstance::FindOrCreateUniqueData()**: Use this in your node's **Update()**, **TopDownUpdate()**, **PostUpdate()** or **Output()** functions. This guarantees that you have access to up-to-date unique data. If the unique data doesn't exist yet, it's created and initialized. If the unique data does exist, its pointer is available. **UniqueData::Update()** is called automatically if the unique data is invalidated when requesting it. The resulting object is valid and current in all ways.

- **AnimGraphInstance::GetUniqueObjectData()**: Use this for direct access to the unique data for the given node. If the unique data does not exist, it returns a nullptr. The unique data might also be invalidated and outofdate. **AnimGraphInstance::GetUniqueObjectData()** might be used in the **Rewind()** method since it's not required to create or update the unique data if the node hasn't been active yet.

### Port an existing custom node to version 1.25

1. Remove the mMustUpdate flag from the unique data if you use the flag to skip heavy operations when shared data changes (a picked joint in the LookAtNode, for example).

2. Remove the mIsValid flag from the unique data and use the error flag m_hasError from the base **AnimGraphObjectData**.

   **Note**
   If you need to populate the error flag up/down the hierarchy, don't check and set it inside **UniqueData::Update()**. Instead, call **AnimGraphNode::SetHasError()** inside the node to automatically populate the update flag.

3. If you use **AnimGraphNode::SetHasError()**, be aware the first parameter has changed from an anim graph instance to a unique data pointer for performance reasons.

4. Override **AnimGraphObject::CreateUniqueData()** for your custom node and return a newly allocated node-custom unique data. No exceptions, the method should always return a newly allocated unique data.

```cpp
AnimGraphObjectData* CreateUniqueData(AnimGraphInstance* animGraphInstance) override {
    return aznew UniqueData(this, animGraphInstance);
}
```

5. Remove the **YourCustomNode::UpdateUniqueData()** and move its contents to **UniqueData::Update()**.

   **Note**
   • There is no need to check for mMustUpdate anymore. We removed this flag in step 1.
• There is no need to manually call UniqueData::Update() manually inside any of the methods called at runtime: Update(), PostUpdate(), Output(). Whenever you retrieve the unique data with AnimGraphInstance::FindOrCreateUniqueData(), it is up to date.

• If you need access to the node itself, you can do this with the following code inside your unique data's Update() method:

```cpp
YourCustomNode* customNode = azdynamic_cast<YourCustomNode*>(mObject);
AZ_Assert(customNode, "Unique data linked to incorrect node type.");
```

6. Make sure to call YourCustomNode::Reinit when a UI element changes that should invalidate the unique datas. This can be done via:

```cpp
>Attribute(AZ::Edit::Attributes::ChangeNotify, &YourCustomNode::Reinit)
```

7. AnimGraphObject::Reinit() default implementation invalidates unique datas for all existing anim graph objects for the called object. Override Reinit() only if you need to do additional things and make sure to call Reinit() from the base class. Remove Reinit() from your custom node if all you need to do is invalidate the unique data of the node.

**Fast Noise Gem**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The FastNoise Gradient Gem uses the third-party, open source FastNoise library to provide a variety of high-performance noise generation algorithms in Amazon Lumberyard. You can use noise generation to generate content in a game.

The FastNoise Gradient Gem provides the FastNoise Gradient (p. 590) component which expresses noise generation algorithms as Gradient signals. Any system that's compatible with the Gradient Signal Gem, such as Vegetation, can use noise generation.

Gradient signals are values that range from 0.0 to 1.0 and are automatically mapped to world positions. They are typically visualized as either greyscale images or waveforms.

Examples of noise algorithms:
Enable the FastNoise Gradient Gem

To make the FastNoise Gradient component available in Lumberyard, you must build and configure your project with the FastNoise Gradient Gem enabled.

**To enable the FastNoise Gradient Gem**

1. Use Project Configurator to add the FastNoise Gradient Gem to your project.
2. Configure your project. Use the following command.

   ```
lmbr_waf configure
   ```

3. Build your project. Use the following command.

   ```
lmbr_waf build_win_x64_vs2019_profile -p all --progress
   ```

For more information on Gems, see the Gems documentation (p. 1064).

GameEffect Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Game Effect System Gem provides fundamentals for creating and managing the visual effects of the Lightning Arc Gem. If you install the Lightning Arc Gem (p. 1152), you must also install the Game Effect System Gem. The Lightning Arc Gem is the only Lumberyard gem that is dependent on the Game Effect System Gem.
GameLift Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Amazon GameLift is an AWS service for deploying, operating, and scaling session-based multiplayer games. With Amazon GameLift, you can quickly scale high-performance game servers up and down to meet player demand without any additional engineering effort or upfront costs.

The GameLift Gem provides a framework to extend Lumberyard networking (GridMate) to work with GameLift resources via GameLift server and client APIs.

Getting Started

To use the Amazon GameLift service with your Lumberyard project, you simply enable the GameLift Gem using Project Configurator.

You will want to familiarize yourself with GameLift concepts found in the Amazon GameLift Developer Guide. GameLift resources like fleet, queue, matchmaking rule, and config need to be deployed prior to running your game on GameLift. For more details, refer to the GameLift CLI.

Implementation

The GameLift Gem provides server and client code. Server code interacts with GameLift server SDK, while client code interacts with the GameLift client from the AWS native SDK.

The GameLift Gem server code is responsible for initializing the server process by initializing the GameLift server SDK and then hosting game sessions for the clients to connect. If run in custom matchmaking backfill configuration, the server is also responsible for starting and cancelling matchmaking backfill requests.

The GameLift Gem client provides options to create, search, join, and matchmaking into GameLift game sessions. Matchmaking is handled using GameLift’s FlexMatch matchmaking system. Clients can create, search, and join game sessions directly on GameLift fleets, or using preconfigured GameLift queues. If matchmaking, clients can use a preconfigured matchmaking configuration to create or join game sessions.

On the server side, the GameLift Gem provides the GameLiftServerService. On the client side, the Gem provides the GameLiftClientService. When you use the GameLift Gem in your game project, the following sequence of events occurs:

- The server starts the GameLiftServerService and listens for events delivered by the GameLift Server SDK.
- The client starts the GameLiftClientService, sends a GameLiftSessionRequest or GameLiftGameSessionPlacementRequest, and searches and joins game sessions using the fleet ID or queue name. The client service also provides an option to create or join game sessions using FlexMatch matchmaking.

These events are illustrated in the following workflow diagrams.

GameLift client-server communication workflow using fleet or queues to create a game session.
GameLift client-server communication workflow using FlexMatch, with automatic or custom backfill.
Sample Code

The GameLift code in this section follows the workflow illustrated in the preceding diagram and is separated into server-side code and client-side code. The code is enabled only when BUILD_GAMELIFT_SERVER and BUILD_GAMELIFT_CLIENT are defined.

Server-side Code

Use the following sample code as a guide when starting and hosting a GameLift server session.

Start GameLiftServerService

```
GridMate::GameLiftServerServiceDesc serviceDesc;
serviceDesc.m_port = settings.m_serverPort;
if (settings.m_logPath)
{
    serviceDesc.m_logPaths.push_back(settings.m_logPath);
}

m_service = GridMate::StartGridMateService<GridMate::GameLiftServerService>(m_gridMate,
    serviceDesc);
```

Host a Session

```
GridMate::CarrierDesc carrierDesc;
carrierDesc.m_port = s_gameLiftSettings.m_serverPort;
carrierDesc.m_driverIsFullPackets = false;
carrierDesc.m_driverIsCrossPlatform = true;

GridMate::GameLiftSessionParams sp;
sp.m_topology = GridMate::ST_CLIENT_SERVER;
sp.m_gameSession = &gameSession;

EBUS_EVENT_ID_RESULT(session, m_gridMate, GridMate::GameLiftServerServiceBus, HostSession,
    sp, carrierDesc);
```

Start/Stop Matchmaking Backfill

```
EBUS_EVENT_ID(m_gridMate, GridMate::GameLiftServerServiceBus, StartMatchmakingBackfill,
    m_updateGameSession, m_session, checkForAutoBackfill=true);

EBUS_EVENT_ID(gEnv->pNetwork->GetGridMate(), GridMate::GameLiftServerServiceBus,
    StopMatchmakingBackfill, m_session, m_ticketId);
```

Client-side Code

Use the following sample code as a guide when using the GameLift client service.

Start GameLiftClientService

```
GridMate::GameLiftClientServiceDesc serviceDesc;
serviceDesc.m_accessKey = settings.m_accessKey;
serviceDesc.m_secretKey = settings.m_secretKey;
serviceDesc.m_endpoint = settings.m_endpoint;
serviceDesc.m_region = settings.m_region;

m_service = GridMate::StartGridMateService<GridMate::GameLiftClientService>(m_gridMate,
    serviceDesc);
```
Send GameLiftSessionRequest / GameLiftGameSessionPlacementRequest

```cpp
GridMate::GameLiftSessionRequestParams reqParams;
reqParams.m_instanceName = "TestSession";
reqParams.m_numPublicSlots = 16;
reqParams.m_params[0].m_id = "param1";
reqParams.m_params[0].m_value = "value12";
reqParams.m_numParams = 1;

// Only need ONE of the below. Queue gets the highest preference, followed by alias and fleet id.
reqParams.m_fleetId = "fleet_id";
reqParams.m_aliasId = "alias_id";
reqParams.m_queueName = "queue_name";

m_sessionRequest = m_service->RequestSession(reqParams);
EBUS_EVENT_ID_RESULT(m_session, m_gridMate, GridMate::GameLiftClientServiceBus, RequestSession, reqParams);
```

Search Active Sessions

```cpp
GridMate::GameLiftSearchParams searchParams;
// Only need ONE of the below. Queue gets the highest preference, followed by alias and fleet id.
searchParams.m_fleetId = "fleet_id";
searchParams.m_aliasId = "alias_id";
searchParams.m_queueName = "queue_name";

EBUS_EVENT_ID_RESULT(m_search, m_gridMate, GridMate::GameLiftClientServiceBus, StartSearch, GridMate::GameLiftSearchParams());
```

Join a Session

```cpp
GridMate::CarrierDesc carrierDesc;
carrierDesc.m_port = 33435;
carrierDesc.m_enableDisconnectDetection = true;
carrierDesc.m_connectionTimeoutMS = 10000;
carrierDesc.m_threadUpdateTimeMS = 30;

const GridMate::GameLiftSearchInfo& gameLiftSearchInfo = static_cast<const GridMate::GameLiftSearchInfo&>(*gridSearch->GetResult(0));
EBUS_EVENT_ID_RESULT(m_session, m_gridMate, GridMate::GameLiftClientServiceBus, JoinSessionBySearchInfo, gameLiftSearchInfo, carrierDesc);
```

Join using FlexMatch Matchmaking

```cpp
m_matchmakingConfigName = "MatchmakingConfig";
EBUS_EVENT_ID_RESULT(m_search, m_gridMate, GridMate::GameLiftClientServiceBus, StartMatchmaking, m_matchmakingConfigName);
```

GameState Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The GameState gem helps you manage and determine, at a high level, the state that the game is in. Because the GameState gem uses a stack to manage game states, returning to a previous state is straightforward.

For information about sample game states and enabling the GameState Samples gem, see Enabling Gems (p. 1064).

**Note**
For a sample implementation of game states, see the GameState Samples Gem (p. 1138). The GameState Samples Gem depends on the GameState gem. You can customize the game states in the GameState Samples gem to meet the requirements of your game and communicate with your game code.

**Examining the Code**

The GameState gem manages a stack (or pushdown automaton) of abstract game states. The GameState gem includes the following code members:

- **IGameState** – Abstract interface that all concrete game state classes must be derived from.
- **GameStateRequests** – EBus (p. 1851) interface that other systems use to submit requests related to the game state.
- **GameStateNotifications** – EBus interface that other systems use to listen for events related to the game state.
- **GameStateSystemComponent** – Implements the GameStateRequestBus interface and sends events over the GameStateNotificationBus.

**IGameState**

IGameState is the abstract interface that all concrete game state classes must be derived from. The interface defines methods that track changes in game state, as seen in the following excerpt from the source code at

`lumberyard_version\dev\Gems\GameState\Code\Include\GameState\GameState.h`

```cpp
// Called when this game state is pushed onto the stack.
virtual void OnPushed() {}

// Called when this game state is popped from the stack
virtual void OnPopped() {}

// Called when this game state is set as the active game state.
virtual void OnEnter() {}

// Called when this game state is replaced as the active game state.
virtual void OnExit() {};
```
Lumberyard User Guide

GameState Gem

//! Called each frame while this game state is the active game state.
virtual void OnUpdate() {};

GameStateRequests

The methods in the GameStateRequests EBus perform essential tasks like creating, pushing, and popping a game state, or getting the active game state or active game state type. For the complete source code, see the [lumberyard_version]dev\Gems\GameState\Code\Include\GameState\GameStateRequestBus.h file.

//! Create a new game state.
//! \tparam GameStateType - The game state type to create.
//! \param[in] checkForOverrides - True to should check for an override, false otherwise.
//! \return - A shared pointer to the new game state that was created.
template<class GameStateType>
static AZStd::shared_ptr<IGameState> CreateNewOverridableGameStateOfType(bool checkForOverride = true);

//! Create a new game state and push it onto the stack to make it the active game state.
//! New game states are created and stored in the stack using a shared_ptr, so they are
//! destroyed automatically after they are popped off the stack (assuming that nothing
//! else retains a reference – for example, through GameStateNotifications::OnActiveGameStateChanged).
//! \tparam GameStateType - The game state type to create and activate.
//! \param[in] checkForOverrides - True to check for an override, false otherwise.
template<class GameStateType>
static void CreateAndPushNewOverridableGameStateOfType(bool checkForOverride = true);

//! Pop game states from the stack until the active game state is of the specified type.
//! \tparam GameStateType - The game state type in the stack that you want to be active.
//! \return True if the active game state is now of the specified type, false otherwise.
template<class GameStateType>
static bool PopActiveGameStateUntilOfType();

//! Query whether the active game state is of the specified type.
//! \tparam GameStateType - The game state type to check whether it is active.
//! \return - True if the active game state is of the specified type, false otherwise.
template<class GameStateType>
static bool IsActiveGameStateOfType();

//! Query whether the game state stack contains a game state of the specified type.
//! \tparam GameStateType - The game state type to check whether it is in the stack.
//! \return - True if the stack contains a game state of the specified type, false otherwise.
template<class GameStateType>
static bool DoesStackContainGameStateOfType();

//! Update the active game state. Called during the AZ::ComponentTickBus::TICK_GAME
//! priority update of the AZ::TickBus, but can be called independently any time if needed.
virtual void UpdateActiveGameState() = 0;

//! Request the active game state (if any)
//! \return - A shared pointer to the active game state (empty if there is none).
virtual AZStd::shared_ptr<IGameState> GetActiveGameState() = 0;

//! Push a game state onto the stack, making it become the active game state.
//! If newGameState is already found in the stack, the call fails and returns false.
//! However, it is possible for multiple instances of the same game state type to occupy the stack.
//! \param[in] newGameState - The new game state to push onto the stack.
//! \return - True if the game state was successfully pushed onto the stack, false otherwise.
virtual bool PushGameState(AZStd::shared_ptr<IGameState> newGameState) = 0;
GameState Samples Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The GameState Samples gem uses the GameState Gem (p. 1135) to provide a set of sample game states that control the high-level flow of a game.

For information about enabling the GameState Samples gem, see Enabling Gems (p. 1064).
Game States Included

The GameState Samples gem includes the following game states. These states commonly occur in the beginning, middle, and end of a game.

- **Main menu state** – Enables any level in the project to be loaded from a button click.
- **Level loading state** – Displays a placeholder loading screen.
- **Level running state** – Active while the game is running.
- **Level paused state** – Enables resuming or returning to the main menu to select another level.
- **Other states** – Game states that react to user sign-in and sign out and controller connections and disconnections.

Flow of Game States

The following diagram shows the flow of the default game states in the GameState Samples gem.
Possible Uses

The following are some possible ways to use the GameState Samples gem:

- **Copy** – Copy the gem to your game project to use as a starting point for further customization. This method offers the most flexibility. However, you should not enable the GameState Samples gem in Project Configurator. Instead, copy each class in the gem that inherits from `IGameState` into your game project. (For the source code, see the `lumberyard_version\dev\Gems\GameStateSamples`
The advantage of this approach over either of the following options is that you can freely modify the samples to fit the specific needs of your game.

- **Derive** – Derive from the code to create your own game states. This approach is recommended if you want to keep the same behavior as the sample game states, but with only minor customizations. For example, you could create a main menu class like the following:

  ```c++
  MyCustomMainMenu : public GameStateMainMenu
  ```

  You could then customize the class through inheritance to load a different main menu UI Canvas. The disadvantage of the "derivation" approach is that it places some logic in the gem and the rest in your game code. This can make your solution hard to follow or debug.

- **Modify** – Modify the GameState Samples gem directly. Because gems can't depend on the game, and therefore can't effectively communicate with any game-specific code, this option is not recommended.

### Gestures Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Gestures gem to recognize common gesture-based input, which includes the following:

- Tap or click – Single-touch, discrete gesture
- Drag or pan – Single-touch, continuous gesture
- Hold or press – Single-touch, continuous gesture
- Swipe – Single-touch, discrete gesture
- Pinch – Multiple-touch, continuous gesture
- Rotate – Multiple-touch, continuous gesture

Single-touch gestures (such as tap, drag, hold, and swipe) can be detected with touch or mouse input. However, multiple-touch gestures (such as pinch and rotate) can only be recognized on multi-touch enabled devices such as iOS or Android. You can extend the underlying C++ gesture recognition framework to support your custom gesture recognizers.

To enable the Gestures gem for your project, see Add modular features and assets with Gems (p. 1064).

**Topics**

- Configuring Gesture Recognizers (p. 1141)
- Responding to Gesture Input (p. 1142)

### Configuring Gesture Recognizers

You can configure gesture recognizers with C++ and the **Gestures** system component in the **System Entity Editor**. For more information, see Configuring Advanced Settings (p. 49).
To configure gesture recognizers

1. In the Project Configurator, click **Advanced Settings**.
2. In the **System Entity Editor**, click **Add Component**, and then expand **Gestures**.
3. For each gesture recognizer, specify your preferred values. For example, if you want to change the **Min Clicks or Taps** for a double press gesture, specify a new value.

   ![Image of gesture recognizer settings]

   **Note**
   
   Pause on the gesture recognizer to see a description and the valid values.

4. Make your changes and then click **Save**.

**Responding to Gesture Input**

Each gesture recognizer that the **Gestures** system component exposes corresponds to a gesture input channel that belongs to a gesture input device.

You can use gesture input channels in the same way as other input channels with C++, Lua, or Script Canvas. You can map the gesture input channels to gameplay actions with an **Input** component. This
component is part of the Input Management Framework (p. 1150) and Starting Point Input (p. 1206) gems.

To add input to an entity, see the Input (p. 642) component.

Example Lua Script

The following script listens for and responds to the default double press gesture.

```lua
function GestureExample:OnActivate()
    self.inputChannelNotificationBus = InputChannelNotificationBus.Connect(self);
end

function GestureExample:OnInputChannelEvent(inputChannel)
    if (inputChannel.channelName == InputDeviceGestures.gesture_double_press) then
        -- Respond to the default double press gesture
    end
end

function GestureExample:OnDeactivate()
    if (self.inputChannelNotificationBus) then
        self.inputChannelNotificationBus:Disconnect();
    end
end
```

For more information, see Input in Amazon Lumberyard (p. 1902).

Graphics Scripting

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Graphics Scripting gem enables graphics features in your scripts. With the gem enabled, you can use Script Canvas or Lua to write scripts to control features such as full screen effects, color correction, environment settings, shadow calculations, and more.

To use the Graphics Scripting gem, you must also enable the Script Canvas (p. 1201) gem. The LmbrCentral Gem (p. 1163) gem, which is also required, is enabled by default and includes material scripting controls and the High Quality Shadow (p. 614) component.

To enable gems, see Enabling Gems (p. 1064).

HMD Framework Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
HttpRequestor Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the HttpRequestor gem to make asynchronous HTTP/HTTPS requests and return data through a user-provided callback function. This gem uses the EBus for communication and provides all requests asynchronously. For more information, see Working with the Event Bus (EBus) system (p. 1851).

Note
This feature is supported only on Windows and replaces CryAction::HttpRequest.

Topics
- Getting Started (p. 1144)
- C++ API Using EBUS_EVENT (p. 1144)
- Example (p. 1146)

Getting Started

To use the HttpRequestor gem, you must enable it in your project.

To enable the HttpRequestor gem

1. In the Project Configurator (p. 43), select your project, and then click Enable Gems.
2. In the list of gems, select the check box next to HttpRequestor.
3. Click Save.
4. Enter the following command to build your project.

```bash
lmbr_waf configure
```

C++ API Using EBUS_EVENT

The HttpRequestor gem has separate sets of APIs for adding requests and adding text requests.

AddRequest, AddRequestWithHeaders, AddRequestWithHeadersAndBody

You can use the AddRequest, AddRequestWithHeaders, and AddRequestWithHeadersAndBody APIs to send generic HTTP requests to any website and receive the returned data in JSON format. The methods return the data received in the callback parameter.

Syntax

```c++
EBUS_EVENT(HttpRequestor::HttpRequestorRequestBus, AddRequest, URI, method, callback)
```

```c++
EBUS_EVENT(HttpRequestor::HttpRequestorRequestBus, AddRequestWithHeaders, URI, method, headers, callback)
```
EBUS_EVENT(HttpRequestor::HttpRequestorRequestBus, HttpStatusCode, URI, method, headers, body, callback)

Each add request method requires the URI, a method and a callback.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URI</td>
<td>AZStd::String</td>
<td>The fully qualified web address, in the following format: scheme:// [user:password@]host[:port]/]path[/query][#fragment]</td>
</tr>
<tr>
<td>method</td>
<td>Aws::Http::HttpMethod</td>
<td>The method type. The following values are supported: HTTP_GET, HTTP_POST, HTTP_DELETE, HTTP_PUT, HTTP_HEAD, and HTTP_PATCH.</td>
</tr>
<tr>
<td>callback</td>
<td></td>
<td>This function is called when the HTTP request is completed. The response body and code are present in the callback.</td>
</tr>
<tr>
<td>headers</td>
<td>HttpRequestor::Headers</td>
<td>The list of header fields for the HTTP request.</td>
</tr>
<tr>
<td>body</td>
<td>AZStd::String</td>
<td>Optional body to send with the request.</td>
</tr>
</tbody>
</table>

Return: No return value.

**JSON Request Callback**

This callback is returned for the AddRequest, AddRequestWithHeaders, and AddRequestWithHeadersAndBody methods.

```cpp
void Callback(const Aws::Utils::Json::JsonValue& json, Aws::Http::HttpResponseCode responseCode);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>json</td>
<td>Aws::Utils::Json::JsonValue</td>
<td>The JSON object. The life span of this object is valid only during the scope of the callback.</td>
</tr>
<tr>
<td>responseCode</td>
<td>Aws::Http::HttpResponseCode</td>
<td>The HTTP response code.</td>
</tr>
</tbody>
</table>

Return: No return value.

**AddTextRequest, AddTextRequestWithHeaders, AddTextRequestWithHeadersAndBody**

You can use the AddTextRequest, AddTextRequestWithHeaders, and AddTextRequestWithHeadersAndBody APIs to send a generic HTTP request to any website and receive the returned data in a text string. The methods return the data received in the callback parameter.
Syntax

EBUS_EVENT(HttpRequestor::HttpRequestorRequestBus, AddTextRequest, URI, method, callback)

EBUS_EVENT(HttpRequestor::HttpRequestorRequestBus, AddTextRequestWithHeaders, URI, method, headers, callback)

EBUS_EVENT(HttpRequestor::HttpRequestorRequestBus, AddTextRequestWithHeadersAndBody, URI, method, headers, body, callback)

Each add text request method requires the URI, a method and a callback.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URI</td>
<td>AZStd::String</td>
<td>The fully qualified web address, in the following format: scheme: [/user:password@]host[:port]/[/path][?query][#fragment]</td>
</tr>
<tr>
<td>method</td>
<td>Aws::Http::HttpMethod</td>
<td>The method type. The following values are supported: HTTP_GET, HTTP_POST, HTTP_DELETE, HTTP_PUT, HTTP_HEAD, and HTTP_PATCH.</td>
</tr>
<tr>
<td>callback</td>
<td></td>
<td>This function is called when the HTTP request is completed. The response body and code are present in the callback.</td>
</tr>
<tr>
<td>headers</td>
<td>HttpRequestor::Headers</td>
<td>The list of header fields for the HTTP request.</td>
</tr>
<tr>
<td>body</td>
<td>AZStd::String</td>
<td>Optional body to send with the request.</td>
</tr>
</tbody>
</table>

Return: No return value.

Text Request Callback

This callback is returned for the AddTextRequest, AddTextRequestWithHeaders, AddTextRequestWithHeadersAndBody methods.

void Callback(const AZStd::string& response, Aws::Http::HttpResponseCode responseCode);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>response</td>
<td>AZStd::string&amp;</td>
<td>The text returned from the server. The life span of this object is valid only during the scope of the callback.</td>
</tr>
<tr>
<td>responseCode</td>
<td>Aws::Http::HttpResponseCode</td>
<td>The HTTP response code.</td>
</tr>
</tbody>
</table>

Return: No return value.

Example

The following example uses the Metastream C++ API to obtain a gateway IP address.
Image Processing

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Image Processing gem enables the Texture Settings Editor, which you can use to customize and process image files and textures.

For more information, see Texture Settings Editor (p. 1734).

In-App Purchases Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The In-App Purchases Gem enables you to implement in-app purchases in your Android and iOS games. Platform-specific information is handled by the provided API, allowing you to use a single implementation of the In-App Purchases Gem for both Android and iOS.

Note
For Android, you must install the Google Play billing library from the Android SDK Manager. You can find this option under the extras section.

Handling Requests for Queries and Purchases

You can access the API through code by connecting to the EBus:

```
EBUS_EVENT(InAppPurchases::InAppPurchasesRequestBus, Initialize);
```

To use the API, include the InAppPurchasesBus.h header file.

You can also access the API through Script Canvas.
Initialize

Call this method first for all platforms. This method handles all necessary setup before the API can be used.

Parameters: None

QueryProductInfo

Use this method when the product IDs are shipped with the game. This method looks for a product ID file (product_ids.json on Android or product_ids.plist on iOS) and retrieves product details using the IDs that are specified in the file.

Parameters: None

QueryProductInfoByIds

Use this method to retrieve product details if the product IDs are provided at runtime, for example if they are retrieved from a server at runtime.

Parameters: AZStd::vector<AZStd::string>& productIds

QueryProductInfoById

Use this method to retrieve product details if the product IDs are provided at runtime, for example if they are retrieved from a server at runtime. Use this method to retrieve details for a single product only.

Parameters: AZStd::string& productId

QueryPurchasedProducts

Use this method to query the Google Play Store for products that were already purchased by the signed-in user. On iOS, this method reads the receipt that is stored on the device and lists the items purchased by the signed-in user.

Parameters: None

RestorePurchasedProducts

Use this method to restore purchases that were made by the user. This applies to purchases made on a different device, where the current device does not have receipts stored locally. This method is supported on iOS only.

Parameters: None

ConsumePurchase

Call this method for all purchases that are consumable, such as virtual currencies, health, and ammo. This method requires the purchase token provided by the Google Play Store when the product was purchased. This method is required and supported on Android only.

Parameters: AZStd::string& purchaseToken

FinishTransaction

Call this method at the end of a transaction. This method requires the transaction ID provided by the iOS App Store when the product was purchased. It also accepts a boolean parameter to indicate whether or not to download content that is hosted on Apple servers. If this method is not called, the transaction will be reported each time the game is restarted. This method is required and supported on iOS only.

Parameters: AZStd::string& transactionId | bool downloadHostedContent
**PurchaseProduct**

Use this method to request to purchase a product from the Google Play Store or the iOS App Store. This method requires the product ID of the product being purchased.

Parameters: AZStd::string& productId

**PurchaseProductWithDeveloperPayload**

Use this method to request to purchase a product from the Google Play Store or the iOS App Store. This method requires the product ID of the product being purchased. It accepts an additional parameter for the developer payload, which is used by Android to associate a purchase with a user account. When you request purchased products, you can use the developer payload to determine if the signed-in user made the purchase. On iOS, the user account is used in fraud detection.

Parameters: AZStd::string& productId | AZStd::string& developerPayload

**GetCachedProductInfo**

Use this method to return product details that are stored in a cache each time there is a query for information. The cache only stores product details that were retrieved during the previous call to QueryProductInfo/QueryProductInfoByIds/QueryProductInfoById.

Parameters: None

**GetCachedPurchasedProductInfo**

Use this method to return details for purchased products that are stored in a cache. The cache only stores details for purchased products that were retrieved during the previous call to QueryPurchasedProducts.

Parameters: None

**ClearCachedProductDetails**

Use this method to clear the product details that were cached by the previous call to query product details.

Parameters: None

**ClearCachedPurchasedProductDetails**

Use this method to clear the details for purchased products that were cached by the previous call to query details for purchased products.

Parameters: None

**Handling Responses to Queries and Purchases**

When a user makes a query or a purchase, the API sends the request to Apple or Google servers. Once a response is received, the API broadcasts the response on the InAppPurchasesResponse bus.

To handle responses to queries or purchases, overload the functions provided in the class in the InAppPurchasesResponseBus.h file.

**ProductInfoRetrieved**

This method is called when product information is retrieved for all requested products. Product information includes product ID, name, description, price, and more. Depending on the platform, the provided pointers must be cast to the appropriate type (ProductDetailsAndroid or ProductDetailsApple).
PurchasedProductsRetrieved

This method is called when details are retrieved for all purchased products. Details for purchased products include product ID, transaction ID, transaction time, and more. Depending on the platform, the provided pointers must be cast to the appropriate type (PurchasedProductDetailsAndroid or PurchasedProductDetailsApple).

Parameters:
```
const AZStd::vector<AZStd::unique_ptr<ProductDetails const>> & productDetails
```

NewProductPurchased

This method is called when a new product is successfully purchased.

Parameters:
```
const PurchasedProductDetails* purchasedProductDetails
```

PurchaseCancelled

This method is called when a purchase is canceled.

Parameters:
```
const PurchasedProductDetails* purchasedProductDetails
```

PurchaseRefunded

This method is called when a purchase is refunded.

Parameters:
```
const PurchasedProductDetails* purchasedProductDetails
```

PurchaseFailed

This method is called when a purchase fails.

Parameters:
```
const PurchasedProductDetails* purchasedProductDetails
```

HostedContentDownloadComplete

This method is called when content that is hosted on Apple servers is downloaded successfully. The transaction ID and download path are provided.

Parameters:
```
const AZStd::string& transactionId | AZStd::string& downloadedFileLocation
```

HostedContentDownloadFailed

This method is called when content that is hosted on Apple servers fails to download. The transaction ID and content ID of the failed content download are provided.

Parameters:
```
const AZStd::string& transactionId | const AZStd::string& contentId
```

Input Management Framework Gem

The Input Management Framework Gem is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The Input Management Framework gem provides a framework for managing cross-platform game input such as keyboard, controller, and touch in Lumberyard with the component entity system.

The gem works with the Starting Point Input (p. 1206) gem, which supplies the processed raw input. The Input Management Framework gem then takes that input and converts it to user-defined gameplay events with the Input (p. 642) component.

For an example, see Working with the Input Component (p. 643).

For more information, see Input in Amazon Lumberyard (p. 1902).

**Landscape Canvas Gem**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Landscape Canvas Gem provides the Landscape Canvas Editor; a node-based graph tool for authoring dynamic vegetation workflows to drive vegetation areas. This is a great improvement over the previous component based dynamic vegetation system because you can now manage an edit all of the inputs in one place, and easily visualize the data flow when you build dynamic vegetation. The Landscape Canvas Editor uses the same UI and UX principles as Script Canvas, making Landscape Canvas intuitive and familiar.

**Note**
Landscape Canvas is backwards compatible. Any Dynamic Vegetation content you have previously authored is automatically parsed and a graph is built for you from your existing levels.
Landscape Canvas has five node groups available that map to the components you previously would use to build dynamic vegetation: Gradient Modifiers, Gradients, Shapes, Utilities, and Vegetation Areas. The workflow is to create a new landscape canvas asset, and layout and connect nodes in the canvas to build a workflow for a vegetation area.

Enable the Landscape Canvas Gem

To make the Landscape Canvas Editor available in Lumberyard, you must build and configure your project with the Landscape Canvas Gem enabled.

1. Use Project Configurator to add the Landscape Canvas Gem to your project.

   Note
   The Landscape Canvas Gem requires the following Gems.
   - LmbrCentral
   - Vegetation
   - GraphCanvas
   - GraphModel
   - GradientSignal
   - SurfaceData

2. Configure your project.

   `lmbr_waf configure`

3. Build your project.

   `lmbr_waf build_win_x64_vs2019_profile -p all --progress`

For more information on Gems, see the Gems documentation (p. 1064).

Lightning Arc Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Lightning Arc Gem creates realistic electric arcing and sparking effects between points in a level.

While active, the entity sparks a new electrical arc to the assigned target entities randomly. The entity is able to trigger new sparks in either game mode or in AI/Physics mode.
Using the LightingArc Sample

The LightningArc Sample uses the LightningArc gem to demonstrate the various prescribed arc types.
Topics

- Enabling the Lightning Gem (p. 1154)
- Placing Lightning Arc (p. 1154)
- Configuring the Lightning Arc (p. 1155)
- Customizing a Lightning Arc Preset (p. 1156)

Enabling the Lightning Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You enable the Lightning gem from the Project Configurator. You must also enable the Game Effect Gem, as the Lightning Gem requires it. You can see the dependencies for gems in the Project Configurator. For more information, see Creating Lumberyard projects (p. 43).

To enable the Lightning gem, see Enabling Gems (p. 1064).

Placing Lightning Arc

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.
When you place a lightning arc entity, you must specify at least one target. The lightning arcs between the lightning arc entity and each target that is linked. The lightning arc appears in Lumberyard Editor when you turn on AI/Physics or enter game mode (Ctrl + G).

**To place a lightning arc**

1. In the Rollup Bar, on the Object tab, click Entity.
2. Under Browser, expand Environment, and then drag LightningArc into your scene.
3. Under Entity Properties, ensure that Active is selected.
4. Click AI/Physics in the bottom toolbar. This makes the lightning arc visible in Lumberyard Editor after you place and link the targets.
5. To place one or more targets, in the Rollup Bar's Objects tab, click AI. Under Object Type, click Tagpoint.
6. Move your mouse into the scene, and click to place the tag point where your lightning will arc.
7. To link your tag point, select your lightning arc entity in the scene.
8. If necessary, scroll down or collapse other headings in the Rollup Bar to find Entity Links. Click Pick Target. Select the tag point you placed. Once it appears in the Link Name list, double-click the link name and change it to Target.
10. Expand materials\effects. Right-click the desired lightning effect. Then click Assign to Selected Objects. Close the Material Editor.

**Configuring the Lightning Arc**

You can configure the properties for the lightning arc entity to make the lightning arc show outside only, toggle wind effects, add delays and variations between arcs, and more. You can also carefully customize your lightning arcs by selecting different presets for the type of arc generated.

**To configure lightning arc entity parameters and properties**

1. In the Perspective viewport, select the lightning arc entity you want to configure.
2. Beneath Entity Params and Entity Properties, select or clear check boxes for the preferred effects.
Lightning Arc Entity Properties

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Activates the effect</td>
</tr>
<tr>
<td>Render</td>
<td>ArcPreset Sets the specified arc preset defined in the lightningarceffects.xml file as explained in Customizing a Lightning Arc Preset (p. 1156).</td>
</tr>
<tr>
<td>Timing</td>
<td>Delay Sets the delay time between arcs</td>
</tr>
<tr>
<td></td>
<td>DelayVariation Sets the variation of the delay based on the delay time</td>
</tr>
</tbody>
</table>

Customizing a Lightning Arc Preset

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can customize your lightning arc entity using the presets in the lightningarceffects.xml file. You can also copy and modify existing presets to create your own customized lightning arc presets.

To use a lightning arc preset

1. In Lumberyard Editor, use the Select tool to select the lightning arc entity you want to customize.
2. In a text editor, open \dev\Gems\LightningArc\Assets\libs\lightningarc \lightningarceffects.xml in the Lumberyard root directory (lumberyard_version\dev).
3. Choose one of the existing presets from the lightningarceffects.xml file (follows Arc name in the example) and, in Lumberyard Editor, under Entity Properties, enter your chosen Arc name into the ArcPreset field.

For example, enter ExtendedArc or KickSparks, which are existing names of presets as shown in the following lightningarceffects.xml file. This sample shows only the partial contents; open the file on your computer to view the full contents of the file.

```xml
<LightningArc>
  <Arc name="Default">
    <param name="lightningDeviation" value="0.2" />
    <param name="lightningFuzzyness" value="0.1" />
    <param name="branchMaxLevel" value="1" />
    <param name="branchProbability" value="2.0" />
    <param name="lightningVelocity" value="0.6" />
    <param name="strikeTimeMin" value="0.35" />
    <param name="strikeTimeMax" value="0.35" />
    <param name="strikeFadeOut" value="0.6" />
    <param name="strikeNumSegments" value="6" />
    <param name="strikeNumPoints" value="5" />
    <param name="maxNumStrikes" value="6" />
    <param name="beamSize" value="0.2" />
    <param name="beamTexTiling" value="0.25" />
    <param name="beamTexShift" value="0.05" />
  </Arc>
</LightningArc>
```
To create a new lightning arc preset

1. Open the lightningarceffects.xml file.
2. Copy the text (between and including <Arc name="Name"> through </Arc>) for an existing preset.
3. Paste it at the end of the file before the </LightningArc> closing bracket.
4. Replace the Arc name with your own custom preset name, then modify the following parameters to fit your needs.

The following table lists definitions for the parameters in the lightningarceffects.xml file.

**Lightning Arc Entity Properties**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lightningDeviation</td>
<td>The smoothness of the effect in meters.</td>
</tr>
<tr>
<td>lightningFuzzyness</td>
<td>The noisiness of the effect in meters.</td>
</tr>
</tbody>
</table>

Version 1.28

1157
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>branchMaxLevel</td>
<td>Allows child branches to strike out of the main beam and child branches to strike out from other child beams if this value is 2 or higher. A setting of 0 or 1 is recommended.</td>
</tr>
<tr>
<td>branchProbability</td>
<td>Probability that child branch will strike out from another beam segment. Consider these examples:</td>
</tr>
<tr>
<td></td>
<td>• 0 – No branch is generated</td>
</tr>
<tr>
<td></td>
<td>• 0.5 – Creates one branch per beam half the time</td>
</tr>
<tr>
<td></td>
<td>• 1.0 – Creates one branch per beam</td>
</tr>
<tr>
<td></td>
<td>• 2.0 – Creates 2 branches per beam</td>
</tr>
<tr>
<td>lightningVelocity</td>
<td>Rate at which a branch shifts upward from its original position after being triggered.</td>
</tr>
<tr>
<td>strikeTimeMin</td>
<td>Minimum time a branch remains visible.</td>
</tr>
<tr>
<td>strikeTimeMax</td>
<td>Maximum time a branch remains visible.</td>
</tr>
<tr>
<td>strikeFadeOut</td>
<td>Time to fade out after a branch disappears. This setting decreases the branch beamSize to 0 instead of actually fading with transparency.</td>
</tr>
<tr>
<td>strikeNumSegments</td>
<td>Number of snaking segments generated.</td>
</tr>
<tr>
<td>strikeNumPoints</td>
<td>Number of points per segment generated to create the noisy effect.</td>
</tr>
<tr>
<td></td>
<td>The number of actual segments generated is defined by strikeNumSegments * strikeNumPoints.</td>
</tr>
<tr>
<td></td>
<td>When the code generates the geometry, it creates a camera-aligned beam with exactly two triangles. This means the number of triangles per strike is strikeNumSegments<em>strikeNumPoint</em>2. Since maxNumStrikes is the hard limit of potential number of sparks active at any time, the potential number polygons of a given lightning effect is strikeNumSegments<em>strikeNumPoint</em>2*maxNumStrike.</td>
</tr>
<tr>
<td></td>
<td>Note that with the LightningArc entity, each lightning strike triggers a new lightning strike. Therefore the total poly count of a given effect can be much higher. The game has internal limits for the total amount of lightning effects, lightning strikes, and polygons that cannot be surpassed.</td>
</tr>
<tr>
<td>maxNumStrikes</td>
<td>Hard limit on the number of beam segments that can be generated.</td>
</tr>
<tr>
<td>beamSize</td>
<td>Width of the beam generated. Child beams have half the width.</td>
</tr>
<tr>
<td>beamTexTiling</td>
<td>Texture tiling depends on the world size. A value of 2.0 means the texture wraps around twice every meter. A value of 0.25 means the texture will wrap around every 4 meters.</td>
</tr>
<tr>
<td>beamTexShift</td>
<td>Rate at which the U coordinate moves in a given direction. While beamTexTiling affects only the U coordinate, the V coordinate is automatically calculated to select one of the texture's frames.</td>
</tr>
<tr>
<td>beamTexFrames</td>
<td>Number of frames in the animation.</td>
</tr>
<tr>
<td>beamTexFPS</td>
<td>Frames per second of the multiframe animation.</td>
</tr>
</tbody>
</table>
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Legacy Terrain Gem enables the legacy terrain system in Lumberyard version 1.24 or later. With this gem, you can use the Legacy Terrain level component in the Level Inspector to add terrain to levels. Levels that were created in Lumberyard versions before 1.24 that use the legacy terrain system display a warning when they are loaded in Lumberyard version 1.24 or later, and the new Legacy Terrain level component is automatically added to the level. Newly created levels have the Legacy Terrain level component added by default.

Note
In Lumberyard versions 1.24 and later, the Legacy Terrain Gem is enabled by default for Lumberyard projects and is required to enable the legacy terrain system. For more information about Gems, see the Gems documentation (p. 1064).

The Legacy Terrain Gem doesn't introduce new tools to edit terrain. Terrain texture layers are created with the Terrain Texture Layers editor. Terrain heightmaps are painted with the Terrain Editor. Terrain can be painted and sculpted in the Perspective viewport with the Terrain Tool. For more information about editing terrain, see Creating Terrain (p. 1220).

In addition to the Legacy Terrain Gem, Lumberyard version 1.24 introduces a new terrain API: AzFramework::Terrain::TerrainDataRequestBus (p. 1160). The legacy terrain system has been refactored to integrate the new terrain API. This new API makes it easier to seamlessly replace the legacy terrain system with your own terrain system. The legacy terrain APIs that are present in I3DEngine.h and ITerrain.h have been marked for deprecation. If your project uses the legacy terrain APIs, you should migrate your code as soon as possible to use the new AzFramework::Terrain::TerrainDataRequestBus. The legacy terrain APIs will be removed in a future release.

Disable terrain editor tools
Lumberyard builds the terrain editor tools by default. If the Legacy Terrain Gem is disabled, a WAF configure-time warning is raised because terrain can’t be added to the level, so the terrain editor tools serve no purpose.

If you are not using the Legacy Terrain Gem, you can disable the terrain editor tools in the WAF build settings. To disable the terrain editor tools, use one of the following options.

- Manually set the build flag enable_legacy_terrain_editor to False in lumberyard_version\dev\_WAF\user_settings.options:

  [Build Options]
  ...
  enable_legacy_terrain_editor = False
  ...

Version 1.28
1159
• Change the value `enable_legacy_terrain_editor` in the Lumberyard WAF options dialog.

1. Open the Lumberyard WAF options from `lumberyard_version\dev` with the following command.

   ```bash
   lmbr_waf show_option_dialog
   ```

2. Find the `enable_legacy_terrain_editor` option in the Build tab and deselect the check box on the right to disable the terrain editor tools.

Legacy terrain system

• Legacy Terrain level component (p. 651)
• TerrainDataRequestBus API (p. 1160)

TerrainDataRequestBus API

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

TerrainDataRequestBus is an API introduced in Lumberyard release 1.24. This API presents an EBus interface to query a terrain system. TerrainDataRequestBus enables you to easily swap different implementations of terrain systems. The Legacy Terrain level component is implemented with the TerrainDataRequestBus API.

The TerrainDataRequestBus is a single address, single handler EBus. This means that only one component that provides the service TerrainService can be active at any given time.
The Legacy Terrain level component (p. 651), which is provided by the Legacy Terrain Gem (p. 1159), is a TerrainService provider and can answer to calls made to the TerrainDataRequestBus.

The TerrainDataRequestBus header file is located here: lumberyard_version/Code/Framework/AzFramework/AzFramework/Terrain/TerrainDataRequestBus.h.

The TerrainDataRequestBus API replaces all terrain-related APIs that historically have been available in lumberyard_version/Code/CryEngine/CryCommon/I3DEngine.h and lumberyard_version/Code/CryEngine/CryCommon/ITerrain.h. The old APIs have been marked for deprecation, along with notes about the new replacement API. The example below is from I3DEngine.h:

```cpp
I3DEngine.h GetTerrainElevation()
```

```cpp
//! LUMBERYARD_DEPRECATED(LY-107351) Use AzFramework::Terrain::TerrainDataRequestBus::GetHeight*(Sampler::BILINEAR) instead.
// Summary:
//     Gets the interpolated terrain elevation for a specified location.
// Notes:
//     All x,y values are valid.
// Arguments:
//     x - X coordinate of the location
//     y - Y coordinate of the location
// Return Value:
//     A float which indicate the elevation level.
virtual float GetTerrainElevation(float x, float y, int nSID = DEFAULT_SID) = 0;
```

Notes on thread safety

TerrainDataRequestBus was designed for multi-threaded usage. The following are some recommendations to efficiently use the TerrainDataRequestBus API with thread safety in mind.

For loops running outside of the Main thread

Unsafe and Fast (Bad)

In the following code, the Legacy Terrain level component is created and destroyed on the Main thread when switching levels or entering/leaving Game Mode.

```cpp
auto terrain = AzFramework::Terrain::TerrainDataRequestBus::FindFirstHandler();
for ()
{
    float height = terrain->GetHeightFromFloats(x,y);
    //Do something.
}
```

Safe and Slow (Better)

The following code locks and unlocks its internal mutex each time a call is made on a thread-safe EBus.

```cpp
```
for (){
    float height = 0.0f;
    AzFramework::Terrain::TerrainDataRequestBus::Broadcast(height,
        &AzFramework::Terrain::TerrainDataRequest::GetHeightFromFloats,x,y,
        AzFramework::Terrain::TerrainDataRequest::Sampler::BILINEAR);
    //Do something.
}

Safe and Fast (Best)

In the following code, EnumerateHandlers locks the EBus mutex only once, allowing you to run
the code you need, and EnumerateHandlers unlock the EBus mutex when the task completes.

auto enumerationCallback = [&](AzFramework::Terrain::TerrainDataRequests* terrain) ->
    bool
    {
        float height = terrain->GetHeightFromFloats(x,y);
        //Do something.
        // Only one handler should exist.
        return false;
    }
AzFramework::Terrain::TerrainDataRequestBus::EnumerateHandlers(enumerationCallback);

A lock-less alternative

Assuming that you have control over when to start or stop threads/jobs, the lock-less alternative
would be to subclass TerrainDataNotificationBus, and stop/restart your threads/jobs by
reacting accordingly to one of these callbacks:

AzFramework::Terrain::TerrainDataNotificationBus

virtual void OnTerrainDataCreateBegin() {};
virtual void OnTerrainDataCreateEnd() {};
virtual void OnTerrainDataDestroyBegin() {};
virtual void OnTerrainDataDestroyEnd() {};

Fast and safe, assuming proper usage of TerrainDataNotificationBus

Assuming threads/jobs are never running while the legacy terrain system is being destroyed or
created, then the following case is safe and fast:

auto terrain = AzFramework::Terrain::TerrainDataRequestBus::FindFirstHandler();
for (){
    float height = terrain->GetHeightFromFloats(x,y);
    //Do something.
}
LmbrCentral Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The LmbrCentral gem contains required code and assets for running Lumberyard features, such as animation, audio, Lumberyard Editor, rendering, scripting, and so on.

**Note**
The LmbrCentral gem is required and enabled by default for Lumberyard projects.

LyShine

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The LyShine gem enables Lumberyard's in-game UI system. With the UI system, you can create dynamic user interfaces for your games.

**Note**
The LyShine gem is required and enabled by default in new Lumberyard projects.

For more information, see Creating and Customizing Project User Interfaces (p. 2874).

Maestro Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
The Maestro gem enables Lumberyard’s cinematic sequence system. With the cinematic sequence system, you can create cutscenes for your games with the Track View and render them as a series of frames and/or a movie in the editor and during gameplay.

**Note**
The Maestro gem is required and enabled by default in new Lumberyard projects.

For more information, see [Create cinematic sequences](p. 1583).

## Metastream Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Twitch Metastream is a feature that allows broadcasters to customize their streams with overlays of statistics and events from their game session. Using any web authoring tool, such as Dreamweaver or CoffeeCup, broadcasters can create custom HTML5 pages to control the information, graphics, layout, and behavior of each unique overlay. With Metastream, broadcasters can create more polished, interactive viewing experiences on any of their favorite streaming services, similar to what you see in professional Esports and TV broadcasts.

Examples of information displayed in an overlay include:

- Character art
- Character strengths and weaknesses
- Player standings
- Stats for two leaders in a match
- Gold collected
- Kills, deaths, and assists
- Damage dealt

Broadcasters can switch between different graphic overlays that are timed to game events. They can also use a picture-in-picture style to display complementary information such as a minimap and live team stats.

To enable broadcasters to use Twitch Metastream, you must do the following:

1. Enable the Metastream gem in your project.
2. Add a single line of code for each event you want broadcasters to access.

**Note**
Twitch Metastream is supported on Windows only.
Adding the Metastream Gem

Enable the Metastream gem in your project to turn on the local HTTP Metastream server that is included with Lumberyard.

To enable the Metastream gem, see Enabling Gems (p. 1064).

Setting Options for the HTTP Server

After you enable Metastream, an HTTP server is embedded into the game client and serves as the access point for exposed data. You can set the following options for the HTTP server.

`metastream_enabled`

Read-only console variable (CVAR) that describes the current state of the embedded HTTP server. 0 = disabled. 1 = enabled.

`metastream_serverOptions`

Sets the options for the embedded HTTP server. Options are a set of semicolon separated key=value pairs.

If a key value requires a semi-colon character ‘;’ or the equal character ‘=’ you may use the $semi macro or $equ.

The embedded HTTP server is based on CivetWeb. You can find the full list of options that can be set at:

For security reasons, the following CivetWeb options are ignored:

- `enable_directory_listing`
- `cgi_interpreter`
- `run_as_user`
- `put_delete_auth_file`

Files that you place inside the document root will be served by the HTTP server. See Accessing Data through the HTTP API (p. 1170).

You can also use the following console commands:

`metastream_start`

Starts the embedded HTTP server

`metastream_stop`

Stops the embedded HTTP server

Exposing Data through Metastream

Metastream exposes data through the C++ API.

C++ API

Controlling the HTTP Server

The Metastream Gem uses the following API to start the HTTP server:
bool result; // True when the server is successfully started, false when an error occurs.
Metastream::MetastreamRequestBus::BroadcastResult(result,&Metastream::MetastreamRequests::StartHTTPServer);

Attempting to start the HTTP server when it is already running has no effect, and the call returns true.

The Metastream Gem uses the following API to stop the HTTP server:

Metastream::MetastreamRequestBus::Broadcast(&Metastream::MetastreamRequests::StopHTTPServer);

If the server is not running, attempting to stop the server has no effect.

**Exposing Data**

The Metastream Gem uses a simple API to expose in-game data using the EBus system. See Accessing Data through the HTTP API (p. 1170) for these values. Currently, the Metastream API supports UTF8 strings, bools, Vec3, doubles, signed and unsigned 64-bit values. The EBus system requires these calls to be discrete. This API allows you to add values to objects and/or arrays and the cache. This allows for a fully flexible system in exposing data to a Web client.

**Add to Cache**

To add an object to the root cache, use the following syntax:

```cpp
void MetastreamRequests::AddStringToCache(const char* table, const char* key, const char* value)
void MetastreamRequests::AddBoolToCache(const char* table, const char* key, bool value)
void MetastreamRequests::AddVec3ToCache(const char* table, const char* key, const Vec3& value)
void MetastreamRequests::AddDoubleToCache(const char* table, const char* key, double value)
void MetastreamRequests::AddUnsigned64ToCache(const char* table, const char* key, AZ::u64 value)
void MetastreamRequests::AddSigned64ToCache(const char* table, const char* key, AZ::s64 value)
void MetastreamRequests::AddArrayToCache(const char* table, const char* key, const char* arrayName)
void MetastreamRequests::AddObjectToCache(const char* table, const char* key, const char* objectName)
```

Definitions for the parameters listed:

- `table`
  - Name of the table.
- `key`
  - Name of the key.
- `value`
  - The value to add. If the value exists, it is updated. If the value type is bool, it is represented in the JSON doc as true or false. Signed, unsigned, and double types are represented as JSON numbers; strings are UTF8 and will be escaped, if necessary.
- `arrayName`
  - The name of the array to add. If no array exists, then empty array is added. The array is deleted after it is added to the cache.
- `objectName`
  - The name of the object to add. If no object exists, then a NULL object is added. The object is deleted after it is added to the cache.
None of the above returns any values.

Add to Array

To add an object to an array, use the following syntax:

```cpp
void MetastreamRequests::AddStringToArray(const char* table, const char* arrayName, const char* value)
void MetastreamRequests::AddBoolToArray(const char* table, const char* arrayName, bool value)
void MetastreamRequests::AddVec3ToArray(const char* table, const char* arrayName, const Vec3 & value)
void MetastreamRequests::AddDoubleToArray(const char* table, const char* arrayName, double value)
void MetastreamRequests::AddUnsigned64ToArray(const char* table, const char* arrayName, AZ::u64 value)
void MetastreamRequests::AddSigned64ToArray(const char* table, const char* arrayName, AZ::s64 value)
void MetastreamRequests::AddObjectToArray(const char* table, const char* destArrayName, const char* sourceObjectName)
```

Definitions for the parameters listed:

- **table**
  Name of the table.

- **arrayName**
  The name of the array to add. If no array exists, then an empty array is added. The array is deleted after it is added to the cache.

- **value**
  The value to add to the array. If value type is bool, it is represented in the JSON doc as `true` or `false`. Signed, unsigned, and double types are represented as JSON numbers; strings are UTF8 and will be escaped, if necessary.

- **arrayName**
  The name of the array to add to. If no array exists, one is created.

- **destArrayName**
  The name of destination array to add to. If no array exists, one is created.

- **sourceObjectName**
  The name of the object to add to the array. If no object exists, then a NULL object is added. The object is deleted after it is added to the cache.

None of the above returns any values.

Add to Object

To add an object to an object, use the following syntax:

```cpp
void MetastreamRequests::AddArrayToObject(const char* table, const char* destObjectName, const char* key, const char* srcArrayName)
void MetastreamRequests::AddObjectToObject(const char* table, const char* destObjectName, const char* key, const char* sourceObjectName)
void MetastreamRequests::AddStringToObject(const char* table, const char* objectName, const char* key, const char* value)
```
void MetastreamRequests::AddBoolToObject(const char* table, const char* objectName, const char* key, bool value)
void MetastreamRequests::AddVec3ToObject(const char* table, const char* objectName, const char* key, const Vec3 & value)
void MetastreamRequests::AddDoubleToObject(const char* table, const char* objectName, const char* key, double value)
void MetastreamRequests::AddUnsigned64ToObject(const char* table, const char* objectName, const char* key, AZ::u64 value)
void MetastreamRequests::AddSigned64ToObject(const char* table, const char* objectName, const char* key, AZ::s64 value)

Definitions for the parameters listed:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Name of the table.</td>
</tr>
<tr>
<td>key</td>
<td>Name of the key.</td>
</tr>
<tr>
<td>objectName</td>
<td>The name of the object to add. If no object exists, then one is created.</td>
</tr>
<tr>
<td>value</td>
<td>The value to add. If the value exists, it is updated. If value type is bool, it is represented in the JSON doc as true or false. Signed, unsigned, and double types are represented as JSON numbers; strings are UTF8 and will be escaped, if necessary.</td>
</tr>
<tr>
<td>srcArrayName</td>
<td>The name of the array to add to. If no array exists, one is created. The array is deleted after it is added to the object.</td>
</tr>
<tr>
<td>sourceObjectName</td>
<td>The name of the object to add. If no object exists, then a NULL object is added. The object is deleted after it is added to the cache.</td>
</tr>
</tbody>
</table>

None of the above returns any values.

Examples

The following example shows how to use the Metastream C++ API in a project:

```
Metastream::MetastreamRequestBus::Broadcast(&Metastream::MetastreamRequestBus::Events::AddToCache, table, key, value);
```

Note

Any value that is added to the cache should be JSON compliant. For information, see the JSON RFC.

The following example shows how to reflect the system information. Basically all of the info is added to a object name, sysInfo, and this object is then added to the cache as systeminfo.

Compound object:

```
Metastream::MetastreamRequestBus::Broadcast(
```
Metastream::MetastreamRequestBus::Events::AddUnsigned64ToObject,
kDataBaseName.c_str(), "sysInfo", "drivespace", GetFreeDriveSpace());

Metastream::MetastreamRequestBus::Broadcast(
    &Metastream::MetastreamRequestBus::Events::AddUnsigned64ToObject,
    kDataBaseName.c_str(), "sysInfo", "memoryload", GetMemoryLoad());

Metastream::MetastreamRequestBus::Broadcast(
    &Metastream::MetastreamRequestBus::Events::AddDoubleToObject,
    kDataBaseName.c_str(), "sysInfo", "cpuloadsystem", GetCPULoadSystem());

Metastream::MetastreamRequestBus::Broadcast(
    &Metastream::MetastreamRequestBus::Events::AddDoubleToObject,
    kDataBaseName.c_str(), "sysInfo", "cpuloadprocess", GetCPUloadProcess());

Metastream::MetastreamRequestBus::Broadcast(
    &Metastream::MetastreamRequestBus::Events::AddUnsigned64ToObject,
    kDataBaseName.c_str(), "sysInfo", "tickcount", GetTickCount64());

Metastream::MetastreamRequestBus::Broadcast(
    &Metastream::MetastreamRequestBus::Events::AddObjectToCache,
    kDataBaseName.c_str(), "systeminfo", "sysInfo");

---

**Metastream Lua Bindings**

As of Lumberyard 1.10, Twitch Metastream reflects using the behavior context, which enables you to use Metastream through Script Canvas and Lua.

The following methods can be invoked from Lua:

```
-- Controlling the HTTP server:
MetastreamRequestBus::Broadcast.StartHTTPServer();
MetastreamRequestBus::Broadcast.StopHTTPServer();

-- Adding to the root cache directly:
MetastreamRequestBus::Broadcast>AddStringToCache(table, key, value);  -- where value is a string
MetastreamRequestBus::Broadcast>AddBoolToCache(table, key, value);     -- where value is a bool
MetastreamRequestBus::Broadcast>AddDoubleToCache(table, key, value);   -- where value is a double
MetastreamRequestBus::Broadcast>AddUnsigned64ToCache(table, key, value);  -- where value is an unsigned 64-bit number
MetastreamRequestBus::Broadcast>AddSigned64ToCache(table, key, value);  -- where value is a signed 64-bit number
MetastreamRequestBus::Broadcast>AddArrayToCache(table, key, arrayName);  -- where arrayName is the name of a temporary array (see below)
MetastreamRequestBus::Broadcast>AddObjectToCache(table, key, objectName); -- where objectName is the name of a temporary object (see below)

-- Adding to a temporary Array:
MetastreamRequestBus::Broadcast>AddStringToArray(table, arrayName, value);
MetastreamRequestBus::Broadcast>AddBoolToArray(table, arrayName, value);
MetastreamRequestBus::Broadcast>AddDoubleToArray(table, arrayName, value);
MetastreamRequestBus::Broadcast>AddUnsigned64ToArray(table, arrayName, value);
MetastreamRequestBus::Broadcast>AddSigned64ToArray(table, arrayName, value);
MetastreamRequestBus::Broadcast>AddObjectToArray(table, arrayName, objectName);

-- Adding to a temporary Object:
MetastreamRequestBus::Broadcast>AddStringToObject(table, objectName, key, value);
MetastreamRequestBus::Broadcast>AddBoolToObject(table, objectName, key, value);
MetastreamRequestBus::Broadcast>AddDoubleToObject(table, objectName, key, value);
MetastreamRequestBus::Broadcast>AddUnsigned64ToObject(table, objectName, key, value);
```
MetastreamRequestBus.Broadcast.AddSigned64ToObject(table, objectName, key, value);
MetastreamRequestBus.Broadcast.AddArrayToObject(table, objectName, key, arrayName);
MetastreamRequestBus.Broadcast.AddObjectToObject(table, objectName, key, objectName);

Accessing Data through the HTTP API

You can access game data that has been exposed through Metastream by using the HTTP API Get requests. You can then use JavaScript to work with the data.

http://localhost:port/pathToFile

Serves a file from the document root. File types include HTML, JS, CSS, images, sounds, resources, or assets.

**Note**
The data path is reserved for Metastream data. Files that are saved to the `document_root/data/` directory will not be accessible.

http://localhost:port/data

Returns a list of available Metastream tables that contain `key=value` pairs.

http://localhost:port/data?table=table_name

Returns a list of all Metastream keys in the specified table.

**Note**
You can retrieve multiple key-value pairs in a single request by listing the keys in a comma-separated list. For example, `http://localhost:8082/data?table=sample&key=key1,key2,key3`

http://localhost:port/data?table=table_name&key=key_name

Returns the value for the specified key in the specified table.

**Note**
Multiple `key=value` pairs can be retrieved in a single request by listing the desired keys separated by commas. For example, `http://localhost:8082/data?table=sample&key=key1,key2,key3`.

To list all keys and their values for a table: `http://localhost:8082/data?table=sample&key=*`

Data requests are returned in the following format:

<table>
<thead>
<tr>
<th>Request</th>
<th>Return</th>
</tr>
</thead>
<tbody>
<tr>
<td>/data</td>
<td>{ &quot;tables&quot;: [ &quot;table1&quot;, &quot;table2&quot;, ... ] }</td>
</tr>
<tr>
<td>/data?table=table_name</td>
<td>{ &quot;keys&quot;: [ &quot;key1&quot;, &quot;key2&quot;, ... ] }</td>
</tr>
<tr>
<td>/data?table=table_name&amp;key=key_name</td>
<td>{ &quot;key_name&quot;: value }</td>
</tr>
<tr>
<td>/data?table=table_name&amp;key=keys_list</td>
<td>{ &quot;key1&quot;: value1, &quot;key2&quot;: value2, ... }</td>
</tr>
</tbody>
</table>
Microphone Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Microphone Gem is a dependency for the Cloud Canvas Speech Recognition Gem (p. 1122). This means that when you enable the Cloud Canvas Speech Recognition Gem in the Project Configurator, the Microphone Gem is also automatically added.

The Microphone Gem's API is located at \dev\Code\CryEngine\CryCommon\MicrophoneBus.h.

This gem connects to a hardware recording device and enables you to capture an audio signal. Before running the game or editor, set the default recording device in your Operating System. Check your levels and adjust the gain accordingly. Once set up, the Microphone Gem connects to that device at application startup. Capturing starts when you start a capturing session and stops when you end the capturing session.

Clients using the mic data are expected to consume the data at a pace that meets or exceeds the data rate of the microphone. If consumption rate is too slow, the captured data can lag progressively behind real-time.

When consuming samples, you can specify a desired output format configuration, and the output is automatically converted.

Note the following:

- Only Windows is currently supported.
- Mono and stereo configurations only are supported for microphone input and client output.
- Only linear PCM samples are supported. This can be in either IEEE float (32-bit) or 16-bit signed integer formats. Typically mics will capture float samples.
- Hardware configuration changes, such as changing the default recording device, aren't handled at run time.
- Choosing a device to connect to is not yet supported. The Microphone gem connects only to the default device.
- Only a single consumer should be used. This is because consuming samples from the Microphone gem advances the read position of internal buffers containing the mic data. If two clients attempt to consume the data, each client obtains only portions of the original data.

Multiplayer Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Multiplayer Gem makes it easy for you to add some basic network functionality to your games without digging too deeply into specific details or customization. To make this possible, Lumberyard has created a Multiplayer Lobby component and CVars for general networking use.

You can also use the Multiplayer sample project (p. 155) for an example of how to build and structure multiplayer games that use the various features of the GridMate networking (p. 1990) library.

For more information about networking in Lumberyard, see Using Lumberyard Networking (p. 1990).
The Multiplayer Lobby Component

You can use the self-contained lobby from Lumberyard's component entity system and add the `MultiplayerLobbyComponent` to a component entity in a scene. The `MultiplayerLobbyComponent` provides a basic lobby that can perform the following tasks:

- Search for an active game session
- Create a visual list of game sessions
- Join a particular game session
- Create a game session
- Name a game session
- Determine the map to load into
- Report errors

Supported Session Services

The `MultiplayerLobbyComponent` supports all of Lumberyard's session services, including `LANSessionService` and `GameLiftSessionService`.

Configuration Settings

The `MultiplayerLobbyComponent` has configuration settings that you can use to customize the hosted sessions that the component creates.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Max Players</td>
<td>The maximum number of players allowed to join the session.</td>
</tr>
<tr>
<td>Port</td>
<td>The port on which the game session operates.</td>
</tr>
<tr>
<td>Enable Disconnect Detection</td>
<td>Enables disconnect detection. If a player's connection does not respond to inquiries from the session host within the specified timeout window, the player is disconnected from the session.</td>
</tr>
<tr>
<td>Timeout</td>
<td>The timeout window, in milliseconds, that a client has to respond to inquiries from the session host before being disconnected, if disconnect detection is enabled.</td>
</tr>
<tr>
<td>Default Map</td>
<td>The default value for the Map field of the display.</td>
</tr>
<tr>
<td>Default Server Name</td>
<td>The default value for the Server Name field of the display.</td>
</tr>
<tr>
<td>Default Matchmaking Config</td>
<td>The default value for the Matchmaking Config to use for GameLift.</td>
</tr>
</tbody>
</table>

Note

This component does not handle the initialization of encryption, but utilizes encryption if it is already enabled. If you want to use encryption with the component, you must configure encryption before you use the component.
LAN Lobby Description

The following image shows a sample LAN lobby and its details.

1. Return – Exits the current lobby and returns to the SessionService selection screen.
2. Session List – Populates with server results from a successful GridSearch. This lists all of the sessions available, the name of each session, and the number of players in each session.
3. Refresh – Performs a GridSearch on the selected SessionService and displays the results in the session list.
4. Join – Attempts to join the currently selected session in the session list. If an error occurs, an error message is displayed. If no GridSession has been selected, this option is disabled.
5. Create a Server – Use these text boxes to configure sessions.
   - Server Name – Specifies the name that will be displayed in the session list when GridSession instances are searched for and the created GridSession is returned.
   - Map – Use to specify the map to be loaded when the GridSession is successfully created.
6. Create Server – Attempts to create a GridSession in the selected SessionService.

GameLift Lobby Description

The following image shows a sample GameLift lobby and its details.
1. **Return** – Exits the current lobby and returns to the SessionService selection screen.

2. **Create Server / Join Server / FlexMatch** – Radio buttons to toggle the details window for the selected radio button. (Current selection = Create Server).

3. Use these text boxes to configure sessions:
   - **ServerName** – Specifies the name that will be displayed in the session list when GridSession instances are searched for and the created GridSession is returned.
   - **Map Name** – Use to specify the map to be loaded when the GridSession is successfully created.

4. Need to fill only one of the below:
   - **Queue Name** – Queue to use to create the server game session (First priority).
   - **Fleet Id** – Fleet id to use to create the server game session (Second priority).
   - **Alias Id** – Alias id to use to create the server game session (Second priority).

5. **Create Server** – Attempts to create a GameLiftSession in the selected GameLift fleet or queue.
1. Need to fill only one of the below:
   - **Queue Name** – Queue to use to join a server game session (First priority).
   - **Fleet Id** – Fleet id to use to join a server game session (Second priority).
   - **Alias Id** – Alias id to use to join a server game session (Second priority).

2. **SessionList** – Populates with server results from a successful GridSearch. This lists all of the sessions available, the name of each session, and the number of players in each session.

3. **Refresh** – Performs a search for available game sessions using queue, fleet or alias. Displays the results as list in session list.

4. **Join** – Attempts to join the currently selected session in the session list. If an error occurs, an error message is displayed. If no GridSession has been selected, this option is disabled.
1. **Config Name** – Matchmaking configuration to use to start GameLift matchmaking.
2. **Start Matchmaking** – Will call GameLift service to try and place the player in available game session based on the matchmaking config. On success, player joins the game session.

**Multiplayer Gem CVars**

For convenience, the Multiplayer Gem provides the following console variable commands that you can use to test features or configurations.

**Client CVars**

**mpphost <port number>**

Creates a GridSession using the LANSessionService on the local machine. The optional port number determines the port on which the grid session runs.

**mpjoin <server address> <port number>**

Performs a GridSearch using the LANSessionService and joins the first session returned. The server address and port number are optional parameters that can be used to refine the GridSearch.

**mpsearch**

Performs a GridSearch using the LANSessionService.

**mpdisconnect**

Disconnects the local client from its active GridSession, if any.

**gm_version**

Sets the GridMate version number.
**gm_netsec_enable**

Specifies whether network level encryption is used for connections. A value of 0 disables encryption and a value of 1 enables encryption. The default for the multiplayer gem is 0 (disabled).

**Note**

In the Multiplayer Sample, this value is overridden to be enabled in `game.cfg`.

**gm_netsec_private_key**

Specifies the private key file (PEM format) for a secure network connection when `FileDataSource` is used as a certificate manager. This setting overrides any previously configured values in `FileDataSource`. If network encryption is enabled, this value must be set on the host of a `GridSession` when the session is created. This setting is disabled in release builds.

**gm_netsec_certificate**

Specifies the private key file (PEM format) for a secure network connection when `FileDataSource` is used as a certificate manager. This setting overrides any previously configured values in `FileDataSource`. If network encryption is enabled, this value must be set on the host of a `GridSession` when the session is created. This setting is disabled in release builds.

**gm_netsec_ca**

Specifies the CA Certificate file (PEM format) for a secure network connection when the `FileDataSource` is used as a certificate manager. This setting overrides any previously configured values in `FileDataSource`. This value must be set on the client when trying to join a `GridSession` using encryption. This setting is disabled in release builds.

**gm_netsec_verify_client**

Enables client verification. If not enabled, only the server is authenticated. Must be set on the host of a `GridSession`. The default is 0, disabled.

**gm_disconnectDetection**

Sets whether disconnect detection is enabled for a particular `GridSession`. Must be set on the host of `GridSession`. If disconnect detection is enabled, clients that do not respond to inquiries within the timeout window are disconnected. The default is 1, enabled.

**gm_disconnectDetectionRttThreshold**

A RTT threshold, in milliseconds, that specifies the time after which a connection is dropped when there is no response. The default is 500.

**gm_disconnectDetectionPacketLossThreshold**

A value between 0 and 1 that represents the percentage of packets that are permitted to be lost in communication with a particular client. If a client experiences a packet loss greater than the specified value, the connection is dropped. The default is 0.3.

**gm_recvPacketsLimit**

The maximum number of packets per second allowed to be received from an existing connection. The default is 0 (no limit).

**gm_ipversion**

Specifies which Internet protocol version to use. Possible values are `IPv4` or `IPv6`. The default is IPv4.

**gm_securityData**

Specifies the security data for session.
gm_replicasSendTime

Specifies, in milliseconds, the time interval between replica updates. A value of 0 binds the interval to the GridMate tick rate. The default is 0.

gm_replicasSendLimit

Limits the amount of replica data sent per second. 0 specifies no limit. The default is 0. This value is disabled in release builds.

gm_burstTimeLimit

Specifies, in seconds, an interval window during which bandwidth capping is not applied. If bandwidth usage continues to exceed the replica send limit outside of this interval, the sent amount is capped at the send limit. The default is 10. This variable is disabled in release builds.

gamelift_fleet_id

Specifies the GameLift FleetId to use for this client when starting GameLiftSessionService.

gamelift_aws_access_key

Specifies the AWS access key associated with the GameLift fleet.

gamelift_aws_secret_key

Specifies the AWS secret key associated with the GameLift fleet.

gamelift_aws_region

Specifies the AWS region associated with the GameLift fleet. The default is us-west-2.

gamelift_endpoint

Specifies the GameLift service endpoint. The default is gamelift.us-west-2.amazonaws.com.

gamelift_alias_id

Specifies the GameLift alias ID to use with the client.

gamelift_player_id

Specifies the GameLift player ID associated with the client.

gamelift_stop_client

Stops the GameLiftSessionService and terminates the current GridSession, if one is connected.

gamelift_queue_name

Specifies GameLift queue to use for this client when creating or joining a game session.

gamelift_matchmaking_config_name

Specifies GameLift FlexMatch matchmaking configuration to use for this client when being placed in a game session.

sv_port <local_port>

Sets the local UDP port that initializes the socket. The default port is 30090. To use the ephemeral port, set the port to 0. This is useful if you want to connect to a server on the same computer as the client.

Server CVars

gamelift_flexmatch_enable

Configures the server process to enable custom matchmaking backfill for FlexMatch.
Multiplayer Analytics Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Multiplayer Analytics Gem is an additional GridMate Gem for analyzing your network traffic live, using an in-game overlay.

When enabled, you can press the HOME key to bring up an in-game UI. The following example is from the Multiplayer Sample included with Lumberyard.

For more information about how to use this Gem in Lumberyard, see Using Multiplayer Analytics (p. 2092).
NullVR Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the NullVR gem to run your level through the head-mounted displays (HMD) framework without a connected VR device. This gem is useful for VR graphics debugging.

The NullVR Gem has a lower priority than other VR gems and their devices. That means that if any other VR gem is enabled and its appropriate VR device is connected, then the HMD framework uses that VR gem. The NullVR Gem is enabled only if no other VR gem is enabled or no VR device is connected.

When Lumberyard is using the NullVR Gem, the following appears in the console:

```
[HMD][Null] - Null Device
```

Console Variables

The NullVR Gem, when enabled, makes certain console variables available. These console variables take effect only if the NullVR Gem is in use; that is, no other VR gems are enabled or no other VR devices are connected.

**Note**
The default values in the following list came from Vive at the time of this writing.

- `hmd_null_aspectRatio`
  Aspect ratio of the null VR implementation.
  Default: 0.9

- `hmd_null_eyeOffsetX`
  Eye X offset (horizontal distance).
  Default: -0.0346999988

- `hmd_null_fov`
  The field of view in radians. Can be updated at runtime.
  Default: 1.91986

- `hmd_null_fovH`
  The field of view height in radians. Used on start.
  Default: 1.84633982

- `hmd_null_fovV`
  The field of view width in radians. Used on start.
  Default: 1.94590104

- `hmd_null_frustumPlane_horizontalDistance`
  Frustum plane horizontal distance.
  Default: -0.0701720715
hmd_null_frustumPlane_verticalDistance

Frustum plane vertical distance.

Default: -0.00206005573

hmd_null_renderHeight

The height of the render texture in pixels. Set once on start.

Default: 1680

hmd_null_renderWidth

The width of the render texture in pixels. Set once on start.

Default: 1512

NVIDIA Blast gem

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The NVIDIA Blast gem uses the NVIDIA Blast library to provide fast, high-fidelity destruction simulation in Amazon Lumberyard.

Note

NVIDIA Blast for Lumberyard requires a SideFX Houdini commercial or indie license to create assets. The apprentice license is not sufficient. For more information on Houdini, see SideFX’s home page.

The precompiled Houdini plug-ins supplied with the NVIDIA Blast gem require Houdini 18.0.

For NVIDIA Blast developer information, see Simulated destruction with NVIDIA Blast (p. 2833).

Contents

- Functionality provided by the NVIDIA Blast gem (p. 1181)
- Enable the NVIDIA Blast gem (p. 1182)

Functionality provided by the NVIDIA Blast gem

The NVIDIA Blast gem provides the following:

- **Blast Family Mesh Data** component that adds NVIDIA Blast meshes to an entity.
- **Blast Family** component that enables NVIDIA Blast simulation for an entity.
- **Blast Configuration** editor available in the Tools menu in Lumberyard Editor.
- **Blast Materials** to set physical properties for NVIDIA Blast assets available in Asset Editor.
- **Blast Script Canvas** nodes to script destruction simulation.
- Plug-ins and Houdini Digital Assets for SideFX Houdini to fracture geometry and export NVIDIA Blast assets.
- A Python Asset Builder to process NVIDIA Blast assets and generate blast slices.
• A public C++ API that allows other systems and gems to access NVIDIA Blast simulation functionality.

Enable the NVIDIA Blast gem

To enable the NVIDIA Blast gem, do the following:

1. Use Project Configurator (p. 44) to add the NVIDIA Blast gem to your project. The NVIDIA Blast gem requires the following gems as dependencies:
   • LmbrCentral
   • PhysX

   **Important**
   Though not required, we highly recommend that you enable the Python Asset Builder gem (p. 1192) with the NVIDIA Blast gem. The NVIDIA Blast gem includes a Python asset builder script that automatically processes mesh assets for NVIDIA Blast and creates a blast slice asset.

2. Configure your project. Use the following command.
   
   ```text
   lmbr_waf configure
   ```

3. Build your project. Use the following command.

   ```text
   lmbr_waf build_win_x64_vs2019_profile -p all --progress
   ```

   For more information on gems, see the Gems system documentation (p. 1064).

**NVIDIA Cloth gem**

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Physical cloth simulations can create more immersive environments and characters. The NVIDIA Cloth gem uses the NVIDIA Cloth library to provide fast, robust cloth simulation in Amazon Lumberyard.

For information on using NVIDIA Cloth, see Simulate cloth with NVIDIA Cloth (p. 2857).

**Functionality provided by the NVIDIA Cloth gem**

The NVIDIA Cloth gem provides the following:

• **Cloth** modifier for Mesh and Actor import in FBX Settings.
• **Cloth** component for entities that contain a Mesh or Actor component.
• Cloth colliders that can be added to actors in Animation Editor.
• Mesh and Actor example assets and slices located in: `lumberyard_version\dev\Gems\NvCloth\Assets`
• A public C++ API that allows other systems and gems to access cloth simulation functionality.
Enable the NVIDIA Cloth gem

To enable the NVIDIA Cloth gem, do the following:

**Note**
By default, NVIDIA Cloth simulation is performed on the CPU. To enable GPU accelerated simulation for NVIDIA Cloth, follow the installation instructions here: [GPU cloth simulation with NVIDIA CUDA](p. 2871)

1. Use Project Configurator (p. 44) to add the NVIDIA Cloth gem to your project. The NVIDIA Cloth gem requires the following gems as dependencies:
   - LmbrCentral
   - Emotion FX Animation
2. Configure your project. Use the following command.

   ```
   lmbr_waf configure
   ```
3. Build your project. Use the following command.

   ```
   lmbr_waf build_win_x64_vs2019_profile -p all --progress
   ```

For more information on gems, see the Gems system documentation (p. 1064).

Physically Based Shaders (PBS) Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Physically Based Shader (PBS) Reference Gem is a simple collection of 32 example materials that you can apply to a Mesh (p. 684) component. They demonstrate a wide range of surface material types that make use of the Illum Shader (p. 1697). These materials range from matte to shiny and metallic or reflective. For more information about rendering physically based materials, see Shader Rendering System (p. 1639).

The PBS Reference Gem is enabled by default in new projects and is also enabled in the default Samples Project. You use the Material Editor to preview, modify, and apply a material to a mesh.

The following procedure describes a very simple example work flow for applying a PBS Reference Gem material to an object. This procedure assumes your project is Samples Project (the default project for Lumberyard).

To apply materials contained in PBS Reference Gem

1. Open a level in Lumberyard.
2. Create a new entity (p. 463).
3. Add (p. 479) a Mesh (p. 684) component to your entity.
4. In the Entity Inspector (p. 475), in the Mesh component, next to the Mesh Asset property, click ‘...’ to specify an asset.

   In the Pick Static Mesh dialog, browse to \SamplesProject\Objects\Primitives. Pick one of the .cfg files in that directory. Click OK.
The object that you picked now appears in your Viewport.
5. Make sure your object is still selected.

Open the Material Editor by pressing M or by navigating to Tools, Material Editor.

6. In the Material Editor's navigation pane, browse to \Gems\PBSreferenceMaterials\Assets\materials\pbs_reference.

Select one of the .mtl files listed.
7. In the Material Editor's toolbar, click the Assign Item to Selected Object icon.
Close or move the **Material Editor** to see your **Viewport**.

The assigned material is now applied to your object.
PhysX

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard's PhysX system acts upon entities to create realistic physical effects such as collision detection and rigid body dynamics simulation. Enable the PhysX gem to use the PhysX system for your game project.

For more information, see Simulating physics behavior with the PhysX system (p. 2772).

PhysX Characters

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The PhysX Characters gem provides physics for your characters in your game. The gem integrates with the EMotion FX Animation Editor system.

Note
To enable the PhysX Characters gem, you must first enable the PhysX (p. 1188) gem.

The PhysX Characters gem adds the following components:

- PhysX Character Controller (p. 729)
- PhysX Ragdoll (p. 757)

For more information, see PhysX system (p. 2772).

PhysX Debug

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The PhysX Debug gem provides features to debug visualizations for your PhysX scene geometry, such as the PhysX Collider (p. 755), PhysX Rigid Body (p. 759) component, and so on.
When you enter console variables or the use the ImGui tool, you can view the PhysX debug lines in editor and game modes. This gem uses data directly from PhysX to show a culled (limited by proximity to the camera) view of the simulated world in real time.

In editor mode, this gem displays PhysX shapes within a given distance of the viewport camera. In game mode, this gem uses the currently active camera to visualize a culled view of the the PhysX scene.

This gem includes the following features:

- Visualize debug rendering of physics geometry, such as collision primitives, terrain, shapes, and forces.
- Control mechanisms using console variables, the PhysX settings menu, and the ImGui tool.
- Visualization frustum culling.
- PhysX visual debugger hooks and controls using the third-party tool visual debugger.
- Proximity based debug visualizations of collision meshes.

**Note**
This feature is similar to the legacy p_draw_helpers=1 console variable.

To enable the PhysX Debug gem, you must first enable the PhysX (p. 1188) and ImGui gems.

For more information, see Debugging PhysX (p. 2826).

### Physics Entities Gem

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Physics Entities Gem is a collection of physics entities used to simulate physical events such as explosions, gravity fields, or wind, or to physicalize objects such as cloth, breakable entities, or ropes. Physical entities that are related to a body instead of an event are connected to an object.

**To access the Physics entities**

1. In the Rollup Bar, on the Objects tab, choose Entity.
2. Expand Physics.
3. Drag the entity into your level in the viewport.
Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Primitive Assets Gem provides primitive objects that are physics enabled and unit size (1x1x1), with a gray checkerboard texture. The checkerboard texture is RGB middle gray (127,127,127) and sRGB middle gray (187,187,187). Diffuse, normal, and specular maps are included. The primitive object models have import settings, a material, and a slice. Each slice contains the object mesh and the appropriate Shape and Rigid Body Physics components. You can use these to add the cube, sphere, and cylinder objects to your level and manipulate the objects, create a placeholder, or test Lumberyard Editor features.

The asset files for the primitive objects are in the `\lumberyard_version\dev\Gems\PrimitiveAssets\Assets` directory.

You can add the primitive objects to your game project by doing either of the following:

- Create a new project from the Default template in the Project Configurator. By default the Primitive Assets Gem is enabled for projects that are created from this template.
- Enable the Primitive Assets Gem for your existing project in the Project Configurator.

For more information, see Creating a Game Project in Lumberyard (p. 45).
Process Life Management Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Process Life Management gem demonstrates how you can respond to various application lifecycle events dispatched by the Lumberyard engine, in order to pause your game, display a modal splash screen, or anything else you may need to do when your application loses/regains focus.

You can access all system-specific events from C++ (even without enabling the Process Life Management gem) by connecting to the appropriate EBus. Lumberyard also generates platform-agnostic events so that you can handle these events for all supported platforms.

Lumberyard Application Lifecycle Events

<table>
<thead>
<tr>
<th>Lumberyard Application Lifecycle Events</th>
<th>iOS</th>
<th>Android</th>
</tr>
</thead>
<tbody>
<tr>
<td>OnApplicationConstrained</td>
<td>applicationWillResignActive</td>
<td>onPause()</td>
</tr>
<tr>
<td>OnApplicationUnconstrained</td>
<td>applicationDidBecomeActive</td>
<td>onResume()</td>
</tr>
<tr>
<td>OnApplicationSuspended</td>
<td>applicationDidEnterBackground</td>
<td>onPause()</td>
</tr>
<tr>
<td>OnApplicationResumed</td>
<td>applicationWillEnterForeground</td>
<td>onResume()</td>
</tr>
<tr>
<td>OnMobileApplicationWillTerminate</td>
<td>applicationWillTerminate</td>
<td>onDestroy()</td>
</tr>
<tr>
<td>OnMobileApplicationLowMemoryWarning</td>
<td>applicationDidReceiveMemoryWarning</td>
<td>onLowMemory()</td>
</tr>
</tbody>
</table>

As demonstrated in ProcessLifeManagementGem.h\ProcessLifeManagementGem.cpp, use the following basic steps to receive process lifecycle events in your game.
To receive process lifecycle events in your game

1. Derive your class from `AzFramework::ApplicationLifecycleEvents::Bus::Handler` (or `AzFramework::[Ios|Android|Windows]LifecycleEvents::Bus::Handler` for platform specific events).
2. Override the functions corresponding to the events that you want to override:

   ```
   void OnApplicationConstrained(Event /lastEvent/) override;
   void OnApplicationUnconstrained(Event /lastEvent/) override;
   void OnApplicationSuspended(Event /lastEvent/) override;
   void OnApplicationResumed(Event /lastEvent/) override;
   ```
3. Connect to the event bus when you want to start listening for events. In addition, be sure to disconnect when you no longer want to receive them. Use the following syntax:

   ```
   ApplicationLifecycleEvents::Bus::Handler::BusConnect();
   ...
   ApplicationLifecycleEvents::Bus::Handler::BusDisconnect();
   ```

Python Asset Builder gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

With **Python Asset Builder**, you can create Python scripts that process custom assets that are produced from content creation tools such as Maya and Houdini, or any content tool with a known file format.

For information on using **Python Asset Builder**, see Process custom assets with Python Asset Builder (p. 448).

Enable the Python Asset Builder gem

To enable the Python Asset Builder gem, do the following:

1. Use **Project Configurator** (p. 44) to enable the **Python Asset Builder** gem in your project.
2. Configure your project. Use the following command.

   ```
   lmbr_waf configure
   ```
3. Build your project. Use the following command.

   ```
   lmbr_waf build_win_x64_vs2019_profile -p all --progress
   ```

For more information on gems, see the Gems system documentation (p. 1064).

RAD Telemetry Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
RAD Telemetry 3 is an instrumentation-based profiling and performance visualization middleware product created by RAD Game Tools. The RAD Telemetry Gem provides a RAD Telemetry 3 integration for Lumberyard for those who have licensed RAD Telemetry.

The RAD Telemetry Gem provides one example of how to integrate instrumentation-based profiling middleware. You could write a gem for your own instrumentation-based profiler and leverage Lumberyard’s existing performance markers. See the Profiler.h file in the /dev/Code/Framework/AzCore/AzCore/Debug directory to see how the RAD Telemetry Gem ties into Lumberyard’s existing performance markers.

**Note**
If the RAD Telemetry Gem is disabled or you do not have the RAD redistributable files for a particular platform, the performance instrumentation compiles to Lumberyard’s performance markers.

**To enable the RAD Telemetry Gem**

1. Extract the Telemetry redistributables from RAD Game Tools to /Gems/RADTelemetry/External. You should see the following subdirectories, which match the subdirectories provided by RAD:
   - Dll
   - Lib
   - Include
   - Docs

   **Note**
   - If you are compiling for case-sensitive platforms, note that the first letter of each subdirectory listed above is capitalized.
   - When compiling a project with the RAD Telemetry Gem enabled, the static lib file for the target platform must exist in the Gems/RADTelemetry/External/ directory. The Waf build system then compiles with the AZ_PROFILE_TELEMETRY defined globally and links RAD Telemetry libraries for the specified platform. You can add additional platforms by editing the rad_telemetry.json file (located in the Gems/RADTelemetry/3rdParty directory).

2. Extract RAD Telemetry Tools to the /Gems/RADTelemetry/Tools directory. This should include telemetry.exe and your license file from RAD.

3. Use the Project Configurator to enable (p. 1064) the RAD Telemetry Gem for your project. You must enable this gem (and any other gem) for each project. Gems are not globally enabled.

4. Build your project (p. 61). You must build using profile (preferred) or debug (p. 61) in order to enable RAD Telemetry.

**Instrumenting Your Code**

With the RAD Telemetry Gem, Lumberyard introduces a set of scoped performance markers:

- **AZ_PROFILE_FUNCTION** – Instruments entire functions. Automatically names the performance event with the function's name.

- **AZ_PROFILE_SCOPE** – Instruments a local scope within a function of interest. You must provide the name.

- **AZ_PROFILE_SCOPE_DYNAMIC** – Instruments a printf style format string to dynamically generate a performance event name. Use the dynamic name sparingly because there may be performance overhead of a string copy and transmission over the network.
A scoped performance marker constructs an object that calls a start event and calls a stop event when it is destroyed. This means that you do not have to worry about early returns. We recommend that you use the AZ_PROFILE events when marking up your code, as it allows you to switch to Driller for a different view of profiling data.

Lumberyard also uses the following legacy performance event markers:

- PROFILE_FUNCTION
- PROFILE_FRAME

Capturing with RAD Telemetry

See the RAD Telemetry documentation for more information. The basic procedure is described below.

To capture with RAD Telemetry

1. Set the console variables for the RAD Telemetry capture using either a configuration file or by entering them into the console at runtime.

   All RAD Telemetry console variables start with radtm_. For example, radtm_Address and radtm_Port if your Telemetry server is on another machine. The console variables are defined in the RADTelemetryModule.cpp file. You can augment these console variables to better suit profiling for your title.

2. Use either telemetry.exe or the standalone telemetry server to start your RAD Telemetry server.

3. Run radtm_ToggleEnabled to begin a capture. You can also set this from the command line when launching your application with +radtm_ToggleEnabled.

4. Run radtm_ToggleEnabled again from the console or the remote console, or shut down your game process to end the session. As currently instrumented, captures can get large quickly, so you may want to perform focused captures around performance scenarios of interest (under 30 seconds in length).

5. Use the Telemetry visualizer (telemetry.exe) to analyze your capture.

Rain Gem

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Rain Gem creates realistic rain effects in your levels, including rain drops, puddles, mist, wet surfaces, and splashes. To enable the Rain Gem in your project, see Add modular features and assets with Gems (p. 1064).

This gem is a game object extension. On initialization, it preloads all textures listed in the raintextures.xml file.
Place only a single Rain entity in your scene.

Placing Rain

You can place rain and customize it for your level by modifying properties for amount of puddles, strength and frequency of puddle ripples, quantity of rain, size and speed of the rain drops, and more.

To add rain to your level

1. In the Rollup Bar, click Entity.
2. Under Browser, expand Environment.
3. Drag the Rain entity into your scene.

Configuring Rain

You can configure the rain's properties under Entity Params and Entity Properties.

### Rain Entity Properties

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amount</td>
<td>Sets overall amount of the rain entity's various effects</td>
</tr>
<tr>
<td>DiffuseDarkening</td>
<td>Sets the degree to which the rain darkens the surface diffuse</td>
</tr>
<tr>
<td>DisableOcclusion</td>
<td>Turns off checking whether an object is under cover and should be occluded from rain</td>
</tr>
<tr>
<td>Enabled</td>
<td>Toggles the rain effect</td>
</tr>
<tr>
<td>IgnoreVisareas</td>
<td>Continue to render rain when player is inside a vis area</td>
</tr>
</tbody>
</table>
### Properties

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PuddlesAmount</td>
<td>Sets the size and number of puddles that the rain creates</td>
</tr>
<tr>
<td>PuddlesMaskAmount</td>
<td>Sets the strength of the puddle mask to balance different puddle results</td>
</tr>
<tr>
<td>PuddlesRippleAmount</td>
<td>Sets the height and frequency of ripples in rain puddles</td>
</tr>
<tr>
<td>Radius</td>
<td>Sets the area on which rain falls</td>
</tr>
<tr>
<td>RainDropsAmount</td>
<td>Sets the number of rain drops</td>
</tr>
<tr>
<td>RainDropsLighting</td>
<td>Sets the brightness of the rain drops</td>
</tr>
<tr>
<td>RainDropsSpeed</td>
<td>Sets the rate at which rain falls</td>
</tr>
<tr>
<td>SplashesAmount</td>
<td>Sets the degree of splashing on a surface</td>
</tr>
</tbody>
</table>

### Using Console Variables for Rain

You can use the following console variables for the rain entity.

**Rain Entity Console Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>r_Rain</td>
<td>Enables rain rendering</td>
</tr>
<tr>
<td>r_RainAmount</td>
<td>Sets rain amount</td>
</tr>
<tr>
<td>r_RainDistMultiplier</td>
<td>Multiplier for the rain layer's distance from the camera</td>
</tr>
<tr>
<td>r_RainDropsEffect</td>
<td>Enables rain drops effect</td>
</tr>
<tr>
<td>r_RainIgnoreNearest</td>
<td>Disables the layer showing the reflection of objects in rainy or wet areas</td>
</tr>
<tr>
<td>r_RainMaxViewDist</td>
<td>Sets the maximum distance at which rain is visible</td>
</tr>
<tr>
<td>r_RainMaxViewDist_Deferred</td>
<td>Maximum distance (in meters) at which the deferred rain reflection layer is</td>
</tr>
<tr>
<td>r_RainOccluderSize</td>
<td>Used to block rain for objects bigger than this value</td>
</tr>
</tbody>
</table>

### Using the Rain Sample

The Rain Sample uses the Rain, Clouds, and LightningArc gems to demonstrate how to use rain as an environment special effects (FX) in a level. The Lightning entity (from the LightningArc gem) shows how the lightning FX can enhance a rain storm with flashes of light and random strikes of lightning on the ground. The clouds are enabled to show how they can fill a scene.
Render to Texture

This feature is in preview release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Enable the Render to Texture gem for your game so that you can use the Render to Texture (p. 781) component. You can use this component to render the scene to a texture from the viewport of the selected camera. For example, you can add game objects such as mirrors, security camera screens, and draw 3D models.

Note
The Render to Texture component currently supports DirectX 11 for Windows.
SaveData Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The SaveData gem encapsulates all the functionality in Lumberyard for saving game and individual user data under a single platform-agnostic set of API operations.

To enable gems, see Enabling Gems (p. 1064).

The SaveData gem uses the Event Bus (EBus) (p. 1851), Lumberyard's general-purpose communication system for dispatching notifications and receiving requests. To make requests related to saving or loading persistent user data, use the SaveData gem's SaveDataRequests bus. To listen for notifications related to saving persistent user data, use the SaveDataNotifications bus.

Making Requests to Save Data

When making requests to save or load data using the SaveDataRequestBus, keep the following points in mind:

- The SaveData gem is responsible only for saving and loading generic data buffers. Your game must serialize or deserialize data using a data format, such as JSON or XML, that you deem appropriate. However, convenience functions are provided that save or load an object that has been reflected using an AZ::SerializeContext (p. 1033).
- Each save data buffer must be uniquely identified by a string. On most operating systems and devices, this string is the name of the file to which the data buffer is written.

Saving Data for Local User IDs

SaveData gem communications that deal with local user profiles depend on the local user ID that uniquely identifies a user on the local device. When using local user IDs, keep in mind the following points:

- A save data buffer can optionally be associated with a local user ID.
- Data buffers that have the same name can be stored separately for each local user ID.
- When you call the save data functions, you must either specify a local user ID or pass in the value AzFramework::LocalUserIdNone. This requirement helps you to consider whether the data that you are saving should be associated with a user.
- Data associated with a local user ID is saved into a container or directory that is unique to the local user ID and the application.
- Data not associated with a local user ID is saved into a 'global' container or directory unique to the application.

For more information about the SaveDataRequests bus, see the commented source code at lumberyard_version\dev\Gems\SaveData\Code\Include\SaveData\SaveDataRequestBus.h.
Getting Save Data Notifications

All save and load operations performed by the SaveData gem are asynchronous. Therefore, you must either subscribe to receive Save Data notifications or supply a callback function that notifies you when a save or load operation completes. This action is always performed in the main thread.

For more information about the SaveDataNotifications bus, see the commented source code at `lumberyard_version\dev\Gems\SaveData\Code\Include\SaveData\SaveDataNotificationBus.h`.

Save Data Code Example

The following example code uses the SaveData gem to save and load buffers and objects to and from persistent storage.

```cpp
const AZ::u64 testSaveDataSize = 9;
const char* testSaveDataName = "TestSaveData";
char testSaveData[testSaveDataSize] = {'a', 'b', 'c', '1', '2', '3', 'x', 'y', 'z'};

void SaveBufferToPersistentStorage()
{
    SaveData::SaveDataRequests::SaveDataBufferParams params;
    params.dataBuffer.reset(testSaveData);
    params.dataBufferSize = testSaveDataSize;
    params.dataBufferName = testSaveDataName;
    params.callback = [](const SaveData::SaveDataNotifications::DataBufferSavedParams& onSavedParams)
    {
        if (onSavedParams.result != SaveData::SaveDataNotifications::Result::Success)
        {
            // Error handling
        }
    };
    SaveData::SaveDataRequestBus::Broadcast(&SaveData::SaveDataRequests::SaveDataBuffer, params);
}

void LoadBufferFromPersistentStorage()
{
    SaveData::SaveDataRequests::LoadDataBufferParams params;
    params.dataBufferName = testSaveDataName;
    params.callback = [](const SaveData::SaveDataNotifications::DataBufferLoadedParams& onLoadedParams)
    {
        if (onLoadedParams.result == SaveData::SaveDataNotifications::Result::Success)
        {
            // SaveDataNotifications::DataBuffer is a shared_ptr, so you can choose to either preserve the buffer (by keeping a reference to it), or just let it go out of scope so it will be deleted.
            SaveDataNotifications::DataBuffer loadedDataBuffer = onLoadedParams.dataBuffer;
            // Use the loaded data buffer...
        }
        else
        {
            // Error handling
        }
    };
    SaveData::SaveDataRequestBus::Broadcast(&SaveData::SaveDataRequests::LoadDataBuffer, params);
}
```
class TestObject
{
public:
    AZ_RTTI(TestObject, "{9CE29971-8FE2-41FF-AD5B-CB15F1B92834}");
    static void Reflect(AZ::SerializeContext& sc)
    {
        sc.Class<TestObject>()
            ->Version(1)
            ->Field("testString", &TestObject::testString)
            ->Field("testFloat", &TestObject::testFloat)
            ->Field("testInt", &TestObject::testInt)
            ->Field("testBool", &TestObject::testBool)
            ;
    }
    AZStd::string testString;
    float testFloat = 0.0f;
    int testInt = 0;
    bool testBool = false;
};

void SaveObjectToPersistentStorage()
{
    // Reflect the test object class (if not already done).
    AZ::SerializeContext serializeContext;
    TestObject::Reflect(serializeContext);

    // Create a test object instance to save.
    AZStd::shared_ptr<TestObject> testObject = AZStd::make_shared<TestObject>();

    // Setup the save data params
    SaveData::SaveDataRequests::SaveOrLoadObjectParams<TestObject> params;
    params.serializableObject = testObject;
    params.serializeContext = &serializeContext; // Omit to use the global
    params.dataBufferName = "TestSaveObject";
    params.callback = [](const
        SaveData::SaveDataRequests::SaveOrLoadObjectParams<TestObject>& callbackParams,
        SaveData::SaveDataNotifications::Result callbackResult)
        {
            if (callbackResult != SaveData::SaveDataNotifications::Result::Success)
            {
                // Error handling
            }
        };
    SaveData::SaveDataRequests::SaveObject(params);
}

void LoadObjectFromPersistentStorage(const AzFramework::LocalUserId& localUserId = AzFramework::LocalUserIdNone)
{
    // Reflect the test object class (if not already done).
    AZ::SerializeContext serializeContext;
    TestObject::Reflect(serializeContext);

    // Create a test object to load.
    AZStd::shared_ptr<TestObject> testObject = AZStd::make_shared<TestObject>();

    // Setup the load data params
    SaveData::SaveDataRequests::SaveOrLoadObjectParams<TestObject> params;
    params.serializableObject = testObject;
    params.serializeContext = &serializeContext; // Omit to use the global
    params.dataBufferName = "TestSaveObject";
    params.callback = [](const
        SaveData::SaveDataRequests::SaveOrLoadObjectParams<TestObject>& callbackParams,
        SaveData::SaveDataNotifications::Result callbackResult)
{  
    if (onLoadedParams.result == SaveData::SaveDataNotifications::Result::Success)  
    {  
        // Use the loaded data buffer...  
        callbackParams.serializableObject;  
    }  
    else  
    {  
        // Error handling  
    }  
};  
SaveData::SaveDataRequests::LoadObject(params);

Scene Processing Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Scene Processing gem to specify the default settings for processing scene files such as .fbx for your games. For example, you can use the FBX Settings tool to specify the file types and settings that you want for your .fbx files. Asset Processor then processes the files so that they are available in the Asset Browser.

Note
The Scene Processing gem is required and enabled by default for Lumberyard projects.

For information about working with file types and settings, see Customize FBX asset export with FBX Settings (p. 409).

Script Canvas Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Script Canvas gem enables Lumberyard's visual scripting environment. With the gem enabled, you can use the Script Canvas editor to create game logic without needing to write your own code.

To enable gems, see Enabling Gems (p. 1064).
For more information about working with Script Canvas graphs, see Creating Gameplay with Script Canvas (p. 2420).

**Scripted Entity Tweener Gem**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Scripted Entity Tweener gem animates entities in Lumberyard and is particularly useful and powerful for your game UI entities. For more information, see Scripted Tweener Entity System (p. 3011).

**Sky Clouds Gem**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Sky Clouds gem creates realistic and detailed cloud and weather effects in your game levels. You can create clouds with either simple, sprite-based shading, or more complex, voxelized 3D volume shading.

To enable the Sky Clouds gem for your project, see Add modular features and assets with Gems (p. 1064).

For more information about creating and placing clouds in your level, see Sky Cloud (p. 830).

For more information about working with clouds, including setting cloud shading parameters, adding 3D cloud shadows, and creating 3D cloud templates, see Adding Clouds (p. 1293).

**Example**
Slice Favorites

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

With the **Slice Favorites** gem, you can flag a slice as a favorite in the **Asset Browser**.

After you create a slice favorite, you can easily access and instantiate it into your scenes from the **Entity Outliner**.

For more information, see **Slice Favorites** (p. 526).

Snow Gem

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the **CryEntity Removal gem** using the **Project Configurator** or the **command line**. To learn more about legacy features, see the **Lumberyard Legacy Reference**.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Snow Gem creates realistic snow effects in your levels, including snowflake and surface effects, such as snow buildup. To enable the Snow Gem in your project, see **Add modular features and assets with Gems** (p. 1064).

**Note**

Place only a single **Snow** entity in your scene.
Placing Snow

You can place your snow and customize it to your level by modifying properties for brightness, gravity, size and quantity of snow flakes, how much snow and frost builds on a surface, and more.

To add snow to your level

1. In the Rollup Bar, click Entity.
2. Under Browser, expand Environment.
3. Drag the Snow entity into your scene.

Configuring Snow

You can configure the snow's properties under Entity Params and Entity Properties.

Snow Entity Properties

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>Enables snow effect</td>
</tr>
<tr>
<td>Radius</td>
<td>Sets the area on which snow falls</td>
</tr>
<tr>
<td>SnowFall</td>
<td></td>
</tr>
<tr>
<td>Brightness</td>
<td>Sets the brightness of the snow effect</td>
</tr>
<tr>
<td>GravityScale</td>
<td>Sets the gravity strength, which determines the rate at which snow falls</td>
</tr>
<tr>
<td>SnowFlakeCount</td>
<td>Sets the quantity of snowflakes</td>
</tr>
</tbody>
</table>
### Properties

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SnowFlakeSize</td>
<td>Sets size of individual snowflakes</td>
</tr>
<tr>
<td>TurbulenceFreq</td>
<td>Sets the frequency of the turbulence affecting the snow</td>
</tr>
<tr>
<td>TurbulenceStrength</td>
<td>Sets the strength of the turbulence affecting the snow</td>
</tr>
<tr>
<td>WindScale</td>
<td>Determines the impact of wind on the falling snow</td>
</tr>
<tr>
<td><em>Surface</em></td>
<td></td>
</tr>
<tr>
<td>FrostAmount</td>
<td>Sets the amount of frost on a surface</td>
</tr>
<tr>
<td>SnowAmount</td>
<td>Sets the amount of snow on a surface</td>
</tr>
<tr>
<td>SurfaceFreezing</td>
<td>Sets the degree to which surfaces appear frozen</td>
</tr>
</tbody>
</table>

### Using Console Variables for Snow

You can use the following console variables [console variables](p. 210) for the snow entity.

#### Snow Entity Console Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>r_Snow</td>
<td>Enables snow rendering</td>
</tr>
<tr>
<td>r_SnowDisplacement</td>
<td>Enables displacement for snow accumulation</td>
</tr>
<tr>
<td>r_SnowFlakeClusters</td>
<td>Number of snow flake clusters</td>
</tr>
<tr>
<td>r_SnowHalfRes</td>
<td>When enabled, renders snow at half resolution to conserve fill rate</td>
</tr>
</tbody>
</table>

### Using the Snow Sample

The Snow Sample uses the Snow and Clouds gems to demonstrate how to use the Snow entity as an environment special effects in a level. The Snow entity shows how snow falls and provides properties that you can set to randomly change the snow fall over time, creating a more dynamic weather experience.
Starting Point Input Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Starting Point Input gem works with the Input Management Framework (p. 1150) gem to map low-level input events to high-level gameplay actions. For example, you can specify in your game that pressing the keyboard spacebar results in a gameplay action, such as jump.

For information about working with input events, see the Input (p. 642) component.

For information about working with input gestures such as touch, swipe, and rotate, see the Gestures (p. 1141) gem.
Twitch v5 Gem

The Twitch v5 Gem is deprecated and will be removed in a future version of Lumberyard. It has been replaced by the Twitch API Gem.

The Twitch v5 Gem is a wrapper for the Legacy Twitch v5 RESTful API. Install this Gem into your Lumberyard project to access legacy Twitch API v5 features.

Warning
Twitch API v5 is deprecated. Consider migrating to the latest version of the Twitch API, which is supported in Lumberyard by the newer Twitch API Gem (p. 1207).

For more information on integrating the Twitch v5 Gem with your Lumberyard project, see Engaging Broadcasters and Viewers on Twitch (p. 2095).

Enable the Twitch v5 Gem

To enable the Twitch v5 Gem, do the following:

1. Use Project Configurator (p. 44) to add the Twitch v5 Gem to your project. The Twitch v5 Gem requires the following Gem as a dependency:

   - HttpRequestor

2. Configure your project. Use the following command.

   `lmbr_waf configure`

3. Build your project. Use the following command.

   `lmbr_waf build_win_x64_vs2019_profile -p all --progress`

For more information on Gems, see the Gems system documentation (p. 1064).

Twitch API Gem

The Twitch API Gem is a wrapper for the Twitch RESTful API. Install this Gem into your Lumberyard project to access Twitch features through the Twitch API. This Gem makes it simple to engage broadcasters and leverage existing Twitch functionality for your game.

The Twitch API Gem does not provide a means for fetching information required to authenticate with the Twitch API, such as User ID, Application/Client ID, or Bearer tokens. You must first provide this information manually.
information to the Gem through EBus calls. Information about the types of Bearer tokens and how they can be acquired are detailed in the Authentication section of the Twitch developer documentation.

For more information on integrating the Twitch API Gem with your Lumberyard project, see Engaging Broadcasters and Viewers on Twitch (p. 2095).

**Enable the Twitch API Gem**

To enable the Twitch API Gem, do the following:

1. Use Project Configurator (p. 44) to add the TwitchApi Gem to your project. The TwitchApi Gem requires the following Gem as a dependency:
   - HttpRequestor
2. Configure your project. Use the following command.
   ```
   lmb_waf configure
   ```
3. Build your project. Use the following command.
   ```
   lmb_waf build_win_x64_vs2019_profile -p all --progress
   ```

For more information on Gems, see the Gems system documentation (p. 1064).

**Twitch Chat API Gem**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Twitch Chat API Gem provides a flexible framework to create customized game interactions between streamers and spectators on Twitch, the world's leading social video platform and community for gamers. By adding Twitch ChatPlay to your project, you can quickly and easily connect to Twitch IRC via WebSocket.

Twitch ChatPlay includes support for chat commands, polls, and surveys that can be triggered by Twitch viewers through the Twitch chat channel. For example, you can create a chat command `#cheer` that triggers celebration animations in your game.

**Gem Setup**

Use of the Twitch Chat API Gem in your project requires the following setup:

1. Add the Twitch Chat API Gem and the Websockets Gem to your project.
   
   The Twitch Chat API Gem has a dependency on the Websockets Gem.
2. Setup an account on Twitch that will be used by the game. You will need to provide your username or a username that you wish to represent you (such as a bot id, potentially with mod permissions in the channel, depending on your goals).
3. Get a Twitch OAuth token.
   
   **Important**
   Keep this token safe and do not share this publicly! This is essentially your password for connecting, and if you share it with others, they can spoof your account.
For more information about **Twitch IRC** and authentication, see the [Twitch documentation](https://www.twitch.tv/docs/IRC).

You are now ready to use the Gem. For details on how to implement Twitch ChatPlay in your game, see [Intro to ChatPlay (p. 2096)](https://docs.aws.amazon.com/lumberyard/latest/userguide/chatplay-intro.html) and [Using the Twitch Chat API Gem (p. 2097)](https://docs.aws.amazon.com/lumberyard/latest/userguide/chatplay-twitch.html).

### UiBasics Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws-gametech-platform.s3.amazonaws.com/download/03DE.txt) or visit the [AWS Game Tech blog](https://aws-gametech-platform.s3.amazonaws.com/download/03DE.txt) to learn more.

The UiBasics Gem is a collection of assets to be used as defaults with the Lumberyard UI Editor, including basic UI prefabs (image, text, button, and text input) and the textures that those prefabs require. For more information, see [Creating and Customizing Project User Interfaces (p. 2874)](https://docs.aws.amazon.com/lumberyard/latest/userguide/project-ui.html).

### User Login Default Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws-gametech-platform.s3.amazonaws.com/download/03DE.txt) or visit the [AWS Game Tech blog](https://aws-gametech-platform.s3.amazonaws.com/download/03DE.txt) to learn more.

The UserLoginDefault Gem provides a default user login implementation for all platforms, which is useful for testing and debugging.

### Video Playback Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws-gametech-platform.s3.amazonaws.com/download/03DE.txt) or visit the [AWS Game Tech blog](https://aws-gametech-platform.s3.amazonaws.com/download/03DE.txt) to learn more.

With the Video Playback gem, you can play videos in a game or level loading screen, or on textures in your Lumberyard level. When you enable the Video Playback gem, the Video Playback component is enabled. For instructions on how to prepare Lumberyard for video playback, and how to set up video playback in your level, see [Video Playback (p. 906)](https://docs.aws.amazon.com/lumberyard/latest/userguide/video-playback.html).

For more information on playing videos in load screens, see [Defining Game and Level Load Screens (p. 2910)](https://docs.aws.amazon.com/lumberyard/latest/userguide/load-screens.html).

### Video Playback Bink Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws-gametech-platform.s3.amazonaws.com/download/03DE.txt) or visit the [AWS Game Tech blog](https://aws-gametech-platform.s3.amazonaws.com/download/03DE.txt) to learn more.

With the Video Playback Bink gem, you can play videos using RAD Game Tools' Bink video codec. The videos are playable in a game or level loading screen, or on textures in your Lumberyard level. When you enable the Video Playback Bink gem, the Video Playback Bink component is enabled. For instructions on how to prepare Lumberyard for video playback, and how to set up video playback in your level, see [Video Playback Bink (p. 913)](https://docs.aws.amazon.com/lumberyard/latest/userguide/video-playback-bink.html).
For more information on playing videos in load screens, see Defining Game and Level Load Screens (p. 2910).

**Important**
A Bink license is needed to gain access to this gem. Please contact RAD Game Tools for information on how to license Bink.

## Virtual Gamepad Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Use the Virtual Gamepad gem to provide your game's UI with touch screen capabilities on mobile devices. After you enable the Virtual Gamepad gem, you can add the virtual gamepad components to your game's UI in the UI Editor.

**Topics**
- Configuring Virtual Gamepad Behavior (p. 1211)
- Virtual Gamepad Component Properties (p. 1213)
- Displaying the Virtual Gamepad at Runtime (p. 1214)

The Virtual Gamepad gem includes a sample UI canvas that you can either customize for your game or use as an example for a new UI canvas. To view this canvas in the UI Editor (p. 2874), open Gems\VirtualGamepad\Assets\UI\Canvases\VirtualGamepad\VirtualGamepad.uicanvas.

There is no limit for the number of active UI canvases that can contain virtual gamepad components. This means you can create many virtual gamepad canvases to display for the appropriate scenarios, or even at the same time. For example, you can show a different UI canvas on each half of your virtual gamepad.

**Example**

To experiment with the Virtual Gamepad gem, run the Advanced_RinLocomotion Sample (p. 151) level from the Samples Project (p. 146) on a device with touch screen support.
You can customize the virtual gamepad's appearance and layout by creating or modifying an existing UI canvas. For more information on working with UI Canvases, see Working with UI Canvases (p. 2888).

**Configuring Virtual Gamepad Behavior**

You can configure the virtual gamepad's behavior in the **UI Editor**.

**To configure virtual gamepad behavior**

1. In the **UI Editor**, add the UI components (p. 2923) **VirtualGamepadButton** and **VirtualGamepadThumbStick** to the UI canvas.
2. For each component, select an **Input Channel**.

For more information about input in Lumberyard, see [Input in Amazon Lumberyard](p. 1902).

To modify the list of available virtual gamepad input channels, use the Project Configurator to edit the virtual gamepad's system component. For more information, see [Configuring Advanced Settings](p. 49).
Virtual Gamepad Component Properties

The Virtual Gamepad gem features two components that you can use to customize input for your mobile games:

**VirtualGamepadButton**

**VirtualGamepadButton** has one property, **Input Channel**. Select the appropriate input.
VirtualGamepadThumbstick

**VirtualGamepadThumbstick** has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Input Channel</strong></td>
<td>The input channel that is updated when the user interacts with this control.</td>
</tr>
<tr>
<td><strong>Thumb Stick Image Centre</strong></td>
<td>The child element that is positioned at the center of the virtual thumbstick.</td>
</tr>
<tr>
<td><strong>Thumb Stick Image Radial</strong></td>
<td>The child element that is positioned beneath the user's finger when the virtual thumbstick is active. The image's position is always clamped to the radial edge of the virtual thumbstick center image.</td>
</tr>
<tr>
<td><strong>Centre When Pressed</strong></td>
<td>If selected, centers the virtual thumbstick when it is pressed.</td>
</tr>
<tr>
<td><strong>Adjust Position While Pressed</strong></td>
<td>If selected, adjusts the position of the virtual thumbstick when it is active. Tracks the player's finger when it moves outside the thumbstick radius.</td>
</tr>
</tbody>
</table>

**Displaying the Virtual Gamepad at Runtime**

You can enable the virtual gamepad for runtime by creating instructions that loads the virtual gamepad UI canvas. You can do this with C++, Lua, or Script Canvas. For more information, see *UICanvasManager (p. 3042)* and *UICanvasComponent (p. 3034)*.

The following example Lua script displays a virtual gamepad UI canvas if touch screen support is detected.

```lua
local touchDevice =
    InputDeviceRequestBus.Event.GetInputDevice(InputDeviceId(InputDeviceTouch.name))
if (touchDevice and touchDevice:IsSupported()) then
    print("Virtual gamepad UI canvas displayed")
end
```
The following example Lua script checks if a physical gamepad is connected. If found, the Lua script disables the virtual gamepad.

```lua
local gamepadDevice = InputDeviceRequestBus.Event.GetInputDevice(InputDeviceId(InputDeviceGamepad.name))
if (gamepadDevice and gamepadDevice:IsConnected()) then
  UiCanvasBus.Event.SetEnabled(self.virtualGamepadCanvasId, false);
end
```

The following Lua script enables the virtual gamepad when a physical gamepad is disconnected and disables the virtual gamepad when a physical gamepad is connected.

You can find a working example of this Lua script in the `lumberyard_version\dev\SamplesProject\AnimationSamples\Advanced_RinLocomotion\Scripts\Advanced_RinLocomotion.lua` file.

```lua
function Example:OnActivate()
  self.inputDeviceNotificationBus = InputDeviceNotificationBus.Connect(self);
end

function Example:OnInputDeviceConnectedEvent(inputDevice)
  if (inputDevice.deviceName == InputDeviceGamepad.name) then
    UiCanvasBus.Event.SetEnabled(self.virtualGamepadCanvasId, false);
  end
end

function Example:OnInputDeviceDisconnectedEvent(inputDevice)
  if (inputDevice.deviceName == InputDeviceGamepad.name) then
    UiCanvasBus.Event.SetEnabled(self.virtualGamepadCanvasId, true);
  end
end

function Example:OnDeactivate()
  if (self.inputDeviceNotificationBus) then
    self.inputDeviceNotificationBus:Disconnect();
  end
end
```

**Virtual Reality Gems**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Oculus and OpenVR Virtual Reality gems support a variety of Virtual Reality head-mounted displays (HMDs).

For more information about how to use and configure the Virtual Reality Gems, see Configuring your Project for Virtual Reality (p. 3249).

**Visibility**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.
You can enable the Visibility gem for your game project so that you can add the VisArea (p. 918) component to an entity. You can use the component to create a visibility area (vis area) that helps manage visibility and culling in a scene.

Websockets Gem

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Websockets Gem provides an easy way to create WebSocket clients for your Lumberyard games and projects. With this gem, you can connect to WebSocket servers and take advantage of the full-duplex communication that they provide.

This gem is designed to work with any platform-specific library that's needed. Each platform is divided out and separated, allowing libraries and features to be added quickly and easily, or to exchange existing or outdated tools with new ones. On Windows and Linux, the gem uses a well-known WebSocket library, WebSocket++, which is included in the gem.

The gem uses the WebSocket protocol to create clients that connect to existing WebSocket servers. Using the gem bus system, you can create multiple WebSocket connections, and then send and receive messages.

Websocket Requests Bus

The Websocket Request bus provides the primary interface for working with the gem. The follow functions are available:

- **CreateClient** – Provides the unique instance connection that will be used with the rest of the buses. It takes three arguments:
  1. The WebSocket server address.
  2. A received message handler function (OnMessage function).
  3. A type of connection. If no type is defined, it defaults to Secure.
- **IsConnectionOpen** – Used to check if the connection is open. Since WebSockets connections are always open, there is no need to verify if the connection has timed out, or to wait for a ping. Connections can be verified immediately.
- **SendWebsocketMessage** – Sends strings to the targeted server.
- **SendWebsocketMessageBinary** – Sends a binary stream to the targeted server.
- **CloseWebsocket** – The expectation for WebSocket connections is that the developer will close the WebSocket before the program is finished, allowing for a clean exit. This system will handle this automatically if not performed, but it is recommended, especially if there is a case where multiple connections are being setup simultaneously, to avoid having sockets open unnecessarily.
Tip
For an example of the usage of these functions, see the source for the Twitch Chat gem, which can be found in dev\Gems\TwitchChatPlay\.

IWebsocketClient
The IWebsocketClient class is an interface that sits at the base of the entire Websockets Gem. It provides a direct interface to the individual connections to WebSockets for users who wish to avoid the bus system in cases where speed is paramount. It provides all of the same functionality as the bus system once the connection has been created, with none of the overhead.

SecureWebsocketClient vs WebsocketClient
The Websockets Gem provides a method to create both secure and normal WebSocket clients, with the default being secure WebSockets connections. Secure WebSocket connections provide OpenSSL (Transport Layer Security) for protecting client-server connections using the standard included in Lumberyard.

OnMessage Function
Every WebSocket connection needs a message handler function to receive incoming messages from the server. The OnMessage function interface provides a simple method for you to provide this handler function. By providing a function pointer or lambda with the signature void (AZ::string_view), you can have your own custom functions handle responses, as shown in the following example:

```cpp
Websockets::OnMessage messageFunc = [this](const AZStd::string_view message)
{
    HandleResponses(message);
};
```

Known Issues
The following are known issues to be aware of when using this gem:

1. Amazon GameLift and the Websockets Gem are not currently compatible. Both GameLift and the gem use Websocket++, but unfortunately, the GameLift version is much older. In monolithic (release) builds, this creates linker issues that will cause a crash when both are active.

    Until a long-term fix is provided, you can make a simple change to the gem to fix this. Modify the WebSocket++ version within the gem to work with a new namespace. For example, change the websocketpp namespace to websocketppaz.

White Box Gem

This feature is an experimental release and is subject to change.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The White Box Gem provides two tools implemented as components; the White Box component, and the White Box Collision component. You can use the White Box component to quickly sketch proxy geometry for your entities. Use the White Box Collision component with the White Box component to provide a collision surface for PhysX simulations.
What is white boxing?

White boxing is a rapid, iterative design process. Simple modeling tools are used to create proxy geometry that defines the shape and dimension of 3D objects and environments. The proxy geometry created in this process has a very low polygon count, but reasonably approximates the size and shape of the final assets. White box entities have a basic material, and simple collision and physics materials if required. The entities created in the white box process can be handed off to artists to be developed into polished production entities.

In Lumberyard, you create entities with the White Box component, using its edit functionality to rapidly sketch 3D assets to serve as building blocks for a level. Because you create white box meshes in Lumberyard Editor with the component entity system, the entities can also contain functionality from other components such as scripts. You can use a rapid build and test iteration cycle to create refined and functional entities before committing to developing production-ready art assets. The resulting white box geometry and entities are used as templates for production assets. This development process is fast, highly iterative, and cost-effective.

Enable the White Box Gem

To make the White Box and White Box Collision components available in Lumberyard, you must build and configure your project with the White Box Gem enabled.

To enable the White Box Gem

1. Use Project Configurator to add the White Box Gem to your project.

   Note
   The White Box Gem has no dependencies. However, if you intend to use the White Box Collision component, you should also enable the PhysX Gem.

2. Configure your project. Use the following command.

   lmbr_waf configure

3. Build your project. Use the following command.

   lmbr_waf build_win_x64_vs2019_profile -p all --progress

For more information on Gems, see the Gems documentation (p. 1064).

White Box component information

For information on the White Box component, see White Box component (p. 946).

For information on the White Box Collision component, see White Box Collider component (p. 960).
Create levels in Lumberyard

A level, also known as world or map, represents the space or area available to the player during the course of completing a discrete game objective. Most games consist of multiple levels through which a player can advance to or move through, although usually only a single level is loaded at a time. Each level can be grouped into multiple layers, which you use to logically group types of objects.

The environment includes lighting, terrain, bodies of water, vegetation, sky, and weather effects.

Topics
- Creating a New Level (p. 1219)
- Creating Terrain (p. 1220)
- Blending Environment Probes (p. 1252)
- Working with Database Libraries (p. 1264)
- Adding Sky Effects (p. 1265)
- Adding Weather Effects (p. 1290)
- Adding Vegetation (p. 1298)

Creating a New Level

The first step in creating a game world is to create a level.

To create a new level
1. In Lumberyard Editor, click File, New Level or press Control + N.
2. In the **New Level** window, enter a file name and select a directory location for the file. Choose **OK**.

3. In the **Generate Terrain Texture** window, for **Texture Dimensions**, select texture dimensions to determine texture tile resolution. Choose **OK**.

## Creating Terrain

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](#) or visit the [AWS Game Tech blog](#) to learn more.

You can add realistic elements such as mountains, valleys, lakes, rivers, and roads to your terrain for your environment levels.

One of the primary tools used to first create a terrain is the Terrain Editor, as the following shows:

---

**Topics**

- Creating High Quality Terrain (p. 1221)
- Importing and Exporting Terrain Data (p. 1222)
- Using the Terrain Heightmap (p. 1226)
- Using Terrain Texture Layers (p. 1232)
- Creating Landforms and Topography (p. 1237)
- Creating Bodies of water (p. 1242)
Creating High Quality Terrain

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

After you create a level, you can refine your terrain to use 2k height and 16k color.

To refine your terrain to a 2k world with 16k color

1. In your Lumberyard Editor level, choose Game, Terrain, Refine Terrain Texture Tiles.
2. In the dialog box, click Yes and in the next dialog, click OK.
3. Save your level.
4. Repeat steps 1 through 3.
5. Choose Game, Terrain, Export/Import Megaterrain Texture.
6. In the Export/Import Megaterrain Texture tool, click and drag to select all of the tiles.
7. Click Change tile resolution, select 2048x2048, and then click OK.

Your result should look like the following. You can now import and export high quality textures.
Tip
You can verify that your texture is in 16k color. Export and then open the texture file in a DCC such as Photoshop.

Importing and Exporting Terrain Data

You can import and export terrain data such as color maps, terrain blocks, and splat maps.

Topics
- Importing a Megaterrain Texture (p. 1222)
- Importing and Exporting Terrain Blocks (p. 1222)
- Importing Splat Maps (p. 1223)
- Terrain FAQs (p. 1224)

Importing a Megaterrain Texture

A megaterrain texture, also known as a color map, is a texture that covers part of or the entire terrain. This texture is visible from a distance and presents sweeping vistas. As the camera moves closer to the terrain, the megaterrain texture is replaced by more detailed terrain textures.

Although you can import data for individual tiles, a more common workflow is to use a single megaterrain texture for the entire terrain.

Note
Lumberyard doesn't match or fix tile edges. Ensure that your tile data is authored so that adjacent tile edges match. Otherwise, your level may render with visible seams. Lumberyard supports the BMP image file type only for megatexture terrains.

To import a megaterrain texture

1. In Lumberyard Editor, choose Tools, Terrain Editor.
2. In the Terrain Editor, choose Tools, Export/Import Megaterrain Texture.
3. Click and drag to select the tiles that you want.
4. Click Import, select your megaterrain texture file, and then click Open.

Importing and Exporting Terrain Blocks
You can import and export terrain areas or blocks. When importing or exporting, you should also import or export the associated terrain texture layers.

**To import a terrain block and texture layers**

1. In Lumberyard Editor, click **Game, Terrain, Import Terrain Block** and select a `.trb` file to import.
2. Click **Terrain, Terrain Texture Layers**.
3. Click **File, Import Layers** and select terrain texture files to import.

**To export a terrain block and texture layers**

1. In Lumberyard Editor, click **Game, Terrain, Export Terrain Block**, and select a `.trb` file to export.
2. Click **Terrain, Terrain Texture Layers**.
3. Click **File, Export Layers**, and select terrain texture files to export.

**Importing Splat Maps**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Splat maps are 8-bit monochrome bitmap `.bmp` files that contain weight information for each vertex in a terrain map. Splat maps are generated using a DCC tool such as World Machine's Splat Converter.
All splat map operations in Lumberyard are done using the Terrain Texture Layers editor.

**To import splat maps**

1. In Lumberyard Editor, choose **Tools, Other, Terrain Texture Layers** (p. 1232).
2. In the Terrain Texture Layers editor, under **Layer Tasks**, assign each splat map to a texture layer by clicking a layer and then clicking **Assign Splat Map**.
3. When prompted, select a .bmp file. You don't need to assign a splat map path to a layer, but you can't assign more than one path either.
4. Under **Layer Tasks**, click **Import Splat Maps**. This clears the current weight map for the terrain and then rebuilds it using the selected splat maps.
5. In Lumberyard Editor, choose **Game, Terrain, Generate Terrain Texture**.

**Note**
You cannot apply masking to an imported splat map.

**Terrain FAQs**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. [Download O3DE](https://aws.amazon.com/serverless) or visit the [AWS Game Tech blog](https://aws.amazon.com/blogs/gaming) to learn more.

See the following troubleshooting tips to resolve issues for your Lumberyard terrains.

<table>
<thead>
<tr>
<th>Issue</th>
<th>Workaround or Fix</th>
</tr>
</thead>
<tbody>
<tr>
<td>How can I center the terrain in world space?</td>
<td>Terrain in Lumberyard is generated from a texture. Texture coordinates (U,V) originate in the lower left corner of the texture. Because terrain is based on a terrain texture, the Legacy Terrain level component is placed with its lower left corner at X: 0.0 and Y: 0.0 in world space. The terrain is placed at Z: 32.0, with an Infinite Ocean below it at Z: 16.0 in world space. This terrain placement has the useful byproduct of ensuring every entity in a level is placed at a positive X and Y coordinate, and that you can create valleys and bodies of water within the terrain.</td>
</tr>
<tr>
<td>Issue</td>
<td>Workaround or Fix</td>
</tr>
<tr>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Lumberyard terrain can't be moved. If your project requires the terrain to be centered at zero in world space, you can remove the Legacy Terrain level component, and remove the Infinite Ocean in the Terrain Editor. You can import a terrain mesh created in a third-party application as you would any other .fbx mesh asset, and place the terrain in the level as an entity at any world space position.</td>
<td></td>
</tr>
<tr>
<td>I expected to create a 2k world, but the Terrain Editor shows tiles that are sized 512 in a 2x2 grid. What does this mean?</td>
<td>512 describes the number of megatexels per tile and is the default resolution for new levels in Lumberyard. With a 2x2 grid, you have a total of four tiles. If you add up all of the megatexels from all of the tiles, it adds up to 2k (2048 megatexels). To increase your tiles' resolution, see Creating High Quality Terrain (p. 1221).</td>
</tr>
<tr>
<td>What does the resolution (512x512, 1024x1024, 2048x2048) mean in terms of the 2k height and the 16k size of the megaterrain?</td>
<td>The heightmap is independent of the megaterrain texture.</td>
</tr>
<tr>
<td>The resolution displayed in the Export/Import Megaterrain Texture dialog is the color megatexel resolution for that tile.</td>
<td></td>
</tr>
<tr>
<td>What is the optimal resolution for imported splat maps?</td>
<td>You should match the heightmap resolution for your splat map resolutions.</td>
</tr>
<tr>
<td>Why does the visual quality get blurry after generating terrain textures? It seems that sectors start fetching mips at various resolutions, making it difficult to determine what it looks like.</td>
<td>Lumberyard uses a texture pool for terrain textures. Its default is set to retain 64 textures at any given time, with each texture measuring 256x256. Consider that a 16k x 16k texture actually contains 5461 individual textures. By default, Lumberyard doesn't keep enough textures in resident memory at any given time to present a clear image. You can increase the texture pool size using the e_TerrainTextureStreamingPoolItemsNum console variable. The maximum value is 4096. You can set this console variable in the level.cfg or project.cfg file. You must set the console variable in one of these files because the value must be present when the system loads. Changes made during runtime don't affect this console variable. For more information, see Using the Console Window (p. 210).</td>
</tr>

### Issue

How are terrain layer materials applied to the terrain? What does the **detail repeat** property do?

- For example, if a dirt map is 2m x 2m, what is the proper detail repeat value to use in the material?
- Are UVs 0..1 per meter/quad?
- How does detail repeat values relate to overall terrain?

<table>
<thead>
<tr>
<th>Issue</th>
<th>Workaround or Fix</th>
</tr>
</thead>
<tbody>
<tr>
<td>How are terrain layer materials applied to the terrain? What does the <strong>detail repeat</strong> property do?</td>
<td>If you author a terrain detail material as a 2m patch, then set the TileU and TileV in the material to 0.5. The shader calculates UV coordinates from world space. Data is passed into the terrain shader that tells it the x-y offset and scale for the texture UVs. The shader then uses that to transform the world space coordinate into a UV coordinate.</td>
</tr>
</tbody>
</table>

### Creating a Terrain Heightmap

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The heightmap is the base of the terrain in your level. You have three options for obtaining a terrain heightmap:

- Create a new heightmap using the Terrain Editor
- Create a new heightmap using a third-party terrain-building tool
- Importing an existing heightmap

#### Topics

- Creating a Terrain Heightmap (p. 1226)
- Setting Heightmap Properties (p. 1228)
- Importing a Terrain Heightmap (p. 1230)
- Exporting a Terrain Heightmap (p. 1231)
- Resizing a Terrain Heightmap (p. 1231)
- Rotating a Terrain Heightmap (p. 1231)

### Creating a Terrain Heightmap

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The first step in creating the heightmap using Lumberyard Editor is to specify the resolution and grid spacing, both of which define the terrain size. Terrain size is determined by multiplying heightmap resolution by meters per texel. This value should not exceed 4096 x 4096 kilometers.

Meters per texel is the distance in meters between two vertices on the grid. So a value of two means there is a grid point every two meters. You can use larger values to create a larger terrain, but it is less detailed for the same heightmap resolution.

The following images show a terrain heightmap and the corresponding generated terrain.
Example Terrain Heightmap

![Example Terrain Heightmap](image1.jpg)

Example Generated Terrain

![Example Generated Terrain](image2.jpg)
If you want to create the highest quality terrain heightmap for a 2K world, use the following settings:

- 2K heightmap
- 2K splatmaps

As the splat weighting is applied and stored in the terrain mesh, the splatmaps should match the terrain heightmap resolution.

- 4K – 16K megaterrain color map

To create a heightmap using the Terrain Editor

1. In Lumberyard Editor, click File, New.
2. In New Level, enter a file name and directory location for the heightmap file.
3. Select the desired Heightmap Resolution and Meters per Texel values and click OK.
4. In the editor menu, click Game, Terrain, Edit Terrain.
5. In Terrain Editor, click Tools, Generate Terrain.
6. In Generation, adjust the following parameter values as needed.

   **Feature Size**
   
   Determines the amount of land created.

   **Bumpiness/Noise (Fade)**
   
   Determines the degree of bumpiness or deformation of the surface.

   **Slope Detail (Passes)**
   
   Determines the number of times that effect is applied.

   **Seed (Random Base)**
   
   Determines the degree of random variation for the heightmap.

   **Slope Smoothing (Blur Passes)**
   
   Sets the number of times that smoothing is applied to the noise filter.

   **Cover (Exp. Substract)**

   **Sharpness (Exp. Base)**
   
   Determines the sharpness of the surface.

   **Sharpness (Freq. Step)**
   
   Determines the number of times that the sharpness filter is applied to the surface.

**Setting Heightmap Properties**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview.
Download O3DE or visit the AWS Game Tech blog to learn more.

You can use the Terrain Editor to set various heightmap properties and parameters that affect the shape of the terrain profile.

Version 1.28

1228
To set heightmap properties

1. In Lumberyard Editor, click **Game, Terrain, Edit Terrain**.
2. In **Terrain Editor**, click **Modify**, and then click and adjust the various following properties and parameters:
   - **Make Isle**
     - Sinks the heightmap so that it is surrounded by ocean.
   - **Remove Ocean**
     - Sets the ocean level to –100000 meters.
   - **Set Ocean Height**
     - Sets the ocean level in meters.
   - **Set Terrain Max Height**
     - Sets the maximum height for the tallest mountain. (Default is 1024 meters).
   - **Set Unit Size**
     - Sets the meters per texel size of the heightmap.
   - **Flatten**
     - Flattens terrain to either a higher or lower point.
   - **Smooth**
     - Removes all hard edges from the heightmap.
   - **Smooth Slope**
     - Removes hard edges from steep areas of the heightmap.
   - **Smooth Beaches/Coast**
     - Removes hard edges from flat areas of the heightmap.
   - **Normalize**
     - Ensures the entire greyscale spectrum is used between the **Max Height** value and zero.
   - **Reduce Range (Light)**
     - Makes heightmap mountains smaller.
   - **Reduce Range (Heavy)**
     - Makes heightmap mountains small.
   - **Erase Terrain**
     - Deletes all heightmap data.
   - **Resize Terrain**
     - Resizes the terrain heightmap.
   - **Invert Terrain**
     - Inverts all greyscale data, changing black to white and vice versa.
Importing a Terrain Heightmap

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

In order to support full, 32-bit heightmap resolution, use one of the following file formats when you import a heightmap file.

- `.asc`
- `.bt` (binary terrain) – Highest precision
- `.tif` (32-bit)

The following file formats are supported but not recommended. These file formats are imported in 16-bit or 8-bit resolution. We recommend using a minimum of 16-bit resolution for heightmaps, as 8-bit resolution can cause blocky-looking terrain.

- `.pgm` (16-bit)
- `.raw` (16-bit)
- `.r16` (16-bit)
- `.png` (8-bit)
- `.bmp` (8-bit)
- `.tif` (8-bit or 16-bit)

Lumberyard Editor supports importing only a single heightmap for the entire terrain. You can, however, import color or texture data to individual tiles within the terrain. For information about importing color maps, see Importing a Megaterrain Texture (p. 1222).

If you attempt to import a file with a different resolution than your existing heightmap, Lumberyard prompts you to do one of the following:

- Clip your imported file to remove any values that are outside the boundary of your existing heightmap.
- Resize your imported file to shrink or stretch to fit the heightmap. Resizing may introduce artifacts that can cause blocky-looking terrain.

**Note**
If your heightmap resolution is greater than your level's resolution, you should downsample your heightmap with an external graphics application before you import it into Lumberyard. If, for example, you attempt to import a 4k heightmap into a 2k level, Lumberyard prompts you to clip or resize your heightmap. This may be sufficient, but using an external graphics application to downsample your heightmap provides superior results.

To import a heightmap

1. In Lumberyard Editor, choose Game, Terrain, Edit Terrain.
2. In Terrain Editor, choose File, Import Heightmap.
Exporting a Terrain Heightmap

You can export a heightmap file that was created in the Terrain Editor to the following file formats:

- .asc (32-bit)
- .bt (32-bit)
- .tif (32-bit)
- .pgm (16-bit)
- .raw (16-bit)
- .r16 (16-bit)
- .bmp (8-bit)
- .png (8-bit)

To export a heightmap

1. In Lumberyard Editor, choose Game, Terrain, Edit Terrain.
2. In Terrain Editor, choose File, Export Heightmap and enter a file name and directory location.

Resizing a Terrain Heightmap

Resizing the terrain heightmap involves changing the resolution of your heightmap. Terrain size is determined by multiplying heightmap by meters per texel. When resizing, this value should not exceed 4096x4096 meters.

Meters per texel is the distance in meters between two vertices on the grid. So a value of two means there is a grid point every two meters. You can use larger values to create a larger terrain, but it is less detailed for the same heightmap resolution.

To resize a heightmap

1. In Lumberyard Editor, click Game, Terrain, Resize Terrain.
2. For Heightmap Resolution, select the desired value.
3. For Meters Per Texel, select the desired value.

Rotating a Terrain Heightmap

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.
Rotating a terrain heightmap involves just a few simple steps.

**To rotate the heightmap**

1. In the Rollup Bar, on the Terrain tab, click Move Area.
2. Click Select Source.
3. At the bottom of Lumberyard Editor, enter the X and Y coordinates for the heightmap center, then click Lock Selection.
4. Click Select Target and repeat Step 3.
5. In Target Rotation, select a value in degrees.

**Using Terrain Texture Layers**

You can create terrain texture layers and paint them to enhance your environment level.

The primary tool for creating and managing terrain texture layers in your level is the Terrain Texture Layers editor.

For information about working with splat maps, see .
Creating Terrain

- Adding a Terrain Texture Layer (p. 1233)
- Applying a Texture Layer Material (p. 1233)
- Importing Terrain Texture Layers (p. 1233)
- Exporting Terrain Texture Layers (p. 1234)
- Painting Terrain Texture Layers (p. 1234)
- Changing Terrain Tile Resolution (p. 1236)

Adding a Terrain Texture Layer

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Create a new texture layer and change the terrain texture and material as desired.

To add a terrain texture layer

1. In Lumberyard Editor, click Tools, Other, Terrain Texture Layers.
2. In Terrain Texture Layers, under Layer Tasks, click Add Layer.
3. Double-click the NewLayer text and assign a unique name to it.
4. Click Materials\material_terrain_default to open Material Editor.
5. In the tree, click Materials\material_terrain_default and adjust material and other settings as needed.

Applying a Texture Layer Material

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

All terrain texture layer materials use the Terrain.Layer Shader (p. 1710). All terrain materials should be "high-passed" in your DCC tool in order for them to work correctly with this shader.

To apply or edit a material for a texture layer

1. In Lumberyard Editor, click Tools, Other, Terrain Texture Layers.
2. In Terrain Texture Layers, double-click the layer you want to apply or edit a material for.
3. In Material Editor, expand the tree and select your asset.
4. Change settings and shader parameters as needed.
6. Close Material Editor.

Importing Terrain Texture Layers

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

By importing a saved layer, all materials, textures, and shader settings can be quickly applied to your level.
To import a terrain texture layer
1. In Lumberyard Editor, click Tools, Other, Terrain Texture Layers.
2. Click File, Import Layers.
3. Select the layer (.lay) file for import, then click Open.

Exporting Terrain Texture Layers

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can export your terrain texture layer, so that you can then reuse it in multiple levels.

To export a terrain texture layer
1. In Lumberyard Editor, choose Tools, Other, Terrain Texture Layers.
2. Click File, Export Layers.
3. Enter a file name and select a directory path for the exported file and then click Save.

Painting Terrain Texture Layers

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

Lumberyard uses two components for painting terrain texture layers:

- The first is a low-resolution texture with color information. This texture is visible from a distance and provides underlying color information for the base terrain texture. This texture should be less than 512 x 512 pixels in size.
- The second is a high-resolution material. This material is visible at close distances and can have several texture maps like diffuse, bump, and specular. The diffuse map should be set to white (255).

The distance at which low-resolution textures are replaced with those of a higher resolution is defined by the DetailLayersViewDistRatio parameter. To access this parameter, in the Rollup Bar, on the Terrain tab, click Environment and adjust the value as needed.

To paint a terrain texture layer
1. In Lumberyard Editor, choose Game, Terrain, Paint Layers.
2. In the Rollup Bar, on the Terrain tab, click Layer Painter.
3. Adjust the terrain brush settings as needed.
Radius

Specifies the size of the brush. Use the slider to adjust the size, or use the following keyboard shortcuts: [ to increase the brush radius size or ] to decrease the brush radius size.

Color Opacity

Specifies the strength of the brush when applying the layer color. The brush is a spray brush that uses the color opacity value to determine the opacity at the center of the brush. The opacity decreases to transparent at the edge of the brush. Lower values create a more translucent brush, and higher values create a more opaque brush. Set the value to 0 to disable the color opacity. You can use the slider to adjust the opacity level, or you can use the following keyboard shortcuts:

- **Shift+[** decreases the opacity.
- **Shift+]** increases the opacity.

You can also use the following keyboard shortcuts to adjust both parameters simultaneously with the same value:

- **Shift+Ctrl+[** decreases both color opacity and detail intensity.
- **Shift+Ctrl+]** increases both color opacity and detail intensity.

Detail Intensity

Specifies the strength of the brush when applying the detail texture to the layer. Like color opacity, the detail intensity value determines the intensity (opacity) at the center of the brush. The opacity decreases to transparent at the edge of the brush. Lower values create a more translucent (less intense) texture, and higher values create a more opaque texture. Set the value to 0 to disable detail intensity. You can use the slider to adjust the intensity level, or you can use the following keyboard shortcuts:

- **Ctrl+[** decreases the intensity.
- **Ctrl+]** increases the intensity.

You can also use the following keyboard shortcuts to adjust both parameters simultaneously with the same value:

- **Shift+Ctrl+[** decreases both color opacity and detail intensity.
- **Shift+Ctrl+]** increases both color opacity and detail intensity.

Mask by Layer Altitude and Slope

Sets the material to paint only between the layer Altitude and Slope parameters defined below.

Mask by

Selects a layer to prevent it from being painted over.

4. Adjust the layer brush settings as needed.

Brightness

Modifies the brightness of the material base color. Click the Color box to open up the color selector and alter the base color of your material. Click Save Layer when done.

Altitude

Sets a minimum and maximum altitude mask for painting; the brush applies only within these boundaries.

Slope (degrees)

Sets a minimum and maximum slope mask for painting; the brush applies only within these boundaries.
Changing Terrain Tile Resolution

A terrain layer can be divided into multiple tiles, each of which can be painted with a resolution between 64x64 and 2048x2048 kilometers. The higher the resolution, the softer the transition between terrain texture layers.

If you know a player spends a lot of time in specific areas of the level and thus have more opportunity to view the terrain, you can save resources by increasing the resolution in just those areas. Follow this two-step process:

You first subdivide the texture layer, then change the individual tile resolution, as follows:

**To subdivide the terrain texture layer**

1. In Lumberyard Editor, click **Tools, Other, Terrain Texture Layers**.
2. Click **File, Refine Terrain Texture Tiles**. The layer is now split into 2x2 (4) tiles.
3. Repeat step 2. The layer is now divided into 4x4 (16) tiles.
4. Repeat only as needed as there is no way to go back and reduce the number of tiles.

**To change terrain tile resolution**

1. In Lumberyard Editor, click **Game, Terrain, Export/Import Megaterrain Texture**.
2. In **Terrain Texture**, click a tile whose resolution you want to change. Then click **Change tile resolution**.
3. Choose a new resolution and then click OK. Click Close.
Creating Terrain

Creating Landforms and Topography

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add realistic mountains, hills, valleys, and other landforms to your terrain in your environment level. The primary method for creating interesting terrain features and landforms involves the following brushes:

- **Rise/Lower brush** – Increases and decreases the local terrain height to quickly create hills, valleys, and river beds, for example.
- **Flatten brush** – Flattens the terrain at a specified height and diameter. Use the **Pick Height** feature to select a height from which to begin flattening.
- **Smooth brush** – Smooths over sharp gradients in the terrain.
- **Holes brush** – Used to make holes in the terrain for creating areas beneath or inside the terrain such as caves.

You can also use the Terrain Editor to modify the terrain heightmap, although this method is not as accurate and does not give you the control you get from working directly in the viewport in Lumberyard Editor. For more information, see Setting Heightmap Properties (p. 1228).

**Topics**

- Using the Rise/Lower Brush (p. 1237)
- Using the Smooth Brush (p. 1238)
- Using the Flatten Brush (p. 1238)
- Using the Holes Brush (p. 1239)
- Terrain Brush Parameters (p. 1239)
- Creating Roads (p. 1240)

**Using the Rise/Lower Brush**

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

The Rise/Lower brush is perhaps the most versatile of all the terrain brushes and is often the first used. With it you can create many macroterrain landforms and features such as mountains, hills, cliffs, valleys, and riverbeds, for example. After using this brush, see Using the Flatten Brush (p. 1238) and Using the Smooth Brush (p. 1238) to learn how to control the shape and overall visual look.

**To use the Rise/Lower brush**

1. In the Rollup Bar, on the Terrain tab, click Modify, Rise/Lower.
2. Adjust the Height slider to the desired height:
Creating Terrain

- Use positive values for landforms that rise above the base level.
- Use negative values for valleys and other landforms that sink below the base level.

3. Adjust the **Outside Radius** and **Inner Radius** sliders (and the difference between the values) to control the steepness of the terrain.

4. In the level, drag the mouse around to achieve the desired effect.

5. Under **Modify Terrain**, adjust **Brush Settings** and **Noise Settings** parameters as needed. See Terrain Brush Parameters (p. 1239) for more information.

6. When done, click **Terrain**, **Modify** or press **Esc**.

### Using the Smooth Brush

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Smooth brush softens sharp gradients in the terrain, such as the sides of mountains, cliffs and lake beds for example. This brush averages out the height of the terrain based on nearby terrain areas to provide a smoother surface.

**To use the smooth brush**

1. In the **Rollup Bar**, on the **Terrain** tab, click **Modify**, **Smooth**.
2. In the level, drag the mouse to create the smoothing effect.
3. Under **Modify Terrain**, adjust **Brush Settings** and **Noise Settings** parameters as needed. See Terrain Brush Parameters (p. 1239) for more information.
4. When done, click **Terrain**, **Modify** or press **Esc**.

### Using the Flatten Brush

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Flatten brush makes any piece of terrain completely flat at a height that you define. This is useful for creating a variety of features such as plateaus, mesas, and buttes as well as creating flat spots wherever needed.

**To use the Flatten brush**

1. In the **Rollup Bar**, on the **Terrain** tab, click **Modify**, **Flatten**.
2. In the level, drag the mouse to create a flat spot. The terrain is flattened at the selected **Height** and **Diameter** brush settings.

3. Under **Modify Terrain**, adjust **Brush Settings** and **Noise Settings** parameters as needed. See **Terrain Brush Parameters (p. 1239)** for more information.

### Using the Holes Brush

This topic references tools and features that are **legacy**. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the **Lumberyard Legacy Reference**.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

The Holes brush makes a geometrical hole in both the terrain layer as well as the visual mesh. It is useful for creating craters, sinkholes, caves, and other areas beneath or inside the terrain. The resulting holes can be filled with various objects such as rocks or vegetation.

**To use the Holes brush**

1. In the **Rollup Bar**, on the **Terrain** tab, click **Holes**.
2. Adjust the **Brush Radius** slider to adjust the size of the hole.
3. Click **Make Hole** to create a hole.
4. In the level, click to place the hole. By default you can see the ocean showing through.
5. To remove a hole, click **Remove Hole**. You are limited to removing one terrain unit adjacent to the existing terrain.

### Terrain Brush Parameters

A number of settings apply to multiple terrain brushes. Use the following parameters to adjust the rise/lower, smooth, and flatten brushes.

**Outside Radius**

The outer edge of the area of the terrain brush effect.

**Sync Radius for All Types**

Select to set the same outer radius value across the flatten, smooth, and rise/lower brushes.

**Inside Radius**

The inner edge of the area of the terrain brush effect. Within this radius the effect of the brush is at its maximum.

**Hardness**

Controls the shape of the fall-off curve between the inner and outer radius of the brush.
Creating Terrain

**Height**
For the rise/lower and flatten brushes, the incremental amount the terrain is be raised/lowered or flattened with each click in the terrain level.

**Enable Noise**
Select to add random terrain variances to the brush.

**Scale**
Controls the strength of the noise effect.

**Frequency**
How often the noise effect is applied.

**Reposition Objects**
Select to realign objects with the modified terrain. Objects remain on top.

**Reposition Vegetation**
Select to realign vegetation with the modified terrain. Vegetation remains on top.

**Creating Roads**

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can add realistic roads to your terrain in your environment level.

For information on the road entity, see Road Entity.

**Topics**
- Creating the Road Entity (p. 1240)
- Applying a Road Material (p. 1241)
- Adjusting Road Spline Geometry (p. 1241)
- Splitting and Merging Roads (p. 1242)

---

**Creating the Road Entity**

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can create and place roads using the Road entity as follows.

When performing this procedure, you may notice that parts of the road disappear into the terrain. The **Align Height Map** step resolves this by stretching the terrain height to match the path of the road based
on its shape and on **BorderWidth** parameter. For information on **BorderWidth** and related settings, see **Road Entity**.

**To create and place the Road entity**

1. In the **Rollup Bar**, on the **Objects** tab, click **Misc, Road**.
2. In your level, start at the beginning of the road and click to place a series of points that define the road’s path.
3. When complete, double-click where you want the road to end.
4. In the **Rollup Bar**, under **Road Parameters**, click **Align Height Map** to adjust the terrain height to match the path of the road.

**Applying a Road Material**

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

After the Road entity has been placed, you can apply a material to the road.

**To apply a material to a road**

1. In the **Rollup Bar**, on the **Objects** tab, click **Misc, Road**.
2. Click **<No Custom Material>** to open the Material Editor.
3. In the Material Editor, expand the tree and select your asset.
4. Modify material settings and shader parameters as needed.
5. When finished, click **Assign Item to Selected Objects**, and close the Material Editor.

**Adjusting Road Spline Geometry**

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can make precise changes to the geometry of a road by adjusting the spline points and parameters.

**To adjust road spline parameters**

1. In the **Rollup Bar**, on the **Objects** tab, click **Misc, Road**.
2. Under **Spline Parameters**, click **Edit**, and do any of the following for the road in your level:
Creating Terrain

- To move a point, drag it.
- To add a new point, hold down Ctrl while you click on the spline at the desired location.
- To delete a point, double-click it.
- To change the angle at a point, select it and adjust the Angle value.
- To change the width at a point, select it, clear the Default width check box, and adjust the Width value.

Splitting and Merging Roads

This topic references tools and features that are legacy. If you want to use legacy tools in Lumberyard Editor, disable the CryEntity Removal gem using the Project Configurator or the command line. To learn more about legacy features, see the Lumberyard Legacy Reference.

Open 3D Engine (O3DE), the successor to Lumberyard, is now available in Developer Preview. Download O3DE or visit the AWS Game Tech blog to learn more.

You can split a road apart or merge two roads together.

To split or merge roads

1. In the Rollup Bar, on the Objects tab, click Misc, Road.
2. Under Spline Parameters, click Edit, and do the following for the road in your level:
   - To split a road apart, select the desired point and click Split.
